Jim Breed (2013-01-25 12:32:11)

A couple of years ago, my wife and I had the good fortune to spend an hour with a scientist for the Manhattan project who must have been in his early 90's. The day we met him he had been working in his garage workshop making a solar heater because he was cold and didn't want to pay for heat. In the course of our conversation, he pointed out radiation burns on his hands that he had incurred during his career at the Lab and performing radiation measurements following atmospheric tests. He jokingly said, "a little radiation must be good for you because most of the people I've worked with are still alive." If I could be working in my shop at 90, I'd take a dose now and then myself. I realize that this is an anecdote. Its just that you run into a lot of folks who have been exposed to radiation far in excess of what is supposed to be bad for you. Seth: I wonder if the radiation in airport scanners prolongs life. But I also worry that they are not properly maintained.

dearieme (2013-01-25 17:28:19)

"Widespread failure of Johnson & Johnson hip replacement." I'm taken by the recent problems of the Boeing Screamerliner. Many problems in aircraft are, I imagine, systems problems that you can try to find only once you've got a few test planes ready. But batteries that ignite sound like a component problem that you can test for in the lab months, or years, before a plane takes the sky. Very odd.

## **What Happens If I Stop Grading? (2013-01-26 05:00)**

I believe two things about teaching:

1. The best way to learn is to do. From [1]an article by Paul Halmos about teaching math. I began self-experimentation to learn how to do experiments.
2. Everyone's different. [2]My theory of human evolution says we changed in many ways to facilitate trading. (For example, language began as advertising.) The more diverse the expertise within a group, the more members of the group can benefit from trade. Following this logic, mechanisms evolved to increase diversity of expertise among people living in the same place with the same genes. (For example, a mechanism that causes procrastination.) The theory implies that there is something inside every student that pushes them toward expertise – they want to learn – but they are being pushed in many different directions – what they want to learn varies greatly. If you accommodate the latter (diversity in what students want to learn), you can take advantage of the former (an inner drive to learn).

The novelty is #2 – the idea that #2 is relevant to teaching. Human nature: People who are the same want to be different. Formal education: People who are different should be the same. At Berkeley, most professors appeared to have little idea of the diversity of their students. (At least I didn't, until I gave assignments that revealed it.) Almost all

classes treated all students in a class the same: same lectures, same assignments, same tests, same grading scheme. I heard dozens of talks about how to teach. Supporting or encouraging individuality never came up. Now and then I told other professors these ideas – at a party, for example. "Everyone's different, but our classes treat everyone the same," I'd say. No one agreed. It was a new and apparently distasteful idea. Too much work was one response.

I believed my theory of human evolution partly because it explained what I saw with my students (Berkeley psychology majors in undergraduate seminars): The more freedom I gave them, the more they learned. I gave them great freedom with their term project (except I forced them to do it off-campus). That worked fine. One student had an intense fear of public speaking. Her project: give a talk to a high school class. She succeeded. "What did I learn? I learned that if I have to, I can conquer my fears," she wrote. I wrote [3]an article about it. I taught a whole class where the students (all 10 of them) were given great freedom to do something off campus. That worked, too. But the class was too niche and the term project too small. It wasn't obvious if the ideas would work in an ordinary class.

The more freedom I gave my students, the more difficult it became to grade them. At Tsinghua I teach a required class for freshman psychology majors called Frontiers of Psychology. There are 20-30 students. It covers recent research. For the first few years, I had students write comments on the reading. "Write something only you could write," I said. The students struggled to figure out what that meant. I struggled to grade their answers.

Before last semester began, I had an idea: no grading. Maybe other sources of motivation, would be enough.

Last semester, my Frontiers class had two parts:

1. Reading. During this section, they read a variety of things: recent experimental papers (e.g., from Psychological Science), book excerpts (e.g., from [4]The Man Who Would Be Queen) where I said "read any 60 pages you want", and [5]my long self-experimentation paper ("read any third you want"). This taught them how to do research, not just subject-matter content. A typical assignment included a class presentation. For example, each student read a different experimental paper (they chose) and gave a presentation about it. Another assignment involved an in-class debate. I discussed the readings – for example, the controversy around The Man Who Would Be Queen – and gave feedback on presentations but rarely lectured. The main lecture I gave was at the beginning to explain the course. This part of the course resembled a traditional course, except (a) no grades, no tests, (b) many class presentations (public speaking is an important skill), and (c) lots of choice in what they read.

2. Doing. This section had two parts: (a) a short (2 week) experiment where they tested the effect of whatever they wanted (chocolate, piano music, exercise, and naps of different lengths were some choices) on brain function measured by [6]a reaction-time test written in R. They gave presentations about their results (I regret not requiring written reports). (b) a long project (4-5 weeks) where they could study whatever psychological topic they wanted. It might or might not involve data collection. The topics they chose to study included dreams, procrastination, the perception of psychologists, [7]fujoshi, the relative femininity of different sports, the accuracy of first impressions, different ways of teaching English, comparison of Tsinghua students and Peking University students (the top two universities in China, with stereotypically different students), cognition in native versus non-native language, reading screens versus reading books, and positive psychology. They could work in groups or by themselves. They had to get my approval for what they did so that they wouldn't try to do too much or too little. At the end they wrote a report and gave a class presentation. I met with each student or group of students individually to discuss their work, usually for 30-60 minutes. During these discussions they provided evidence (e.g., photographs, recordings) that they had done what they said.

I did give grades (I was required to) but they were minimal. The final grade was entirely based on the final project. I divided each project into parts (e.g., background research, data collection, class presentation) and gave

each part a point value such that the points add up to 96 (= A). If you finish Part X, you get the associated points. (Everyone completed all parts.) If they did really well I gave them slightly more points (e.g., 97). If they failed in some serious way I gave them slightly fewer (e.g., 94). So grading was close to binary: yes or no. You could get a good grade simply by doing what you said you would do.

It was the most pleasant teaching experience of my life. It was also the easiest by far, in contrast to my Berkeley colleagues' claim that my ideas led to "too much work." The hours I had spent every week grading homework in previous versions of the course – the part of the course I liked least – was gone. At the end of the class, I spent many hours discussing the student projects, but I enjoyed these discussions. They didn't feel like work. The students had chosen topics they wanted to study and seemed happy to talk about what they had done. Unlike an oral exam, almost nothing was riding on what they told me and they could be proud of what they were talking about, since it was almost entirely their idea.

The students's work was the highest quality I have ever seen. Two of their final projects might be publishable. (And these are first-semester freshmen.) It's not my field, so I can't be sure, but they have great inherent interest and no obvious flaws. The students seemed to like the class, too. On the final day, which happened to be Christmas, they gave me a Christmas card signed by everyone in the class. One student gave me a card separately. "Thank you," I said. "Why did you give me this?" Among other things, she said I had high standards. Given the absence of grades, that was interesting. Maybe it came from the fact that after every presentation, I would point out something I liked and something I thought could be better. I tried to do that with all of my feedback. Another student told me, after the final class, that what I had said about "the best way to learn is to do" was, in her case, very true. She said she had learned more in my class than in all her other classes put together.

There were about 25 students and 12 assignments = 300 (= 25 x 12) assignments total. There were about 4 instances where a student did not do an assignment. In other words, the students did the assignments 99 % of the time although there was no obvious penalty for not doing an assignment. Had I given grades, I might have gotten 100 % compliance rather than 99 %. To use a costly (in terms of time and student anxiety) grading scheme to get a 1 % improvement in compliance is absurd. Yet that may be what most professors are doing – at least, my experience suggests they could get very high compliance without expensive grading.

I think this class worked well for both my students and me because it contained several elements: 1. A "core curriculum" (recent psychological research) taught in several different ways. 2. Good-quality materials. For example, *The Man Who Would Be Queen* is much better than what psychology students typically read. One student told me she read the whole book even though only a third of it was assigned. 3. Plenty of doing. A class presentation counts as doing. 4. Plenty of student choice. 5. Absence of grading, which has bad side effects.

I think several things caused students to learn a lot: 1. The material was interesting. 2. To some extent – far more than in other classes – they could choose what they wanted to learn, especially during the second half of the class. 3. Peer pressure. They wanted to look good in front of their peers. It would have been embarrassing to not be able to do a presentation when called upon. 4. The instinct of workmanship. Thorstein Veblen wrote a book called [8]The Instinct of Workmanship. People inherently want to do a good job, said Veblen. I agree. 5. Doing is fun.

Would this work with other students? My students were/are very smart, yes. Tsinghua is extremely hard to get into and entrance is mostly based on a standardized test. My students, in other words, did very well under the usual system of teaching. This can be interpreted two ways: (a) They like the usual way of teaching, it fits them (they succeeded because of the usual methods) or (b) like everyone else, they dislike the usual way of teaching but unlike everyone else figured out how to learn on their own. The first interpretation suggests that my students would benefit less than other students from the novelty of my approach. The second interpretation suggests they would benefit more. What is clear is that Tsinghua students are known for studying very hard – yet my class required no studying beyond reading and understanding.

What did I learn? I learned that I can stop grading and things get much better, not worse. I learned that motivations other than grades are plenty powerful.

Nancy Lebovitz (2013-01-26 05:37:11)

John Holt eventually became a leader of the home schooling movement because he noticed that third and fourth graders were so distracted by grading that they were just inventing arithmetic answers instead of thinking. An Alexander Technique teacher told me that he graded his college courses on attendance because he found that people couldn't let themselves more easily if they were thinking about grades. The Alexander Technique was invented by F.M. Alexander about a century ago because he was an actor who'd lost the ability to speak. After much self-observation in three-way mirrors, he found that he was pulling his head down and back before he started to speak. After more self-experimentation, he found a way to not pull his head down and back, and found that his general functioning improved, including clearing up some breathing problems he'd had since childhood. Seth: I taught a class at Berkeley with a woman who had benefited greatly from Alexander Technique. She told me about his emphasis on self-observation. I haven't heard of grading college courses on attendance. I didn't take attendance. Sometimes students are sick. It seems unfair to reduce their grade because of this. In any case I had no problems with attendance.

Babar (2013-01-26 05:44:38)

Yay! An independent discovery of progressive teaching! Seth: I looked it up: [1]progressive education. Yes, two of the 14 elements describing progressive education ("Emphasis on learning by doing" and "Highly personalized education") are exactly what I was aiming for.

1. [http://en.wikipedia.org/wiki/Progressive\\_education](http://en.wikipedia.org/wiki/Progressive_education)

Three Pipe Problem (2013-01-26 06:24:56)

IMO the resistance to individualization is not coincidental. As Terry Gilliam said, "Usually you spot how societies work by what they glorify: it's usually the thing they're deficient in."

Mark (2013-01-26 06:40:56)

I know from past posts that Seth is not so much a fan of Popper... I am a huge fan of Popper. Popper claimed that we only learn new things via trial and error, and I very much agree with this. Because of this, I think that grades can only hurt true learning (how can one learn from making errors if every error is counted against you?). Our daughter attends a Quaker school where they give no grades and take no standardized tests (all the way through high school), and they seem to teach mostly via trial and error. I love this. Seth: I was under the impression that a lot of learning is imitation. If someone else has learned X (can be anything, e.g., how to drive a car, what is the capital of Texas), you can learn X by imitating that person. If no one has learned X, then you will have to resort to trial and error. I did not know that there are Quaker schools that teach without grades. Can you give a link to more information about this?

Koanic (2013-01-26 11:46:33)

You missed the other, correct possibility. Very intelligent and conscientious people are selected for by Tsinghua admissions system. These people are intellectually curious, and will produce higher quality work when given freedom. The same is not true of other people, who will slack. Seth: That's what I meant with my second possibility. Your comment is very interesting because you propose some connection between very intelligent, conscientious, and intellectually curious. Maybe you have something there. Tsinghua admissions on the face of it does select for people who are very intelligent and conscientious, as you say. Why such people should be unusually "intellectually" curious is not obvious. I've heard it said that high curiosity leads to high intelligence, which makes some sense. Nothing was said about conscientiousness. The saying "genius is an infinite capacity for taking pains" echoes your connection of conscientiousness and intelligence, without mentioning curiosity.

gwern (2013-01-26 16:02:39)

> Very intelligent and conscientious people are selected for by Tsinghua admissions system. These people are intellectually curious, and will produce higher quality work when given freedom. IQ and (Big Five) Conscientiousness are very weakly positively, or actually negatively correlated. Big Five Openness, a pretty much exact math to 'intellectually curious', has only a weak correlation with IQ (IIRC 0.2). Given the extreme selection from the Chinese population to produce the Tsinghua student body, using tests that test pretty much only IQ & Conscientiousness from every description I've heard of them, there's no reason to expect an extreme level of Openness in the student body. So perhaps Roberts is merely seeing what a little freedom looks like when applied to the most elite & capable. I'd question whether they performed as well in that respect as comparable students from Harvard or Oxford, except I think Tsinghua is more selective than either...

Adesomer (2013-01-26 17:04:44)

Hi seth! I just happened upon your blog through an internet search...and I wasn't sure how to contact you about a post you had written, but you had closed the comments on, so I apologize. Let me tell you just a wee bit about myself. I am a mom of 6 who returned to school as a biology major with the inclination to teach secondary education. I was diagnosed celiac a year ago and have had digestive issues most of my life. I have found myself leaning more toward paleo eating and am intrigued by fermented foods to heal the gut. So here is my question...in one of your posts you discuss why you believe these bacterium are good for our guts and why the human race tends toward these flavours...but why does our stomach acid not kill these bacterium? Why is it all not killed prior to hitting the intestines? Feel free to email me directly, should you wish. I am in the beginning stages of food fermentation, beginning with kombucha and on my way to sauerkraut and traditional polish borscht. Thanks in advance!! Alena Seth: Stomach acid kills only what is on the surface. We do not atomize our food in our mouths. It goes into our stomach in lumps. What's inside the lumps is safe from the acid.

Txomin (2013-01-26 17:56:36)

When students are self-motivated, it is possible to do away with many of the "standard" resources available to teachers, including grades, exams, etc, even formal teaching/lecturing can go. When students are not self-motivated, the responsible teacher cannot dismiss any resource out of hand. And, let's be honest, some students are motivated by grades. As a test, give lowish grades to your students at Tsinghua and see how they perform afterwards when they see their efforts ignored and unrewarded in their transcripts.

Jonathan Shewchuk (2013-01-26 19:05:33)

Do you see any element of this I could apply in my 530-student Data Structures class (now in progress at Berkeley)? Seth: Maybe next time I'm in Berkeley we can talk about this over coffee. My short answer is: 1. Give students substantial length of time (such as 4 weeks) for a final project, which can be anything they like involving the course material. Have teaching assistants vet each project for appropriate degree of difficulty. The final project will get an A so long as the student completes each of the promised elements. Each student gives a progress report to the class each week in section. No lectures during this period. Lecture time devoted to the best progress reports. 2. Make the final project involve improving the data structure for someone on campus (student, professor, staff). I don't know if this is feasible. 3. Make the final project involve improving the data structure for someone off campus (e.g., parents, friends of parents). Again, I don't know if this is feasible. The general idea is to introduce freedom (option 1) and realism (options 2 and 3) and reduce worry about grades (option 1).

Around the Web: Mid-Winter Edition | Perfect Health Diet (2013-01-26 20:03:55)  
[...] Seth Roberts believes two things about teaching. [...]

Mark (2013-01-27 06:02:55)

Of course it's true that simple facts (e.g., the Capitol of Texas) can be learned through imitation or memorization. However, I would submit that one cannot learn \_to do \_ anything (e.g., drive a car) except through trial and error (hopefully, fairly minor errors). You can learn that the ignition does X, the accelerator does Y, and brakes do Z through imitation or memorization, but you can't learn not to over-steer or over-break except by doing it and correcting your (hopefully small) errors. Anyway, here's a Quaker school link, note in particular the section on evaluation: <http://www.cfsnc.org/page.cfm?p=421> You might also be interested in the overall philosophy, as it's very close to some of what you've written here: <http://www.cfsnc.org/page.cfm?p=362>  
Seth: Thanks for the links. The part about evaluation says in part: "Student evaluation at CFS is constant and thorough and is not reduced to letter grades." This is not a good description of my approach because I was not "constant and thorough". At the very end, I gave a lot of feedback about term projects. Before that, I gave considerably less feedback. After a class presentation, I would point out one thing I thought was good and one thing where there was room for improvement. I did not give each presentation a thorough critique. That would have taken too long and been overwhelming.

Nancy Lebovitz (2013-01-27 07:59:54)

The teacher believed he had to grade on something— for administrative reasons, I think, and since there were no other Alexander teachers in town and he believed that anyone who showed up would learn, he graded on attendance. He mentioned another Alexander teacher who graded on class notes. I don't know why (I thought the class was very good), but it was down to four students by the end. The reason I brought up the story is that a skilled person concluded that students weren't at their best if they were being graded. Any suggestions for other systems developed from self-observation and experimentation? Offhand, I can think of Bob Cooley's resistance stretching, Gerda Alexander's Eutonics (no relation FM Alexander), and Kenny Werner's Effortless Mastery (cultivating efficiency and intensity for playing music). Tomin, you're arguing that students can be demotivated by lowish grades, which is not the same thing as saying that they will be motivated by a chance at high grades.  
Seth: Thanks for clarifying that. To answer your question ("any suggestions...") lots of weight-loss diets have been developed by self-observation and experimentation. South Beach, for example.

Eric (2013-01-27 11:28:35)

I've been using a variation of this in some of my Computer Science courses at Bowdoin for years. The longer I'm here, the more I'm convinced that the specific material in upper level courses is not particularly important, all that matters is student engagement. When students are engaged they are learning machines and mostly my job is to stay out of their way.  
Seth: I'd like to hear more about what you do.

Bob Levinson (2013-01-27 18:49:48)

Paragraph six of the Halmos article says: "Having stated this extreme position, I'll rescind it immediately. I know that it is extreme, and I don't really mean it—but I wanted to be very emphatic about not going along with the view that learning means going to lectures and reading books. If we had longer lives, and bigger brains, and enough dedicated expert teachers to have a student/teacher ratio of 1/1, I'd stick with the extreme views—but we don't." So Halmos is talking about an ideal. Jonathan Shewchuk's question (above) gets to the heart of issue.  
Seth: Halmos's "extreme position" is no use of books and lectures. He recognizes that is impossible. I don't agree with Halmos's extreme position. I had few lectures but plenty of reading. I gave in-class public feedback on student presentations (all students could hear what I said about Student X's presentation), which vaguely resembles lecturing. The essence of what I'm saying doesn't have much to do with Halmos. It is that a desire to individualize education (= make it different for each student) led me to stop grading. When I did so, things were fine. My students, it turned out, had plenty of motivation from other sources. Grading is so time-consuming and irksome for teachers that this is an interesting outcome.

Koanic (2013-01-28 13:20:53)

"IQ and (Big Five) Conscientiousness are very weakly positively, or actually negatively correlated. Big Five Openness, a pretty much exact match to 'intellectually curious', has only a weak correlation with IQ (IIRC 0.2)." So do horoscopes. Who cares? Self reporting is BS to make work for psych pros. Seth: "So do horoscopes"? Your point is unclear. Are you saying that intellectual curiosity (= openness) as measured by self-report personality tests, doesn't correlate with anything important? If so, that's an interesting and surprising claim, which I haven't heard before. What do you base it on?

Babar (2013-01-29 03:49:03)

Seth, I think more than 2 out of 14 things match between your insight and progressive education. I am pointing this out not to be a stickler but because I sense a kinship of approach - you might learn from them and them from you. Also - I have taught a few classes - unfortunately lecture style - and have to say that it's not strictly correct that one assumes that all students learn the same way. I always tried to explain things many different ways to cover different ways of seeing things and I always was open to questions and thinking things through with students. That being said I agree your approach is better. I didn't have the authority to make those decisions though. Seth: What are the other similarities between what I do and progressive education? I looked again at [1]that list of 14 characteristics of progressive education and failed to find more similarities. Unless you mean an emphasis on projects and "varied learning resources".

1. [http://en.wikipedia.org/wiki/Progressive\\_education](http://en.wikipedia.org/wiki/Progressive_education)

Koanic (2013-01-29 11:47:53)

"Are you saying that intellectual curiosity (= openness) as measured by self-report personality tests, doesn't correlate with anything important?" Yes. And I am saying that all 5 Big 5 self-report dimensions are hopelessly flawed. Taking people's self-descriptions at face value is not an intelligent way to practice psychology, even if it does permit large scale data collection. It is like studying cars by color. There will be some semi-interesting correlations, but nothing actually reliable. The problem is that there are radically different types of people who describe themselves in similar ways, or in ways opposite to or orthogonal to what they actually are compared to the general population. The "publishable results" system has led to an explosion in worthless statistically-significant results. As a result, psychology has moved further and further away from anything resembling an intelligent grasp of human nature. Psychologists can't afford to go under the hoods of cars one at a time. So instead they count car colors from a highway overpass. Useless. Seth: [1]This cites many studies that disagree with what you say about openness (lack of correlation). For example, <http://psycnet.apa.org/?&fa=main.doiLanding&doi=10.1037/0033-2909.120.3.323>. What evidence supports your view ("hopelessly flawed")?

1. [http://en.wikipedia.org/wiki/Openness\\_to\\_experience](http://en.wikipedia.org/wiki/Openness_to_experience)

Koanic (2013-01-29 18:44:35)

I didn't say "lack of correlation". I said "semi-interesting correlations". I think you and I have very different ideas about how useful psychology should be. You're impressed by useless vague correlations of the Big 5. I'm not. What's it good for? If I am blind screening applicants for a job, I will a million times take an IQ test over a Big 5 test. One of the concepts of PUA is "value elicitation." And one of the ironies is that often the values are the opposite of what the person is really like. I have studied the life histories of over 50 applicants to my Neander Hall, in the process of typing them. I can never simply take what they say about themselves or their values at face value. It all must be placed into life context, and compared to what other people like them and different from them said and did. Real psychology will be founded on biological axes, such as testosterone and facial shape. It must account for things like social status, charisma, and actual extro/introversion. Naive interpretation of self-description will never accurately reveal these traits. Even the most benighted psychologist should realize that a guy's self-reported notch count can be quite misleading, and his subjective rating of the women's attractiveness even more so. Self description is nice for publishing papers but doesn't give us any better grasp on human nature. It is only one of three crucial elements - the other two being biology and biography. Seth: I'm sorry you have not seen fit to provide evidence for your view that personality psychology - at least, the part based on self-report - is worthless.

Koanic (2013-01-29 21:45:16)

I presume you mean a study, which is a small subset of the word "evidence". You linked to Wikipedia, which is untrustworthy on this topic, and a paper behind a paywall. Link to the best paper I can access and let's see whether Big 5 and MBTI are good

for anything practical, or are just for academic promotion and horoscope-style self-discovery. And keep in mind, this argument started because someone said something about how openness was more important than high IQ for self-directed coursework. The very idea of naively comparing Chinese vs American students' self descriptions of openness is ridiculous, and even more so for Tsinghua students. Yet if you give those kids an inch they zoom off into independent genius mode. Hmmm.... Seth: I've found some relevant evidence. Is it possible that it might be your turn to do so?

JKB (2013-01-30 08:24:15)

Interesting. You might be interested in this report Teaching Boys and Girls How to Study' (1919) by Peter Jeremiah Zimmers, Superintendent of City Schools, Manitowoc, Wisconsin (scanned online, Google Books) about the very good results the school system had when they shifted away from the teacher-dominated lecture system to the problem method of teaching. Sadly, such innovations never took widespread hold and we became stuck with the lecture style instruction that has long been known to induce "school helplessness" in students. The first reference I've found to the damage school does to creative and innovative thinking was a minor discussion in a book published in 1886. "In spite of the fact that schools exist for the sake of education, there is many a school whose pupils show a peculiar "school helplessness"; that is, they are capable of less initiative in connection with their school tasks than they commonly exhibit in the accomplishment of other tasks."

John (2013-02-02 11:52:22)

From a comment above (and totally irrelevant to the posted article): "Seth: Stomach acid kills only what is on the surface. We do not atomize our food in our mouths. It goes into our stomach in lumps. What's inside the lumps is safe from the acid." However, by the time food is ready to leave the stomach it is far away from being "lumps." It is a chalky, watery mix called chyme, having been totally massaged and mixed with acidic, watery, "mucus-y" secretions. Many/most (?) bacteria survive the acid of the stomach, but not because they are inside the lumps (boluses) of food that came down the esophagus. These "lumps" are totally liquefied before they enter the small intestine, and have been thoroughly exposed to gastric acids.

Koanic (2013-02-08 00:19:49)

"I've found some relevant evidence. Is it possible that it might be your turn to do so?" IIRC, you've admitted that psychology is mostly useless. That's because the science is in its infancy. Here are the green shoots of real, hard psychology that I've described above. It will correlate biomarkers with actual, not just self-reported, psychological traits. sources: <http://www.ncbi.nlm.nih.gov/pubmed/7272664> [http://facelab.org/bc/jones/Teaching/files/Penton-Voak\\_2006.pdf](http://facelab.org/bc/jones/Teaching/files/Penton-Voak_2006.pdf) <http://www.molecularautism.com/content/2/1/15> <http://bps-research-digest.blogspot.com/-2009/09/physiognomy-redux-link-found-between.html> [http://books.google.com/books?id=cywujk9axNwC &pg=PA172 &lpg=PA172 &dq=Kozeny+1962+700+faces+convicted &source=bl &ots=IUOV9AbdAq &sig=ICzEBy4NRKU8HJwx19XED-kqgL8 &hl=en &sa=X &ei=X6IUUYHqG4-K9QTJnoHYBw &ved=OCDAQ6AEwAA #v=onepage &q=Kozeny %201962 %20700 %20faces %20convicted &f=false](http://books.google.com/books?id=cywujk9axNwC&pg=PA172&lpg=PA172&dq=Kozeny+1962+700+faces+convicted&source=bl&ots=IUOV9AbdAq&sig=ICzEBy4NRKU8HJwx19XED-kqgL8&hl=en&sa=X&ei=X6IUUYHqG4-K9QTJnoHYBw&ved=OCDAQ6AEwAA#v=onepage&q=Kozeny%201962%20700%20faces%20convicted&f=false) [http://www.dailymail.co.uk/sciencetech/article-2273857/Neurologist-discovers-dark-patch-inside-brains-killers-rapists.html](http://www.dailymail.co.uk/sciencetech/article-2273857/Neurologist-discovers-dark-patch-inside-brains-killers-rapists.html#ixzz2KHQmQhSi) #ixzz2KHQmQhSi Seth: Thanks for the links. I don't know about the brain damage study. The correlation between facial features and behavior is very weak. Nothing here suggests to me that this work is better (or will ever be better) than the self-report psychology you disparage. Why do we listen to what other people say? Because there is usually some truth to it. Why do you think speech evolved? Because it was useful. Self-report personality psychology is just psychology based on what people say. Many many things in the world are based on what people say and work fine. Sure, roughly all psychology research is useless. Same with all academic research. An engineering graduate student at Berkeley told me that 95 % of the research in her department was useless. Update: this article provides considerable evidence of the practical value of self-report psychology: [http://www.washingtonpost.com/national/on-leadership/why-extroverts-fail-intr-overts-flounder-and-you-probably-succeed/2013/01/28/bc4949b0-695d-11e2-95b3-272d604a10a3\\_singlePage.html?tid=obnetwork#](http://www.washingtonpost.com/national/on-leadership/why-extroverts-fail-intr-overts-flounder-and-you-probably-succeed/2013/01/28/bc4949b0-695d-11e2-95b3-272d604a10a3_singlePage.html?tid=obnetwork#)

Koanic (2013-02-11 21:10:45)

You are correct that the face reading studies are not very good yet. I happen to know that they will get much better, but you can't know that yet. I know why they are not very good - because they haven't found the right things to measure. Human facial inference is still better than academic methods. Introversion / extroversion is by far the least polluted and most accurate of the big 5 self report dimensions. There are certainly accurate self-report dimensions - for example male partner count is accurate.

The page you linked does not specify that the assessment was self-report. The paper has not yet been published. However, I agree with the pro-ambivert result. But this result is not very interesting, by itself, because it does not cover the biological or biographical angles. Seth: May I ask how you know that face reading studies will get much better? I haven't heard that before.

Koanic (2013-02-12 07:21:28)

Because I'm doing it - matching facial patterns to hardwired psychological dimensions, and seeing how the different ways they work out in biographical patterns. <http://www.koanicsoul.com/blog/2012/09/01/paleo-phrenology-and-the-new-face-i-sm/> The most important facial dimensions and corresponding psychological dimensions have not been measured yet in a study. For the most part, psychologists do not even pay attention to the hardwired psychological dimensions I have uncovered. This is because they are mostly not independent axes on self-reporting. Extro/introversion most closely corresponds to the recession of the eyeball from the upper brow bone, aka socket depth.

Koanic (2013-02-12 07:22:31)

should be "eyebrow bone shelf above" not "upper brow bone"

## Movie Directing and Teaching (2013-01-28 05:00)

In [1]my last post I described the result of giving my students more freedom. The more freedom I gave them, the harder it became to grade them. So I stopped grading them – giving them even more freedom. Here is what the director Steven Soderbergh said in [2]a recent interview about giving actors freedom:

INTERVIEWER You've talked at length about giving actors as much freedom as possible. That's resulted in a number of performances that have launched, revived, and revitalized careers. In the case of Jennifer Lopez in Out of Sight, you're responsible for her only good film performance.

SODERBERGH It's not that I never say no; I'm just not trying to control them. I'm looking to amplify and showcase whatever it is about them that I find compelling.

I assume that each of my students wants to learn something (related to the class). I try to make use of that desire rather than push them to learn something else. Whatever my students are good at, I want to make them better at. [3]Here is an old post of mine about how this way of teaching resembles the way good managers manage.

Alex Chernavsky (2013-01-28 06:56:24)

Have you never had students who were unmotivated and didn't perform well on the unstructured projects that you assigned? I'm not proud of it, but I have to say that the threat of bad grades kept me from slacking in many of the classes I took. There were so many potential distractions in my life, all competing for my attention. I'm not sure that I would have done well in high school and college if all my classes were free-form. Seth: I've only tried not grading once. In this particular case, nobody performed poorly. What I conclude is there are other powerful motivators besides grades. One is an innate desire to learn. Another is a desire to look good to your peers (in class presentations). Maybe your teachers never made good use of these two motivations.

Darrin Thompson (2013-01-28 11:51:39)

Thinking out loud: I can't help but wonder how that would work in a more technical class. At the end of the class can you execute proofs or write programs in C or multiply numbers? I suppose there's a case to be made for that fact that the current system of education in STEM subjects seems to favor a tiny minority of white males. I'm working in software engineering. A huge part of our jobs is combining a bunch of people's backgrounds, having a lot of conversations, and finally executing on something, whatever best idea we could come up with. The execution is sometimes a surprisingly small part of the job. Yet that background in technical knowledge has to come from somewhere and you either have it or don't. What you also sometimes have or don't is the ability to use that background effectively with others. That said, I can see the value in a class where you "go make something, like with a computer or whatever." And I wonder how much background students would have needed to "cover" before we all could be confident that they'd succeed at something. Seth: see my next post for an answer to this question.

dearieme (2013-01-28 15:49:55)

As an undergraduate I found most chemistry lectures dull but chem lab satisfying. I found many physics lectures interesting but most physics lab dull. I enjoyed maths lectures and also enjoyed doing computer programming. I don't offhand see any particular pattern there. But I did feel sorry for my friends who were on courses that seemed to involve only learning by listening, reading and writing, and no learning by doing.

### **Giving Computer Science Students Freedom (2013-01-29 05:00)**

After [1]my post about how I stopped grading, Eric Chown, who teaches computer science at Bowdoin, [2]said he did something similar. In upper division courses, he wrote, "All that matters is student engagement. When students are engaged . . . my job is to stay out of their way." I asked him for details. His reply:

Independent Study: I run a lot of them. Many are in areas that I'm not an expert in. This started out of necessity - some of our students wanted to learn things that we simply do not have in our curriculum and if they were exceptional students I knew they'd be able to learn those things on their own. Over the years I've come to see that all any of our students need to succeed in an independent study is a high level of motivation. I make sure they have picked a useful topic and are sufficiently motivated and have a general plan. After that I turn them loose. I meet with them once a week to see where they are. I rarely give them explicit assignments. I'm almost never disappointed by what they learn and accomplish.

Projects: I teach a Projects course. The goal of the course is engagement pure and simple. Students choose a project at the start of the term (approved by me). There are no lectures in the course nor any required reading. Course time is used for 1) weekly short (5-10 minute) student presentations on where they are, what problems they are having, etc., 2) to meet with each other if they are working in groups, 3) to share ideas. Students hand in weekly "work logs" (which I don't grade). As the course goes on, I encourage the students not only to present on their project, but also on the process of the project. Themes always emerge, particularly "what I expected to accomplish versus what I actually accomplished" and "how I learned to motivate myself". At the end of the term they do traditional presentations of their projects and hand in their software and a short paper about it. Student projects have become so central to our curriculum that we now require that all majors take at least one project-centric course to graduate. Probably more than half of our upper level courses have migrated in this direction.

Mobile Computing: Last year I started teaching a course on Mobile Computing. I had zero experience in this area. My goal was to try and stay about a week ahead of the class. . . . I told them that as computer scientists they should be able to do what I was doing - figure stuff out on the fly and learn where to look to find answers. Most of the grade for the course was based on a large project (no tests and a couple of easy warm up assignments). Students absolutely didn't care that I wasn't an expert, they were simply thrilled to have an opportunity to work in an area they were excited about. Many have since told me that it was their favorite course at Bowdoin. My experience as

a computer scientist was all the expertise that they required. I'm teaching it again this term and while I'm more of an expert now I doubt the course will be more successful. If anything, my increased expertise may be a little more threatening to them. Around the college people are amazed that I would try something like this (I suspect some folks are even offended that I would teach outside my training). It has been great and has helped energize me.

**Cognitive Architecture:** I base what I do in this course largely on how my advisor taught at Michigan. I assign readings for each class but never lecture. A lot of the course is about the advantages of "Active Learning" and I try to put it into practice in how I run the course. When we come to class I have the students make a list of questions inspired by the reading. Class is spent discussing those questions. As the semester goes along the choice of readings becomes more and more influenced by the particular interest of the students. I give students a choice between a project and a final. The only constraint on the project is that it should have something to do with the topics of the course and that I'd like them to connect those topics to their major (I get a lot of Neuroscience and Psych majors). Sometimes the biggest problem with the projects is that students simply get too involved. That happened this term with a group that made a robot boat based on Braitenberg's "Vehicles" using Arduino [open-source prototyping]. Neither they nor I knew anything about Arduino ahead of time, but they had an absolute blast with it. Not only did they learn a lot more about Braitenberg's ideas, but they learned about Arduino and even how to solder! By the end of their project I found myself reminding them that they had other classes.

**RoboCup:** I'm head of the Bowdoin RoboCup team. [3]RoboCup is a worldwide competition where robots play soccer against each other. I started teaching robotics to get students interested in Computer Science. My knowledge of robotics going in was basically that one of my best friends in graduate school was a roboticist and I helped him implement some cognitive theories on a mobile robot. I told my students that RoboCup looked like fun and I didn't see why Bowdoin couldn't have a team (I had an NSF grant to start a robotics lab). That was in 2005. By 2007 we had won the world championship, beating teams like Carnegie Mellon. We're still competing almost 10 years later. My best students still know more about robotics than I do. What I know is how to engage them, how to put them on tasks that suit their particular talents and how to see the big picture. I'm a huge believer in the idea of "ownership" so I absolutely give the students ownership of the team. When they make choices that I disagree with I simply make my opinion known. Sometimes I am proven right, often I am proven wrong. We are competing with the top engineering schools in the world as a dinky (1800 students) undergraduate college of liberal arts students. My students on the team (typically from 8-12 at any given time) learn way more doing RoboCup than they do in their classes. Mostly they do this in their free time. Occasionally they can work on it as part of one of my classes or an independent study. They want to learn and they do. I give them opportunity. A steady stream of them are ending up in graduate school at CMU, Georgia Tech, Michigan, etc. [When I was 8 years old, I learned the concept of college major. I asked my mother: "What did you major in?" "Extracurricular activities," she said. She spent more time on the student paper than on her classes. - Seth]

I asked him how his approach differs from what other computer science teachers do.

Here are some differences:

- 1) I don't see my job as trying to transplant my knowledge to my students. I see my job as a facilitator and guide.
- 2) I tell my students ahead of time in some of my courses that I'm not going to tell them everything they need to know. Instead I'm going to try and teach them what to do when they don't have all of the knowledge they need.
- 3) I try to adjust what I do on the fly to the students I have (this is easier at a small school). If I can get the students to come to key material through their own means (normally projects) it will be far more meaningful to them

and they will learn it much better.

4) I'm not afraid of not knowing everything. If I only teach what I know everything about, it really limits what my students can get from me.

5) Fairly open ended projects are a great way for students to learn, and they don't have to be a time sink for me. However, even the most motivated students need "nudges." Part of my job is to figure out (or help them figure out) what nudge any given student needs. Weekly logs, frequent short presentations, etc. seem to work well.

Computer Science lends itself well to projects. However, many or most CS courses are typically taught either through a series of small, well-defined programs, or by standard projects where everyone in the class has the same goal. Most people in the field cling tenaciously to a core of material that they feel absolutely must be taught. Sometimes I think we're headed in a direction where half of the people teaching CS will use the same Power Point slides for their lectures (which helps explain the appeal of things like Coursera). My feeling is that if I can get a student excited about just about anything within the field they will naturally encounter the important stuff in the course of engaging their interests.

Ed (2013-01-29 07:50:32)

Thank you for posting this. This style of teaching sounds like it would do well for an online or online/ in person mix type of class structure, where the teacher would meet with the student one on one online, instead of the typical one to many power point presentation. Do you think that this style of teaching could happen online? Thanks

Eric (2013-01-29 10:14:28)

RE: Ed. Yes, I think it could work online. Of course most of the interest in online learning comes from the idea of scale. I get a bit of scale in what I do in that I can do more independent studies and so forth than most professors, but that pales when compared to the kind of scaling people are excited about for things like Coursera.

TomGinTX (2013-01-29 18:23:48)

Forgive me for stating the obvious, but this is a lot more like the actual day-to-day work that computer scientists do. Traditional courses surely have their place for teaching the basics and getting a student started, but the project-based courses sound like a great idea.

### **Assorted Links (2013-01-30 05:00)**

- [1]Johnson & Johnson executives knew about problems with hip implant but did not tell doctors and patients. Surely an example of a larger problem.
- [2]Evidence that smell involves quantum physics. A theory that almost all smell scientists reject.
- [3]From 210 to 160 pounds via the Shangri-La Diet, and still losing.

- In [4] this history of the NFL's response to brain trauma, doctors, such as Elliott Pellman, acted far more often against player protection than for player protection.
- [5] The Sierra Club has taken lots of money from gas companies. Which makes sense. If you have a lot of money to spend, should you give it to those who agree with you or those who disagree with you? Which recipients will change more per dollar? Peter Gleick failed to understand this. [6] Noam Chomsky is even more confused.
- [7] Overweight associated with lower, not higher mortality. "Relative to normal weight . . . grades 2 and 3 obesity were associated with significantly higher all-cause mortality. . . . Overweight [25 < BMI < 30] was associated with significantly lower all-cause mortality."

Tom (2013-01-30 06:50:59)

Boeing knew about problems with the 787 battery, hid previous failures: <http://www.nytimes.com/2013/01/30/business/boeing-aware-of-battery-ills-before-the-fires.html>

Tom Passin (2013-01-30 06:58:32)

Interesting that in the study of mortality vs weight, the authors report the results for "overweight" and "Grade I Obesity" using rather different wording despite the fact that the numerical results were essentially the same: "overweight was associated with significantly lower all-cause mortality" but "Grade 1 obesity overall was not associated with higher mortality"

Matt (2013-01-30 07:28:19)

Does the weight/mortality study account for people who smoke cigarettes tending to be leaner than non-smokers?

Nancy Lebovitz (2013-01-30 08:18:40)

So far as I know, cigarette smoking only affects weight by 10 or 15 pounds. Would that be enough to have a large effect on the statistics?

Nancy Lebovitz (2013-01-30 08:22:15)

Could the olfactory sensors be sensitive to weight as well as shape?

Korben Dallas (2013-01-30 08:24:13)

@Matt: it was a meta-analysis, maybe some of the original studies they analyzed did adjust for smoking. But it could also be that slightly overweight people try to limit their sugar consumption more than normal weight people, and as such end up healthier, or that they get more nutrition from eating more kcals.. The Sierra club taking money doesn't make much sense to me, you're giving your most vocal opponents money? How does that make sense? If I have a political party, then surely the best way to spend money is to spend it on our own campaigns and not finance the campaigns of others? Seth: "How does that

make sense?" Well, yes, it isn't obvious. It makes sense because they will change. Political parties and gas companies have different goals. Political parties want to win elections, take over government. Gas companies want favorable treatment by government.

Matt (2013-01-30 09:02:29)

@Nancy: Yes, 10-15 pounds, if uncorrected not accounted for, would have a massive effect. An average normal weight person who gains ten pounds will usually be pushed into the overweight category.

dearieme (2013-01-30 14:01:26)

It looks as if the mortality vs weight curve is U-shaped, with a rather flat minimum in the range  $25 < \text{BMI} < 35$ . It would be clearer had they reported results for the scrawny ( $\text{BMI} < 18.5$ ) and separate results for not only the plump (grade 1 obese) but also the fat (grade 2 obese) and the spherical (grade 3). What chance that the scrawny die earlier than the fat? I think we should be told. I wonder whether the data sets are complete enough to allow recalculation using the new, improved definition of BMI proposed recently by some people at Oxford.

dearieme (2013-01-30 14:29:27)

Mind you, can it make any sense to recommend desirable BMIs without reference to age or sex (or, conceivably, race)? (I take it that the point of these correlative studies isn't mere intellectual curiosity - they're intended to yield recommendations, aren't they?)

TomGinTX (2013-01-30 20:10:21)

"If you have a lot of money to spend, should you give it to those who agree with you or those who disagree with you? Which recipients will change more per dollar?" This would explain why the gas companies would offer the money. But I too am puzzled as to why the Sierra Club would accept it. And why all the secrecy? Seth: I am not puzzled. Sierra Club leaders accept it because "it's for a good cause," they tell themselves. They accept it in secret because they think their members will be outraged.

Patrik (2013-01-31 00:54:21)

I hate to break the news to Seth's readers - but ALL of your favorite non-profit causes (environmental or otherwise) take money happily from their ostensible opponents - in fact, some orgs entire *raison d'être* has evolved is to extract money from their frenemies (shakedowns that benefit both parties), while the initial motivating cause is simply window-dressing.

Tom (2013-02-01 01:10:27)

Yes. I always thought this would be an easy way to get rich, if one didn't have much pride.

Hugh (2013-02-01 05:19:57)

Thanks, Seth, for the shout-out!

Paul N (2013-02-01 10:10:13)

A rough Canadian equivalent to the Sierra Club is the Pembina Institute, and environmental think tank, focusing on energy issues. However, they take a different approach, and actively engage with energy companies (and government, and public), and even do corporate consulting" to most of the oil companies in Canada. I say a different approach as not only do they engage with these companies, and receive money from them for doing so, but do not try to hide the fact. How much change they have been able to achieve in their 30yrs of doing so is debatable, but the same question can be asked of the Sierra Club too. At least one of these bodies does not try to hide anything - if you disagree with what Pembina is doing, then you don;t have to donate/associate, but at least they are clear about what they are doing and how they are funded - something many other advocacy groups are not.

Paul N (2013-02-01 11:04:51)

Sorry, link not working above. [1]Pembina Institute

1. <http://www.pembina.org/corporate-services>

M&M (2013-02-14 16:45:17)

Interesting article on the weight/mortality findings. What are your thoughts on this Seth? Seth: I think that as we get older, smell-calorie associations naturally get stronger (they are based on experience, which older people have more of). This raises the setpoint so average weight increases. Being far from the average in either direction generally indicates something is seriously wrong, which would also increase mortality. That's the best I can do.

## Guest Post: What Makes a Good Clinician? (2013-01-31 05:00)

This post is by Adam Clemans.

Marco Arruda, an MD and PhD in the Department of Pediatric Neurology at the Glia Institute (São Paulo, Brazil) is the author of [1]a recent editorial in JAMA Pediatrics about the use of [2]Triptan for headaches in children. There's a lot of controversy because placebos work very well for headache – so much so that they often have to use some tricky methods to actually show a treatment effect with the real drugs.

In [3]a recent article on Medscape, Dr. Arruda is quoted as saying: "Although placebo is the enemy of great clinical trials, it is likely the best friend of good clinicians."

This makes me wonder what he thinks makes a good clinician. If Triptan and a placebo are equally effective, it is curious that anyone would skip the placebo and prescribe the drug, which has listed as side effects:

Anaphylactic shock, angina, angioedema, breast pain, colitis, coronary artery vasospasm, hemiplegia, hypertension, myocardial ischemia, MI, neuropathy, rash, seizure, syncope, tachycardia, ventricular fibrillation, ventricular tachycardia

Why does putting patients in harm's way make one a good clinician?

dearieme (2013-01-31 06:06:13)

Has anyone studied the side effects of placebos?

Paul N (2013-01-31 11:47:28)

placebos have definite side effects for drug companies

Paul N (2013-01-31 11:53:42)

To the post itself, I'm not quite sure what Adam is getting at with his last question. "Although placebo is the enemy of great clinical trials, it is likely the best friend of good clinicians." implies a good clinician would make use of some sugar pills (placebos)... "This makes me wonder what he thinks makes a good clinician." It would seem he thinks it is one that uses sugar pills sometimes "Why does putting patients in harm's way make one a good clinician?" His idea is that the clinician

\*didn't\*, by using sugar pills. Am I missing/misreading something here? I wonder what the malpractice status is for a doctor that gives a placebo - for it to work, he must tell the patient it is actually a drug. The lawyers could have a field day with that one...

Elizabeth Molin (2013-01-31 12:40:45)

Apparently placebos often work even when the patient is told, "This is a sugar pill with no active ingredients, but it has helped some people with your condition."

Adam (2013-01-31 16:45:01)

Paul, I was a little unsure of what he meant at 1st too, but if you read the linked article, it is clear he is advocating using Triptans: "... when possible, treat within label by giving preference to approved drugs; and when no evidence is available, or when first-line therapies have failed, select a drug based on plausibility, proved efficacy in studies with adults, and proved safety of the drug in children." The problem is, there is no proof that these drugs are safe in children. It is obvious that Placebos are safer and, apparently, equally effective.

nicholas (2013-01-31 17:07:41)

A placebo is a tricky thing for a clinician and for patients. Personally, I would feel a little disappointed if I made the effort to come to a doctor and they told me to take a sugar pill, even if it was shown to be equally effective, and even if my logical brain believed that. Also, people dramatically underestimate 'no treatment' and in doing so over-estimate the placebo effect. Just doing nothing cures many problems and 'no treatment' is rarely run as a 2nd control. Maybe in children you can get away with prescribing pure placebos, but I'm not surprised that it just doesn't catch on with doctors and their adult patients. So... what if, instead of pure placebos, we had a movement towards 'low dose' medicines. Why not give someone low-dose aspirin at 1/5th or 1/10th of the normal dose? It will have very minimal side effects and would be something that both practitioners and patients can feel like is 'at least something'. It could get some real-world momentum, and would really reduce over treatment and side effects if it did.

Alex (2013-02-01 00:57:36)

"Arruda [...] points out that these studies "force us to remember that 'no evidence of efficacy does not mean the evidence of no efficacy'." sigh... Seth: It's one of the Consolations of Pseudo-Science, that you can say things like that.

Phil Goetz (2013-02-15 16:07:09)

Have the aforementioned side-effects also been compared to the side-effects of placebos?

Adam (2013-02-15 18:39:12)

In Triptan trials, the placebo groups usually have few side effects because they believe (or are told?) that Triptans have few side effects as well. In one trial patients were told they might be receiving an antidepressant but received placebo; side effects included dry mouth, drowsiness, constipation, and sexual problems. In another trial patients were told they might get an anticonvulsant but received placebo; they experienced more drowsiness & sleepiness. These are not at all comparable to heart attack, anaphylaxis, seizures, etc.

Seth Roberts (2013-02-16 02:14:12)

In some cases, "placebo effect" is confused with the effect of time passing. For example, if a patient gets better after getting a placebo, this is called a placebo effect even though it isn't clear that the placebo was responsible. The improvement might have happened if nothing was done.

### End-of-Life Medicine: Enormous Lack of Informed Consent (2013-02-01 05:00)

A few weeks ago I blogged about [1]undisclosed risks of medical treatments. Undisclosed risks are common. They might be the norm. The situation would be even worse – in some sense, much worse – if doctors knew of these risks and failed to tell their patients. It was unclear if doctors knew of the undisclosed risks I wrote about.

Recently [2]Tyler Cowen quoted [3]a newspaper story about Israeli doctors giving birth control injections to Ethiopian women immigrants "without their knowledge or consent." Every commenter thought this was repugnant.

[4]The latest RadioLab podcast ("The Bitter End") is about the dramatic difference between how doctors want to be treated when they are near death (they want no CPR, no ventilator, no dialysis, no surgery, no chemotherapy, no feeding tube, no antibiotics, nothing except pain medicine) and how the general public wants to be treated (most people want CPR, ventilator, dialysis, surgery, chemotherapy, feeding tube, antibiotics, and so on).

The RadioLab guys were puzzled by the difference. Upon investigation, they learned that the big differences exist because all those medical procedures (except pain medicine) have much worse outcomes than the public is told. The doctors know about the bad outcomes. It is better to die, the doctors decide. Unless doctors have less tolerance for being in a vegetative state, having ribs broken, and so on than the rest of us, it is clear that most people agree to these procedures because of ignorance. They fail to know what actually happens because the people who know – doctors – fail to tell them.

In other words, a huge number of sick people are being treated without having given informed consent. Doctors are doing many things to the sick people that benefit the doctors without telling the sick people how bad those things are. If end-of-life doctors told the truth, they would have a lot less work.

The RadioLab podcast hints at the moral retardedness implied by this practice in an interview with a medical student, whom I assume was randomly chosen. Why aren't people told the truth? the interviewer asks. "I don't know how to communicate that effectively," says the student. Then he communicates the truth quite effectively. Why don't you say that? says the interviewer. People don't want to hear that, says the student (changing his answer). They don't want to, but they need to, says the interviewer. The student says it would be "presumptuous" to tell them the truth. Presumptuous. What universe is he in? The absurdities and pathetic justifications given by the medical student to rationalize his behavior suggest that the whole medical profession doesn't understand there is a big problem.

The comments on the RadioLab podcast at the website also suggest that doctors fail to grasp there is a big problem. Many commenters are doctors. Some agree with the facts in the program. None expresses even discomfort with the situation. One commenter is Joseph Gallo, the Johns Hopkins medical school professor who runs the study that revealed the enormous difference between what doctors want and what the general public wants. "I second the sentiments about nurses being great," wrote Gallo. "I would add that studies that have asked nurses about their end-of-life preferences have found similar desire to limit care." The two sentences contradict each other. There is nothing "great" about anyone who sees this happening and does nothing.

jon (2013-02-01 07:15:45)

It would be nice if there was a free market in medicine, maybe doctors would have a better relationship with their patients then.

derp (2013-02-01 08:13:20)

The best article I've ever read on the topic: <http://www.zocalopublicsquare.org/2011/11/30/how-doctors-die/ideas/nexus/>  
Yes, it's most often the doctors. You don't go to med school because you are a good communicator, you go there for good grades. Even when motivated to learn how to communicate, my personal "end-of-life and bad news communication" course in med school comprised of 60 minutes. I had a lecture on the staging and treatment of super-rare eye cancers, lasting 90 minutes. Talk about priorities. Of course, sometimes family members are dumb as hell. But that's the minority of cases.

Sally (2013-02-01 09:31:23)

How do you know if someone is in fact "end of life"? The fact is, that it is not as clear as many in the general public, and nurses, would like to think. There are people, who are alive and active, albeit with disabilities, who have been declared "end of life" for the last 25 years by various nurses and other health professionals. Would you like to be one of them, would you like to have supports limited? If it comes to their own children, are the doctors quick to withdraw all treatment? Also, many people change their minds entirely, once they are actually in this situation of needing major medical help. Often enough, those who thought they wanted to die suddenly don't. I think this is very dangerous territory with lots of risks for rampant abuse of "the right to live". How many people are being euthanized because the care providers have determined that it is the best thing to do, according to their own knowledge and beliefs. (This is important: Judgements, even when it comes to life, death, medical care, etc., are made within the confines of a few people's knowledge, beliefs, and prejudices. Isn't it nice to play God? Isn't it nice to think of yourself as possessing the knowledge of the universe, being able to decide over life and death? How easy it is to say: "There is nothing one can do!" When, in effect, it would be more honest to state that "there is nothing I (and my colleagues) can do".) Holland, a state that is famous for its pro-euthanasia laws, had a veritable holocaust of sick, old and disabled people (being killed without their consent), because it was so easy to do so and so publicly acceptable. In order to protect the lives of people in the system (medical/care) it is important to err on the side of "life", even if it cuts into the profits of insurance companies. This question of cost, which is the real reason these discussions are being popularized (not because of human suffering), cannot be addressed by limiting our approach to health to the newest drug, surgery, or other traditional intervention. Of course, there is little money to be made by preventing disease and disability (which can never be eliminated, but can be reduced). However, I am not a supporter of always employing the most aggressive care. You are making a good point, that the benefits of treatment always have to be weighed against the risks. I am not in favour of pushing unwarranted risky treatments on patients, which would kill them faster than doing nothing, or which have no proven benefits. (This very common approach is very prevalent in medicine. Chemotherapy may be given, even though it does not improve outcomes and causes suffering. Statins and antidepressants are prescribe like candy, causing much harm,... and the list goes on. How much "end of life" is being caused by medical intervention?) So much for my ramblings. As a health professional my opinions are not as clearly defined and a lot more variable, depending on the individual circumstances. And there is always the nagging in my mind, reminding me, that with all my training and years of experience, I know very little. So I choose to leave the decisions over life and death up to God, and do what I am supposed to be doing: to help. Seth: I disagree. I think life and death decisions should be made by the sick person (and their families) after they have been told the truth about the alternatives available.

Alex (2013-02-01 10:53:13)

What do you mean by "moral retardedness"? Seth: The way they put what's best for them (telling the truth makes their life slightly worse) above what's best for the sick person in their care, who suffers considerably because they do not tell the truth.

Sally (2013-02-01 11:04:13)

Yes, Terry Wahls was once "end of life", so was Jill Bolte Taylor and many more famous and not so famous people.

Christopher Burd (2013-02-01 11:44:08)

"I second the sentiments about nurses being great" He may just be patronizing them and hasn't thought through the implications.

Mehmet (2013-02-01 12:42:09)

I lost my father due to lung cancer two years ago (I do not live in the US). I have two related experiences: 1) My father was at the hospital at the time of his death. When nurse understood that he was dying, she called the doctors and told us to leave the room. When we were leaving the room, I told the doctors not to do anything like CPR. However, when they left the room after my father's death, they told me that they did CPR without giving him any pain. They probably had to do CPR due to some legal responsibilities. However, doing CPR in that case was nonsense: if his heart would start, it would stop in a short time again because his organs were all failing. Not doing CPR should be the default option for dying cancer patients. 2) When my father was diagnosed with late stage lung cancer, he did not want to have chemotherapy. But all of his relatives (including me) insisted him to get chemo. I still regret that. Chemo has less than 1 % chance to cure extensive lung cancer (probably much more less than 1 %). The prolonged life expectancy for a few months is considered as success but that is just prolonged suffering. Chemotherapy is the single treatment that is proven to be ineffective for extensive lung cancer. I would prefer any other treatment than chemo if I am diagnosed with the same disease.

Rachael (2013-02-01 13:31:51)

A very close friend of mine recently died of cancer. He was 45, and not at all ready to die and he chose to do every single possible treatment. The odds for chemo lengthening life after a recurrence, after failing several previous rounds, were slim to none. No one was honest or direct about that with him, and I was alone in saying that. My friend's single greatest fear in life was suffocating, he had a sleep disorder as a child, and severe asthma, and the sensation of breathlessness caused panic for him. No one on his care team explained that a possible side effect of chemo was damage to the alveoli. Once he developed that damage and had to be on round the clock oxygen, no one said it was because of the chemo. It wasn't until he finally was admitted to hospice less than two days before he died that someone explained that it was related to the chemo. He would never have done the last round, or even the second to last round of chemo if someone had explained that. In the end, he suffocated to death, and it was horrifying and painful for his mother and all of us to watch. I don't think anyone had bad intentions, and neither he nor his family wanted to hear those truths. But had someone been brave enough to be truly honest, different decisions would have been made.

Sally (2013-02-01 14:55:19)

Yes Rachael, this is sad, and what you said is right on. This man may have lived just as long or even longer doing nothing, with less pain and suffering. He may even have had a chance for alternative treatments, which may or may not have helped, but at least would not have made him even sicker or would have had less side effects. The statistics for some cancers state as much. I think doctors feel compelled to do "something" (they think it is expected of them), or else, they may want to "cover their butts" by doing what is being prescribed to them (by the professional watchdogs). Seth: I'm not talking about whether doctors "do something." I am talking about who controls whether they do something - in particular, whether patients and their families are told the truth before they decide what to do. Lying to them is taking control away from them. Patients and their families are, in many many cases, not told the truth - by doctors. The treatment alternative is described as better than it actually is. I disagree that doctors are "compelled" to lie. I also disagree that doctors "cover their butts" by lying like this. Quite the opposite: I think they expose themselves to lawsuits based on lack of informed consent.

Sally (2013-02-01 17:44:55)

I agree that patients (and their families, friends, etc.) need to be told the truth. I always try to do this myself. On the other hand, all these doctors often know is what they learned, in university, from their superiors, from their associations, from seminars (usually put on by someone who has something to sell). They may be some of the most brainwashed people out there, and sometime their patients are better informed than they are. It takes time and effort to look deeper into things, and it takes courage to swim against the current. Doctors ARE being punished for not complying with the main-stream. When it comes to lawsuits it usually matters if things were done according to currently accepted rules. If the rule is to prescribe statins for high cholesterol, then a doctor can get in trouble for not prescribing them, when the authorities think this is what should

be done. If the person taking the statins gets diabetes and dementia from taking those statins years later (and all that comes with it), the doctors are usually safe, if they stuck to what is considered current practice. If you deviate from the norm, you may lose your license. I think it is like this in many professions. Millions of people are harmed all the time, because what is taught in schools and universities may be wrong or outdated, or the subject may have been omitted from the lessons altogether (there is only so much time). Later on these doctors get swamped with the usual propaganda and long hours at work, and other pressures, leaving little time to rebel or even question anything. I am not a friend of every doctor, but there are many with the best of intentions, who truly want the best for their patients. Do you always know the truth, Seth? I don't! Doctors are NOT gods. They are NOT powerful and all-knowing. Do you always tell others the truth, Seth, even if it is uncomfortable, even if it is going to crush the other person? I think I am not worthy enough for this blog. I don't seem to get it. I personally see the opposite problem a lot more often, the widespread withholding of treatments and supports for people who are considered doomed (by some professional and other Gods) anyway, why prolong life? They do not all have end-stage lung-cancer, they may have had a large stroke like Jill Bolte-Taylor or they may have been in a coma for 19 years (Polish guy), only to wake up after all this time to resume their lives. Of course, many people would have rather ended their "suffering" than giving them a chance. Seth: "When it comes to lawsuits it usually matters if things were done according to currently accepted rules." Currently accepted rules include allowing people to give informed consent. They cannot give informed consent if they are not told the truth. Please give me one example where a doctor got in trouble for telling the truth. I am not talking about what doctors "prescribe" (meaning offer) – for example, whether they prescribe statins or not. I am talking about whether they tell the truth about what they offer – for example, whether they tell the truth about the consequences of taking statins. You blame "brainwashing" and "the usual propaganda" and "long hours at work" and "other pressures" (such as?) for why doctors fail to "rebel" or "question anything". When a powerful person (the doctor) tells a less powerful person (the sick patient) the truth, it is not "rebelling" or "question[ing] anything." It is common decency. Failing to tell the truth, failing to allow the sick person to make an informed choice of what is done to them, is lack of common decency, to put it mildly. Why you are making excuses for it puzzles me. "Do you always tell others the truth, Seth, even if it is uncomfortable?" When I am asked a question, I try to tell the truth as gently as possible. I figured that out in my twenties. I found it gets easier with practice. Nothing terrible happens. Most people – maybe even everyone – appreciates being gently told the truth. You seem unaware of this.

Sally (2013-02-01 18:10:06)

I should let you know that my own father was revived three times between the ages of 25 and 50. Then he ended up in a coma in a cardiac ICU at age 73. My mother insisted that he gets maximum treatment. She insisted that my father wants to live, at all costs. She got the usual talk from the doctors, stating the complexity of the circumstances, the questionable outcomes of the treatments, and the unlikely recovery of my father. But, accepting the wishes of my mother, and presumably my father, the doctors gave it all they could. The nurses, however, pressured my other to "let go", to accept the "inevitable". To make a long story short, my father recovered. He is continuing his life. He is still needed. Thank God nobody turned off the ventilator and refused to revive him. Seth: I'm puzzled that you are changing the subject. The subject is: Doctors routinely fail to tell sick people the full truth about the treatments they offer.

Sally (2013-02-01 19:04:31)

But that is not all you were writing about. you were writing about all kinds of different things, and your examples were all over the place. So, enough of it, we overlap somewhere in the middle, like the two circles in math class, and then we have the rest of our respective circles (of opinions and beliefs), which do not match. That's fine! I wish you well! May the world become a better place for you and others. I am all for it!

Jerry (2013-02-02 09:58:17)

This post reminds me of the other great nexus where sex, violence, pain, lack of medical ethics, and lack of informed consent all meet: circumcision. I am referring to routine infant circumcision of male newborns, as currently practiced in the US. Do doctors (male and female) circumcise their sons? At what rate compared to the overall population? An even more interesting question: do intact (i.e. uncircumcised) male doctors circumcise their sons? Seth: I don't know of any data suggesting that doctors and everyone else differ greatly on circumcision rate.

Sara Lake (2013-02-02 20:36:07)

Seth, this is a very intriguing discussion. Why do doctors want something different for themselves than what they suggest to their patients? Of course, the patient needs to be offered all options, but it seems somehow unfair that those 'in the know' don't tell the whole truth about what those options involve in terms of quality of life. I think there may be some truth that most hospital doctors have to answer to someone higher up. I have actually heard of a doctor giving the mostly unvarnished truth, and he was a consulting specialist (so, essentially, self-employed). The story is pretty sad, involving a friend of mine whose small child (2 y.o.) had an aggressive genetic cancer which was diagnosed at an advanced stage. The specialist said, when asked what he would do if it was his child, "nothing, just pain relief". That's not what they ended up doing, but they appreciated the honesty (and, later agreed that this would have been a kinder tactic). I think it's a good, honest tactic for doctors to say 'this is what I'd do if it was me/ my child/my husband'. They are the ones that should know, after all.

Terry Elliott (2013-02-03 09:04:23)

I once had a political science professor sum this up. He said that we all need to make an important decision: who's on tap and who's on top? He was of a mind that the individual is always on top and the experts are always on tap. Of course, if you get fed a raft on well or ill-intentioned half-truths about end of life issues it is impossible to make that on top decision. I prefer to be told the truth and the odds so that I can make the decision. We must not abdicate this duty to remain responsible to ourselves even if we might make a mistake.

Slipping Away | stocker cary (2013-02-05 13:45:01)

[...] like this Seth Roberts blog about a RadioLab broadcast called "The Bitter End." It's about the information [...]

Mary (2013-02-05 14:00:03)

A "living will" signed by a patient can be revoked at any time by the patient by law! And unfortunately also (under threat of a law suit) by family members against the patient's will in most acute care places, if the patient is unable. I am a retired health care worker. In my advanced health care/POA for health care I have left specific instructions, including up to three months with treatment except a surgically implanted feeding device, among other things. All hospitals, by federal law, have ethics committees that can be accessed by physicians, nurses, and a group of family members if any of them wishes- if they have any issues in this regard.

### **New Terry Deacon Website (2013-02-03 05:00)**

Terry Deacon is a professor of anthropology at UC Berkeley. I [1]have blogged about the accusation of plagiarism (using Alicia Juarrero's ideas without citing her) against him. In addition to [2]the website accusing him of plagiarism, there is now [3]a website at berkeley.edu (UC Berkeley) meant to restore his reputation. It contains the report of a UC Berkeley committee that concluded there was not enough evidence to be sure Deacon had gotten certain ideas from Juarrerro, whom he had heard talk about them. Except in one instance, they could also not conclude the opposite - that he did not get certain ideas from Juarrero. There wasn't enough evidence to be sure of that, either.

The new website attempts to discredit Michael Lissack, one of Deacon's accusers. Here, in its entirety, is how the website describes Lissack:

Michael Lissack was formerly a managing director of a Wall Street municipal bond department. In 1998, the SEC issued an order finding that "Lissack willfully violated" federal securities laws and "that he undertook such conduct with an intent to deceive." According to the New York Times, later that year, the Manhattan District Attorney's office charged Lissack "with using the Internet to harass executives at his

old firm.” Media reports indicated that Lissack subsequently pled guilty to second-degree harassment. Lissack’s web site identifies him as the founder and executive director of the Institute for the Study of Coherence and Emergence (ISCE), as well as “the ISCE Professor of Meaning in Organizations, and a serial entrepreneur.” His posted CV states that he received a BA from Williams College, an MBA from Yale School of Management, and a Doctorate of Business Administration from Henley Management College.

Okay, maybe that’s relevant. Here’s [4]what’s also true:

[Michael Lissack] is notable as the whistleblower who exposed a yield burning scandal in the 1990s, whereby financial firms made illegal profits from the structuring of U.S. Government investment portfolios associated with municipal bonds. . . . In 1994 Lissack exposed a major yield burning scandal on Wall Street. The issue was eventually settled by a number of firms for over \$200 million, to which Lissack was entitled to at least 15 % per federal whistleblower laws. Lissack used some of these funds for charitable purposes including endowing a professorship in Social Responsibility and Personal Ethics at his alma mater Williams College.

I asked Lissack for comment on the committee report. He said, “By publishing the report the way they did and building a permanent web site they have ensured that anyone who attempts to treat Deacon seriously will read Juarrero and that was in many respects the goal.”

My expertise is too far from Juarrero’s and Deacon’s work for me to judge if the many similarities might be a coincidence, as Deacon claims. [Update: Juarrero has explained the reason for alleging plagiarism to me and I now agree, the similarities are no coincidence. I will post about this again.] I am sure, however, that Juarrero was right to be very upset that her work wasn’t cited.

I know the feeling. When I was a graduate student, at Brown University, I did several experiments with rats on the cross-modal transfer of time discrimination – the first such experiments in animals. They showed that rats had something like a concept of time. After I left graduate school and became a professor, my graduate school advisor, [5]Russell Church, and a new graduate student, [6]Warren Meck, essentially copied one of my experiments and the underlying theoretical idea. Needless to say it was not a case of independent invention. I had told Church about my experiments, which were done in his lab. I [7]published my results before they [8]published theirs. In spite of this, Meck and Church gave me as little credit as possible consistent with citing my work. Their introduction doesn’t mention my work – as if they had thought of their experiments without my help.

Strangely enough, I happened to be in Church’s office, visiting him, when the issue of the journal containing the Meck and Church paper arrived. I took the journal out of its brown paper cover. I looked at the table of contents. I saw their article, which I had not known about. (I wonder why.) I started to read it. I saw that, in the introduction, it didn’t mention my work. “Why did you do that?” I angrily asked Church. To get more credit, he said.

In my experience of academia, powerful people often take credit for what less powerful people have done. [9]The discovery of streptomycin, for which the powerful person received a Nobel Prize and the less powerful person did not, is an example. In the Terry Deacon case, Lissack has helped outsiders decide who deserves credit for what.

dearieme (2013-02-03 05:11:26)

The most outrageous academic crook that I encountered personally was eventually sacked, under the pretence of ill-health early retirement. It really was hard to get rid of a professor in an ancient British university, but they managed it in the end. I never learned how; perhaps they threatened him with jail.

## The Clouded Crystal Ball: A Psychic and Her Employees (2013-02-04 19:41)

The New Yorker used to have a mini-department called [1]The Clouded Crystal Ball: examples of bad predictions taken from "newsbreaks" – little bits of text used to fill a column. In [2]an interview, a friend of mine named Margaret Meklín told of a different sort of clouded crystal ball:

My first job in the U.S. was passing out flyers for a fortune teller on Powell and Market in San Francisco. She did not trust her psychic powers enough to guess who was doing a truly good job (it was me!), so she would periodically hide in the tourist crowds to check if we were passing out flyers quickly and efficiently and to a sufficient number of passersby. She gave a higher pay rate to my co-worker, thinking that he was more productive, but she had no idea that he would simply toss a whole stack of flyers into a trash can when she wasn't watching him.

## Why Alicia Juarrero Got Mad at Terry Deacon (2013-02-05 05:00)

In response to allegations that Terry Deacon, a Berkeley professor, plagiarized from Alicia Juarrero, a professor at [1]a community college, UC Berkeley created [2]a website that (among other things) [3]tried to smear Michael Lissack, one of the accusers. Less obvious is that the committee that investigated the allegations ignored their core: The overlap with Juarrero is relentless. It goes on and on. Juarrero explained this to me when I asked her what she thought of [4]the committee report:

I'm disappointed, but not surprised. Not sure what the difference is between "reckless" (which their definition of plagiarism includes) and "negligent" (which they critiqued as a "novel interpretation" of plagiarism). I'll tell you how my cri de coeur spreadsheet came about: as I read Deacon [Incomplete Nature] I got angrier and angrier, so I decided to start the spreadsheet. The index in my own book [Dynamics in Action] is very bad (my fault, my inexperience) and so I was having a hard time finding the parallel material in my own work. I knew I had said something to that effect somewhere in the book but couldn't remember where and couldn't find the entry in my own index. But suddenly, a pattern emerged: All I had to do was read on a few pages or paragraphs further down from the previous "problem," and there would be the next item. This happened over and over again in huge chunks of the work (which I highlighted to point out the big chunks of seriatim similarities) – it's the seriatimness (!) that's so damning and to me, clear evidence this wasn't just someone who vaguely remembered what I had said in a talk and then reconstructed the ideas for himself. The sheer number and sequential nature of the similarities are just too improbable to be a coincidence, or two people working in the same field. He was quite clever about it. He hid it with neologisms, talking about whole-part instead of top-down causality, insisting that self-organization is not enough (and then turning around in advocating it), etc. And, of course, not discussing intentional action, which is the explicit subject of my book.

The spreadsheet for Dynamics in Action and Incomplete Nature is on my website, [5][www.aliciajuarrero.com](http://www.aliciajuarrero.com). It was the seriatim nature of the parallels that really got to me and made me complain to Norton and UC Berkeley – anyone can discuss two or three of the same authors; or two or three of the same themes, or use two or three of the same examples; but that many, in pretty much the same order? The examples UCB picks (Benard cells, whirlpools) are indeed standard ones and if these were the only ones there would be no case. It's the cumulative impact that makes the case, in my opinion. The comments that I really object to in the report are "The idea that it is possible to reconceptualize teleology in terms of dynamical systems theory has been discussed and developed by many theorists" and "The connection between ideas about self-organization and ideas from thermodynamics and information theory has been made by many writers in this area..." The UCB report should have cited sources and dates. Simply to state, "is not in our view original to Juarrero..." and "we see no evidence that Deacon's use... shows any influence of Juarrero's" simply begs the question.

Re the Kant & Self-organization piece: it's true that everyone seems to be mentioning Kant in this connection (as if folks commonly read the Third Critique where Kant discusses this stuff). I suspect Deacon got this reference from his buddy Stu Kauffman (I would bet the rent Deacon didn't read the Third Critique!) – but at least Kauffman included me in his bibliography, if not in the footnotes. But I don't think Deacon could have afforded to include DiA in the bibliography – there's just too much of Dynamics in Action in Incomplete Nature – he just hoped no one would catch the parallels with a community college professor who published 10 years ago. As a philosopher I probably would never have read Incomplete Nature – but then I saw the Wall Street Journal review and the ideas sounded awfully familiar...

I'm happy to put the two works side by side and let readers judge for themselves.

How did Michael Lissack get involved?

First contact I had with him was in 2000, when he phoned my house to ask, "Is the phone ringing off the hook because of the book?" My answer: No, it isn't, who are you? He invited me to give a talk at his ISCE [Institute for the Study of Coherence and Emergence]

institute in Boston that year, and then invited me to be on the ISCE board. He also became a one-man publicity campaign for Dynamics in Action , including a long discussion about it with Kauffman, Deacon and Evan Thompson at Esalen in 2003. They spent hours discussing it. Which reminds me: Evan Thompson published a review in Nature in December 2011 in which he explicitly states that Deacon failed to cite him – and me. And Colin McGinn (whom I've never met), really lit into Deacon in the New York Review of Books in June 2012. None of this was mentioned in the UCB report, which makes it appear that Deacon's just the victim of a witch hunt by Lissack, Rubino and me.

ISCE was the publisher for the Rubino-Juarrero anthology on Emergence that's in question with the Deacon-Cashman article, so I think Michael feels ISCE organization is indirectly compromised by this mess – but it's mostly that he has never seen a fight he's run away from.

dearieme (2013-02-05 13:12:48)

That's a bit like Edwards' demonstration of Lewontin's Fallacy - the key bit is not the individual items, it's the correlation structure of the items. Ah, the wonders of Big University - I trust that the lefties who control the joint are really proud of their efforts.

Tom (2013-02-05 20:01:58)

Ooh, a tea partier who thinks everything is about "lefties." How unusual.

asdf (2013-02-06 00:02:34)

"Ooh, a tea partier who thinks everything is about "lefties." How unusual." LOL. U Mad?

dearieme (2013-02-06 01:23:36)

The Boston tea party was perpetrated by tea smugglers who were outraged that a reduction in the duty on tea meant that they would no longer be able to undercut the legit importer and thus would lose their livelihoods. I have no connection with that event which happened some time before I was born. Seth: Interesting. I hadn't heard that explanation before but it makes more sense than what I was taught.

dearieme (2013-02-06 08:50:19)

If I may say so, various chunks of what Americans have been taught about such events make little sense.

Todd Fletcher (2013-02-06 13:14:43)

Large chunks, not just various.

dearieme (2013-02-06 15:09:13)

My first draft said "huge".

Paul (2013-02-06 17:10:26)

The fact that Juarerro uses the phrase "begs the question" correctly—i.e. with complete fidelity to the *\_petitio principii\_* of classical logic—is a good sign that she knows what's going on. It's always windbags like Deacon who screw those things up. (BTW, re "leftie academics": Based on my own acquaintances I'd bet dollars to donuts that Juarerro is more left-wing than Deacon.)

dearieme (2013-02-07 08:35:48)

I'm sure that leftie academics are happy to misbehave towards someone from a lesser institution, whether they be righty or further-lefty. Equal opportunities and all that.

Alexander Boland (2013-02-07 13:35:47)

Not surprised about the sleep study—my experience has been that I can focus much better on mundane tasks while sleep-deprived because my mind is not as easily understimulated. Back in college, a sleep deprived day meant I listened better to lectures, but had a harder time completing problem sets. I've also hypothesized, similar to the study, that "taking a break" in order to solve a problem will be much less effective if that break is spent on noisy stimuli such as internet surfing.

chi (2013-02-07 17:35:40)

since when are 23 year olds "boys"? Seth: Since women in their 20s started calling themselves "girls". Whenever that was.

Txomin (2013-02-07 22:13:56)

"In the past journalism was an act of courage, revealing truths in the face of powerful establishments and risking jail or even death." No, it wasn't. While some journalist have indeed behaved in such a manner, most by far have never done so, even remotely. Journalism has always and mostly been a form of advertisement whether social, political, or simply commercial. Seth: I think his point is that such cases ("act of courage") were more common.

Txomin (2013-02-08 01:51:03)

If that was his intention, he was not clear. Besides, even if he had been more circumspect in his assertions, there are too many self-promoting myths surrounding journalism (it is, after all, one of the main functions of journalism) to accept such claim at face value. A good example is the alleged versus real role of the press in the Watergate scandal. Seth: Let me give some examples of journalistic courage. Ida Tarbell. Veronica Guerin, the reporter who was killed in Ireland. [1]Here is a list of journalists killed in Russia. [2]Here is more on journalists being killed. Yes, most journalists do not work in war zones or expose corruption, as you say. But since some do, for minimal rewards, journalists are not the first people I would accuse of cowardice.

1. [http://en.wikipedia.org/wiki/List\\_of\\_journalists\\_killed\\_in\\_Russia](http://en.wikipedia.org/wiki/List_of_journalists_killed_in_Russia)

2. <http://www.globalpost.com/dispatches/globalpost-blogs/rights/record-number-journalists-killed-worldwide-2012>

nicole (2013-02-08 17:48:53)

The second link is to the NYtimes article mentioned in number 3. Seth: Fixed, thanks.

Scot (2013-03-01 10:57:31)

This relates to personal science and sleep: a blog I read regularly CoolTools contains a review of safety glasses the reviewer uses with orange lenses to block UV/other blue light during evening activities to reduce sleep. Seems like a cheap, easy, self-initiated and controlled method for personal sleep research. [http://kk.org/cooltools/archives/10178?utm\\_source=feedburner&utm\\_medium=feed&utm\\_campaign=Feed %3A+CoolTools+ %28Cool+Tools %29](http://kk.org/cooltools/archives/10178?utm_source=feedburner&utm_medium=feed&utm_campaign=Feed%3ACoolTools+%28Cool+Tools%29)

## **Impossible Things That Are True: The Shangri-La Diet and the Behavior of Goldman Sachs (2013-02-08 05:00)**

It simply cannot be that drinking sugar water causes weight loss. Sugar caused the obesity epidemic! It simply cannot be that eating fat will cause weight loss. Eating fat is why we're fat! Everyone knows this. It simply cannot be that whether you smell a food while you eat it makes any difference. Weight loss is all about calories in, calories out. The Shangri-La Diet says all three things are true. I cannot think of an historical precedent. Science has uncovered all sorts of unlikely stuff but nothing so surprising that is also immediately useful.

I thought of the Shangri-La Diet when I read [1]this description by Michael Lewis of what Goldman Sachs has recently done:

Stop and think once more about what has just happened on Wall Street: its most admired firm [Goldman Sachs] conspired to flood the financial system with worthless securities, then set itself up to profit from betting against those very same securities, and in the bargain helped to precipitate a world historic financial crisis that cost millions of people their jobs and convulsed our political system. In other places, or at other times, the firm would be put out of business, and its leaders shamed and jailed and strung from lampposts. (I am not advocating the latter.) Instead Goldman Sachs, like the other too-big-to-fail firms, has been handed tens of billions in government subsidies, on the theory that we cannot live without them. They were then permitted to pay politicians to prevent laws being passed to change their business, and bribe public officials (with the implicit promise of future employment) to neuter the laws that were passed—so that they might continue to behave in more or less the same way that brought ruin on us all.

"The theory that we cannot live without them" was advocated by some of the most prestigious economists in the country.

What Goldman Sachs did – impossible-seeming, but it happened – is a sin of commission. Visible, at least to Michael Lewis, and capable of being pointed out (as Lewis does here) and marveled at.

The Shangri-La Diet seems like a bizarre thing, the diet from outer space, the crazy diet, whatever. It can't be true, but it is. Yet the Shangri-La Diet, strange as it sounds, is actually the only visible sign (at least, visible to many people) of a massive sin of omission: failure to do good research about health. Obesity has been a major health problem for a very long time, more than a hundred years, and an overwhelmingly large problem since about 1980, 30 years ago. Yet conventional thinking about it is so bad – because mainstream research is so impotent – that people still take seriously ideas that date back to the 1950s and before, such as calories in calories out. A weight loss method discovered more than a hundred years old (cutting carbs) is still a big deal. It is as if people were still marvelling at electricity.

The commonality of the two situations (Shangri-La Diet and Goldman Sachs) is that the people who are supposed to understand the world (health scientists in the case of SLD, economists in the case of Goldman Sachs) have in both cases so bungled their jobs that truly terrible things happened. In the case of SLD, the obesity epidemic happened. (Not to mention epidemics of depression, diabetes, auto-immune diseases, and so on. ) A slow-moving unmissable worldwide epidemic that has made hundreds of millions of people feel ashamed every time they look at themselves. In the case of Goldman Sachs, what happened was the 2008 financial crisis and subsequent poor recovery and the fact that the "solution" to the crisis left in place what had caused it.

1. <http://www.newrepublic.com/article/112209/michael-lewis-goldman-sachs>

---

Morex (2013-02-08 09:17:29)

Hi Seth. Yes, SLD sounds like a very crazy idea and a stupid thing to do. How on earth will you lose weight drinking frigging oil? This morning I was just thinking on how will I explain my new look to my parents when they see me? Last time I went to visit them (December 2012) I was about 125 kilos. After only a month living in Shangri-la I am 105 kilos... or something like that. They'll be in shock and they'll want to know my new "diet" because all their life have been struggling with weight too. We're a family of big people and terrible nutrition habits! SLD is not for people thinking inside the box. SLD means reading, researching and willing to experiment in oneself. Sadly not everyone is comfortable doing that.

Alex Chernavsky (2013-02-08 13:14:34)

Morex – you lost 20 kilograms in one month? That's almost 1.5 pounds per day. That doesn't sound possible.

dearieme (2013-02-08 14:18:33)

My dear sir, are you suggesting that people who deal with Goldman Sachs should wear nose-clips? Seth: It seems that way, doesn't it?

Morex (2013-02-08 16:45:17)

Alex, I forgot to mention I am a runner and I am training for a marathon. That may be it :)

Txomin (2013-02-08 17:20:36)

If you do strange things, you will obtain strange results.

BenSix (2013-02-09 09:22:11)

*Morex — you lost 20 kilograms in one month? That's almost 1.5 pounds per day. That doesn't sound possible.* Some boxers and MMA fighters have lost 50 pounds extremely quickly but much of this water weight. I'm not sure you could lose 20 kilograms of fat and muscle in so short a time without amputating a leg.

Tim Beneke (2013-02-10 12:35:20)

There is a sense in which one key insight of SLD is deeply implicit in our everyday understanding of hunger, eating and overeating. If you ask people who would weigh more, someone eating a diet of plain brown rice and steamed vegetables, or someone eating a diet that included a lot of cakes, cookies, ice cream, and so on, everyone will say the latter would cause weight gain. But ask them why? Why wouldn't they both eat the same number of calories that would satisfy their hunger and why wouldn't that be exactly the same. Why wouldn't they both eat the same number of calories and stop? Then people will slowly find themselves reasoning in such a way that leads to the conclusion that something about cakes, cookies and ice cream must somehow generate more hunger, must cause them to "pig out" or get "addicted". The most stunning comment anyone ever made to me about weight loss was when I weighed 280 pounds, and after I described my diet and the foods that I pigged out on (high in sugar and fat), Seth said to me: "Interesting that no one ever pigs out on fruits and vegetables." It stopped me cold...

### **Value of Self-Experimentation With Chronic Conditions (2013-02-09 05:00)**

A reader with an autistic son sent me a link to [1]a story in the New York Times Magazine by Susannah Meadows about a boy with arthritis who was cured by dietary changes, including omega-3 and probiotics. Conventional doctors and the boy's father had resisted trying the dietary solution; Meadows is the boy's mother. An expert in the boy's problem, Dr. Lisa Imundo, director of pediatric rheumatology at New York-Presbyterian/Columbia University Medical Center, told Meadows that "she [Imundo] had treated thousands of kids with arthritis . . . and diet changes did not work." It took only six weeks of the dietary change to discover it did work. Eventually the boy's arthritis was completely gone. It may have been caused by antibiotics he'd been given for pneumonia. The antibiotics may have killed his gut flora making his intestines too permeable.

Had Meadows accepted what mainstream doctors told her, her son would have taken medicine for the rest of his life – medicine that wasn't working well. Dr. Imundo wanted to double the dose.

The reader with an autistic son explained how it related to this blog:

It particularly supports the value of self-experimentation in these chronic conditions, especially when there is heterogeneity. The heterogeneity of autism was obvious to me from early on, although I've come to realize it's not obvious to everyone else. Autisms of known genetic causes have different tracks (Fragile X is the best-studied). Broad studies of autism start with a huge disadvantage: they are studying different disorders of similar presentation, and what helps in one case may harm in another. After the steady drip drip of your talking about n=1 experiments, it dawned on me that this applied to our situation. You didn't need to do a massive, double-blind, placebo-controlled study of acne medication any more than I needed to enroll a thousand families in a study of diet and autism. I could start with dinner.

The reader found dietary n=1 experimentation with her son to be very helpful.

Update. After I wrote this, Michelle Franci, a chemist who writes for Slate's Medical Examiner column, [2]complained about the "alternative medicine" in Meadow's piece. Franci fails to mention that dietary changes completely cured the problem, thus avoiding the need for dangerous drugs that weren't working. Franci says that Meadows has

"an irrational fear of chemicals".

1. <http://www.nytimes.com/2013/02/03/magazine/the-boy-with-a-thorn-in-his-joints.html?pagewanted=all>
2. [http://www.slate.com/articles/health\\_and\\_science/medical\\_examiner/2013/02/curing\\_chemophobia\\_don\\_t\\_buy\\_the\\_alternative\\_medicine\\_in\\_the\\_boy\\_with\\_a.html](http://www.slate.com/articles/health_and_science/medical_examiner/2013/02/curing_chemophobia_don_t_buy_the_alternative_medicine_in_the_boy_with_a.html)

---

Rachael (2013-02-09 09:19:26)

I thought the follow up article got one thing right, chinese medicine, and indeed herbal medicine is just as much "chemical" in nature as pharma. There are some advantages and disadvantages to "natural" medicines. Disadvantages are lack of standardization, lack of research, etc. Advantages can be that you have access to herbals without going through a medical gatekeeper. But I think the fear of chemicals and the chinese medicine were red herrings anyway. Failure of tight junctions and subsequent auto-immune processes being triggered isn't even "alternative." Every time you turn around there is a new article linking intestinal permeability to auto-immunity in the conventional medical literature. That the doctors treating this disease are un-aware of the current research and the paradigm shift in understanding of auto-immunity is far more interesting to me than the reflexive rejection of "alternative" medicine. One article about intestinal permeability and auto immunity: <http://www.ncbi.nlm.nih.gov/pubmed/19538307>

derp (2013-02-09 09:40:39)

Francl is completely off-topic. I don't see chemophobia in the original article – only a concerned parent who was not willing to put her kid on life-long high-side-effect drugs. If I don't want to live next to a nuclear power plant with my kids, will some physicist accuse me of nucleophobia? Seriously?

gwern (2013-02-09 10:24:47)

> If I don't want to live next to a nuclear power plant with my kids, will some physicist accuse me of nucleophobia? Given that more people died in the Fukushima evacuation than will ever die of the radiation release, and that just Germany's increased coal consumption is killing >100 people a year, I don't think 'nucleophobia' should be mocked as it's a very real thing with fatal effects.

Alex (2013-02-09 12:38:22)

Rachael is right that the "chemophobia" claim is a red herring. Without the artificial time pressure of the six week deadline, the mother could have sensibly tried the diet changes without the herbal medicine for six weeks, then added the herbal medicine if the diet changes alone didn't work.

Lisa (2013-02-10 07:27:03)

Rachael makes the point that there is little research available on the efficacy of herbal medicines, which is wholly incorrect. Also, the difference between herbal and as you say 'pharma' chemicals are many and wide ranging. The 'danger' of herbal medicine is always overplayed as Rachael does here. Yes of course, there are plants that can kill, and/or make you feel very sick, but medicinal herbs are plants that have been used by humans and animals for a long time (longer than any 'well tested' drug) have a totally different risk profile to using 'pharma' chemicals.

Around the Web: Happy Chinese New Year! | Perfect Health Diet (2013-02-10 14:29:42)

[...] Seth Roberts comments on a New York Times magazine story chronicling how a boy with juvenile arthritis was cured by dietary changes that remodeled his gut flora. [...]

Rachael (2013-02-10 14:55:39)

Lisa, I find your comment interesting as I in no way said herbal medicine is dangerous in my comment. I think we can agree that self administering foxglove (digitalis) can be dangerous, and many herbal medicines are extremely safe. The point I was trying to make is that their interactions with our bodies are because of the ways that chemicals interact with our bodies, be they from plants or from factories. I think western medicine neglects and ignores many safer and less side effect producing compounds because they have a bias against plant based substances. I do stand by my claim that relative to pharma compounds herbal medicines are seriously under-researched to the detriment of medicine. Because we have systematically defunded foundational medical research of all kinds and instead have almost exclusively private funded research in the US we close off many probably useful areas of therapy. Who is going to fund large scale research comparing HT2 receptor antagonists to whole ginger extractives? You can't patent ginger, no one would profit from that research. So doctors will continue using HT2 receptor antagonists when it may very well be that the ginger is safer, more effective, and cheaper as well. Or not, we have no way of knowing in the current paradigm until the research is done. At any rate, I suspect you and I are on the same side, sorry if I offended you with my earlier comment.

Lisa (2013-02-11 03:51:04)

Rachael, I appreciate your comment in response. I too think that we probably agree on more points than we disagree, and why we are both reading this blog. However, to counter your ginger argument - there has been quite a bit of published research on ginger! I googled 'H. Pylori and ginger' and came up with this article - top of the list! <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2849670/> Admittedly, it is research on mongolian(?) gerbils but there are plenty more articles. So to agree again, it would be good to see more studies on humans :) Although I would like to see more research using herbal medicine, I think the methods used research pharma compounds are necessarily different. Pharma compounds are by definition 'novel' and therefore it is not only the efficacy that should be studied but the safety (i.e. characterisation of side effects). To study the efficacy of ginger to treat specific conditions could be much cheaper as safety is much less of an issue. (I am aware of ginger's anti-platelet activity which needs to be considered when prescribing it for patients on blood thinning medication). Anyway, it isn't going to happen anytime soon and I am happy to work with what we already have out there in terms of research, combined with the rich herbal medicine tradition, as a guide to my own personal experimentation.

## What I Learned From My Writing Class (2013-02-10 05:00)

Last semester I taught Academic Writing to Tsinghua undergraduates (psychology majors). Two earlier posts ([1]here and [2]here) summarized what they learned. This post is about what I learned.

When I was an undergraduate, I hated the writing assignments I was given, most of them in English classes. I would have to become nauseous with fear before beginning them. I had nothing to say. When I became a professor and had something to say, everything changed. Writing was easy. This is why - in spite of believing the best way to learn is to do - I gave my students only one actual writing assignment: write a personal statement, which they had to do for graduate school applications. On the last day of class, I asked them: If I had assigned you to write something, what would you have written? Answers varied from diary entries to a literature review about nuclear panic. Then I asked them if they would have preferred a class like that. Half said yes, half said no. If I teach the class again, I would make it an option: do the regular homework assignments, or write and revise something you want to write.

1. <http://blog.sethroberts.net/2013/01/05/how-to-write-lessons-from-my-writing-class/>

2. <http://blog.sethroberts.net/2013/01/06/how-to-write-what-one-student-learned/>

---

dearieme (2013-02-10 05:55:36)

Unless my memory deceives me, I have never in my life had to write a Personal Statement. Thank God.

Tony (2013-02-11 05:43:51)

You should write a book on your teaching experiences. They are interesting and insightful.

M&M (2013-02-14 16:09:39)

Agree with Tony. I would be one of the first to buy. We homeschool(ed) our kids. One is now a top-level IB (International Baccalaureate) student and the younger ones are at home. The best lesson I've learned is teaching them, at an early age, to become self-directed.

### **If a Chinese Person Says You Are "A Good Student" What Does It Mean? (2013-02-11 05:00)**

An American writer named James McGregor (in *One Billion Customers*) called China "a nation of bookworms". In China, entry into college is heavily controlled by a nationwide test called the gao kao taken near the end of high school. For hundreds of years, China had the most sophisticated civil service entrance exams in the world. Chinese students study much harder than American students. Amy Chua's *Battle Hymn of the Tiger Mother* (in which a mother puts a huge amount of pressure on her daughters to succeed in conventional ways) was presented by Chua as reflecting Chinese parenting values. It's true that Chinese parents push their children much harder to do well in school than American parents.

All of which might lead unsuspecting Americans to believe that Chinese people value being a good student. Not at all. A Chinese friend explained to me that being called "a good student" is essentially an insult. "You are a good student" is what you say to someone when you can't think of anything nice to say. It means

1. You are not interesting.
2. You have no sense of humor.
3. You have no interests outside of school.

Drone might be the closest English equivalent to the Chinese "good student", except that no one would ever say to someone "you are a drone" and the meaning of the term has recently changed (to mean mini-planes flown remotely).

---

dearieme (2013-02-11 07:46:01)

In the UK, "you are a swot" comes close. It implies that to do well in exams you have to devote your time to them rather than being so naturally bright that you can make time to fit lots of other things into your life too. Of course, it rather overlooks the

fact that some children are probably well fitted to being swots, and that some who disparage swots could scarcely do well in an exam however many hours they worked.

JerseyCynic (2013-02-11 17:37:16)

Well "Bless their little hearts"!

Bob Levinson (2013-02-12 19:59:30)

Is your friend a young person? I have a Chinese roommate who is a PhD candidate at Berkeley in microbiology. He says this attitude is a generational change, partly as a backlash to the huge pressure, and partly due to the shift to money-making as a desirable goal. Seth: Yes. My friend is in her twenties. Consistent with what your roommate says.

Myrick (2013-02-16 23:30:05)

years ago among young people in Taiwan describing a girl as "very patriotic" was a popular wink-and-a-nudge euphemism for "pretty unattractive". don't know if this expression is still current, or if there was/is a mainland equivalent, but sounds close to the "good student" thing.

Janet (2013-02-26 10:38:45)

A "tool" is the same thing as a Chinese "good student."

### **A Little-Known Problem With Being a Doctor (2013-02-11 15:16)**

When she was a little girl, a Korean friend of mine, when asked, said she wanted to be a doctor. She got the idea from her mother – it is what her mother wanted. When she was older, she had a friend whose father was a doctor. The friend told her that when her father was sick, he had to pretend that he wasn't sick, and that this made her sad. After my friend heard that, she decided she no longer wanted to be a doctor.

---

Theragingwalrus (2013-02-12 13:15:54)

Doctors have to pretend they're not sick? What are you on about? Seth: At least in Seoul, Korea.

### **Assorted Links (2013-02-12 05:00)**

- [1]Interview with Royce White, the basketball player. I agree with him that addictions should be considered mental disorders. I think they are usually self-medication for a mood disorder, such as depression. His view that more than half of Americans have a mental disorder is consistent with my view that you need to see faces in the morning to have your mood control system work properly. Hardly anyone sees enough faces in the morning.
- [2]Racial quotas at Harvard by Ron Unz. "Top officials at Harvard, Yale, and Princeton today strenuously deny the existence of Asian-American quotas, but their predecessors had similarly denied the existence of Jewish quotas in the 1920s, now universally acknowledged to have existed."

dearieme (2013-02-12 06:45:41)

Golly! [http://www.nytimes.com/2013/02/12/science/testing-of-some-deadly-diseases-on-mice-mislead-report-says.html?pagewanted=1&\\_r=1](http://www.nytimes.com/2013/02/12/science/testing-of-some-deadly-diseases-on-mice-mislead-report-says.html?pagewanted=1&_r=1) Seth: Thanks. I have already written a post about it, which will appear in a week or so (backlog).

Darrin Thompson (2013-02-12 08:28:02)

On seeing faces, I get up every morning and my wife and I get our pile of kids off to school. I forget, but, doesn't that count as seeing faces? Isn't that very common? Seth: If you have 30 minutes of face-to-face conversation, that should have an effect.

Rashad (2013-02-12 10:50:28)

Apparently the Unz article is based on some uneven statistical sources which makes the Jewish over-representation a bit of an exaggeration. <http://andrewgelman.com/2013/02/that-claim-that-harvard-admissions-discriminate-in-favor-of-jews-after-checking-the-statistics-maybe-not/>

Rashad (2013-02-12 10:51:21)

Oh, oops, wrong Unz article. That one could be fine.

Nancy Lebovitz (2013-02-13 11:25:26)

Speaking of mice being different from people: [http://www.ted.com/talks/richard\\_weller\\_could\\_the\\_sun\\_be\\_good\\_for\\_your\\_heart.html](http://www.ted.com/talks/richard_weller_could_the_sun_be_good_for_your_heart.html) People who live in places with more sunlight seem to be much less likely to have heart attacks. (Studies mentioned are within Great Britain and Britain vs. Australia.) Subjects were exposed to UVA, which doesn't produce Vitamin D. Nonetheless, they produce more nitric oxide, and their blood pressure went down a little. It turns out that people (mice don't, which made studying the phenomenon more difficult) have stores of precursors of nitric oxide precursors in their skin, and sunlight activates them. A moderate amount of UVA exposure is enough to lower blood pressure enough to affect heart attack rates. (Note number of other factors which might be left out!) The effect is stronger in older people. The NO precursors may come from diet- specifically vegetables. He finishes by saying that as a dermatologist, he tells people to stay out of the sun, but he actually thinks there should be more work on a risk/benefit analysis for sunlight considering that heart attacks are a hundred times more common than skin cancer. Anyway, the reason I found this especially interesting is that it seems to me that depression correlates with grayish-looking skin, and depression is considered an independent risk factor for heart attacks. So there might be something in there about how much blood gets to the skin. (I've also seen people stably lose that greyishness, I think there's an emotional component.)

## Shangri-La Success in Detail (2013-02-13 05:00)

An Indianapolis man named Hugh, who goes by Nufftin on the Shangri-La Diet forums, has been [1]blogging about his weight loss (including graphs) at increments of 10 pounds lost (he writes a post when he's lost 10 pounds, 20 pounds, etc.). So far he's lost more than 50 pounds and is close to his goal weight, which is near his weight in college.

I decided to read all the entries and note what I learned. He started more than a year ago.

November 2011. He's been gaining weight for a long time. He is about 5 feet 6 inches tall and weighs more than 200 pounds, giving him a BMI in the 30s. He does not explain why he decided to try it. He has nice clothes that no longer fit.

April 2012 (10 pounds down). It took a long time to lose the first 10 pounds because he started just before Thanksgiving and Christmas, big eating holidays, and he gave up. He started again January 1 and gave up again. Then he started again in February. Daily weight spikes can be as much as 4 pounds (he weighs 4 pounds more on Tuesday than he did on Monday), but that only happened once (New Year's Party?). After he becomes consistent with the diet (in February), the graph of his daily weights is enormously convincing that the diet works.

May 2012 (20 pounds down). Here's exactly how he does the diet: "a shot glass full of extra-light tasting olive oil in the morning, with no eating for an hour each side; two heaping tablespoons of table sugar dissolved in as much water as it will take to dissolve it in the evening." (You can see why I would write a rather short book about such a diet.) He also does 15 minutes of exercise most days but I won't describe it in detail since it doesn't seem to matter – he stops exercising but keeps losing weight. Some old clothes now fit again. Only two people have commented on his weight loss. Maybe everyone notices but intentional weight loss is so rare it could be he's dying. (Which is what one of my Berkeley colleagues thought about my weight loss. He actually said, "Are you dying?") No one wants to hear that.

July 2012 (30 pounds down). The diet does require some effort. "I lost concentration for a couple of nights and, BOOM. To be fair, it was due to two great dinner parties (feta cheese hamburgers and The Descendants at one, Cuban sandwiches at the other)." These two "losses of concentration" did not have long-term effects. After 5-6 days – how long it took an unusually large amount of food to pass through his body and his salt balance to return to normal? – after those parties, his weight returned to its usual downward line.

September 2012 (40 pounds down). One of his shirts is now too big for him. He gained 6 pounds during a two-week trip. The gained weight comes off quickly (in about a week) but this time there is a noticeable long-term effect: Weight loss resumes at the same rate as before but the function is shifted by two weeks. He stops his 15 minutes of exercise and nothing happens to his rate of weight loss.

January 2013 (50 pounds down). It has taken 15 months to lose 50 pounds. There was one serious plateau, from December 2012 to January 2013, where he did not lose weight. Almost all of his pants are too big. He can take off his shirt at the pool.

---

1. <http://permanentquivive.wordpress.com/category/ongoing-series/the-diet/>

Chuck (2013-02-13 10:03:26)

Your "are you dieing" observation is right on. After losing 25lbs on a strict paleo diet, a long time barista at a Starbucks where I had been a regular customer took me aside after not seeing me for a couple of months and ask if I was "ok" (are you sick, do you have cancer, are you dieing). Even my adult children expressed their concern to their mother. I'm small framed and the weight loss was quite noticeable. Funny thing is, my new weight was/is exactly what I weighed in my twenties - at that time I was just the small guy, not the sick guy. Cheers

Hugh (2013-02-14 16:55:26)

Wow. Stunned. Thanks, Seth, both for the diet, and this write-up.

Jay (2013-02-26 14:46:41)

Great info, I have also had good success with this diet. The best part is the lack of hunger. Most diets are an arm wrestling match between the conscious and sub-conscious in regards to cravings for foods which I believe are related to the taste associations. I eat a regular breakfast at 5am. I do the ELOO at 9am. Around 1pm I am rarely hungry, and I have found a large apple or a cup of coffee and a handful of nuts works the rest of the day. Around 4pm I do the ELOO again and usually have dinner around 7pm. Not having to rely on will-power is the best thing about this diet.

## **Who Is Listened To? Science and Science Journalism (2013-02-14 05:00)**

[1]This book review of Spillover by David Quammen is quite unfavorable about [2]Laurie Garrett, the Pulitzer-Prize-winning science journalist. Several years ago, at the UC Berkeley journalism school, I heard her talk. During the question period, I made a comment something like this: "It seems to me there is kind of a conspiracy between the science journalist and the scientist. Both of them want the science to be more important than it really is. The scientist wants publicity. The science journalist wants their story on the front page. The effect is that things get exaggerated, this or that finding is claimed to be more important than it really is." Garrett didn't agree. She did not give a reason. This was interesting, since I thought my point was obviously true.

The book review, by Edward Hooper, author of *The River*, a book about the origin of AIDS, makes a more subtle point. It is about how he has been ignored.

When I wrote *The River*, I did my level best to interview each of the major living protagonists involved in the origins-of-AIDS debate. This amounted to well over 600 interviews, mostly of two hours or more, and about 500 of which were done face-to-face rather than down the phone. Although the authors of the three aforementioned books (Pepin, Timberg and Halperin, Natrass) all devote time and several pages to *The River*, and to claims that I definitely got it wrong, not one of them bothered to contact me at any point - either to challenge my findings, or to ask me questions. However, I have been contacted by someone through my website (a lawyer and social scientist) who asked me several questions, to all of which I responded. Later, this man read the first two of these three pro-bushmeat books and contacted the authors of each by email, to ask them one or two simple questions about their dismissal of the OPV hypothesis [= the AIDS virus came from an oral polio vaccine]. His letters to Pepin, Timberg and Halperin (which he later forwarded to me) were courteous and non-confrontational, and in two instances he sent three separate letters, but apparently not one of the authors could be bothered to reply to any of these approaches.

In other words, there is a kind of moat. Inside the moat, are the respected people - the "real" scientists. Outside the moat are the crazy people, whom it is a good idea to ignore. Even if they have written a book on the topic. Hooper and those who agreed with him were outside the moat.

Hooper quotes Quammen:

"Hooper's book was massive", Quammen writes, "overwhelmingly detailed, seemingly reasonable, exhausting to plod through, but mesmerizing in its claims..."

I look forward to the day that the Shangri-La Diet is called "seemingly reasonable". Quammen and Garrett (whose Coming Plague has yet to come) write about science for a living. I have a theory about their behavior. To acknowledge misaligned incentives (scientists, like journalists, care about other things than truth ) and power relationships (some scientists are in a position to censor other scientists and points of view they dislike) would make their jobs considerably harder. They are afraid of what would happen to them – would they be kicked out, placed on the other side of the moat? – if they took "crazy" views seriously. It is also time-consuming to take "crazy" views seriously ("massive . . . exhausting"). So they ignore them.

David (2013-02-14 06:29:09)

Reminds me of a thought attributed to Max Planck -- much of the time, new paradigms in science aren't accepted by scientists after much debate and introspection. No, new paradigms become accepted only after one generation dies, and a new, younger generation comes into power.

lef (2013-02-14 09:53:26)

related to davids comment about Max Planck. Many readers of this blog we are probably interested in the topic: extension of lifespan. so this is something to make us feel uncomfortable. Also there is the thought that nature by using death gives various benefits to evolution. Science is not a very natural activity so maybe the choice nature has made for our lifespan is bad for doing science, if Max Planck was right maybe it should have been smaller. Seth: I think the problem is self-correcting in a way different from what Planck said. Science, although unnatural, produces great benefits. Those benefits increase how much free time we have, time that we don't have to work. During their free time, some people do science as a hobby. Science was a hobby for Mendel and Darwin, for example. When science is a hobby, the scientist is perfectly free to seek the truth and nothing but the truth. As our free time increases (and the cost of doing science decreases) more and more people will do science as a hobby. Personal science – science done to help yourself – is a big part of what they will do. As hobby science increases, total science – professional science plus hobby science – will become more accurate.

dearieme (2013-02-14 15:17:42)

Decades ago I saw a mention of the work of someone who had looked at the data about scientists changing their minds in the light of some substantial theoretical advance. He said that the evidence proved Planck wrong. On a different tack: I used to have a colleague, an ambitious but rather dim fellow, whose favourite dismissive phrase was "not mainstream".

Phil Goetz (2013-02-15 15:38:16)

This reminds me of something I found while writing a review of breast cancer prevention methods. Back in the 1980s, an amateur scientist had noticed that some women she (he? don't remember now) knew who wore their bras in their sleep had gotten breast cancer. So she interviewed many women at random and found that women who wore bras at night were something like 20 times as likely to develop breast cancer. Unfortunately, instead of getting a respectable scientist interested, she published a book on her findings. This made the breast cancer/bra connection toxic. Despite indicating a much stronger association with breast cancer than any known behavioral factor, no "respectable scientist" in America or western Europe has ever investigated this. Now two studies have come out on it, one in China and one in Eastern Europe, both indicating a strong connection between wearing a bra at night and breast cancer. This discovery could not have been made in the US or in western Europe, because the claim had been made toxic "crank" material by being promoted by amateurs. Seth: I remember that finding, which I read about in the National Enquirer. I think the researcher failed to control for breast size – women with larger breasts were more likely to wear a bra at night. It's no surprise that if you have larger breasts (i.e., more breast cells) you are more likely to get breast cancer. This may be why it was ignored.

Paul N (2013-02-16 12:14:05)

I think there is more to the bra-breast cancer thing than just breast size. There have been various studies that do show correlation of breast size with cancer, but there are also others that suggest the wearing of bras, especially at night, interferes with the function of lymph nodes by constriction. Impaired lymph function can also lead to a decrease in melatonin, a known risk factor for cancer. I'm sure it would be hard to get funding for a serious bra- breast cancer study! Seth: Yes, that makes sense. And I agree with your basic point that the connection should have been studied, once it was noticed.

### **If You Ever Visit Seoul, You Might Want To Skip Bean Table Restaurant (2013-02-15 05:00)**

A restaurant near Seoul named Bean Table got [1]a surprisingly bad review:

Then came a massive chicken salad dish, given the number of people we had we over ordered. The patrons we brought were split 50/50 on enjoyment for the chicken. We had so much leftovers and were wasting so much food, I asked the waiter to wrap the leftovers. . . . Asking the waiter to wrap this chicken came with a resounding "no", so again to the kitchen to talk to a manager. Actually ended up talking to a chef, a young man who speaks good English, who also declined our request. We had a six year old and a three year old with us and that was the only food they were eating minus the pungent sauce.

Our driver then proceeded to get angry and went to talk to the chef, Sungmo Lee, and surprisingly Mr. Lee and our driver had a conversation that the whole restaurant could hear despite repeated requests by our driver to discuss outside. As that incident occurred being concerned for my family who flew on average 7,000 miles and were picked up for a total driving commute of two hours to come eat at this restaurant I went to calm both parties down. Things progressed from worse to horrible. I identified myself as a food critic, and Mr. Lee proceeded to take that as a threat and stated, "You don't know who I am." . . . My father, a man in his 70s, tried to speak reason to him only to be found that we were asked to leave.

At the end of the day, police were called, we weren't allowed to pay the bill till police arrived even after we stated we wished to leave and skip the remaining courses. Police came and scolded Mr. Lee, telling him that if a customer pays for food then containers should be allowed for the customers to take food home. Keep in mind we are talking about cooked chicken, not fish, or tartar, etc. (Mr. Lee's argument was that there were no take out containers in the restaurant and remained adamant about the no take out policy when we asked the driver to buy some containers). After the police came they asked us to leave while they dealt with Mr. Lee only to find an employee chasing out bus to pay the bill. No discounts, full

price and another time suck of 20-30 minutes and the rest of the meal was safely kept in their fridge due to their “no takeout” policy. . . .

Before all of this nonsense came down my whole Korean family all thought that the restaurant was over rated and there was no single outstanding dish.

Until the Internet, stuff like this was never reported.

1. <http://www.seouleats.com/2013/01/shitty-family-dinner-restaurant-bean-table/>

### **Web Browsers, Black Swans and Scientific Progress (2013-02-16 05:00)**

A month ago, I changed web browsers from Firefox to Chrome (which recently became [1]the most popular browser). Firefox crashed too often (about once per day). Chrome crashes much less often (once per week?) presumably because it confines trouble caused by a bad tab to that tab. “Separate processes for each tab is EXACTLY what makes Chrome superior” to Firefox, says [2]a user. This localization was part of Chrome’s original design (2008).

After a few weeks, I saw that crash rate was the only difference between the two browsers that mattered. After a crash, it takes a few minutes to recover. With both browsers, the “waiting time” distribution – the distribution of the time between when I try to reach a page (e.g., click on a link) and when I see it – is very long-tailed (very high kurtosis). Almost all pages load quickly (< 2 seconds). A few load slowly (2-10 seconds). A tiny fraction (0.1 %?) cause a crash (minutes). The Firefox and Chrome waiting-time distributions are essentially the same except that the Chrome distribution has a thinner tail. As Nassim Taleb says about situations that produce Black Swans, very rare events (in this case, the very long waiting times caused by crashes) matter more (in this case, contribute more to total annoyance) than all other events combined.

Curious about Chrome/Firefox differences, I read [3]a recent review (“Chrome 24 versus Firefox 18 – head to head”). Both browsers were updated shortly before the review. The comparison began like this:

Which browser got the biggest upgrade? Who’s the fastest? The safest? The easiest to use? We took a look at Chrome 24 and Firefox 18 to try and find out.

Not quite. The review compared the press releases about the upgrades. It said nothing about crash rate.

Was the review superficial because the reviewer wasn’t paid enough? If so, Walt Mossberg, [4]the best-paid tech reviewer in the world, might do a good review. [5]The latest browser review by Mossberg I could find (2011) says this about “speed”:

I found the new Firefox to be snappy. . . . The new browser didn’t noticeably slow down for me, even when many tabs were opened. But, in my comparative speed tests, which involve opening groups of

tabs simultaneously, or opening single, popular sites, like Facebook, Firefox was often beaten by Chrome and Safari, and even, in some cases, by the new version 9 of IE . . . These tests, which I conducted on a Hewlett-Packard desktop PC running Windows 7, generally showed very slight differences among the browsers.

No mention of crash rate, the main determinant of how long things take. Mossberg ignores it – the one difference between Chrome and Firefox that really matters. He's not the only one. As far as I can tell, all tech reviewers have failed to measure browser crash rate. For example, [6]this review of the latest Firefox. "I'm still a big Firefox fan," says the reviewer.

Browser reviews are a small example of a big rule: People with jobs handle long-tailed distributions poorly. In the case of browser reviews, the people with jobs are the reviewers; the long-tailed distribution is the distribution of waiting times/annoyance. Reviewers handle this distribution badly in the sense that they ignore tail differences, which matter enormously.

Another browser-related example of the rule is the failure of the Mozilla Foundation (people with jobs) to solve Firefox's crashing problem. My version of Firefox (18.0.1) crashed daily. Year after year, upgrade after upgrade, people at Mozilla failed to add localization. Their design is "crashy". They fail to fix it. Users notice, change browsers. Firefox may become irrelevant for this one reason. This isn't Clayton Christensen's "innovator's dilemma", where industry-leading companies become complacent and lose their lead. People at Mozilla have had no reason to be complacent.

Examples of the rule are all around us. Some are easy to see:

1. Taleb's (negative) Black Swans. Tail events in long-tailed distributions often have huge consequences (making them Black Swans) because their possibility has been ignored or their probability underestimated. The system is not designed to handle them. All of Taleb's Black Swans involve man-made systems. The financial system, hedge funds, New Orleans's levees, and so on. These systems were built by people with jobs and react poorly to rare events (e.g., Long Term Capital Management). Taleb's anti-fragility is what others have called hormesis. Hormesis protects against bad rare events. It increases your tolerance, the dose (e.g., the amount of poison) needed to kill you. As Taleb and others have said, many complex systems (e.g., cells) have hormesis. All of these systems were fashioned by nature, none by people with jobs. No word means anti-fragile, as Taleb has said, because there exist no products or services with such a property. (Almost all adjectives and nouns [7]were originally created to describe products and services, I believe. They helped people trade.) No one wanted to say buy this, it's anti-fragile. Designers didn't (and still don't) know how to add hormesis. They may even be unaware the possibility exists. Products are designed by people with jobs. Taleb doesn't have a job. Grasping the possibility of anti-fragility – which includes recognizing that tail events are underestimated – does not threaten his job or make it more difficult. If a designer tells her boss about hormesis her boss might ask her to include it.
2. The Boeing 787 (Dreamliner) has had battery problems. The danger inherent in use of a lithium battery has a long-tailed distribution: Almost all uses are safe, a very tiny fraction are dangerous. In spite of enormous amounts of money at stake, Boeing engineers (people with jobs) failed to devise adequate battery testing and management. The FAA (people with jobs) [8]also missed the problem.
3. The designers of the Fukushima nuclear power plant (people with jobs) were perfectly aware of the possibility of a tsunami. They responded badly (did little or nothing) when their assumptions about tsunami likelihood were criticized. The power of the rule is suggested by the fact that this happened in Japan, where most things are well-made.
4. Drug companies (people with jobs) routinely hide or ignore rare side effects, judging by the steady stream

of examples that come to light. An example is the tendency of SSRIs to produce violence, including suicide. The whole drug regulatory system (people with jobs) seems to do a poor job with rare side effects.

Why is the rule true? Because jobs require steady output. Tech reviewers want to write a steady stream of reviews. The Mozilla Foundation wants a steady stream of updates. Companies that build nuclear power plants want to build them at a steady rate. Boeing wants to introduce new planes at a steady rate. Harvard professors (criticized by Taleb) want to publish regularly. At Berkeley, when professors come up for promotion, they are judged by how many papers they've written. Long-tailed distributions interfere with steady output. To seriously deal with them you have to measure the tails. That's hard. Adding hormesis (Nature's protection against tail events) to your product is even harder. Testing a new feature to learn its effect on tail events is hard.

This makes it enormously tempting to ignore tail events. Pretend they don't exist, or that your tests actually deal with them. At Standard & Poor's, which rated all sorts of financial instruments, people in charge grasped that they were doing a bad job modelling long-tailed distributions and [9]introduced new testing software that did a better job. S & P employees rebelled: We'll lose business. Too many products failed the new tests. So S & P bosses watered down the test: "If the transaction failed E3.0, then use E3Low [which assumes less variance]." Which test (E3.0 or E3Low) was more realistic? The employees didn't care. They just wanted more business.

It's easy to rationalize ignoring tail events. Everyone ignores them. Next tsunami, I'll be dead. The real reason they are ignored is that if your audience is other people with jobs (e.g., a regulatory agency, reviewers for a scholarly journal, doctors), it will be easy to get away with ignoring them or making unrealistic assumptions about them. Tail events from long-tailed distributions make a regulator's job much harder. They make a doctor's job much harder. If doctors stopped ignoring the long tails, they would have to tell patients That drug I just prescribed – I don't know how safe it is. The hot potato (unrealistic risk assumptions) is handed from one person to another within a job-to-job system (e.g., drug companies market new drugs to the FDA and to doctors) but eventually the hot potato (or ticking time bomb) must be handed outside the job-to-job system to an ordinary Person X (e.g., a doctor prescribes a drug to a patient). It is just one of many things that Person X buys. He doesn't have the time or expertise to figure out if what he was told about risk (the probability of very bad very rare events) is accurate. Eventually, however, inaccurate assumptions about tail events may be exposed when people without jobs related to the risk (e.g., parents whose son killed himself after taking Prozac, everyone in Japan, airplane passengers who will die in a plane crash) are harmed. Such people, unlike people with related jobs, are perfectly free to complain and willful ignorance may come to light. In other words, doctors cannot easily complain about poor treatment of rare side effects (and don't), but patients and their parents can (and do).

There are positive Black Swans too. In some situations, the distribution of benefit has a very long-tailed distribution. Almost all events in Category X produce little or no benefit, a tiny fraction produce great benefit. One example is scientific observations. Almost all of them have little or no benefit, a very tiny fraction are called discoveries (moderate benefit), and a very very tiny fraction are called great discoveries (great benefit). Another example is meeting people. Almost everyone you meet – little or no benefit. A tiny fraction of people you meet – great benefit. A third example is reading something. In my life, almost everything I've read has had little or no benefit. A very tiny fraction of what I've read has had great benefits.

I came to believe that people with jobs handle long-tailed distributions badly because I noticed that [10]jobs and science are a poor mix. My self-experimentation was science, but it was absurdly successful compared to my professional science (animal learning research). I figured out several reasons for this but in a sense they all came down to one reason: my self-experimentation was a hobby, my professional science was a job. My self-experimentation gave me total freedom, infinite time, and commitment to finding the truth and nothing else. My job, like any job, did not. And, as I said, I saw that scientific progress per observation had a power-law-like distribution: Almost all observations produce almost no progress, a tiny fraction produce great progress.

It is easy enough for scientists to recognize the shape of the distribution of progress per observation but, if you don't actually study the distribution, you're not going to have much of an understanding. Professional scientists ignore it. Thinking about it would not help them get grants and churn out papers. (Grants are given by people with jobs, who also ignore the distribution.) Because they don't think about it, they have no idea how to change the "slope" of the power-law distribution (such distributions are linear on log-log coordinates). In other words, they have no idea how to make rare events more likely. Because it is almost impossible to notice the absence of very rare events (the great discoveries that don't get made), no one notices. I seem to be the only one who points out that year after year, the Nobel Prize in Physiology/Medicine indicates lack of progress on major diseases. When I was a young scientist, I wanted to learn how to make discoveries. I was surprised to find that everything written on the topic – which seemed pretty important – was awful. Now I know why. Everything on the topic was written by a person with a job.

With long-tailed distributions of benefit, there is nothing like hormesis. If any organism has evolved something to improve long-tailed distributions of benefit, I don't know what it is. Our scientific system handles the long-tailed distribution of progress poorly in two ways:

1. The people inside it, such as professional scientists, do a poor job of increasing the rate of progress, i.e., making the tails thicker. I think you can make the tails thicker via subject-matter knowledge (Pasteur's "chance favors the prepared mind"), methodological knowledge (better measurements, better experiments, better data analysis), and novelty. Professional scientists understand the value of the first two factors, but they ignore the third. They like to do the same thing over and over because it is safer. Great for their careers, terrible for the rest of us.

2. When an unlikely observation comes along, the system is not set up to develop it. An example is [11]Galvani's discovery of galvanism, which led to batteries, which led to widespread electricity. This one discovery, from one observation, arguably produced more progress than all scientific observations in the last 100 years. Galvani's job (surgery research) left him unable to go further with his discovery. ("Galvani had certain commitments. His main one was to present at least one research paper every year at the Academy.") His research job left him unable to develop one of the greatest discoveries of all time. In contrast, Darwin (no job) was able to develop the observations that led to his theory of evolution. It took him 18 years to write one book, longer than any job would have allowed. He wouldn't have gotten tenure at Berkeley.

After a discovery has been made, the shape of the benefit distribution changes. It becomes more Gaussian, less long-tailed. As our understanding increases, science becomes engineering, which becomes design, which becomes manufacturing. Engineering and design and making things fit well with having a job. Take my chair. Every time I use it, I get a modest benefit, always about the same size. Every time I use my pencil, I get a modest benefit, always about the same size. No long-tailed distribution.

Modern science works well as a way of developing discoveries, not making them. An older system was better for encouraging discovery. Professors mainly taught. Their output was classes taught. They did a little research on the side. If they found something, fine, they had enough expertise to publish it, but nothing depended on their rate of publication. Mendel was expert enough to write up his discoveries but his job in no way required him to do so. Just as Taleb recommends most of your investments should be low-risk, with a small fraction high-risk, this is a "job portfolio" where most of the job is low benefit with high certainty and a small fraction of the job is high benefit with low certainty. In the debate over climate change (is the case that humans are dangerously warming the planet as strong as we're told?) it is striking that everyone with any power on the mainstream side of the debate (scientists, journalists, professional activists) has a job involving the subject. Everyone on the other side with any power (Stephen McIntyre, Bishop Hill, etc.) does not. People without jobs are much more free to speak the truth as they see it.

We need personal science (using science to help yourself) to better handle long-tailed distributions, but not

just for that reason. Jobs disable people in other ways, too. Personal science matters, I've come to believe, for three reasons.

1. Personal scientists can make discoveries that professional scientists cannot. The Shangri-La Diet is one example. [12]Tara Grant's discovery of the effect of changing the time of day she took Vitamin D is another. For all the reasons I've said.

2. Personal scientists can develop discoveries that professional scientists cannot. Will there be a clinical trial of the Shangri-La Diet (by a professional weight-control researcher) in my lifetime? Who knows. It is so different from what they now believe. (When I applied to the UC Berkeley Animal Care and Use Committee for permission to do animal tests of SLD, I was turned down. It couldn't possibly be true, said the committee.) Long before that, the rest of us [13]can try it for ourselves and tell others what happened.

3. By collecting data, personal scientists can help tailor any discovery, even a well-developed one, to their own situation. For example, they can make sure a drug or a diet works. (That's how my personal science started – testing an acne medicine.) They can test home remedies. By tracking their health with sensitive tests, they can make sure a prescribed drug has no bad side effects. Individualizing treatments takes time, which gets in the way of steady output. You have all the time in the world to gather data that will help you be healthy. Your doctor doesn't. People who have less contact with you than your doctor, such as drug companies, insurance companies, medical school professors and regulatory agencies, are even less interested in your special case.

Average Joe (2013-02-16 06:18:40)

Speaking about Browser Tests, check this one <http://liferhacker.com/5976082/browser-speed-tests-chrome-24-firefox-18-internet-explorer-10-and-opera-1212> oh btw Opera browser announces transition to WebKit engine [http://www.theregister.co.uk/2013/02/13/webkit\\_sucks\\_on\\_webkit\\_chromium/](http://www.theregister.co.uk/2013/02/13/webkit_sucks_on_webkit_chromium/)

Allen K. (2013-02-16 06:33:37)

Whenever Chrome is slow for me, I get a new tab, do Shift-ESC, and find the process that is running slowly. (Mysteriously, it is usually in control of \_several \_ tabs, so when I End Process it kills all of them. I thought the point of Chrome was to fully

separate these.) Anyway it means I never crash Chrome, and I never wait minutes – if something doesn't load in 5 sec or so, I End its Process and load the pages one by one, pretty instantly.

Elizabeth Molin (2013-02-16 08:49:32)

I beg to differ. There is a word. Anti-fragile = robust.

Roger Sweeny (2013-02-16 10:07:16)

Durable? Strong?

derp (2013-02-16 10:19:23)

First of all, thank you Seth, for that article. "All of these systems were fashioned by nature, none by people with jobs." - quote of the day! As an MD, I rather give people useful advice on what changes to make and what to measure instead of prescribing stuff. Elizabeth, Roger: Please read the introduction to Taleb's Anti-Fragile. Fragile means losing from disorder (entropy). Robust, durable, strong means NOT losing from disorder. Anti-fragile means gaining from disorder. That's the main point.

Reanna (2013-02-16 11:27:42)

Resilient? Hardy? Stable? I think Taleb just wanted to secure his google results by coining a new phrase.

Reanna (2013-02-16 11:29:58)

Whoops, just read the last comment. Okay. Still think resilient is a candidate. Seth: derp is right. Anti-fragile means gains from disorder. Resilient, hardy, stable mean doesn't lose from disorder. I suppose Taleb was slightly wrong in the sense that hormetic means something pretty close to "gains from disorder". Hormetic things (= things that show hormesis) gain from disorder – up to a point. But they are the only anti-fragile things that exist. I read the book before publication. Blame me for not point this out at the time.

Matt (2013-02-16 13:41:59)

One of the most fascinating examples of this to me is incubators and who they choose to fund. What's interesting is that the only reason incubators can exist is because the few black swans that account for their returns. Most companies suck, and a few fall in the "succeed, but don't make us money" category. Only a fraction do well enough to make the incubator money. Here's Paul Graham, who runs one of the most successful incubators in the world, talking about how they specifically DON'T pick an investment strategy that would make them the most money, because they want a steady stream of "pretty good" companies to look good at their job, rather than picking a strategy that would be more successful, but would cause them to look bad. <http://paulgraham.com/swan.html> Seth: That's an excellent example.

Matt Weber (2013-02-16 21:30:40)

I've read your complaints about the professionalization of science many times, but it just occurred to me that they make a prediction: Why don't scientists at liberal arts colleges make all the breakthrough discoveries? They're like the olde-tyme professors you describe – they have the training of professional scientists, but their advancement is determined by teaching success, with discovery viewed as a nice bonus. I can think of a few reasons: (1) They actually are making the breakthroughs (unlikely, but possible) (2) They actually have similar publication incentives as scientists at research universities (possible, especially at higher-tier colleges) (3) Only bad scientists end up at liberal arts colleges (doubtful – faculty hiring is extremely competitive) (4) The teaching load at most liberal arts colleges is incompatible with any time-consuming hobby, including science (possible; 3-4 courses per semester is a lot, and they don't have grad students to do the grunt work) (5) They are trained by professional scientists and have imported that worldview – they see a teaching career as hamstringing, not liberating, their ability to do what they think of as science (my guess for Seth's preferred answer) Seth: One thing to keep in mind: liberal-arts colleges don't cover many subjects. For example, much of my research is about the intersection of nutrition and psychology. Liberal-arts schools don't have nutrition departments.

dearieme (2013-02-17 04:20:05)

I ask from ignorance: do such colleges have the quality and quantity of research lab space, equipment and technical support that one would need? I don't mean that they must equal the ever-growing empires of the top research universities, but there may be some ill-defined minimum that's necessary and which these colleges don't provide. On the other hand: in Britain the funding bodies used to chunter about "critical mass" in research, an evident ploy to shut down any small research groups (or individuals) that might flourish. I say "ploy" because I was once at a meeting where a bigshot bureaucrat was explaining this business and when I asked him about the evidence for his critical mass premise he could produce none. That's "none" as in zero - not even a little bit. I refrained from pointing out that his reasoning was therefore without weight, because the joke would have gone right over his head. Scientists are happy to conspire with such oafs because it's the oafs who direct the funding for the scientists' dreams of glory. Seth: At Reed College, in psychology, it seemed to me that the professors had enough resources to do most research. But psychology might be the lowest-tech laboratory science.

MJB (2013-02-17 06:24:57)

A related issue is 'educated incapacity.' I also often use the phrase to describe the limitations of the expert—or even of just the "well educated." The more expert—or at least the more educated—a person is, the less likely that person is to see a solution when it is not within the framework in which he or she was taught to think. When a possibility comes up that is ruled out by the accepted framework, an expert—or well-educated individual—is often less likely to see it than an amateur without the confining framework. For example, one naturally prefers to consult a trained doctor than an untrained person about matters of health. But if a new cure happens to be developed that is at variance with accepted concepts, the medical profession is often the last to accept it. This problem has always existed in all professions, but it tends to be accentuated under modern conditions. [http://www.hudson.org/index.cfm?fuseaction=publication\\_details&id=2219](http://www.hudson.org/index.cfm?fuseaction=publication_details&id=2219) Seth: I agree, that is another important way that jobs (or job training) are disabling.

CC (2013-02-17 08:02:25)

Outstanding post, Seth. As others have alluded to, Taleb makes a big deal out of the fact that "robust" is not the opposite of "fragile". That would be like saying that "bland" is the opposite of "delicious", where in fact "foul-tasting" is really the opposite of "delicious".

Chris Hynes (2013-02-17 08:39:39)

That's a very interesting hypothesis. If you accept it, a lot of confusing things fall into place. I'll definitely have to do a lot of thinking on the subject. I tl;dr'd it here: <https://plus.google.com/u/1/100434688393505441858/posts/iKiuoMVF2Gz> for my friends that won't read long stuff. Hopefully I captured the gist. Seth: Thanks, you summarized it well.

Nancy Lebovitz (2013-02-17 09:16:43)

A lot of interesting points. News media (especially if on paper) suffer from the job problem on the production side, too. They need to produce a certain amount of "news" per time period, regardless of how much is actually happening. I haven't been able to find a useful review of back-up software. It's easy to find reviews of how easy it is to get the software to make backups (the job), but I haven't seen any reviews of how well the software restores (the black swan). Have you read Root-Bernstein? ( \_Discovering \_, \_Sparks of Genius \_) If I remember correctly, he says that great scientists pay a lot of attention to their tools so they can be sure they're measuring what they think they're measuring, and great discoveries tend to come from trying to solve a practical problem which is somewhat outside their specialty. He probably has more that I don't remember. Seth: News media is a very good example. They are so clearly disabled in other ways by their job, not just by the need for steady output. There are many things they can't say no matter what the truth is. I have read Discovering by Root-Bernstein but not Sparks of Genius. Discovering is one of the books I was thinking of when I said the advice about how to make discoveries was poor. Discoveries has about 10 or 20 pieces of advice that don't fit together well. None of which struck me as useful or explained anything I noticed myself. Sparks of Genius might be better, I'll look for it.

Jonathan Shewchuk (2013-02-17 16:56:27)

Excellent post. Have you written anywhere a complete article summarizing your arguments for how the institutionalization of

science harms its progress? Have you read Bruce Charlton's "The Story of Real Science"? He gives reasons, some similar to yours, some different, for why he thinks science is dying in western civilization. <http://thestoryofscience.blogspot.com/> Seth: A complete article, no. That's a good suggestion. I didn't know about Bruce Charlton's "Story of Real Science", thanks for pointing it out.

Alex (2013-02-17 18:44:11)

Firefox crashing daily? Either your hardware is defective or you're doing something way too extreme (50+ tabs open at the same time, 20+ youtube videos playing at the same time or something like that). As I see, on my home machine I had 19 crashes since Jul 2010, last one was 1 Dec 2012. Previously most of the crashes were caused by buggy plug-ins, but once they were externalized into an independent process they no longer crash the browser. Seth: I doubt it's my hardware since crashes became much rarer when I switched to Chrome. I never have 50 tabs open; I often get to 10. I rarely play more than 1 youtube video at a time. I think there must be a third explanation. Maybe the explanation is that lots of websites have buggy software, but I'm not sure. Maybe you have more memory than me. Maybe it has something to do with being in China. In any case, localization was a feature of Chrome – a difficult feature to add – from the beginning for this very reason: because crashes happen pretty often. How do you explain the increasing popularity of Chrome at the expense of Firefox? Crash rate is the only big difference between them that I've noticed.

Nancy Lebovitz (2013-02-18 01:32:35)

I've only read parts of Sparks of Genius, but it didn't seem wildly different about research. The parts about different mental skills were interesting.

Nancy Lebovitz (2013-02-18 07:38:14)

Seth, any thoughts about how more people could have the free time to do independent work? Seth: I think this is already happening. As people become more productive, they need to work less to produce enough money. Less work, more free time.

Alex (2013-02-18 09:00:51)

Seth, I'd still run a memtest. It does not take much time (overnight) and it can eliminate or confirm the diagnosis. Firefox and Chrome do have a different memory footprint and memory allocation, so it is very possible that one hits a defective memory cell more often than another, causing more crashes. Seth: I did a memory test. No problems were found.

Jirka (2013-02-19 00:58:18)

I agree with the previous posters - this crash rate if either browser is definitely not normal, I would recommend running a stress-test on your hardware (OCCT - [www.ocbase.com](http://www.ocbase.com) - is free, popular, and offers several mixes of CPU/memory tests). Also, Adblock Plus plugin could help a lot, since most buggy code is some kind of intrusive advertising. Seth: I'm curious: how do you know what crash rate is normal? If crash rate is usually very low – as you seem to imply – why did the designers of Chrome include localization from the beginning?

Jirka (2013-02-19 09:29:05)

Taking advantage of multiple processor cores, security, and of course minimizing impact of any crashes - this does not imply that they are expected to be frequent, even rare crashes could be annoying if they take down the whole application. Normal crash rate = what I observe across multiple computers and users. I personally use Chrome all day, every day on two different computers, visit a lot of "suspicious" sites and experience several crashes a year at most. Maybe you just have some atypical browsing habits, maybe there is a problem in some of your plugins (Flash), but frequent crashes could indicate a hardware problem - I had the same problem when I built a new computer; one of my memory sticks was faulty (as diagnosed by Memtest86+), the problem went away when I replaced it.

James (2013-03-04 05:12:22)

Chrome is [1]actually going down in market share by some counts. Firefox 18 and 19 have been noticeably more crashy than 17 IME, but there's also a long-term supported release of 17 if you prefer stability. They did have to be berated to produce

it. Chrome also wants a steady rate of updates, so I'm not sure why you hold that against Firefox. Mozilla did [2]investigate using separate processes to display the browser UI, web content, and plugins, but it was [3]put on hold because it was a giant undertaking and they decided to deliver some smaller gains first instead, including memory usage (How much memory does your Chrome use?) They are [4]starting work on it again now, starting from the mobile version first. Your use of localization conflicts with its standard use in computing, which is adapting an interface to another language, primarily by string translation.

dearieme (2013-02-17 05:22:30)

"... people started backing away from this nonsense": even pretty young dieticians will now advise you to that effect. Although, alas, they preface their advice with the untrue "research has now shown ..." instead of the truthful "the idea was always a load of rubbish, unsupported by any evidence". Hell, even that dreadful liar Ancel Keys said that cholesterol in your food would do you no harm.

dearieme (2013-02-17 05:25:49)

Hah! "... people with higher egg consumption had a 25 % ... lower risk of developing hemorrhagic stroke." Ha bloody ha!

dearieme (2013-02-17 05:28:08)

P.P.S. In a British journal should that have been spelled "haemorrhagic"?

Andrew (2013-02-17 12:25:55)

Ned Kock did a moderating effects analysis of an earlier study that had found a link between egg yolk consumption and carotid plaque. Turns out that what the study really showed was a correlation between being old and liking eggs. <http://healthcorrelator.blogspot.com/2012/12/the-2012-atherosclerosis-egg-study-more.html> Seth: Lotta great stuff at Kock's blog, which I didn't know about. Very easy to read.

derp (2013-02-17 12:52:54)

That egg-heart connection is nonsense and has been pushed by a certain Dr. Spence who takes quite some money for a pro-statin-pushing agenda. Seth: It is nonsense, I agree. Many years ago it seemed like lots of people said that. Simply because eggs were high in cholesterol.

Nancy Lebovitz (2013-02-18 07:36:15)

What was more interesting was that when there turned out to be no evidence that eggs were dangerous, instead of saying that, they said "Well, you can have a few eggs a week". See also, evidence that moderate drinking might be good for people resulting in saying "but that doesn't mean we think anyone should start drinking".

Paul N (2013-02-18 13:19:42)

@ Nancy - Ned Kock did an [1]excellent analysis of that one also. It is amazing how often the advice/conclusions of these studies get "politically corrected" such that it is at odds with the very data they have produced!

1. <http://healthcorrelator.blogspot.ca/2013/01/how-much-alcohol-is-optimal-maybe-less.html>

Joe (2013-02-19 13:17:14)

Found a good one in the Economist this week, about a study showing bacteria in the stomach helps regulate blood pressure: <http://www.economist.com/news/science-and-technology/21571844-gut-bacteria-help-regulate-blood-pressure-sniffing-out-hypertension>

dearieme (2013-02-19 15:56:08)

A friend was mildly concerned about her blood pressure - it was on the high side. Now, perhaps six months later, it's tickety-boo. The only change to her diet that she can think of is that she's started eating half a banana at breakfast every day. Then again, perhaps it's just one of those things. Seth: Evidence that bananas lower blood pressure: <http://news.bbc.co.uk/2/hi/health/264552.stm>

## The Yakult Women of Seoul (2013-02-19 05:00)

Their name in Korean means Yakult women: street peddlers who sell several probiotic drinks, including Yakult. I encountered them in a Seoul suburb ([1]Bundang) on the way to the subway. During one 15-minute walk, I saw three of them. Other street peddlers in Bundang were often men (selling cookware or socks, for example) but the probiotic sellers were always women. I haven't seen street peddlers selling probiotic drinks anywhere else. In Japan, Yakult and other probiotic drinks [2]are sold door-to-door but apparently not on the street.

I asked a Korean friend how she (and Koreans in general) got the idea that probiotic drinks are good for health (which I am sure is true). She said she knew it before she went to school and believed she picked it up from TV ads. Apparently these ads are more successful in Korea than elsewhere. General Foods recently [3]paid \$9 million to settle a legal case based on Yoplait Yo-Plus ads in America that made similar claims. The lawyers who sued General Foods claimed that healthy people don't benefit from Yoplait Yo-Plus.

I can think of several reasons that Yakult women exist in Korea but (apparently) nowhere else. Maybe the fact that Koreans eat a lot of kimchi makes them more likely to believe that a probiotic is healthy. Maybe Koreans care more about health than other people. Maybe Koreans are unusually sophisticated about health. Bundang's density (it is full of tall apartment buildings) is surely one reason, because Yakult women weren't the only street peddlers. American suburbs, where I almost never see street peddlers, are much less dense. Another certain reason is that Bundang is a wealthy suburb. A third certain reason is that Yakult and similar drinks help you digest lactose. Lactose intolerance is much more common in Asia than elsewhere.

It would be interesting to compare the rate of digestive problems in South Korea versus other countries, especially the United States. I think they are likely to be much less common in South Korea.

2. <http://thestar.com.my/health/story.asp?file=/2007/10/28/health/19073245&sec=health>

3. <http://www.foodproductdesign.com/news/2013/02/general-mills-settles-yoplait-yogurt-lawsuits-in.aspx>

---

Mikael (2013-02-19 07:00:12)

Yakult is also extremely popular in Singapore, where I lived for a few years. There were ladies who knocked on apartment doors and sold six-packs (or some other quantity, maybe 8-packs) at slightly reduced prices compared to the shops. My kids (and other kinds) loved Yakult.

vic (2013-02-19 09:13:50)

Gastric cancer rates are generally much higher in East Asia than in the US or Europe Seth: I was under the impression that was because of high salt content. For example, miso is salty.

Robin (2013-02-19 09:38:19)

I can't imagine how Yakult which is just loaded with sugar is a very good way to get probiotics. But yes here in Singapore people give this sugary stuff to their kids and feel good about it. Then again they also pass off watered down chocolate/malt beverage(aka Milo) as a healthy sports drink to rival Gatorade.

Arthur (2013-02-19 10:34:51)

Selling Yakult door to door is quite common in São Paulo, Brazil, not on the street though. Seth: I read that in Brazil Yakult is considered a way to become lactose tolerant.

Morex (2013-02-19 17:33:33)

Yakult is very popular in Mexico. There are peddlers selling it door to door and in the street, specially outside elementary schools. Peddlers even have a subscription business model! Thanks to an ad in the 80's, moms now trust Yakult. I recall the tv ad was an anime that explained how probiotics fought evil bacteria inside the human body. It was funny. Also, Mexico is a country where most of the population suffers from gastritis and colitis thanks to spice and peppers in pretty much any meal. Hell, even candy are hot. It's thought that Yakult helps prevent and heal those diseases. Drinking Yakult is a must for millions. Even more, Yakult has a very good reputation now a days thanks to charismatic and inspiring Carlos Kasuga Osaka, Yakult's CEO for Mexico (Distribuidora Kai). He speaks in conferences and is a YouTube star here. Ergo, a lot of people love Yakult. I like it, but have it maybe once a year.

Erikku (2013-02-20 02:26:38)

Yakult Ingredients: Water, Sugar, Skim Milk Powder, Glucose, Natural and Artificial Flavors, Lactobacillus Casei Shirota (<http://www.yakultusa.com/yakult-nutrition-information.php>) Seth: It's puzzling that they don't add more bacteria, which would make the product more valuable.

## **More Trouble in Mouse Animal-Model Land (2013-02-20 05:00)**

Mice – inbred to reduce genetic variation – are used as laboratory models of humans in hundreds of situations. Researchers assume there are big similarities between humans and one particular genetically-narrow species of mouse. [1]A new study, however, found that the correlation between human genomic changes after various sorts of damage ("trauma", burn, endotoxins in the blood, and so on) and mouse genomic changes was close to zero.

According to [2]a New York Times article about the study, the lack of correlation "helps explain why every one of nearly 150 drugs tested at huge expense in patients with sepsis [severe blood-borne infection] has failed. The drug tests all were based on studies in mice."

This supports what I've said about [3]the conflict between job and science. If your only goal is to find a better treatment for sepsis, after ten straight failures you'd start to question what you are doing. Is there a better way? you'd wonder. After twenty straight failures, you'd give up on mouse research and starting looking for a better way. However, if your goal is to do fundable research with mice – to keep your job – failures to generalize to humans are not a problem, at least in the short run. Failure to generalize actually helps you: It means more mouse research is needed.

If I'm right about this, it explains why researchers in this area have racked up an astonishing record of about 150 failures in a row. ([4]The worst college football team of all time only lost 80 consecutive games.) Terrible for anyone with sepsis, but good for the careers of researchers who study sepsis in mice. "Back to the drawing board," they tell funding agencies. Who are likewise poorly motivated to react to a long string of failures. They know how to fund mouse experiments. Funding other sorts of research would be harder.

In the comments on the Times article, some readers had trouble understanding that 10 failures in a row should have suggested something was wrong. One reader said, "If one had definitive, repeatable, proof that the [mouse model] approach wouldn't work.....well, that's one thing." Not grasping that 150 failures in a row is repeatable in spades..

When this ground-breaking paper was submitted to Science and Nature, the two most prestigious journals, it was rejected. According to one of the authors, the reviewers usually said, "It has to be wrong. I don't know why it is

wrong, but it has to be wrong." 150 consecutive failed drug studies suggest it is right.

As I said [5]four years ago about similar problems,

When an animal model fails, self-experimentation looks better. With self-experimentation you hope to generalize from one human to other humans, rather from one genetically-narrow group of mice to humans.

Thanks to [6]Rajiv Mehta.

Tom (2013-02-20 06:46:33)

Yet despite the issues with mouse research, they're phasing out research with animals more like us. <http://www.nytimes.com/2011/12/16/science/chimps-in-medical-research.html> Seth: Rats are more similar to humans than mice. Maybe they will be a better animal model.

Walter Bushell (2013-02-24 05:56:25)

Reminds me of a Mulla Nasrudin (after Idres Shaw. Seems the Mulla was on his hands and knees under a lamp post. When asked why he was, the Mulla said, "I'm looking for my keys." Several people started to help him, and after a while someone asked him where he lost his keys. He said, "Over there in that dark area." "Then why are you looking here!?" "The light is better here, I'd never find them in the dark." Perhaps we could use raccoons, they have similar diets and have hands. Oh, yes and the problem of using genetically identical animals makes statistical analysis easier, but misses the point, some things may be quite toxic to a small fraction of the population and harmless to the vast majority or vice versa. For example, some people are very salt sensitive and get high blood pressure, but the majority has trivial effects from salt. So there is a movement to cut down salt from everybody.

sam (2013-02-21 06:38:11)

"Unable to make good products" is an interesting point of view. How to measure "a good product" if not in market adoption and sales?

Chris K (2013-02-21 06:57:20)

Seth, I really enjoy your blog, as well as SLD. But I have to point out that the cheap shot at Gates is unwarranted, and just plain wrong. There are many like me, a successful entrepreneur and product developer, who feel that Microsoft has developed dozens of great products. We appreciate the non-closed system, unlike Apple. We sometimes need additional capabilities not available in slicker, but dumbed-down, software, particularly so in engineering. Sales numbers may not tell everything, but they can't be ignored. Seth: Here are two examples. Word is okay now. For a long time, it struck me as worse than WordPerfect, which it supplanted. I would never call Word a good product, given that it was a step backward. WordPerfect showed how to do it, they couldn't even be bothered to copy it. Likewise, Windows used to crash a lot. It never seemed like a good product. I agree about the non-closed system. I think the sales numbers can be attributed to near-monopoly status, not great engineering.

max (2013-02-21 08:03:55)

Agree; disappointed to see microsoft-bashing here. Saying that microsoft is "unable to make good products" is at best totally false, and at worst, an oversimplification that doesn't give the company the benefit of the doubt, by failing to consider all the factors that go into determining whether a product is "good" or not. Seth: Yes, not very charitable of me. I persist in believing that Microsoft products – the ones I used heavily, including Word and Windows – could have been much better. I like PowerPoint. No complaints there.

Paul N (2013-02-21 10:00:41)

@ Sam, Those are measures of "sales success", which is quite different from a "good product" Measures of a good product include performance, reliability, and user preference compared to competing products. How do you think Microsoft compares to Linux or Apple on those? Microsoft succeeded because they were the first to come out with a platform that all PC's could use. Once they had the market cornered, it became that much harder for others to break into it, no matter how good their products were. Microsoft was not the best, just the biggest - something quite different.

Joe (2013-02-21 14:12:19)

Gates' objective was never to make a "good product." It was to make a great deal of money, and he definitely has, no?

Nile (2013-02-21 15:50:24)

What I know of Bill Gates I don't like, and I don't like Microsoft. I personally use Linux for almost all of my work. Personal feelings aside however, there is no denying Bill Gates was both a computer genius and a business genius. While Microsoft products may not have been perfect judged against a zero defect policy they were the best in class at the time when all things were considered. What makes more sense for a Fortune 500 company – a Wang word processor or MS Word? Can you do a spreadsheet on HP-UX or Solaris? The ecosystem matters and no matter how much better Multimate or WordStar or ?? were

compared to MS Word (and I don't think they were better ) they did not have an ecosystem and did not adapt to the GUI world.

Lemmy Caution (2013-02-21 16:08:02)

The decline in worldwide infant mortality mentioned in Gates article is a big deal. Microsoft products work perfectly fine.

Tom (2013-02-22 00:48:25)

It's awesome that Gates no longer spends his time ripping off other people's innovations. But Microsoft products are a disgrace. I can't believe anyone is actually criticizing Seth for pointing out the obvious. Microsoft has been putting profits first and customers last for over a decade. They don't upgrade products; they hobble them, forcing trapped customers to update to keep functionality that they've already paid for. This year alone they killed Mesh to force movement to the crippled SkyDrive, plus if you want the same functionality, they recommend paying for both Cubby and LogMeIn Pro. They are shutting down Messenger to force movement to Skype. They are shutting down Hotmail to force the move to Outlook.com; they have not announced it but it is obvious that they will be destroying Live Mail (their free email client) to force payment for Outlook, either in the cloud or locally. But they jumped the shark when in Win 8 they destroyed the desktop interface they stole in 1990 just to try to force their customers onto an interface they hoped would kill iOS. In their hubris, it looks like they have mortally wounded themselves. I understand that Ballmer sees the writing on the wall with the coming decline of WinOS and Office, and that this is his plan to keep revenues high. However, there is nothing in this plan for me, the lowly customer. I love that Win 8, Windows Phone and the Surface tablets are all catastrophic failures. It's a triad of too little, too late tone-deaf mistakes that will leave this company a pale shadow of its former self. I'm looking forward to Microsoft's demise, and resent that in America incompetent CEOs only fail upwards.

dearieme (2013-02-23 03:04:19)

Ahoy, Seth: does this ring true to you? <http://www.independent.co.uk/life-style/food-and-drink/from-vegetarian-to-confirmed-carnivore-8505787.html>

Brian (2013-02-23 23:00:54)

My two cents: Visual Studio seems to beat Eclipse in capabilities, by far. In 2013 it appears to me that Windows crashes less than Ubuntu and in fact all NT derivatives seem very reliable and they seem to have been commonplace for anybody that cared since about 1998. C Sharp and it's ecosystem of objects cannot help but be better than the previous general purpose "best" that was Java and it's own ecosystem of objects because it's kind of hard not to be better when you have something immensely useful/great to start with and then you set out not to innovate radically but just incrementally improve. A local disk installed copy of Excel seems far more polished than anything else.

## **Posit Science: More Questions (2013-02-22 05:00)**

[1]Posit Science is a San Francisco company, started by Michael Merzenich (UCSF) and others, that sells access to brain-training exercises aimed at older adults. Their training program, they say, will make you "remember more", "focus better", and "think faster". A friend recently sent me a[2] 2011 paper ("Improvement in memory with plasticity-based adaptive cognitive training: results of the 3-month follow-up" by Elizabeth Zelinski and others, published in the Journal of the American Geriatrics Society) that describes a study about Posit Science training. The study asked if the improvements due to training are detectable three months after training stops. The training takes long enough (1 hour/day in the study) that you wouldn't want to do it forever. The study appears to have been entirely funded by Posit Science.

I found the paper puzzling in several ways. I sent the corresponding author and the head of Posit Science a list of questions:

1. Isn't it correct that after three months there was no longer reliable improvement due to training according

to the main measure that was chosen by you (the investigators) in advance? If so, shouldn't that have been the main conclusion (e.g., in the abstract and final paragraph)?

2. The training is barely described. The entire description is this: "a brain plasticity-based computer program designed to improve the speed and accuracy of auditory information processing and to engage neuromodulatory systems." To learn more, readers are referred to a paper that is not easily available – in particular, I could not find it on the Posit Science website. Because the training is so briefly described, I was unable to judge how much the outcome tests differ from the training tasks. This made it impossible for me to judge how much the training generalizes to other tasks – which is the whole point. Why wasn't the training better described?

3. What was the "ET [experimental treatment] processing speed exercise"? It sounds like a reaction-time task. People will get faster at any reaction-time task if given extensive practice on that task. How is such improvement relevant to daily life? If it is irrelevant, why is it given considerable attention (one of the paper's four graphs)?

4. According to Table 2, the CSRQ (Cognitive Self-Report Questionnaire) questions showed no significant improvement in trainees' perceptions of their own daily cognitive functioning, although the p value was close to 0.05. Given the large sample size (500), this failure to find significant improvement suggests the self-report improvements were small or zero. Why wasn't this discussed? Is the amount of improvement suggested by Posit Science's marketing consistent with these results?

5. Is it possible that the improvement subjects experienced was due to the acquisition of strategies for dealing with rapidly presented auditory material, and especially for focusing on the literal words (rather than on their meaning, as may be the usual approach taken in daily life)? If so, is it possible that the skills being improved have little value in daily life, explaining the lack of effect on the CSRQ?

6. In the Methods section, you write "In the a priori data analysis plan for the IMPACT Study, it was hypothesized that the tests constituting the secondary outcome measure would be more sensitive than the RBANS given their larger raw score ranges and sensitivity to cognitive aging effects." Do the initial post-training tests (measurements of the training effect soon after training ended) support this hypothesis? Why aren't the initial post-training results described so that readers can see for themselves if this hypothesis is plausible? If you thought the "secondary outcome measure would be more sensitive than the RBANS" why wasn't the secondary outcome measure the primary measure?

7. The primary outcome measure was some of the RBANS (Repeatable Battery for the Assessment of Neuropsychological Status). Did subjects take the whole RBANS or only part of it? If they took the whole RBANS, what were the results with the rest of the RBANS (the subtests not included in the primary outcome measure)?

8. The data analysis refers to a "secondary composite measure". Why that particular composite and not any of the many other possible composite measures? Were other secondary composite measures considered? If so, were p values corrected for this?

9. If Test A resembles training more closely than Test B, Test A should show more effect of training (at any retention interval) than Test B. In this case Test A = the RBANS auditory subtests and Test B = the secondary composite measure. In contrast to this prediction, you found that Test B showed a clearer training effect (in terms of p value) than Test A. Why wasn't this anomaly discussed (beyond what was said in the Methods section)?

10. Were any tests given the subjects not described in this report? If there were other tests, why were their results not described?

11. The secondary composite measure is composed of several memory tests and called "Overall Memory".

The Posit Science website says their training will not only help you “remember more” but also “think faster” and “focus better”. Why weren’t tests of thinking speed (different from the training tasks) and focus included in the assessment?

12. Do the results support the idea that the training causes trainees to “focus better”?

13. The Posit Science homepage suggests that their training increases “intelligence”. Was intelligence measured in this study? If not, why not?

14. Do the results support the idea that the training causes trainees to become more intelligent?

15. The only test of thinking speed included in the assessment appears to be a reaction-time task that was part of the training. Are you saying that getting faster on one reaction-time task after lots of practice with that task shows that your training causes trainees to “think faster”?

Update: Henry Mahncke, the head of Posit Science, said that he would be happy to answer these questions by phone. I replied that I was sure many people were curious about the answers and written answers would be much easier to share.

Further update: Mahncke replied that he would prefer a phone call and that some of the questions seemed to him hard to answer in writing. He said nothing about the sharing problem. I repeated my belief that many people are interested in the answers and that a phone call would be hard to share. I offered to rewrite any questions that seemed hard to answer in writing.

Tim Beneke (2013-02-22 12:20:24)

Just a wonderful example of clear critical thinking.

Jazi Zilber (2013-02-24 15:27:43)

Brain training usually does not transfer to other domains / tasks. Some reviews looked into it and found no transfer, and they considered multiple studies. My a priori assumption is that a specific software will not be better than the sum of the studies. Seth: Here is an example of a meta-analysis that found no clinical relevance of working memory training: <http://psycnet.apa.org/journals/dev/49/2/270/>

## Celiac Experts Make Less Than Zero Sense (2013-02-23 05:00)

In the 1960s, Edmund Wilson reviewed Vladimir Nabokov's translation of Eugene Onegin. Wilson barely knew Russian and his review was a travesty. Everything was wrong. Nabokov wondered if it had been written that way [1]to make sense when reflected in a mirror.

I thought of this when I read [2]recent remarks by "celiac experts" in the New York Times. The article, about gluten sensitivity, includes an example of a woman who tried a gluten-free diet:

Kristen Golden Testa could be one of the gluten-sensitive. Although she does not have celiac, she adopted a gluten-free diet last year. She says she has lost weight and her allergies have gone away. "It's just so marked," said Ms. Golden Testa, who is health program director in California for the Children's Partnership, a national nonprofit advocacy group. She did not consult a doctor before making the change, and she also does not know [= is unsure] whether avoiding gluten has helped at all. "This is my speculation," she said. She also gave up sugar at the same time and made an effort to eat more vegetables and nuts.

Fine. The article goes on to quote several "celiac experts" (all medical doctors) who say deeply bizarre things.

"[A gluten-free diet] is not a healthier diet for those who don't need it," Dr. Guandalini [medical director of the University of Chicago's Celiac Disease Center] said. These people "are following a fad, essentially." He added, "And that's my biased opinion."

Where Testa provides a concrete example of health improvement and refrains from making too much of it, Dr. Guandalini does the opposite (provides no examples, makes extreme claims).

Later, the article says this:

Celiac experts urge people to not do what Ms. Golden Testa did — self-diagnose. Should they actually have celiac, tests to diagnose it become unreliable if one is not eating gluten. They also recommend visiting a doctor before starting on a gluten-free diet.

As someone put it in an email to me, "Don't follow the example of the person who improved her health without expensive, invasive, inconclusive testing. If you think gluten may be a problem in your diet, you should keep eating it and pay someone to test your blood for unreliable markers and scope your gut for evidence of damage. It's a much better idea than tracking your symptoms and trying a month without gluten, a month back on, then another month without to see if your health improves."

Are the celiac experts trying to send a message to Edmund Wilson, who died many years ago?

1. <http://www.theparisreview.org/blog/2012/02/29/document-nabokov%E2%80%99s-notes/>

2. <http://well.blogs.nytimes.com/2013/02/04/gluten-free-whether-you-need-it-or-not/>

Koanic (2013-02-23 05:44:49)

One super effective treatment for IBD - fasting and eating less. I have never heard anyone suggest this until recently, in an email. I went from bloody stool to almost perfect (better than nearly everyone's) in 24 hours, with nothing inbetween. This is unprecedented for me. A 24 hour fast is very hard if you are eating a Standard American Diet, for various reasons, but very easy if you are eating paleo. The optimal diet for IBD seems to be yoghurt and lean meat (including shellfish). This is nutritionally complete and the lowest residue possible. Instead, doctors run expensive, invasive tests that only reveal damage progression, and prescribe drugs with often dangerous side effects that merely mask the problem and permit it to become more severe, until the drugs stop working. Then they cut out a piece of bowel.

Tom Passin (2013-02-23 06:28:24)

I'd have to say that Dr. Guandalini's statement that "[A gluten-free diet] is not a healthier diet for those who don't need it," could well be true. In fact, it seems to be a tautology, with no useful content. The real issues are 1) as Seth points to, how can you find out if you have a gluten problem?, and 2) what if you don't have say IBS, try no-gluten and it doesn't seem to make a difference. Are there nevertheless long term health issues for you if you keep eating gluten? Dr G, and his fellows, don't seem to have anything useful to say about 2). Seth: I'm unsure what it means to "need" a diet. If the statement is revised to be clearer - "A gluten-free diet is not a healthier diet for those who don't benefit from it" - it's a tautology.

Alex (2013-02-23 09:33:36)

If I were Dr. Guandalini's patient, I would be concerned. In an article filled with unsupported pronouncements, his took the cake. As Tom Passin points out, the most charitable interpretation of it is as a useless tautology. The subject of gluten-free diets seems to spark a reflexive irrationality in many healthcare providers. Evidence-based medicine is all well and good, but only when the evidence is handed down from on high. Evidence based on what works for you is often greeted with condescending hostility. Doing an ABA trial of a gluten-free diet seems like the lowest of low-hanging fruit to address a chronic condition. Who needs gluten? Yet when Kelly Dorfman, author of Cure Your Child with Food (<http://cureyourchildwithfood.com/book/>) did a Q & A about gluten-free diets at the Washington Post, here again was the "concern." Given the typical lag of years between the onset of symptoms and the diagnosis of celiac disease, this concern seems misplaced. Q. WHO NEEDS A GLUTEN FREE DIET I think there should be an emphasis on the NEED of a Gluten Free Diet. It's fine if that is what the doctor ordered. However, right now, it seems to be the "in" thing to be Gluten Free when it's not necessary. Agree? - February 21, 2013 11:12 AM A. KELLY DORFMAN : There is a little bit of the 'latest thing' going on here with gluten free living. I agree. However, without a tight test for non-celiac gluten sensitivity, waiting for your doctor to point it out could be an exercise in pain and frustration. I have a long list of horror stories I could share (but won't). - February 21, 2013 12:52 PM <http://live.washingtonpost.com/gluten-free-kids-0221.html> #Who-NEEDS-a-GI

Tom (2013-02-23 13:01:52)

Hi, Seth, Off-topic, but I'm pretty sure you'll find the following on niacin therapy for mental illness interesting: [http://www.orthomolecularvitamincentre.com/a\\_hoffer\\_schizophrenia.php](http://www.orthomolecularvitamincentre.com/a_hoffer_schizophrenia.php)

Tom (2013-02-23 13:49:12)

One last link. The comments are interesting, too: <http://high-fat-nutrition.blogspot.com/2013/02/complex-i-hoffer-and-b3.html>

Babar (2013-02-24 07:36:47)

I have thought about cutting out gluten just to see if it is a problem for me (I suspect no, no reason to think it is) but I can't think of a good experiment. If I just stop eating bread I will change other things (fewer cheese sandwiches means less cheese maybe, or substituting spelt for wheat means more spelt, not just less gluten). At the very least less wheat means more of something else! So what experiment can I do that is sensitive enough to capture what is probably a small effect? Seth: So what if you change other things. You will still reduce gluten. If you reduce gluten substantially and notice no changes, that is evidence against the hypothesis that gluten is a problem for you. If you reduce gluten substantially and notice improvements, that is evidence for the hypothesis that gluten is a problem for you. How to increase sensitivity: Reduce gluten a lot. Notice what might have changed. Start measuring those things carefully. Increase gluten. Do they get worse?

Mary (2013-02-24 10:38:06)

I am not a 'celiac' but I was a sufferer of GERD and severe heartburn for many years. I read several articles online about 'leaky gut syndrome.' I eliminated wheat, including my beloved scotch. The results were almost immediate- within weeks I no longer needed omeprazole or Nexium and I have taken no acid inhibitor for four years. Anecdotal? Certainly. Would I go back to the SAD recommendations of x number of whole grain servings? When pigs fly!!! Seth: As far as strength of evidence for causality goes, your "anecdote" is much stronger evidence than many non-anecdotes.

Alex (2013-02-27 20:12:35)

Babar, don't overthink it. You're not trying to wow the Nobel committee, you're just figuring out what works for you. You can do a month off gluten, a month back on, another gluten-free month, and see if there are any changes. Then you can try something else, maybe pursue anything interesting that arose in the first experiment. If cutting out cheese sandwiches makes a difference, try a month without cheese and a month without bread to see which one is having an effect. Get going, and have fun.

KM (2013-02-28 15:24:57)

I stopped gluten and dropped 40 lbs. My skin cleared up. I no longer get acid reflux. My sleep problems improved. Doctor G would have me go back on gluten and have a bunch of tests done to determine if I have a problem with it. Hmm. I think I may disregard his opinion. Seth: Yeah, exactly. His advice makes less than zero sense.

KBS (2013-02-28 15:28:11)

One note of caution-I have been diagnosed with Celiac, but it took almost a year for me to feel better without gluten, in part because of complications due to having Celiac for so many years. Just going gluten free didn't help, at least not at first. So if a month without gluten doesn't make you feel better, you could still have Celiac.

MNP (2013-02-28 17:20:21)

My wife has celiac disease, she was diagnosed about a decade ago. As far as we're concerned, MORE POWER TO THE FAD. It increases her options in buying food in the supermarket and at restaurants, raises awareness, and lowers prices. Since she can't just "quit" eating gluten free, this is very important. Note: I do not have any problem with gluten, and in fact love to eat breads and pastas full of the stuff. We evolved a workable method so she doesn't get sick and I don't have to eat gluten free all the time.

Joe (2013-02-28 20:45:15)

For nearly a year I suffered from excruciating joint and muscle pain, a host of digestive problems, fatigue and weakness. I improved by removing gluten, but then I became intolerant to other foods while at the same time becoming more sensitive to trace amounts of gluten. Gluten free brands such as Bob's Red Mill I became unable to eat because of cross contamination with oats and gluten grains. I am still trying to figure out why food is such a problem (it's been 4.5 years since my onset of symptoms, though I sometimes think acne and fatigue problems starting in my teenage years were somehow related to gluten or other food intolerances) and why no doctors can help me. I don't have celiac disease or a wheat allergy; I've been tested for food allergies but the only things that came back positive were foods I had already been avoiding. I can only guess that I have gluten sensitivity, which has gotten worse as I removed ever smaller amounts of gluten from my diet. If I could remove it completely, perhaps I would be better. This is all my long-winded way of saying there is much science doesn't know about gluten related illnesses and sometimes you can only trust what you feel.

meredith (2013-02-28 20:52:03)

Or you can quit gluten for a couple weeks (with, in my case, immediate and vast improvements in multiple domains) and then have an eating companion prepare a series of meals into one of which is slipped a quantity of vital wheat gluten. Bonus points if he also slips an array of novel powders into the other meals that alter the flavor and consistency of the food in novel-to-you ways (e.g. sorghum, almond meal, flax, nutritional yeast). Extra bonus points for replication and a larger control group of naive diners. NOBEL PRIZE NOW PLEASE But really the celiac test is not totally stupid - I would be much more careful about gluten exposure and cross-contamination if I had any evidence of actual celiac rather than a pretty obvious sensitivity.

And because I self-experimented prior to getting tested, I had to go back on gluten for several weeks for the antibody/scope tests to have any chance of detecting anything, so I really would recommend getting tested and THEN commencing with the rampant and exuberant self-experimentation. Seth: Since you quit gluten and noticed big improvements, why did you bother to get antibody/scope tests? In your case it does sound like the celiac test is "totally stupid". Nor do I understand why you need "evidence of actual celiac" to be very careful about gluten exposure. You have evidence of gluten sensitivity.

meredith (2013-03-01 15:18:30)

I'm careful, but not obsessively so. From my (limited) understanding of celiac, damage to the intestine can result from exposure that doesn't necessarily cause other more overt symptoms, and this damage is related to longer-term complications, so avoiding that requires being really super vigilant about eliminating any potential sources of cross-contamination – e.g. maintaining separate "clean" sets of cookware that have never been used with gluten-containing ingredients, avoiding food from bulk bins, etc. Whereas, as far as I know, as long as I keep my exposure sub-symptomatic there is no reason to think I'm doing permanent damage to myself if I have a sip of beer on occasion or use the communal toaster oven. Could be wrong – since nobody seems to know much yet about the mechanisms of gluten sensitivity – but the convenience is currently worth the risk to me (and would not be with a celiac diagnosis). Seth: Thanks for the explanation, but I'm afraid I don't follow your reasoning. I still don't understand why you would bother to have the tests necessary for an "official" celiac diagnosis. You have already learned that you are sensitive to gluten.

MNP (2013-03-02 00:23:39)

Celiac disease is an autoimmune disorder, and some restrictions or limitations that apply to people with other autoimmune diseases apply to people with celiac's. Even absent that, even gluten seems to make you feel better it might be something else and not sensitivity to gluten. It's still important to test for that if you might have it to both increase knowledge about your symptoms and develop the most effective treatment. Then there's always the chance for a placebo effect. If you're already convinced you're sensitive to gluten and then you reduce gluten you might just feel better because you expect to.

## **Progress in Reducing Acne (2013-02-24 05:00)**

[1]A new study has found that persons with [2]Laron Syndrome (a kind of dwarfism) get almost no acne. Persons with this syndrome, because of a mutation, are insensitive to growth hormone. As a result, they produce much less IGF-1 (insulin-like growth factor) than normal. When given synthetic IGF, they may develop acne; when the dose is reduced, the acne goes away. The authors say: "The findings suggest that an interaction between IGF-1 and androgens is necessary for the development of acne." This is great progress because people with Laron Syndrome are different from everyone else in just one tiny way (albeit a tiny way with many consequences).

The first important step in understanding the cause of acne was [3]finding two ("primitive") groups of people with no acne. This suggested that acne has an environmental cause. There were thousands of differences between the lifestyle of those people and "modern" people, so this was just a start. It was hard to know which differences mattered. The Laron Syndrome finding is consistent with the earlier result (no acne in two groups of "primitive" people) because a "Western diet with [its] high intake of hyperglycemic carbohydrates and insulinotropic dairy over-stimulates IIS" (insulin-like/insulin signaling).

This view predicts that if you replace hyperglycemic foods with foods lower in glycemic index acne should be reduced. [4]This study did that and, indeed, acne decreased (compared to a control group) after ten weeks. The study ended after ten weeks. The patient who reduced his/her glycemic index the most saw the greatest decrease in acne. [5]A second study found the same thing: a low-glycemic-index diet reduced acne. It lasted twelve weeks. With longer follow-up, there might have been even more improvement.

Thanks to Paul Nash.

Tuck (2013-02-24 06:10:41)

I'll buy that carbs cause acne (there's a book by Loren Cordain called "The Paleo Diet for Acne", you know...), but I find the dairy hypothesis less compelling. The smallpox vaccine was discovered because milkmaids had beautiful skin; they lacked the pockmarks that can result from either smallpox or bad acne. Would they still have had smooth skin if dairy (which, one imagines, they weren't avoiding) caused acne also? Lots of interesting observations from this thread over at PaleoHacks, including one person who breaks out from pasteurized milk, but not from raw milk. "Anyone got rid of acne on paleo diet without going low-carb? <http://paleohacks.com/questions/117824/anyone-got-rid-of-acne-on-paleo-diet-without-going-low-carb>

Alex (2013-02-24 06:58:42)

The high-glycemic link with acne squares with my experience. I eat paleo and have no acne. After a couple of times when I decided to just eat what was served at friend's house at dinner I had acne the next day, in addition to the unhappy digestion. One particular dinner resulted in three pimples, which lasted for a few days. I can usually manage at restaurants, but I've taken to eating a full meal before I go to dinner at my friends' homes.

Theragingwalrus (2013-02-24 07:56:10)

@Tuck Yes Cordain really ties it together in his book on acne. Supposedly the mechanism for carbs is insulin->increased igf-1 by liver->increased anti-apoptotic proteins -> tight junctions not disassembled properly -> large skin cell aggregates -> clogged up pores. The raw milk could explain the lack of acne in milkmaids. A question that still need to be answered afaiak is: is comedone formation purely dependent on these sticky skin cells, or is there immune involvement in this step as well?

Mehmet (2013-02-24 11:53:55)

Considering that people with Laron syndrome also do not get cancer, it would be interesting to look at the correlation between acne and cancer incidence for the whole population. Seth: Excellent idea.

Vic (2013-02-24 15:47:01)

I believe I've seen a number of studies in the past showing an inverse association between acne and cardiovascular disease

Paul N (2013-02-26 08:54:25)

@ Tuck, A bit of googling on dairy and acne finds a few articles written on this very subject, like this one [1]Acne, dairy, and cancer Seems that acne often an indicator for breast and prostate cancers, which are hormone responding glands. As for the milkmaids, we can speculate on that. One guess would be that they often came from families with a long history of dairying, so they might be naturally more tolerant. In any case, dairy foods, and especially the whey portion of dairy, is highly insulinemic, which is why body builders love it so much. Body builders are also prone to acne...

1. <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2715202/>

Sean (2013-02-27 10:45:09)

Interesting stuff. A key to all of this is that there are many types of acne. Folks are always looking for one cause. Though most are likely hormonal. Not determined the cause of mine yet, but t's not affected by glycemic index, carbs or milk. It clears up a ton with a lot of sun exposure. 2 months working in San Antonio had it looking better (though still there). Within a week back in London and I had cysts on my neck again. Same thing each time I go to a sunny location. The other big factor for me is digestion. No gallbladder means slower "movements" which I assume means poor removal of toxins. Thanks so much for continuing to focus on acne research. Acne has a huge impact on mental stress and social disorders. Seth: You're welcome. In your case, what's the connection with digestion? You mean that your acne got worse when your gallbladder was removed? Or what? Could you provide details?

Mark (2013-03-01 20:18:40)

I think you are headed in the wrong direction as far as treating acne is concerned. New research has shown that acne patients have low glutathione levels and high interleukin-8 levels. Taking action to correct that can improve not only your acne but your cognition amongst other things. It is not a quick fix—it takes a few weeks to notice results. If you have acne and want to find out if you have low antioxidant function, get a spectracell micronutrient test done. Seth: [1]Here is a study about acne and low glutathione levels. I can't find anything about what happens when the low glutathione levels are raised. Do you know of such a study?

1. <http://www.ncbi.nlm.nih.gov/pubmed/21896138>

## **Bitter Pill: Why Medical Costs Are Killing Us by Steven Brill (2013-02-25 05:00)**

Steven Brill has a great article in Time called [1]Bitter Pill: Why Medical Costs are Killing Us. I found it nauseating and terrifying – and I have health insurance. It is nauseating that helpless sick people are billed huge amounts of money that bear little relation to costs. It is terrifying that our government has failed to protect us from this.

Brill's article is about the details of health care costs in America, especially hospital costs. Markups are huge. One example is a test strip for measuring blood sugar. The patient was charged \$18 for each strip. On Amazon, the strips cost \$0.50 each. The patient had no choice and was not told the wildly-inflated price. Brill gives many examples of similar markups. Hospitals, including nonprofit hospitals, are large prosperous businesses with very well paid CEO's (e.g., \$1 million/year). Yet Americans pay far more for health care than people in any other country and, judged by life expectancy, get worse results than people in about 40 countries. Brill's article begins to explain the discrepancy.

Asked to explain their prices, many hospitals refused. One of them, MD Andersen in Houston, gave a statement that Brill quotes in part:

The issues related to health care finance are complex for patients, health care providers, payers and government entities alike . . . MD Anderson's clinical billing and collection practices are similar to those of other major hospitals and academic medical centers.

Judging from the widespread refusals to explain and answers like this ("everyone does it"), the prices are indefensible.

The term stagnation – America is in the grip of profound stagnation – may be misleading because it makes it sound like things are staying the same. People point to a lack of increase in the median income over the last 30 years as indicating "stagnation". Beneath stagnation is problems stacking up unsolved. (When they are solved, spread of the solutions produces an increase in income.) The problems aren't staying the same: They're getting worse. Health care

costs are a good example. Health care costs have gone up faster than inflation for a long time, with plenty of signs that the American excess (the difference between what Americans pay and what everyone else pays) is completely wasted. (Or worse, given the many bad effects of drugs, surgery, and other high-tech medicine.) The American excess isn't trivial, so median income, adjusted for it, has been going down for a long time, over the same period of time that median income in almost every other country has gone up. Quite a comment on the quality of our government.

As Brill says, the health care debate has been about who will pay? The question are prices too high? has been ignored. [2]Jon Stewart said, "This should be a Silent Spring moment."

1. <http://healthland.time.com/2013/02/20/bitter-pill-why-medical-bills-are-killing-us/>

---

Tuck (2013-02-25 05:57:39)

A huge part of the problem is that hospitals are not subject to the market in the way most other businesses are. During WWII, the Feds set up a regime that made health insurance tax deductible if bought by the employer for the employee. Without going into why that happened, that is the regime health care has been provided under for most people ever since. What that means is that the market for health care bought directly for the end-user is tiny. Hospitals and health insurers don't really cater to it, which is why individual health insurance is difficult to acquire, and hospitals don't provide competitive retail pricing. The fact that this is the case is demonstrated by the competitive retail market for medical procedures that are not covered by health insurance: elective procedures like Lasik or plastic surgery. These procedures have transparent, up-front pricing, use technology to control costs, and have seen prices decline as the procedures become more efficient. If all healthcare behaved this way, we would have a much smaller crisis, if we had one at all. So long as the end-user is discouraged from directly purchasing the product, the market will be dysfunctional. Unfortunately with a single-payer model, things get worse, as one can see in the United Kingdom. At that point, the end-user become a cost, not the customer, which is a large part of the reason why the NHS provides such horrific "care": participating in mass euthanasia. Of course the NY Times' political bias prevents them from making this argument. It's not a new one, it's been made for decades. Our elected officials seems to like the concentration of power under the current system, where, effectively, they're the end-user, not the patient. They get all the attention, and the end-user gets screwed. (This is not to say that using a market makes things perfect. The medical profession, like any other human enterprise, is subject to corruption, but market discipline is a much more effective check on that than is regulation.) Seth: "With a single-payer system, things get worse, as seen in the United Kingdom." People in the United Kingdom live longer than Americans (80.4 vs 78.8 yrs) and pay much less for health care. There are far fewer personal bankruptcies in the UK due to health care costs than in the US. So it is far from clear that things are worse there. Do other data support your idea that a single-payer system would make things worse?

BenSix (2013-02-25 07:02:03)

[1]Of relevance, and possible interest. ...*which is a large part of the reason why the NHS provides such horrific "care": participating in mass euthanasia.* The NHS [2]can be appalling - there is no disputing that. But I would be interested to see the measures by which it is extraordinarily bad.

1. <http://www.medpagetoday.com/Geriatrics/Dementia/37202>

2. <http://www.midstaffspublicinquiry.com/home>

Brian (2013-02-25 07:45:58)

How much of the difference is due to the US' abnormally high infant mortality or other causes?

Alex (2013-02-25 08:48:27)

Tuck, I suspect you didn't read the article. since you refer to "the NY Times' political bias" and the article appeared in Time magazine. You make a good point about the far more efficient and transparent pricing of procedures like plastic surgery that are paid for by patients. However the real money pits of medical care are not optional single procedures but events like cancer or strokes, where the costs are open-ended and outcomes uncertain. I can price a tummy tuck and decide yay or nay, but colon cancer doesn't work that way. It's hard to envision a free-market solution when the buyer has no choice on whether to buy. That's not a free market. "Unfortunately with a single-payer model, things get worse, as one can see in the United Kingdom." Worse based on what? Outcomes, costs? Certainly not by any data I've ever seen. Here, with pictures: <http://www.piiie.com/blogs/realtime/?p=516>. "NHS provides such horrific 'care': participating in mass euthanasia." Any evidence on this? We do have death panels in the US: they are run every day at hospitals' accounting offices. Read the first page of Brill's article so see how MD Anderson's death panels operate.

Steve (2013-02-25 08:52:05)

Do you know this blog, Cassandra Does Tokyo, by an investment banker specializing in Japanese finance? The blogger has an interesting post on the cost of medical procedures in France, and how transparent the pricing is there. Well worth a read: <http://nihoncassandra.blogspot.ca/2011/07/price-isummmerrrr-wrong-part-2.html>

dearieme (2013-02-25 10:07:36)

I decided long ago not to be so insolent as to advise Americans how to improve their medical system (let's pretend that "system" is the right word) save to say "don't copy the NHS". <http://www.independent.co.uk/life-style/health-and-families/features/a-daughters-tribute-to-the-nhs-by-now-i-am-convinced-it-is-the-nearest-we-get-to-a-benevolent-deity-its-free-care-for-american-immigrants-for-absent-parents-for-the-only-father-i-will-ever-have-8507647.html>

Scott P. (2013-02-25 12:04:29)

It is my understanding that fees not recovered are tax deductible so a hospital can charge something outrageous, be unable to collect on a large portion of it and then write it off. I believe there a place for government in health care but Obamacare is a fiasco of the first order.

Daniel Lemire (2013-02-25 13:12:59)

I was told that part of the problem in the US is that many people do not actually pay (or are not insured) so that many hospitals have to take a loss on a fraction of the patients. If so, this makes overcharging a necessity. Disclaimer: I am Canadian.

Tom (2013-02-25 14:57:45)

off-topic, but interesting read: Pennsylvania farmer drops weight rapidly on raw milk + fermented foods diet: <http://www.yourfamilycow.com/fresh-thoughts/i-really-shouldnt-tell-you-this>

dearieme (2013-02-25 15:04:52)

Ahoy, Seth: Spaniards thrive on a Spanish diet. <http://www.forbes.com/sites/larryhusten/2013/02/25/large-trial-shows-cardiovascular-benefits-of-mediterranean-diet/>

SB (2013-02-25 15:58:41)

@Scott A lot (most?) hospitals are not-for-profit, so they don't pay taxes anyway.

libfree (2013-02-25 19:04:37)

@Seth I believe its wrong to make an assumption treating life expectancy as a result of health care. Could getting more and "better" health care reduce life expectancy? Second, personal health practices probably have more to do with life expectancy than our health care system. Also, I would be careful about how much more we spend on health care than other developed nations. For example, doctors pay their way through medical school and then repay their student loans with higher fees in the US. In Europe, their education is paid for and they don't have the resulting student loans. We might be moving expenses into significantly different buckets in different nations Seth: Yes, getting more and supposedly "better" health care could easily

reduce life expectancy. Lots of common treatments have significant (and undisclosed) bad effects. The difference between what Americans and people in other countries pay for health care is so large it couldn't be due to anything as small as the need of American doctors to repay student loans.

Tuck (2013-02-26 10:12:54)

"Do other data support your idea that a single-payer system would make things worse?" For starters, measuring health care outcomes by life expectancy is a bad way to judge: non-health-care-related factors like murder rates and car fatalities play a large role in the difference between countries, and don't reflect health care quality. Second, measuring health-care outcomes across country is fraught with error: "For example, babies who are not viable and who die quickly after birth are more likely to be classified as stillbirths in countries outside the United States, especially in Japan, Sweden, Norway, Ireland, the Netherlands, and France. This is especially likely for babies who die before their birth is legally registered.[9] In the United States, however, nonviable births are often recorded as live births, making the US infant mortality rate appear misleadingly high. In a detailed study of medical records and birth and death certificates in Philadelphia, Gibson and colleagues found that infant mortality had been overstated by 40 percent, merely as a result of these nonviable births that were recorded as live births.[10]" "US health care: A reality check on cross-country comparisons" <http://www.aei.org/outlook/health/global-health/us-health-care-a-reality-check-on-cross-country-comparisons/> I suspect that it's near impossible to do, especially since there's such a large political component to any analysis. Third, if you want to look at actual health-care quality outcomes, rather than potentially-misleading epidemiology, the US system starts looking pretty good compared to single-payer systems: "The United States spends more on cancer care than European countries. However, a study published in the newly released April issue of Health Affairs suggests that investment also generates a greater "value" for US patients, who typically live nearly two years longer than their European counterparts." [http://www.healthaffairs.org/press/2012\\_04\\_10.php](http://www.healthaffairs.org/press/2012_04_10.php) "Cancer survival is known to vary between the regions of the USA covered by the US National Cancer Institute's (NCI) Surveillance, Epidemiology and End Results (SEER) Program,<sup>21</sup> but the range of survival in Europe is much wider. Furthermore, survival from breast cancer during 1985-94 was higher in each of the nine SEER areas than in any of the 22 countries participating in the European study of cancer survival (EUROCARE).<sup>7,22</sup>" "Cancer survival in five continents: a worldwide population-based study (CONCORD)" <http://healthcare.procon.org/sourcefiles/CONCORDCancerSurvivalStudy.pdf> Again, there are many confounders: for instance, cancer screening is much more aggressive in the US than in Europe, which may affect time to survival, but doesn't speak to the poor quality of US healthcare. Fourth, the only other place where I've ever heard of horrible care like this: "There are around 450,000 deaths in Britain each year of people who are in hospital or under NHS care. Around 29 per cent - 130,000 - are of patients who were on the LCP [euphemism for euthanasia]. "Professor Pulicino claimed that far too often elderly patients who could live longer are placed on the LCP and it had now become an 'assisted death pathway rather than a care pathway'" "Top doctor's chilling claim: The NHS kills off 130,000 elderly patients every year" <http://www.dailymail.co.uk/news/article-2161869/Top-doctors-chilling-claim-The-NHS-kills-130-000-elderly-patients-year.html> "Between 400 and 1,200 patients are estimated to have died needlessly at Stafford Hospital in central England between January 2005 and March 2009 in one of the worst scandals to hit the NHS since it was founded in 1948." "NHS ravaged by hospital scandal" <http://uk.reuters.com/article/2013/02/07/uk-britain-hospital-idUKBRE9150RV20130207> "More than 100 hospitals may face tough new inspections in the wake of the report into the Mid Staffordshire scandal. "The Care Quality Commission has concerns about an alarming 20 per cent of hospitals in England and plans to carry out spot checks into their care of patients. "The Sunday Mirror can reveal the healthcare watchdog is drawing up a hit list of hospitals and, in many cases, experts will probe alleged neglect which mirrors the shocking breaches that led to the needless deaths of 1,200 people at Stafford Hospital between 2005 and 2009...." "Bosses are worried about standards at 20 % of hospitals" <http://www.mirror.co.uk/news/uk-news/stafford-hospital-scandal-more-than-100-1648044> ...Is in the US Veterans Administration Hospitals, also a single-payer system. (You know, where \*One Flew Over The Cuckoo's Nest\* took place?) "The waits in California and elsewhere are so bad that thousands of veterans are dying before their claims for physical and mental injuries are approved. In 2011-12, the VA paid \$437 million in posthumous benefits to families of nearly 19,500 veterans, up from just \$8 million three years earlier, the Center for Investigative Reporting says." <http://www.sacbee.com/2013/02/20/5202015/vets-wait-and-wait-for-va-to-fix.htm> | #storylink=cpy Seth: Thanks for the information. That makes clearer what the case against one instance of single-payer (England) is. As for the cross-country comparisons, I agree they can be improved. I look forward to learning what better comparisons show. I especially look forward to cross-national surveys of how people feel about their health, especially older people (when health care effects should be larger). Death is one endpoint; how

you feel while alive is another. For any measure of health (let's call it X), it can always be argued that X depends on lots of other stuff besides health care, just as you can point to flaws in any research. That's not interesting, at least to me. What I find interesting is better comparisons. That provides a test of the idea that the "lots of other stuff" make a big difference.

andrew (2013-02-26 10:47:14)

I've read the differences in life expectancy are mainly due to violent crime and obesity which are two problems the health care system can do little to change. What about the famous Rand study that finds no link between healthcare consumption and health outcomes? [http://www.overcomingbias.com/2007/05/rand\\_health\\_ins.html](http://www.overcomingbias.com/2007/05/rand_health_ins.html) Using Seth terminology this is a gatekeeper problem. The prices and costs that we complain about are a result of that. We cannot change the prices and expect better outcomes. The main issues with Gatekeepers is they inhibit innovation.

Tuck (2013-02-26 10:51:50)

"...and obesity which are two problems the health care system can do little to change." Arguably the obesity epidemic is a result of the health-care system, but that's a whole 'nother discussion. :)

rcm092 (2013-02-26 13:09:58)

What's not discussed is the enormous amounts of money the American Hospital Association and big pharma spend on lobbying congress to keep the game going. In addition, Congress tells us that Medicare is unsustainable and must be cut to make it affordable. Obviously, that's not true. Medicare would be fine if we focused our efforts on reducing the cost of care - like allowing Medicare to negotiate prescription drug prices. The American people are being taken for fools just like when they were flushed down the drain by Wall Street. Seth: Brill mentions the enormous amounts of money spent on lobbying by health care advocates. It's a small part of his piece, however, and I agree with you that it is very important.

Tuck (2013-02-26 16:20:06)

"That makes clearer what the case against one instance of single-payer (England) is." As a more general point of the economic problems with a single-payer provider of any service, look at the US Postal Service. It loses a ton of money and is hugely inefficient in the one area where it has a monopoly: letter delivery. Logically, but for human nature, that should be hugely profitable. It's much more efficient in package delivery, where it has to compete against two brutally-efficient competitors, UPS and FedEx. Of course that's because the consumers can pick and choose. USPS knows that it either has to match UPS and FedEx or exit the business. It can be dreadful in letter delivery, as there's no choice. Seth: US Post Office rates are set by Congress. Perhaps the rates are too low? What about the [1]2006 Postal Accountability Act? Maybe that was a mistake? Consider other examples. The US has a single currency now. Most people think that is better than when there were multiple currencies (and therefore more choice of currency provider). In the US, almost all libraries are government-run. Is the library system doing a bad job? What about the FAA? Airlines have no choice. Is it doing a bad job?

1. [http://en.wikipedia.org/wiki/Postal\\_Regulatory\\_Commission#Changes\\_under\\_the\\_Postal\\_Accountability\\_and\\_Enhancement\\_Act\\_of\\_2006\\_-\\_H.R.\\_6407](http://en.wikipedia.org/wiki/Postal_Regulatory_Commission#Changes_under_the_Postal_Accountability_and_Enhancement_Act_of_2006_-_H.R._6407)

Paul N (2013-02-27 00:12:54)

While we are at the game of comparing health care systems, Hong Kong's government system [1]consumes just 3 % of GDP (another 3 % for private) and the HK citizens are amongst the healthiest in the world. I think one of the real problems with the US system (speaking as a Canadian) is tying it to employment. It means if a business wants to take on an employee, it must also, one way or another, take on their health care. This is a huge deterrent to hiring part time employees, amongst other things. A (well run) government system frees up people, and their employers, from worrying about that, leaving them more time and energy for innovation. The trick is to create any well run government system, of course... Seth: And HK citizens have few personal bankruptcies due to health care costs.

1. <http://www.newworldeconomics.com/archives/2009/092509.html>

nihoncassandra (2013-03-01 03:42:14)

Tuck exemplifies an individual with a fine grasp of political ideology, but little understanding of the different systems of Healthcare and their finance. This ignorance is displayed by a failure to comprehend that the NHS is a single-provider system

(run in parallel with an independent private system). It is NOT a single payer as conceived in other, probably better functioning, though slightly more costly systems on the European continent. The hospitals and practitioners respectively are owned by and work for the NHS. Costs are contained by complete vertical integration (which is effectively evidenced by the spend as % of GDP), but with all its attendant political & bureaucratic failures, that often result in sub-standard care, waiting lists, rationing, and lack of convenience. That said, it is the low-cost global provider and by any measure provides the UK with an excellent value proposition. The parallel private system in part benefits from the NHS existence (many providers have both public and private practices), but is far from efficient or cost-effective. France represents the best model of the true single-payer, and uses its advantage. Contrary to Tuck's derision, Libertarians and conservatives should take note and admire it since it combines the political goals of universal coverage, cost containment, with the best of the market ideas such as competitive independent service providers (less so in hospitals), complete freedom of consumer choice, and freedom of providers to price accordingly, bounded by the pricing discipline and transparency instilled by a single payer. By contrast, even though one pays taxes for use of the NHS, if a patient "goes private", there is no "voucher" or contribution by the NHS to that service, and the patient must foot the entire price untethered by a single-payer. In France, like school vouchers promoted by conservatives and libertarians in the US, one visits a Doctor of choice. The single-payer reimburses a designated amount (like the Canadian usual & customary). If that doctor is the top heart surgeon, he will likely charge a premium, and the patient is free to pay the difference or visit a more economical provider. In practice, most doctors charge the reimbursement rate because most French people cannot afford anything else. And eminent doctors often do pro-bono work where the case is clinically interesting or unusual need. The result is a pricing discipline that prevents absurdities like those cited in Brill's Time article and this is a huge step in the right direction. The same people like Tuck who hyperventilate about such pragmatic hybrid (but ultimately market-based solutions) funnily enough are happy with regulated monopoly provision of public services in other areas like municipal water, electric and gas utilities, Police, etc. precisely because a regulated monopoly in some economic circumstance produces far better outcomes for almost everyone (save the few institutions that are gorging at the trough of the current US "system"). Seth: Very helpful, thanks.

jon (2013-03-02 00:04:08)

Seth, This is the result of highly regulated "monopolies" granted by the state. If you are interested I can dig a lengthy paper on the subject written back in the 90s describing many of the problems. It would be nice to have a truly free market, then we would see the prices going down, not up. Dr Mary J. Ruwart wrote a good book called "Healing Our World: In an Age of Aggression." Which goes over how using the initiation of force (government granted monopolies, like licensing, etc) cause more harm than the good they were initially created to do. I've read "Silent Spring." In the book the author shows how the most egregious polluter of the environment was the government itself (as it continues to be today). It was a great book. The author never advocated the outright banning of DDT. She only asked that it be used responsibly and very little of it be used, if any at all. I think she got it wrong though when she did propose more aggression to solve problems that were caused by the initiation of force to begin with. Peace and love is the path, not more hate and harm. I know that sounds cheesy but I think it is the truth.

Bbcw03 (2013-03-06 22:18:27)

How do you think this problem can be solved? Seth: I don't know. Maybe the book Catastrophic Care has some good ideas.

Jeevan D (2013-03-18 01:29:04)

I am a British citizen & yes there are problems with the NHS (even more so now Cameron is tearing it apart) but let us not be fools, GDP & population is about 5x the difference so it is easy to compare, the UK spends 9.8 % of GDP on healthcare but the US spends 16.8 % (I imagine to provide decent coverage for all would be well beyond 20 %), so the problem isn't the NHS being rubbish, it is underfunded, even if its budget was increased by 10-25 % we would still be spending 25 % less than the US does but our NHS would improve so much. I also want to make it clear, many right wingers say you wouldn't be allowed to pick your own GP, my family picked mine when I was born, and when they retired they picked a new GP, and then a few years ago I picked my own GP

justine cook (2013-03-22 07:21:49)

will you please sign my petition Hi, Time Magazine recently ran an article 'why medical bills are killing us' and included the story of the Recchi's who MD Anderson charged over 83,000 for cancer treatment MD Anderson is supposed to be a non profit

but made a 26 percent profit last year and the head of MD Anderson made more than 2 million dollars last year. I think they should reimburse the Recchi's 26 % of the 83,000 and apologize to them for not giving them assistance or treating them with compassion at the time they most needed it. I do not know the Recchi's but I was absolutely furious when I read this. this type of rip off by the medical community has got to stop. That's why I created a petition to MD Anderson Cancer Treatment Center, Manager, Asm MD Anderson. Will you sign this petition? Click here: [http://signon.org/sign/md-anderson-reimburse?source=c.em.mt & \\_by=857231](http://signon.org/sign/md-anderson-reimburse?source=c.em.mt & _by=857231) Thanks!

## **Consistent- versus Inconsistent-Handed Predicts Better than Right- versus Left-Handed (2013-02-26 05:00)**

At Berkeley, [1]Andrew Gelman and I taught a freshman seminar about left-handedness. Half the students were left-handed. We did two fascinating studies with them that found that left-handers tend to have left-handed friends. I kick myself for not publishing those results, which I bring up in conversation again and again.

After the class ended I got a call from a journalist who was writing an article about ridiculous classes. I told him the left-handedness class had value as a way of introducing methodological issues but all I cared about was that his article be accurate. He decided not to include our class in his examples.

Stephen Christman, who got his Ph.D. from Berkeley (and did quirky interesting stuff even as a graduate student), and two colleagues have now published [2]a paper that is a considerable step forward in the understanding of handedness. They argue that what really matters is not direction of handedness but the consistency of it. The terms left-handed and right-handed hide a confounding. Right-handers almost all have very consistent handedness (they do everything with the right hand). In contrast, left-handers much more often have inconsistent handedness: they do some things with the left hand, some with the right. I am a good example. I write with my right hand, bat and throw left-handed, play tennis left-handed, ping-pong right-handed. In fact, I am right-wristed and left-armed. When something involves wrist movement (writing, ping-pong) I use my right hand. When something involves arm movement (batting, throwing a ball, tennis), I use my left hand. Right-handers are much more similar to each other than left-handers.

Christman and his co-authors point to two things: 1. When you can get enough subjects to unconfound the two variables, it turns out that consistency of handedness is what makes the difference. Consistent left-handers resemble consistent right-handers. 2. Consistency of handedness predicts many things. Inconsistent-handers are less authoritarian than consistent-handers. They show more of a placebo effect. They have better memory for paragraphs. And on and on – about 20 differences. It isn't easy to say what all these differences have in common but maybe inconsistent-handers are more flexible in their beliefs. (Which would explain the friendship findings in our handedness class.)

I think about these differences as another example of how every economy needs diversity and our brains have been shaped to provide it, one idea underlying [3]my theory of human evolution. Presidents of the United States are left-handed much more than the general population. For example, Obama is left-handed. The difference between Presidents and everyone else is overwhelming and must mean something. Yet left-handers die younger. I would say that in any group of people you need a certain fraction, not necessarily large, to be open-minded and realistic. That describes inconsistent-handers (who are usually left-handed). These people make good leaders because they will respond to changing conditions. People who are not open-minded make good followers. Just as important as realism is cooperation, ability to work together toward a common goal.

---

dearieme (2013-02-26 05:49:15)

My mother told me that I was left-handed as a tiny child and seemed to have swapped to right-handedness by copying the rest of the family. Does that happen or was my mother mistaken? A counterargument is that falling in with people around me is not one of my most conspicuous traits. A supporting argument is that as a soccer player I was noticeably more "two footed" than most of my teammates - so much so that I was usually played on the left. Seth: maybe there is also "inflexible handed" and "flexible handed". You are flexible handed. Your story about changing the hand you write with suggests testing everyone to see how good they are at writing with the less-usual hand (e.g., right handers write with their left hand). That would be good research. Would not depend on self-report (e.g., "which foot do you prefer to kick with?").

CC (2013-02-26 06:09:02)

Left-handers die younger? Then why didn't my life insurance company ask me if I was left-handed? Seriously, I thought this was urban legend that was debunked long ago (people once claimed a 7 year difference in life expectancy, which is crazy). But maybe there's new information I don't know about? Seth: I looked around for new evidence about the longevity difference. I couldn't find any. As far as I could tell, several studies support the idea that left-handers die younger, and a few studies do not, in the sense of no significant difference (either way). Absence of a significant effect is weak evidence.

Greg (2013-02-26 06:40:46)

This is very interesting. I've always had trouble specifying which is my dominant hand. I do things such as writing and brushing my teeth with my left hand, but when I was learning to play golf, left-handed clubs didn't work out. I also use my right hand for tennis and ping pong. Saying that I'm inconsistently handed seems much more accurate.

Tom Passin (2013-02-26 07:30:12)

My handedness is exactly the same as Seth has described. I think of it as being lefty for forehand actions and righty for backhand ones, but the wrist-arm breakdown may be closer to the mark. I'm not that good a leader, though.

Stuart Buck (2013-02-26 15:01:11)

I'm left-handed for eating and writing, but right-handed for all sports.

John Tarantino (2013-02-26 15:26:43)

Very interesting. Like some of the earlier posters I've never known how to properly specify which hand is dominant. I write with my right, play golf, lacrosse and bat with my left, snowboard goofy (typical for lefties), play ping pong right, etc. Never occurred to me that there might be a difference in handedness between arm and wrist as Seth writes. I'm also clearly right eye dominant which may play into things.

Paul Winter (2013-02-26 18:47:51)

I am right-handed except for two handed sports. In cricket I bowl right-handed, & bat left-handed I shoot & play golf left-handed. This is because my left eye is my master eye.

Kudzu Bob (2013-02-27 16:12:16)

As an inconsistent-hander, I have always snickered at those detective stories that include a scene in which a left-handed potential suspect is ruled out because some crime was obviously committed by a right-hander. I wonder how much this particular misconception has affected real police work.

Baduin (2013-02-28 01:15:02)

I would suggest a book by Iain McGilchrist, *The Master and His Emissary*, about the differences between brain hemispheres. His theory seems to agree with your findings. <http://www.iainmcgilchrist.com/>

"A small, blinded, controlled study of lead concentrations in three different types of organic chicken broth ...": well, 'organic' - whatcha expect?

Alex (2013-03-06 09:32:50)

Chris Kresser countered that the amount of lead in the broth with the highest lead content, 9.5 parts per billion, was still below the limit for lead in drinking water, 15 parts per billion. <http://chriskresser.com/bone-broth-and-lead-toxicity-should-you-be-concerned>

### Teaching With or Against Human Diversity (2013-02-28 05:00)

Mark Edmundson, a professor of English at the University of Virginia, defended traditional lectures in [1]a New York Times op-ed titled "The trouble with online education". He described how he teaches. When he teaches, he fails to

1. Pay attention to what students want to learn.

2. Treat different students differently (beyond giving them different grades).

[2]A few weeks ago, I described how doing these two things made teaching much easier. It's like swimming with or against the current. You can take advantage of human diversity (my approach) or you can ignore it (Edmundson's approach), which means fighting against it.

1. <http://www.nytimes.com/2012/07/20/opinion/the-trouble-with-online-education.html>

2. <http://blog.sethroberts.net/2013/01/26/my-ideas-about-teaching-put-into-practice/>

---

Scott (2013-02-28 06:13:43)

Seth, How can we translate your thinking about diversity in teaching to how managers guide people to get work done in the work place - e.g., flexible work schedules or working from home. Seth: There is a book called First Break All the Rules that discusses exactly this point. I blogged about it here: <http://blog.sethroberts.net/2007/05/12/my-theory-of-human-evolution-business-book-edition/>. I can't remember what it says. I have never been a manager, but I guess I would meet with each employee and start by saying something like this: "I have no interest in making you like everyone else. All I care about is that you get your work done and help your co-workers get their work done. How do you think you can best accomplish that?" Workers in many jobs are much more interdependent than students so I suppose if someone works from home they would need to be always available for phone calls during working hours except during lunch hour.

Three Pipe Problem (2013-03-01 06:21:07)

Seth, how could you omit Rhineheart's sublime name for this substance – "soylent". Because it \*becomes\* people, I suppose? Best quote in article: "After a week advertisements for fast food looked repulsive. All I crave is Soylent." Fascinatingly, the conclusion he may be testing here is that Soylent is actually healthier than fast food? Sudden dystopian visions...

David C (2013-03-01 08:11:56)

I'm sure Rhineheart's experiment would make Michael Pollan roll his eyes.

Lemmy Caution (2013-03-01 16:38:47)

In the book soylent, stood for soy + lentils.

Adam (2013-03-01 16:44:15)

Actually there are quite a few people who have dramatically reduced the amount of sleep they get & report positive results after a difficult adjustment period; google: "polyphasic sleep". Seth: I can't find any examples where someone maintained it for a year or more. For a few weeks, sure. The Wikipedia article on the subject mentions Buckminster Fuller but I don't trust him.

Adam (2013-03-02 06:58:25)

Steve Pavlina (1st page of Google results) claims he sustained it for about 5 months. There was another quite detailed account of a woman who sustained it for a long time, maybe a year? before her life situation forced her to go back to a siesta style sleep pattern (long sleep at night, nap in the afternoon). Seth: to me, 5 months = unsustainable. You'd think that something that increased your free time by 100 % would do better than that.

ken (2013-03-02 20:07:52)

The Rhineheart link seems less like self-experimentation and more like marketing. He explores the positive effects in detail but glosses over the negative effects with oblique descriptors. Seth: You might have something there. However, I don't know what he's marketing. What is he glossing over? I didn't notice that.

Will (2013-03-15 02:38:30)

This guy slept polyphasicly for over a year: <http://akshatrathi.wordpress.com/2010/05/30/my-tryst-with-polyphasic-sleeping/> I only managed 4 weeks before it caught up with me. I think overall that melatonin is too important to mess around with, regardless of whether reduced sleep schedules are feasible. Rhineheart really doesn't know what he is doing. He hasn't taken into account nutrient interactions affecting bioavailability either. He's bothering with adding things like ginkgo biloba whilst

ignoring choline, creatine, MCTs etc.

## How to Encourage Personal Science? (2013-03-02 05:00)

I wonder how to encourage personal science (= science done to help yourself or a loved one, usually for health reasons). Please respond in the comments or by emailing me.

An obvious example of personal science is self-measurement (blood tests, acne, sleep, mood, whatever) done to improve what you're measuring. Science is more than data collection and the data need not come from you. You might study blogs and forums or the scientific literature to get ideas. Self-measurement and data analysis by non-professionals is much easier than ever before. Other people's experience and the scientific literature are much more available than ever before. This makes personal science is far more promising than ever before.

Personal science has great promise for reasons that aren't obvious. It seems to be a balancing act: Personal science has strengths and weakness, professional science has strengths and weaknesses. I can say that personal scientists can do research much faster than professionals and are less burdened with conflicts of interest (personal scientists care only about finding a solution; professionals care about other things, including publication, grants, prizes, respect, and so on). A professional scientist might reply that professional scientists have more training and support. History overwhelming favors professional science – at least until you realize that Galileo, Darwin, Mendel, and Wegener (continental drift) were not professional scientists. (Galileo was a math professor.) There is very little personal science of any importance.

These arguments (balancing act, examination of history) miss something important. In a way, it isn't a balancing act. Professional science and personal science do different things. In some ways history supports personal science. Let me give an example. I believe my most important discovery will turn out to be [1]the effect of morning faces on mood. The basic idea that my findings support is that we have a mood control system that requires seeing faces in the morning to work properly. When the system is working properly, we have a circadian rhythm in mood (happy, eager, serene during the day, unhappy, reluctant, irritable at night). The strangest thing is that if you see faces in the morning (e.g, 7 am) they have no noticeable effect until 6 pm the same day. There is a kind of uncanny valley at work here. If you know little about mood research, this will seem unlikely but possible. If you are an average professional mood researcher, it will seem much worse: can't possibly be true, total nonsense. If you know a lot about depression research, however, you will know that there is considerable supporting research (e.g., in many cases, depression gets better in the evening). It will still seem very unlikely, but not impossible. However, if you're a professional scientist, it doesn't matter what you think. You cannot study it. It is too strange to too many people, including your colleagues. You risk ridicule by studying it. If you're a personal scientist, of course you can study it. You can study anything.

This illustrates a structural problem:

[2]

This graph shows what personal and professional scientists can do. Ideas vary in plausibility from low to high; data gathering (e.g., experiments) varies in cost from low to high. Personal scientists can study ideas of any plausibility, but they have a relatively small budget. Professional scientists can spend much more – in fact, must spend much more. I suppose publishing a cheap experiment would be like wearing cheap clothes. Another limitation of professional scientists is that they can only study ideas of medium plausibility. Ideas of low plausibility (such as my morning faces idea) are "crazy". To take them seriously risks ridicule. Even if you don't care what your colleagues think, there is the additional problem that a test of them is unlikely to pay off. You cannot publish results showing that a low-plausibility idea is wrong. Too obvious. In addition, professional scientists cannot study ideas of high plausibility. Again, the only publishable result would be that your test shows the idea is wrong. That is unlikely to happen. You cannot publish results that show that something that everybody already believes is true.

It is a bad idea for anyone – personal or professional scientist – to spend a lot of resources testing an idea of low or high plausibility. If the idea has low plausibility, the outcome is too likely to be "it's wrong". There are a vast number of low-plausibility ideas. No one can afford to spend a lot of money on one of them. Likewise, it's a bad idea to spend a lot of resources testing an idea of high plausibility because the information value (information/dollar) of the test is likely to be low. If you're going to spend a lot of money, you should do it only when both possible outcomes (true and false) are plausible.

This graph explains why health science has so badly stagnated – every year, the Nobel Prize in Medicine is given for something relatively trivial – and why personal science can make a big difference. Health science has stagnated because it is impossible for professionals to study ideas of low plausibility. Yet every new idea begins with low plausibility. The Shangri-La Diet is an example (Drink sugar water to lose weight? Are you crazy?). We need personal science to find plausible new ideas. We also need personal science at the other extreme (high plausibility) to customize what we know. Everyone has their quirks and differences. No matter how well-established a solution, it needs to be tailored to you in particular – to what you eat, when you work, where you live, and so on. Professional scientists won't do that. My personal science started off with customization. I tested various acne drugs that my dermatologist prescribed. It turned out that one of them didn't work. It worked in general, just not for me. As I did more and more personal science, I started to discover that certain low-plausibility ideas were true. I'd guess that 99.99 % of professional scientists never discover that a low-plausibility idea is true. Whereas I've made several such discoveries.

Professional scientists need personal scientists to come up with new ideas plausible enough to be worth testing. The rest of us need personal scientists for the sake of our health. We need them to find new solutions and customize existing ones.

Koanic (2013-03-02 05:29:47)

I'd suggest a combination of the website <http://dontbreakthechain.com/> and a weekly personal experimentation log. A week seems to be an excellent length for a wide variety of personal experimentation. Checkboxes to indicate adherence, notes or rating fields for results in each day. Easily viewable, trackable, and adherable. Let people set the starting day of the week. Plus a listing of experimental results, in an area separate from the calendar.

Alex (2013-03-02 07:09:08)

Good insight. As to your original question, how to encourage personal science, I think the answer lies in graph. Look at the low cost side: begin anywhere. Just pick something and start tracking it. Then pick something you'd like to try. The first trial will likely give you insights and ideas to suggest the next one. Soon you may have a backlog of ideas to try. The interesting results will motivate you to keep going. The road blocks come when you think of personal science as though you were doing professional science. You overthink the situation, as though you were working in the professional science portion of the graph, allocating limited resources, taking risks. Begin anywhere. If you didn't pick the right things to track and test, change what you're doing. Begin again. There are no committees. There is no cost to failure. Seth: I already do plenty of personal science. The question is: what can I do to encourage other people to do it? I don't understand your answer.

Alex (2013-03-02 08:41:33)

No, no, I meant "you" as in the person trying to get started in personal science. You (Seth) already did all of the above. You're the paragon of it, in fact. I think people look at the meaningful results you achieved with self-experimentation and feel like they have to shoot for that right from the start. As you point out, though, this is not a "go big or go home" situation.

Tom (2013-03-02 08:44:30)

Create a reddit where people can chat about what they're tracking? Gamification: A website that gives non-money prizes (badges a la Foursquare) for interesting micro-discoveries and for confirmations by others. They're are a ton of habit-tracking apps. One or more might make personal science easier.

Adam (2013-03-02 17:59:23)

One thing that would encourage more people to self-track would be more reports of the positive effects self-trackers have attained. For example, I've noticed that in many of the QS videos the speaker talks about what they were tracking & how they did it, but don't mention any specific benefit. The recent video by Amelia Greenhall was an exception – the positive benefit she got out of tracking was obvious to me. I would say probably the last 4 videos I watched from QS were interesting, but not useful. If I don't see a clear upside to what they tracked, it doesn't motivate me to track.

Paul N (2013-03-02 22:22:40)

My suggestion is to broaden the definition of "personal science" - it can be many more things that just health related. People can do their own experiments with new ways to make/cook foods, (new combinations, recipes, ferments etc). new ways to grow gardens, new ways to build stuff, tinker with engines etc. Some people learned, by experiment, how to make a microwave smelter. That sounds like an implausible idea, that you certainly couldn't get a research grant to test, but it's cheap and easy enough to try yourself. This could perhaps more accurately be called "amateur science" or "innovations", and these can lead to new discoveries. The difference between just normal "hacking" and "personal science" as I see it, is the application of some amount of scientific method to turn a "hack" into an experiment, or even just making observations of things and noticing what changes. A gardener notices that different combinations of plants do better or worse, and then starts tracking the changes and results. The key elements are the desire to learn by doing, rather than just by reading/watching, and to seek to formulate and test hypotheses. Implicit in this is being willing to be wrong, and question your (and other's) assumptions. That is how I got taught in high school science, though I'm not sure if kids are still being taught like that these days.

Alex Chernavsky (2013-03-03 15:13:52)

There should be some kind of "self-experimentation for dummies" guide written for people who may be intelligent and motivated but who don't have experience in designing experiments or analyzing the resulting data. I think that such a guide would help prevent people from floundering around, getting discouraged, or possibly coming up with spurious results. Seth: I am struck by how often "fear of spurious results" comes up. Whereas I think that if you gather data you are much more likely to improve things than make things worse.

Alex Chernavsky (2013-03-03 15:14:55)

In the comment above, I probably should have written, "personal science" instead of "self-experimentation".

vs (2013-03-04 11:24:07)

Hi Seth, Great post as always. I would imagine a number of your readers found this blog, and in turn personal science, by reading your book *The Shangri-La Diet*. A short book on morning faces and the value of personal science, possibly an ebook culled from your blog, might be a good idea. It would make a compelling story: "Morning Faces: The simple, safe, and revolutionary way to fight depression without prescription drugs and harmful side effects". Blogger James Altucher has written about his experience self publishing free and low cost ebooks and on-demand print books with Amazon. I read his free ebook "How to be the luckiest person alive". It collected a number of his favourite blog posts into a coherent story: <http://www.jamesaltucher.com/2011/05/why-and-how-i-self-published-a-book/>

Anonymous coward (2013-03-05 13:22:17)

Link is dead: <http://blog.sethroberts.net/wp-content/uploads/2013/03/2013-02-28-personal-professional-science-in-plausibility-space.jpeg> "This graph explains why health science has so badly stagnated — every year, the Nobel Prize in Medicine is given for something relatively trivial — and why personal science can make a big difference. Health science has stagnated because it is impossible for professionals to study ideas of low plausibility." I don't know if the Nobel is given for trivial things, but your other points are correct, obvious, and denied by most people. Part of the problem is the eagerness of big business and of those who have funded laboratories to deny entry to startups by increasing government regulation. But even when there are no regulations, biology has bought the meme that amateurs are dangerous and should be crushed. Look at the medical community. Doctors don't want patients to receive their own test results or DNA sequences; they don't want them to be allowed to start their own IVs at home without a nurse; they don't want them to be able to choose their treatment or the medicines they use; they don't want them to take vitamins. It starts by trying to force the patient to pay a doctor every time they take a crap, but it ends with the doctors believing their own propaganda. For instance, Jackson Labs does a background check on anyone trying to buy lab mice, to ensure they're "legitimate" researchers. What exactly is this supposed to prevent? It's not to protect mice. Anybody can go to PetSmart and buy a dozen mice to feed to their pet pythons. All it does is prevent amateurs from doing animal studies, such as seeing how long various genetically-altered Jax mice live. Invitrogen won't even sell you glassware unless you can prove you're "legitimate". Seth: The link works for me now. It failed first time. The explanation of why this could happen is a little complicated, I will skip

it. The Nobel Prize is given for work on problems that are relatively trivial compared to the major sources of death and disability (heart disease, cancer, depression, obesity, diabetes, and so on) – that's what I meant. I agree with what you say. Yes, why in the world does Jackson Labs do a background check? It seems like the main effect of that check is to slow down progress.

dearieme (2013-03-03 08:15:51)

Ahoy, Seth: this is interesting. <http://extragoodshit.phlap.net/index.php/heart-surgeon-speaks-out-on-what-really-causes-heart-disease/#more-208026> But is it genuine?

Elizabeth Molin (2013-03-03 08:50:11)

Dearieme, I looked into Dr. Lundell. See <http://www.quackwatch.org/11Ind/lundell.html>

dearieme (2013-03-03 14:17:51)

I did smell a rat. It comes from having read so much Global Warming rubbish, I suppose.

garymar (2013-03-03 17:23:16)

I often look for Korean-made kimchi in the supermarkets here in Japan. You read the labels of the regular stuff and its filled with sorbitol, MSG, etc – typical long list of chemical labels. Japan's processed food industry is second to none! Seth: Since

the Japanese live longer than anyone else, even South Koreans, apparently food processing isn't so bad. Yakult is the one processed food I eat regularly, not counting flaxseed oil.

James (2013-03-04 05:15:11)

<http://opinionator.blogs.nytimes.com/2013/02/27/its-the-sugar-folks/> <http://www.plosone.org/article/info%3Adoi%2F10.1371%2Fjournal.pone.0057873> "In other words, according to this study, it's not just obesity that can cause diabetes: sugar can cause it, too, irrespective of obesity. And obesity does not always lead to diabetes. The study demonstrates this with the same level of confidence that linked cigarettes and lung cancer in the 1960s"

### **Butter = Antidepressant? (2013-03-04 05:00)**

On the Shangri-La Diet forums, [1]babyhopes wrote:

At 10 am, I NCd [nose-clipped] a cup of milk, coffee and 2 small spoons of butter (I really like the anti-depressant effects of butter so I am making it part of my breakfast every day)

I noticed something similar the first time I ate a lot of butter (about 60 g). It was at lunch. A few hours later I felt a pleasant warm feeling in my head. The butter was the only unusual thing I had eaten.

When I googled "butter antidepressant" the first result was this blog – [2]I wrote about this three years ago. Well, here is new evidence.

1. <http://boards.sethroberts.net/index.php?topic=8394.msg106906#msg106906>

2. <http://blog.sethroberts.net/2010/05/22/butter-new-antidepressant/>

---

q (2013-03-04 06:33:50)

i found the same kind of thing when i started doing sld with butter (i'm not depressed but it improved my mood) but the effect didn't last more than a week for me.

dearieme (2013-03-04 07:42:23)

Good Grief, what sort of breakfast doesn't automatically include butter? With what does he normally separate the toast and the marmalade?

Brian (2013-03-04 08:33:11)

Well, the normal American diet includes only margarine or other butter substitutes. I'd imagine that most Americans no longer know what butter tastes like or why food at certain restaurants tastes so much better than what is prepared at home.

in praise of dearieme (2013-03-04 11:25:39)

dearieme You are everywhere! I've been seeing your comments for years on the blogs I have found most interesting at various stages; CiF, Chris Dillow, CynicusEconomicus, Marginal Revolution (or is it Money Illusion?) and FOFOA (?) When you're ready to give up the toast (gluten) and marmalade (sugar) maybe you should start putting grass-fed butter in your morning coffee <http://www.bulletproofexec.com/how-to-make-your-coffee-bulletproof-and-your-morning-too/>

dearieme (2013-03-04 13:28:45)

Good God almighty! Thank you for that appalling insight, Brian. Maybe General de Gaulle was right.

derp (2013-03-04 15:23:32)

I wonder if lard has the same effect.

john (2013-03-04 15:42:27)

I often notice a delayed positive effect of high amounts of tallow or butter. If I eat a lot, I actually get sort of queasy, but hours later I feel good. During exercise, my face and extremities become warm, and I can handle much more volume (my recovery during high fat eating is improved as well—weightlifting and ballet), from both an increase in motivation and decrease in fatigue.

shtove (2013-03-05 01:56:19)

@in praise of dearieme I've followed some of those blogs too. And they often refer to groupthink. Aagh!

dearieme (2013-03-05 02:03:51)

"you should start putting grass-fed butter in your morning coffee": thank you for the suggestion, but when I want a morning treat I add double cream to my coffee. Seth: I have used both (butter and cream) many times in my morning tea. Cream is better but butter is adequate.

## **A Revolution in Growing Rice (2013-03-05 05:00)**

Surely you have heard of [1]Norman Borlaug, "Father of the Green Revolution". He won a Nobel Peace Prize in 1970 for

the introduction of these high-yielding [wheat] varieties combined with modern agricultural production techniques to Mexico, Pakistan, and India. As a result, Mexico became a net exporter of wheat by 1963. Between 1965 and 1970, wheat yields nearly doubled in Pakistan and India.

He had a Ph.D. in plant pathology and genetics. He learned how to develop better strains in graduate school. He worked as an agricultural researcher in Mexico.

You have probably not heard of Henri de Laulanié, a French Jesuit priest who worked in Madagascar starting in the 1960s. He tried to help local farmers grow more rice. He had only an undergraduate degree in agriculture. In contrast to Borlaug, he tested simple variations that any farmer could afford. He found that [2]four changes in traditional practices had a big effect:

- Instead of planting seedlings 30-60 days old, tiny seedlings less than 15 days old were planted.
- Instead of planting 3-5 or more seedlings in clumps, single seedlings were planted.
- Instead of close, dense planting, with seed [densities] of 50-100 kg/ha, plants were set out carefully and gently in a square pattern, 25 x 25 cm or wider if the soil was very good; the seed [density] was reduced by 80-90 % . . .
- Instead of keeping rice paddies continuously flooded, only a minimum of water was applied daily to keep the soil moist, not always saturated; fields were allowed to dry out several times to the cracking point during the growing period, with much less total use of water.

The effect of these changes was considerably more than Borlaug's doubling of yield:

The farmers around Ranomafana who used [these methods] in 1994-95 averaged over 8 t/ha, more than four times their previous yield, and some farmers reached 12 t/ha and one even got 14 t/ha. The next year and the following year, the average remained over 8 t/ha, and a few farmers even reached 16 t/ha.

The possibility of such enormous improvements had been overlooked by both farmers and researchers. They were achieved without damaging the environment with heavy fertilizer use, unlike Borlaug's methods.

Henri de Laulanié was not a personal scientist but he resembled one. Like a personal scientist, he cared about only one thing (improving yield). Professional scientists have many goals (publication, promotion, respect of colleagues, grants, prizes, and so on) in addition to making the world a better place. Like a personal scientist, de Laulanié did small cheap experiments. Professional scientists rarely do small cheap experiments. (Many of them worship at the altar of large randomized trials.) Like a personal scientist, de Laulanié tested treatments available to everyone (e.g., butter). Professional scientists rarely do this. Like a personal scientist, he tried to find the optimal environment. In the area of health, professional scientists almost never do this, unless they are in a nutrition department or school of public health. Almost all research funding goes to the study of other things, such as molecular mechanisms and drugs.

Personal science matters because [3]personal scientists can do things professional scientists can't or won't do. de Laulanié's work shows what a big difference this can make.

[4]A recent newspaper article. The results are so good [5]they have been questioned by mainstream researchers.

Thanks to Steve Hansen.

derp (2013-03-05 10:15:31)

Just curious, but how do you stumble across such findings? Seth: A friend sent me a link.

Paul N (2013-03-05 16:58:58)

The SRI article is really quite interesting, and it prompts me to think of another difference between personal and professional science. That is, does the result lead to something that is sellable/patentable? It is a common evaluation criteria for grant funding "will this lead to any patentable results?" So this automatically biases project creation and selection to things that create controllable intellectual property, rather than just things that create useful results. But Laulanié's method could not be patented or controlled, or sold, in any way, so why would any professional scientist pursue it, or any government fund it, if it can't be "sold" to the world? And, potentially, it goes against the interest of corporations that fund agricultural research. Who benefits, other than the farmers themselves, from a method change that increases yield with no new seed varieties and no use of fertilisers or pesticides? Personal science is pretty much about results above all else. Increasingly, professional science uses results as a pathway to "all else". Seth: Very true. Professional scientists, however, are not particularly interested in selling things, although their funders may be. Leaving aside the influence of their funders, professional scientists have a big problem: they get most or all of their status from their job. And two things are true: useless is higher status than useful, making it hard

for them to do useful research; and big (= expensive) is higher status than small (= cheap), making it hard for them to do small research. Laulanié wasn't worried about status. Most people are.

## Modern Food Reduced Diversity of Oral Bacteria (2013-03-06 05:00)

A new paper in Nature Genetics describes research into the bacteria in ancient teeth plaque. When modern food came along, the bacteria became less diverse. [1]One of the researchers said:

The composition of oral bacteria changed markedly with the introduction of farming, and again around 150 years ago. With the introduction of processed sugar and flour in the Industrial Revolution, we can see a dramatically decreased diversity in our oral bacteria, allowing domination by caries-causing strains.

Whether the decrease in diversity was due to (a) more sugar and flour or (b) less bacteria-laden foods is hard to say.

Again, data suggest we need bacteria to protect us against bacteria. You'd never know this from food safety laws or how freely pediatricians prescribe antibiotics. Again, it is hard to know without more research what caused this or that historical change in health (e.g., more tooth decay when sugar and flour became popular). The obvious answer (e.g., sugar causes tooth decay) might be wrong. If you believe that cavities are caused by too much sugar, the solution is to eat less sugar. What if cavities are caused by not enough bacterial diversity? Then other solutions might work better, such as eating more fermented food.

Thanks to Vic Sarjoo.

---

Ahrand (2013-03-06 06:51:35)

I have found that instead of combating bacteria in your mouth (flossing, brushing, rinsing with anti-bacterials), it is more helpful to gently guide them to behave and force them to diversify. I use Xylitol (a non-fermentable sugar) after meals and before bed,

it is difficult to digest for (certain) bacteria so they cause less problems (the population adapts but seems to be less virulent). Trying to wipe out all bacteria never works as there are always means/places for them to hide and come back (stronger) after the anti-bacterials have flushed. Surprising results after 2 years: whiter teeth, less dental plaque, less sinus infections, ...

Evelyn M. (2013-03-06 07:08:16)

Thank you, Ahrand, for your post. I, too, am convinced that xylitol is an unmitigated blessing. I suffered from terrible oral lichen planus that medical science could do nothing about. A desperate web search convinced me to try xylitol. A half-teaspoon three to four times a day after eating within three months showed that the lichen planus was receding, and after six months it was clearly in remission. My dentist was astounded. My mouth has never been in better shape - even the "geographic tongue" that I had since adolescence is gone - and at basically no cost using a substance that anyone can buy off the web. Read the literature, especially from Finland, where they have done many clinical trials on children. Seth: That's fascinating. Good work!

Paul N (2013-03-08 09:57:26)

Certainly hard to separate the causes (sugar v bacteria) especially since they are related. Eating sugar encourages the growth of sugar loving bacteria, regardless of what other bacteria are eaten. Weston Price concluded that the "displacing foods of modern commerce" - sugar and white flour - were the primary cause. Not only do they make the problem worse, they displace other foods, often fermented ones, so both causes are in operation. Incidentally, in Jared Diamond's "Collapse" he talks about some pacific island where sugar cane naturally grew, and the islanders squeezed the juice, as a source of fresh water. Not surprisingly, their teeth had lots of cavities, and old skulls showed the same. We should also keep in mind that various vitamins, particularly D, K2, C and various minerals (calcium, magnesium, phosphorous) contribute to dental health. A diet deficient in these could still have dental problems even with low sugar and high good bacteria. Indeed, even Weston Price wrote about this, and found that [1]places with naturally high fluorine in the water had lower rates of dental decay. I would posit that neither the absence of sugar nor the presence of beneficial bacteria alone, is sufficient to ensure optimal dental health, though they are unquestionably major factors. Seth: I agree. I found that my gums became much healthier when I started drinking flaxseed oil. It is quite possible that the traditional diets of Weston Price, not just the modern ones, had too little omega-3.

## How Meritocratic is Chinese Higher Education? (2013-03-07 05:00)

A friend of mine taught at Harvard for a few years. Her husband needed a job, so he taught a writing class. He said his students were so bad it appeared to be an experiment: How stupid can you be and succeed at Harvard? They had not been admitted based on SAT scores or grades, that was clear. In [1]a recent article called "The Myth of American Meritocracy", Ron Unz described considerable evidence of exactly what my friend's husband noticed: Harvard admission not based on the usual "meritocratic" measures, such as SAT scores and grades. For example, he found evidence of an Asian quota. If Asians weren't penalized for being Asian, far more would be admitted.

In [2]a follow-up article, Unz wrote:

Near the beginning of my article [about meritocracy] I had noted that although complaints about official corruption of every sort are a leading topic on the Chinese Internet and also in Western media coverage, I had never once heard such a claim about admissions to elite Chinese universities. This led me to conclude that the process was entirely meritocratic, and a couple of individuals with good knowledge of China confirmed this. However, during one of my recent Yale Law events, a student from China stated that he and his friends were firmly convinced that any of China's 350 Central Committee members could easily obtain an admissions slot for his friends or relatives, so my claim was incorrect. This conflicting evidence may be reconciled if the number of such corrupt admissions each year is so tiny—perhaps a few hundred

out of over eight million—that it is completely invisible to the general public. I should note that the New York Times just ran another major story on colleges in China, emphasizing every possible unfair aspect of the system, but nonetheless indicating that admissions were entirely meritocratic and objective.

Here is one reason that there is zero discussion of corruption in admission to elite Chinese universities (such as Tsinghua, where I teach): Rich Chinese universally want their children to go to college outside China, especially America. The more money you have, the easier this is. I'd guess all children of Central Committee members attend college outside China. None of them attend Tsinghua, as far as I know. At least among my students, this is utterly obvious – that education outside China is superior and anyone who can go outside China will. The brake on this is purely cost. One of my students said she didn't want to burden her parents with the cost.

The test that Chinese high school students take to get into college is the gaokao. One of my students got the highest gaokao score in Beijing. An astonishing achievement. He didn't get in to any American university. The Chinese public was shocked. Many newspaper articles were written about it. The rest of my students knew about it. His family is not well-off. This is why he failed where thousands of Chinese students from rich families – who didn't bother to take the gaokao, but surely would have had a lower score – succeeded. Although he went to Tsinghua as a freshman, he too wanted to escape Chinese higher education. First he transferred to the University of Hong Kong. Then he transferred to MIT.

Why is Chinese higher education so bad that everyone who can avoids it? One of my students (a psychology major) said that as the economy quickly improved, the government quickly expanded the college education system. There weren't enough good teachers to fill the slots. That's one reason. Another reason is a certain ethos. I asked a friend of mine, a Tsinghua student not majoring in psychology, "In what fraction of your classes do the professors lecture by reading from the textbook?" 80 %, she said. That's at Tsinghua. Below Tsinghua it's worse. Of course students go to college outside China for reasons that have nothing to do with quality. The most obvious is prestige: It is prestigious to go elsewhere.

Lack of higher education meritocracy in China has a more subtle aspect. It is much easier to get into elite universities, such as Tsinghua, if you live in Beijing or Shanghai than if you live elsewhere, especially poor provinces. Is this unfair? It isn't easy to say because the gaokao is different in different places. I don't know the official reason for this (different textbooks?), but the difference in tests makes it easier to have lower admissions cutoff scores for students from Beijing and Shanghai. A Beijing student at Tsinghua will usually have a lower gaokao score than a student at Tsinghua from a poor province. Of course it is much more expensive to live in Beijing and Shanghai than elsewhere. Moreover, a big chunk of the gaokao is about English proficiency. A student's English proficiency depends heavily on amount and quality of English education, which depends heavily on family income. The richer you are, the better your children's English.

All this makes political sense. Richer people – whose children have better English – have more political power than the less rich. Those who live in Beijing and Shanghai have more political power than people in poor provinces. Allowing their children get into Tsinghua with lower gaokao scores (Beijing and Shanghai residents) or writing the gaokao so that their children have an advantage (English proficiency) is one way to keep them happy.

Elizabeth Molin (2013-03-07 09:28:33)

This is only peripherally related, but when I was managing editor of a social-sciences journal, I was continually amazed at the inability of the Ph.D.s whose articles we published to write grammatical English. This was the more striking (to me) because it was a linguistics journal, although it also certainly applies to other fields: [http://www.elizabethmolin.com/?page\\_id=19](http://www.elizabethmolin.com/?page_id=19).

dearieme (2013-03-07 16:03:49)

Surely nobody thinks Harvard is the best university in the Boston area?

Lemmy Caution (2013-03-07 18:21:22)

I would be surprised if harvard students were actually stupid. Maybe that guy was just a bad teacher.

Jonathan Shewchuk (2013-03-07 22:49:40)

Do you know if professors lecture by reading from the textbook in the engineering and math departments too? Seth: No I don't know. I will ask.

Shawn (2013-03-09 12:25:03)

Hmm, funny thing, I wonder why you haven't wrote about the fact that Unz's article points out that gentiles are underrepresented relative to their qualifications?

kelo (2013-03-10 20:10:14)

Hmm, As an Mainland Chinese, born in an poor province(HeNan) and graduating from an Top 10 university, I totally agree with what u say. The reason of all those phenomenons -the drastic competition of gaokao and the desire to go out of China-lies in one thing: No money, no living. As my uncle and father always say:"No matter what u do, you only can survive and get respect because of your money." Haw-haw, funny but depressing.....

## **Great Side Effects of the Shangri-La Diet (2013-03-08 07:32)**

In [1]a recent post on the Shangri-La Diet forums, Morex, who lives in Mexico, describes several great side effects of the Shangri-La Diet:

1. At peace with food. "I am in control of what I eat. If I want I have a piece of chocolate or some peanuts, but food is no longer in command. Food is no longer an obstacle or an excuse. This is FANTASTIC! For 40 years I had a horrible relationship with food. It commanded my every activity in the day. I was always on the look for better flavors and foods that would quench my never fading hunger. This is no longer an issue."
2. No more junk food. "Thanks to SLD, I quit junk food. I no longer crave it and when I have tasted it, it's horrible! Too salty and greasy. Or too sweet. That means no soda, pizza, chips, donuts, candy or anything like that. When I want something sweet in the afternoon, I'd have a teaspoon of honey and that's it."
3. More money. "We eat so little that we are saving extra cash. Who knows, maybe we could soon afford a nice vacation on the beach! (Vacations for Mexicans in Mexico are VERY expensive.)"
4. More time. Much more time. "Since we have been doing SLD, our days are longer! Because of the fact that we eat so very little portions, we are barely cooking. And when we do, it lasts for about 4 days! Before SLD we spent

about an hour a meal. 30 mins. cooking, and 30 mins. eating. Some days it was longer, depending on what we cooked. That means that we spent about 3 or 4 hours a day cooking and eating. Now we prepare meals in about 10 minutes and eat in about 5!!! That's right. For breakfast I have half a bran cookie, some cereal or some fruit. For lunch I just heat up in the microwave something we cooked. For dinner we have a little oatmeal or cereal. And that's it! My days are longer for 3 hours! We have been reading our books (we're book worms here), watching movies we didn't have the time to watch and going out for walks!! FREAKING AWESOME!"

I didn't have the first two problems (loss of control and junk food) but I too distinctly noticed saving money and (especially) time. Just like he says. It's been a long time since I wrote The Shangri-La Diet but I think I failed to mention how much time and money I saved. (If I'm wrong, please correct me.)

What about his weight? He doesn't have a scale but says this: "Before SLD I was size 44. Today [after 2 months of SLD] I am 38, which I haven't been able to wear since I was in the University (19 years old)." He wants to get to size 36. He also posts several pictures, before and after.

Thanks, Morex.

Meegs (2013-03-08 15:48:16)

I have had a very similar experience. I even do the teaspoon of honey thing.

### **Tea and News: Rinse First (2013-03-08 17:00)**

While living in China, I discovered that it was a good idea to rinse tea with hot water before brewing it. The rinse removes a certain rough taste – easy to notice in [1]side-by-side comparisons. [2]A Chinese college student made an interesting analogy:

Entertainment news is like drinking tea, first time is like washing tea leafs, no one really cares. Maybe 2nd or 3rd time it will have the sweet taste, but in the end it gets weaker and weaker.

1. <http://blog.sethroberts.net/2012/11/10/the-power-of-the-willat-effect-rinsed-versus-unrinsed-tea/>

2. [http://shanghaiist.com/2009/12/04/the\\_secret\\_is\\_out\\_her.php](http://shanghaiist.com/2009/12/04/the_secret_is_out_her.php)

---

RT (2013-03-08 18:24:45)

Yeah, rinse all the lead out! Congrats on the discovery.

in praise of dearieme (2013-03-08 21:26:54)

Is there only taste benefits ? Could it remove Mycotoxins? Are mycotocins something to care about?

Adam (2013-03-09 17:58:47)

I've noticed that expensive tea doesn't need to be washed as much as cheap tea. I inherited a huge amount of cheap tea from HaiNan (not known for quality tea). If I try to drink it straight, it is awful (too strong, bitter, something just off), but if I wash it (pour on hot water, leave on 5 seconds, pour off) it tastes just like expensive tea. Sorry this comment has nothing to do with news.

Kaleberg (2013-03-11 19:44:29)

It depends on the tea. You don't want to do this with an oolong, but it is the only way to get a drinkable cup of pu-er tea. Go to a good tea shop and they'll tell you how to get the best cup when you brew. (We learned a lot at high-end Ten Ren.)

Mo Ibrahim (2013-03-14 19:34:46)

Wow, I've had an intuition to rinse my tea for years, but I've never done it! I'm going to try it tonight and probably from now on...Thanks Seth.

### **Posit Science: Does It Work? (Continued) (2013-03-09 05:00)**

In [1]an earlier post I asked 15 questions about [2]Zelinski et al. (2011) ("Improvement in memory with plasticity-based adaptive cognitive training: results of the 3-month follow-up"), a study done to measure the efficacy of the brain training sold by Posit Science. The study asked if the effects of training were detectable three months after it stopped. Henry Mahncke, the head of Posit Science, recently sent me answers to a few of my questions.

Most of my questions he declined to answer. He didn't answer them, he said, because they contained "innuendo". My questions were ordinary tough (or "critical") questions. Their negative slant was not at all hidden (in contrast to innuendo). For the questions he didn't answer, he substituted less critical questions. I give a few examples below. Unwillingness to answer tough questions about a study raises doubts about it.

His answers raised more doubts. From his answer to Question 7, I learned that although the investigators gave their subjects the whole RBANS, (a) they failed to report the results from the visual subtests and (b) these unreported results did not support their conclusions. Mahncke says this result was not reported "due to lack of publication space." The original paper did not say that some results were omitted due to lack of space. I assume all favorable results were reported. To report all favorable results but omit some unfavorable results is misleading.

To further explain the omission, Mahncke says

We used the auditory measures as the primary outcome measure because we hypothesized that cognitive domains [by "cognitive domains" he means the cognitive gains due to training – Seth] would be restricted to the trained sensory domain, in this case the auditory system. [emphasis added]

He doesn't say he believed the gains would be greater with auditory stimuli, he says he believed they would be restricted to auditory stimuli. The Posit Science website says their training increases "memory", "intelligence", "focus" and "thinking speed". None of these are restricted to the auditory system – far from it. Unless I am misunderstanding something, the head of Posit Science doesn't believe the main claims of the Posit Science website.

Why Mahncke fails to see a difference between methods (Question 13) and results (Question 14), fails to see

a difference between methods (Question 11) and discussion (Question 15), and gives a one-word answer ("yes") to Question 12, I cannot say. In each case, however, he errs on the side of not answering.

My overall conclusion is that this study does not support Posit Science claims. The main measure (RBANS auditory subtests) didn't show significant retention. A closely related set of measures (RBANS visual subtests) didn't show significant retention. A third set of measures ("secondary composite measure") did show retention, but the p value was not corrected for multiple tests. When the p value is corrected for multiple tests, the secondary composite measure may not show significant retention. Because of the large number of subjects (more than 500), repeated failure to find significant retention under presumably near-optimal conditions (e.g., 1 hour/day of training) suggests that the training effect, after three months without training, is small or zero.

I assume that Posit Science sponsored this study because they believed it was unrealistic for subjects to spend 1 hour/day for the rest of their life doing their training. One hour/day was realistic for a while, yes, but not forever. So subjects will stop. Will the gains last? was the question. Apparently the answer is no.

If Mahncke has any response to this, I will post it.

This is another illustration of why personal science (science done for your own benefit, rather than as a job) is important. Professional scientists are under pressure to get certain results. This study is an example. Mahncke was a co-author. Someone employed by Posit Science is under pressure to get results that benefit Posit Science. (I am not saying Mahncke was affected by this pressure.) A personal scientist is not under pressure to get certain results. For example, if I study the effect of tetracycline (an antibiotic) on my acne, I simply want to know if it helps. Both possible answers (yes and no) are equally acceptable. We may need personal scientists to get unbiased answers.

Here are my original questions along with Mahncke's answer or lack of answer.

1. Isn't it correct that after three months there was no longer reliable improvement due to training according to the main measure that was chosen by you (the investigators) in advance? If so, shouldn't that have been the main conclusion (e.g., in the abstract and final paragraph)?

Not answered.

[Seth: Here is Mahncke's substitute question: "Why do you conclude that "Training effects were maintained but waned over the 3-month no-contact period" given that the "previously significant improvements became non-significant at the 3-month follow-up for the primary outcome"?"]

2. The training is barely described. The entire description is this: "a brain plasticity-based computer program designed to improve the speed and accuracy of auditory information processing and to engage neuromodulatory systems." To learn more, readers are referred to a paper that is not easily available – in particular, I could not find it on the Posit Science website. Because the training is so briefly described, I was unable to judge how much the outcome tests differ from the training tasks. This made it impossible for me to judge how much the training generalizes to other tasks – which is the whole point. Why wasn't the training better described?

Not answered.

[Seth: Here is Mahncke's substitute question: "Could you describe the training program in more depth, to help judge the similarity between the training exercises and the cognitive outcome measures?"]

3. What was the "ET [experimental treatment] processing speed exercise"?

The processing speed exercise is a time order judgment task in which two brief auditory frequency modulated sweeps are presented, either of which may sweep up or down in frequency. The subject must identify each sweep in the correct order (i.e., up/up, down/down, up/down, down/up). The inter-stimulus interval is adaptively manipulated to determine a threshold for reliable task performance. Note that this is not a reaction time task. The characteristics of the sweeps are chosen to match the frequency modulated sweeps common in stop consonant sounds (like /ba/ or /da/). Older listeners generally show strong correlations between processing speed, speech reception accuracy, and memory; which led us to the hypothesis that improving core processing speed in this way would contribute to improving memory. This approach is discussed extensively in "Brain plasticity and functional losses in the aged: scientific bases for a novel intervention" available at <http://www.ncbi.nlm.nih.gov/pubmed/17046669>

3. [continue] It sounds like a reaction-time task. People will get faster at any reaction-time task if given extensive practice on that task. How is such improvement relevant to daily life? If it is irrelevant, why is it given considerable attention (one of the paper's four graphs)?

Not answered.

4. According to Table 2, the CSRQ (Cognitive Self-Report Questionnaire) questions showed no significant improvement in trainees' perceptions of their own daily cognitive functioning, although the p value was close to 0.05. Given the large sample size ( 500), this failure to find significant improvement suggests the self-report improvements were small or zero. Why wasn't this discussed? Is the amount of improvement suggested by Posit Science's marketing consistent with these results?

Not answered.

5. Is it possible that the improvement subjects experienced was due to the acquisition of strategies for dealing with rapidly presented auditory material, and especially for focusing on the literal words (rather than on their meaning, as may be the usual approach taken in daily life)? If so, is it possible that the skills being improved have little value in daily life, explaining the lack of effect on the CSRQ?

Not answered.

6. In the Methods section, you write "In the a priori data analysis plan for the IMPACT Study, it was hypothesized that the tests constituting the secondary outcome measure would be more sensitive than the RBANS given their larger raw score ranges and sensitivity to cognitive aging effects." Do the initial post-training tests (measurements of the training effect soon after training ended) support this hypothesis? Why aren't the initial post-training results described so that readers can see for themselves if this hypothesis is plausible? If you thought the "secondary outcome measure would be more sensitive than the RBANS" why wasn't the secondary outcome measure the primary measure?

In a large-scale clinical trial such as IMPACT, it is considered best practice to pick as the primary outcome measure a measure that has been employed in earlier studies. We had used the RBANS in two previous studies (references 8 and 17 in the paper). While we had seen significant results in both studies, it was also clear from those studies that the RBANS had ceiling effects in cognitively intact populations that would limit the statistical sensitivity of the measure. For example, the RBANS list recall measure had 10 words, and a reasonable portion of participants get all 10 correct at baseline, leaving no room for improvement regardless of the efficacy of the intervention. Given that observation, we added measures to the IMPACT study that we hypothesized would be more sensitive. For example, the RAVLT has 15 words, leaving more room for improvement and fewer ceiling effects. [It is unclear that more words = more sensitivity. It depends on the words – Seth] However, since we had not used those measures in previous studies, we decided to define these new measures as secondary outcome measures in the data analysis plan. This issue is discussed in depth in the methods section of the main training effect paper (reference 6), and of

course that's where all of the initial post-training results you mention are described. This improved sensitivity of the secondary outcome measures was quite evident in the post-training data; however for reasons of publication length we did not discuss it in that paper. The comparative data would make an interesting publication, and one that might be helpful to other researchers in this field.

7. The primary outcome measure was some of the RBANS (Repeatable Battery for the Assessment of Neuropsychological Status). Did subjects take the whole RBANS or only part of it? If they took the whole RBANS, what were the results with the rest of the RBANS (the subtests not included in the primary outcome measure)?

Participants took the entire RBANS. We used the auditory measures as the primary outcome measure because we hypothesized that cognitive domains [by "domains" he means "gains" – Seth] would be restricted to the trained sensory domain, in this case the auditory system. Interestingly, there was a significant effect on the overall RBANS measure, however there was no significant effect on a composite of the RBANS visual measures. This interesting result was not included in our papers for reasons of publication length.

[Seth: As I said earlier, a surprising answer.]

8. The data analysis refers to a "secondary composite measure". Why that particular composite and not any of the many other possible composite measures? Were other secondary composite measures considered? If so, were p values corrected for this?

The measures used were the Rey Auditory Verbal Learning Test total score (sum of trials 1–5) and word list delayed recall, Rivermead Behavioral Memory Test immediate and delayed recall, and Wechsler Memory Scale letter-number sequencing and digit span backwards tests. These measures were chosen a priori as more sensitive than their RBANS cognate measures, and a priori we conservatively chose to integrate all 6 into a single composite measure. Individual test scores are all shown in table 2. This issue is discussed in depth in the methods section of the main training effect paper (reference 6). It's straightforward to evaluate what the effects shown on other potential composites would be simply from inspecting the individual test data in table 2. In the methods section of the main training effect paper (reference 6), we discuss our approach to multiple comparisons, where we state "A single primary outcome measure (RBANS Memory/ Attention) was predefined to conserve an overall alpha level of 0.05. No corrections for multiple comparisons were made on the secondary measures." I can see that it would have been helpful to re-iterate that statement in the 2011 paper, and my apologies for the oversight.

[Seth: He doesn't answer my question "were other secondary measures considered?"]

9. If Test A resembles training more closely than Test B, Test A should show more effect of training (at any retention interval) than Test B. In this case Test A = the RBANS auditory subtests and Test B = the secondary composite measure. In contrast to this prediction, you found that Test B showed a clearer training effect (in terms of p value) than Test A. Why wasn't this anomaly discussed (beyond what was said in the Methods section)?

Not answered.

10. Were any tests given the subjects not described in this report? If there were other tests, why were their results not described?

All outcome measures performed in the study are reported in the publication.

[Seth: I have no idea how this answer is consistent with (a) the subjects took the visual subtests of the RBANS and (b) the paper fails to report the results of those tests (see answer to Question 7). The paper does not say that the subjects took the visual subtests of the RBANS.]

11. The secondary composite measure is composed of several memory tests and called "Overall Memory". The Posit Science website says their training will not only help you "remember more" but also "think faster" and "focus better". Why weren't tests of thinking speed (different from the training tasks) and focus included in the assessment?

Not answered.

12. Do the results support the idea that the training causes trainees to "focus better"?

Yes.

[Seth: That's his whole answer.]

13. The Posit Science homepage suggests that their training increases "intelligence". Was intelligence measured in this study?

At the time we designed IMPACT, we were focused on establishing the effect of the training on memory, as the most common complaint of people with general cognitive difficulties. As IMPACT was in progress, Jaeggi et. al published their very interesting paper on the effect of N-back training on measures of intelligence, where they stated that improving working memory was likely to improve measures of intelligence. It would be quite interesting to repeat the IMPACT study with those or other measures of intelligence, given the improvements in working memory documented in IMPACT. The statement on the Posit Science web page relates to the Jaeggi et. al. paper, given that the Posit training program (BrainHQ) includes N-back training.

13 (continued). If not, why not?

Not answered.

[Seth: In Question 12, Mahncke failed to explain his answer about focus ("yes") apparently because I left out "if yes, please explain how". In this question, he dislikes my inclusion of "if not, why not?"]

14. Do the results support the idea that the training causes trainees to become more intelligent?

This question appears to be redundant with 13.

[Seth: Question 13 asked: Was intelligence measured? (A methods question.) This question asked: What about the results? Do they support claims about intelligence? (A results question.)]

15. The only test of thinking speed included in the assessment appears to be a reaction-time task that was part of the training. Are you saying that getting faster on one reaction-time task after lots of practice with that task shows that your training causes trainees to "think faster"?

This question appears to be redundant with 11.

[Seth: Question 11 was a methods question. This is a question about what the results mean – a discussion question. I still have no idea why Posit Science says their training causes trainees to "think faster" or why I should care that their subjects get faster on a laboratory task after lots of practice.]

Alex Chernavsky (2013-03-09 08:33:32)

I remember about twenty years ago or so, I read a good deal of Michael Merzenich's research on somatic maps in the cortex. Seemed like he was doing good work at the time. I see that Merzenich is now the co-founder and Chief Scientific Officer of Posit Science. I don't know enough about the claims made by Posit Science to have a strong opinion, but Mahncke's attitude certainly gives me pause. Too bad Posit Science can't answer simple questions about their research. Reminds me of standard practices in the pharmaceutical industry. Seth: I too like Merzenich's work on somatic maps.

## The Rise of Personal Science: One Example, About Acne (2013-03-11 05:00)

Looking around for evidence connecting glutathione level and acne ([1]it has been proposed that low glutathione causes acne), I found [2]this at acne.org, from a 20-year-old woman:

As a personal choice research and viewing other people's experiences with supplements is safer than taking my doctor's advice. My doctor insisted I go on the pill, insisted I get on antibiotics [a common prescription for acne], insisted nothing was wrong with me and even did a hormonal test...said I was "healthy and normal" and to leave the office because my hormones were normal as well as everything from the liver onwards. I stared at him and told him he was wrong: 1. hormone tests will lie if I'm on the pill and 2. I have acne, never had it before in my life and it came about too fast ... If acne is a symptom then something is wrong. I personally don't trust doctors because they generalize [too much] and from personal experiences [where] I've been laughed at and dismissed and even told "leaky gut doesn't exist". Personal research goes a long way and it's so great to have communities like this where everyone can help each other out.

This is personal science in the sense of trying to learn from other people's data. What's interesting is that she says this. Nobody forced her to. She isn't try to sell something or look good. Her discovery of the power of "research and viewing other people's experiences" – better than trusting a doctor – (a) interests her and (b) she thinks will interest acne.org readers. Her own experience certainly supports what she says.

Long ago, it was discovered that the Earth is round. Before the discovery, nobody said that. After the discovery, people discussed it for a while ("Have you heard? The Earth is round."), maybe a few hundred years. When knowledge of the Earth's roundness became part of everyone's belief system, people stopped discussing it.

In other words, this comment suggests that a new truth is coming into being. Her experience is the same as mine with regard to acne: Can't trust what a doctor says. My dermatologist prescribed two medicines. Studying myself showed that only one of them worked, a possibility my dermatologist seemed to have never considered.

derp (2013-03-11 07:12:15)

Well, doctors aren't scientists. My medical training made it obvious to me that every scientific thinking is removed from daily medical work. Don't investigate. Don't understand mechanisms. Don't use solutions that work, only because they counteract your intuition or "common medical wisdom" or "state of the art" or your private pet theory. Use the guidelines Big Pharma wrote for us, repeat every therapy even if it has shown to work poorly ("it's the best we have" \*barf\*) and don't listen to the the patient who has a different experience - he's the layman, after all. Doctors obey. They are the modern version of Pythagorean acousmatics. Seth: Doctors obey, yes, but they supposedly obey scientists. Such as medical school professors.

dearieme (2013-03-11 07:13:29)

"Long ago, it was discovered that the Earth is round. ... When knowledge of the Earth's roundness became part of everyone's belief system, people stopped discussing it." Until a 19th century American fabricated the notion that medieval man supposed the earth to be flat.

Nancy Lebovitz (2013-03-11 07:26:33)

Off topic: [http://www.nytimes.com/2013/03/07/science/unreported-side-effects-of-drugs-found-using-internet-data-study-finds.html?hp&\\_r=1](http://www.nytimes.com/2013/03/07/science/unreported-side-effects-of-drugs-found-using-internet-data-study-finds.html?hp&_r=1) &

Chuck (2013-03-11 07:42:16)

It's quite evident that doctors, and scientist, forget that personal science is the foundation of all science and medical treatments. Their attitude is: "If it's not Western, it's not valid. If it's not Modern, it's not valid." Humans have been tinkering around with ways and means to cure or heal themselves since the first time they stubbed their toe. Some things worked, some things didn't. The things that worked were passed down and shared with others. Thinking that an individual is incapable of finding a cure or making some scientific discovery is asinine. Cheers and good health

Nile (2013-03-11 14:43:22)

The contact email given on the home page does not work for me. i hope you don't mind using comments to contact you. "email" follows Dr. Roberts- This may interest readers of your blog. Allan Savory has discovered a counter intuitive way to reverse the increasing desertification of arable land. His method goes against conventional wisdom. This method sequesters carbon, provides increased food and restores grassland all at a very low cost. Having lived in the Horn of Africa I think this is revolutionary. I only hope he can get more traction. I think it is akin to the story about Father Henri de Laulanié and his discoveries about growing rice. They were counter intuitive as well. Here is Mr. Savory's TED talk. [http://www.ted.com/talks/allan\\_savory\\_how\\_to\\_green\\_the\\_world\\_s\\_deserts\\_and\\_reverse\\_climate\\_change.html](http://www.ted.com/talks/allan_savory_how_to_green_the_world_s_deserts_and_reverse_climate_change.html) Best, Nile

Kaleberg (2013-03-11 19:39:03)

I've been lucky. Most of my doctors consider me an excellent test subject, so they often put me on a medication with a specific plan to see if it is working. When I had an infection, I was told to expect improvement in so many days, and otherwise to call in and arrange for a stronger antibiotic. When I started medication for a chronic condition, we did an initial test and arranged for me to return and see if the drug was having the desired effect. There was a plan B, if it had failed. Seth: You have low standards if you are impressed that if a drug doesn't work, your doctor will try a different one.

Christina (2013-03-31 17:24:15)

The side effects of drugs on acne really does concern me. I have to constantly take probiotics because this medication just upsets my stomach. Aside from the topicals we are using, has anyone used LED Light Therapy? I know we can get treatments like this in medical offices but in this article I found, they are talking how there is an FDA approved LED Light Therapy handheld at home device. This info is at the bottom of the article which highlights skin care devices. Please tell me if any of you have tried it because I for one am tired of the medication. <http://www.examiner.com/article/the-year-ahead-skin-care>

Pierre (2013-04-09 18:16:39)

Are doctors educated for acne even?

## The Pizza Paradox: Home Cooking and Personal Science (2013-03-13 05:00)

Last week I had pizza at the home of my friends Bridget and Carl. It tasted divine. The crust was puffy, chewy and the right amount. The thin-crust bottom was slightly crunchy. The tomato sauce had depth. The toppings (two kinds of mushrooms, Jerusalem artichokes, zucchini, onions, goat cheese) were tasty, creamy and a little crunchy. It was pretty and three-dimensional. It was easily the best pizza I'd ever had, the best home cooking I'd ever had, and much better than the lamb I'd had at Chez Panisse the night before, although the lamb was excellent. The pizza hadn't been hard to make nor were the ingredients expensive. Do other people wonder why this is so good? I asked my friends.

At some level I knew why it was so good – why the sauce was so good, for example (see below). The puzzle – let me call it the Pizza Paradox – was that commercial pizza, even at fancy restaurants (such as Chez Panisse), is so much worse. In restaurants, pizza-makers make dozens of pizzas per day. Business success is on the line. That should push them to do better. Professional cooks study cooking, have vast experience. They use a pizza oven. My friends have never studied cooking, never cooked professionally. They might make pizza once/month. Nothing is on the line. My friends don't have a pizza oven. High-end restaurant pizza should be much better, but the opposite was true.

In my experience, high-end restaurant food usually is much better than home-cooked versions. Why is high-end pizza a big exception – at least, compared to Bridget and Carl's version?

My explanation has two parts. First, the concept of pizza is brilliant. It taps more sources of pleasure than any other food I can think of. Chewiness from crust. Fat from cheese. Umami, sweet, and sour from tomato sauce. Protein from cheese and meat. Complexity of flavor from sauce and toppings. Variety of texture from toppings and crust. Variety of flavor from toppings. Attractive appearance from toppings and bright red tomato sauce. Most foods fail to tap most of these sources. For example, a soft drink isn't chewy, doesn't have protein, doesn't have fat, doesn't have variety of texture or variety of flavor, and isn't attractive.

My friends had one goal: to make the best possible pizza. It couldn't take too long or cost too much but they

weren't trying to save time or cut costs. Over the years, they tweaked the recipe various ways and their pizza got better and better. Experimentation was safe. If a variation made things worse, it didn't matter. It would still taste plenty good. (Due to the brilliance of pizza.) Variation was fun. After making pizza in a new way, they'd eat the pizza themselves (with guests) and find out if the new twist made a difference.

Professional pizza makers don't do this. After a restaurant opens, they make pizza roughly the same way forever. The pizza at Chez Panisse, for example, looks the same now as many years ago. The owner might want to make the best possible pizza but is unlikely to experiment month after month year after year. The actual cooks just want to make satisfactory pizza. Making the best possible pizza is not part of the job. The owner might benefit from better pizza but the cooks would not. They're cranking it out under time pressure (watch Hell's Kitchen). They do what they're told. Owners fear experimentation: It might be worse. It won't be what's expected. Don't mess with success.

This illustrates what I've said many times: job and science don't mix well. To do the best possible science or make the best possible pizza, you need freedom to experiment. People with jobs get stuck. All jobs – including professor at research university, [1]rice grower, and pizza maker – depend on steady output of the same thing again and again. Trying to maximize short-term output interferes with long-term improvement. To do the best possible science or make the best possible pizza, you also need the right motivation: You care about nothing else. People with jobs have many goals. This is why we need personal science: To overcome the (serious) limitations of professional science.

All this should be obvious, but curiously isn't. Long ago, philosophers such as John Stuart Mill claimed that people "maximized utility", apparently not realizing that maximizing output (which happens when people work "hard") slows down or prevents innovation. Later thinkers, such as Frederick Hayek and [2]Milton Friedman, glorified markets. They too failed to grasp, or at least say anywhere, that market demands get in the way of innovation.

The recipe for my friends's pizza had several non-obvious features:

1. Pizza dough from Trader Joe's. At Chez Panisse and other high-end restaurants, this would be taboo. It might produce better results – you still couldn't do it.
2. Pizza stones above and below the pizza. My friends use an ordinary oven. Maybe an ordinary oven with two pizza stones produces better results than a pizza oven.
3. Balsamic vinegar in the tomato sauce. They got the idea from a friend. American cooks, including professional ones, routinely fail to understand how much fermented foods (such as balsamic vinegar) can improve taste. My friends also use more traditional flavorings (marjoram, basil, and garlic) in the tomato sauce.
4. Plenty of goat cheese. They scatter goat cheese slices over the top of the sauce.

There you have the secret of Bridget and Carl's Pizza.

2. <http://www.marketobservation.com/blogs/index.php/2012/05/17/milton-friedman-on-innovation?blog=10>

Tom (2013-03-13 05:59:35)

Great post. It reminded me of something James Altucher wrote a while ago: "A friend of mine once ran a chain of 100 pizza restaurants. He bought them out of near-bankruptcy and completely turned them around. I asked him what was the key to success of running 100 pizza restaurants. "I'll tell you the one secret," he said. "Make round pizzas". It turns out that too often the pizzerias were making odd-shaped pizzas. Or would be delivered with the wrong ingredients. Or would be delivered too early or too late. He basically said, "don't make basic mistakes" and you will be successful. He didn't set out as his goal to make "the best pizza in the world". Nothing close (almost by definition: his chain was made up all of Dominos pizza stores). He just wanted to do nothing wrong. The stores completely turned around and became super successful. He eventually sold them and made a lot of money."

LisaW (2013-03-13 06:07:35)

What a lovely article! Left me with lots to think about and an appreciation for the fascination of pizza. Thank you :)

August (2013-03-13 06:16:03)

The implications sound much like some of the stuff Celia Green says. The aristocracy and/or those with fortunes end up being the real source of innovation, because they have the time and the insulation from other peoples mores, to do the work. For a variety of reasons, one can innovate in pizza rather well, but I suspect there are a lot of projects for which being a wage-slave still gets in the way. Seth: I will check out Celia Green's work. I have requested her book *The Decline and Fall of Science*. Is this where she writes about similar ideas? It's very true that the aristocracy, etc., "end up being the real source of innovation." Darwin was independently wealthy, Mendel, as a monk, was in a kind of aristocracy.

jay (2013-03-13 06:32:39)

you are leaning too heavily on the idea of taste as a fixed value; many people prefer different toppings, or thickness of crust in their pizza, more traditional preparations from Naples only use raw tomatoes for the tomato sauce, not a prepared cooked "pizza sauce" typically found on north american variations. some folks may prefer the sweeter/saltier sauce than the raw tomato and vice versa. this amounts more to preference than absolute taste. this is akin to making a case for the best way to drink coffee- people have highly preferential ways to drink coffee, no matter how traditional or statistically better one way is presented its about personal preference. the pizza you insist was the best ever may not be an opinion shared by each person who ate that same pie. Seth: There are widely-shared preferences. This is what allows the food industry to create popular products. For example, soup tastes better with certain amount of salt than no salt.

Matt Weber (2013-03-13 08:16:41)

I make pizza at home every so often (less now with the baby), and I've had the same experience - it easily competes, except on convenience, with anything we can buy. But I'm not sure how much it has to do with experimentation. Our first pizzas were already amazingly good; we have tweaked the recipe to optimize it within reason (our constraints are similar to Bridget and Carl's), but I'd say our improvements have been incremental. We did start off with homemade dough and sauce, and local mozzarella, all of which are noticeably better than packaged alternatives - but those, in turn, still make homemade pizza that is better than almost anything we can buy. We do typically put caramelized onions on our pizza, which is an unusual topping, but it's still very good when we don't. Seth: Perhaps your tomato sauce could taste more complex. The usual recipes do a poor job of producing complexity. Likewise, mozzarella does not have a complex flavor.

DDR (2013-03-13 12:34:42)

This guy does some serious pizza experimentation. <http://www.varasanos.com/PizzaRecipe.htm>

Lemmy Caution (2013-03-13 12:46:23)

My kids eat a lot of pizza and they appreciate pizzas from different stores. There is something about the minor differences that they like, even though they pretty much get the same toppings every-time. If you order from the same store all the time they habituate to the taste and don't like it as much. This isn't the same as coffee where people get cross-addicted to an exact brand served in the same way.

Alex (2013-03-13 13:46:20)

Thanks, I needed this perspective. I often feel like I'm doing a lousy job at personal science, because my record-keeping is the pits, I do experiments in fits and starts, etc. If this were my job I'd never get tenure. But in the past couple of years I've made significant progress on big problems, and I've gained important insights. I couldn't run a pizzeria for a day, but I'm turning out great pizzas at home. By the way, Celia Green is, if nothing else, delightfully quotable: [http://en.wikiquote.org/wiki/Celia\\_Green](http://en.wikiquote.org/wiki/Celia_Green) "It is easier to make people appear equally stupid than to make them equally clever, so teaching methods are adopted which make it practically impossible for anyone to learn anything."

dearieme (2013-03-13 14:08:43)

Here is my wife's great advance in pizza-making. We like to eat cheese fondue. There is always some left - a mixture of gruyere and emmenthal, flavoured with riesling, nutmeg and whatnot. We put it in the fridge and use it next time she does a pizza. Yowee!!!!

Paul N (2013-03-13 15:57:49)

"job and science don't mix well." this may be true, but where you have an owner-operator, rather than a wage employee, it is often not true. Farmers are probably the best example. Many great innovations, like the stump jump plough and the combine harvester were invented by individual farmers (though it often needed a company to bring the invention to market). Farmers sometimes experiment with other things - crop and livestock management, and sometimes the "experiments" happen by themselves - unusual seasons/weather/soil conditions, noticing a difference between early and late planted X, or what happened when they didn't plough/spray, or when they overgrazed, etc i'd say the key ingredient is a motivation to invent/innovate/learn. It is not just the independently wealthy who have it, but also those who need to do more/better for their own good. This is not often wage earners. Seth: The revolution in rice farming I wrote about recently happened because a non-rice-farmer got involved. One person. His work revealed that the millions of rice farmers were not doing nearly enough experimentation. Maybe they can do engineering (e.g., stump jump plough). They can't do science (here, agricultural science).

babar (2013-03-13 18:25:19)

'high end' really doesn't exist for pizza - i can't think of many places you can spend \$50 on a pizza meal in the US). the cost of your friends' labor on the pizza alone at their normal pay rate would have been much higher than \$50 i am sure.

babar (2013-03-13 18:27:25)

to be clearer: the reason that you can't get really good pizza is that very few people will pay for it - there's no market for high end pizza. there are some places in brooklyn, franny's for example, and some newish places like motorino, that do things you can't realistically do at home. price point is much higher than most people are prepared for when they think 'pizza'. Seth: Why is the pizza at Chez Panisse so bad, compared to what it could be? They could make much better pizza at almost exactly the same cost. They sell plenty of pizza at their price.

Paul N (2013-03-13 22:47:13)

With the farmers, many used to do their own science(experiments in productivity and land improvement), and a few still do (e.g. Joel Salatin). But almost all of them these days have been brainwashed into leaving it to the "experts", be it universities, USDA, Monsanto etc. there is certainly scope for fresh ideas from outside, like the rice example, but there is also scope from inside. Salatin's example shows that many cattle ranchers are doing it wrong too. The key thing is whether their ideas are picked up and implemented by others, otherwise, like your pizza example, the personal science only gets applied by/to that one person. I will certainly agree it is easier to experiment with things, like pizza or personal health, that you are not dependent on for your living. But some farmers and other owner operators still do their experiments too, we just don't always hear about them. Seth: A book called The Power of Duck describes how a rice farmer vastly improved the yield from a small piece of land. I agree, there are exceptions.

George (2013-03-14 05:46:05)

The best pizza makers in New York produce fantastic pizza that I am 100 % sure is much better than your friends pizza, and it is their job, so I don't think there is really much in what you are saying. I think it has more to do with the fact that a restaurant not geared towards pizza, like Chez Panisse, won't prioritize it, and further and perhaps more importantly, MANY Americans have awful taste in pizza, so few places are incentivized to produce truly great pizza. My brother in law, from San Jose, hates New York style pizza and loves the crappy stuff you get at Mountain Mike's. Making fantastic pizza doesn't require too much innovation - only at the beginning, until you get it right, and nothing essential about a job will make that harder to do. Indeed, it seems like having an indiscriminating consumer base for pizza (most Americans) as well as not specializing in it but merely having it as one item among many, is what's responsible, with number 1 being the main culprit, judging by how bad pizza is in America generally, even at fancy restaurants, with the one exception being New York which happens to have an extremely discerning consumer base for pizza. This example isn't really a good basis for making generalizations about the nature of jobs - yes, jobs can be poorly designed so that they stifle experimentation, but then again, there is nothing essential about a job that does this. Seth: "There is nothing essential about a job that does this." Let me try again to explain it. Foragers can either "explore" (look for new food sources) or "exploit" (revisit known food sources). They can't do both at once. Jobs are essentially exploit, not explore. You hire someone to do something that will make money. I can think of thousands of examples. I can't think of a single case where someone was hired to explore. Sure, some people on some jobs do a small amount of exploration. Google encourages this - but they have to encourage it. Otherwise it would almost never happen.

Evolutionarily (2013-03-14 07:09:22)

Perhaps you have quite refined tastes compared to the "average" individual. I tend to view these circumstances organically in that as these businesses grow ever larger they are forced to satisfice a widening but middle dominated area of the bell curve of tastes, as that is where the numbers are... It is actually an evolving process but rather it devolves to be generic overtime as that becomes the most acceptable pizza on average. Seth: I don't think I have refined tastes, at least with pizza. (Maybe with tea.) I rarely eat pizza, I am not a connoisseur. I think everyone, not just me, wants a tomato sauce with a deep complex flavor. I think everyone wants a variety of textures. And so on.

q (2013-03-14 13:54:06)

Seth: Why is the pizza at Chez Panisse so bad, compared to what it could be? They could make much better pizza at almost exactly the same cost. They sell plenty of pizza at their price. I don't know first hand about Chez Panisse because I haven't eaten there. I live in NYC and it's not convenient. Among people that I know, a lot of them think that Chez Panisse used to be better than it is, and now even though they aren't as good as before they can charge a premium based on their reputation. I don't know if this is true in the case of Chez Panisse but it does happen a lot in the restaurant business (and not just the restaurant business!) I was thinking about your article today and if you think about it a whole lot of food items are like this. For instance I can make a much better cheese sandwich with ingredients from most stores than I can from almost any restaurant. Peanut butter sandwiches too. Why?

Matt (2013-03-14 14:04:35)

This reminds me of the story behind Umami Burger and how he made an amazing hamburger without professional culinary training. <http://www.lamag.com/features/2012/05/01/empire-of-the-bun>

George (2013-03-15 12:30:23)

Regarding the best pizza to be had in New York, the 3 I like best, in descending order of excellence, are Difara in Flatbush, Totono's way out in Coney Island, and Grimaldi's by th Brooklyn Bridge. Now this is just from the places I have tried. Supposedly authentic pizza places are popping up all over Brooklyn and NY that many say are the equal of the above named places, but I haven't eaten at most of them, and the few that I have, like 88 on Atlantic avenue downtown, was very good with great fresh ingredients, but fell short of top honors. One of these days I have to make a pizza tour of NYC - mostly Brooklyn, really - and see if I have to revise my estimates :) But I doubt. Pizza cant get any better than the first two of those places.

Paul (2013-03-15 15:38:51)

Grimaldi's by the Brooklyn Bridge is fantastic. Grimaldi's in Hoboken is utterly mediocre. They use the same kind of coal-fired brick oven, the same ingredients, and reportedly the same preparation techniques, but their pies are soggy, doughy, and not particularly flavorful. I don't know nearly enough about pizza to theorize as to why that is.

Kirk (2013-03-15 16:48:37)

Cooking is the easiest place to learn the rewards of self-experimentation. And in my opinion, guacamole is easier than pizza. Base: either mashed or cubed avocado Vegetables: one or more of: tomato, peppers (green, red, jalapeno . . . ), onion, garlic Herbs and Spices: one or more of: cilantro, cumin, onion powder, garlic powder, cilantro, salt Citrus: lemon juice or lime juice Seth: I suggest adding balsamic vinegar. And irregularly chop the red pepper.

Kirk (2013-03-16 07:26:38)

Regarding guacamole, I experimented with variations about 25 years ago (using different recipes). I finally came to the conclusion that onion and peppers overwhelm the avocado, that the tomato must be peeled and chopped into tiny pieces, that cilantro must be used sparingly, and that the flavors to add are cumin, coriander, onion salt, and garlic powder. I haven't taken the test further to determine if lemon juice or lime juice is best (or balsamic vinegar in your case . . . . I don't like vinegar). It's a small group of ingredients which can be combined quickly to create side-by-side comparisons, with no baking required. The only problem is that after creating your own recipe this way, no restaurant guacamole compares. All the others are a variation on, 'how disappointed am I going to be?' Seth: That's good to know. You don't like vinegar? Apparently you like sour, since you use lemon juice or lime juice. I fail to see the difference between using vinegar and using them. None of your ingredients produces a complex flavor. I think there is room for improvement.

Alex Chernavsky (2013-03-17 10:05:54)

There is a large dose of arbitrariness in such discussions of optimal recipes. With regard to the pizza cooked by Seth's friends, I doubt that I would have liked it much, even back in the day when I ate dairy products. To me, goat cheese always had an unpleasant odor and flavor.

Kirk (2013-03-17 19:57:40)

Sometimes the best approach when cooking is to bring out the essence of the food. For example, I prefer most vegetables to be boiled in salted water until they're halfway between crisp and soft, then drain them and dress with butter. As for guacamole, my recipe enhances the essential flavor of avocado while generating a different flavor. I will experiment with adding fermented food and will send you a link to the results. I'm actually not here to argue about recipes. My understanding is that you're writing a book about how people can benefit by personal experimentation. I suggest that cooking is an easy way to introduce the concept, and that guacamole may be an easier introduction than pizza.

Alex Chernavsky (2013-03-18 05:46:11)

@Kirk, the last two times I made guacamole, I added chunks of fresh grapefruit flesh (minus all the yucky membranes). It was surprisingly good.

Chris (2013-03-18 18:55:09)

How do your friends make use of the second pizza stone? Seth: They put it above the pizza.

Isn't that the point of tenure? You prove you're smart and capable of strong scientific contributions. and then you draw a paycheck for life and you're free to work on whatever you want to work on. It may be onerous to get tenure, but there has to be some selection mechanism and I'm not prepared to suggest a better one. Seth: I agree, tenure does increase freedom. But

not enough for all purposes.

### **The Climategate Leaker Speaks (2013-03-14 05:00)**

The person who assembled and disseminated the Climategate emails has now [1]explained his or her actions:

The first glimpses I got behind the scenes did little to [increase] my trust in the state of climate science – on the contrary. I found myself in front of a choice that just might have a global impact.

Briefly put, when I had to balance the interests of my own safety, privacy\career of a few scientists, and the well-being of billions of people living in the coming several decades, the first two weren't the decisive concern.

It was me or nobody, now or never. Combination of several rather improbable prerequisites just wouldn't occur again for anyone else in the foreseeable future. The circus was about to arrive in Copenhagen. Later on it could be too late.

Most would agree that climate science has already directed where humanity puts its capability, innovation, mental and material "might". The scale will grow ever grander in the coming decades if things go according to script. We're dealing with \$trillions and potentially drastic influence on practically everyone.

Wealth of the surrounding society tends to draw the major brushstrokes of a newborn's future life. It makes a huge difference whether humanity uses its assets to achieve progress, or whether it strives to stop and reverse it, essentially sacrificing the less fortunate to the climate gods.

We can't pour trillions in this massive hole-digging-and-filling-up endeavor and pretend it's not away from something and someone else.

If the economy of a region, a country, a city, etc. deteriorates, what happens among the poorest? Does that usually improve their prospects? No, they will take the hardest hit. No amount of magical climate thinking can turn this one upside-down.

It's easy for many of us in the western world to accept a tiny green inconvenience and then wallow in that righteous feeling, surrounded by our "clean" technology and energy that is only slightly more expensive if adequately subsidized.

Those millions and billions already struggling with malnutrition, sickness, violence, illiteracy, etc. don't have that luxury. The price of "climate protection" with its cumulative and collateral effects is bound to destroy and debilitate in great numbers, for decades and generations.

Conversely, a "game-changer" could have a beneficial effect encompassing a similar scope.

If I had a chance to accomplish even a fraction of that, I'd have to try. I couldn't morally afford inaction. Even if I risked everything, would never get personal compensation, and could probably never talk about it with anyone.

I took what I deemed the most defensible course of action, and would do it again (although with slight alterations – trying to publish something truthful on RealClimate was clearly too grandiose of a plan ;-).

Even if I have it all wrong and these scientists had some good reason to mislead us (instead of making a strong case with real data) I think disseminating the truth is still the safest bet by far.

From my point of view, the best thing about the Climategate emails is that they were more evidence that mainstream thinking about something can be grossly wrong – that a "crazy" position can be right. My self-experimentation taught me this over and over (e.g., the Shangri-La Diet).

1. <http://tomnelson.blogspot.com/2013/03/mr-foia-speaks-time-to-tie-up-loose.html>

---

Alex Chernavsky (2013-03-15 13:03:35)

My "crazy" position is that many standard practices in the mental-health industry are harmful. In part, that view is become slightly less controversial, as we get increasing evidence of the dangers of psychotropic drugs. But I think that many non-pharmacological interventions are harmful, as well. For instance, addiction treatment may very well produce worse outcomes than no treatment.

### **Omega-6 is Bad For You (2013-03-15 05:00)**

For a long time, nutrition experts have told us to replace saturated fats (solid at room temperature) with polyunsaturated fats (liquid at room temperature). One polyunsaturated fat is omega-6. Omega-6 is found in large amounts in corn oil, soybean oil, and most other vegetable oils (flaxseed oil is the big exception). According to *Eat Drink and Be Healthy* (2001) by Walter Willett (and "co-developed with the Harvard School of Public Health"), "replacing saturated fats with unsaturated fats is a safe, proven, and delicious way to cut the rates of heart disease" (p. 71). "Plenty of proof for the benefits of unsaturated fats" says a paragraph heading (p. 71). Willett failed to distinguish between omega-3 and omega-6.

[1]A recent study in the BMJ shows how wrong Willett (and thousands like him) were. This study began with the assumption that omega-3 and omega-6 might have different effects, so it was a good idea to try to measure the effect of omega-6 separately.

They reanalyzed data from a study done in Sydney Australia from 1966 to 1973. The study had two groups: (a) a group of men not told to change their diet and (b) a group of men told to eat more omega-6 by eating more safflower oil (and reducing saturated fat intake, keeping overall fat intake roughly constant). The hope was that the change would reduce heart disease, as everyone said.

As these studies go, it was relatively small, only about 500 subjects. The main results:

Compared with the control group, the intervention group had an increased risk of all cause mortality (17.6 % v 11.8 % [emphasis added]; hazard ratio 1.62 (95 % confidence interval 1.00 to 2.64); P=0.051), cardiovascular mortality (17.2 % v 11.0 %; 1.70 (1.03 to 2.80); P=0.037), and mortality from coronary heart disease (16.3 % v 10.1 %; 1.74 (1.04 to 2.92); P=0.036).

A 50 % increase in death rate! The safflower oil was so damaging that even this small study yielded significant differences.

The authors go on to show that this result (omega-6 is bad for you) is supported by other studies. Walter Willett and countless other experts were quite wrong on the biggest health issue of our time (how to reduce heart disease, the #1 cause of death).

1. <http://www.bmj.com/content/346/bmj.e8707>

---

MikeW (2013-03-15 07:38:56)

The BMJ article is interesting, but that old Sydney study has drawbacks that make it almost meaningless today. First of all, 70 % of the participants were smokers. That may have been representative of Australian men in the 60's, but nowadays that level of smoking prevalence is unheard of in the West. Most of these guys had 2 strikes against them already, the omega 6 consumption may have had just a minor effect that pushed them over the edge. Second, trans fats. Nobody was talking trans fats in those unenlightened times, so nobody measured the trans fat of the Miracle margarine that was fed to the intervention group. The BMJ article's response section has a good post from the authors arguing why they don't think trans fat was the problem, but the bottom line is we just don't know how much trans these men were eating. Today almost everyone (including Walter Willett) agrees that trans fats are far worse than saturated fats. Seth: The article I cite considers several other studies. Taken together, they support the main conclusion of the Sydney study.

dearieme (2013-03-15 08:12:14)

The striking lesson is that all that health propaganda was bruited about without there being any worthwhile data to support it. The propagandists were reckless bastards, eh?

Nancy Lebovitz (2013-03-15 08:49:08)

What do you think about the safety of olive oil? Seth: Safe in small amounts, shown by studies supporting the Mediterranean diet. Dangerous in large amounts because it is high in omega-6. I much prefer flaxseed oil to olive oil.

Paul N (2013-03-15 13:35:08)

@ Mike W, I don't think we can rule out this study because some of the participants were smokers. There is no avoiding the fact that the intervention group, following the best medical advice of the day, had a 50 % increase in death rate. A good discussion on this study, and the various doctors responses, is at [1]George Henderson's website. From there, is this quote from Professor Jean Gutierrez of Washington University; "In addition to increasing PUFA intake, participants in the intervention group reported reduced dietary saturated fat, cholesterol, and calorie intake from baseline. A negative energy balance was verified with a slight mean drop in BMI. As expected, circulating total cholesterol and triglycerides were reduced in the intervention group, but mortality outcomes were not improved consequent to these circulating lipid and anthropometric changes, which is unexpected and interesting. The more important question arising from this study may be why a dietary intervention that improved all of these commonly used surrogate end points did not reduce all-cause mortality? " So these people did what we are told to do today - eat less sat fat, lose weight and lower cholesterol, and for doing all that, they died 50 % faster! A modern version of this trial, the LOOK Ahead trial, was stopped last year after 11 years of diet and lifestyle intervention (following the advice of the ADA and the National Cholesterol Education program) failed to show any improvement in cardiovascular outcomes. Again, the intervention group showed "improvement" (lowering) in cholesterol, and a small BMI decrease, but did not show improvements in CV event or death rates. Good discussion of the trial at Hyperlipid. Not only is there a refusal by the medical community to consider that omega-6 might be unhealthy, there is equally a refusal to consider that lower cholesterol (achieved by "diet" or drugs) might not be healthy either.

1. <http://hopefulgeranium.blogspot.ca/2013/02/the-results-show-that-omega-6-linoleic.html>

Valtsu (2013-03-15 14:02:45)

Hi Seth! Regarding heart disease, have you read about Broda Barnes and his work on CVD? Quite interesting IMHO... <http://180degreehealth.com/2009/01/master-broda> <http://valtsus.blogspot.fi/2013/01/thyroid-hormones-and-heart-disease.html> (my article with more references... )

dearieme (2013-03-15 14:53:43)

Ahoy, Seth. <http://www.dailymail.co.uk/health/article-2293948/Could-olive-oil-key-weight-loss-Scientists-discover-SMELL-make-feel-full.html>

dearieme (2013-03-16 07:17:07)

"I much prefer flaxseed oil": but do I want my salads to smell of cricket bats? Seth: on salads I use olive oil.

Paul N (2013-03-16 08:35:51)

We can get a (US) population wide picture of Omega 6 consumption by looking at this paper, which charts trends in food, and n-3 and n-6 fat consumption over the last century. The most amazing change is the spike in soybean oil (mostly comprised of n-6) consumption since the late 60's. there is also an increase in (soy based "shortening" while lard and butter decreased) Why did this increase? "The historical event immediately preceding the largest increase in apparent consumption of soy oil in the United States was the 1961 American Heart Association (AHA) Central Committee Advisory Statement (32) that advised Americans to replace their saturated fat intake with polyunsaturated fats. " And what was the impact on heart disease from 1970 to now? From the American Heart foundation's website, we can see from [1]this graph that the incidence of heart disease, as measured by hospital admissions, has \*doubled\* from in that period. Now correlation is not causation, of course. But if something is anti-correlated - like the decrease in sat fat consumption with the increase in heart disease - chances are it is \*not\* the cause. The dramatic increase in consumption of soy-fed (and anti-biotic treated) chicken probably hasn't helped, either. Seth: Your "this paper" link doesn't work. I cannot find where you get the idea that the incidence of heart disease doubled from 1970 to now.

1. [http://www.heart.org/idc/groups/heart-public/@wcm/@sop/@smd/documents/downloadable/ucm\\_449847.pdf](http://www.heart.org/idc/groups/heart-public/@wcm/@sop/@smd/documents/downloadable/ucm_449847.pdf)

dearieme (2013-03-16 12:43:52)

"the idea that the incidence of heart disease doubled from 1970 to now": once you allow for the age of the population, incidence has fallen, has it not? For reasons nobody understands (except for the effect of smoking); similarly, nobody knows why it raced upwards from about the 20s to the 60s (with the same exception). Or so I understand, but I'm no expert. The trouble is, the experts don't seem to be experts either.

Paul N (2013-03-16 21:33:05)

I'll try again. The paper in question is [1]Changes in consumption of omega-3 and omega-6 fatty acids in the United States during the 20th century. Which I found from a 2011 post from [2]Stephan Guyenet on the topic of n-3 and n-6 consumption. It is an excellent summary of dietary changes over this time. As for the idea that incidence had doubled, that is from the [3]graph on page 19 of the charts excerpt from the AHA 20123 statistical update. The number of "discharges" from hospitals for CV diseases went from 3.3m in 1970 to 6.2m in 2000 - an 88 % increase. Discharges means a patient that was admitted, and left, alive or dead, with a CV diagnosis. Whereas the more commonly used "mortality" means dead only. Mortality rates have improved, but that is due to better acute care. I didn't account for population. It was 200m in 1970, and 280m in 1980, so the CV incidence rate per capita increased by 35 % over that time. So, not as dramatic, but certainly in the wrong direction. That paper shows that n-6 has increased and sat fats decreased over the last century, and most dramatically in the 60's-80's. If n-6 was good, and sat fat bad, this should cause a noticeable decrease in CV events, yet they have only increased. So I would say it is "not looking good for the myth"

1. <http://www.ncbi.nlm.nih.gov/pubmed/21367944>

2. <http://wholehealthsource.blogspot.ca/2011/04/us-omega-6-and-omega-3-fat-consumption.html>

3. [http://www.heart.org/idc/groups/heart-public/@wcm/@sop/@smd/documents/downloadable/ucm\\_449847.pdf](http://www.heart.org/idc/groups/heart-public/@wcm/@sop/@smd/documents/downloadable/ucm_449847.pdf)

Clyde Adams III (2013-03-17 00:06:16)

You say one group was told to eat "more sunflower oil," then you say the "safflower oil was so damaging." Which kind of oil was it, sunflower or safflower? Seth: Safflower. Thanks for pointing this out.

Matt (2013-03-17 05:27:58)

Flaxseed oil is 10 % of calories from omega-6, about the same as olive oil. Obviously it may be healthful because of the omega-3 content, but consumption should probably be limited to a few tablespoons a day.

Jess (2013-03-18 15:09:57)

So are we reasonably sure that omega-3 is good for us? Is that a conclusion unlikely to be challenged in the next decade? Otherwise, I think it's back to the drawing board for this field. Seth: I'm sure omega-3 is good for me. The benefits are clear and repeatable.

George Henderson (2013-03-18 23:08:05)

Is omega-3 good for us? Well all these things are contingent. Greenland Eskimo with very high 3 and low 6 have such thin blood they suffer regular nosebleeds and stroke is more common than CVD. I think more to the point is that a balanced 3:6 ratio is better than a badly skewed one, and essential fatty acids are essential. The old "eat more PUFA, less SFA" advice was concocted before the role of omega 3s in diet was even discovered. It was a leap in the dark. "Eat a little more fish, fruit and greens and a lot less carbohydrate if your heart's a bit dicky, and for God's sake stop smoking and while you're at it don't drink so much and reduce your exposure to environmental toxins and dodgy drugs" would have been better advice. The form of PUFA is also important: <http://www.nutritionandmetabolism.com/content/10/1/23> n-3 PUFA added to high-fat diets affect differently adiposity and inflammation when carried by phospholipids or triacylglycerols in mice

Zeo will certainly be missed.

## DIY Medicine (2013-03-17 05:00)

[1]A medium-length article in The Scientist describes patients with fatal diseases taking their treatment into their own hands. Here's what happened with lithium and ALS:

Humberto Macedo, an ALS patient in Brazil, started a Google Docs spreadsheet to track self-reported ALSFRS-R scores. And Karen Felzer, a research scientist on the US Geological Survey's Earthquake Hazards team whose father had ALS, built a website to host the project. At 3 and 6 months, Felzer, who has a background in statistics (normally devoted to analyzing earthquake aftershocks), examined the data. Both times, she found no evidence that lithium slowed progression. By November 2008, when Felzer posted her second report on the project's website, most patients had stopped taking the drug.

Drug companies don't like the new movement:

Drug companies are understandably wary of any movement that could jeopardize their chances of success, including patient-initiated trials. Drug developers go to great lengths to control the variables in clinical trials, to optimize the dosing and the treatment window in order to reduce side effects while maximizing therapeutic gain, and to monitor patients' health. If patients outside the clinical research system start taking experimental drugs on their own, the likelihood of something going wrong is greatly magnified. And if something does go wrong—something that may not have been caused by the drug at all—entire drug development programs could be shut down prematurely.

The author of the article, Jef Akst, was impressed enough to start [2]a blog about the subject.

1. <http://www.the-scientist.com/?articles.view/articleNo/34433/title/Do-It-Yourself-Medicine/>
2. <http://diymedicine.wordpress.com/>

---

Paul N (2013-03-17 13:21:10)

Interesting article. It really illustrates the difference in thinking between a drug company and a terminally ill patient. Drug company (and medical profession in general) worry about what can go wrong - which could damage their reputation/financial status and don't want to go forward unless they can control/eliminate that. Patient - sees the prospect of something that might go right, and is willing to risk poorer health or even earlier death to try it. These are two completely different value sets, and for the drug cos to tell the terminally ill patients not to do it because it \*might\* hurt them highlights this difference. The patient is willing to take a risk the drug companies are not - the drug co's, FDA etc should not have the right to stop them.

derp (2013-03-18 01:58:32)

The drug companies and doctors are interested in the average, while the terminally ill patient decides he's either content with this average (a couple of months of low-symptom living till death) OR the option of trying something totally different and gaining years (maybe, theoretically, even curing himself). If I understood Taleb correctly, this is an example of "the long tail". Right, Seth? Seth: The term "the long tail" was used by Chris Anderson, not Taleb, and refers to something else. The situation you describe might be called misaligned incentives or simply different goals. The patient has different goals than the doctors and drug companies.

## Two Cents about Renata Adler (2013-03-18 05:00)

Renata Adler's two novels, *Speedboat* (1976) and *Pitch Dark* (1988), have just been reissued by New York Review Books. I was pleased to see [1]a recent New York article about her. Here is my two cents:

1. [2]*Gone: The Last Days of The New Yorker* (2000) is one of my favorite books. It can be summed up like this: Genius corrupts. I first came across it in the Berkeley Barnes & Noble. I couldn't stop reading it. When I left the store hours later my scooter had a parking ticket.
2. Her libel lawsuit is described [3]here.
3. She wrote [4]a book about the Bilderberg Group called *Private Capacity*. It was announced then cancelled.
4. During a panel discussion televised on C-Span, she took a phone call. It appeared to be from her daughter.
5. For several years she [5]taught journalism at Boston University. A student said she told great stories.
6. In a book review, she said that Woodward and Bernstein's *Deep Throat* was made up. Apparently she was wrong about that.
7. During a dinner I had with [6]Aaron Swartz last summer, he praised [7]her article attacking Pauline Kael ("*The Perils of Pauline*", 1980).
8. When her article about Kael came out, a friend of mine said, Now she'll be known as the person who attacked Kael. My friend was wrong. She is better known as [8]the person attacked by eight articles in the New York Times when *Gone* was published. One short non-best-selling book, eight negative articles from the most powerful pulpit on earth.
9. *Gone* and some books by Jane Jacobs were the only books I took to China. I also adore *Totto-Chan* but I suppose I have memorized it. I mostly read books by men, so I am puzzled that all my most favorite books are by women. A Chinese friend of mine stayed in my Beijing apartment while I was gone. Her English isn't very good but she praised *Gone*, which she called *Lost*.

BenSix (2013-03-18 05:26:37)

*She wrote a book about the Bilderberg Group called Private Capacity. It was announced then withdrawn. Allegedly, it was [1]cancelled because "a full length book treatment of the subject is probably not necessary". Yearly assurances that the conference is merely a few old blokes playing gold notwithstanding, I find that very hard to believe.*

1. <http://offonatangent.tumblr.com/post/45518984101/renata-adler-and-the-mysterious-never-published>

Paul (2013-03-18 18:09:08)

I love reading the Amazon reviews of *\_Gone\_*. There are a bunch of 1-star reviews right around the year of its publication. Not a lot of people wrote reviews on Amazon back then; it's pretty obvious what was going on. Adler is a treasure. Seth: I agree, the Amazon reviews are interesting.

Bryan (2013-03-18 18:25:42)

Seth, Is #7 based on personal knowledge? I couldn't find anything in the first link saying Swartz praised Adler's Kael attack. I'll for sure read *\_Gone\_* but Pauline rulez. Seth: Yes, #7 is based on personal knowledge. I had dinner with Aaron.

Elisa (2013-03-19 09:24:12)

Re: "I mostly read books by men, so I am puzzled that all my most favorite books are by women." A theory: It's more difficult for women to be taken seriously as authors (see the gender counts on the VIDA website) so they have to be better to rise to the top. Along the same lines, maybe you should choose a female surgeon? Seth: Plausible theory.

dearieme (2013-03-19 05:41:09)

Our dinner last night was a particularly good Bigos - a Polish dish of sauerkraut and meats. We decided that it was distinctly better for having been in the freezer for a couple of weeks. I checked Wikipedia where I found that this is a known phenomenon. My question is: are there other fermented foods that gain from being frozen (or refrigerated) for a while? Seth: My experience is that dishes get better after a day or so in refrigerator when they are soups or casseroles or the like and have lots of spices. Back then I never ate fermented foods so can't comment on that aspect of it. I have always suspected that the dish gets better because the first time you eat it it is a new flavor (home cooking is inexact) and the flavor becomes associated with calories. The second time you eat it - after refrigeration or freezing - the flavor-calorie association makes it taste better. So I predict something you don't say: The Bigos was home-cooked and this was not the first time you ate it.

dearieme (2013-03-19 07:37:20)

<http://en.wikipedia.org/wiki/Bigos> "As with many stews, bigos can be kept in a cool place or refrigerated and then reheated later - it is said that its flavour actually intensifies when reheated. " We've eaten Bigos for decades - my wife had Polish neighbours when she was a child, and a Polish flatmate later. She (my wife) used to make Bigos as a one-off, but recently made plenty and froze the surplus. We were struck by how much richer the previously frozen dish tasted last night. We did NOT think that the improvement was due to the meats tasting better - the whole dish did, and the dominant component is the sauerkraut. So we concluded that it was the sauerkraut that gained by being frozen. Maybe we should try freezing sauerkraut alone?

PeterC (2013-04-14 15:34:35)

Seth On an old post about Natto (<http://blog.sethroberts.net/2009/03/28/natto-shopping/>), you say to a commenter something like, "Nice try, spammer, natto never has corn syrup in it." I wanted to comment there, but comments are closed. A Japanese friend discovered, much to her horror, that all six brands of natto available at Sunrise Mart, a popular Japanese market in New York City, contained corn syrup. She had never looked at the ingredients before, but I recently got her eating along the general lines of Perfect Health Diet. Another Japanese friend mentioned that if you ever see these ingredients on a label, they are different forms of HFCS: C6H12O6 C6H12O6 C6H12O6 C6H12O6 Best Peter Seth: Thank you for correcting me.

Adam (2013-04-15 02:32:13)

Reminds me I didn't eat my natto for the day! The brand I'm eating here in Shanghai, China has plain old sugar, no fructose. None of the natto I've ever eaten has been sweet, so I wonder just how much HFCS is in that natto your friend looked at.

PeterC (2013-04-15 17:40:22)

True, the natto never is sweet, which is why the presence of HFCS is so strange and never suspected. But I did some more research and discovered this page, which claims that the sweetener (either sugar or corn syrup) is for the accompanying flavor packet, which may be discarded. <http://theconsciouslife.com/top-probiotic-foods.htm> So I guess we're good. Seth: THAT makes sense.

## "Most [Scientists] are Trapped" (2013-03-20 05:00)

We need personal science, I say, because professional scientists lack freedom and have goals (e.g., status) other than progress. [1]Art Robinson agrees:

"Most [professional scientists] are trapped," [he said.] Trapped by government money. Filling out grant requests, politicking to be well-liked, serving on grant review boards, going to the meetings to be seen by others, will take half your time. The project itself had better be popular. "You're only going to get the money for something that everyone has heard of and thinks is the coming thing," he said. As for politically sensitive areas such as global warming, "your research had better come up with the results they want." At private research institutions, where half the money may come from private endowments, the research is nonetheless still held hostage. "Professors in these [institutions] who are candid with you will say, Well, we can't really do what we want here because half of our money comes from the government so we can't afford to put it at risk."

He also agrees with me about the importance of hormesis.

In the 1970s, when he worked at the Linus Pauling Institute, Robinson did a mouse experiment that found at certain doses Vitamin C increased cancer. This was contrary to what Pauling had claimed, and he reacted badly. As Robinson tells it,

Pauling responded to the unwelcome news by entering Robinson's office one day and announcing that he had in his breast pocket some damaging personal information. He would overlook it, however, if Robinson were to resign all his positions and turn over his research. When Robinson refused, Pauling locked him out and kept the filing cabinets and computer tapes containing nine years' worth of research. They were never recovered. Pauling also told lab assistants to kill the 400 mice used for the experiments. Pauling's later sworn testimony showed that the story about the damaging information was invented, while experiments by the Mayo Clinic conclusively proved that the theory about cancer and Vitamin C was wrong. . . . When he found himself locked out of his own office, Robinson sued Pauling for breach of contract, slander, and fraud. . . . The case was settled out of court with Pauling paying Robinson \$575,000.

Pauling wrote a book saying that large doses of Vitamin C shortened colds and another book about Vitamin C and cancer. Long ago, I took large doses of Vitamin C when I got a cold. It was hard to tell if it helped. Later I tried zinc, which definitely helped. After I improved my sleep, however, [2]I no longer got unpleasant colds. I stopped taking zinc. For me, Pauling's belief that megadoses of Vitamin C reduce colds was a dead end. (And [3]dangerous. It isn't reassuring that Pauling's wife, who took megadoses of Vitamin C for many years, died of stomach cancer.) Improving sleep isn't hard, and I suspect a much better way to improve immune function than megadoses of Vitamin C.

1. <http://www.independentscientist.com/>

2. <http://escholarship.org/uc/item/2xc2h866/>

3. <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC1541262/pdf/clinexpimmunol00225-0180.pdf>

Sentinel (2013-03-20 09:50:44)

"Improving sleep isn't hard." - This seems like a gross generalization. If only it were so for everyone! :) Some folks with long-term insomnia like myself bounce from supplement experiment to supplement experiment (D3, l-theanine, melatonin, valerian, magnesium, etc., etc.), try one-leg standing and skipping breakfast, etc., and get no results. Seth: Have you tried getting an hour of sunlight every morning, as early as possible?

Sentinel (2013-03-20 10:39:24)

I have done so whenever it's feasible. Feasible = sunny + before 8 am (when I must leave for work). The advent of Daylight Savings Time has made this much more difficult (for now). BTW, I really value your original essay on self-experimentation and your subsequent discussions on insomnia on this blog, and it has led me to carefully track various n=1 sleep experiments. M negative comment above is purely out of frustration with myself, not with your theories or observations. (BTW, is "black coffee" - void of protein, carbs, or fat - forbidden under the "no breakfast" program? I'll ask again at some future time if I am getting off topic.) Seth: If you are waking up tired a few hours before you usually drink black coffee you should certainly try cutting it out. The caffeine may produce anticipatory waking. Drinking a lot of caffeine will certainly cause sleep problems. Cutting it out is something else to try.

David (2013-03-20 10:51:59)

Agree that figuring out sleep issues is complicated. I tried D3 in the morning, exercise variations, sunshine, and many other ideas. For me, taking supplemental glycine did the trick. Sometimes by making gelatin, other times by simply popping a glycine pill.

dearieme (2013-03-20 13:25:32)

Sentinel, have you tried the artificial daylight lamps? My wife uses one in winter: it cheers her up but if she uses it too late in the day it can cost her sleep. So she uses it early in the day.

dearieme (2013-03-20 13:26:58)

By the way, I hadn't known Pauling was such a shit. Are there any leading scientists who are decent humans? Was the last really Clerk Maxwell?

Joe (2013-03-20 13:47:58)

Magnesium (oxide) didn't work for me as a sleep aid until I stated to take it throughout the day, with a larger dose right before bedtime (about one hour). My eyelids get heavy and out I go. 400mg in the morning, again around noon, and then 800mg at night. Works like a charm.

Sentinel (2013-03-20 14:02:27)

Dearieme, I have not tried an artificial daylight lamp; from what I know they are more for treating SAD, which I do not have. Do you believe, from your experience, that they work for circadian-rhythm-related sleep disorders (as opposed to the Seth-recommended "real sunlight" first thing in the morning)? Joe, regarding the magnesium dosage and timing, that's interesting. Today I took Natural Calm (ionic magnesium citrate) for the first time during daylight hours, just to see what would happen. One thing I've learned from Seth's blog is that details like timing and dosage are essential (witness Seth's discussion re Vitamin D3 timing), but these details are often left out by someone (doctor, blogger, etc.) making a recommendation. That's why I asked (above) if black sugarless coffee is "breakfast" for the purposes of Seth's "no breakfast" approach; that's also why I wonder the extent to which Seth exhausts a leg during his leg stands. :) Seth: I always do the one-leg stands to exhaustion. I found that artificial fluorescent lights with sunlight-similar spectrum improved my sleep.

dearieme (2013-03-20 14:45:36)

"Do you believe, from your experience, that they work for circadian-rhythm-related sleep disorders": I don't know since neither of us has such a problem. But their prices seem to have fallen a long way in recent years so I suppose it wouldn't cost too much to try.

Kudzu Bob (2013-03-20 16:03:01)

"By the way, I hadn't known that Pauling was such a shit." Speaking only for myself, I still don't know any such thing. I can only be certain that these two intelligent and opinionated men did not get along, and that Linus Pauling cannot offer a rebuttal. Seth: "Did not get along"? That understates what happened and the power asymmetry. Pauling fired Robinson for no good reason. And destroyed his data. And, apparently, threatened to destroy him. Robinson did not do anything like that to Pauling.

CC (2013-03-21 09:16:13)

Alright smart guys. I see all this talk of insomnia here, but do any of you have ideas on how to treat HYPERsomnia? I have a friend who needs to sleep 10-11 hrs/day or else she's positively exhausted. Any advice? The doctors are stumped.

Sentinel (2013-03-21 09:50:00)

Hi Seth, thank you so much for your responses. I now see that elsewhere you defined "to exhaustion" as "until it hurt too much to continue." That helps to clarify a bit. Regarding your statement that "artificial fluorescent lights with sunlight-similar spectrum improved my sleep", do you know what # "K" temperature fluorescent bulbs do this well, and how many bulbs/watts would be necessary to have a positive impact on sleep? BTW, I am very jealous that (as cited in your "Effect of One-Legged Standing on Sleep" blog entry) your daily "Rested" ratings only fluctuate in the narrow band between 99 % and 100 % (or when things are bad, between 95 % and 100 %). I think I am usually in the 0 % to 60 % category! :) Seth: I used 4 ordinary length fluorescent lamps. Their color temperature was about 5-6000. My face was about 4 feet away, they were shining upward I was looking forward. I wrote about this in my long self-experimentation paper (where I also discuss standing and sleep).

Joe (2013-03-21 11:44:51)

CC: That's above my pay grade, but hypersomnia is the need to sleep during the day. You didn't mention if your friend sleeps well at night. So this sounds like it might be related to depression rather than a need for more sleep. And possibly fibromyalgia, too.

Joe (2013-03-21 11:47:59)

Sentinel: "Today I took Natural Calm (ionic magnesium citrate) for the first time during daylight hours, just to see what would happen." So...what happened? And don't forget that dosage counts. At least for me, it does.

Sentinel (2013-03-21 14:44:22)

Joe, it made me a bit sleepy at the time I took it ( 3pm); as for the night time effect of daytime Natural Calm, it was inconclusive; if this Comment forum is still open in a few days, I will post something then about the effect daytime use of Natural Calm on nighttime sleep, after I accumulate some data.

CC (2013-03-21 18:39:42)

Joe: You're right... maybe hypersomnia wasn't the right term. Let's just say that she needs a \*lot\* of sleep. I think she sleeps well at night, but she still needs 10-11 hours. I think the doctors have considered depression and fibromyalgia, but I'll check. If you guys have any other ideas, let me know.

Sentinel (2013-03-22 08:45:30)

Joe, After my second day of mid-day Natural Calm magnesium citrate (2:30pm), I actually had a very good (for me) night of sleep. Fell asleep in 5 minutes, slept for six hours straight, which is unusual for me. In compliance with Dr. Roberts, I faced the rising sun for 30 minutes out of an open window from 7:30 to 8 AM. (Had to slink off to workplace.) Hopefully mid-day magnesium plus sun, applied consistently, will yield solid results. Thanks to all for support and advice.

Joe (2013-03-22 13:10:46)

Sentinel: Great. Why not try taking some magnesium right before bedtime, too? Yes, in addition to the magnesium you're taking at noon. Nota bene: There are many kinds of magnesium salt, and they vary widely in the amount of elemental magnesium therein. I recommend that you read "The Magnesium Miracle," by Carolyn Dean, M.D., N.D. for the full skinny.

Magnesium is as important for overall health as Vitamin D, in my opinion. PS to CC: It helps with depression and fibromyalgia, too.

Sentinel (2013-03-23 09:22:36)

I will try it! Many thanks.

Sentinel (2013-04-10 03:09:10)

Update: unfortunately, more Natural Calm (magnesium citrate) in afternoon and before bed, delaying 1st coffee 2.5 hours, and increasing exercise and 1st-in-AM sunlight (plus 6000K light, albeit only 45W) has had no effect on the early awakening. Usually I only have 1/2 to 1-1/2 cups of coffee in a day, and typically I have no trouble falling sleep at first, so I doubt eliminating the remaining coffee will solve the problem. I am developing n=1 fatigue.... :) Seth: You might try: 1. eating more animal fat. 2. one-legged standing. 3. Vitamin D3 in the morning.

Sentinel (2013-04-12 06:05:22)

Thanks again, Seth. I will try to increase animal fat intake; this might be a challenge for me, paleo but pescatarian. One-legged standing did not work for me, though I cannot say I continued doing it after a couple of weeks. I have taken 10k IU of D3 (Solger) almost every day for months but it has not changed my sleep.

### Seoul Restaurant Story (2013-03-21 05:00)

I was in Seoul for a few days. I wanted to go to a really good Korean restaurant. I did a lot of research. Finally I returned to where I started – [1]an article about "the ten best restaurants in Seoul" – and carefully picked one of them: Yong Su San.

I phoned the restaurant, got directions. It was almost dinnertime. To my surprise, it was only a mile away so I decided to walk. I didn't have a map but I could aim for the nearest subway station. I walked toward that subway station for a while, then asked someone for directions. She said another branch of that restaurant was closer to where I was. It was as if after extensive research I had decided that the best meal in New York was at McDonald's.

The restaurant was extremely good. For only \$60 I had a fascinating and delicious meal. At the end they give you a choice of "main food". I chose bibimbap. Bibimbap is all cheap ingredients (rice, vegetables, sometimes egg, hot sauce, sometimes a small amount of meat or fish) and strikes me as the best possible way of combining those ingredients. This is an eternal question – given a small amount of money, what's the best you can do? It's surprising that the best answer comes from a small country (Korea).

1. <http://travel.cnn.com/seoul/eat/10-best-korean-restaurants-seoul-114014>

---

dearieme (2013-03-21 05:50:40)

Restaurants be damned. What we had for dinner for two yesterday: it really didn't cost a lot. First course: a timbale of basmati rice, a couple of ounces of smoked salmon discovered when stocktaking the freezer, red onion, and dill, accompanied by a green salad. Second course: aubergine (i.e. "egg plant") stuffed with minced lamb, red pepper ("capsicum"?) and onion, with spices (smoked paprika, cumin, ....). Third course: no room. We dined like kings, don't you think? Seth: I agree. I go to restaurants for social reasons, rarely for the food.

libfree (2013-03-21 10:16:15)

Did you mean to put \$60? That sounds expensive to me.

Morex (2013-03-21 10:33:41)

Here at home Shangri-la rules and we have been saving a lot of money in food. With something like \$20 we buy food for a week, for 2 people. That includes breakfast, lunch and dinner. We buy at a local community market full with local producer. We avoid supermarkets. (Community markets are common in Mexico and they are super cheap) Here are some examples of what we eat: Breakfast: half a cup of chopped fruit, coffee or tea. Sometimes half an egg and a small piece of bread. Lunch: About a couple table spoons of pasta, rice, salad, meat... you name it. We can't eat much because AS is very very strong. Dinner: A couple cookies and some milk. Sometimes half a quesadilla (one corn tortilla folded, with cheese inside). Sometimes I would have only a cup of coffee with cream and sugar. Oh and all the three meals include a lot of plain water. I don't think it can get cheaper than that. Since my girlfriend and me eat so little, we avoid restaurants. That may change when we enter maintenance phase, I guess.

Morex (2013-03-21 10:42:24)

Addendum! We did eat in Church's Fried Chicken the other day and ordered the kids meal for each. It was too much! That's when we decided to pass on restaurants for the time being.

Ashish (2013-03-30 21:03:18)

My recent memory of Seoul is that you could get a very good and quite large Korean meal for around \$5-6. (Which was the same price as a Starbucks sandwich, or an ice cream cone, or coffee and a donut.) \$60 seems sky-high for Korean food in Korea. Seth: It was a fancy restaurant.

### **Furikake (Japanese Condiment): Attention Crazy Spicers! (2013-03-22 05:00)**

From a trip to Japan a friend gave me a mystery jar of some sort of flavoring. It turned out to be wasabi-flavored [1]furikake. Furikake is used to season rice, I learned. It vaguely resembles salt and pepper but is far more complex and powerful. A version I bought has 25 ingredients, including sesame, wheat flour, lactose, salt, MSG, salmon, fish bone powder, and soybean protein. I use it many ways: on roast beef, eggs, and yogurt, for example. It is the easiest way I know to make hamburgers taste good.

The nearest Japanese market (in Berkeley) has 25 different types, I discovered. They cost about \$4 each. I bought

four. I'm going to buy ten more, to use for [2]crazy spicing (randomly varying the smell of food to prevent strong smell-calorie associations from forming).

1. <http://en.wikipedia.org/wiki/Furikake>

2. <http://boards.sethroberts.net/index.php?topic=7063.0>

---

B.B. (2013-03-22 06:12:41)

I am surprised that you accept a seasoning that has MSG. Russell Blaylock wrote a book called Excitotoxins that condemned MSG and aspartame, among other chemicals, for harming the brain and leading to disease. I have heard from therapists that many of the kids they treat for ADD get better when MSG and aspartame are removed from their diets. Do you have a view on whether MSG is harmless? Seth: MSG gave a friend of mine nightmares. It isn't harmless. At least in the doses I eat it, it doesn't give me nightmares, however.

Alex Chernavsky (2013-03-22 07:09:29)

Seth, can you describe your current crazy-spicing regimen? I'm looking for ways to improve upon the effectiveness of Shangri-La dieting (in order to produce further weight loss). Seth: I do little with crazy spicing. What about eating more food nose-clipped?

Janet (2013-03-22 11:56:59)

I used Furikake for about 10 years, but I stopped when I found that the sugar-salt combination (and especially if there was MSG) in every single flavor of them made food taste more addictive, and I wanted to eat more, not less. Seth: You mean you wanted to eat less, not more?

Richard Sprague (2013-03-24 10:19:06)

My family and I love furikake, which I discovered while living in Japan in the 80s and 90s. I find it easy to buy in the US, sometimes even at bigger grocery stores. (You can also order it [1]at Amazon.) The brands I buy (including the one linked through Amazon) do not have MSG. It's easy to make your own too: just buy some crisp Japanese seaweed (Nori), crunch it up and mix with some sugar and salt. We often eat rice just with the nori.

1. <http://www.amazon.com/JFC-Nori-Komi-Furikake-Seasoning/dp/B0006G5KEY/>

### Assorted Links (2013-03-23 05:00)

Adam (2013-03-23 07:34:08)

Do prescriptions serve patient needs in the first place? The idea is that the doctor & pharmacist know more than you & have to protect you from yourself. It may be true that the experts know more than the patient in many cases, but information is spreading faster & faster these days. Anyone with an internet connection can check out a drug on Wikipedia & search PubMed. Because the relationship is set up this way (doctor tells patient what they need & gives them the permission slip to get it) patients may be more likely to blindly trust that what their doctor ordered is good for them, safe, etc. In fact, the opposite could just as easily be true. If patients could freely choose their own medicine, maybe they would more carefully research the options & potential consequences. Maybe it would reduce lawsuits against doctors (you can't sue a doctor for a drug you yourself decided to purchase & take!) and help lower healthcare costs across the board. Seth: I completely agree, that's an idea worth testing. It's quite plausible. Surely drug companies, pharmacists (whose advice would be more valued), and the general public would like it. Only doctors and perhaps lawyers would be against it.

Roger Sweeny (2013-03-24 09:25:23)

Wow, that article about "Cancer: the importance of what surrounds a cell (its microenvironment)" is more than five years old (magazine dated December 12, 2007). Seth: It's a classic.

## **Earwax Transplant Story (2013-03-24 05:00)**

I think [1]this actually happened:

A man came to the [University of Pittsburgh] clinic with a chronic infection in his left ear. He told doctors that other doctors had tried everything: anti-fungal drops, antibiotics, and many other treatments. The Pittsburgh doctors gave him additional antibiotics. The patient came back to the clinic a week later and said he was cured. The clinic doctors told him they were glad they had helped him. He said: "You didn't. I suffered so much after your drugs I took some earwax from my right ear and put it in my diseased left. In two days I was fine, infection cured." . . . The good ear contained good bacteria that killed off the bad in the bad ear.

I predict that people will eventually realize that the 2005 Nobel Prize for "ulcers are caused by bacteria" was [2]a big mistake.

Thanks to Mark Griffith.

1. [http://hpr1.com/opinion/article/six\\_pounds\\_of\\_stuff/](http://hpr1.com/opinion/article/six_pounds_of_stuff/)

2. <http://blog.sethroberts.net/2009/04/03/nobel-prize-cluelessness-stomach-ulcers/>

---

dearieme (2013-03-24 06:34:19)

Have a care, Seth. You'll have us sticking earwax up our bottoms next.

Dan (2013-03-24 08:12:57)

Confused. If you believe his story, and you say you do right up top, then how does it follow that you say bacteria wasn't involved? Seth: I don't say "bacteria wasn't involved". The 2005 Nobel Prize in Medicine was awarded for the "discovery" that ulcers are caused by a certain species of bacteria. The earwax story implies that some bacteria are helpful: they hold down other (bad) bacteria. The broader implication is that when people get stomach ulcers it may be because other bacteria were not holding the bad bacteria in check. If this is true – and I think it is likely – then giving antibiotics for ulcers is a poor idea, even though it may help for a while.

Around the Web: Palm Sunday Edition | Perfect Health Diet (2013-03-24 11:49:10)

[...] Seth Roberts believes in earwax transplants for ear infections. [...]

Dan (2013-03-24 17:46:17)

OK, got it. You may not give this much value, but I work with a guy that promotes juicing and a juice machine and he has a proven way to fix stomach ulcers and it's with cabbage juice. He was involved in a Stanford University study in the 50s with an M.D. that proved it. A way to make it that's more palatable is called the 3 C's and that's cabbage, carrot, celery at 1/3 each. Drink three times a day for a week or two. Not sure how this fits into your bacteria/not bacteria theory, but based on people who have had success, all it takes is freshly made cabbage juice. I could send you links if you care for it, but if you think this is too easy and food and diet isn't the answer to most trouble Americans have, then I won't bother you with it. I like most of your stuff Seth, but I'm also bothered by your lack of credence to people's own experiences that show stuff works. You downplay evidence-based approaches, which is a shame. Seth: My "lack of credence to people's own experiences that show stuff works"? Could you give an example? This post ("earwax transplant") gives credence to an unusual way of treating an ear infection based on one person's experience.

Dan (2013-03-25 14:04:56)

Perhaps I'm mistaken, but I recall you saying in various posts that you were negative to "evidence-based" medicine. Maybe we have different definitions for the term. The main reason I read your blog is because you show stories like this one today and the fermentation ones, and all the others. Perhaps you meant it in a different way. I didn't save your posts so I'll have to wait until you bring it up again. Maybe you didn't say "evidence-based", perhaps it was a different term you used to distinguish scientific studies from people's actual experiences and from current medical practices. Sorry for the confusion on my part. I'm very interested in the experiences of you and others in finding ways to be healthy that work. Today in this new crowd sourcing era, we have an unprecedented opportunity to learn from millions around the world about health giving approaches that were previously unavailable to us. Some things will work and some won't of course, but the alternative is the same top-down health care we already have. Seth: Well put. I have a low opinion of "evidence-based medicine" because in practice the practitioners ignore a lot of evidence. I am against ignoring evidence. I wrote about this [1]here – the example of tonsillectomies where the "evidence-based medicine" reviewers ignored a vast amount of evidence that tonsillectomies are dangerous.

### **Does Unfamiliar Food Cause Weight Loss? (2013-03-25 05:00)**

[1]My theory of weight control predicts that eating unfamiliar food will cause weight loss. As food becomes familiar, we learn to associate its smell with its calories. Stronger smell-calorie associations produce a higher set point than weaker ones. Unfamiliar food has not yet gone through this learning process.

One way to eat unfamiliar food is to travel to another country. When I've done this, I've usually come home a few pounds lighter, supporting the prediction.

Another way is to have someone else choose what you'll eat. This is what [2]Dan Goldstein did. "I emailed my friend Dan Reeves, who has a fitness-expert sister named Melanie Reeves Wicklow, to request a healthy diet I could follow for seven days with no exceptions." He thought of it as a diet where he would make no decisions about what to eat.

Here's what happened on Day One:

Discovered that if you eat oatmeal with an egg in it instead of just oatmeal, you feel full for much longer.

Here's what happened overall:

I lost 15 pounds in about a couple months after the "no-decision" diet. (I lost no weight during the week of the diet).

My explanation: During the week of the diet, he ate the specified amounts, which were more than he would have eaten based on hunger. This kept his weight up. During the following weeks, three things happened: 1. He resumed eating according to hunger. His lower set point caused lack of hunger, which caused less eating, which caused weight loss. 2. Because he ate less, his set point went down. 3. During the no-decision week, he picked up some new habits, causing him to eat less familiar food during the following weeks. He says that the no-decision week "changed his cravings" and caused him to "commit to eating better".

He also says the no-decision week caused him to exercise more but no details are given. I doubt this made a difference. Few people lose 15 pounds in two months from exercise so minor that they don't bother to describe it.

Thanks to Andrew Gelman.

George (2013-03-25 16:45:41)

It's interesting that only people who travel to countries where people are thin lose weight. You went to France, where people are thin, and lost weight. I went to Thailand and lost weight, another thin country. It's quite common for people to lose weight specifically on trips to France, if reports on the web are to be believed. You conclude it's the unfamiliar food, but nobody loses weight when traveling to England or Australia where the food is equally unfamiliar, so that doesn't make sense. It seems far more likely that there are certain things about the eating habits of people in thin countries that have an effect even on visitors, causing them to eat less. It could be smaller portion sizes having a psychological effect - you feel weird eating so much more than the locals. It could be simply seeing so many thin people everywhere and becoming ashamed of your weight, or even aware for the first time that you are overweight (many Americans are shockingly delusional about this). Nor are the people who live in these countries - who are thin - eating unfamiliar food. It seems far more likely that what is keeping French people thin begins to exert an effect on visitors - in other words it makes more sense that there is one common factor that explains both French people being thin and visitors to France lose weight, and that can't be unfamiliar food.

babar (2013-03-26 06:00:33)

a week isn't very long - i know my weight pops up and down a lot probably based on water - so he might have lost as much as a pound that week, who knows.

## **Introduction to Inside Tracker (2013-03-26 05:00)**

[1]Inside Tracker sells blood panels - for example, 20 things measured in your blood (e.g., hemoglobin, magnesium, Vitamin D). It was founded in 2009 in Boston, Mass., by Gil Blander, a biology Ph.D., and two other people. They started offering the service in late 2011. Their main customers are athletes (20 % professional, 30 % amateur) and many Quantified Selfers (20 %). I recently interviewed Dr. Blander:

What have you learned from the data you've collected?

Around 60 % of the population has low Vitamin D.[What's low Vitamin D?] As of today, if you look at the ranges of the diagnostic companies, they are saying that everything below 30 ng/ml is low Vitamin D. We are giving you your optimal zone based on age, gender, athletic activity and ethnicity. We also compare you to your peers.

What else?

More than 50 % have high cholesterol (total and LDL). With folic acid, about 40 % of the population have high folic acid. This is because of supplementation.

High creatine kinase (CK) is another common problem. When you exercise, some of the muscle cells break down and this protein leaks into the blood. An example is a marathon runner. Before the marathon it's below 200 U/L. After the run it can be as high as 10,000 U/L. If you over exercise the level might be above 1000, and you have a much higher chance of getting injured. A bit more than 30 % of our customers have high CK. It has a half life of 5 days. Your steady state CK should be less than 1000. Some supplementation can lower it, such CoQ10 and others.

Another marker we measure is hemoglobin. It measures the amount of iron in your blood cells. If you have low hemoglobin you compromise your athletic ability and decision making. About 30 % of our customers have low hemoglobin. Another marker related to Iron is ferritin (protein that binds to free Iron), If you have low ferritin, take iron supplementation or eat iron rich food, that will increase both ferritin and hemoglobin. If you have normal ferritin and low hemoglobin, there are limited interventions to help you increase your hemoglobin, you may need to go to a high altitude place. Women below 50 tend to have low ferritin. The percentage is 10 % among non-athletes, jumping to 30 % among athletes. We also find it in athletic males. When you exercise, you have microbleeding from your gut. Among male athletes, 10-12 % have low ferritin. The major concern is that they don't know this.

What have you learned about how to increase Vitamin D?

When we started, we looked at the literature, it said you should take 400-800 IU/day. We found that even if you just take 1000 IU/day you will just maintain the level you already have. To increase it you need to consume at least 2000 IU/day. I started by testing myself. I found I had pretty low Vitamin D. At first I tried just food – fatty fish and mushrooms. I ate fish twice/day and a lot of mushrooms for a couple of months. Then I measured it again. It hadn't changed. Then I took 1000 IU/day. I tested my blood again and it still hadn't gone up. Then I went to 4000 IU/day and this brought me to the optimal level. And we saw the same with some of our customers.

Testosterone is a very interesting hormone. It's hard to measure. When you overexercise, it's low, because of the stress. It's strongly influenced by amount of sleep, if you don't sleep well, it will go down. We found if you look at the average consumer, around 10 % have low testosterone, and none of them knew it. It's an expensive test. Insurance companies won't pay for it unless there is a reason.[What's low testosterone?] The adult male: below 348 ng/dl. Women have about 20 times less testosterone. Only a tiny percentage of women, about 1 %, have low testosterone.

TO GET 10 % OFF ON INSIDE TRACKING TESTS, USE THIS CODE: SHANGRILA10

1. <http://www.insidetracker.com/>

---

nandalalrasiah (2013-03-26 10:42:53)

To put the prices in perspective, an anabolic steroid panel (without coverage under insurance) from Labcorp (through privatemdlabs) costs \$300 (though you can buy the female hormone panel for \$60 and check the box for 'male' which gives you total testosterone and a limited blood panel.) All sans value-add advice of course.

Alex (2013-03-27 10:47:50)

Hyperacusis from exposure to loud noise sounds to me like the ear's version of phantom limb pain: the cochlear fibers die, but the nerves that relayed their signals remain. I wish I could think of an analogue to the mirror therapy that helps sufferers of phantom limb pain.

Ahrand (2013-03-28 04:04:51)

Another good link : <http://news.harvard.edu/gazette/story/2013/03/major-weight-loss-tied-to-microbes/> So obesity is just a case of having too few of the good bacteria and too much of the bad ? Who knew ? Maybe it's even the bad bacteria that are hijacking our reward/craving mechanisms and forcing us to continue these obvious bad habits, how about that ? Maybe you can join your 2 favorite topics (we need more good bacteria + smell/calorie association) here Seth ?

shtove (2013-03-28 18:21:32)

Interesting paper - How the Mid-Victorians Worked, Ate and Died: <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2672390/>

q (2013-04-01 14:33:06)

very sad, these stories about hyperacusis. many people have had success with white noise therapy. in many cases it's an anxiety disorder (sound makes you anxious and anxiety makes you more sensitive to sound) and so treating the anxiety is helpful too, or at the very least being aware of the role that anxiety plays in oversensitivity. in most cases there isn't anything actually wrong with people's ear fibers or nerves, they have just been trained into hypersensitivity to the point where normal noises are startling or in some cases threatening. (disclosure: i don't have hyperacusis but have other ear problems including chronic tinnitus. no reason that doctors can see, which isn't that surprising given the delicate anatomy of the ear, and so no prospect of a cure. it's a completely "subjective" ailment but one where focusing on the symptoms - even to measure them - makes it worse.)

## Make Yourself Healthy: Crohn's and the SCD Experiment (2013-03-28 05:00)

In 2010, a Chicago woman named Johanna was diagnosed with Crohn's disease. She was 27 years old. Doctors told her to take drugs. She resisted. Here's what happened, from a 2011 interview:

What do you do for living?

I'm an IT project manager. I'm on disability now because of flare-ups of my Crohn's. I'm just getting a portion of my paycheck until the doctor thinks I'm healthy enough to work. When my flare up was bad, I had horrible joint pain, horrible cramping in the morning and throughout the day (pain was 8-10 on a 10-point scale). Chronic diarrhea, maybe 5-10 times/day. I'd be in meetings and doubled over in pain. My GI said I had one of the most inflamed colons he'd ever seen.

When were you diagnosed with Crohn's?

April 2010. My symptoms started in January 2010. Bad gas, got worse. Diarrhea. In March, pooped my pants at work. Never happened before. Ran home and changed. Went to the ER 5 or 6 times from January to March because I was in so much pain. They thought it was Irritable Bowel Syndrome. One doctor said it was stress. "You need to manage your stress better." I didn't know what doctor to see. Only when I went to the Northwestern University ER did they say you might have a GI problem. Then I got a colonoscopy and was diagnosed with Crohn's.

How was it treated?

With Prednisone, a steroid with horrible side effects. It caused me to have a big swollen moon face, a big belly, facial hair, cold sweats all night, I gained 15 pounds (from 120 to 135). I started taking it in April 2010. I took it until August 2010. I stopped taking it because I still had the same amount of diarrhea. It wasn't working. I told my GI at the time. He gave me bad info about how to stop taking it. I did stop taking it and found a new GI. The new GI put me on Humira, an immunosuppressant, a TNF [tumor necrosis factor] blocker. I started it August 2010. No one told me about diet - "eat whatever you want" [she was told]. It was a shot I would get every 2 weeks. At first I got 4 shots. Within days of the first shots, I felt much better. I was a completely normal person. The Crohn's symptoms were completely gone.

What happened next?

Led a totally normal life, worked at my company with success, everything was good. At the end of July 2011, I started having pain. In early August, I went to a new GI at Rush University Hospital. They have a really good GI and nutrition team. They are among the first studying the SCD [Specific Carbohydrate Diet]. I told him I had stomach pain, etc. He said to double the dose of Humera. That wasn't a bad call. I doubled the dosage of Humera and got much worse. That's when I started developing the joint pain and mouth sores. Cramping, horrible horrible pain. I had diarrhea for about two months.

Now we've reached the place where your blog starts? [She started a blog called [1]The SCD Experiment]

Correct. I couldn't absorb any nutrients. I had to quit work. From 31 August to 3 September I had a 102-3 degree fevers every day. I hoped it would pass. I stayed in bed the whole week. Then I started vomiting. I decided to go the hospital. I had lost 10 pounds in a week or two. I went to the hospital 4 September. In the hospital I lost even more weight. It turned out I had both an infection and antibodies to the Humera.

The first hospital I went to on 4 September was St. Francis Hospital. They were meticulous with my diet, gave me gluten-free lactose-free meals. I was very well taken care of there. All types of specialties to figure out what was going on. I had an infectious disease specialist. The infectious disease specialist was adamant I had an infection.

How did you learn about SCD?

I was in St. Francis hospital trying to figure out what to do about my future. I was looking at all the treatment options. I was researching Remicade. It had been recommended. The next logical step. I went to a ton of forums. Wide range of outcomes. Even if it worked, I would be tied to it. Always a chance of infection. You have to go to a hospital every 8 weeks, at best. I want to start a family. I don't want to be tied to a drug. I didn't want to do it.

My sister sent me a link to the Amazon reviews of Breaking the Vicious Cycle. You should really try this, she said. I thought there's got to be something to this. These people made it work, why couldn't I? What did I have to lose by trying it? I wanted to try a natural solution before blasting my body with something else. My last day at St. Francis I started to do the SCD.

I left St. Francis after 5 days because I had an appointment with the top GI doctor at Rush, Dr. Keshavarvian. He told me my problems were due to a flare-up of the Crohn's. Including the fever. He said nothing about my suppressed immune system and the way it makes you more vulnerable to infection – although to be fair I knew this. To his credit, he said to eat a lot of yogurt.

As soon as I saw him, he admitted me to Rush right away to begin Remicade infusions. Remicade is another immunosuppressant, very similar to Humera.

I asked a lot of questions about Remicade. I asked a lot of questions about diet. They said just do the Remicade, and eat whatever you want. It's a big hospital. Huge overwhelming swarm of lab coats pushing Remicade on me. More than five doctors told me to take Remicade. All of them worked for the GI doctor I'd seen in the morning. They were part of his team. I told the nutritionist I had Crohn's. They sent me a lunch tray with processed turkey meat, a ton of gravy, and a brownie, and tomato bisque soup. Not one thing I could eat or digest. My husband brought me SCD-safe food I could eat. Once I saw that brownie, I decided to refuse Remicade. You're going to tell me what I eat has no effect on my body, I'm going to tell you you're wrong.

They were trying to set up the Remicade infusions. I said I needed one more night to sleep on it. The next morning, the 10th, I said thanks but no thanks. I'm going to try this diet and see what happens. They made me sign a waiver and I went home. At St. Francis they put me back on Prednisone, at lower doses. I've been tapering off.

The first week I was super-scared. Is this diet going to work? I was very weak, couldn't stand up in the shower. I still had major Crohn's symptoms. Every Thursday I got/get blood work. The first Thursday after I started SCD, the blood work results were better [see website for details], but I still felt bad. The second week, amazing. I felt like a new person.

On 23 September I had a follow-up with Dr. K at Rush. I gave him all my blood work and told him what I was doing. He was concerned. He said the diet was hard to stick to and that the legal/illegal list – what you can and can't eat – was different for different people. He said that the diet fails for 3 out of 4 people. When you're on the diet, you can have a flare-up so bad that you need to have your colon removed. These are the risks that you are facing by not taking the Remicade or Imuran. However, he's one of the people spearheading the study of SCD at Rush. He told me we don't have any studies showing that this diet works so I can't in good faith recommend it.

By Week 5 she was much better. By Week 19 she was cured, in the sense of feeling normal and having normal lab results. "I don't even THINK about Crohn's disease," she wrote. "Unless it's to reflect on how so very thankful I am that my sister Angela discovered this diet and talked me into trying it. I owe her my life back." She started her blog at the same time she started SCD.

Doctors told her the diet has a 70 % failure rate. As the lab results and experience reported in her blog show, the diet worked.

Tuck (2013-03-28 07:16:25)

Scary. The medical profession has a serious problem.

Tuck (2013-03-28 07:17:56)

And my question to that Doc would be, how often does the diet succeed \*in people who strictly follow the diet?\* I'd guess it's a lot higher than 25 %...

Daniel Lemire (2013-03-28 19:00:35)

Do people ever read the research? Here is what I found when I looked a recent review article: "Numerous studies claim that corticosteroids fail to induce mucosal healing in the treatment of CD, while small uncontrolled studies showed mucosal healing with enteral nutrition. Specifically, the latter studies reported downregulation of mucosal pro-inflammatory cytokine profiles in both the ileum and the colon after enteral nutrition – potentially very interesting observations in respect of achieving a healthy mucosal immunity. Given that the ultimate goal in the treatment of CD is mucosal healing (in addition to symptomatic improvement), this advantage of enteral nutrition over corticosteroid is valuable in therapeutic decision-making. (...) Further well designed large trials are necessary to support the current knowledge on enteral nutrition including long-term benefits of these interventions. Improved evidence to support the role of dietary interventions for inducing and maintaining clinical remission could lead to reduced need for drug therapy with its associated risk for adverse effects." (YAMAMOTO et al., 2009, <http://onlinelibrary.wiley.com/doi/10.1111/j.1365-2036.2009.04035.x/full>) What does that tell you?

AI (2013-03-30 20:51:57)

That's a really interesting story. Thank you for sharing it, and the mention of her blog. I've been reading about the SCD for years now, and it seems that, as much as American doctors criticize it, or claim that scientific research to support it does not exist, there are patients out there who claim it has helped them. I can't escape the sense that something about the American medical educational system, the FDA, big Pharma, and the various state boards of health is broken. They have this permanent, ingrained bias against certain therapeutic approaches. This is highlighted by the fact that, in other countries (e.g. Japan and the UK), enteral nutrition is a front line therapy used by the official, mainstream medical system for Crohns sufferers. (See the book "Beat Crohns!" on Amazon for more on this). So, why does medical science in the UK and Japan endorse a dietary-based, primary therapy for Crohns, while medical science in the US can never quite find support for anything but surgery and drugs? It makes no sense. Seth: I agree, well-put.

LisaW (2013-04-03 13:08:19)

Enteral nutrition is only the frontline treatment for young children with Crohn's in the UK. It is a bizarre situation where the medical establishment have decided that it is effective, but only use it for children as they can't justify dosing them with steroids etc due to the awful side effects, especially on their growth. Adults on the other hand are treated just as they are in the US, with a barrage of drugs and surgeries. It is beyond sense.

Adam (2013-04-04 04:08:36)

<http://www.ncbi.nlm.nih.gov/pubmed/23546607> New study links corticosteroids with risk for Venous thromboembolism (Blood clots).

## **Does Scientific Research Cause Economic Growth? (2013-03-29 05:00)**

Many scientists say that science should be funded because it leads to economic growth. Today's discovery, tomorrow's new product, that sort of thing. It's certainly plausible that more research will produce more growth.

Terence Kelley, a biochemist who was vice-chancellor of the University of Buckingham, [1]points out that some facts do not support this argument:

Two key pieces, one British, one American. The British one is very simple. The British agricultural and industrial revolutions took place in the 18th and 19th centuries in the complete absence of the government funding of science. It simply wasn't government policy. The British government only started to fund science because of the Great War [World War I]. The funding has increased heavily ever since, and there has been absolutely no improvement in our underlying rate of economic growth.

But the really fascinating example is the States, because it's so stunningly abrupt. Until 1940 it was American government policy not to fund science. Then, bang, the American government goes from funding something like \$20 million of basic science to \$3,000 million, over the space of 10 or 15 years. I mean, it's an unbelievable increase, which continues all the way to the present day. And underlying rates of economic growth in the States simply do not change.

I believe the connection between research and economic growth is complicated. Veblen was certainly right, "pure" (= useless) research is high-status, "applied" (= useful) research is low-status. In the long run, this is a good way to allocate effort because although almost all the "pure" research is useless, a tiny fraction is not. And that tiny fraction might never have been done if pure research weren't high-status.

Yet after pure research turns up useful stuff, professional scientists have serious difficulty making something useful from it. Almost all of my discoveries, such as the Shangri-La Diet and the effect of morning faces on mood, relied heavily on pure research. Without the pure research, I couldn't have made them. The "pure" discoveries I used were well-known yet professional scientists were unable to grasp how they could be turned into something useful. I was able to go further than them for three reasons: 1. I was willing to spend a long time (decades) on a one problem. Professional scientists can't wait that long. 2. I was trying to find a useful solution. Professional scientists tend to think useful research is low-status, as I said. 3. Studying myself instead of other people made me much more sensitive to unexpected effects.

1. <http://www.scientificamerican.com/article.cfm?id=the-economics-of-science>

---

Daniel Lemire (2013-03-29 06:20:21)

The fact that pure research is high status would not change if government stopped funding pure research. Einstein gave us the theory that made the laser possible and you can't give too much credit to the German State or to the UK for that... the idea of the laser was pursued by various academics and finally built at a private company... This all happened before the US had a science policy per se. So we are back at the core question asked by Kealey, is government funding for science warranted? I have a related (recent) blog post you might enjoy with some hard references that tries to validate Kealey's point from a government policy point of view: Does academic research cause economic growth? <http://lemire.me/blog/archives/2013/02/26/does-academic-research-cause-economic-growth/> One could argue that if science wasn't funded in a socialist manner, then people would have to show more interest in being genuinely useful. One step you have not taken, as a researcher, is to go for "true" public funding via sites such as kickstarter. With the kind of research you do, I bet you would get people to support you financially. True: you could never match what the State can offer... (hard to get 300k \$ a year through kickstarter)... still, it could be very interesting to try... Anyhow, I think that the question Kealey is really asking is what role should the government play in science, if any?

dearieme (2013-03-29 07:21:18)

"In the long run, this is a good way to allocate effort because although almost all the "pure" research is useless, a tiny fraction is not." I've always found this argument - or at least, related arguments - dodgy. If you might stumble across potentially useful truths by doing pure research, you might equally stumble across pure truths by doing applied research. Recall that Thermodynamics was discovered because of research into steam engines, not vice versa. Of course the first really good steam engine, Watt's, presumably benefited from Watt's spell as a research assistant to Black at Glasgow, but thermodynamics did not develop from Black's work but from Watt's. Seth: I think both things are true: It helps to work on real-world problems; and it helps to do "pure" research. We need both. The second point was behind the essay "The unreasonable effectiveness of mathematics". That essay gives many examples.

Kevin (2013-03-30 21:14:48)

I disagree that underlying rates of economic growth in the US have not changed. I'll present a very simple analysis I did a few months ago: Using the data from <http://www.measuringworth.com/usgdp/>, I did two separate fits for 1790-1929 and 1946-2011, skipping the Great Depression/WWII fluctuation. The post-WWII data is smoother (higher  $R^2$ ) and has a higher slope. <http://www.kjplanet.com/gdp-s.png> I certainly do not claim that increased funding of scientific research is solely responsible, nor even that it necessarily contributes (although I think it does), but the premise of unchanging economic growth does not hold.

James A. Donald (2013-04-01 15:07:41)

I would say that government funding ends science by turning it into a state sponsored religion - that science, by and large, died in the early 1940s See the cartoon <http://dresdencodak.com/2011/04/19/dark-science-09/>

Kevin (2013-04-12 13:36:13)

There is a 4th reason: You had the courage to pose solutions people instinctively would think are ridiculous.

## **Make Yourself Healthy: Diverticulitis (2013-03-30 05:00)**

You have [1]diverticulitis when "diverticula in your digestive tract become inflamed or infected. Diverticula are small, bulging pouches." [2]A man in his forties named Tuck had a serious case:

In my twenties I got really sick; lying in bed for 5 days, bleeding from the lower part of my digestive tract:

not pretty. . . Delirious days later and ten pounds lighter and I was recovered, except for one problem: I had diarrhea for the subsequent 14 years. . . . Two years ago [2008] I passed out on the toilet on a ski weekend. The emergency room at Bennington Hospital [Vermont] told me it was a stomach flu.

Four weeks later I got cramps at work. I had to lie on the floor until it passed. Then I drove to my doctor's office, and he told me that I had diverticulitis, and I had to go to the emergency room. I drove myself, and barely made it. I was in agony; I nearly passed out again while they were interviewing me to see if it was "serious". . . . I had a perforated colon. . . . I spent the next four days in the pre-operative ward, so if it got worse they could cut me open immediately. I lost 10 pounds. Then I started bleeding, and I realized these were all the same symptoms that I had had 14 years before. My blood pressure got so low that the automated blood-pressure machine wouldn't work . . .

I mentioned to all three of the doctors I saw that I had had constant diarrhea for the last 14 years, since the first attack, and they shrugged. They told me to eat more fiber, and whole wheat, even though that was what I had been eating for the last 20 years. So I avoided surgery, started eating salad with salad dressing (containing industrial seed oils) and lots of whole wheat. . . . But the more salad and whole wheat I ate, the worse it got. I couldn't understand why. Finally had to have eight inches of my colon removed. The diarrhea continued, so obviously the cause remained.

Then something happened that, before blogging, wasn't possible:

Someone sent me a post that [3]Stephen Guyenet did about how dental problems were pretty much all due to diet, not genetics, as I'd been told. As someone who'd had a ton of cavities, and 8 teeth pulled, and was determined to spare his daughters the same fate, I found this of interest.

I started reading the blog. 6 months later, I decided to stop eating seed oils, which eliminated my carb cravings, hence no wheat. Two days later, [unexpectedly] my diarrhea stopped. A good bit of trial and error, some accidental, ensued. [I learned that both] wheat and seed oils cause distress, but different types. The two combined can cause me to pass out. If I eat wheat by accident, then eating saturated animal fats (like cream) causes things to settle down.

He found that "traditional" oils (palm, coconut, olive) are okay. Industrial oils (corn, canola, cottonseed) are not. Animal fats (butter, lard, beef tallow) are best.

After 16 years my symptoms are now completely under my control. . . . I read the ingredients on everything. I make a big mistake once every 6-9 months. [Other benefits:] I'm much more resistant to sunburn, for instance, and my vision improved a bit.

So his problems were due to (a) wheat and (b) too much omega-6. His doctors had no idea.

The Mayo Clinic recommends a "[4]diverticulitis diet" that is clear liquids and low-fiber foods. [5]According to the Mayo Clinic, "mild cases of diverticulitis can be treated with rest, changes in your diet and antibiotics. But serious cases of diverticulitis may require surgery." The Mayo Clinic, it appears, has no idea what causes diverticulitis.

Tuck added:

It really pisses me off when people dismiss this, because it really makes a difference. I had a colleague who was in the hospital for a colon resection for diverticulitis. When he heard my story, he had the hospital

put him on a gluten-free diet. Four days later, instead of having surgery as scheduled, he checked out: cured. He's symptom-free on a gluten-free diet to this day.

I agree. As someone on [6]the Shangri-La Diet forums put it, "you are handed a GIFT." A story like this is a gift.

Koanic (2013-03-30 06:04:18)

That's good. I found my regimen for living in China. Small meals of plain yoghurt spaced through daylight hours. Limit 2 liters per day. One package of free range organic pork, pressure cooked and otherwise plain, per day. No gorging or fasting. Seth: You seem to be saying your health was better when you did this. What was the health improvement and what was the earlier diet (correlated with worse health)?

derp (2013-03-30 11:23:42)

Wow. I knew that inflammatory bowel disease and a whole mountain of other diseases can be made symptom-free with an exclusion diet, but I didn't suspect gluten to be the bad boy in diverticulitis, too. Is there any common disease that \*isn't\* aided, abetted, induced, entertained or linked to grains? Besides the flu? Is there currently any internet project collecting such first-hand stories, categorizing them and allowing for comments, questions, etc. ...?

Evelyn M. (2013-03-30 20:15:56)

Seeing the reference to "seed oils" in this interesting post reminds me of a conversation I had with a biologist some 20 - 25 years ago whose "animal" was the locust. This was when the scientific community was telling everyone to shun animal fat and eat only polyunsaturated oils. She told me that grasses (including all cereal grains) defend themselves against locusts by increasing the amount of defensive insecticide they produce when attacked. This natural insecticide is found in seed oil. She was worried that encouraging people to ingest large amounts of oil from new sources, untested over the centuries, such as corn, safflower, etc., instead of traditional sources, such as olives, nuts, and animal fats/butter was not wise, since harvesting affects grasses the same way that locusts do.

## **Better Balance and Gums From Flaxseed Oil (2013-03-31 05:00)**

When I took flaxseed oil capsules for reasons connected with the Shangri-La Diet, I noticed, to my surprise, that my balance improved. The next time I saw my dentist, he told me that my gums were much better. A reader of this blog named Chuck Currie has noticed the same things.

I ran across a reference to your book again which led me to your website. And, like I said, from there to Mark Sisson and all the rest.

I had already ran across information about flax oil and cholesterol and heart health. So I started taking two tablespoons a day [of flaxseed oil] - morning and night. I noticed my balance improvement while doing yoga, but thought

it was due to practice. After reading several paleo blogs, I switched to fish oil - one table spoon a day in the morning. Then after reading some other studies regarding possible negative effects of over-consumption of fish oil, I stopped that also.

During this time I really became a strict paleo/primal eater and exerciser. No carbs other than leafy greens and non-starchy vegs. No more chronic cardio. Stopped swimming due to shoulder issues. Started using kettlebells and body weight tabata exercise. Went back and forth on supplementation. My weight dropped to below 120. [He's 5 feet 8 inches tall.]

I was getting totally confused on what was legit and what was BS. Sure I lost weight, but I must have looked sick because people were asking if I was all right. I think they thought I had cancer or AIDS. I felt great though. No more 2 o'clock naps and I slept great. Then I read Kurt Harris's 2.0 blog and that set me straight - and straight back to your blog.

It made me think, OK what works on the individual level, not the hypothesis level. I had also noticed that my balance had deteriorated (I thought it was because I stopped doing yoga) and my gums were bleeding again - I had forgotten that they had stopped bleeding. [After he switched from flaxseed oil to fish oil, his balance slowly got worse.] Sort of back to basics. Sun, lots of it, or D3 - 10,000 units (I am sitting in the sun as I type this on my iPhone). Omega 3 - your posts about flax oil made sense - [sudden release of short-chain omega-3 causes] slow release [of long-chain omega-3] - and is more sustainable than cold water fish and fish oil. Magnesium at night for better sleep and muscle cramps. (when I first went full paleo, I suffered from terrible leg cramps during the night until I found magnesium). And extra butter - beyond cooking with it.

I tested the flax/balance question by continuing to not practice yoga or any other balancing exercises and [measure my balance] just using my ability to wash my feet in the shower without leaning against the wall - which had been my normal habit before my first improvement and then again when it went away. After about a week - perfect balance - both washing and drying my feet. Also, no gum bleeding. So as some would say, "the shit works".

[He added later:] I can definitely say, with a high degree of confidence, that my balance is not as good when taking fish oil as it is when taking flax oil. Fish oil does provide a small improvement over not supplementing any omega-3. But the big improvement comes with flax oil.

---

Tom (2013-03-31 05:59:13)

One interesting thing about improved balance - there is a strong correlation between the ability to stand up without bracing oneself with one's hands and mortality: <http://www.dailymail.co.uk/health/article-2247402/Can-floor-using-hands-If-he-ading-early-grave.html>

Pauline (2013-03-31 10:32:45)

The flaxseed oil I have tried makes me feel slightly ill and has an aftertaste and I have read mixed reviews about its use. I see they also use it as a drying agent in paint: <http://en.wikipedia.org/wiki/Flax> Any comments?

Tom (2013-03-31 12:04:30)

Flax oil is linseed oil. Yes, it has been used to thin paints for centuries. Petroleum refining didn't exist in Rembrandt's day.

dearieme (2013-03-31 12:53:31)

Pauline, I simply mix linseed (= flax seed) into my muesli: about a generous half a (British) tablespoon into the jar in which I mix enough muesli for eight breakfasts. That's obviously a small intake compared to spoonfuls of the oil but I assume that it does me good. Whether it does as much good as the three tablespoons of toasted coconut I don't know. :)

Meegs (2013-04-01 08:18:09)

I usually get a lot of tartar buildup in my teeth. Since I began taking the flaxseed oil, I noticed that there is minimal tartar buildup in addition to the weight loss.

Pauline (2013-04-01 08:37:39)

Thanks for tips, do you think our bodies' can extract the oil if we buy the whole linseed, or do we need to grind it to get to the best out of it? I just wonder if like other seeds it just passes through when digested. Seth: I'm pretty sure you need to grind it.

Alex Chernavsky (2013-04-01 11:31:22)

@Meegs - my tartar buildup didn't seem to change much, but my staining decreased. My dental hygienist always used to comment on the staining (which she attributed to my coffee-drinking). After I started taking 3.5 tablespoons of flaxseed oil daily, the staining decreased.

Ed (2013-04-01 13:17:27)

Has anyone tried taking Flaxseed Pills? would that work or do you need to take the oil? Thanks Seth: Flaxseed oil capsules work, but you need to take a lot of them (like 30/day) to get the best effect. I started taking capsules - that's how I discovered the balance improvement - but switched to flaxseed oil (liquid) when I realized how much the best dose was.

David Lloyd-Jones (2013-04-02 13:03:45)

I've been eating ground flax seed two tablespoons every morning for perhaps three months, a tablespoon or so every now and then for a few months before that. Unlike others writing here, I haven't noticed any effects on my teeth and gums, though both have been in fair shape anyway for the last few years, i.e. ever since I started using an electric toothbrush. On the other hand I feel generally good all around, something I attribute in part to the flax seed, in part just to the overall process of looking after my diet with some care and imagination. -dlj Seth: You might get better results if you take more. I've taken 2 tablespoons/day of flaxseed OIL, not flax SEED. Flaxseed oil has a higher density of omega-3 than ground flaxseed. It's also possible that the omega-3 in the ground flaxseed has gone bad, if it is not freshly ground.

Pauline (2013-04-04 08:27:49)

Seth, is there a particular brand you can recommend, apologies if this has been answered before. Also I thought all plant oils were generally bad for one (even Olive oil should be eaten sparingly?) and that saturated fats were better? I have never got my head around all the oil debate, just assume that meat cooked with animal fat seems the logical way our ancestors would have chosen. Seth: I once compared different brands, found no difference between Spectrum, Barlean's, and Whole Foods.

Sam (2013-04-13 19:43:19)

Your going to think this is weird but flax seed oil prevents me from having depression. I used to feel very darkly depressed. My Dad had some flax seed oil in capsules so I tried a few. I noticed my depression lifted. Stopped taking them. Depression. So now I take a couple of tablespoons each night. I make it like the Budwig diet (supposed to cure cancer). The Budwig diet is probably nonsense but I figure it can't hurt and it taste better than pure flax seed oil. In a blender put two tablespoons or so flax seed oil, four tablespoons cottage cheese, and I pour a half a cup of milk to help it blend and go down smoother. Taste a little tangy like buttermilk. Not bad. Works for me. When ever anyone mentions depression or flax seed oil I always think what it did for me. Awful to be depressed. It doesn't make me happy but does lift the worst of my depression.

crosswind (2013-04-15 14:37:12)

I appreciate you writing this. I have gum issues too. For years, i took Barleans flax oils blends because BARLEAN'S is the freshest i know. They press it on the day of ordering for customers/stores. I usually buy Flax Omega Berry Swirl (with plant DHA) for a few years and it always helped me severe PMS moods, cramps, painful cystic breasts etc.. I have not taken in a few months and i have had horrible PMS & cycle since, which required high doses of ibuprofen. Good to konw on the GUMS too. I will keep an eye on them to see if it helps. In the past when I took Barlean's i did not need to take any pain pills for pms. So, after googling many articles, including yours with other reader's comments, it confirms i need to go back on what was working.

## 8.4 April

### Maybe We SHOULD Eat More Fat? (2013-04-02 05:00)

In [1]a review of Salt Sugar Fat by Michael Moss, a new book about the food industry, David Kamp writes:

The term "bliss point" . . . is used in the soft-drink business to denote the optimal level of sugar at which the beverage is most pleasing to the consumer. . . .

The "Fat" section of "Salt Sugar Fat" is the most disquieting, for, as Moss learns from Adam Drewnowski, an epidemiologist who runs the Center for Obesity Research at the University of Washington, there is no known bliss point for fat — his test subjects, plied with a drinkable concoction of milk, cream and sugar, kept on chugging ever fattier samples without crying uncle. This realization has had huge implications in the food industry. For example, Moss reports, the big companies have come to understand that "cheese could be added to other food products without any worries that people would walk away."

By "fat" Moss means animal fat (the fat in cheese, for example). I haven't seen the book but I'm sure Moss doesn't consider the possibility that "there is no known bliss point for fat" because people should be eating much more animal fat. In other words, it is hard to detect the bliss point when people are suffering from severe fat deprivation.

My view of how much animal fat I should eat changed abruptly when I found that large amounts of pork fat made me sleep better. One day I ate a lot of pork belly (very high fat) to avoid throwing it away. That night I slept much better than usual. I confirmed the effect experimentally. Later, I found that butter (instead of pork fat) made me faster at a mental test. This strengthened my belief that I should eat much more animal fat than countless nutrition experts have said. ([2]Supporting data.)

My sleep and mental test evidence was clear and strong (in the sense of large t value). The evidence that animal fat is bad (based on epidemiology) is neither. That is one reason I trust what I found rather than what I have been told.

Another reason I trust what I found the fact that people like the taste of fat. That evolution has shaped us to like the taste of something we shouldn't eat makes no sense. (Surely I don't have to explain why this doesn't mean that sugar – not available to prehistoric man – is good for us.) In contrast, it is entirely possible that nutrition experts have gotten things backwards. Epidemiology is a fledgling science and epidemiologists often make mistakes. Their conclusions point in the wrong direction. [3]Here is an example, about the effect of beta-carotene on heart disease:

Epidemiology repeatedly found that people who consumed more beta-carotene had less heart disease. When the idea that beta-carotene reduces heart disease was tested in experiments, the results suggested the opposite: beta-carotene increases heart disease.

[4]"Fat will become the new diet food" (via [5]Hyperlipid).

---

Alex Chernavsky (2013-04-02 09:37:16)

Seth, do you know of any plant fats that might have comparably beneficial effects? I know that the [1]Buttermind experiment suggested that coconut fat didn't compare favorably to butter. But I wonder if there are any other type of plant-derived fats or oils that may be promising. Seth: I can't think of any plant fats that resemble animal fats. They would need to be solid at room temperature – which wouldn't work well for a plant.

- <http://blog.sethroberts.net/2011/01/29/the-buttermind-experiment/>

Mike C (2013-04-02 09:59:36)

Perhaps you could say a bit more on your final point? Any individual study could be wrong, but the idea that I could increase my chances of having a heart attack by eating too many carrots (and thus more beta carotene) sounds ridiculous.

Nancy Lebovitz (2013-04-02 12:31:00)

I think there's a bliss point for fat– people generally don't eat butter or cream alone unless they have a theory saying they should.

Evelyn M. (2013-04-03 05:56:59)

I agree with Ms. Lebovitz. Mr. Moss' test for the "bliss" point for fat was flawed because he added sugar to the mix - and I think he added sugar because he knew that when eating pure fat, even delicious fat such as butter, one reaches a saturation point fairly quickly, and that would undermine the point he was trying to make.

JW (2013-04-03 08:51:09)

Nancy: Agreed. I do drink heavy cream alone, often an entire pint, and have for months. There is certainly a "bliss point." My consistent experience has been that it leaves me both incredibly full and sated, for quite a number of hours. After which point I can hardly imagine eating another thing. What one would expect from 190g of saturated fat, albeit in only two cups. If anything I suspect the fat concoction fed to those individuals is not fatty enough. Not so much because they are fat deprived, but likely because the levels of saturated fat considered "safe" are absurdly low (and therefore who would venture such a thing?) Also, the note about cheese is absurd. Cheese is hardly pure fat or anywhere close to it; even many "high fat" cheeses are mostly protein. Again, fat-is-scary relativism at work. In a world of adequate fat consumption, cheese is a low fat product. In the world of ultra-conservative guidelines, it is notably scary as a fatty food additive.

Bob (2013-04-03 12:44:00)

More accurately the book states that there is no known bliss point for fat up to heavy cream. It mentions that a couple of times but doesn't really emphasize it. bob

Greg (2013-04-03 16:44:29)

I would like to see the bliss point experiment done with pure lamb tallow.

CC (2013-04-04 18:39:59)

"Another reason I trust what I found the fact that people like the taste of fat. That evolution has shaped us to like the taste of something we shouldn't eat makes no sense." As much as I want to believe this, Seth, there are other possibilities: 1. Prehistoric man only had access to small amounts of animal fat. Maybe small amounts are good for you but the amounts we can obtain nowadays are unhealthy. 2. Animal is actually very good for you until age 60 (for instance). Maybe eating a lot of animal fat makes you more likely to have a heart attack at age 60 and beyond; this would have made no difference to prehistoric man. What do you think? I'd love to be wrong about this!

## **Canker Sores Quickly Cured by Walnuts: More Evidence for Importance of Omega-3 (2013-04-03 05:00)**

A reader of this blog named PSB, who lives in New Jersey, told me the following:

I'm 52. I happen to like walnuts and was snacking on them and noticed the pain from canker sores was lessened. I kept eating [walnuts] the next couple days and found the sores healed quickly, painlessly and were gone within a few days. They usually take quite a while to go away. The walnut thing was accidental and just from observation noticing the change in the sores. The sores are still gone and although I haven't been eating lots of walnuts, I usually grab them here and there.

Her daughter "has suffered from canker sores for years . . . [and] gets multiple at a time and they are usually very painful." Her daughter is resistant to eating walnuts. I asked why. "Doesn't listen to her mother, knows it all and I sometimes thinks she prefers to complain. Other than that, no real reason, hahaha," said PSB.

I've blogged before ([1]here and [2]here) about canker sores cured by omega-3. Walnuts are high in omega-3, supporting what I said. [3]The Mayo Clinic lists eight possible causes of canker sores, including "A diet lacking in Vitamin B-12, zinc, folate (folic acid) or iron". Nothing about omega-3.

1. <http://blog.sethroberts.net/2009/06/04/canker-sores-and-omega-3/>
2. <http://blog.sethroberts.net/2009/06/06/yes-canker-sores-prevented-and-cured-by-omega-3/>
3. <http://www.mayoclinic.com/health/canker-sore/DS00354/DSECTION=causes>

---

dearieme (2013-04-03 06:13:48)

Walnuts and goat's cheese make a tasty combination.

Vic (2013-04-03 07:53:30)

Walnuts are also high in omega-6. And didn't you blog before that walnuts didn't help your sleep or brain activity, or something? I could be misremembering... Seth: Right. Eating walnuts did not help me. Nor did it help 3 of my students. In each case, the measurements were brain-related. Perhaps brain-related measurements are more sensitive to omega-6 content than canker sores. It's also possible that if you begin an experiment high in omega-3, walnuts have a different effect than if you begin low in omega-3.

Chuck (2013-04-03 08:26:22)

Walnuts are also a good source of folate, iron and zinc - no B-12. Even though they have the highest level of n-3 than any other nut, they have four times higher omega-6. However: "Along with omega-3 fatty acids, walnuts contain ellagic acid. Memorial Sloan-Kettering Cancer Center reports that ellagic acid contains antiviral and antibiotic properties and is now found to have anticancer properties as well." - via Livestrong. So it could be the antiviral and/or the antibiotic properties at work here. Or a combination of all of the above. Cheers

Kevin (2013-04-03 08:53:57)

I suffer from frequent and painful canker sores. I will give walnuts a try; there is very little available for conventional treatments, and "eating more walnuts" certainly won't hurt. Seth: I hope you'll let me know what happens, either way (helps or doesn't help).

Alex (2013-04-03 10:05:42)

Haven't had any canker sores since starting Paleo back in 2011. Used to get them once a month before that. Seth: When you started paleo, did you increase or decrease or leave unchanged your omega-3 intake?

Morex (2013-04-03 15:00:19)

I have been 3 months in SLD and my jaw just hit the floor. Since I was a kid I have always suffered of painful canker sores. I've been having them all my life... But now that I'm reading this, I realized I haven't had any canker sore in my 3 months doing SLD. I have been taking 4 tablespoons of canola oil a day. I was careful to choose a brand with more omega-3 than others. I am very impressed and happy :)

dearieme (2013-04-03 15:18:36)

My wife has a bottle of walnut oil in the kitchen. She uses it for salad dressings and when preparing a chicken for roasting.

chris (2013-04-03 15:43:39)

Suffered for 30 years with canker sores....problem was cow's milk...eliminated from diet haven't had a canker sore in a decade. RAST and skin tests were negative for milk allergy/sensitivity FWIW.

Jake (2013-04-03 17:23:21)

I was a chronic sufferer of canker sores since childhood. Four years ago I gave up wheat and have not had one canker sore since.

Greg (2013-04-03 17:42:48)

Canker sores can be treated medically with amlexanox, an anti-inflammatory, which lends support to the approach of addressing the immune system, via anti-inflammatory diets or omega-3 supplementation. And walnuts apparently contain anti-inflammatory compounds in addition to their omega-3s.

Alex (2013-04-04 05:43:59)

>Seth: When you started paleo, did you increase or decrease or leave unchanged your omega-3 intake? Increased n-3 pretty significantly. Eating about a pound of salmon a week, sardines, some supplementation (LEF Mega EPA/DHA)... about 3-4g/day of n-3 and less than 10g of n-6 according to Chron-o-meter. Seth: Thanks. Supports more omega-3 -> fewer canker sores idea.

LV (2013-04-10 04:00:25)

Like others I found my lifelong canker sores (or mouth ulcers as we call them in the UK) stopped when I stopped eating gluten. That was three years ago and the only ones I've had since have followed accidental gluten ingestion. Prior to this I was eating a broadly Weston Price style diet (including oily fish and cod liver oil) for several years; if there was any improvement on moving to this from a standard 'healthy' western diet it was modest - I wasn't looking for and don't recall noticing any significant change. Are the people who do see improvement from increasing omega-3 actually deficient in omega-3 as such, or do they need more omega-3 to correct an underlying state of inflammation? Are they eating diets generally deficient in omega-3 compared to people who never get canker sores? Seth: I think as a matter of definition if eating more omega-3 cures canker sores then you were deficient in omega-3. That's how deficiency is usually defined. I see your point, however, which is that even if omega-3 cures the canker sores there may be other ways to improve matters.

Paul N (2013-04-10 08:27:32)

LV wrote; "Are the people who do see improvement from increasing omega-3 actually deficient in omega-3 as such, or do they need more omega-3 to correct an underlying state of inflammation? " I'm sure there are many cases where the underlying inflammation is the cause. Wheat/gluten (or soy) causing trouble is a good example - does any amount of omega 3 make wheat "safe" - probably not. SO, if you are eating toxins, omega 3 might mitigate some or even all of the effects, but better to remove the toxins first. Similarly for other deficiencies, like magnesium, or (especially) K2, omega 3 can only do so much. The current fad where fish oil is being sold as a cure all is, in many cases, simply creating "licensing" behaviour, where people continue to eat badly, but think its OK because they are taking fish oil.

Nate (2013-04-10 14:12:03)

How can you tell which brand of canola has more omega-3's? Thanks

## **First Quantified Self Meeting (2008) (2013-04-03 18:13)**

The first Quantified Self meetup was held at Kevin Kelly's house in 2008. Tim Ferriss has posted [1]his notes from that meeting. I was one of the speakers and his notes show how much I repeat myself.

1. <http://www.fourhourworkweek.com/blog/2013/04/03/the-first-ever-quantified-self-notes-plus-lsd-as-cognitive-enhancer/>

Mark Sanders (2013-04-04 10:22:24)

Re resveratrol and wine - one of the interesting theories I've read about wine's benefits (can't remember where I saw it) is that it has to do with the alcohol. Many people think the biggest danger of high blood sugars is in the first 2 hours or so of eating. Meals that might spike blood sugars really high in a person susceptible to carbs/sugars are ameliorated by the alcohol in the wine since alcohol apparently will stop the liver from chugging out sugars into the blood. By the time the alcohol is processed, the danger of high BS is past. Don't know if this is true, but it's an interesting theory to me.

dearieme (2013-04-04 10:52:21)

"Foreign-born children residing in the United States had half the risk of developing allergies than those who were born here." When I was a child (1950s) it was a subject of some amusement in Britain that Americans were forever complaining about their allergies. That may have been when I had the first glimmering of the notion that many American health problems are probably caused by making far too many visits to the dentist. Seth: Maybe antibiotics were/are more freely prescribed to children in America than children in Britain. It is a little shocking how freely they are given out here.

## Practical Use of Our Liking For Complex Flavors (2013-04-05 05:00)

People like complex flavors. I suppose this is why I prefer black tea to green tea. My evolutionary explanation is that this preference caused our ancestors to eat more bacteria-laden food. Bacteria make food taste more complex and bacteria-laden food are healthier than bacteria-free food.

Phil Alexander sent me a story from [1]this book that illustrates this preference:

We entered the saloon. Not a customer was there — a very surprising fact, considering that it was New Year's Eve. The only person in sight was the bartender who paced back and forth in front of the bar like a caged beast.

"Well, whatta you want?" he asked savagely.

"Why, we just want a little New Year's drink," I returned. Winterbill was too surprised to say anything.

"Mix 'em yourself," the bartender replied. "I'm through with the saloon business."

"If you feel that way about it," I said, "why don't you sell out?"

"Well, the first guy who offers me \$300 can have the works."

Somewhat amused and thinking he must be joking, I retorted, "I'll give you \$300 — provided it includes all your stock, the cash register, and other equipment."

"Mister, you've bought yourself a saloon!" he snapped. "I'll not only include all the stock and equipment — I'll throw in a full barrel of whiskey I've got in the basement."

Winterbill now joined in the fun and began to take an inventory.

The owner took off his apron and handed it to me. "Gimme the three hundred bucks."

I gave him the money, still believing it was a joke. He put the money into his pocket, got his hat and coat and departed. To our complete bewilderment, we found ourselves in the saloon business.

A few minutes later, our first customer came in. He evidently had not made our place his first stop. I hurriedly put the apron over my evening clothes and asked for his order.

"Martini," he said in a thick voice.

"Martini," I repeated to Winterbill.

"Stall him!" Winterbill whispered.

"Coming right up," I told the customer. He didn't mind waiting. He was at the stage where he wanted to talk and so proceeded to do.

Meanwhile Winterbill racked his brain, for he had only the vaguest idea how to mix a Martini. He finally settled upon a recipe. He put a dash of everything from the numerous bottles behind the bar into one drink. I stirred it up and handed it to the customer. We watched anxiously while he drank it down.

"That was good!" he exclaimed. "Best Martini I ever tasted. Mix me another."

Again Winterbill started to mix.

"How do you feel?" I inquired, none too sure of the consequences.

"Me?" asked the customer. "Fine. Never felt better in my life."

He didn't show any bad results after the second drink, and we both were relieved. As time went on more customers came in. They ordered whiskey sours, Manhattans, and Martinis. Winterbill had just one formula and that's what he gave them all. Nobody complained.

. . . By the time we closed that night we had taken in more than the whole outfit cost us!

1. [http://books.google.com/books?id=pgjACVyd\\_xMC&pg=PA106#v=onepage&q&f=false](http://books.google.com/books?id=pgjACVyd_xMC&pg=PA106#v=onepage&q&f=false)

---

Alex Chernavsky (2013-04-05 10:40:05)

I once made [1]this Ethiopian stew (the recipe lists ten different spices – and I used all ten). It was OK but not great.

1. <http://www.theppk.com/2008/10/ethiopian-spicy-tomato-lentil-stew/>

dearieme (2013-04-05 13:46:19)

That's the spirit in which I approached my first chemistry set: "I'm going to the garden shed, Mum, to mix everything up". The result, as far as I remember, was brown.

CD (2013-04-05 17:27:33)

Hey Seth, It reminds me of this story: [http://www.joe-ks.com/archives\\_jul2004/Chili\\_Cheater.htm](http://www.joe-ks.com/archives_jul2004/Chili_Cheater.htm) A guy won a Texas chili cookoff by combining samples from all the entrants. Seth: Reminiscent of psychology research that found that a face photo constructed by averaging many faces was more attractive than any of the individual faces.

Alex Chernavsky (2013-04-06 20:08:02)

The *New York Times* just ran this interesting article about spices: "[1]The Transformational Power of the Right Spice"

1. <http://www.nytimes.com/2013/04/07/magazine/the-spice-is-right.html??gwh=97DA3B24AB9F1131E78A32EBD6B8E1C8>

## **Speech Pathology Confidential (2013-04-06 05:00)**

Bryan Castañeda told me the following:

I was talking to a good friend of mine who's a speech pathologist. He works for a woman who runs a private practice in Connecticut. Says that a third of his patients require the amount of treatment his boss

recommends, a third require treatment but less than she recommends, and a third require no treatment at all. But his boss is skilled at preying on parents' insecurities (and their clientele has a lot of money), so she makes a killing. He agreed with your advice that people should be more skeptical of the claims of medical professionals and do their own research to evaluate to those claims.

The woman who runs the practice has a Master's in speech pathology, same as Bryan's friend. I asked about the treatments. Bryan's friend replied:

It depends on the diagnosis. If it's a speech disorder, we do articulation therapy. Articulation therapy usually consists of drills, correcting erred sounds by shaping the articulators appropriately and then having the client produce the sound in isolation, at the word, phrase, and sentence levels, and then in reading aloud and in conversation until they've reached 100 % or close to 100 % accuracy.

If it's a language disorder, we do language therapy. Language therapy is a little more complicated. We target specific language areas based on the results of previous testing. It can vary a lot, but some of the more common things I do is read passages and have the client answer questions about it, teach grammar, work on formulating sentences appropriately, teach vocabulary, and word classification activities. A lot of worksheets and games too – materials that my boss writes off at tax time. We bill by the hour, so more hours certainly equals more pay for her," he says. "We are all salaried, so the tighter she crams our schedules the more she gets to keep at the end of the day.

At least the unhelpful treatments are harmless, in contrast to a large fraction of mainstream medicine, where children [1]have their tonsils removed, and so on.

1. <http://boingboing.net/2012/01/10/tonsillectomy-confidential-do.html>

---

MJB (2013-04-07 05:23:22)

So what did cause the long-term doubling of life expectancy in England from 32 in 1680 to 65 in 1942? There is general agreement that medicine was not responsible and that the major factor was better resistance to disease, and that the only thing that could have made this possible was better nutrition. How much has modern medicine contributed to the increase in life expectancy? The answer seems to be about 20 per cent, much less than improved nutrition and improved sanitation. It is easy to adopt a patronizing attitude to those patients who, from 425 BC to 1865, imagined their doctors were doing them good when they were only doing them harm. But we too are credulous. We owe much less to modern medicine than we can imagine Wootton, David (2006-06-22). *Bad Medicine : Doctors Doing Harm Since Hippocrates* (Kindle Locations 4196-4200). Oxford University Press. Kindle Edition. Seth: In addition to better nutrition, there were big improvements in public hygiene, e.g., cleaner water. It became a lot safer to live in a city.

Nancy Lebovitz (2013-04-07 09:35:56)

I'm reasonably sure that intrusive teaching can cause emotional damage, even if there's no surgery or drugs involved.

dearieme (2013-04-07 13:07:43)

MJB's remark implies to me that economic historians have grossly underestimated economic growth rates during the Agricultural and Industrial Revolutions: that doubling of life expectancy, after all, was accompanied by large population growth rates.

## **"Brain Games are Bogus": More Trouble for Posit Science (2013-04-07 19:06)**

[1]A post on the New Yorker website called "Brain Games are Bogus" provides considerable evidence for that conclusion. The evidence is about the use of brain games to raise the IQ of children and young adults, whereas Posit Science's training program – [2]which I raised questions about – is aimed at older people. However, it would be surprising if brain games have no effect until you reach a certain age. More plausible is that they never provide substantial benefits – at least, benefits broad enough and strong enough and long-lasting enough to be worth the training time (one hour/day for many weeks).

I read a Posit Science paper, with older subjects, that seemed to me to show that its training had little lasting benefit. The stated conclusions of the paper were more positive. Too bad the head of Posit Science didn't answer most of my questions.

Thanks to Alex Chernavsky.

1. <http://www.newyorker.com/online/blogs/elements/2013/04/brain-games-are-bogus.html>
2. <http://blog.sethroberts.net/2013/02/22/questions-for-posit-science/>

---

Ashish (2013-04-07 22:09:50)

Then there's the meta-question of whether IQ is the limiting reagent in most people's recipe for success in life. Beyond a not-very-high point, I doubt very much that it is.

Nancy Lebovitz (2013-04-08 03:22:18)

I've been doing Posit's exercises for a couple of months, and there seems to be an anti-depressant effect for me. It's hard to be sure that the exercises are the cause because I'm doing more than one thing to oppose depression, but it's enough to be worth the time and money so far. (I'm doing the \$10/month rental.)

Bob Levinson (2013-04-09 18:49:37)

So what can people do to improve their brain power, if not games? Seth: Better food, for one thing. Omega-3, butter, probably other foods as well. Avoid omega-6. It's also possible that better sleep improves brain power.

Alex Chernavsky (2013-04-10 03:49:36)

Seth, what about more exercise? "[1]For a Healthy Brain, Physical Exercise Trumps Mental Workout" Seth: I have found that walking improves my brain test scores for a half-hour or so (I haven't carefully measured how long the effect lasts).

1. <http://www.livescience.com/24180-physical-exercise-boosts-brain-health.html>

## **Cod Liver Oil in Morning Improves Sleep (2013-04-08 05:00)**

Kim Øyhus, a programmer who lives in Norway, writes:

Each midwinter and summer I tend to lose my feeling of when it is day or night, especially if I am in the northern parts of Norway, or if the weather is dark clouds for a long time, which often happens. So sorry, no statistics, just my sense of being unhinged from the diurnal cycle.

Taking 1-2 spoons [= 7-14 ml] of cod liver oil in the morning [7-9 am] got me back to this rhythm in about 3-5 hours. It even works for fixing my diurnal rhythm after partying to sunrise, but only after a days rest.

Is this due to Vitamin D3? (I [1]have collected many examples of Vitamin D3 in the morning improving sleep.) Quite possibly. Cod liver oil contains Vitamin D3. When taking a Vitamin D3 supplement, the minimum dose needed to see the effect, based on the examples I've collected, seems to be about 1000 IU. [2]I didn't notice anything when I took 2000 IU. The effect first appeared at a dose of 4000 IU and was a bit larger at 6000 IU. Kim is taking 600-1100 IU of Vitamin D3, so that is consistent with the Vitamin D3 in the cod liver oil being the source of the effect.

1. <http://blog.sethroberts.net/category/sleep/vitamin-d3-and-sleep/>

2. <http://blog.sethroberts.net/wp-content/uploads/2012/09/2012-09-24-The-Growth-of-Personal-Science-Implications-For-Statistics.pdf>

---

dearieme (2013-04-08 14:06:54)

After breakfast, every morning in winter - cod liver oil capsules were part of the Standard British Childhood in the 50s. And often your breakfast had been a kipper (after a bowl of porridge).

Hamish Barney (2013-04-08 17:28:12)

There might be co-factors in the cod liver oil that make the smaller dose of vitamin D more effective.

Paul N (2013-04-10 08:19:52)

I'll second the co-factor hypothesis. CLO contains lots of vit A, small amounts of EPA and DHA, and some trace minerals too. all around good stuff - just doesn't taste like it!

Jamie Holland (2013-04-17 19:18:29)

Cod liver oil helps with the vitamin deficiency overall and anytime you heal the body from a vitamin deficiency you're going to help the sleep cycle. I'm a huge believer though in Cod Liver oil, I appreciate how the norwegians are super healthy!

Pauline (2013-04-18 06:34:02)

I supplemented with Oral spray Vit D3 (1000iu) since October last year until now. I increased to Vit D3 (3000 iu) since feb as we have an a bitterly cold and extended winter. I have had no cold, no flu (friends and family were very sick) and I supplement with fermented liver/butter oil one capsule at night. This is the first time I have done this consistently through winter in the UK and my first time of no flu symptoms whatsoever. I may have the odd day of a snuffly nose/or cough but nothing ever develops from it. I am particularly amazed as I do mix a lot with people who are often coughing and sneezing but still no problems for me. I am waiting now to see as Spring arrives how my recent pollen allergy is going to work out. I have started taking home-made Kefir as a possible improvement remedy for seasonal allergies. I wait and see, so far so good.

Pauline (2013-04-18 06:38:01)

I wanted to add my sleep has also improved, I sleep noticeably more deeply but I put that down to magnesium 2 x 250mg a night but it may well be the Vit D3, the K2 and the magnesium.

Brook (2013-04-19 10:11:55)

OK, so I am not really talking cod liver oil... though I have been taking it occasionally because flaxseed scares me just a bit. It doesn't have the same profile of fish oil exactly but people take it for the omega 3. However last night I was studying a bit on enzymes and was listening to a lecture found here <http://www.rawfoods bible.com/index.php?page=misc/Vitalzym> It just started playing. By the end of the discussion he said to avoid flaxseed because of the lignans. Apparently they are a phytoestrogen that acts much like the isoflavones in soy and increase estrogen! I have been trying to find out more about this this morning. For those interested I found three sites so far that have my curiosity (since lignans are especially high in all nuts) see page four here <http://books.google.com/books?id=Uu4nzKx74noC&pg=PA24&lpg=PA24&dq=lignans+and+nuts&source=bl&ots=H7f7PPBAV9&sig=zz4cBeLc9QIE9Us5xt6qXnAd2hl&hl=en&sa=X&ei=9eVwUblHO5CUigKRplC4Aw&ved=0CFIQ6AEwBQ#v=snippet&q=lignans%20and%20nuts&f=true> You can see the percentages of lignans... I am liking pecans more and more Then this site [http://medcomres.com/articles/soy\\_isoflavones.htm](http://medcomres.com/articles/soy_isoflavones.htm) (Beans never did sit well with me.... guess I know one more reason why) Apparently some people can negate some of the bad effects of lignans while on antibiotics because some gut floras help digest it (bad) instead of passing it on. Yet lignans are everywhere in food and is usually found in the most fibrous parts of the plant, but not all fiber has the bad lignan impact. I am finding out that it is because there are many types of lignans and we don't understand them all very well.... certain one however we KNOW increase bad hormone levels of estrogen (like the ones very active in flax... that is why it is sometimes recommended for menopausal symptoms) I imagine that would be very bad for men. Surely there has been more study on this topic... and maybe there really are some good lignan types out there.... for now I am trying to understand this study <http://ethesis.helsinki.fi/julkaisut/laa/kliin/vk/mazur/phytoest.pdf> Until we understand lignans better maybe cod liver oil or algae oil is the way to go. Thanks for your awesome blog Seth. I keep bumping into it during my searches.... its a keeper

Sentinel (2013-04-21 06:55:36)

Seth, For the purpose of battling insomnia, do you have any suggestions on how we can reconcile skipping breakfast, with taking D3 supplements and/or cod liver oil first thing in the morning? Will a pre-breakfast supplement run the risk of setting up anticipatory waking? (Vitamin D3 capsule might be flavorless, thus perhaps no anticipatory waking, but cod liver oil definitely has a taste. Yum.) Is it better to delay the supplements until time of 1st-food (10am or 11am, or whatnot)? Thanks! Seth: There are no calories in vitamin D3. So it produces no anticipatory waking. Cod liver oil early in the morning might be a problem.

## **Why Fujoshi? Experiment by Tsinghua Freshmen (2013-04-09 05:00)**

In January I [1]blogged about teaching a class in a new way. The obvious novelty was that I did no grading, but I was also pleased by the high quality of the student work.

The class, at Tsinghua University, is called Foundations of Psychology. It's required of psychology majors and is taken by freshmen. Last time there were about 25 students. The biggest assignment was a final project where I allowed students to work on their own interests. They could do almost anything they wanted related to psychology and they could work alone or with others. I "graded" their work via a checklist: X points for doing this, Y points for doing that, and so on, with the possible points adding up to an A. The checklist was different for every project. They had about five weeks.

Here is a summary of one project, by Vista Zeng:

In the Frontiers of Psychology class this term, we, a group of three freshmen (Vista Zeng, Joy Wu and Michael Wu) conducted an experiment on [2]Fujoshi. Fujoshi is a subculture that started in Japan and spread in East Asia. It has influenced many of our classmates and friends. When recruiting participants, we found 14 Fujoshis out of about 720 female students in Tsinghua University.

According to Wikipedia, fujoshi is synonymous with yaoi fandom:

Yaoi fandom refers to readers of yaoi (also called Boys' Love, BL), a genre of male-male romance narratives aimed at a female audience, and more specifically those who participate in communal activities organized around yaoi, such as attending conventions, maintaining or posting to fansites, creating fanfiction or fanart, etc. Most fans are teenage girls or young women. . . . In Japan, female fans are called fujoshi.

It's easy to raise questions like "why don't those girls enjoy heterosexual romance narratives?", "why is boys becoming fans of female-female romance narratives and creating another sub-culture (yuri) not so big an issue?", or "why did this phenomena first occur in Eastern society?". Vista Zeng believed that the main reason may be the traditional ethics in Eastern world (China and Japan, to be specific) on women. Traditional Chinese moral principles assume that women are not supposed to appear in these sexual scenes, so the girls turn to male homosexual products to satisfy themselves, and to avoid the condemnation from our society.

Since there are very few researches on this topic, and all of them use research methods like interviewing, Vista decided to conduct an experiment to test her explanation. Joy and Wu joined the project.

The study included 30 Fujoshis and 30 non-Fujoshis in Tsinghua University. [The students recruited about half of their Fujoshi subjects going door to door in the dormitories, the other half by making announcements in classes.] The subjects were asked to read several paragraphs including erotic scene, and the only difference between them was the gender of the two characters. The first story includes two male characters, the second one a man and a woman ("he" and "she"), the third one a man and the reader herself ("he" and "me"). (The idea was inspired by the study about judgments of intentionality by Joshua Knobe, which the class introduced.) What's more, a neutral paragraph was put between two paragraphs. The subjects were asked to estimate her emotional feelings (we mainly focused on embarrassment and the sense of guilt) on a scale before and after reading each paragraph aloud in front of 3 strangers, and the 3 observers would also estimate the subject's extent of embarrassment.

The answer to our assumption was yes. The most important finding was that the Fujoshis felt less guilty than non-Fujoshis when reading the male-homosexual paragraph, but far more guilty when reading the heterosexual one, showing that they agree with the idea that women are not supposed to appear in these sexual scenes. We also found that women are prone to put themselves into the sexual scene in which women are constantly involved, and they are therefore embarrassed and guilt about their own feelings.

We think our study found an example about how the traditional ethics from thousands of years ago still influence the teenagers nowadays in China, and implied a lack of sense of equality and self-esteem of Chinese women – they don't see their natural desire and rights legitimate. However, the Fujoshis are also the ones who dare to show their demands of sexual narratives (generally, we found Fujoshis more open to sexual topics than Non-Fujoshis), which can be seen as a progress in Chinese society. We are glad that we conducted the first experiment on Fujoshi (as far as we know) and got such findings which are worth thinking about.

Anonymous (2013-04-09 09:40:34)

"why don't boys become fans of female-female romance narratives and create another sub-culture?" Looks like someone didn't think the wikipedia link to yuri was important Seth: You are correct. I have fixed the sentence. The students knew about yuri.

Elizabeth Molin (2013-04-09 09:58:10)

But then why is slash fiction so popular in the US? (And other English-speaking countries; perhaps in other languages as well, but I am only familiar with slash in English.) Given the popularity of e.g. Harlequin Romances, it wouldn't seem that there is a lot of heterosexual sexual guilt among US women.

Ken (2013-04-09 10:22:34)

Can you tell me more about glorious Japan and their bushido code? I am also very interested in the Kantana.

Adam (2013-04-09 15:52:33)

Interesting! I have a Chinese friend who is living in Japan & fluent in Japanese. She has talked about "boy-boy love" before.

dearieme (2013-04-10 08:22:39)

OK, what about semi-dried plums i.e. prunes?

bjk (2013-04-10 11:32:46)

Hairdresser story reminded me of Victor Davis Hanson, a farmer in California who wrote a book on Greek history. None of the other historians knew anything about farming, so he had a great advantage writing about just that topic.

Matilde (2013-04-11 02:33:57)

I have noticed in the cited article that the dried plum diet consists on 25 % w/w dried plum. I wonder if this is sustainable for humans without having other side effects.

dearieme (2013-04-11 06:51:24)

"I wonder if this is sustainable for humans without having other side effects." I suspect you're thinking more of bottom effects.

Matilde (2013-04-12 01:13:50)

Exactly. I suppose the authors would not mention this kind of effect in mice. To me, this is one more example of ill-designed mouse experiments.

### **First Make Yourself Healthy Meetup April 24 (Wed) (2013-04-10 20:17)**

Encouraged by the success of the Quantified Self Meetup group, I have started [1]a Meetup group called Make Yourself Healthy. It is about how non-experts – the rest of us – can improve on expert advice about health. The first meeting will be April 24 (Wed.) in the meeting room of the North Branch of the Berkeley Public Library, 6:00 pm to 7:30 pm.

The group is about solving your health problems yourself, before or after mainstream medicine fails to help or provides inferior solutions. Access to health information via the Internet makes this more and more possible; so does new technology, which make it easier to measure health problems.

The first important practitioner of Make Yourself Healthy was Richard Bernstein, a New York engineer with diabetes, who in the 1960s bought a new machine that could measure blood sugar with only a single drop of blood. Bernstein used it to measure his own blood sugar many times per day – in contrast to getting it measured once a month at a lab. What he learned from frequent measurements allowed him to stabilize his blood sugar level, which doctors' advice had never managed to. His health greatly improved. His promotion of what he had done led to the glucometers you can find in any drugstore. Nowadays diabetics take self-measurement for granted.

I have managed to improve my health in many non-standard ways. Acne, sleep, mood, weight, and brain function, especially. On the face of it, you might think: He did a lot of self-experimentation and discovered cool stuff. At first, that's how it looked to me. I wrote a paper called "[2]Self-experimentation as a source of new ideas". But that's misleading. Self-experimentation wasn't new, it was ancient. Yet my discoveries were quite new – quite different from what people already believed. What really led to my successes was: 1. Better information. Before the Internet, I spent thousands of dollars on a UC Berkeley library service called BAKER, which photocopied journal articles that I requested by phone and delivered the copies to my campus mailbox. Xerox machines made this possible. 2. The prison of professional science. There are so many things that professional scientists (such as medical school professors) cannot do. There are so many ideas they cannot test. They have left a lot to be discovered and it turns out that non-scientists (such as me – I was not a sleep researcher, a mood researcher, etc.) can discover at least some of it. In other words, I wasn't successful just because I did self-experimentation, I was successful because I did wise self-experimentation. I chose wisely what to do.

Behind this Meetup group is my belief that anyone who does this – tries to do better than expert advice – probably can teach and learn from other people trying to do the same thing, even if their health issue is different from yours.

If you are coming to this Meetup and have experience (successful or unsuccessful) trying to improve on expert health advice, and are willing to share your experience, please contact me.

## Journal of Personal Science: Xylitol Cures Lichen Planus and Geographic Tongue (2013-04-12 05:00)

### Xylitol Improves Lichen Planus and Geographic Tongue

by Evelyn M., Westchester County, NY

#### Background

In my forties – I am now 75 – my gums started to bother me. Newly-returned to the United States from Iran, I searched for a good dentist. The first one told me to get a cap on a tooth with a small chip. That was no help. A colleague recommended a specialist in gum problems. The specialist advised "scaling," which didn't help. Then he said I was not cleaning my teeth well enough. He put a substance on my teeth to reveal incomplete cleaning and was flummoxed when he could find no evidence of bad brushing or flossing. I gave up trying to solve my gum problem.

When I was about 50, a "crisis tooth" (a molar on the upper right) forced me to see a dentist. I found a very good dentist, sensible and conservative in approach. After the problem tooth was removed, he turned to the overall condition of my mouth. I told him about the gum treatments I'd had. Then he showed me an x-ray that revealed an abscess under the root of a tooth on the lower right hand side. That tooth didn't hurt, and looked OK, but was leaking pus into the gum, inflaming the entire lower right hand side of my gums. The gum specialist had missed it completely. After that tooth was removed, and the surrounding area healed, my gums were fine for many years.

Two years ago, I developed a condition called [1]*lichen planus*. The entire inside of my mouth was inflamed and swollen – gums, tongue, the inside of my cheeks, all of it. I could not brush my teeth or eat anything except the blandest of foods. I also had a metallic taste in my mouth. It was torture.

After diagnosing the condition ("you have lichen planus"), my dentist sent me to an oral pathologist. The pathologist said there was no cure that he could guarantee and gave me two prescription drugs – one to treat problems caused by fungi, the other to deal with bacteria. Neither helped. I confirmed on the web what the dentist and the oral pathologist had said.

Concluding that medical science couldn't help, I starting searching the web for other suggestions. I found Seth Roberts's blog, which suggested taking flaxseed oil to improve gums. I tried it. My psoriasis improved but the lichen planus remained.

#### Source of Idea

In November 2011, the Drudge Report led me to [2]an announcement that UCLA scientists were working on a mouthwash to prevent cavities. [3]A comment said: "Xylitol is a plant sugar that kills s[treptococcus] mutans, and has been around for years as a toothpaste, mouthwash and gum. This is not new at all. Regular use of xylitol does all this, is cheap, and is NOT patentable. So, UCLA, this is nonsense."

I found a wealth of data on the web about xylitol, mainly research from Finland. The evidence showed that it killed bacteria that cause tooth decay and helped re-mineralize decayed teeth. The reports often mentioned that general oral health had improved in patients using xylitol. I decided to try it.

## **Method**

Most xylitol research has been done using gum that children chew after meals three or four times a day. I do not like to chew gum. I found other studies showing that taking a quarter to a half a teaspoon of the sugar (made from birch bark) four times a day is equally effective. I put the xylitol in my mouth, it melts, I swish it around my mouth until the saliva that it produces is quite extensive (60-90 seconds) and swallow it.

## **Results**

I started taking xylitol more than a year ago. After six weeks, the metallic taste was gone and my inner cheeks were noticeably less inflamed. After three months it was clear that my tongue was improving. Now I am sure that the lichen planus is in remission.

My most recent dentist visit was six months ago [October 2012], after I'd been using xylitol for ten months. My dentist and hygienist were astounded. They had been expecting the lichen planus to look the same as when they had seen it before (one year earlier). By then, however, my mouth had healed substantially.

That wasn't the only improvement. I'd always had what dentists call [4]geographic tongue- deep fissures that make a pattern on the surface of the tongue. It never bothered me. I never noticed it until a dental hygienist pointed it out to me (in horror!). I went from having a tongue full of fissures and "ruffled" around the edges to a tongue that was completely healed and looked better than it had in many years. My dentist could still find some of the lace-like effects that lichen planus produces on the inside of my cheeks. The geographic tongue is now [March 2013] completely gone, as is all the plaque on my teeth, the redness of my gums, and the soreness and inflammation I had experienced from the lichen planus on the inside of my cheeks, my hard and soft palate, and uvula.

## **Discussion**

When I told my dentist I was using xylitol, he knew what it was and was happy to see the improvement, but it had never occurred to him to suggest I use it. It is not a regular dental technique. I continue to use it, keeping jars of xylitol next to the kitchen stove and the computer screen (my two favorite haunts!) so that it is always at hand.

At the turn of the year (2012 to 2013) I emailed friends and family encouraging them to try xylitol. One friend started using xylitol by the end of January and in March told me about her progress. She has already noticed a great improvement in her gums. She said that she hadn't been perfect in dosing herself, sometimes forgetting a day, often only using it three times a day instead of four or five, but since she now had evidence that it actually helps, she was determined to take it more religiously. She bought xylitol gum for her children, putting xylitol mints in their lunch boxes.

---

Deidre (2013-04-12 07:58:46)

I have had geographic tongue all my life for which I was told there was nothing wrong and nothing to be done....really? Occasionally have had very bad bouts of painful lesions on the tongue which have recently been diagnosed as "burning mouth syndrome" for which I was told there is no cure...nothing can be done...really? It has (so far) almost completely abated using xylitol as part of regime by a dentist I found via comments on the PaleoHacks website. <http://www.drellie.com/Ellie-Phillips-My-Recommendations.php> The funny thing is I had just been using Xylitol while waiting to find a couple of her other recommendations. So far, the lesions are gone and the tongue is almost normal. Her regime is part of an overall oral health/cavity free goal. Everything can be purchased at a Walgreens. I may never need to see a dentist again.

Jon (2013-04-12 12:31:08)

I have geographic tongue too. I've been taking Zinc supplements with some success (going out and getting some sun seems to help some too). I wonder if it is a combination of not getting enough sun which caused a deficiency in Zinc which allowed some bacteria to over populate my tongue. I would have to do some research, but it is a hypothesis to start with! I also, haven't been drinking enough water which caused painful fissures on my fingers. I'll have to try the Zylitol too. I had been using it a little bit as I was doing Ellie Phillips regime, but I haven't been consistent with it.

Joe (2013-04-12 14:33:03)

Xylitol is great stuff. So is this book: Kiss Your Dentist Goodbye, by Ellie Phillips, DDS.

David Johnston (2013-04-12 16:56:45)

I suffered from gum disease and cavities from my teen year until a couple of years ago. The progression seemed to get worse when I moved to the USA in 1999. Then I switched dentists and they did (at some considerable cost to myself) an oral DNA analysis, which revealed a number of pathogens, including what they considered the 'bad' one which was an anaerobic bacteria that buries into the gums and does bad things. They gave me a bunch of antibiotics and 3 monthly

cleanings and the progression halted and the gums became less inflamed. Then I became aware of two bits of information, first about omega-3 and gum health from this blog, and secondly about the way anaerobic bacteria in the gut can't metabolize saturated fats (with downstream consequences). So switching my diet to (as far as is possible) saturated fats, with the exception of a shot glass of flax seed oil in the mornings (omega-3) and in the following two years my pockets improves and my gum inflammation went away entirely. The response from my hygienist has been most interesting - her: "I see you've been really on top of your cleaning and flossing". Me: "No, I rarely brush and never floss, I just followed up on some inflammation research and switched to saturated fats and some omega-3s in my diet.". She didn't want to hear any more and has stopped talking about it. I assume the mental dissonance was too great for her. My only regret is that I changed multiple variables at a time, so it's hard to know whether all or a subset of those interventions was the primary cause of the improvement.

Rlen (2013-04-13 02:41:14)

I always try to find some negatives on a good story. On this story I found it here: <http://www.thehealthyhomeeconomist.com/xylitol-not-as-sweet-as-its-cracked-up-to-be/> At least it raises some points about the manufacturing and sources for Xylitol that users should be aware of. Seth: Good idea, thanks.

Pauline (2013-04-15 06:17:04)

i have been reading about Xylitol for a while and even recently saw that a new sweet containing Xylitol was going to be launched in the UK stores to prevent teeth infections. After reading the article above, when we went away this weekend I thought I would try to find some Xylitol gum while I was out shopping. I found Smints which contain xylitol, I kept taking a small mint after a meal or a drink over the weekend. Friday I noticed a small ulcer causing irritation on the inside of my mouth. Without making any connection after popping Smints with xylitol on Saturday and one before bed, on the the drive back home on Sunday I noticed my ulcer had gone! completely. Now that was weird!

Pauline (2013-04-15 06:20:29)

Here is an interesting link from Dr Ellie Phillips page: <http://www.drellie.com/Elle-Phillips-My-Recommendations.php>

john (2013-04-15 22:54:41)

@Rein, thanks for your find. One should be aware of potential pitfalls. eg <http://www.xylitol.org/questions-about-xylitol> Is xylitol toxic to dogs? Many dog owners are aware that chocolate, coffee, and grapes are toxic to dogs, but are aware of the risk from ingesting the common natural sweetener, xylitol? Xylitol is a natural sweetener that is found in a variety of products, including chewing gum, toothpaste, mints, floss, candy, chewable vitamins, and sugar-free baked goods. While xylitol offers many health benefits to humans, it can be deadly to dogs and should not be fed to any pets. Ingesting 100 milligram of xylitol per kilogram of bodyweight may cause a rapid release of the hormone insulin, causing a sudden decrease in blood glucose (potentially life-threatening hypoglycemia, low blood sugar) for dogs. The drop in blood sugar occurs within 15 minutes, while the symptoms of hypoglycemia (vomiting, depression, loss of coordination, seizures, or coma are all possible symptoms) may be seen within 30 minutes after the dog consumes the xylitol-containing product. Exposure to higher doses of xylitol may possibly result in fatal liver failure in some dogs An cautionary note is sounded by this person who points to diet as a factor in out of balance oral cavity flora. [http://www.curetoothdecay.com/Tooth\\_Decay/xylitol\\_tooth\\_decay.htm](http://www.curetoothdecay.com/Tooth_Decay/xylitol_tooth_decay.htm)

## **Xylitol Research (2013-04-13 05:00)**

After learning about [1]the dramatic effects of xylitol on lichen planus, I looked around for a good summary of xylitol research and found [2]this:

Xylitol and other natural sweeteners were tested extensively in Finland as potential replacements for sugar during the early 1970's. A series of over 20 research reports (edited by Professors Arje Scheinin and Kauko Makinen) was published together in Acta Odontologica Scandinavica, Supplement 70, in 1975.

These investigations became known collectively as the “Turku Sugar Studies.”

Sweeteners were tested for their effects on dental and general health. The main trials involved the long-term substitution of either fructose or xylitol for sucrose (ordinary table sugar). This involved a huge cooperative effort between scientists and food producers. Separate fructose and xylitol versions of common food items were provided for the volunteers.

These trials (including blood and urine tests) established the safety of relatively large amounts of xylitol (often 70 grams per day or more) consumed regularly over a period of years. The xylitol group reported that xylitol-sweetened foods were comparable to the familiar sugar flavors.

The control group who consumed normal amounts of sugar continued to experience tooth decay, as would be expected. The fructose group also continued to have tooth decay, although progression appeared to be somewhat slower.

The results of a xylitol diet on oral health were dramatic. New tooth decay was practically eliminated. A therapeutic remineralizing effect was noted where the decay process was reversed. A parallel study achieved similar 90 % reduction in tooth decay simply by adding a small amount of xylitol, delivered in chewing gum after meals) to a normal (regular sugar) diet.

Here are some of the major findings of the Turku Sugar Studies:

- Xylitol can be incorporated into a wide variety of food items to directly replace sugar. More than 100 different products were made with xylitol.
- The taste and overall quality of the xylitol products was comparable, and in some cases superior, to regular sugar items.
- Substantial amounts of xylitol can be consumed regularly with no adverse health effects.
- No potentially damaging bacterial adaptations to xylitol occurred.

Especially early on, there were some instances of gastrointestinal discomfort and even osmotic diarrhea in the xylitol group. After a short period of adaptation (few weeks), these symptoms diminished and became no more frequent than in the other groups. A few individuals were more sensitive than the rest of the group. Even exceptionally high intakes of xylitol of over 200 grams in a day did not necessarily cause any problems. Discomfort was more likely to occur with liquid ingestion on an empty stomach.

It is not necessary to eliminate sugar to dramatically reduce tooth decay. Similar results can be obtained simply by adding a small amount of xylitol to a “normal” diet. Xylitol can provide a natural “antidote” for the damaging dental effects of ordinary sugar. A little more than a teaspoon of xylitol per day can provide amazing protection against tooth decay, when used in chewing gum after meals and snacks.

The last point is especially interesting. Xylitol doesn’t work because you eat less sugar. It works, apparently, because it stops/prevents something that sugar starts, perhaps adhesion of certain bacteria to teeth and gums.

[3]Here (video) is coverage of xylitol research in American mainstream media (in this case, ABC News). The useful information (about a xylitol study) is diluted by unhelpful information about xylitol in fruit and brushing and flossing.

Chris (2013-04-13 08:54:05)

Check out the sites of dentist Ellie Phillips– [ultimateoralhealthguide.com](http://ultimateoralhealthguide.com) and [Zellies.com](http://Zellies.com).

Mikael (2013-04-13 10:15:03)

Is this not widely known in the US? In Scandinavia we have been chewing xylitol gum for >30 years already because of these studies. Strange how it hasn't apparently spread. Seth: Yeah, very interesting. How much other really useful health information has failed to spread...

Rob (2013-04-13 13:06:19)

From my understanding xylitol destroys the biofilm of the bacteria - something our bodies immune system has a hard time doing. [http://www.scielo.br/scielo.php?script=sci\\_arttext&pid=S1806-83242013000100004](http://www.scielo.br/scielo.php?script=sci_arttext&pid=S1806-83242013000100004)

Tom (2013-04-13 14:51:32)

Mikael, except on blogs, Americans mostly hear about things that are under patent protection.

RT (2013-04-13 16:19:40)

Seth, I only ever chew Spry gum. Check it out. Seth: I got some Spry gum, too. But it is easier to use xylitol as a sweetener in tea and yogurt.

Bilbo (2013-04-13 18:11:46)

Just wondering if all the Ellie Philipps mentions could be spam on this post and your previous one? It would be easy to do if one had a Google alert for xylitol or something. So far we got her websites, her recommendations and her book under 10 comments? I've been using xylitol for about two months now 4x/day for around 2 tsp total a day. My gum bleeding didn't get any better at the time of this comment. Seth: Phillips has been by far the biggest American promoter of xylitol. You might want to try flaxseed oil for the gum bleeding.

Christopher Burd (2013-04-14 11:22:04)

"Seth: Yeah, very interesting. How much other really useful health information has failed to spread..." There's probably some network analysis to be done here. I imagine ideas from the centre (Harvard, say) quickly propagate everywhere, while ideas from the periphery (Univ. Helsinki) usually remain at the periphery. A few, but only a few, may make it upstream to the centre. I also have a theory that linguistic and political barriers (semi-permeable barriers, that is) may foster innovation by sheltering research and innovation communities from the forces of centralization.

## How Things Begin: LightSail Energy (2013-04-14 05:00)

[1]LightSail Energy is a Berkeley company that makes compressed-air energy storage devices. It was started in 2008 by Danielle Fong and Steve Crane. A year later, they got significant funding. When I think of energy storage, I think of batteries or flywheels or pumping water uphill. Use of a quite different technology intrigued me. Compressed-air energy storage is sometimes disparaged ("[2]a lousy way of storing energy").

Fong went to college (Dalhousie) when she was 12. She studied physics, computer science, math, economics, and

philosophy. When it came time to apply to graduate school, she decided she wanted to work on something important. Energy was important. She had read and admired

### The Limits to Growth

(1972). We are running out of convenient fossil fuels, she thought. We are running out of other things, too, such as arable land and aquifers, but solving these problems would require energy.

She decided to go to Princeton and study plasma physics, hoping to improve fusion technology. It was not what she expected. Her professors were brilliant, working on exciting things, such as compact magnetic confinement devices. In the background, however, “everyone’s jumping through hoops,” she says. Her professors were constantly writing grants. Their grant proposals were hard to understand. They went to “dark and foreboding” federal organizations, where they were misunderstood. Funding was cut “randomly and mercilessly” by forces outside the professors’ control. Among the graduate students, she found “a cadre” of interesting people but most of them, she thought, were overly concerned with finding something that had not been done before that meshed with a professor’s interest, in contrast to doing something important that they themselves found interesting. She also thought the other graduate students were not concerned enough with foundational questions. There were “too many good soldiers.”

Why rely on political whims I can’t control when I can create my own fortune and fund whatever research I want, she thought. If you were a mediocre physicist at any top graduate school, you could go to Wall Street and become a quant or go to Silicon Valley and build stuff. In 2007, she talked to Wall Street quants. “I was studying their derivative and option pricing theories,” says Danielle. “They assumed that price was given by an infinite series of small independent factors.” The independence assumption struck her as unlikely because much of the market relied on the same pricing theory. “This foundational assumption was poorly founded,” she says. It works, the quants said. The market collapsed three months later. Before it did, she decided to leave Princeton (after two years) and go to Silicon Valley.

She moved to the Bay Area and started couch surfing. During her first year there, she worked on several different projects with different cofounders and consulted for a variety of startups. Her “theory” was that she would learn how things work and find the right thing to do. She met Paul Graham and consulted for Y Combinator companies. She realized her “limiting factor” – what she needed the most – was a good co-founder. “Innovation is social,” she says. David McIntosh, a co-founder of Redux Games, “read [her] blog” and put her in touch with Max Crane. Max Crane is Steve Crane’s son. Steve was helping someone else start a video game company in Petaluma that needed a part-time programmer. Danielle was living in San Francisco at the time. Steve offered her the job and offered to drive her to Petaluma. “Every time we would drive up we would talk about different ideas,” said Danielle. “I had 50 different ideas for startups.” The one she kept coming back to, kept thinking about, was making a compressed-air-powered vehicle.

A friend, Nick Pilon, had asked her, “How far can you drive with the [solar] energy you could collect on a garage roof in a day? Is it enough to handle the average American commute?” To answer this, she had to provide a solution to the problem of making a practical, efficient vehicle. Batteries were a serious problem. They are expensive, heavy, and degrade relatively fast. Better energy storage would make a solar-powered vehicle more plausible. Several years earlier, her dad had sent her a link about a car that ran on compressed air. In that case, the CEO had been arrested for fraud. The car didn’t exist. However, MDI International in France had made some progress. (Well before [3]Peugeot.) She suggested this possibility to Steve. It could be very inexpensive and fast to refill. They could make a scooter. Steve got really excited. “I’d love to help you get this funded,” he told Danielle. Eventually he put in \$100,000 and joined Danielle as a co-founder. He left his other jobs to work with her.

The thermodynamics of air compression were discouraging. (So much so that in 2009 Berkeley researchers published [4]a paper arguing that a compressed-air vehicle would not be viable any time soon. “The BEV [battery electric vehicle] outperforms the compressed-air car [CAC] in every category. Uncertainty in technology specifications is considerably higher for CACs than for BEVs, adding a risk premium.”) When air is compressed, it gets hot – and heat may leak away. When air expands, it cools – and cold air provides little pressure. Danielle realized that you could solve both problems

by adding heat capacity to the air. This could be done by adding water (mist) during compression to absorb heat and using the stored heat to warm the air during expansion. If you could continuously supply the expanding air with heat, efficiency would increase from the low 20s to 70-85 %. Such an engine – driven by compressed air – would be cheaper, lighter, and more powerful.

They spoke to Ed Berlin (whom Steve called “the most brilliant inventor I know”). Coincidentally, Ed had been working on a compressed-air hybrid vehicle. They joined forces. Ed introduced them to Keith McCurdy, who advised them about financing. At a party, Keith told Vinod Kholsa, the venture capitalist, about the idea. This led to a meeting with Ford Tamer, one of Kholsa’s partners, who specialized in two-wheeled vehicles. He was more excited about what they could do for the power grid (by storing excess power during times of low demand). They had a whole PowerPoint presentation about vehicles. They scrapped it and made another one.

Steve and Ed built the first prototype. Danielle measured its performance. “Ed had a machine shop in his garage and knew how to use it,” says Danielle.

An especially important early hire (Employee Number 6) was Kevin Walter, who became Vice President of Development (developing the engine that compresses the air). He had previously worked for one of the top racing car teams in the world and had developed many race-car engines.

“We knew how to build engines in theory,” says Danielle, “but he had actually built them.” He knew, for example, where to drill holes so that oil would get to the right places. He also contributed a great deal of (psychic) energy, focus, and perseverance.

Being located in the Bay Area really helped. The Bay Area has many people (in the “low thousands”) who are good at making things. One LightSail employee (Liam McNamara) made a steam-powered automobile from scratch for Burning Man and won Junkyard Wars. Another (Keith Johnson) built electric cupcake cars and an electric pumpkin carriage. The Bay Area has “an atmosphere of possibility,” says Danielle. “The idea that when you have a great idea that is doable, you should do it. No one else is going to do it. Burning Man is a condensation of this. After people come, they feel they really can do something. And once they start, the deadline helps make sure they get it done.”

Vic (2013-04-14 14:57:13)

I'd be wary of any new energy company funded by khosla - his track record in the area is full of grandiose boasting followed by underperformance and bankruptcy.

Adam (2013-04-14 16:38:27)

People who go on to do great things often have a track record of failures. You can't predict the future by looking at the past.

## **Make Yourself Healthy Meetup: Underlying Ideas (2013-04-15 05:00)**

As I [1]blogged earlier, I've started [2]a Meetup group called Make Yourself Healthy. It is about doing better than expert advice. Doing better than taking prescription drugs for a problem, for example. The first meeting is Wednesday, April 24, 6:00 pm to 7:30 pm, in the meeting room of the North Branch of the Berkeley Public Library (1170 The Alameda).

I've found ways to improve on expert advice. I've found new ways to lose weight, sleep better, and so on. More to the point, many other people have done this. I [3]wrote about some of them for Boing Boing. The specific things they learned about how to be healthy – for example, [4]Dennis Mangan's discovery (or confirmation of someone else's discovery) that megadoses of niacin eliminated Restless Leg Syndrome – are not just important in isolation but also as part of a pattern: showing that such a thing is possible. Their solutions were vastly better than what their doctors recommended. This is counter-intuitive. We don't see this in other areas of life. We don't see amateurs building better cars than professionals, for example. But it's happening.

I believe two things about this:

1. The solutions will generalize. What Person X discovers improves her health turn out to help with other problems. I started drinking flaxseed oil because it improved my balance. It turned out to improve my brain function measured in other ways. And it turned out to improve my gums. I don't have lichen planus or geographic tongue, [5]which xylitol can cure, but I am taking xylitol because I believe (backed up by research) it reduces plaque.
2. The methods will generalize – what you do that finds a solution to Problem X is worth trying with other problems. With me, self-experimentation is an example. When studying my acne, self-experimentation showed how to better than my dermatologist's advice. Later, it helped me improve my health on [6]other dimensions (weight, mood, sleep, etc.).

The Make Yourself Healthy Meetup group can spread the solutions, the methods, and the knowledge that such a thing is possible. It can encourage people to try to improve on expert advice and help them do so.

## **New University of California: A Good Idea (2013-04-16 05:00)**

A California assemblyman named Scott Wilk has proposed a "New University of California" whose only purpose would be to provide certification tests – tests that show you have learned the material of this or that college class. Here is what [1]his bill says:

(1) The New University of California shall provide no instruction, but shall issue college credit and baccalaureate and associate degrees to any person capable of passing examinations.

(2) The New University of California is authorized to contract with qualified entities for the formulation of peer-reviewed course examinations the passage of which would demonstrate that the student has the knowledge and skill necessary to receive college credit for that course.

This is not online education. You can learn the material however you want – for example, by reading a book.

An unsigned New York Times editorial called the idea "[2]particularly ludicrous" but did not say why. I think it's a good idea. It gives students much more power: They can choose the learning methods and materials and times that fit them best (listening to lectures at work, for example), in contrast to the one-class-fits-all approach at almost all colleges. The cost in time and money will be much less than attending a typical university. The proposal helps employers because passage of these tests reflects a skill useful in many jobs: ability to learn on one's own.

Compared to an ordinary college degree (say, from Berkeley), a degree or certification from the New University of California fails to show that you did well enough in high school to get admitted to Berkeley. This could be remedied by showing your prospective employer a letter of admittance to Berkeley.

---

Alex Chernavsky (2013-04-16 06:26:05)

Thomas Edison State College (in New Jersey) seems to be doing this already: <http://www.nytimes.com/2013/02/25/education/25degree.html?pagewanted=all>

"We don't care how or where the student learned, whether it was from spending three years in a monastery," said George A. Pruitt, the college's president, "as long as that learning is documented by some reliable assessment technique."

Chuck (2013-04-16 06:51:21)

This is a great idea.

DZ (2013-04-16 07:22:48)

This needs to become a reality soon. I live in California and find no way to leverage my independent interests and studies in topics without having to jump through the hoops of accreditation as it stands now. You know all that stuff that people list under hobbies or interests, which shouldn't really be on a resume anyway? This would provide great incentive to get them accredited. So far I've felt helpless doing this without the investment of time and money that a formalized education track entails. As for the NYTimes editorial, it shows they're still living in the past. It's riddled with condescending vocab. It's not logical. Look at this statement: "At the same time, however, the Legislature is awash in bills that seem to assume that online education is the answer to the problem. One particularly ludicrous bill would create a "New University of California" that offered no instruction but would issue credentials to people merely for passing exams." The first sentence doesn't follow the other. This is not about online education, it's about offering no instruction and letting the student determine the best means to seek their instruction. It's a hit-job. I used to live in NYC and attended a college there, and I think it's in line with the usual wariness they show towards California education initiatives. Let them focus on their own backyard. But even the local power structure feels threatened: <http://www.dailycal.org/2013/04/01/bill-proposes-fourth-state-university-system/> At this point I feel there is no

recourse and it's a bit frustrating.

Sentinel (2013-04-16 07:49:59)

Great idea, Seth. Not only does the Times not give strong reasons for calling the "New" schools "ludicrous," but the editorial actually acknowledges that online courses "work well for highly skilled, highly motivated students" – is this not a benefit to California? Also, one might ask a more fundamental question about California's education system: that is, why colleges are used as warehousing for "large numbers of struggling students who lack basic competencies and require remedial education."

dearieme (2013-04-16 07:53:48)

This is like an extension and loosening of the classic Oxbridge system: the Colleges did the teaching and the University set and marked the exams. That system partially broke down with the arrival of science and its expensive labs. I have yet to see a sensible account of how lab teaching and similar "practical" activities will be provided for online-educated students : it should not be beyond the wit of man to cope, especially since the content and educational merit of practical classes have been so heavily diluted Since My Day. Perhaps that point generalises: O/L education may be a poor thing compared to what a university education should be - but compared to what it has widely decayed into, O/L education might be fine.

Paul N (2013-04-16 08:20:19)

The NYT has missed the point. The main idea here is to have an independent, \*objective\* examination to assess what the student has learned, not how they learned it. We already have a real world version of this, in every state and country - the driving test for your drivers licence. This test is administered by the state (though this service may be contracted out) and it doesn't matter how you learn, you have to pass the test. There are similar admissions tests for public (civil) service, bar associations and numerous professional groups. This is merely an extension of the same, well proven concept. As Dearieme alludes, they might want to exclude testing for certain areas that would have a large practical/laboratory component (physics, chemistry, engineering, medicine) though even those disciplines grade their students by examinations. I think we will see more of this, and I thoroughly support the concept.

Jonathan Shewchuk (2013-04-16 10:21:21)

Seems to me that the way to find out whether this idea is good or ludicrous is to do it and see how the market responds to the NUC's college credits. I think that would depend in part on how rigorous the examinations are. If all the NUC did were to provide a substitute for IQ tests that isn't illegal in hiring as IQ tests are, that could attract a lot of businesses. Seth: Yes, I think it might help a lot if the actual scores were provided, not just whether or not they passed a certain threshold. Perhaps along with a percentile derived from other people who had taken the test. Let the test taker decide if that info will be provided.

Robbo (2013-04-16 11:03:30)

Yes. It is basic specialisation / division of labour to unbundle accreditation from teaching. The best teachers and students will benefit enormously, the mediocre will have to find something they are better at.

Mehmet (2013-04-16 12:10:43)

I also think that it is a great idea but I am very much surprised by your last paragraph. I think the whole point of such a university is eliminating the need for an admittance letter to Berkeley. A student who did not work hard in high school should not suffer its consequences as long as he/she acquired the required skills for the job market. If high school knowledge is essential for the job market, it can also be objectively assessed. Seth: Maybe how well you do in high school has predictive power. In other words, maybe people who do better in high school do better at Job X than people who do worse. If that's true, and I were hiring for Job X, I'd want to take high school performance into account.

Brandon (2013-04-16 13:02:31)

Didn't this used to happen more often? My step-father (who is 79 years old) said he went to a junior college (San Mateo?) for two years. Transferred to Cal and attended one year then took the engineering test, passed and went to work for the State of California for the next 40 years without having graduated from Cal.

Nancy Lebovitz (2013-04-17 09:53:13)

I'm reading \_Shadow Scholar\_ which is about cheating and education— the author writes papers for other people. The stakes are so high that a credentialing organization had better administer the test in person with strict ID requirements. Seth: At one point, while I was teaching at Berkeley, I was worried about cheating on a test. I wanted a larger classroom for the test so that the students could sit further apart. The chairman of my department told me: "We're not in that business" (of preventing cheating).

AI (2013-04-18 13:24:47)

Three comments: 1. The bill says that the NUC is authorized to contract with "qualified entities". It's important that these entities be selected objectively and not because, say, they have funded someone's political campaign. 2. There are at least a couple other areas where the government currently provides a certification exam but does not require government training, per se: building contractor exams and real estate broker exams. 3. Part of the value of a UC education has long been that it is selective. Not just anyone gets in. And the NUC could well be as selective as the existing UC, using the same types of criteria as current UCs do. Or, it could use a more or less selective set of criteria. It need not abandon application selectivity altogether. Seth: The UC system is not very selective at the undergraduate level, at least in terms of graduation. Many students transfer in from junior colleges, which are not selective at all. In any case, the notion of needing to pass a threshold in order to take a test that measures what you want to measure doesn't make a lot of sense. If you want to find good plumbers, for example, it doesn't make sense to prevent anyone from taking a test of plumbing skill. Your Point #3 does bring out what a big change a test-centered "university" could cause.

Richard Gay (2013-04-20 08:01:40)

This is indeed the best thing since sliced bread, if implemented properly. It makes more sense to have a strong industry input component – the companies that will do the hiring should be able to design a set of test criteria in order to get exactly the knowledge / skill set they want in an applicant. Passing a certain set of tests would take care of most if not all of the technical component of the interview process; the remainder would be personal compatibility and other soft factors which would be more particular to the hiring company. There is no reason for the process of learning to be limited in any way, by arbitrary selectivity for entry, ability to pay, or any other way. It's time to take the universities out of the credential business. Their costs are too high.

### **The Jenijoy La Belle Tenure Case at Caltech (2013-04-17 05:00)**

Jenijoy La Belle is a Professor of English at Caltech. Her tenure case, which started in the 1970s, is the main topic of [1]this interview. Because of one person – Robert Huttenback – she was at first denied tenure. Amazingly, she managed to get tenure anyway. In the middle of the fight, which promised to become very embarrassing to Caltech, Huttenback became Chancellor of UC Santa Barbara.

Here is a related story from [2]another interview:

One day on a Saturday or Sunday, I was in Baxter [Baxter Hall of Social Sciences and] picking up my mail upstairs. There was nobody else there but Huttenback and a young Turk— a young professor of economics, I guess, who is now of course a famous full professor somewhere, perhaps even retired. They were in the office that Jenijoy was going to have and next to it was the men's toilet. And they were talking about playing a joke. The goal was to make the situation as uncomfortable—more than uncomfortable, offensive—for Jenijoy as possible. And I will not—I remember exactly what they were doing, but it is so crude that I will not tell you.

Here is one of La Belle's comments:

In 1982, someone sent me a clipping from the Santa Barbara News and Review, from a column that sounded more like gossip than news. But it simply began: "Even in UCSB circles familiar with Chancellor Robert Huttenback's perquisites of power, the situation has caused comment. Why do university cars and drivers transport Freda Huttenback, his better half, on personal business? Campus employees, from maintenance to clerical workers, tell us of receiving a Xeroxed map to the Huttenbacks' home and directions to chauffeur her wherever she asks. These trips have reportedly included visits to a Ventura chiropractor. "Huttenback defends the practice by calling his wife a consultant to the university on interior design matters, saying that she occasionally needs a university car and driver for decorating business. Huttenback first denied he or his wife ever used the car for personal errands: 'Whoever told you that must be someone I fired,' was his reply."

Huttenback was eventually convicted of fraud. He defends himself [3]here .

## **Lose Smell, Lose Weight: Evidence For the Theory Behind the Shangri-La Diet (2013-04-18 05:00)**

A friend of this blog writes:

What prompted me to try SLD: When I first went paleo I dropped 30 pounds with no exercise or food restriction, but my weight has been stable for about a year. In January and February [2013] I went through a bad allergy spell, with my nose congested all the time. I dropped six pounds in that time. When the seasonal allergy went away, the weight came right back. Calories without smell suddenly look like a big factor.

[1]Here is a paper about the theory behind the Shangri-La Diet.

1. <http://media.sethroberts.net/about/whatmakesfoodfattening.pdf>

John (2013-04-18 06:37:06)

Seth, Have you seen this article about smell and weight loss? [http://www.nytimes.com/2009/06/18/fashion/18skin.html?\\_r=0](http://www.nytimes.com/2009/06/18/fashion/18skin.html?_r=0) Also, It would be very interesting to hear an update on your current implementation of the Shangri-la diet. Do you do oil or sugar? Has your weight stayed low? Do you see other health benefits related to the weight loss? -JW Seth: I noseclip a bunch of foods, including cheese and yogurt with honey and ground flaxseed. I'm a lot more muscular than I used to be so weight comparisons are misleading. I didn't see health benefits from weight loss - I wasn't particularly fat to begin with.

dearieme (2013-04-18 13:46:57)

O/T <http://www.telegraph.co.uk/news/uknews/crime/10001149/Scientist-jailed-for-faking-medicine-test-results.html>

Kaleberg (2013-04-19 20:24:32)

My sister is anosmic. She tries to watch her weight. She's had some success, but she has the same challenge as every one else I know limiting what she eats. Lack of smell might help some in some situations, but I know at least one counterexample.

A friend of this blog (2013-04-20 07:06:40)

Kaleberg, it seems to be different if the loss of smell is temporary versus a sense you never had. The weight loss happened over three weeks. Six pounds in three weeks would be pretty good for a weight-loss plan. It was remarkable for an unintentional loss. If I didn't read this blog I probably wouldn't have made the connection. Coincidentally, my young daughter and adult sister are anosmic as well. My sister has generally been slim. It will be interesting to see how my daughter's anosmia affects her weight in adulthood. I am teaching her to practice personal science, so we may be getting some reports from her in a decade or two.

## **Is Red Meat Dangerous? (2013-04-19 05:00)**

[1]A recent paper from the Cleveland Clinic reports more than a dozen studies that add up, say the authors, to the conclusion that red meat and other meats cause heart disease at least partly by increasing trimethylamine-N-oxide (TMAO), which is made from carnitine by intestinal bacteria. Meat, especially red meat, is [2]high in carnitine.

The results were reported all over the world, including [3]the New York Times. There are several reasons to question the conclusion:

1. The association between meat and heart disease is weak. An [4]epidemiological paper from the Harvard Nurses Study found estimated reductions in heart disease on the order of 10-20 % when a "healthy" food was substituted for meat. Conclusions about causality (eating Food X causes Disease Y) based on the Harvard Nurses Study have predicted wrongly over and over when tested in experiments, so even this weak association is questionable. [5]A 2010 meta-analysis found no association between red meat consumption and heart disease. The absence of any correlation is surprising because red meat is widely believed to be unhealthy. People who eat more red meat would presumably do more other "unhealthy" things. (Perhaps the error rate of the underlying epidemiology is high. Errors push associations toward zero.)

2. Within the Cleveland paper, the associations between carnitine and TMAO and heart disease are weak. For example, people with the greatest sign of heart disease ("triple" angiographic evidence of heart disease) had only slightly more carnitine in their blood (about 15 % more) than people with the least sign of heart disease. (Maybe it is peak levels of carnitine rather than average levels that matter.)

3. [6]A 1996 epidemiological study (via [7]Chris Kresser ) that looked at the correlates of various "healthy" habits among people especially interested in health (e.g., they shop at health food stores) found no detectable effect of be-

ing a vegetarian. For example, vegetarians had the same all-cause mortality as non-vegetarians. Other factors were associated with reduced mortality, including eating wholemeal bread daily and eating fruit daily. This study looked at a large number of people (about 11,000) for a long time (17 years), so I consider the lack of difference (vegetarians versus non-vegetarians) strong evidence against the idea that modest amounts of meat are harmful. (And I am going to start eating wholemeal bread in small amounts.)

I don't dismiss the paper. Among people who eat more than modest amounts of meat, there may be something to it. Now and then epidemiology turns up a powerful risk factor – something associated with a risk increase by a factor of 4 or more (people at a high level of the risk factor get the disease at least four times more often than people at a low level of the factor). History shows that such correlations are likely to tell us something about causality. With weaker correlations (such as the correlation between red meat and heart disease), it is much more a guessing game.

To me, the important clue about heart disease is that it is very low in both Japan and France, much lower than in countries with high rates of heart disease. The two countries that have little in common besides the fact that in both people eat a lot more fermented food than in most places. In France, they drink wine, eat stinky cheese and yogurt. In Japan, they eat miso, pickles, and natto. Maybe fermented food protects against heart disease.

---

zip zop zoop zim zat zed zak (2013-04-19 05:09:42)

" ... the telling fact about heart disease is that it is very low in both Japan and France, much lower than in countries with high rates of heart disease. " ??? Seth: I don't understand your point or question.

Mark (2013-04-19 06:51:54)

From my perspective, the authors of this study immediately lost all credibility based on their interpretation of the results from the recent Med diet trial... It was either a very disingenuous way to support their own conclusions, or they have no idea how to interpret randomized trials. I suspect it was the former. In that trial, BOTH groups were counseled to avoid red meat, so it was in no way a randomized test of the red meat hypothesis like the Cleveland Clinic authors contend.

Paul N (2013-04-19 07:42:00)

The fermented foods eaten in Japan and France also have lots of vitamin K2, which is known to help prevent heart disease. Of course, eating fermented foods also helps with gut flora, b vitamins and a few other benefits. [1]Paul Jaminet has written a good response to that last study on TMAO. The major standout, to me was that once they gave the participants antibiotics, to kill their gut bacteria, and then "rebuilt" their gut flora, the TMAO levels increased \*seven fold\* compared to before. So is the problem carnitine, or disordered gut bacteria? The French and Japanese use less antibiotics and, from the fermented foods, have much better gut bacteria (and both eat far less "factory foods") Small wonder they are much healthier.

1. <http://perfecthealthdiet.com/2013/04/lessons-from-the-latest-red-meat-scare/#comments>

Vic (2013-04-19 10:25:20)

Paul N: from where do you get the idea that the French and Japanese use less antibiotics? You must not know much about those countries. Also, Seth, why change your diet to include wholemeal bread? whatever you've been doing till now appears to be working given you lowered your coronary calcium score fairly dramatically...

Alex Chernavsky (2013-04-19 16:30:19)

Here's an interesting article about an island in Greece where the inhabitants typically have very long lifespans: "[1]The Island Where People Forget to Die"

1. <http://www.nytimes.com/2012/10/28/magazine/the-island-where-people-forget-to-die.html?pagewanted=all>

Kas Thomas (2013-04-19 18:40:22)

Agreed, the association with cardio disease is weak at best. The association with colorectal cancer is much stronger, but even there, you have a lot of confounding variables (potentially) to consider: method and degree of cooking, fat content, etc. I'm not worried about the carnitine nonsense so much as I am about heterocyclic amines, on which the literature is vast. HCAs are scary. Japan is a country of skinny people. France not quite so much, but compared to the U.S., French are lightweights. Low BMI is the route to low CVD. Seth: I explain the thinness of people in Japan and France as partly due to a gourmet strain – good taste in food. They eat little "ditto food". There are few McDonald's in Tokyo, for example. I think this goes along with a taste for fermented food.

Todd (2013-04-20 15:48:16)

I think that Chris Masterjohn wrote the most interesting dissection of this TMAO study here: <http://www.westonaprice.org/blogs/cmaterjohn/2013/04/10/does-carnitine-from-red-meat-contribute-to-heart-disease-through-intestinal-bacterial-metabolism-to-tmao/> Seth: I didn't link to this discussion because I disagreed with its main points. For example, Chris says that fish has much more TMAO than meat. But since TMAO is made from the carnitine in meat, this does not mean that fish causes more TMAO inside the body than meat – which is what matters. Another example is that Chris complains that the mice experiments involved meat dosages that resembled eating 100 steaks per day. He said that was unrealistic. Because of the vast lifespan differences between mice and people, I don't dismiss this experiment. I don't think it is obvious what the "equivalent" number of steaks is.

## **Shangri-La Diet Success, Including Better Sleep (2013-04-20 05:00)**

Greg Pomerantz writes:

Over the Thanksgiving [2012] holiday, I suggested to a relative, Richard, that he try the Shangri-la Diet. At the time I had heard about it but did not know anyone who had tried it. I did not have any particular reason to think it would work, but since Rich had tried a number of other diets (including low carb, which he is still following for the most part) I thought it would be worth a shot.

He started the diet over the Thanksgiving holiday and has kept it up since then with a few breaks. He lost 13 pounds in the first month and another 6 pounds over the next two weeks. Altogether he lost a total of 32 pounds over the 16 weeks following Thanksgiving, an average of 2 pounds per week. During this period, he traveled a fair amount and was not able to maintain the diet every day. However, he reported that one of his favorite things about the Shangri-la Diet is how easy it is to restart after a lapse. He began using extra light olive oil but has switched to walnut oil.

There were two surprising results other than the weight loss (which I think is exceptional in its own right). First, his blood sugar control has improved, even compared to the low carbohydrate diet he was (and still is) consuming. Second, he has been sleeping better at night due to a reduction in his nighttime appetite. I believe the two may be related – one of his medications for type 2 diabetes greatly increases his appetite and causes weight gain. He has been using much less of that medication because of his improved blood sugar on the Shangri-la Diet. Therefore, reduced appetite from the diet plus a reduction in an appetite-increasing medication results in lower nighttime appetite and therefore better sleep.

---

Nancy Lebovitz (2013-04-20 11:49:27)

Off topic: [1]Knitting stretches– check the comments, these stretches have made considerable improvements for some of the posters, including some with pain that their doctors weren't able to help. I don't knit and don't have major hand problems, but the stretches made my hands and lower arms feel quite a bit better.

1. <http://knitfreedom.com/being-a-knitter/top-5-stretches-for-knitting-pain-relief>

Jim breed (2013-04-21 19:03:14)

Any info on why he changed from ELOO to walnut? Seth: To get more omega-3, I'd imagine.

manish m (2013-04-23 13:15:35)

What about the coconut oil? How does that compare to walnut?

dearieme (2013-04-21 16:13:52)

There's a sort of mock table salt available with potassium replacing the sodium. Is that worth taking? If so, how much per day?

Ashish (2013-04-23 11:27:45)

Does the quantity of good bacteria vary by fermented food type and manufacturer? (Surely it must.) Do you have a list of "Top 20" commonly available fermented foods and brands? I know the information is sprinkled throughout the blog. To ask it another way, are Yakult, natto, and other "exotic" fermented foods really worth it, or can I just eat some pickles and sauerkraut? Seth: No I have no such list. I try to get a range of bacteria. The bigger the range the better.

Ed O'Brien (2013-04-27 12:53:43)

Hi Seth, Have you seen this article? : [http://www.nytimes.com/2013/04/08/health/study-points-to-new-culprit-in-heart-disease.html?smid=fb-share&\\_r=1](http://www.nytimes.com/2013/04/08/health/study-points-to-new-culprit-in-heart-disease.html?smid=fb-share&_r=1) & might work into your idea about the importance of bacteria and how fermented foods are healthy.

## Oral Rehydration Therapy For Diarrhea (2013-04-22 05:00)

Oral rehydration therapy (ORT) is given to people (usually children) suffering from diarrhea, which before ORT was often fatal. It is very simple: The sufferer drinks water with sugar and salt ad libitum (as much as they want). You probably haven't heard of ORT – at least, I hadn't. Everyone has heard of antibiotics. Yet "[1]in 10 years [ORT] saved more lives than penicillin had in 40." Infant diarrhea was once (and may still be) the main cause of death in poor countries.

[2]A history of its discovery supports several things I've said on this blog. One is Thorstein Veblen's point about the disdain among professional scientists for useful research:

ORT might also have been developed long before 1968 but for the attitudes of the dominant medical establishment toward practical experimentation, which the Cholera Research Laboratory and the National Institutes for Health shared. Nalin believes that "the people at the lab ... got kudos for the extent to which [their] work was not practical. As soon as it became practical it was discarded like a soiled towel—it was too common, too hands-on... so the prestige went to people who measured trans-intestinal fluxes or electrical currents".

No one who has attended an elite law school, medical school, or graduate program in education will be surprised by this.

Another is the great resistance among the medical establishment to cheap and effective solutions:

The formidable and persistent ignorance of the Western medical establishment, which continues over twenty-five years after the discovery of ORT, is phenomenal. While its refusal to advocate ORT may be

due in part to the notion that ORT is only necessary for people in the developing world, its actions appear to be driven also by financial considerations. Most hospitals do not train physicians in the use of ORT since they have no financial reason to do so. [I think "since" overstates what is known – Seth] The use of intravenous therapy, which often involves keeping a dehydrated child overnight, assures [greater] insurance reimbursement. Sending children home with ORT would [reduce] profits. Furthermore, recent studies show that diarrhoeal illness among the elderly may incur even greater health care costs that could also be reduced by the use of ORT. At a time of heated discussion about cost-containment in health care, it seems all the more ironic and egregious that a superior, cheap, and proven therapy [fails to replace] a far more expensive one. Estimates based on the cost of hospitalizations and physician visits suggest that ORT could save billions of dollars annually.

As an example of the resistance of American doctors to a better therapy, an ORT researcher, who had used it on Apache reservations in America, told this story:

I had an anthropologist friend who adopted an Apache child from the [Arizona] reservation where we were working. He used to be the anthropologist on the reservation. And then he [left the reservation and] went to Arkansas to teach and the Apache child came down with severe diarrhea and he called me up and he said desperately, "Look, my son's in the hospital and they're giving him all sorts of intravenous fluids. The diarrhea's not stopping, he's losing weight, they're not feeding him. I know that you did this work in Arizona [on the reservation] and it didn't look like that. . . . Would you call this professor of pediatrics and just collegiately talk to him?" So I called up the professor and told him that in our experience with Apache children this is what we found and here's the publication and so on. And he said to me, "Doctor, doctor, our [Arkansas] children are not the same as your [reservation] children". He was treating an Apache child from the same reservation.

Shades of Downton Abbey (where Lady Sybil died because a London doctor was listened to instead of a rural doctor).

Morex (2013-04-22 08:15:22)

ORT in Mexico is very popular and fully endorsed by the government. It's even in our law. Here's the Official Mexican Norm for Children's Health (In Spanish). <http://www.salud.gob.mx/unidades/cdi/nom/031ssa29.html> If you go to a public clinic you can get packets with a powder to prepare serum at home, for free. It's called Suero Vida Oral (Oral Life Serum) and it saves countless lives a year. Over the years, since I have memory, there have been very aggressive health marketing campaigns. Now everyone knows where to get the serum and how to use it. Here's a PDF of a flyer you'd find in public elementary schools and clinics. [http://www.promocion.salud.gob.mx/dgps/d\\_escargas1/programas/1\\_postal\\_vida\\_suero\\_oral\\_dgps.pdf](http://www.promocion.salud.gob.mx/dgps/d_escargas1/programas/1_postal_vida_suero_oral_dgps.pdf) It's a surprise to me that this hasn't been implemented in other countries. Here's

Morex (2013-04-22 08:19:26)

Addendum. Here are a couple of TV commercials. This one is a 30 seconds cartoon with a cherished Mexican character, Cantinflas. This aired in the 80's He explains how to use the serum and how it can save a kid's life. <http://www.youtube.com/watch?v=jY9hVRknI3M> Here is a 2:30 minutes commercial with a little more info. This one is from the 90's. <http://youtu.be/LF8g8oVOQm4?t=7s>

Dena Shunra (2013-04-22 08:23:30)

FWIW, I came across oral rehydration therapy in a BBC World Service broadcast. Noticed it immediately, because the long words were in such stark contrast to the simple meaning: "drink water. With salts/sugar melted in." I'm pretty sure this was more than a decade ago.

Paul (2013-04-22 08:53:57)

Dena, it is not quite that simple. The ratio of salts is important. Water on its own won't work. If there is too much sugar it will make the diarrhea worse. Too much salt is really bad. For instance, sports drinks have too much sugar and won't work. When I had diarrhea recently I just drank Pedialyte. It is interesting to note that they don't seem to make anything targeted at adults although as far as I can see there is nothing child-specific in Pedialyte.

Nancy Lebovitz (2013-04-22 09:04:43)

I've heard of it now and then for twenty years or more, and I've spent my life comfortably in the middle Atlantic of the US. I'm not sure whether either of us has unusually weird information resources.

Nancy Lebovitz (2013-04-22 10:20:33)

[1]A poll about whether people have heard of ORT. 10 yes, 1 no. I'm pretty sure my readers are mostly American and European. My tentative theory is that science fiction readers (me and probably a large majority of my commenters) are likely to pick up odd facts, even before the internet. One commenter mentioned that Gatorade and Pedialyte are well-known remedies.

1. <http://nancylebov.livejournal.com/575641.html?nc=3#comments>

Lauren Rosenthal (2013-04-22 12:37:36)

Seth, would it be possible for you to have a facebook link after each post so that reposting your blog posts would be easy? Lauren

Adam (2013-04-22 15:06:08)

I dispense ORT regularly as a pharmacist, but I often see what you mention too - doctors prescribing IV fluids, IV antiemetics, etc. Although we haven't had a case at my place of work, a local Chinese pharmacist told me she has seen Dystonias (uncontrollable muscle tightening, similar to a seizure) in a child treated with these anti-nausea medications. Sometimes simple is better.

Jim (2013-04-22 19:04:20)

Seth, Your comment about medical and law schools reminded me of a conversation I had with one of my law school professors. He had gone to an Ivy League law school, and then into private practice (big NY law firm) for three years. He said that if he had stayed at the law firm any longer, his resume would have been "tainted," and it would have been difficult for him to get a job as a law professor.

## **Cuban Data Refute Mainstream Health Beliefs (2013-04-23 05:00)**

[1]A new BMJ paper looks at Cuban health before and after the economic crisis of 1991-1995, when the Cuban economy nose-dived. There wasn't enough gasoline for cars. so bike riding greatly increased. In addition, people ate less. What effect did these changes (more exercise, less eating) have on health?

You know what is supposed to happen: Better health. Walter Willett, the Harvard epidemiologist, wrote [2]a commentary about the study that concluded "The current findings add powerful evidence that a reduction in overweight and obesity would have major population-wide [health] benefits." In other words, Willett said that what happened supports conventional beliefs.

But it didn't. In several ways, what happened contradicts conventional beliefs.

1. A popular belief is that exercise causes weight loss. However, the percentage of "physically active individuals" doubled from 1985 to 2010 (from about 30 % to 60 %). In spite of this, the prevalence of obesity considerably increased (from about 13 % to 18 %) at the same time. Apparently exercise is considerably less important than something else. I have never heard a public health advocate say this.

2. A graph showing rates of heart disease, cancer, and stroke (the three main killers) over the period showed no change in rates of cancer and stroke. In spite of big changes in both exercise and obesity. The rate of heart disease stayed constant during the period when obesity went down. It steadily dropped during the period of time when obesity went up. Apparently the factors that control obesity and the factors that control heart disease are quite different (contradicting the usual view that exercise reduces both).

3. There is no simple connection between diabetes and obesity. During the economic crisis, when the prevalence of obesity went down by half (from 15 % to 7 %) and exercise greatly increased, the prevalence of diabetes slightly increased. Only after the crisis did the usual correlation (more obesity, more diabetes) emerge.

4. The only lifestyle factor to have its conventional effect: smoking. When you stop smoking, you gain weight is the usual belief (which I also believe). The data definitely support this connection. A huge reduction in the fraction of people who smoke (from 30 % to 10 %) did not reduce cancer but did coincide with a great increase in obesity.

5. Cubans are doing something right, as shown by the considerable decrease in heart disease and diabetes deaths. Apparently they are also more health-conscious, as shown by much higher rates of exercise and much lower rates of smoking. (Assuming that cigarettes did not become too expensive.) They are getting fatter, too, but apparently that is less damaging than we are told.

Willett and the authors of the study look at subsets of the data and use theories about "time-lag" to draw reassuring conclusions. In fact, large portions of the data are not easily explained by conventional ideas, as I've shown. You can look at the data many ways, but to me the study makes two main points. 1. During a period when everyone was forced to do what doctors recommend (exercise more, eat less), health did not improve. 2. During a period (post-crisis) when obesity got steadily worse, health improved (heart disease rates went down, cancer stayed the same, diabetes mortality went down). Cuba is too poor for the improvement to be due to better high-tech modern medicine. Taken together, these findings suggest we should be more skeptical of what we are told by doctors and health experts such as Willett.

---

Koanic (2013-04-23 06:37:13)

Nice. There's no animal study that shows a negative health effect from smoking. The global epidemiology on smoking is totally contradictory to the mainstream view. Clearly what the Cubans were eating was more important than how much.

Ed M. (2013-04-23 06:55:33)

Guys, I would take any study coming from Cuba with a grain of salt. Having lived in Miami and knowing many refugees, including a nurse, the situation there is deplorable beyond words... Scabies being spread in hospital, dentists requiring bribes like soap before working on you... It is an experience so far removed from our (dare I say it) privileged existence that might a

well be mars. Potemkin study. -Ed

Alex Chernavsky (2013-04-23 08:37:59)

Koanic wrote, "There's no animal study that shows a negative health effect from smoking." This Wikipedia entry suggests that there *are* such studies: [http://en.wikipedia.org/wiki/Animals\\_and\\_tobacco\\_smoke](http://en.wikipedia.org/wiki/Animals_and_tobacco_smoke)

Matt Weber (2013-04-23 09:34:20)

I wonder if the Cubans were exercising more because they were getting fatter.

arbitrage (2013-04-23 10:08:24)

Seth - I could not parse two data points you laid out. I have not read the original study. You say in #1 that "In spite of this, the prevalence of obesity considerably increased (from about 13 % to 18 %)" and then you say in #3 that "During the economic crisis, when the prevalence of obesity went down by half (from 15 % to 7 %)". Thanks! Seth: Look at the dates associated with the two sets of percentages (13-18 and 15-7). They are quite different.

Tuck (2013-04-23 12:36:44)

Ed M.'s got a good point, but there's a related, and larger one: communist governments are famous for faking statistics to make themselves look better. The CIA learned the hard way that trusting the official statistics coming out of the USSR was not a wise course of action. This one deserves a far larger grain of salt than Willett's work usually requires! "...But Raúl Castro has demanded more accurate information since he stepped in for Fidel Castro, his ailing brother, in July 2006 and officially became president in February last year. "In a speech to parliament in 2006 he attacked shoddy data as "preventing us from knowing what has been done and what remains to be done"." If Cuban statistics stink, you'd think Castro would know... <http://havanajournal.com/business/entry/national-statistics-office-in-cuba-re-leases-more-business-and-economic-data/>

Koanic (2013-04-23 18:23:58)

"This Wikipedia entry suggests that there are such studies:" As far as I can tell from the entry, I've seen all or nearly all of the studies listed. Painting tar on skin is not smoking. The only tumors that developed were in breeds that develop tumors everywhere, and due to tobacco's stimulative effects on blood flow the tumors were somewhat larger in the lungs. Tracheotomizing dogs is obviously not going to improve their life expectancy. There were other handling problems with studies. Basically as long as the smoke didn't reach asphyxiating levels, the animals who smoked always lived longer than the controls. Feel free to refute by providing one pdf that shows a clear negative result for smoking without cheating in some ridiculous way.

Alex Chernavsky (2013-04-23 19:14:49)

Koanic - I'm not sure where this is going. Do you believe that it's a myth that smoking causes health problems in humans? If it's not a myth, then why wouldn't you expect smoking to cause health problems in animals?

Koanic (2013-04-23 19:57:00)

I don't know why you need to know where this is going to provide the pdf requested, if you disagree with what I've written so far.

Alex Chernavsky (2013-04-24 04:35:10)

I don't disagree so much as I think the implied idea (that smoking is harmless) is very... unusual. I thought that the harmfulness of smoking was about as well-supported as any medical hypothesis can be (and consistent with my own personal experience of observing chain-smoking relatives dying from emphysema and cancer). I was asking you to provide more information. I have no PDFs to post.

Koanic (2013-04-24 04:59:41)

"I thought that the harmfulness of smoking was about as well-supported as any medical hypothesis can be" Now you have reason to suspect that it is not, and apparently that's as far as it will go with you, which I'm fine with. Anyone else who wishes to provide a pdf proving causal link is welcome to do so.

Alex Chernavsky (2013-04-24 05:02:07)

"Now you have reason to suspect that it is not'. Actually, I don't – as you haven't given me any reason. Not any *substantial* reason, anyway. I thought there might be something relevant on your homepage, but it all seems to be dedicated to blog posts about picking up women.

Koanic (2013-04-24 08:27:54)

Then apparently you don't understand the difference between correlation and causation.

Adam (2013-04-24 15:20:05)

Interesting read here: <http://smokescreens.org/lungcancer.htm> "Based upon what the media and anti-tobacco organizations say, one would think that if you smoke, you get lung cancer (a 100 % correlation) or at least expect a 50+ % occurrence before someone uses the word 'cause.' Would you believe that the real number is < 10 % (see Appendix A)? Yes, a US white male (USWM) cigarette smoker has an 8 % lifetime chance of dying from lung cancer but the USWM nonsmoker also has a 1 % chance of dying from lung cancer (see Appendix A). In fact, the data used is biased in the way that it was collected and the actual risk for a smoker is probably less." Haven't fact checked the numbers, but if true, it is interesting.

dearieme (2013-04-24 16:22:44)

1) "I thought that the harmfulness of smoking was about as well-supported as any medical hypothesis can be": well, as well-supported as it can be in the inevitable absence of controlled experiment on humans. 2) Eightfold, Adam; wouldn't it depend on how much he smoked? And for how long? The rule I've seen quoted says that the 25-a-day smoker increases his risk of contracting lung cancer 25-fold. (Or perhaps that refers to his risk of dying of lung cancer: my memory isn't clear on that.) How many years he has to smoke to qualify for "the rule of 25" also escapes my memory. But the lack of any allusion to the extent of smoking in your quotation makes me leery of it. And as for its source, I just guffawed at "It first appeared on the Journal of Theoretics".

Koanic (2013-04-24 19:20:38)

"well, as well-supported as it can be in the inevitable absence of controlled experiment on humans." False, it is not established by controlled studies in animals, as I have stated. For example, it could be that there's something generally carcinogenic in the USA, and the bloodflow stimulating effects of tobacco merely grow the tumors faster in the lungs compared to other parts of the body. Or that tobacco alone doesn't cause cancer, but only in combination with some aspect of the American diet. It could be like sunshine and melanoma - if in other places in the world people get lots of sun without getting skin cancer. There is no way it is a very well established medical fact, UNLESS someone can provide a simple animal study proving causation.

dearieme (2013-04-25 02:01:09)

"False, it is not established by controlled studies in animals, as I have stated." Don't be silly, nobody gives a hoot whether smoking would kill animals. The question is whether it kills people, and the only evidence that would be conclusive would be controlled experiments on people. Since those can't be done, people have to settle for the inconclusive but highly suggestive results of epidemiology.

dearieme (2013-04-25 02:03:19)

While we're on the subject of your silliness, Koanic, why the parochialism of your use of "USA" and "American": aren't you taking American Exceptionalism a little far?

Koanic (2013-04-25 09:57:45)

You're wrong. Cancer is a very straightforward disease to induce. If cigarettes don't give cancer to monkeys or mice, they won't to humans either. Seth: How do you explain the strong association between smoking and lung cancer? With high rates of smoking (e.g., 2 packs/day) the association is very strong (compared to other epidemiological associations). With low rates of smoking (e.g., a cigarette/day) it is entirely possible that smoking is beneficial, as [1]this book argues.

1. <http://www.amazon.com/The-Health-Benefits-Tobacco-Smokers/dp/9962636434>

dearieme (2013-04-25 15:10:35)

I suppose that these would have to be American monkeys and US mice?

Alex Chernavsky (2013-04-25 18:29:26)

"If cigarettes don't give cancer to monkeys or mice, they won't to humans either." Apparently, arsenic causes cancer in humans but not in animals. See, for example: <http://www.ncbi.nlm.nih.gov/pubmed/8891790>

Koanic (2013-04-25 19:26:09)

If I recall correctly, the cancer smoking connection looks compelling when you take a naive look at American epidemiology snapshot, but fails to hold when looking at time series or international comparisons, as you partially discovered with Cuba. The "1/d healthy, 2 packs/d unhealthy" hypotheses \*really\* doesn't fit the international data, since other countries tend to smoke much more than the US, yet have far less cancer. The data fits a melanoma type hypothesis much better - American doctors rightly tell Americans to stay out of the sun, but sun doesn't actually cause cancer for more paleo countries or for people eating more paleo diets. Quite the opposite, sun is actually healthy. This would explain why animals who smoke live longer in properly controlled experiments. "Apparently, arsenic causes cancer in humans but not in animals." Key word, apparently. What you should have said is there is a correlation between arsenic exposure in humans and cancer. I have no information about whether this correlation is reliable enough to be considered established without any controlled experiments to back the causal link.

dearieme (2013-04-26 02:16:51)

The cancer-causing properties of smoking were first discovered in pre-war Germany. Apparently those abroad who noticed the results rejected them on the grounds that they probably were just pandering to Hitler's dislike of smoking. So the study that changed everything was a postwar British one by Bradford Hill and Doll. At the very least, then, you have to explain why smoking apparently mows down Krauts and Brits and Yanks. I wouldn't be surprised if smoking affects different races differently, even races as similar as, say, Germans and Italians. Even if one accepted the idiocy that race is just a social construct, one could look at habits - including diet - that varied among, say, the European nations, but one would need to come up with a hypothesis as well supported and biologically plausible as the smoking hypothesis. Still, never say never, eh?

Koanic (2013-04-26 05:07:34)

The origination of the theory in three countries does not mean the theory is correct in three countries. Furthermore, this is a logical fallacy: "but one would need to come up with a hypothesis as well supported and biologically plausible as the smoking hypothesis." I certainly do have my own hypotheses, better informed than those here, but I do not need to advance them. I am content to shred the logical errors of the defenders of the status quo view, which I have done. That nobody has offered evidence to alter my opinions strengthens my estimation of their accuracy. It is precisely this sort of thinking that has permitted the fat theory of obesity to dominate.

Koanic (2013-04-26 05:16:48)

As another example, there is much talk about how a sedentary lifestyle is bad, but my own observation is that a sedentary lifestyle has no impact on my health. At most, modest exercise when healthy is nice but not necessary, and overtraining is quite bad. Instead, I have observed a very strong correlation between being sick and being sedentary, with the causation running the other way. Therefore I conclude the epidemiological emphasis on the health benefits of exercise for the non-obese is mostly garbage. Rather, when one is healthy one will naturally not be sedentary, in the sense of at least walking around, up stairs, etc. The only exception would be extremely long working hours at a desk. If humans are adapted to long periods of inactivity during e.g. winter, then evolutionary biology supports my conclusion.

Theragingwalrus (2013-04-26 05:16:55)

haha love how these comments are completely off-topic you should see koanic on his youtube channel, smoking like it's his day job

Koanic (2013-04-26 05:23:38)

When I say garbage, I mean it is positively harmful. Not that there aren't benefits from exercise, but people who are sedentary are probably unhealthy, and therefore need to be sedentary, aka rest. Telling them to exercise expends or overexpends their limited energy resources, preventing them from taking actions that would actually make them healthier, such as improving diet and environment, getting more sleep, or whatever. Given the many documented positive effects of smoking, it is likely that the correlation between sick people and smoking is similar to the correlation between sick people and being sedentary.

dearieme (2013-04-26 11:25:40)

Well, I'd be obliged if you could demonstrate that light pipe smoking is good for you, Koanic. I do miss it.

Koanic (2013-04-26 20:55:29)

I will not do so, but there's a fellow who will: Nightlight who posts on FORCES, Longevity and other places. Google for your pleasure.

Valentin (2013-05-03 06:35:33)

Difficult to interpret data indeed. But after reading the original article I have to disagree with a few of your points: > 3. There is no simple connection between diabetes and obesity. > During the economic crisis, when the prevalence of obesity > went down by half (from 15 % to 7 %) and exercise greatly > increased, the prevalence of diabetes slightly increased. Only > after the crisis did the usual correlation (more obesity, more > diabetes) emerge. This is true for prevalence - but not for incidence. I.e. people were not cured from diabetes, but fewer got sick. This shows up clearly. > 2. A graph showing rates of heart disease, cancer, > and stroke (the three main killers) over the period > showed no change in rates of cancer and stroke. There is no graph showing the rates of these diseases - the graph shows the mortality attributed to these diseases. Makes a big difference when thinking about whether the "time lag" hypothesis is believable (in that it is for mortality much more than for prevalence). But also making it even more difficult to interpret the data, because changes in treatment for these conditions (e.g. treatment for high blood pressure) could also affect the mortality by a lot.

## **Cheap Good Science (2013-04-24 05:42)**

Last weekend I attended [1]EG, a TED-like conference in Monterey. One of the speakers, a woman named [2]Hong Yi, made representational art from cheap materials – a portrait from coffee-stained napkins, for example. The most stirring talks were by Matt Harding ([3]dancing video) and Jo Montgomery and Chuck Johnson ([4]circus school) but she, more than anyone else, seemed to have done something with big implications. Her art was attractive, profitable, very cheap, and diverse (many materials, many representational styles). If anyone else has ever done this, I don't know about it. She is an architect in Shanghai and her art began because she was in China. At a wholesale supply store, she came across very cheap candles. She realized she could buy enough of them to make a picture with one candle = one pixel. I imagine people will be watching Harding's video a hundred years from now and the underlying point of Montgomery and Johnson's circus school will be valid forever, but both were enormous expensive unique efforts. Hong's work was much easier and cost almost nothing. The benefit/cost ratio was very high and millions of people could do something like what she did.

I realized that my work resembled hers. She had discovered how to make cheap good art – not just once but many times, using a wide range of materials (e.g., different foods) and representational styles. I had figured out how to do cheap good science, answering not just one question (e.g., how to sleep better) but many questions (how to sleep better, how to lose weight, how to be in a better mood, etc.). My science cost almost nothing, so I could do a lot of it (do thousands of experiments) and managed to discover many things. In both Hong Yi's case and mine, the Internet was not needed to do the work but was essential for publicizing it. It didn't fit the usual channels.

For a long time, I called my work self-experimentation. It's true, but misleading, because almost all self-experimentation you've heard of isn't like mine. The book [5]Who Goes First? The Story of Self-Experimentation in Medicine is full of self-experimentation quite different than mine. Most of it is by doctors, designed to show that a new treatment is safe. The scientist tries the treatment himself to protect others. The self-experimentation in Who Goes First? is closer to demonstration than experiment. In contrast, the treatments I've studied (e.g., butter, morning faces, standing a lot) are perfectly safe. My work is about finding new ideas. It is about changing my own beliefs, not trying to convince other people of what I believe.

More recently, I might describe my work by saying it's an example of the Quantified Self (QS) movement. Again, this is true, but also somewhat misleading. My work does involve self-quantification and self-tracking. Like many QSers, I do hope to become healthier as a result. What's misleading is that the tracking is only part of the effort, I don't measure many things, and my tracking isn't high-tech. I'm trying to discover new cause-effect relationships (e.g., new ways to improve sleep). This is not a large part of the QS conversation.

If I describe my work as cheap science, on the other hand, what you automatically think of is pretty accurate. Scientists look for cause-effect relationships (it is central to science); I look for cause-effect relationships. Scientists do many experiments; so do I. Scientists pay great attention to the scientific literature (what has already been done, what is already known); so do I. When something becomes much cheaper (e.g., photography or computing becomes much cheaper), everyone understands that the activity can be done by many more people. That is inherent in my work. I am doing science that many people can do – many more people than can do professional science. The terms self-experimentation and quantified self do not convey this.

Like the term cheap travel, the term cheap science suggests freedom. That too is a big part of what I do. I have vastly more freedom than professional scientists. I can test treatments they can't. I can entertain ideas ("crazy") they can't. I can spend longer on one project than they can. So if I describe what I do as cheap science, the rest of what I say ("I've discovered new ways to sleep better, lose weight, etc.") makes more sense. And maybe the whole activity sounds more accessible, whereas self-experimentation and quantified self seem like the sort of activities that caused the word geek to be invented.

Nancy Lebovitz (2013-04-24 10:39:21)

You may be leaving out up-front costs– Hong's Yi's learning to draw well and your background in statistics. Seth: I don't think my statistics background has made much difference. But you're right there are "infrastructure" costs. I'm not sure that Hong Yi needed to draw well to produce her work.

Daniel Lemire (2013-04-24 19:31:03)

I propose the following term "ridiculously easy science". Seth: Thanks. That's a good way of putting it.

alexi de sadesky (2013-04-24 20:42:10)

Whether you know it or not, you and Hong Yi are exact opposites. She is most certainly an insider in the art world (or at least wants to be). One look at her architecture models is enough to tell you that. Seth: Have you looked at my animal-learning papers?

shtove (2013-04-25 12:38:16)

Thanks for the link to Hong Yi. Here's her blog: <http://www.ohiseered.com/> So good natured, and I got a good laugh from the uplifting photos and commentary. The use of materials is original. I get the feeling she's at one with the world of marketing. Maybe she's a natural behavioural psychologist. I'll have to think about it.

Pauline (2013-04-26 01:09:07)

I love Hong Yi's work, her ability to imagine amazes me, and inspires - almost like a child who sees patterns in everything and plays with it all. I always notice patterns and shapes in nature and the effects of light and shade. This desire for pattern, design and insight is linked to curiosity and play - isn't that also part of this desire to re-design our selves whether its through sleep, eating, walking, socialising - its the desire to discover new ways of being in the world. Maybe we should call it 'curious science of self creation through feedback'.

David (2013-04-26 02:43:36)

I believe your work and discoveries, just like Hong are very inspirational. You share information and new knowledge to everyone around the globe with the use of the Internet. It sends a message that every individual has the potential to contribute something to society even with no or limited budget. We now have the Internet which we can use to publicize our work without any payment. Seth: "It sends a message that every individual has the potential to contribute something to society even with no or limited budget." I agree, thank you. From my privileged position, I think I tend to miss this point. People want to improve their own health, of course. Economists endlessly discuss self-interest. My work shows a new way of improving one's own health. But people also want to contribute something to society, just as you say - which is not so obvious, at least to economists. My work shows a new way of doing this, too. I am impressed with the work of Adam Grant, which shows that if you can make a job appear more helpful to others, people like doing that job more. Making a job seem more helpful to others is quite different than increasing how much the job helps the person doing it.

Paleophil (2013-05-14 16:20:42)

Once again, cheap science proves superior: Now that the West is forced to seek alternatives to expensive antibiotics whose use has produced supergerms and helped drive up medical costs, it is looking at old-fashioned Russian bacteriophage therapy. Phage therapy is cheaper and "far more robust to heat" (<http://scienceblogs.com/mikethemadbiologist/2006/09/30/phage-therapy>), can adapt to changing bacteria [http://www.bacteriophagetherapy.info/ECF\\_40946-8E2F-4890-9CA6-D390A26E39C1/Pros%20and%20cons%20of%20phage%20therapy.html](http://www.bacteriophagetherapy.info/ECF_40946-8E2F-4890-9CA6-D390A26E39C1/Pros%20and%20cons%20of%20phage%20therapy.html), is more targeted and less likely to cause side effects or resistance, and is equally effective and in some cases more so, but more difficult to mass-manufacture (and thus not favored by corporations). [http://en.wikipedia.org/wiki/Phage\\_therapy](http://en.wikipedia.org/wiki/Phage_therapy), <http://www.npr.org/templates/story/story.php?storyId=89380684>, <http://www.npr.org/2013/04/12/177029253/looking-to-nature-for-antibiotic-inspirations>

## **Make Yourself Healthy Meetup Group: Report of First Meeting (2013-04-25 13:28)**

The first meeting of the Make Yourself Healthy Meetup group happened last night in Berkeley. It went great. About 15 people attended. We heard four fascinating talks - five, if you count mine. About 10 people wanted to talk so there was far more material than time (the meeting lasted about 2 hours).

Here are brief recaps of the talks.

Me. I explained why I started the group. I described how I came to believe that non-experts can discover impor-

tant things about health that health experts, such as doctors, don't know. These non-expert discoveries deserve more attention than they would get on a online forum (e.g., a [1]MedHelp forum about acne). They can help people with other problems and can encourage people with other problems.

Katie Reid. After her youngest child was diagnosed with autism, she tried many things that didn't work. She tried removing gluten from her daughter's diet – a common treatment – and that made things somewhat better. The partial success encouraged her to look further at food. On someone's blog, she came across the idea that MSG (monosodium glutamate) can cause autism symptoms. To her surprise, she learned that MSG is in many things, including toothpaste and juice, without explicit statement on the label. When she removed all MSG from her daughter's diet, her daughter greatly improved and now, three years later, attends class with normal children. All of her autistic symptoms are gone. Katie herself felt much better when she stopped eating any MSG. She lost weight and a low-grade headache disappeared. She has [2]a website and [3]a video about this. [4]Here is a video about this by someone else.

Anonymous. He is 29 years old and has struggled with depression, anxiety and lack of motivation. No long term progress in therapy. Yoga has helped. He found some benefits from meditation, but to get the benefits requires consistency and consistency requires hope, which I don't always have. He started thinking critically about what he eats. Read Eat to Live by Furman and Disease-proof Your Child. Eating whole foods plant-based lowered his blood pressure to 90/60, His weight went from 170 to 155 and is now in low 160s. (It was 160 when he was 19.) He has food addiction and technology addictions, demons that he is battling. Other attendees suggested six things he might try, such as eating more animal fat.

Kylene Miller. She spoke about the value of anti-oxidants. She became a Type 1 diabetic at age 5 and has been sick a lot in her life. She met Dirk Pearson and Sandy Shaw, who told her to eat a lot of anti-oxidants. She started eating large amounts of Vitamins E and C. Then she started trying get her antioxidants from food. She discovered healthy chocolate – cold-pressed so that the anti-oxidants aren't destroyed – made by the Xocai company. It has a huge [5]ORAC (oxygen radical absorbance capacity) score. She had gastric paresis. Four years of throwing up first thing in the morning. She had stopped taking lots of antioxidants. After she started taking them again, her gastric paresis disappeared. She is a distributor for the chocolate. She passed out samples of the chocolate.

Janet. When she was 19 (she is now 22) she suddenly felt very tired most of the time, even though she was sleeping 12 hours per night. She decided what tests she wanted, but her doctor would not order them. After her doctor gave her the blood-test-order form to bring to the testing center, she checked the boxes for the tests she wanted. Three supplements have been especially helpful, including isocort and progesterone (both OTC, over the counter). You can listen to her talk [6]here (thanks to Jane Cho).

I had worried that too few people would have stories to tell, but one attendee lived one block away She had high blood pressure and had lowered it without medicine. I wanted to videotape the talks but during the second one the camera battery died – and, anyway, I was doing it wrong, someone told me. I asked whether the next meeting should be in one month or two months and everyone voted for one month. We need a venue that permits longer meetings.

Alex Chernavsky (2013-04-25 16:25:00)

Sounds wonderful! If anyone is interested in starting a similar group in or near Rochester, NY, please email me at [alexc@aya.yale.edu](mailto:alexc@aya.yale.edu).

Kirsten (2013-04-25 19:24:04)

Hi Seth- I've been reading your blog for years-was briefly a member of the SLD forums in about 2007-and appreciate the mindset of looking into things yourself rather than leaving it the hands of doctors. As my husband likes to say: No one will care about your money (or health, or time, etc.) as much as you do. Which is maybe why, when I was diagnosed with Hashimotos thyroiditis last fall, I started looking into alternatives. The standard medical prognosis is depressing-Hashis is an auto-immune condition, in which the immune system attacks the thyroid. Standard treatment is to give thyroid medicine to support the diminished organ. You feel better, then the immune system (which is trying to save your life, after all) mounts an even bigger attack. So they increase the dose-and so on until the thyroid gives out and you require thyroid hormone supplements for the rest of your life. I lived through one cycle of that, and it was miserable. Plus, once you have one auto-immune condition, you're likely to develop others. So I started looking-and sure enough, there a group that believes auto-immune conditions start with a damaged gut, and if you heal the gut (and replace good bacteria) you can calm the auto-immune attack. I'm a member of a Facebook page called Hashimotos 411 that has more than 5000 members from all around the world, all following the protocol to some degree. i also help moderate a sub-group, the Elimination/Provocation Diet, which has about 1000 members. (Feel free to look us up!) Different things work for different people, but there are some large commonalities: often natural desiccated thyroid works better for people than synthetic medicine, and often people feel much better when they go on an elimination diet using the auto immune protocol (which removes common auto-immune triggering foods), to start pinpointing their food sensitivities. Certain supplements seem to work for a lot of people, and people seem to have common sensitivities. Anyway, the page is full of people who've been scoffed at by doctors-"There's no such thing as adrenal fatigue" or "Natural thyroid hormone is impossible to dose and will give you heart attacks." Meanwhile, people go on self-experimenting and sharing their findings. In my case, I started on the auto-immune protocol diet in November and by mid-February my blood tests were showing my auto-immune antibodies within normal range-so, for all practical purposes, the condition was in remission. And based on my labs, my doctor recommended that I step down my thyroid medication by 20 %. I'm not out of the woods yet. I've spent the last three months fighting a distressing and completely unexplainable weight gain....until today I traced it (I think) to a probiotic which, it turns out, has dairy and soy. Those of us with damaged guts will often have out-of-proportion reactions to foods or chemicals...but they're signs of what we should avoid. Anyway, thought you'd be interested to know about a large self-experimenting community that's having a lot of success self-treating an otherwise untreatable auto-immune disease. Kirsten

T. Bergenn (2013-04-25 22:03:43)

Dear Kirsten, I am one of the practitioners who has seen the tremendous effect of which you speak: Many autoimmune conditions respond to healing and reconditioning the flora of the gut. I attended the event that Seth hosted last night, and am very inspired by people looking to heal themselves. I had to heal myself as well. I would love to get to know you better, as a colleague. Feel free to connect on LinkedIn (T. Bergenn) and/or Facebook (Ti Bergenn) Best to you with Hashimoto's - we'll keep learning and keep healing! T. Bergenn Longevity Advisor 510-292-9976

alexi de sadesky (2013-04-26 10:04:25)

Seth and Katie Reid, Interesting. Aren't there a lot of free glutamates in things like kelp and fermented foods? What are the implications of that vs. its use as an additive?

### **QS Contest: What Would You Do With a Body Media Armband? (2013-04-25 17:07)**

A la Google Glass, [1]Gary Wolf announces a Quantified Self contest/give-away:

In conjunction with our upcoming [2]QS Europe Conference in Amsterdam on May 11/12, our friends at BodyMedia have agreed to donate a complete personal [3]SenseWear System (retail price \$2,500), a state-of-the-art wearable sensor that allows raw data output. That's going to be our prize. So if you have good questions, we can supply you with a way to collect the data.

The best answer wins the sensor.

### **More Wrinkles = Too Little Vitamin K2? (2013-04-26 05:00)**

[1]This post ("The vitamin deficiency that's written all over your face") by Sarah Pope at Healthy Home Economist is very good. It takes various pieces of data and puts them together to suggest that people who don't get enough Vitamin K2 will get facial wrinkles sooner. The most interesting data is the difference between women in Shanghai, Bangkok and Tokyo – [2]the Tokyo women had the fewest wrinkles. They eat the most natto, of course, and natto is notoriously high in Vitamin K2. Pope should have added that Tokyo women probably also eat a lot more of other fermented foods than Shanghai and Bangkok women – for example, more pickles and miso.

Another example of the same sort of reasoning:

Further research which bolsters the notion that getting plenty of K2 in the diet makes for smoother facial features is found in the research of Korean scientists and was published in the journal Nephrology in 2008. The rate at which the kidneys are able to filter the blood is an important measure of overall kidney function. Researchers found that reduced renal filtration rate was associated with increased facial wrinkling. What does decreased kidney filtration rate predict? You guessed it – Vitamin K2 deficiency, according to American research published the year after the Korean study.

I wonder what other nutritional deficiencies poor kidney function is associated with. These associations are far from convincing but it is a new (to me) and testable idea. And Vitamin K2 is quite safe.

1. <http://www.thehealthyhomeeconomist.com/the-vitamin-deficiency-that-is-written-all-over-your-face/>

---

August (2013-04-26 06:03:50)

Sounds plausible. My skin seemed to smooth out pretty nicely at a 5mg dose. I started wondering why women, many of whom seem to obsess about skin products, were buying all those products and not K2. I don't think my skin was particularly bad before I started taking it, but the difference to the touch was certainly noticeable.

derp (2013-04-26 11:24:37)

I'm not old enough yet to think about my wrinkles. I've been taking 5mg/day MK4 for the last 6 weeks and my blood pressure went down. As I do not measure it regularly and the K2 supplementation is for entirely different purposes, I cannot be sure to think of it as causative and therefore put it forward as an n=1 hypothesis. K2 is the most underrated of the generally underrated micronutrients.

Darius Bacon (2013-04-26 13:58:22)

I believe K2 cured my (self-diagnosed) psoriasis. I had the problem for 6 months and tried other things first (sunlight helped), and it started coming back after I ran out of K2.

CC (2013-04-26 15:58:39)

Any advice on dosing or if one form of K2 is better than another?

CC (2013-04-26 18:52:55)

Oh whoops, just noticed the 5mg suggestion. Looks like it's sold in 100 mcg doses, which means you have to take 50 pills. Am I missing something?

garymar (2013-04-26 19:14:37)

CC, check out [relentlessimprovement.com](http://relentlessimprovement.com) for larger dose K2.

Pauline (2013-04-27 00:45:25)

August, can you recommend the brand K2 you use and the dose you found effective?

Pauline (2013-04-27 03:44:06)

I see you posted 5mg, I take the Weston Price recommended Fermented Butter/Cod liver Oil, only one cap at night. It recommends 2 a day. I have always had good skin which needs looking after as the climate I now live in is different and the water here is much harder, dosages would vary according to how our bodies absorbed, and upon our deficiency and need of K2?

derp (2013-04-27 05:09:26)

5mg is really high-dose and part of my self-experimentation. Overdosing is quite unlikely, so given that 100mcg capsules cost more per dose than the 5mg ones, I shot for the latter. I've read that Vitamin K2 MK4 has a very short half-life in serum (1-2 hours), so my idea was to have a dose that I only need to take once a day.

Tony (2013-04-27 05:30:52)

[http://www.amazon.com/Carlson-Labs-Vitamin-K-2-Capsules/dp/B003B3P4I6/ref=sr\\_1\\_1?ie=UTF8&qid=1367065797&sr=8-1&keywords=carlson+vitamin+k2](http://www.amazon.com/Carlson-Labs-Vitamin-K-2-Capsules/dp/B003B3P4I6/ref=sr_1_1?ie=UTF8&qid=1367065797&sr=8-1&keywords=carlson+vitamin+k2)

Pauline (2013-04-27 07:14:34)

In terms of dosage when trying something new, I always tend to take the minimum dose to give my body time to adjust. I read somewhere that you often need to find the minimum dose required to fix something - ie less is often more. As these things also build up in your system over time. Personally I usually take child dosages when I experiment because I may be sensitive to some additive that may be part of something I am trying for the first time , so its a quick way to test.

Tom (2013-04-27 10:30:15)

I don't trust that fermented butter oil. Green pastures doesn't say how much K2 is in it. And as far as I can tell, it's just incredibly overpriced ghee.

Pauline (2013-04-27 11:09:35)

I have been re-reading some of the stuff Richard Nikoley wrote on this topic of K2 and fermented cod liver/butter oil with commenters adding their thoughts: <http://freetheanimal.com/2012/01/vitamin-k2-menatetrenone-weston-a-price-activator-xor-whateverits-amazing.html>

Adam (2013-04-27 16:00:42)

Natto / 納豆 has 1100 mcg (1.1 mg) Vitamin K per 100 g AND it is delicious! Seth: It is unclear if different forms of Vitamin K have the same effects.

Adam (2013-04-27 18:08:56)

Updated my blog (link above) with some info about Vitamin K2 & Bone health. I have to admit, I scoured PubMed the other day looking for anything about Vitamin K2 & skin health / wrinkles & didn't come up with anything I thought was interesting. The article linked in the main post doesn't give enough of a citation of sources to track anything down. She also asserts that women living in Japan, Bangkok, & Shanghai are comparable in every way except their consumption of natto, which is absolutely not true.

Pauline (2013-04-30 08:55:33)

In my research I came across the interesting link on Vitamin K2, very interesting: <http://www.womentowomen.com/bonehealth/vitaminkbenefits-heartbones.aspx>

Evolutionarily (2013-05-02 10:33:18)

There is some confusion in the comments here about Vitamin K2 dosage which I would like to clear up... Simplified K2 comes in two forms, MK-4 which is synthesized by animals, and MK-7 which is synthesized by bacteria. MK-4 comes in MILLigram dosages in the 1-15mg/range and MK-7 comes in MICROgram dosages 50-150mcg. I don't have any evidence but I would posit it unwise to try take 5mg of MK-7! As always Stephan clears it up: <http://wholehealthsource.blogspot.com.au/2009/03/are-mk-4-and-mk-7-forms-of-vitamin-k2.html>

Sentinel (2013-05-04 10:02:03)

Seth, you've talked a lot about the importance of Vitamin D3 for improved sleep. I've read that Vitamin K2 has a dramatic effect on how the body uses D3 — but I've only seen discussion of how it increases the D3's ability to help the body properly absorb calcium. Is there reason to believe that K2 might also help D3 in its role as "improved sleep promoter"?

## **Standing Improves IBS Symptoms (2013-04-27 05:00)**

At least in one case. A 23-year-old woman, who lives in Manchester UK and works as a typist, wrote me:

I've recently been trying out a standing desk, partly due to reading the posts you made about them. For the past few weeks, I have been tending to stand instead of sit when at my laptop, normally for more than 3 hours a day. I sit down when I get bored of standing and I walk around lots.

I was looking out for mental clarity effects but I've not seen a clear effect in that direction. What I did find surprising, though, is that my chronic but mild IBS symptoms have abated. I get heartburn/acid reflux regularly, and gut cramping, but since standing more these have all but stopped. I think it's because standing up puts less pressure on my stomach and gut and leaves them more opened up.

I asked how long she'd had the symptoms (heartburn/acid reflux, etc.):

I think the last 3-4 years, but it's hard to say when. I think my IBS probably started happening when I started having problems with anxiety but I wasn't keeping track back then. :) I've suffered from recurring depression for 10 years now, but severe anxiety for me is relatively new. I think it would make sense if it coincided with the anxiety - I've heard of Citalopram (an anti-anxiety medicine) also being prescribed in a low dose for IBS, and some of my friends who have taken Citalopram + who have had IBS have had it go away. I never actually got a diagnosis for IBS, but it seems a fair description. The symptoms are heartburn, gut cramping (sometimes very painful) and my stool being quite variable in solidity.

I asked how long had she been standing more than usual:

4 weeks, when I've been able to. At work I have to sit, often with bad posture, but the last two weeks I have been on holiday. When I stand, I notice an improvement on the same day that I've been standing more. Part of what motivated me to stand with using my computer was when I recently spent a day walking around Manchester (where I live). I noticed that my energy levels were much smoother even though I hadn't eaten very much and that my gut and stomach felt more OK than usual.

I asked what other remedies she'd tried:

About a year after I started regularly getting heartburn, a friend told me about antacids, so I started taking them when I needed them, but they weren't always effective and they don't help with gut cramping. Peppermint tea worked to some extent but would give me strange headaches and made me feel bloated. Peppermint oil capsules were an improvement - no bloating but still giving me headaches. I've also tried various dietary changes. I find that dry carbs (like toast or potato crisps) tend to bring on or make worse heartburn and cramping so I sometimes avoid those. Also when I'm hungry I get heartburn quite badly, so I've tried to eat things that level out my blood sugar over time more (e.g. eating more fat and protein, fewer sugars and carbs). I tried probiotic soy yoghurt (I'm vegan) to see if that would help but it doesn't agree with my stomach. I also have tried probiotic supplement but I'm not sure that I've seen improvement from that either.

She added, "I haven't had IBS symptoms on days that I have been standing yet!" So it is perfectly clear that this is cause and effect – standing reduces IBS symptoms.

dearieme (2013-04-27 10:35:08)

I used to work standing sometimes: I'd simply put a small drawing board on top of a filing cabinet, rather like a lectern, and work away, sitting only to use my desktop computer. Since I had a row of four filing cabinets it meant that I had a huge horizontal surface for paper-shuffling. Nowadays use of a laptop would make everything easier.

Sam (2013-04-29 01:35:56)

When I wear trousers which are too tight I get stomach cramps, too, after sitting a few hours. Funny thing is, apart from the cramps I won't notice they are too tight. So when I buy new trousers sometimes I end up with severe cramps and even circulatory problems up to fainting before I notice the clothing being too tight.

## **News You Can Use: Tonsillectomies Are a Bad Idea (2013-04-29 05:00)**

A reader named Nicole, who lives in Washington D.C., writes:

I have been an avid follower of Seth's blog since Boingboing.net first posted something about or by him. And when I heard that my brother was planning to get my niece's tonsils removed, I remembered [1]the Boingboing article Seth wrote about tonsils and their important, if not completely understood, role as part of our immune system. So I sent that article along. My brother responded quickly with: "Wow, thanks. I won't be getting her tonsils out any time soon."

Nice to hear!

1. <http://boingboing.net/2012/01/10/tonsillectomy-confidential-do.html>

---

Ahrand (2013-04-29 06:42:28)

PS. Seth, also look up the latest research from dr. Scott Napper (Canada) and dr. Hilary Longhurst (UK) why are saying that both nose picking and nail biting is good for your immune system as it introduces small amounts of bacteria.

Char (2013-04-29 20:50:02)

I noticed this article about ADHD maybe being caused by sleep deprivation. This part is interesting: A full half of the original A.D.H.D. group who received tonsillectomies — 11 of 22 children — no longer met the criteria for the condition. In other words, what had appeared to be A.D.H.D. had been resolved by treating a sleeping problem. [http://www.nytimes.com/2013/04/28/opinion/sunday/diagnosing-the-wrong-deficit.html?ref=opinion&\\_r=1&utm\\_source=feedly](http://www.nytimes.com/2013/04/28/opinion/sunday/diagnosing-the-wrong-deficit.html?ref=opinion&_r=1&utm_source=feedly) Any thoughts? Seth: It's an excellent article. A new and persuasive idea that I hadn't heard before. That the author himself had sleep & ADHD-like problems partly explains its excellence, I think.

Alex Chernavsky (2013-04-30 06:45:49)

Here's another interesting article about ADHD. Could the underlying cause be sleep deprivation? "[1]Attention Problems May Be Sleep-Related" Seth: I agree, very interesting. Someone noted this in a comment on the previous post.

1. <http://well.blogs.nytimes.com/2012/04/16/attention-problems-may-be-sleep-related/>

gwern (2013-04-30 08:58:36)

> I point out that certain results in the BMJ are impossible And they reply you are misreading it and it's based on different populations, so it's not violating the conjunction rule. Seth: Thanks, I hadn't seen that. Their explanation of the discrepancy is that the two graphs are based on different populations.

Sonephet du Pertinent (2013-04-30 11:37:16)

Your picking out 1999 ACJN journal is cherry picking a study of very limited value. I am shocked by the very strong selection bias due to the fact that participants are selected for absence of prior disease despite a very high median age (49 for non-vegetarians). There are many other problems, namely a lower-than-national-average intake of meat for meat-eaters, no checking whether labeled "vegetarians" still were vegetarians throughout the study, etc Also, many other studies state exactly the contrary (for instance <http://www.biomedcentral.com/1741-7015/11/63>, based on the same EPIC cohort) so at best I think we'll have to wait for more studies and an honest transversal study on that subject. For the time being, just stating "No mortality difference between vegetarians and non-vegetarians" is purely speculative. Seth: All studies have "selection bias" in the sense that you use it. If "vegetarians" were not actually vegetarians, that would reduce observed differences between "vegetarians" and "non-vegetarians" – the wrong way for your claim that the study should be disregarded. I don't know what a "transversal study" is.

Felix (2013-05-03 14:24:54)

Hi All, first thanks for the nice blog and the free information we get here. The blog by itself is really thought provoking. I have learned a lot from this blog and also i changed my diet .I tried to eat a more fermented food, unfortunately i have developed an intolerance to alcohol. This intolerance is so strong, that i can not drink eat alcohol or eat minimal fermented food like sauerkraut and curd. Does anyone know some other possibilites to get the needed fermented food without the alcohol? The only thing i did find through coincidence was the medicamentation perenterol which has milk bakteria in it and also reduces

my acne a lot. (The skin gets drier)

### Acne Club: A New Way to Fight Acne (2013-05-01 05:00)

Recently [1]I posted that my work resembles the work of [2]the artist Hong Yi. Her work shows that profitable beautiful art can be made from the cheapest materials; my work shows that non-trivial useful science can be done by anyone. A reader named David [3]commented:

Your work and discoveries, just like Hong's, are very inspirational. . . . They send a message that every individual has the potential to contribute something to society even with no or limited budget.

This hadn't occurred to me. It should have. I could have made this point in talks, for example. Beyond the obvious point, David was saying that the more your personal science could help others, the more likely you would be to do it. The prospect of helping yourself and others will surely be stronger motivation than the prospect of helping only yourself.

How can one person's personal science help others? This doesn't happen automatically, it has to be arranged. My [4]Journal of Personal Science and the [5]Make Yourself Healthy Meetup group are two ways of facilitating this. What about other ways?

David's comment made me think of another way: Acne Club, that is, a high school club for people with acne. The purpose of the club is to promote personal science about acne. Members of the club try to find the causes of their acne, partly by self-experimentation. They meet to share results and ideas (e.g., treatments to try, how to measure acne) and encourage each other. [6]The discovery of two groups of "primitive" people who have no acne suggests that all acne has environmental causes. If a high school group could identify even one environmental cause, it would be a huge contribution to human well-being – especially the well-being of high-school students. I think this is quite possible.

I had acne as a teenager. If you start such a club, I would be happy to help you however I can. For example, I could give advice about measurement and experimental design and could publicize what you learn.

6. <http://www.ncbi.nlm.nih.gov/pubmed/12472346>

DZ (2013-05-01 06:09:43)

I always get uneasy whenever I see some grandstanding on this site. No sir, the difference between you and Hong Yi is that she has left something tangible in the physical realm as an artist. You just say that you pioneered this idea that science can be done by anyone, something which my first-grade science kit also claimed. Your work shows interesting causations and correlations, but you didn't teach anything to anybody who wasn't already primed and teachable. To show just how in-house and local baseball your claim is, you need to look at the out of touch examples you provide. Who, in their right mind, would want to have anything associated with an ACNE CLUB??? What a way to seek out even more ostracism for those unlucky kids who suffer from it. Seth: Weight loss produced by the Shangri-La Diet – is that anti-tangible? It would take an unusual person to start an acne club, but unusual people exist.

Tom (2013-05-01 07:07:42)

Also, those who desired to participate while preserving anonymity could do so if there were an Internet component to the club (such as a forum) that allowed people to choose their own handle. Actually, Seth, there may already be an internet forum like that. Maybe you could post there and offer your support. I think having access to your expertise could transform a lot of young lives.

Nancy Lebovitz (2013-05-01 07:19:54)

I think self-experimentation clubs would be a better idea than acne clubs, but the acne club could work as an online forum.

Tom Passin (2013-05-01 08:45:03)

About acne and self-experimentation, when I was a teenager I also had bad acne. At one point I went to a doctor who prescribed a liquid (to be gotten from a pharmacist) that turned out to be mostly alcohol. Presumably it would remove oils from my skin, which was naturally oily, and prevent the pores from clogging. It would help moderately for a while (weeks, usually). The other thing I had heard was not to wash your face with soap (or perhaps not to wash it at all). So I tried that, too. It also would help modestly for a period of time. I ended up alternating between the two methods for several years. I always had acne but after each switch of treatments, it would lessen for a time. I learned from this that the body somehow has a tendency to return to its previous condition. This should be but rarely is taken into account when experiments are run. So I was not surprised to learn that most people regain weight after a weight loss diet, or that antibiotics become less effective. It seems much harder to produce lasting changes.

dearieme (2013-05-01 15:42:24)

Instead of an acne club to fight acne, would an acne rapier not be more suitable?

alexi de sadesky (2013-05-02 05:50:57)

The acne club. Yes. I believe they might find that fist blows to the face result in poppage of pimples.

BQ (2013-05-03 09:19:19)

Maybe it's been too long since you've been a teenager? When I had acne as a teen, I wanted to hide, to be invisible. I didn't want to acknowledge (or have anyone else acknowledge) that I had acne. Even though mine wasn't super bad, every tiny pimple felt like a giant glowing beacon of shame. I can't imagine anyone wanting to start a club about it. And even so, I can't imagine attending a club about it. Or posing for the yearbook photo with the rest of the club? Yeah. Seth: I disagree that all teenagers are the same.

CC (2013-05-03 19:34:04)

"No sir, the difference between you and Hong Yi is that she has left something tangible in the physical realm as an artist. " I don't know about you, but I'd much rather have a cure for obesity and a cure for acne than a piece of art. And I have to say that an online forum would be better than an actual club that meets after school. The acne.org regimen and zinc picolinate supplements might be all you need though.

Serbian boy (2013-05-04 02:34:28)

Dear friends, I am 100 % sure that acne is related to stress. Also it doesnt have to do much with age, even older people in 30-ties or 40-ties could have it. It is a question of your state of mind. Being very relaxed, worried free, and just leting things go is the first thing to so. Just dont be afraid of life and belive that slowly you will get to the point where you would be optimistic, energetic, satisfied, loveble person. Thats all. Try and let us know if it worked for you. Spending money on silly medicenes is not long term solution.

Bex (2013-05-05 10:21:25)

I think its an great idea to start an acne club after school. I am a teenager having acne problem. I would invite some friends of mine and discuss about it. Lets see how it goes... Seth: I'm very curious to hear what happens, good or bad.

Rose (2013-05-13 07:02:34)

On the same line, I wouldn't want to join an obese club. Why not just a forum where all acne sufferers can get support?

### **Acquired Butterphilia (2013-05-04 05:00)**

Because of [1]my finding that butter improved my mental speed, in 2012, Dustin Lee, a programmer in Bozeman, Montana, decided to try eating lots of butter. He thought he'd do it for a month.

He ate a half-stick (2 ounces = 57 grams) every day. Nothing fancy: Kirkland Salted Sweet Cream Butter. At first it was repulsive. He had trouble eating it. He ate it with other foods, such as soup or pancakes. Or he would take lots of tiny slices (without other foods). It felt like more butter than he wanted.

After about two weeks of this, however, he decided this is pretty good. He was enjoying it. He began looking forward to the slices. He made them larger. He prefers the butter hard, straight out of the fridge. He now enjoys eating the fat on meat. He stopped limiting how much animal fat he eats. (His wife still cuts it off meat.) Now he gets lots of fat from lots of sources. Butter is the easiest source.

His children (7 and 9 years old) don't eat butter directly, but he allows them to eat as much as they want. They eat a lot more butter than other children. At other people's houses, he jokes about it. Incidentally, he tried taking Vitamin D3 in the morning (around 7 am) but it made him so sleepy in the evening he stopped.

This impressed me. I'd been eating a half-stick of butter per day for a few years (half as much was less effective), but I always ate it with a little bit of meat, e.g., sliced roast beef (Berkeley) or roast pork (Beijing). That was less than ideal because I kept running out of the meat. I started eating it Dustin's way (straight) and found it's fine. It's like dessert, halfway between ice cream and cheese.

---

1. <http://blog.sethroberts.net/wp-content/uploads/2012/09/2012-09-24-The-Growth-of-Personal-Science-Implications-For-Statistics.pdf>

Txomin (2013-05-04 06:06:50)

OK. Our friend developed a taste for butter but, did he get the alleged benefits of it?

Chuck (2013-05-04 08:51:25)

Here's a delicious (I think anyway) way to enjoy a little extra butter: Melt together (lowest temp possible): 1 Stick of butter (I use Kerrygold salted) 1 Tablespoon cocoa butter 2 T unsweetened cocoa powder 1 T raw honey 1/4 tsp vanilla I pour it on to a piece of parchment paper placed over a 7 inch square dish which has raised sides. Place in the fridge to harden. Before it becomes completely hard, score with a knife into 2 inch squares. Because of the high fat content, it melts quickly, so keep in fridge. If you don't like salty chocolate, use unsalted butter - I would add a pinch though. I also add a splash of concentrated coffee - it seems to enhance the chocolate flavor. Using more cocoa butter should make it melt slower. I'm going to make a batch with a couple of tablespoons of raw crunchy almond butter. Shredded coconut (Mounds). Coconut & almond butter (Almond Joy). My cocoa butter/powder and vanilla are from bulletproofexec. Enjoy

Wil B (2013-05-04 09:00:22)

Here's another idea. In the past I have melted the butter in the microwave and then added grated parmesan cheese to it. Delicious. Your piece today, Seth, inspires me (with an idea from my spouse), to try something else: in addition to the melted butter and the parm I will add some cream and garlic powder and create what amounts to alfredo sauce. Sounds great. I'll let you know how it turns out. :-)

Kirk (2013-05-04 09:29:11)

Did you ever experiment comparing butter to cream? If so, any difference in mental speed?

Wil B (2013-05-04 09:37:06)

Ok I just whipped up a small amount of my Alfredo sauce idea; and you know what? It is damn good! Better than desert. No pasta necessary or desirable. :-) Next time I'm making a much larger batch.

dustin (2013-05-04 10:01:16)

@txomin: I would say there was a small increase and it seems fairly persistent. I don't know that I \*felt\* my brain working more quickly but there was a bump on my graph. I don't know that I would have continued eating butter just for the brain effects. I just enjoy it now. I think the description of it being between ice cream and cheese is pretty accurate.

Tom (2013-05-04 10:30:07)

Dustin, have you tested a grassfed butter like KerryGold? I wonder if you would see a difference.

dustin (2013-05-04 11:49:27)

@tom: I haven't tried any other type of butter (though I do know that unsalted butter is \*not\* something I enjoy eating directly). I may try returning to experimenting with this again but I found that once I went into "high fat mode" my brain speed scores didn't change much no matter what type of fat I was primarily consuming.

Joe (2013-05-04 12:10:48)

Butter is my cheese. KerryGold is fantastic. But the best butter you'll ever taste is Italian butter from Parma, Italy. You can usually get it at local stores for about \$5 for 8 oz. It's the Parmigiano-Reggiano of butter. [http://www.amazon.com/Delizia-Butter-Parma-8-Oz/dp/B002CXX6EA/ref=cm\\_cr\\_pr\\_product\\_top](http://www.amazon.com/Delizia-Butter-Parma-8-Oz/dp/B002CXX6EA/ref=cm_cr_pr_product_top) Tip: Spread it THICK on virtually any (I eat paleo) pastry and you'll never eat pastry any other way. Buon appetito

Mike C (2013-05-04 13:00:47)

I'm open-minded about all this, but a half stick daily does seem like a significant variance from the norm. Is there any science suggesting hinting at whether or not this might ultimately cause health problems (esp atherosclerosis)?

dearieme (2013-05-04 13:01:15)

By the time I've put herb butter on my steak, and butter on my veggies, and also (gasp!) butter on my toast and oatcakes, I don't feel a need for any more. Except sometimes on biscuits. Or on scones. And in sandwiches. Or just plain bread-and-butter. Or bread-and-butter pudding. And in all sorts of cooking of course. I see no difficulty in enjoying butter as part of the normal course of things. I understand that Americans eat margarine instead. How terribly ill-advised.

dustin (2013-05-04 13:20:52)

@mike: This does give me some pause. If I read LCHF or paleo writers they reference papers that seem fairly convincing that fat (and in particular saturated fat) is unfairly demonized and that most people would be healthier if they substituted a major portion of their carbs with fat instead. I've been reading a lot on this recently and I'm still sticking with LCHF but it does bother me that I'm basing my opinion on what is still a minority view of fat and heart health. FWIW, I've been low carb for over 2 years at this point and my total cholesterol is in the healthy range, my HDL is pretty good (about as good as it has ever been - and higher than some earlier periods in my life) and my total cholesterol to hdl ratio is better than average. The only thing that makes me wonder is that my LDL is a little high (just high of the optimal range), but the more I learn about how that is measured and how reliable a heart health marker it is the less I'm concerned.

Alex Chernavsky (2013-05-04 13:42:10)

Dustin, what brain test did you use, exactly? And can you post the data? I'm interested in doing my own experiments. Thanks.

shtove (2013-05-04 14:58:37)

Try bullet-proof coffee: tablespoon of non-salt butter mixed into the hot brew. I add cocoa and cream. Tasty + replaces the chewable breakfast + covers a chunk of your daily butter requirement. On top of that I have tried fermented cream for lunch over the past six months, but my conclusion is ... pinchable fat.

Meeds (2013-05-04 19:23:12)

I found that eating butter this way worsened my tinnitus. I stopped eating butter straight and the tinnitus got better. But if I eat it with other food, it doesn't cause problems. I am somewhat lactose intolerant (causes things like eczema in me).

Txomin (2013-05-05 02:39:17)

Thank you for the reply, Dustin.

Adam (2013-05-05 16:41:58)

Funny! I've been eating a chunk of butter in my morning coffee & chewing a big chunk of butter before lunch for a couple of weeks now. I never found it disgusting, I only worried that other people would think I had gone insane if they saw me gnawing on straight-up butter. The flavor is great of course & the way it melts in your mouth isn't really like any other food I know of.

Pauline (2013-05-06 08:20:40)

I was inspired by this blog on butter, went to Waitrose today and found this traditional Italian Butter called Gran Bonta in small 125 g packages plus another brand called Gold Top (lightly salted butter purely from Jersey & Guernsey Cream). I looked for the italina parma butter but could not find it. I started eating more butter in everything a few years ago and I think it contributed to completely healing an eczema problem I used to have and urticaria (itchy welts) I used to get int response to eating cheese and coffee/chocolate and other things my body seemed to be intolerant too. Hurray for butter I say!

Pauline (2013-05-07 00:54:09)

Added note: in the UK butter usually comes in 250 g blocks/sticks, so seeing 125 g of italian butter is unusual.

---

Lemniscate (2013-05-09 02:44:40)

Thought you would be interested in this experiment: <http://robrhinehart.com/> One criticism I would imagine you would share with me is the lack of bacteria in his diet. Otherwise an interesting idea to test nutrientism to its extreme. Seth: Yes, not enough bacteria in his diet. I also wonder if he is getting enough omega-3 and Vitamin K2. I give him credit for two things: improving his diet; and doing the improvement in a sustainable and intellectually engaging, non-dogmatic way. Lots of people improve their diet in non-sustainable and/or dogmatic ways.

## How Much Benefit from the Human Genome Project? (2013-05-06 05:00)

Ten years ago researchers finished the first sequencing of an entire human genome. To mark the anniversary, Eric Green, the director of the National Human Genome Research Institute at the National Institutes of Health, spoke to an unnamed reporter at the New York Times. Here is the final question of the interview:

What about the naysayers who [say], “Where are the cures for diseases that we were promised?”

I became director of this institute three and a half years ago, and I remember when I first started going around and giving talks. Routinely I would hear: “You are seven years into this. Where are the wins? Where are the successes?”

I don’t hear that as much anymore. I think what’s happening, and it has happened in the last three years in particular, is just the sheer aggregate number of the success stories. The drumbeat of these successes is finally winning people over.

We are understanding cancer and rare genetic diseases. There are incredible stories now where we are able to draw blood from a pregnant woman and analyze the DNA of her unborn child.

Increasingly, we have more informed ways of prescribing medicine because we first do a genetic test. We can use microbial DNA to trace disease outbreaks in a matter of hours.

These are just game changers. It's a wide field of accomplishment, and there is a logical story to be told.

There you have it. The head of the Human Genome Project, a very big deal, says in an oblique way that the project has had little practical benefit so far. Note the present tense: "We are understanding cancer". Nothing about decreasing cancer. In a short discussion of benefits, he mentions microbial DNA. In a short discussion of benefits, he says, "We are able to draw blood from a pregnant woman and analyze the DNA of her unborn child." Genetic tests of fetuses are not new. I think he means that the number of rare genetic diseases that can be detected has increased (by how much?). Well, yes, not surprising. It is an increase of something that was already happening and helps only a tiny number of people. Not a "game-changer".

---

Zach (2013-05-06 16:17:09)

What is a reasonable time frame to expect successes from a project like this? Seth: I think a fair comparison is with (a) other ways the money might have been spent (e.g., how much would these other projects have accomplished in the same time?) and (b) claims made when the money was being asked for.

dearieme (2013-05-07 06:32:24)

At least the science was, I presume, sound. Compare with the "climate scientists" and renewable energy people, who not only waste the money but do lousy, indeed mendacious, science into the bargain.

Myles (2013-05-07 21:22:34)

Would you bemoan the work of early cartographers for not being able to predict ocean currents? There's certainly a lot of hubris around mapping the genome, but I think that we first need a map before we can begin to make any sense of the territory. Picking nits with the map-makers over how they justify their work certainly isn't helping. Seth: They think disease has a lot to do with genome, I don't. I don't think it makes your point of view more persuasive to call a different point of view "nit-picking".

### **Next Meeting of Make Yourself Healthy Group (2013-05-07 05:00)**

The next meeting of the [1]Make Yourself Healthy Meetup group will be May 23 (Thursday) at the Telegraph Ministry Center (5316 Telegraph, Oakland). Social time will start 6:30 pm, the meeting proper at 7:00 pm. It will last about 2 hours. Admission is \$3, payable at the door, to cover the cost of renting the space. The first speaker will be Robin Barooah, who will tell how he cured his RSI (Repetitive Strain Injury). The doctors he saw were no help.

---

Sara Lake (2013-05-12 00:25:28)

Have you written a guide to running a 'Make Yourself Healthy' group? Or even an outline? I'm keen to start one here in NZ, but feel a bit inadequate... :-/ Seth: I am still trying to figure it out. Your interest is very encouraging, eventually I will have something to say about it.

## **The Power of Lassi, an Underappreciated Fermented Food (2013-05-08 05:00)**

[1]Lassi, you probably know, is an Indian drink made from yogurt. It is rarely sold outside Indian restaurants and supermarkets. However, last week at Whole Foods I saw a product called Pavel's Pro Sea Salt Lassi Yogurt Drink, [2]so new it is not yet on the [3]company website. I have no idea why Pro is part of the name. I bought a bottle. I was surprised how good it was.

I tried making it myself. I found I could easily make better lassi than Pavel's by optimizing the amount of salt, adding an optimal amount of sweetener ([4]xylitol – Pavel's lassi was unsweetened), and flavoring it, for instance with vanilla.

Yogurt companies of the world (except maybe Pavel's) seem to have failed to notice that lassi is a very unusual food. It provides pleasure in eight ways: (1) satisfies thirst, (2) creamy, (3) frothy (if you shake the bottle before drinking), (4) salty, (5) sour, (6) sweet, (7) complexity (yogurt alone is slightly complex, vanilla increases complexity) and (8) flavor novelty (if you vary the flavor). To a small extent, (9) it satisfies hunger and, if you're hot, (10) cools you off. It's also (11) very convenient – easier to take a swig of lassi than a spoonful of yogurt – and (12) very healthy. I can't think of another food with twelve strengths. [5]My friends' pizza provided pleasure in ten ways but wasn't convenient or healthy. There are several similar yogurt drinks in other cultures, such as [6]doogh, perhaps because lassi has such a high benefit/cost ratio.

To make lassi, mix 3 parts yogurt with about 1 part water, add sweetener and salt and flavoring to taste, mix. I'm going to try adding cardamon and maybe replace the water with tea, to increase complexity.

Alex Chernavsky (2013-05-08 07:34:25)

There's also this cultured coconut drink from So Delicious: <http://sodeliciousdairyfree.com/products/cultured-coconut-milk/plain-cultured-coconut-milk-beverage> I buy it on occasion, although it's a bit bland for my taste. I could probably "doctor

it up”, though, per Seth’s ideas regarding cardamom, etc.

d (2013-05-08 08:39:53)

Unrelated, sorry: Seth, get the Sleep Cycle app. It proved to me last night that pork helps me to have better sleep.

Morex (2013-05-08 10:10:18)

I will definitely try this at home! Thanks, Seth!

Kirk (2013-05-08 10:25:07)

My sweet version: yogurt, frozen mango, pinch of salt, sweetener. Basic version: yogurt, ice water, lemon juice, pinch of salt. I started making lassi using a recipe from one of Madhur Jaffrey’s early cookbooks.

Joe (2013-05-08 10:51:09)

Sounds like kefir. Try kefir made from goat’s milk. It’s got all 12, too. Yummy! Seth: do you make your own kefir? I have found it harder to make than yogurt.

garymar (2013-05-08 18:31:53)

In my experience kefir has exactly the same difficulty as yogurt – almost no difficulty at all. I don’t follow instructions to strain the kefir, just skim some off the top for the next batch. That’s because I let it ferment until a small 1 cm band of clear whey appears on the bottom. I do use my yogurt maker since our house lacks central heating, Temperature setting is 28C. After 12 hours it’s done. Delicious, carbonated, complex. Seth: That’s a good idea, use a yogurt maker to make kefir.

Aldo (2013-05-08 23:25:59)

This looks like ayran. <http://en.wikipedia.org/wiki/Ayran> Although ayran is unsweetened.

Joe (2013-05-09 10:53:24)

To Seth: No way! Too doggone lazy for that. Plus, I have no access to fresh goat’s milk. I get this brand: <http://www.redwoodhill.com/kefir> The plain goat’s milk kefir. I get it at a local health food and nutrition store. It seems to be very highly rated, too. It’s so tasty that I have to watch that I don’t drink too much. I drink about 6 ounces per day. It’s delicious! Seth: Thanks for the recommendation. Yeah, maybe I should be that lazy.

Pauline (2013-05-10 00:44:00)

As I have recently started making my own kefir, I have been on the lookout for anything similar in the supermarkets here. I recently noticed Lassi on the shelves in the UK stores, near the milk/yoghurt section, wondered what it was: <http://www.tesco.com/groceries/Product/Details/?id=271748553> They have more than one brand. Thanks for the info. I am going to buy and try some.

Scot (2013-05-10 17:05:54)

A couple of years ago in Turkey we discovered Ayran. After learning it was yogurt, we ordered it every time we ate out. Usually the wait staff were surprised and amused when we did, but I’m convinced it protected me from stomach complaints due to unusual foods for the duration of our trip. It was also very tasty. I found Ayran to be saltier than the sweet Lassi we order at the Indian restaurant. More similar to the Salt Lassi, although thinner.

## **Teeccino Tasting Notes (2013-05-09 05:00)**

I started drinking lots of tea when I started the Shangri-La Diet. The diet made me crave food with smell, which tea provided. I started chewing gum, too, but that was less enjoyable, maybe because I never became a gum connoisseur.

I recently learned about [1]Teeccino coffee-substitute "tees" (brewed like tea) from Patrick Pineda of [2]Tisano. They resemble [3]Pero but with more flavor and variety. I really liked the first two flavors I tried (Vanilla Nut and French Roast) so I wrote to Teeccino asking for samples of all the flavors. In addition to no caffeine, Teechino drinks are high in [4]inulin, a soluble fiber.

Here are my comments on the samples.

Dandelion Dark Roast. Similar to French Roast (relatively strong coffee taste) but more earthy-tasting. Maybe that's the dandelion.

French Vanilla. Strong vanilla taste. Too much like vanilla for me, I want something more complicated.

Caramel Nut. Halfway between caramel and burnt caramel, which I like. As complex as French Roast.

Mocha. Excellent. Complexity of coffee plus complexity of chocolate.

Chocolate. Like mocha, except darker coffee flavor.

Original. Excellent. Weaker coffee flavor plus fruity complexity.

Almond Amaretto. Wonderful combination of coffee flavor with nutty almond/amaretto flavor.

Java. Rounded coffee flavor.

**Chocolate Mint.** Enough mint but not enough chocolate and coffee.

Southern Pecan. Delicious. Pecan and coffee flavors well-balanced. I wonder: What does Northern Pecan taste like?

Maya Chai. Tastes like chai. I would prefer, in addition, a dark coffee taste.

4. <http://en.wikipedia.org/wiki/Inulin>

---

dearieme (2013-05-10 02:24:42)

There's a wonderful soda pop, originating I think in the North of England, called Dandelion and Burdock. You may care to get hold of some and rate it for complexity of flavour.

dearieme (2013-05-10 09:12:01)

Talking of good soda pop, there was a good one we came across in NZ: L & P. I don't drink soda pop usually, but thought I'd try a Kiwi version. Top notch. And, ironically, it's owned by a manufacturer of 'orrible brown sugar water.

Scott Pierce (2013-05-11 05:26:18)

"Southern Pecan. Delicious. Pecan and coffee flavors well-balanced. I wonder: What does Northern Pecan taste like?" Sh\*t. Sorry, a little provincial pride showing through ;)

Rayca (2013-05-15 06:59:58)

I've been drinking Teeccino for 12years. Bought your book. Hope it works. Thx.

## **How Things Begin: Tisano Tea (2013-05-11 05:00)**

[1]Tisano Tea, based in San Francisco, sells chocolate tea. It was started in 2010 by Patrick Pineda, Leonardo Zambrano, and Lucas Azpurua. I was curious about the company because I like two chocolate tea blends very much: Red Cloud Cacao (a black tea/chocolate tea blend from Peet's, no longer available but they will bring it back) and Coco-Mate (from [2]American Tea Room).

Patrick's father was an ambassador from Venezuela. Patrick grew up in California and England and went to college at the University of East Anglia. After studying for a Master's in Film Production from Columbia University (New York), he started working for Al Jazeera in Venezuela making documentaries. He also worked for a local TV station making segments for a children's program. One segment was about cacao. He learned that Venezuelan cacao beans were among the most highly-valued cacao beans in the world. The cacao beans from one valley (Chuao) sold for ten times the usual price.

While making the segment, he met cacao farmers. He discovered a group of cacao farmers whose beans had been organically certified by the United States Department of Agriculture (USDA) due to local NGO sponsorship (the NGO paid for it). The farmers saw it as free training. The organic certification took lots of paperwork to maintain. The farmers had hoped that the certification would allow them to sell their beans at a premium. However, after four years, this hadn't yet happened. At the end of each harvest, they'd had to sell their beans at the conventional (non-organic) price.

This struck Patrick as an opportunity – a niche (organic) within a niche (Venezuelan). In the US, there was a growing demand for organic products. The co-op grew about 16 metric tons of organic cacao beans each year. In 2009, with the financial help of his older brother and friends, he bought 10 metric tons ( \$40,000). A month earlier, he hadn't known that chocolate comes from cacao.

He soon realized there was a problem: How to get it out of the country? If taken straight out, the government would fumigate it and it would lose its organic certification. It would have to be processed in Venezuela. There were several cacao processing plants in Venezuela but to them 10 metric tons was nothing. Patrick finally convinced one of them that organic might be the future. He taught the employees how to process the beans organically while learning it himself. After that it was relatively easy to get the processing plant certified organic.

During processing, 12 % of the weight is "lost" in shells that are normally discarded. Patrick took the shells with him back to America hoping he could do something with them. In Venezuela, he had met an indigenous tribal community that drank tea made from cacao shells as remedy for asthma and to sooth coughs. He looked academic journals for other uses. He eventually found about 120 published papers. The shells had been used as toothpaste and to increase the Vitamin D content of milk by feeding them to cows. The only common uses, it turned out, were as fertilizer (due to the nitrogen content) and animal feed (due to the fiber and Vitamin D content). Neither use was high-price.

What about tea? Patrick sent samples to his partners. They were unenthusiastic. "This tastes like grass. Why would anybody drink tea from a by-product?" However, he was selling chocolate butter and nibs online. With each order,

he included an 8-ounce pouch of cacao shells with instructions how to brew the tea. His customers – at least, some of them – were enthusiastic: How unique, how great, they emailed him. A German woman said she hadn't drunk such tea since World War II ended. During World War II, cacao shells had been added to tea to extend it. His customers wanted to buy more.

He convinced his partners to go to a trade show. In 2010, they went to Expo West, a natural and healthy food product show in Anaheim. Out of all of their products, the tea got the most attention. It won Best in Show for tea. Out of about 500 new products, it was one of four that won Best New Product of Show. People from Twinings Tea and Stash Tea complimented them on their product.

After the trade show, Patrick decided the tea was a good concept and decided to make it a separate brand. Dark chocolate without the guilt. No sugar, no caffeine. He launched Tisano. The name comes from tisane (herbal tea in French) and artesano (artisanal in Spanish).

When I tasted Tisano's chocolate tea, it tasted very familiar. That's because Tisano's cacao shells are the cacao shells in both American Tea Room's CocoMate and Peet's Red Cloud Cacao. There is no doubt that Patrick has created a new niche within the American (and maybe world) tea market: chocolate tea. I don't know how well CocoMate is selling at American Tea Room but I decided to buy it after smelling maybe 40 teas. At Peet's, Red Cloud Cacao sold surprisingly well and they will bring it back seasonally.

## The Lessons of Tisano Tea (2013-05-12 05:00)

I was curious [1]how Tisano Tea began (yesterday's post) because it was an unusual product (chocolate tea). There wasn't any point I was trying to make. At a party last night, however, I found myself talking to the daughter of a diplomat (Tisano Tea was started by the son of a diplomat). I told her the story of Tisano Tea. And I couldn't help pointing out two generalizations it supports:

1. I've [2]blogged many times about the value of insider/outsiders – people who have the knowledge of insiders but the freedom of outsiders. Patrick Pineda, the founder of Tisano Tea, was not an insider/outsider but he connected two worlds – the United States and Venezuela (in particular poor Venezuelan farmers) – that are rarely connected.

2. When people from rich countries try to help people in poor countries, the usual approach is to bring something from the rich country to the poor country. Nutritional knowledge, medicine, dams, and so on. One Laptop Per Child is an extreme example. Microcredit is [3]a deceptively attractive example. In recent years, the flaws in this approach have become more apparent and there has been a shift toward local solutions to problems (e.g., the best ideas to help Uganda will come from Ugandans and those who have lived there a long time). Tisano Tea illustrates something that people in rich countries have had an even harder time imagining: people in a poor country (Venezuela) knew something that improved life in a rich country (the United States) – namely, that you can make tea from cacao husks. A small thing, but not trivial (maybe chocolate tea supplies important nutrients). An American desire for Venezuelan cacao husks improves life in Venezuela. [4]Ethnic food trucks are a more subtle example. When immigrants from poor countries manage to make a living in a rich country – using knowledge of their own cuisine is a good way to do this –

they often send money home. As far as I know, this possibility has been ignored in development studies.

My research, which shows how a non-expert can do research that teaches something to experts, is related to the second generalization. For example, [5]my research on faces and mood has something to teach experts on depression and bipolar disorder. Although the term "home remedy" is standard, and lots of non-experts have improved their health in ways not approved by doctors, I have never heard a health expert show a realization that this could happen.

Alex Chernavsky (2013-05-13 11:02:08)

The story of the diving coach reminds me of the ridiculous swimming tests that some colleges still require of undergraduates: <http://cornellsun.com/blog/content/2012/11/29/cornell-defends-swim-test-tradition-wall-street-journal-article>

Alrenous (2013-05-13 13:43:52)

Yeah, we should care, but rephrase. "Real diploma-holders can't make top diving coach." This is not the first time I've noticed that a conventional diploma looks like a handicap. Instead of putting the lump of butter on the toast, put it on the knife, and then use the toast's natural roughness to rasp off layers of butter. Especially effective, in comparison, if your butter is cold. If instead it's warm, the amount can be controlled by carefully angling the knife. It scatters crumbs, but doesn't toast tend to do that anyway?

garymar (2013-05-13 16:11:06)

"The bacon-lover rode 'shot-bun' in the Wienermobile through her hometown". Ha!

Robbo (2013-05-15 01:55:09)

The coach is not at fault because he didn't try to deceive. The hiring manager is being pragmatic rather than following the rule of his institution. The rule is wrong, and the harm is that the school is making conditions in its advertising that it does not actually follow - a low level of lack of integrity - and thereby is depriving itself of the potential services of even better coaches who lack a degree and who took the school at its word that a degree was required. I'm not affected, I don't care much, but others should care a little.

Ed O'Brien (2013-05-15 08:50:06)

### **Academic Job Advice: Be Able to Say Why You Study What You Study (2013-05-14 05:00)**

Recently I interviewed two job candidates for an assistant professor position at Tsinghua. I asked both of them: "Why did you decide to study this?" (this = their field of research). One had no answer at all. The other had an answer that didn't make sense. I didn't mean it as a tough question. If they had said "because that's what they were doing where I got a postdoc" I would have been perfectly happy. If that were the answer, I might have asked "why does your advisor study it?" - to which "I don't know" would have been perfectly acceptable. Of course, there are better answers.

When I was a graduate student, I read *Adventures of a Mathematician* by Stanislaw Ulam (a very good well-written book). One of the book's comments impressed me: That John Von Neumann was able to distinguish the main lines of growth of the tree of mathematics from the branches. My research was about how rats measure time. The relevance to big questions in the psychology of learning wasn't obvious.

I wondered: Am I studying something important? Or something that will be irrelevant in twenty years? My advisor didn't seem to have thought about this.

When I interviewed for jobs at various universities, no one asked me why do you study this? But it was still a question worth answering. As a grad student I had no choice. But eventually I would have a choice: I could continue to study how rats measure time. Or I could study something else. (Eventually I did change - to studying what controls variation in behavior.)

Here's what I would say now about how to choose a research topic.

What's best is a new method. If you can use a new method to answer questions in your field, do that. The cheaper, easier and more available the method, the better. As a graduate student, I developed [1]a new way to study how rats measure time, which I called the peak procedure. It made it easier to determine if an experimental treatment affected an animal's internal clock.

What's second best is a new experimental effect. Discovering a new way to change something of interest. The bigger, cheaper, newer, and more surprising the effect, the better. Using the peak procedure, my colleagues and I discovered [2]a large and surprising effect (at a certain time during the peak procedure, the variability of bar-press duration - how long a rat holds down the bar when pressing it - became much larger). When I first saw the result, I assumed it was due to a software mistake. It turned out to be a window in what controls the variability of behavior - an easy way of studying that. In that sense it was also a new method.

I don't know if the two job candidates I interviewed were doing either of these two things. Maybe not. My broader point is that if you don't have a good understanding of how to choose a research topic you will have to retreat to

studying something simply because others are studying it. Which is exactly the wrong thing to do if you want to be an innovator and a leader.

1. <http://www08.homepage.villanova.edu/michael.brown/Psych%20175/Roberts1981.pdf>
2. [http://media.sethroberts.net/about/2006\\_variation\\_of\\_bar\\_press\\_duration.pdf](http://media.sethroberts.net/about/2006_variation_of_bar_press_duration.pdf)

---

Nancy Lebovitz (2013-05-14 11:18:00)

Off topic: <http://www.fao.org/docrep/018/i3253e/i3253e.pdf> This is a UN report on insects as food for humans– apparently insects have a really excellent nutritional profile, and I've wondered if a paleo diet should include insects.

### **Sous Vide Secrets (2013-05-15 05:00)**

A few weeks ago, based on the good experiences of friends, I bought a [1]sous vide cooker. As promised, food [2]cooked sous vide (sponsored link) (at very low temperatures, such as 135 degrees F., for long periods of time, such as 48 hours) was excellent, clearly better than other cooking methods. For example, I made short ribs. They came out a perfect texture (slightly chewy), very moist and full of flavor. I also made eggs. At the right temperature, they turned a wonderful custard-like texture.

Sous vide isn't new. [3]Professional chefs have been using it for many years. The equipment has been too expensive (such as \$1000). What's new is lower prices. A friend paid about \$350 for a sous vide cooker and vacuum sealer.

My brief experience suggests two conclusions I haven't read anywhere else:

1. Don't pay that much. I bought a [4]Dorkfood DSV controller ( \$100). It turns the electricity to a crockpot on and off to maintain the right temperature. (A new crockpot is about \$20. I already had two.)

The controller is much better than "home sous vide" cookers (about \$400) because it takes up much less space and can be used to control anything, not just crockpots. I can use it to make yogurt, for example. I no longer need a yogurt maker ( \$15, in China). The only problem with the Dorkfood controller is that you can hear it operate. It makes audible clicks. My crockpots and yogurt maker, which do the same thing at fixed temperatures, are silent.

2. You don't need a vacuum sealer. You put the food in a bag, which is submerged in a water bath. Yes, sous vide means "under vacuum" but vacuum sealing may be inferior to using ordinary freezer bags, which cost less, are much easier to get, and unlike vacuum-sealed bags allow opening and re-closing. When I use an ordinary freezer bag I put the top of the bag above the water so as to not worry about leakage. My low-end vacuum sealer (Seal-a-Meal, \$40) works with ordinary freezer bags, not just the special bags you are supposed to buy. I will eventually do a side-by-side

comparison: cook the same food two ways (vacuum-seal and freezer bag).

1. <http://en.wikipedia.org/wiki/Sous-vide>
2. <http://www.cuisinesolutions.com/>
3. [http://www.nytimes.com/2005/08/14/magazine/14CRYOVAC.html?\\_r=0](http://www.nytimes.com/2005/08/14/magazine/14CRYOVAC.html?_r=0)
4. <http://www.dorkfood.com/>

---

libfree (2013-05-15 07:12:39)

Seth, I think that the primary purpose of getting all the air out is to keep the item completely submerged. It cooks better when it is completely submerged. Seth: I found that the item can be completely submerged using freezer bags. It is easier to get complete submersion with vacuum-packing, that's true.

B.B. (2013-05-15 09:33:46)

Maybe I am paranoid, but I worry about the chemicals in plastic bags contaminating the meat while it cooks all day. That is not a problem with ceramic or metal cookware.

Tom (2013-05-15 10:39:27)

Thanks for this post. I'd been thinking about the Sous Vide Supreme but couldn't justify the cost or space lost. This looks like a home run. Off topic, Seth, but pretty interesting: Powdered food is way more fattening than non-powdered amounts of the same nutrients: <http://kindkehealthnotes.blogspot.com/2013/04/powdered-food-carbs-appears-to-be-very.html> Seth: The powdered food effect is a lot like one of Israel Ramirez's experiments, for example that baked bread is more fattening than the same dough uncooked.

Rene (2013-05-16 06:46:53)

As B.B says, i dont think you have thought about all chemicals there are in "normal" plasticbags, the sous vide plasticbags, are tested and made for cooking at different temperatures, but a lot of cheap plasticbags/frostbags, are NOT, cause they are not made to heat/cook in them! Think about that aswell, for me it is a big thing there always sous vide plastic bags and a vacuumsealer Seth: I agree, this is an important issue.

Michael (2013-05-16 11:17:36)

I have a Sous Vide Supreme (SVS) and I heartily recommend it. Before that, I, too, used a temperature controller connected to a multi-cooker. As far as I can tell, yogurt made in the sous vide supreme is a bit better than my old method due to the superior temp holding capabilities of the SVS vs a multi-cooker or crock pot. (Crock pot will significantly overshoot and undershoot for up to a 5-10F swing). For most things it might not matter too much, but when you are cooking at the low end, say 131F, a significant portion of time spent under the 131F food safety cutoff could result in less than a 7D reduction in bacteria. I use mine enough that it has dedicated counter space, but I do understand the virtues of something that takes up less space.

Tom (2013-05-16 14:24:38)

Michael, if you look at the Amazon reviews, you will see people who are testing the accuracy of the dorkfood unit controlling an ordinary crockpot with very high-quality lab thermometers and finding that the dorkfood unit keeps the crockpot within .25°F of desired temp.

Steve (2013-05-17 07:45:54)

Seth, great insights! Glad to hear the Dorkfood unit works well. It seems like there's no reason that sous vide ovens couldn't eventually be as cheap as crock pots. Here some more info on the plastic safety issue: <http://nomnompaleo.com/post/12463202060/cooking-sous-vide-plastic-safety>

Jazi Zilber (2013-05-18 05:20:06)

hihi The problem is with meats etc. that have germ risk. these will not be sterilized with this device. If you have read the "how to get Smarter" guy (this with the Russian name, hope you remember), then you will see that this method of cooking eliminates the health issues he claims to be had with high temperature cooking

Dave Tufte (2013-05-28 20:28:15)

I have the older Auber control (which still works great after 4 years). Rice cookers work better than crockpots because they heat from the bottom. Definitely need to add to the tips that, since you're using an offboard temperature controller, you need to make sure that the onboard temperature controls are minimal or non-existent (again, points for the rice cookers). Bags that float can be weighted down with fishing sinkers and alligator clips (the lead will be on the outside of the bag, not the inside). When making stuffed grape leaves, Mediterranean cooks will simmer them with a weight on a plate on top. I've had great luck with putting a stoneware soup bowl on top of my bags, and then having the water level fill the bowl and go just above the top. The stoneware rises fairly quickly to the ambient temperature of the water, and keeps your floaters under control.

## **Journal of Personal Science: One Child's Autism Eliminated by Removal of Glutamate From Her Diet (2013-05-17 05:00)**

by Katherine Reid

I am a mother of five children. I live in Fremont, California. In 2009, my youngest child, who was three, was diagnosed with autism. The diagnosis came from her social and communication impairment and highly repetitive behavior. She did not play with other children. She had no imaginary play. She made no eye contact with anyone. She had no spontaneous language. She did not understand questions. Her language was restricted to repeating what she heard (echolalia). In other words, she didn't use language to communicate. She could stack blocks for hours. She would line up toys and have a meltdown if you moved a toy out of line. Everything had to be according to her rules or she was in chaos. She had highly repetitive routines that would escalate into unrest or panic. For example, she would go to wash her hands, turn the water on, turn the water off, turn the water on, and so on. Each time through the routine she would get more upset that she couldn't stop. These loop-like routines might last hours, typically ending because of exhaustion from crying. She also had episodes of absence (blank stares) that lasted 15-30 seconds.

My husband and I tried a number of popular therapies. We tried [1]Applied Behavioral Analysis (ABA) for 3 months. She got worse; her loop-like routines occurred more frequently. We tried speech therapy for 6 months. It increased her vocabulary, but did not improve her communication in other ways. The third therapy we tried was [2]auditory integration training. We did the full series twice, which took a total of 3 months. There was no improvement. Then she started going to a special-needs school, where each student is given an individualized program. At this point, she was 3.5 years old.

Around the same time that she started the new school, we started changing her diet. I had been looking at nutritional deficiencies associated with autism. As a result, we added green veggie smoothies (for example, kale, cucumber, cilantro, nuts, seeds, fruits, it varied with the season) to her diet, supplemented with a multivitamin, magnesium, B complex, Vitamin D3, Omega 3's (EPA and DHA) and probiotic blends (a mix of pills from different companies, such as New Chapter and MegaFoods). Within three days, she began to look people in the eye and began responding to her name. Before the autism diagnosis, we had taken her for a hearing test, because of her lack of

response to her name.

This encouraged us to think that diet was important. We eliminated gluten and casein (dairy) from her diet. Many parents had seen improvement after they made this change. These changes were often not large enough to make the children no longer autistic, but they did improve. Our daughter's response was similar. Her social and communication skills improved, but she was still about a year behind her peers. She still had long outbursts and meltdowns. We were sure it was the new diet, not the new school, that caused the improvement because several times she had eaten gluten or casein at school by accident (e.g., pizza) and her language and behavior regressed. This happened about ten times. Twenty-four hours after these exposures, she was considerably worse. She wouldn't be able to articulate words and her language comprehension decreased. She also became much more emotional and picky (e.g., had to take a certain route home). The regression lasted about five days.

These improvements encouraged me to read more about diet and autism. I read a few clinical studies – there were hardly any. On blogs, I read about parents' experiences. On one blog – I can't remember which one – I read a comment from a parent that he found that his son benefited from removing gluten and casein, and, importantly, MSG made his son worse. What idiot feeds his child MSG? I thought. I was wrong.

I have a Ph.D. in biochemistry, with an emphasis in protein chemistry, from UC Santa Cruz. I have spent 20 years conducting research and development on proteins for therapeutics and molecular diagnostic applications. Proteins are made of amino acids, the most abundant of which is glutamic acid. When a protein breaks down, glutamic acid is released. I discovered that I had been feeding my daughter plenty of glutamate. I started researching [3]connections between glutamate and autism and convinced myself it was plausible that too much glutamate caused behaviors associated with autism, as well as other brain disorders. Suddenly I understood why removal of gluten and casein might help. Both proteins have a high glutamate content (= a large fraction of their amino acids are glutamic acid). Common types of food processing break down these proteins. For example, fermentation, ultra-pasteurization, adding acid (such as lemon juice), and adding enzymes (e.g., when making cheese) all create free glutamate.

I started looking into food labels. [4]Glutamate can be hidden in many ways, I learned. For example, "natural flavor" may be up to 60 % glutamic acid. Perhaps my daughter had a predisposition to glutamate sensitivity; my research revealed that many of us do. There are glutamate receptors all over the body, including the brain. For example, glutamate receptors in the pancreas regulate insulin secretion. To reduce the amount of glutamate in her food, I tried to remove all processed proteins from her diet. This wasn't simple. Apple juice may have "natural flavors". Toothpaste may have glutamate. Our new diet mainly consisted of organic vegetables, fruits, seeds, nuts, meat, quinoa, and rice. We stayed away from any product with processed soy, corn, or wheat (because of the processed protein). Corn on the cob or edamame was fine because they aren't processed.

This was a huge shift in the family diet and was met with protest. My husband was hesitant because the advice from a team of neurologists had been to try behavioral therapy again. (ABA is one type of behavioral therapy.) They thought a better therapist might help. That was their main advice. They told us they hadn't seen gluten-and-casein-free diets produce improvement.

In May 2010, we made the big dietary changes. After we started the new diet, my daughter never again had a meltdown. She had had one the previous week. About a month later, at the end of the school year, we were contacted by the special-needs school. They said she had improved so much that she should go to a mainstream pre-school. At this point she was almost four. Her language and social skills quickly caught up with her peers. Of my five children, she is the most social and outgoing. Today, at 6 years old, she attends a public school kindergarten. At a September 2012 parent-teacher conference, her kindergarten teacher was shocked to find out that she had been previously diagnosed as autistic.

I decided to make it my mission to educate and raise awareness of the amount of free glutamate in our food and the health ailments associated with it. The name of my mission is Unblind My Mind. More information can be found at [5]unblindmymind.org.

Katie spoke about this at the first [6]Make Yourself Healthy Meetup.

Darrin Thompson (2013-05-17 09:24:46)

Interesting. I'll go out on a limb and agree with the evil experts statement: "They told us they hadn't seen gluten-and-casein-free diets produce improvement." IMHO they say that because, in fact, they have probably seen lots of people attempt gluten-and-casein-free diets which produced no improvement. Back in the day when autism intervention diets were hard, you couldn't eat anything packaged or processed. Now there are whole factories making easy processed packaged foods which are GF and sometimes GFCF. And we don't see any improvement in the kids symptoms. So I fully understand where the medical professionals were coming from. "Our new diet mainly consisted of organic vegetables, fruits, seeds, nuts, meat, quinoa, and rice. We stayed away from any product with processed soy, corn, or wheat (because of the processed protein). Corn on the cob or edamame was fine because they aren't processed." That's hard to do. That's more than GFCF. That's old-school GFCF. And it's probably what is needed to really see an improvement. We do something like that, we've seen enormous progress in our children who have autism. However, it's hard to cook \_all\_ the time. Eating out is a crap shoot every time. At school the most well meaning staff will sometimes make a mistake, feed your kid something off list, and you won't know, other than your really effective diet mysteriously quits working for a day or three. This glutamate angle is interesting. We've been pursuing a low lectin approach for awhile but we'll have to queue this up for later. Seth: These results make clear why a GFCF diet could sometimes work, sometimes fail. They sometimes fail because there is so much glutamate in the rest of the diet that even when gluten and casein are eliminated there is still a disabling amount of glutamate left. The real expert failure here is not their statement about GFCF diets, which could easily be accurate, but their failure to learn from this success.

Reanna (2013-05-17 14:41:44)

I've been meaning to comment for a while: The Fertility Awareness Method is another good example of people using personal science to solve problems one step ahead of traditional medicine. Here's a video that gives you some idea of how it can be applied: <https://kindara.zendesk.com/entries/23375112-Video-Kati-s-Experience-With-FAM>

shtove (2013-05-17 17:54:48)

Katie Reid is very impressive, and the clip of her little girl at the end of her video is brilliant - so bright and full of character - vid is here (13:35): [http://www.youtube.com/watch?v=J\\_ZfldDCpdU](http://www.youtube.com/watch?v=J_ZfldDCpdU) But I can imagine other parents who have failed with similar methods getting frustrated with her certainty. "There is a real sense in which dietetics is harder than cosmology." - Martin Rees.

AlexiDSadeski (2013-05-18 14:50:27)

Seth, you have been advocating a lot of fermented foods. Does Katie's research change your mind on that at all? Katie, do you see things like sauerkraut having an affect on your daughter? Have you stopped eating fermented foods and would you recommend that to others? Seth: No, this work doesn't change my mind. The benefits of fermented food are clearly huge. Maybe some people are more sensitive to glutamate than usual – perhaps for enviromental reasons, perhaps for genetic reasons. Sauerkraut is not fermented protein; only fermenting protein produces glutamate.

babar (2013-05-18 18:52:29)

well she's lucky her kid wasn't an extremely picky eater (this means that any change with eating routines causes extreme anxiety) like many kids on or near the spectrum.

Mike H (2013-05-19 18:01:32)

I just stumbled on this site, but the older posts on this subject were closed to comments so I just thought I'd comment here. I'm a Vitamin D and sleep enthusiast, but the theory I follow has nothing to do with the time you take Vitamin D. Instead, it's all about what your level is. (60 - 80 ng/ml being optimal). I didn't see her theory mentioned anywhere so I thought I would direct you to it. <http://drgominak.com/> I also highly recommend her YouTube videos. I think she's onto the real mechanism between Vitamin D and sleep.

Katie Reid (2013-05-21 20:56:38)

In response to Alex about fermented foods: the fermented processes that I find concerning are when we fortify our food with protein (such as in the baking of many wheat breads) and then add high concentrations of bacteria or yeast to speed the fermentation process and "add flavor". The natural fermentation processes that are slow and on foods naturally low in protein are not the issue.

ChristianKI (2013-05-18 06:41:16)

As Ranbaxy is an Indian company jailing its owners is something that the Indian government should do. It's probably not the job of the US government to jail the executive of the companies of foreign countries.

Nancy Lebovitz (2013-05-18 12:54:17)

Good news about the Yelp reviews of prisons- if Kermit Gosnell's abortion clinic had been reviewed, I don't think it could have been that bad for that long.

Nancy Lebovitz (2013-05-18 13:05:27)

As for Roxio and many other problems, cheap reliable quantitative chemical analysis would help a lot. When I say "cheap", I mean cheap enough that a lot of people have their own kits.

dearieme (2013-05-21 07:31:19)

"Jail for the owners?" With fake drugs, it maybe you could pin murder on them, and then there's no need to stop at jailing.

Adam (2013-05-22 04:21:27)

No need to stop at jailing? I was actually thinking that they might be doing some patients a favor by giving them Placebo instead of active drug!

### **"You Can't Change Something Unless You Love It": The Case of Dr. Gilmer and Dr. Gilmer (2013-05-19 05:20)**

"It's a funny thing," Jane Jacobs told an interviewer in an interview I cannot find, "you can't change something unless you love it." (By "change" she meant improve.) She had seen that people who disliked cities gave poor advice about improving them and understood that it wasn't just cities. To improve something, it isn't enough to have a good idea. You also need to (a) pay close attention and (b) overcome obstacles. (a) and (b) aren't easy. You are unlikely to do them without strong motivation, such as love.

Jacobs's point is at the heart of the success of my personal science. My personal science is hugely different from professional science, but different may or may not be better. It has succeeded, I'm sure, because of what Jacobs says. How did I manage to find new ways to sleep better, lose weight, and so on? I had good ideas, yes, but so do many people, including professional scientists. One reason for my success: I observed myself closely. Now and then I noticed outliers (e.g., nights when I slept unusually well, days when I lost my appetite). These gave me ideas to test. In professional science, this rarely happens. For one thing, they can't wait for outliers. They are under pressure to get results soon. Another reason for my success: I persisted. For many years, I measured my weight, sleep, mood, and so on. Unlike a professional scientist, I had no required output. I could spend as much time as necessary.

I keep coming back to this because Jacobs's point is absent from conventional American thinking, such as New York Times op-eds. But it is illustrated again and again. A recent episode of *This American Life*, titled "[1]Dr. Gilmer and Mr. Hyde", is about two doctors named Gilmer: Dr. Benjamin Gilmer and Dr. Vince Gilmer (who are unrelated). VG kills his father and goes to jail. BG replaces him at a rural clinic. His patients tell him what a nice man VG was. This puzzles BG: Why would such a nice man kill his father? The legal system had ignored this question or at least not provided a convincing answer. BG, on the other hand, actually cares. (Spoiler alert.)

He gathers information about the case and visits VG in prison.

With the help of a psychiatrist friend, he comes up with a new idea: VG has [2]Huntington's disease, whose symptoms include aggression (such as murder). In prison, VG has been far too aggressive. His hands shake some of the time; this had been called "malingering" (faking) by a psychologist. When tested, it turns out VG does have Huntington's disease, in the sense that he has the gene for it. When VG was given medication appropriate for Huntington's disease,

he got much better.

BG, who cared about VG, managed to improve his condition. The legal system, which did not care about him, did not. The implication for all health care, including research, is straightforward: Empower those who care.

---

Allen K. (2013-05-19 05:39:37)

Of course, where this point is present in American op-ed thinking is in those that call for government-hater politicians to get out of the way of those who would actually attempt good governance. Seth: You might be right: people who dislike government will be bad at it. But the original claim is about the objects of governance.

idyll (2013-05-19 06:32:21)

A corollary: if people do NOT love an institution, it will change, but not for the better.

Tom (2013-05-19 10:41:21)

Without love, you not only can't change something, you can't even truly understand it. Loving a thing gives you the opportunity to know it. This is also true of creative endeavors. Sometimes people who don't like a given creative genre – say, country music – will still set out to write something in the idiom, thinking it is "easy." They invariably do atrocious work. The audience for creative works – and perhaps for things like cities, phones, etc – is itself there in the hopes of loving the thing. So only through love does the creator have even a chance of creating a thing a user would love. Love from creators is crucial yet undervalued. And the result on the audiences' side is delight, which is also usually an afterthought. A good case in point is New York's repurposing of the disused elevated train tracks into a park. For years it was mocked as a foolish idea. Now cities all over the world are falling over themselves to create their own parks in the sky.

Jon (2013-05-19 20:20:54)

As such government should get out of the way of people that love to help others. Remove licensing laws (AKA "grants of monopoly").

Jon (2013-05-19 20:27:10)

Allen K., I agree with you whole heartedly. We need to help those that truly care about good governance by getting rid of the monopoly of government, or rather, statism. This would enable those that truly care about others, through the free market, to help their fellow countrymen. As we saw from Seth's anecdotal story (which holds much truth) the monopolies don't work, it is the individual who has interest in making a difference that does. Unfortunately monopolies only create bureaucratic entities that don't care about their customers.

Duncan (2013-05-20 02:22:41)

By happy chance, I just read this typo on Dave Winer's blog: "So let's solve the problem."  
<http://threads2.scrippling.com/2013/may/usersMailListForDropbox>

## Give and Take by Adam Grant (2013-05-20 09:42)

The publisher sent me a copy of Give and Take by Adam Grant after I sent several emails asking for a review copy. I expected it to be the best book about psychology in many years and it is.

The book's main theme is the non-obvious advantages of being a "giver" (someone who helps others without concern about payback). Grant teaches at Wharton, whose students apparently enter Wharton believing (or are taught there?) that this is a poor strategy. With dozens of studies and stories, Grant argues that the truth is more complicated – that a giver, properly focussed, does better than others. Whether this reflects cause and effect (Grant seems to say it does) I have no idea. Perhaps "givers" are psychologically unusually sophisticated in many ways, not just a relaxed attitude toward payback, and that is why some of them do very well.

I was more impressed with two other things where cause and effect is clearer. One is a story about communication style. It is the best story in a book full of good stories. About ten years ago, Grant was asked to teach senior military officers how to motivate their troops. His first class was a four-hour lecture to Air Force colonels in their forties and fifties. Grant was 24. The feedback forms, filled out by the students after the class, reflected the age – and presumably wisdom – discrepancy. One comment was: "More quality information in audience than on podium."

Grant taught the class again, to another group of Air Force colonels. Instead of talking about his credentials at the start of the class, he began like this:

I know what some of you are thinking right now: What can I possibly learn from a professor who's twelve years old?

Everyone laughed. Grant does not say what he said next – how he answered the question. He went on to give the same lecture he had given before. The difference in feedback was "night and day". Here is one of the comments: "Spoke with personal experience. He was the right age! High energy; clearly successful already."

This is great. A non-obvious, seemingly small change produces a huge outcome difference. Grant clearly understands something enormously important about communication that isn't not found in other psychology books, such as introductory textbooks. It isn't easy to interpret (why exactly did Grant's new opening have its effect?) nor study experimentally – but that's fine. In Give and Take, Grant follows this story with research about what is called "the pratfall effect": Under some circumstances making a blunder (such as spilling a cup of coffee) makes a speaker more likeable. But Grant's opening ("what can I learn...") isn't a blunder. Grant calls it an "expression of vulnerability", a category broad enough to include pratfalls – fair enough.

What can we learn from Grant's story? Above all, that something mysterious and powerful happens or might happen at the beginning of a talk and that ordinary feedback forms are sensitive enough to detect it. What Grant did was highly specific to the situation (young speaker, older military officers) so you can't copy it. To use it you really have to grasp the general rule. Which remains to be determined.

Tomorrow I will blog about another impressive part of the book.

Tim Beneke (2013-05-20 11:34:15)

Perhaps with the generals he established his insight immediately by getting inside what many were already thinking – with humor (emotion). They were then attached to perceiving him as "insightful" and framed his observations that way, had a positive cognitive bias that led to confirmation bias as they heard him talk. In working with other people for the first time, I always try hard to impress them initially.... It's a fascinating story... Seth: I agree, a plausible interpretation and quite different than what Grant says.

Alex Chernavsky (2013-05-20 11:48:06)

A couple of months ago, *The New York Times Magazine* ran a cover story about Grant and his research: [1]<http://www.nytimes.com/2013/03/31/magazine/is-giving-the-secret-to-getting-ahead.html>

1. <http://www.nytimes.com/2013/03/31/magazine/is-giving-the-secret-to-getting-ahead.html?pagewanted=all>

George (2013-05-20 14:19:39)

Wait a minute, what Grant did was extremely obvious and easily replicated in many situations - he was sensitive to the ego of his audience. He understood that old people resent being taught wisdom by young people - a fairly obvious observation that any of us might make - and acknowledged that he was in fact, inferior to his audience in wisdom but had a special message to relate, thus pleasing their ego and allowing them then listen to his message. It is quite common for people to let their ego and sense of self-importance make them close-minded - if you can disarm their ego defenses, they listen to you more. This is basic stuff - in ANY situation being sensitive to the ego of your audience will disarm potential mind-closing resentment and increase receptivity to the message. Seth: You might be right. But it's far from "extremely obvious". Grant explains it quite differently.

vic (2013-05-20 16:35:03)

He penetrated his audience's defenses with a disarming joke - hardly rocket science. I hope there is more to the book than this... Seth: Was his audience "defensive" as you say? Not clear from Grant's description. As for the "disarming" joke, the question is why was it disarming? Lots of jokes at the start of talks have roughly zero effect, as far as I can tell.

Tom (2013-05-20 17:17:34)

The book is awesome. Really looking forward to hearing more of your insights on it, Seth.

George (2013-05-20 17:36:54)

Well, Grant showed *humility* - how this can be seen as anything other than a concession to your audience's sense of self-importance I do not know. I guess I'll have to read the book to find out, but I hope it isn't just another attempt to explain something fairly simple through over-complicated theories in an attempt to be original. In any event, showing humility is always a disarming strategy and can reduce ill-will, resentment, jealousy, and thus reduce attempts to "take you down". Seth: Is it humble to state the obvious, in this case your age? Humility is usually about more subtle characteristics, such as wisdom. Maybe Grant was humble in what he said next (which he doesn't tell us), after the joke about being 12 years old.

ken (2013-05-20 21:06:43)

There is a great book about improv acting called *Impro* by Keith Johnstone. A reliable way to get a laugh as an improv actor is to change the social status you are playing on stage. If I recall the book correctly, it postulated that students respect/fear the teacher who plays high-status; they can appreciate the teaching who always plays low status; but they love the teacher who vacillates back and forth between the two extremes.

asdf (2013-05-21 10:43:12)

I feel like shaking my head at some of these butthurt commenters. Go be killjoys somewhere else.

jason (2013-05-21 11:42:16)

the general rule is to figure out what the other person is thinking and feeling and refer to it in a way that doesn't express judgment. clever salesmen do this all the time and it's a standard tactic in the pick-up artist's repertoire. heck, grant uses the

same move in his interview on the newyorker site to make the interviewer more comfortable: "you've probably encountered many takers". it's rapport building 101. when it's described as a 'tactic' it sounds cheap and exploitative but you can't know what the other person is thinking or feeling if you don't empathize with them. "i know what you're thinking.." is often a reliable signal of genuine sympathy and interest.

Li (2013-05-21 19:20:03)

Seth: Why did you expect the book to be the best one about psychology in many years? Seth: Because I'd heard about his work about improving call-center performance at the University of Michigan: He figured out how to make the callers think their jobs are helping people and this made the callers perform much better. An extremely impressive result. (I blogged about it in the next post.)

### **More about Give and Take by Adam Grant (2013-05-21 05:00)**

Yesterday I commented about Give and Take by Adam Grant, a professor at Wharton who teaches organizational psychology.

When Grant was a graduate student (at the University of Michigan), he was asked to help people at the university's fund-raising call center raise more money. They call alumni, asking for money. The person who ran the center had tried the usual motivational tactics, such as offering bonuses. They hadn't worked.

Grant noticed that most of the money being raised went for scholarships. He tried various ways of making the call center employees aware that the money they raised helped students directly. The most effective way turned out to be a 5-minute meeting with a scholarship recipient. This had a staggering effect:

The average caller doubled in calls per hour and minutes on the phone per week . . . Revenue quintupled: callers averaged \$412 [per week] before meeting the scholarship recipient and more than \$2000 afterward.

A huge effect – and a useful huge effect. And one that is not even hinted at in countless introductory psychology books. Notice that physical conditions of the job and the "physical" payoff (the salary) didn't change. All that changed was employees's mental models of their job.

I conclude that people are far more motivated by a desire to help others than you would ever guess from reading psychology textbooks – and, even more, from reading economics textbooks. Grant says nothing about this, at least in the book, but I'd guess that the employees were considerably happier at their jobs as well. You might think that there has been so much research on job design that there were no big effects left to be discovered. You'd be wrong.

MikeW (2013-05-21 10:08:05)

Well my inner skeptic is saying, is this just another version of the Hawthorne Effect? I.e. their productivity improved simply because they knew someone was trying to improve their productivity. He says he tried things that didn't work, so maybe it's not the same effect. A key distinction would be if the productivity gains persisted long term. At Hawthorne, it always fell back to baseline eventually. Seth: Lots of things didn't improve productivity. It's not the Hawthorne effect.

garymar (2013-05-21 15:18:22)

Doesn't an economics education *decrease* altruistic behaviors?

jason (2013-05-23 09:05:53)

motivation is the result of specific mental states. maybe meeting the scholarship recipients made it easier for the cold-callers to invoke the recipient's desires and 'borrow' their motivation? the increase in motivation/effectiveness may come from something as simple as asking and answering the question "what would i do if i were a scholarship recipient? empathy is a powerful tool. in any case, interesting.

### **More on the Synergy of Walking and Learning (2013-05-22 05:00)**

A few years ago, [1] discovered that walking made studying Chinese more pleasant and studying Chinese made walking more pleasant. It's a big effect. While walking on a treadmill I could easily study Chinese for 40 minutes; while sitting or standing still, 5-10 minutes. The general idea seems to be that walking creates a thirst for novelty, for dry information. An evolutionary explanation is that this effect caused us to better explore our surroundings. Such exploration paid off too rarely and/or with too-long delays to be supported by the usual reward-action mechanism.

Jeremy Howard, the president of Kaggle, [2] discovered the same effect independently while studying Chinese. A few days ago, I heard from Patrick Roach, a medical student in the Midwest, who also discovered the same effect independently – in his case, studying anatomy rather than Chinese. He [3] blogged about the Anki/treadmill combination. I asked him if walking on a treadmill made it easier to study Anki? He replied:

Absolutely. I originally tried this with a 3100 card deck I created while studying anatomy in med school. The format (Image/Name) was perfect for reviewing while walking, as there wasn't too much text to read. I imagine your experience with learning a new language was similar. Anyways, Treadmill + Anki (+Music) along with my Tablet / Wiimote combo was *much* more productive than either task alone. I could easily spend 1-2 hours and not notice the time passing in the same way it dragged on when trying to study endless flashcards sitting in a quiet room. Getting tired or losing focus was less of an issue as well - I noticed I had less distractions/extra attention to spare while walking.

Thanks for getting in touch, Patrick. As [4] Lewis Carroll said, "What I tell you three times is true."

August (2013-05-22 06:39:07)

This is what Google Glass is good for. Unfortunately, they are pushing all the 'social' nonsense.

gwern (2013-05-22 07:44:48)

> The general idea seems to be that walking creates a thirst for novelty, for dry information. An evolutionary explanation is that this effect caused us to better explore our surroundings. Or, besides the far-fetched evolutionary just-so story, walking is serving the same function that music does - it serves as a distraction and interruption when one gets briefly bored, and the more one likes the music, the worse one performs on a memory task, eg. <http://dl.dropbox.com/u/85192141/2012-perham.pdf> > Twenty-five undergrads completed several serial recall tasks. They were presented with strings of eight consonants and had to repeat them back from memory in the correct order. Performance was best in the quiet condition, but the key finding was that participants' performance was worse when they completed the memory task with a song they liked playing over headphones (Infernal's "From Paris to Berlin"), compared with a song they disliked (songs such as "Acid Bath" from the grind core metal band Repulsion). In case you're wondering, participants who liked Repulsion were excluded from the study. Particularly germane, about that same study: > A further intriguing detail from the study is the participants' lack of insight into the degree of distraction associated with each type of music. Asked to judge their own performance, they determined correctly that their memory was more accurate in the quiet condition, but they didn't realise that their performance was poorest whilst listening to the music they liked. So, call us after you've randomized some days or weeks of walking/no-walking and observed an increase in average grade or something. This should be a cheap easy experiment to run, especially if it really is "a big effect"...

Tom (2013-05-22 08:08:46)

*besides the far-fetched evolutionary just-so story* The rotary press is less than two centuries old, making it impossible for our brains to be evolved to do it particularly well. Humans have been walking and needing to recognize and remember locations of food, water, dangers & opportunities for millions of years. So, without the snottiness, how is this idea "far-fetched"?

gwern (2013-05-22 08:35:28)

> So, without the snottiness, how is this idea "far-fetched"? \*Any\* evolutionary story is far-fetched without supporting evidence. Why? Because there are bazillions of possible mechanisms and theories out there: what singles out, from all these possibilities, 'walking has to trigger an entirely new specialized reward system because I vaguely speculate that such a thing might be adaptive'? You might as well say that people love Justin Bieber because his smooth skin reminds them of ripe fruits and this would be adaptive on the African savannah. It is simply privileging the hypothesis. You don't get to just make up random crap and say that any criticism of it is 'snottiness'!

nick (2013-05-22 09:42:34)

I experienced something similar but under different circumstances. I've been watching some educational online courses and while doing that did some physical exercises for the back, shoulders and legs. Normally if I just sat and watched my attention span would be gone in 10 minutes or so and I would get bored quickly. Combined with physical exercise, though, I could do with no issue an hour long session which in my world is a lot. The nice thing is also that after completing the session I felt I could do more and did not feel as tired as I would usually feel. Looks like general physical exercise could be very beneficial to brain activity. Seth: Interesting, I haven't tested other exercises. I noticed that if I am sitting down I would rather watch a movie than study Chinese. Whereas if I am walking I would rather study Chinese.

August (2013-05-22 10:25:45)

We need a hypothesis to test. This is no 'just-so' story. You may be able to term it a 'just try' story. This is the realm of personal science. I realize in the grant writing/granting realm certain stories are there to completely obliterate any testing. The recent hullabaloo surrounding Richwine is a good example, since he inadvertently got squashed by the 'just-so story' known as equality, which stops rather than encourages research.

gwers (2013-05-22 19:59:32)

> We need a hypothesis to test. There is a hypothesis, yes. It is 'walking improves memory performance or concentration'; like most hypotheses framed, it is probably wrong and I've given some examples of why Roberts and other people might have a subjectively mistaken impression, but the hypothesis is certainly not impossible - if saccading can improve memory in right-handed people or chewing gum temporarily boost performance, I don't see why walking couldn't cause an alerting effect too. And you're talking about testing? This is easily testable: this can be tested objectively by Anki's built-in statistics collection or window-tracking (for memory performance and procrastinating, respectively). Roberts has chosen not to do so.

> This is no 'just-so' story. But there is also a just-so story here. It is the just-so story that this hypothesized effect of walking is due to some story about our ancestors walking on the savannah and needed more delayed reward cycles and this explains why the hypothesized effect exists (ah, just so!). This is literally in the first paragraph of the post: "The general idea seems to be that walking creates a thirst for novelty, for dry information. An evolutionary explanation is that this effect caused us to better explore our surroundings. Such exploration paid off too rarely and/or with too-long delays to be supported by the usual reward-action mechanism."

Valerie (2013-05-22 21:09:57)

I am not sure if my example is the exact same phenomenon, but I think most people will be familiar with it: Listening to music on the radio is rather boring. Sweeping the floor is rather boring. Sweeping the floor while listening to music is much more enjoyable (I would not call it fun, but it is not boring). In the same vein, exercising is boring. Exercising while listening to music is ok (again, not quite fun, but much less boring). I wonder if mixing any two rather boring activities makes the mix more fun, or if it needs to be one mental activity with one physical activity. Sweeping the floor while exercising (without music) seems very unappealing to me, though I have never actually tried. Seth: People choose to listen to music in many situations - hard to say that it is usually "boring". I think it is more complicated than what you say. Sitting at a desk doing nothing is very boring - but sitting at a desk studying Chinese isn't much better. Walking on a treadmill doing nothing is very boring - but walking on a treadmill studying Chinese is pleasant.

Donald (2013-05-23 04:05:09)

The article that appeared on my netvibes after reading yours, somewhat relevant: "I tricked myself into loving my workout" - <http://lifehacker.com/how-i-tricked-myself-into-loving-my-workout-509289090> Seth: In the article she says she reads novels during her workout. Similarly, I watch TV I enjoy. What was shocking was to discover that, during treadmill walking, studying Chinese was more pleasant than watching favorite TV. While sitting, the reverse was true.

Pauline (2013-05-24 08:47:27)

I had a similar experience this week. I got bored listening to a video on internet even though the topic was something I am very interested in it. I decided to do some exercises while listening with laptop nearby on the floor. Somehow doing the two together your brain engages more while your body is busy. You are distracted from your own boredom and that focuses attention more.

Brian Person (2013-05-26 09:28:23)

It's not a stretch to say doing a physical activity increases attentiveness and tunnel vision. And that there would be evolutionary advantages to this. The most popular drug on the planet's purpose is to get the effects of physical activity without physical activity. Methamphetamine stimulates the mind to be more attentive to those with attention deficient. Some children have trouble learning if they're just sitting around. It also makes sense for the mind to not assert itself when sitting still to help conserve energy. As a thought experiment, evolutionary psychology can work if you think about it long enough. If your interest in doing the experiments to prove it, by all means. But this isn't a stretch of the imagination. Because you can make it up doesn't mean on it's face fallible, it just means it's not proven. Just ask pre experiment Einstein.

Sam (2013-06-02 17:14:05)

I imagine I'm late to the comment party, but exercise is known to boost BDNF levels. This and or other chemical responses to exercise may be responsible for your enhanced abilities while exercising.

## Next Meeting of Make Yourself Healthy Group is Tomorrow (Thursday) (2013-05-22 09:23)

The next meeting of the [1]Make Yourself Healthy Meetup group is tomorrow (May 23, Thursday) at the Telegraph Ministry Center (5316 Telegraph, Oakland). Social time will start 6:30 pm, the meeting proper at 7:00 pm. It will last about 2 hours. Admission is \$3, payable at the door, to cover the cost of renting the space.

The first speaker will be Robin Barooah, who will tell how he cured his RSI (Repetitive Strain Injury). What his doctors told him to do didn't work.

1. <http://www.meetup.com/Make-Yourself-Healthy-Meetup-Group>

---

Alex Chernavsky (2013-05-27 06:56:12)

Seth - how did it go? By the way, if anyone in Buffalo / Rochester / Syracuse/ Finger Lakes (Upstate New York) wants to form such a meeting, contact me at [1]alex@aya.yale.edu. Seth: Robin's talk was fascinating. But there were only about 8 attendees, which worries me.

1. <mailto:alex@aya.yale.edu>

## Anti-Procrastination Software Available (2013-05-26 18:16)

[1]

This graph shows how much work I did in early 2013 (one point = one day). It gradually rose from about 2 hours/day to about 8 hours/day. I did not literally get to 8 hours/day because some tasks got counted extra. For example, one minute of Chinese counted as 2 minutes and one minute of book writing counted as 1.5 minutes. The data is in three blocks because sometimes I didn't use the tracking program (e.g., due to travel).

I gathered the data with a program that gave [2]percentile feedback. Percentile feedback compares where you are now (measured in various ways, such as time of day, e.g., 3 pm) to where you were at the same time on previous days and summarizes the comparison with a percentile: 75 means more work done than on 75 % of previous days at the same time; 50 means more work done than on 50 % of previous days at the same time. Displays of such feedback, I noted [3]earlier,

are curiously likable. They usually praised me, in the sense that the percentile score was usually well above 50. . . . They are calm, in the sense that they do not change quickly. . . . Every improvement was noticed and rewarded — and every non-improvement was also gently noted. It was as if the display cared.

Nick Winter [4]used with an earlier version of percentile feedback ([5]video). "The percentile feedback has been a huge success," he wrote. "I'm getting way more done than I ever did, and I'm much better at prioritizing toward my main project."

The new version has several improvements. The biggest change is weights – different tasks may have different weights. Tasks that are more valuable or more difficult get more weight. If you keep failing to do something important, you increase its weight, making it more attractive. For a long time, I have had trouble making myself study Chinese. This has helped a lot.

It has also pushed me away from blogging (less valuable) toward book writing (more valuable). I am writing a book about personal science. The chapter I am writing now is about procrastination.

This program has been a big help with procrastination and has improved my use of time in other ways. To get material for the procrastination chapter, I am making the program (written in R) available, along with a draft of the procrastination chapter. I want to find out what happens when other people use it.

To get the program and use it, you need to install [6]R (which runs under Windows, MacOS, and many UNIX platforms), use Dropbox, and use PayPal. You can do some work away from the computer but it won't work unless you do most of your work at or near the computer.

For better or worse I have learned it is a waste of time to give software to others for free. If you are interested in using it, please send me an email with the following information:

1. Your job.
2. Why you want to try this.
3. How much you will pay (non-refundable after 2 days).
4. How long you will commit to using it.
5. How much you will pay if you don't meet the commitment (= a refundable amount).

I'll pick the highest bidders. If you're one of them, you'll give me the amount in #3 plus the amount in #5 via PayPal. I'll install the program on your computer via Dropbox and show you how to use it (in addition to the written instructions). If you use it for the promised length of time, I'll refund the amount in #5.

---

Nile (2013-05-26 21:50:29)

I am not familiar with R. Will you be making source code available or is it an executable? I think I can compile R under Linux but if I do, I don't believe an exe file made for Windows would run under Linux. If the software is source code however it should run in either Windows or Linux. Seth: I will provide an R workspace that contains the source code. You run it by loading the workspace and typing instructions. Now that you mention it, I realize it should run under Linux.

Alex Schell (2013-05-27 06:50:43)

How much time do you spend every day using the program? Seth: 12 hours or more.

Alex Schell (2013-05-27 07:26:41)

I meant to ask how much time goes into the actual tracking process, i.e. what's the time cost of using this program? Seth: It takes 10-20 seconds to log a change (starting or stopping something). Go to R, type command, go back to whatever I was doing.

Thomas Johnson (2013-05-27 11:00:37)

Do you feel like this is significantly better than the kind of feedback that RescueTime offers? Seth: I haven't used RescueTime. However, I have tried simply tracking my work, which is the main thing RescueTime does (and provide summaries of the data). I have found this much more helpful.

Jim (2013-05-27 13:54:16)

H Seth, Sorry, I don't see your contact information on the site. Maybe I'm looking in the wrong places?

Jim (2013-05-27 14:31:51)

OK. Found it. Thanks.

tim (2013-05-29 08:49:06)

I am interested - cant find your contact info anywhere on this blog Seth: Look under Ask Me Anything.

Ilya (2013-06-04 16:10:43)

Seth, are you familiar with beeminder.com ? Seth: Just a little. Thanks for mentioning it.

Matthias (2013-06-05 18:00:58)

"For better or worse I have learned it is a waste of time to give software to others for free." What do you mean by that? Seth: It's a waste of my time in the sense that I take time to give Person X the software and, after that, get no feedback.

Ross (2013-06-12 08:37:40)

Professor Roberts, I presume the folks you have chosen are alpha or beta users. When do you think the software will be generally available? - Ross Seth: In a few months, I hope.

## Useful Knowledge: Arithmetic and Chinese (2013-05-27 07:10)

Long ago, a friend told me that when she was in first grade, she had a lot of pennies. She knew how to add but not subtract so after she spent some, she would have to count them again to know how many were left.

I have finally reached the last lesson (Lesson 12) in my beginning Chinese textbook, which I have been using (fitfully) for more than a year. Later lessons build on earlier lessons. When I didn't know a word in a later lesson, I scanned the new-word lists from earlier lessons to find it. I have just discovered there is a word index.

---

Elizabeth Molin (2013-05-27 09:55:07)

I did the same thing when I was tutoring a Dutch high school student in English. We were reading a YA book together, and I was making her translate as we went along. When she didn't know a word, I would have to come up with a Dutch equivalent for her. When we got to the end of the book, we discovered the glossary.

gwern (2013-05-27 12:16:45)

> "Irritating! Whenever a man finishes building his house, he discovers what he needed to know to begin. The melancholia of finished things! ..." -Nietzsche, *Beyond Good and Evil* \_

Michael Flagg (2013-05-29 14:47:42)

Thanks for the continued posts on the benefits of fermented foods. I've branched out into them thanks to the info I've read here. Speaking of foods, have you been following any of the "Soylent" story? An engineer has reduced food to the chemical inputs and developed a drink that "has everthing the body needs." He and his associates have started a crowdfunding campaign (<http://www.soylent.me/>) that did an initial ask for \$100,000 and as of this writing has raised nearly \$350,000. His blog is at <http://robrhinehart.com/> and he documents the first three months of his experience shifting from regular food to Soylent starting back in February. A lot of interest out there in changing how we eat. Amazing numbers (to me) on his crowdfunding effort. Seth: I hope that something about nutrition is learned from this, but science is very different from engineering. I don't believe for a second that his drink has everything the body needs, much less the optimal amounts. That shows his ignorance of basics. Whether he can figure this out – his ignorance – is the interesting point for me at the moment.

Reanna (2013-05-29 14:52:07)

Seth, I don't know if the probiotics blog post counts as a "good experience" yet. It sounds like something is going on, and the patient has faith. I'd like to see some test results before calling it a good experience. "Die off" always sounds a lot like "I feel like crap but my faith is strong" to my ears.

Walter (2013-05-29 18:59:44)

I am planning to buy the Dorkfood controller because I like sous vide and I think the side benefit is to annoy my wife with the name of the product. Is the coupon only for Dorkfood website or is it also useful for Amazon? Seth: only Dorkfood website.

garymar (2013-05-29 20:58:29)

The list of indigenous fermented foods was great. After reading thru I made an online order for some Japanese "Hama Natto" – fermented the old-fashioned way for 15 months (pretty pricey though). Picture and (Japanese copy) [1]here. Seems to come from the Hamamatsu area (not Hamanadzu – misprint) which is also the area around Lake Hamana.

1. [http://www.ymy.co.jp/shop\\_hamanatto.htm](http://www.ymy.co.jp/shop_hamanatto.htm)

Dan (2013-05-29 22:38:17)

I'm having a hard time taking the Yahoo! article seriously given its author's inability to spell Ms. Mayer's last name correctly. Seth: Is there something in the article you disagree with?

garymar (2013-05-30 19:09:44)

Update on my Hama Natto comment: My Hama Natto arrived this morning. Completely unlike regular natto: whole soybeans, but not slimy, not stinky, dark brown, tastes like miso. Like the package says, much deeper 'body' than miso. Lingers in the mouth. Should be a great condiment on rice.

Paul N (2013-05-31 08:29:49)

The sous vide/plastic stuff is interesting. One comment somewhere suggested what seems to me to be a good way to avoid all the plastic/silicone - use sausage casings! You can buy rolls of sausage casing online from various online suppliers like [stuffers.com](http://stuffers.com) or [malabar spices](http://malabarspices.com), and if you buy the "natural" ones - made from the intestines of pigs, sheep, and cattle, then you can eat it with whatever you cooked in it. They also have artifical casings made of collagen, cellulose and (of course) plastic. To try before you buy, just buy some real sausages (from a real butcher) and try - keep them linked and clip the ends of the string. I have never liked the taste of boiled sausages, but maybe this would work if they were sauteed in butter after cooking, just to brown them a little bit...

Brandon Berg (2013-06-02 01:55:30)

Regarding the natto ice cream, I've also found that natto is much more palatable when eaten in a partially frozen state. This somewhat weakens the taste, but more importantly eliminates the slimy texture which is arguably its most objectionable quality.

## Hospitals and Their Employees: Stuck in the 1800s (2013-05-30 10:01)

[1]An article in the New York Times describes how difficult it has been for hospital administrators to get their employees to wash their hands. Hospital-acquired infections are an enormous problem and cause many deaths, yet "studies [in the last 10 years] have shown that without encouragement, hospital workers wash their hands as little as 30 per cent of the time that they interact with patients." Hospitals are now – just now – trying all sorts of things to increase the hand-washing rate. The [2]germ theory of disease dates from the 1800s. Ignasz Semmelweis did his pioneering work, showing that hand-washing dramatically reduced death rate (from 18 % to 2 %), in 1847.

So hospitals are only now (in the last few years) grasping the implications of facts and a well-established theory from the 1800s. What goes unsaid in the usual discussion of how awful this is – how dare doctors refuse to wash their hands!, a sentiment with which I agree – is how backward both sides of the discussion are. A discussion in which many lives are at stake.

The Times article now has 209 comments, many by doctors and nurses. The doctors, of course, went to medical school and passed a rigorous test about medicine ("board-certified"). Yet they don't know basic things about infection. (One doctor, in the comments, calls hand-washing "[3]this current fad".) They appear to have no idea that it is possible to improve the body's ability to resist infection. I read all the comments. Not one mentioned two easy cheap low-tech ways to reduce hospital infections:

1. Allow patients to sleep well. The body fights off infection during sleep, but hospitals are notoriously bad places to sleep. Patients are woken up by nurses, for example. You might think that everyone knows sleep helps fight infection . . . but apparently not hospital administrators nor the doctors and nurses who commented on the Times article. It was in the interest of these doctors and nurses to suggest alternative solutions because they dislike washing their hands.

2. Feed patients fermented foods (or probiotics). Fermented foods help you fight off infections. I believe this is because the bacteria on fermented food are perfectly safe yet successfully compete with dangerous bacteria. In any case, plenty of studies show that probiotics and fermented foods reduce hospital infections. In [4]one study, "use of probiotics reduced the new cases of C. difficile-associated diarrhea by two thirds (66 per cent), with no serious adverse events attributable to probiotics." Maybe [5]this just-published article (Probiotics: a new frontier for infection control") will bring a few people who work in hospitals into the 21st century.

That hospital administrators and their doctors and nurses – and, in this discussion, their critics – are stuck in the 1800s is clear enough. What is slightly less clear is that our understanding is better now than it was in the 1800s and some of the new knowledge is useful.

Thanks to Bryan Castañeda.

nansen (2013-05-30 18:35:54)

"Patients are woken up by nurses, for example." I was amazed that psych hospitals have fire doors that slam shut all through the night as staff go in and out of the ward...

Koanic (2013-05-30 20:24:10)

Yet another example of the uselessness of the medical establishment. The gastro doctor I went to in the USA refused to prescribe me UDCA. After doubling or tripling my dose of UDCA in China, my limitation of only being able to eat a 1000 calorie diet, and my symptom of having pale colored stool disappeared. This doctor prescribes UDCA to many patients, knows that it has practically no side effects at any dose and can be generally regarded as safe, knows that all his patients who are on it love it, yet when I explained my symptoms and theory, and requested UDCA, he refused to prescribe it. Instead he ordered tests which came back inconclusive, and I languished on, sick for months, with no resolution. This same doctor flushed red when I pointed out the obvious fact that he had not done anything much for [family member] over years of treatment. He became combative and critical towards me. Afterwards attending family members felt I had been rude for mentioning this fact in passing - even though it was a necessary component of the answer to a question he had asked me. Then I went back to Asia, where UDCA is not limited by prescription, and fixed it myself. Doctors are evil idiots, insulated from delivering results, and regulation destroys incentives for good care.

Craig (2013-05-31 08:16:17)

Robert X. Cringely has interesting article related to this What Intel and AMD clean rooms could teach hospitals "Hospitals follow the same mindset and have generally believed they can deal with most problems by cleaning and sterilizing after the fact. The circulating air and every person that enters a patient's room is introducing contamination. Once you understand the full implications of this, you can make hospitals MUCH cleaner and safer." <http://www.cringely.com/2013/05/27/what-intel-and-amd-clean-rooms-could-teach-hospitals>

### **"Because It Costs More": An Example of Medical Reasoning (2013-05-31 05:00)**

Melody McLaren, a friend of mine, lives in London. Her husband has Parkinson's Disease and receives treatment through the National Health Service. His treatment has included "[1]deep brain stimulation" - implantation of an electrical device that stimulates subcortical brain areas. It is a standard treatment for Parkinson's. It cost the National Health Service about £35,000.

She was surprised to discover that in the United States, the same procedure involved implantation of two batteries, one for each side of the brain. The device implanted in England has only one battery. It worked fine. My friend wondered why two batteries were used in the United States. She asked her husband's neurologist, a French woman practicing in London. "Because it costs more," she said. There was no other reason.

At the San Mateo Maker's Faire a few weeks ago, I heard [2]a talk by a doctor named Amy Baxter, who had developed a device for pediatricians that makes shots hurt less. (She had a child and noticed the problem.) She went to considerable trouble to develop a product that could be used by working doctors and presented the product several times to potential buyers. Again and again she was told *It has to be disposable*. Meaning one use per package. Nothing else will fit the supply chain. She did not say why she was told this, but the obvious reason was that disposable

products are more profitable.

[3]Steven Brill's cover story in Time two months ago was about one way American health care takes advantage of sick people with little choice – hospitals, including nonprofits, charge patients for products and services far more than what they cost the hospital. This is another way.

1. [http://www.ninds.nih.gov/disorders/deep\\_brain\\_stimulation/deep\\_brain\\_stimulation.htm](http://www.ninds.nih.gov/disorders/deep_brain_stimulation/deep_brain_stimulation.htm)

---

Chuck (2013-05-31 07:25:04)

Disposable, one use, needles are used for sanitation reasons. This became an issue back when AIDS first hit. Auto mechanics also charge customers for products and services far more than what they cost the garage. Cheers Seth: I'm not sure it's that simple why needles are disposable. Lots of things are sterilized...there exist machines whose function it is to sterilize stuff. Needles did not have to be disposable to be sterile. In any case, sterility is far more important for something you stick into the body than Amy Baxter's device, which touched the skin. With auto mechanics, consumers have far more choice.

Tom (2013-05-31 08:02:01)

I was hospitalized briefly recently. One of the devices used to track you is called a pulse oximeter. It's a small noninvasive device that clips on the end of a finger and shoots LED light through the fingertip toward a sensor on the other side (to track pulse, I think.) It was in a disposable adhesive form, which I thought strange because it could easily have been made to last fifty years. Another strange thing was that instead of leaving it on me (it was painless and as light as a bandaid), the nurse at the hospital put a new one on for each reading, requiring several rather than one. I couldn't figure out why. Now I realize that fraud was why.

Chuck (2013-05-31 10:34:08)

Because of disposable needles, you can now get shots at drug stores - and much cheaper than going to the doctor. I don't think they would take the risk of trying to keep a ready supply of syringes and needles sterilized. Besides, everything would have to be glass and stainless steel to withstand the sterilization process - and needles get dull after a few uses. I just took my dog to the local pet store for a by-annual shot - they have vaccination clinics once a week - all the needles were disposable - they couldn't/wouldn't provide this service if they had to sterilize everything in advance. All of the vaccines were pre-loaded in the syringe, in a sealed pack - very convenient for the vet when he has twenty dogs in line and a steady stream coming through the door - and, once again, it was way cheaper than going to the vet. I don't think disposable needles and pre-loaded syringes are what's driving up healthcare costs. And the risks of using non-disposable - soon to be bio hazard - equipment is too high. Cheers Seth: What about recyclable needles? In any case, I urge you to watch Amy Baxter's talk and see if there are good reasons – besides profitability – for requiring her invention to be recyclable. It costs a lot more than a needle.

Joe (2013-05-31 13:16:04)

"I just took my dog to the local pet store for a by-annual shot" Keeping with the spirit of Seth's post, your dog doesn't need by-annual shots. Do YOU need any bi-annual shots? Then why should your dog? It used to be annual shots for dogs, because that's how vets made their money. Yes, at the expense of their canine patients' health, because over-vaccination is a cause of many canine ailments. Now there's a three-year protocol for pets that will eventually lead to even longer intervals. <http://drjeandodds.pethealthresource.tumblr.com/post/34024828409/dodds-canine-vaccination-protocol-2012>

dearieme (2013-05-31 14:12:53)

oximeter: if that's what I think it is, the NHS method involves a clip-on device which is cleaned with an antiseptic swab - before your very eyes - before it grips your fingertip. If only the doctors cleaned their fingers as regularly. Seth: yes, Amy Baxter's device could be cleaned that way. Yet somehow that was unacceptable.

Mike C (2013-06-01 13:50:07)

I'm a little leery of so quickly dismissing these as waste. There may be good engineering reasons (e.g., redundancy) for having two batteries, and that rationale may not have made it to the doctor in question. As for a reusable device somehow involved with injections, as others say, you have to consider the risk that the item will not be properly cleaned. I give blood somewhat regularly, and am frequently surprised at how many errors the nurses/phlebotomists make in their sterile procedures. In the computer field, we often know that rebooting or reinstalling computers is a good way to clear out entropy (viruses and other baddies). There's a lot to be said for "rebooting" anything involved with injections by just using a new one.

Mike C (2013-06-01 13:51:27)

P.S. If you have any thought that Americans (at least) are any good at following safety procedures, five minutes on any freeway should disabuse you of that notion...

TalkingRat (2013-06-01 14:03:18)

Disposable needles reduce the risk of overdose and disease, and reusable needles generally have larger diameters, and get dull, which adds to discomfort. Disposable flu shot needles are now as thin as insulin needles. I don't trust sterilization to get a used syringe clean. It has more in it than medicine, if they pull back on the plunger to be sure they aren't in a vein. Premeasured, there's less chance of the wrong dose, less chance of bottle contamination, and less chance of distraction causing a doctor to accidentally re-use a needle. That happened on a live TV demo of flu shots, the doctor accidentally refilled a used syringe. With disposables, empty means dirty. Plus, once you've broken the seal on a bottle, you have issues with shelf life and temperature control. A major concern of accidental needle sticks is hepatitis, the odds are extremely high. The odds are worse for injection vs. needle stick. I bet the dog vaccine was for kennel cough. Nose drops last a year, but dogs hate them. Shot only lasts 6 months.

Tom (2013-06-01 15:48:19)

Not sure why everyone's perseverating on needles. They weren't mentioned in the post. Disposable needles aren't where the fraud is. Seth: I agree, they are not where the fraud is.

Joe (2013-06-02 08:22:50)

Same thing for "kennel cough" (Bordetella) vaccination: <http://www.dogs4dogs.com/blog/2012/03/21/bordetella-does-your-dog-really-need-the-kennel-cough-vaccine/>

### "The \$2.7 Trillion Medical Bill" (2013-06-02 09:00)

The New York Times has started a series called Paying Till It Hurts about high medical costs. [1]The first installment is called "The \$2.7 Trillion Medical Bill" and is about the high cost of common procedures, such as colonoscopies, in the United States compared to other countries. (Which I blogged about [2]quite recently.) The most extreme example is that a certain (unspecified) amount of lipitor costs \$124 in the United States and \$6 in New Zealand. Other treatments that cost much more in the United States include hip replacements and MRI scans.

This series might be a turning point, leading to government regulation of what health care providers can charge, which is how other countries control health care costs. To read the huge number of comments (already > 1000) is to see the suffering caused by these prices. One comment: "An acne medication was over \$550 for a small tube of ointment. The [prescribing] Dr. had no idea it was that expensive."

The high prices are the tip of the iceberg of American health care dysfunction. Less obvious is the poor research that sustains them. Acne is an example. It surely has environmental causes (probably diet). If we knew what those are, you wouldn't have to pay anything to cure acne.

1. <http://www.nytimes.com/2013/06/02/health/colonoscopies-explain-why-us-leads-the-world-in-health-expenditures.html?hp&r=0>
2. <http://blog.sethroberts.net/2013/05/31/because-it-costs-more-an-example-of-medical-reasoning/>

---

Alex Chernavsky (2013-06-02 09:34:36)

Speaking of Lipitor (atorvastatin): "[1]Can Statins Cut the Benefits of Exercise?"

1. <http://well.blogs.nytimes.com/2013/05/22/can-statins-curb-the-benefits-of-exercise/>

The Skeptic (2013-06-02 11:21:46)

*This series might be a turning point, leading to government regulation of what health care providers can charge, which is how other countries control health care costs.* I'm curious as to what fuels your optimism. Didn't the PPACA debacle provide us with enough evidence to suggest that government and industry are one and the same? Seth: On the one hand, the level of outrage is very high. On the other, the NY Times is essentially saying "we, as Americans, should be ashamed". This hasn't happened

before. It reminds me of when the civil rights movement began to be effective. It is one thing for medical costs to be high. It is quite another for them to be shamefully high.

dearieme (2013-06-02 11:44:06)

Fair enough, Alex, but I would ask Can Statins Cut the Mustard?

Alex Chernavsky (2013-06-02 13:25:01)

You know what else is shameful? I'm paying about the same amount for health insurance this year as last year, but my coverage is much worse this year. Essentially, my wife and I have only catastrophic coverage. Up to a certain point, we have to pay out-of-pocket for all our medical bills, including prescriptions. To add insult to injury, my health insurance company is calling this plan the "Consumer-Driven Option", as if the insurer is being inundated with impassioned requests to provide much crappier coverage. Consumer-driven, indeed. Do they think we're all stupid?

Tom (2013-06-02 13:33:53)

No, they know we have no choice.

Chuck (2013-06-02 17:10:39)

The problem is too much government meddling and regulation, no free, open market for either healthcare or medical insurance, CYA testing by doctors to protect them from malpractice law suits, the fact that people have forgotten what the definition of "insurance" is when it comes to healthcare (they think it's a medical discount payment plan), i.e.: Can you preexisting damage coverage for auto insurance? How about after death life insurance? And it's not just that we pay too much for prescription medications, other countries pay too little - they need to pay their fair share, as liberals like to say. Seth: It isn't clear to me how government meddling causes colonoscopies to cost much more in the United States than in other countries. There is plenty of government meddling in other countries. Are you saying that the cost of health care is unreasonably LOW in all other countries? Cheers

Tom (2013-06-02 19:19:44)

The amount of pseudo-intellectual Twister-playing that Libertarians do to fit trillion-dollar corporate theft - that's happening *right in front of them* - into their worldview blows my mind.

SB (2013-06-03 04:43:24)

I hope more companies follow the example set by Safeway. This has a chance of putting a serious dent in the increase in healthcare costs.

Nancy Lebovitz (2013-06-03 07:43:13)

Off topic: <http://infoproc.blogspot.com/2013/05/exercise-response.html> There's less scientific evidence about the value of exercise for everyone than you might think- there's at least 10 % of people whose blood markers get worse from exercise, and 20 % (I think) who don't improve. Also, exercise doesn't improve CVD for diabetics.

Adam (2013-06-03 15:34:02)

Nancy, the video won't load for some reason. What blood markers are worsening? Is it transient or prolonged? What kind of exercise?

Nancy Lebovitz (2013-06-04 08:58:46)

Here's the video: [#](http://www.youtube.com/watch?feature=player_embedded&v=E42TQNWhW3w)! I'm planning to take notes on the video so that I've got the details, but meanwhile, you can watch it.

jeff (2013-06-04 23:01:57)

"Seth: It isn't clear to me how government meddling causes colonoscopies to cost much more in the United States than

in other countries. There is plenty of government meddling in other countries. Are you saying that the cost of health care is unreasonably LOW in all other countries?" Hospitals and medical offices are horrifically inefficient and much of this is the direct results of government interference. One example is that a hospital had a do-it-yourself checklist system for managing operations and patient care (basically, developing a system of best practices). This was shot down by the FDA or some other such agency. Multiply this type of nonsense by 100 and then add in the artificially low number of physicians along with the epic risk of litigation (which increases market risk and makes it necessary for everyone with invested capital to earn higher initial fees to compensate for the risk) and you can pretty much sum up a lot of the extraneous costs in our system.

## **Resistance to Fecal Transplants as Treatment for C. diff. Infection (2013-06-03 05:00)**

One of the worst infections you can get in a hospital is C. difficile. It is notoriously unpleasant and hard to get rid of. It has recently been discovered that fecal transplants are highly effective against this infection. Here's [1]what happened next:

The Food & Drug Administration (FDA) [decided] to require an [2]Investigational New Drug (IND) application for stool transplants—formally known as “fecal microbiota transplants (FMT)” —for the treatment of C. difficile colitis. “C. diff,” as it is known, is a severe inflammation of the bowel . . .

Over the last 10 years of my practice, I saw a change in the patients I treated for C. diff. More patients were affected, they were generally more severely ill, and the infection became increasingly difficult to treat. . . . often being refractory to therapy. . . . I also began to see patients floridly septic from C. diff, occasionally needing emergency surgery to remove their colon (colectomy). [I began] to wonder whether we shouldn't be treating severe cases of acute C. diff with stool transplants. I reasoned that it was a better alternative to an emergency colectomy. . . .

There are barriers to doing so, however:

First, there is the “ick” factor. Thus far, resistance to transplants I have recommended has not come from patients or their families, who are desperate for relief. It has come from other health care workers, especially physicians, who seem to find the idea particularly distasteful. [emphasis added. [3]This article supports the idea that doctors are a major source of resistance to this treatment.]

There is cost and time—while the “medicine” is inexpensive and readily available, current recommendations are that the [4]stool donor be tested for a variety of infectious diseases at a cost of \$1500-2000. There might be a week's delay, while the donor is tested for hepatitis and other infections. . . . And now there is the new FDA requirement for an IND, which will be the coup de grace for this treatment. . . . INDs are incredibly burdensome, time-consuming, and expensive for an independent practitioner to obtain. They involve hours of paperwork (my office practice consisted of me and 1-1.5 secretaries; who has time?).

Given the awfulness and danger of this infection, I think it is fair to say that the home-treatment approach (via enema) is very easy. The author of this post, Dr. Judy Stone, complains about home treatment:

Then the sole data will come from some ambitious citizen science group [which is terrible because . . . ? – Seth], and acutely or seriously ill hospitalized patients, too ill to be treated at home, will be deprived of potentially life-saving treatment.

Dr. Stone is serious – deadly serious, you could say. According to [5]this article, "more than 9 % of C. diff-related hospitalizations end in death." Fecal transplants are [6]very effective. Stone predicts that patients will die because "hours of paperwork" are too much trouble, at least for her ("who has time?"). A more persuasive article would have explained why patients who need this treatment cannot be sent to doctors who decide that "hours of paperwork" are doable if that is what it takes to save lives.

Thanks to Paul Nash.

---

dearieme (2013-06-03 06:00:46)

Perhaps one should store one's own poo in a fridge in the garage in case it is needed in future? Seth: If you are going to be staying in a hospital and given antibiotics, that would make a lot of sense.

Chuck (2013-06-03 07:47:27)

Once again, government meddling and regulation, increasing the cost of healthcare. As costs continue to rise, medical vacations to Mexico and Central America will become more reasonable (dental care in Mexico is already more reasonable) and common. Cheers

Lin Wright (2013-06-03 11:15:04)

Not everyone responds to the traditional treatment. Yes, it costs to screen the donor but one 10-day supply of Difficid is \$3800. Vancomycin is not much cheaper, and doctors are leaving patients on it for months and then we relapse as soon as it is stopped. Patients with refractory C Diff who have not responded to the antibiotics are going to die, deaths that could have been prevented. Has anyone talked about the FDA getting pressured by Big Pharma to stop fecal transplants so the drug companies can recoup the monies they have spent on bringing these drugs to market, even though they don't always work?

Adam (2013-06-03 15:03:02)

Who has the time to save lives? Not this Doctor! Wow... just wow...

David Johnston (2013-06-03 15:38:56)

Perhaps hospitals could seek out people with excellent poop with optimal therapeutic properties and pay them for their poop. The paperwork for the doner need only be done once, but many can benefit. As a career choice, I think it would be much less stressful than my current job designing cryptographic circuits. I could sell home-care packages on the side over ebay.

Mister Telawy (2013-06-03 17:52:51)

"A more persuasive article would have explained why patients who need this treatment cannot be sent to doctors who decide that "hours of paperwork" are doable." Because there are very few. Seth: Surely there will be more. You can do the paperwork once for many patients.

Resistance to Fecal Transplants as Treatment for C. diff. Infection – the debate continues (2013-06-05 00:42:12)  
[...] via Seths Blog » Blog Archive » Resistance to Fecal Transplants as Treatment for C. diff. Infection. [...]

Chuck (2013-06-05 05:35:21)

Seth says: "You can do the paperwork once for many patients." I doubt it. This is the government we're talking about. David Johnston says: "Perhaps hospitals could seek out people with excellent poop with optimal therapeutic properties and pay them for their poop." Poop Banks. Give blood and poop at the same time. (Actually not a bad idea...but could you imagine?) Cheers

## **Aquatic Ape Theory Revised (2013-06-04 05:30)**

I became interested in the [1]aquatic ape theory of evolution because it pointed me in a fruitful direction – testing omega-3 fatty acids (e.g., flaxseed oil), which turned out to have easy-to-detect [2]benefits (better brain function, [3]better gums). That is more than I can say for alternatives to that theory, such as the savanna theory. Marc Verhaegen, a Belgian doctor, has [4]recently proposed a new version of the aquatic ape theory. Some of his main points:

- An extensive overview of the literature by Stephen Munro showed that virtually all known archaic Homo [= pre-Homo sapien] sites (including those in 'savanna') were associated with permanent water and edible shellfish.
- Only regular diving can explain archaic Homo's pachy-osteo-sclerosis (POS), the extreme thickness and density of cranial and postcranial bones of most erectus-like fossils. . . . POS is only seen in slow littoral divers, e.g. [5]dugong and manatee, walrus, [6]Kolponomos, [7]pakicetids, Odobenocetops, and Thalassocnus spp. Marine biologists agree POS has a hydrostatic function (ballast).
- The abundant brain-specific nutrients in aquatic foods (e.g. DHA, iodine) facilitated fast brain growth (sapiens' poorer post-aquatic diet required a longer youth to grow the same brain size).
- Man is the opposite of a savanna inhabitant. Humans lack sun-reflecting fur, but have thermo-insulative subcutaneous fat layers, which are never seen in savanna mammals. We have a water- and sodium-wasting cooling system of abundant sweat glands, totally unfit for a dry environment. Our maximal urine concentration is much too low for a savanna-dwelling mammal. We need much more water than other primates, and have to drink more often than savanna inhabitants, yet we cannot drink large quantities at a time.
- Maps of human population densities show that, although we have become fully terrestrial today, we are still a waterside species, and almost half of human dietary calories still come from the water (e.g. rice, aquaculture, fish, shell- and crayfish).

I find the water-drinking point especially persuasive. We need to drink throughout the day, or at least feel bad if we cannot. Almost all workplaces, including cafes, have a source of water. This is inconsistent with savanna living and consistent with waterside living. The term aquatic ape is somewhat misleading. A better name would be aquatic-food ape.

---

steve (2013-06-04 06:00:11)

I recall reading a comment of Buckminster Fuller's a very long time ago that he believed that man came from the sea. This aquatic ape theory is very interesting. Seth: He came from near the sea, no doubt.

Koanic (2013-06-04 06:29:04)

Amen Seth. Realizing this was the first key to my recovery; doubling the UDCA dose was the second. Not paleo nor primal, not FODMAPS nor GAPS- aquatic and herder for bio that's hacked. "Off the food grid" calls it the "pleistocene diet". <http://eatingoffthefoodgrid.blogspot.com/2010/02/pleistocene-diet-update.html> <http://paleohacks.com/questions/755/the-pleistocene-diet-your-thoughts#axzz2VFvnruqH>

Koanic (2013-06-04 06:52:06)

Couple of immediate applications for the aquatic diet: shrimp test: <http://www.koanicsoul.com/blog/2013/05/18/a-simple-experiment-to-determine-whether-biology-trumps-meditation/> note shrimp cannot be pre-cooked, that removes the seawater. seawater has almost same mineral composition as blood. swap pork fat for sardines

Tuck (2013-06-04 07:44:44)

I don't find this particularly compelling... "Man is the opposite of a savanna inhabitant. Humans lack sun-reflecting fur, but have thermo-insulative subcutaneous fat layers, which are never seen in savanna mammals." We evolved to stand upright to better allow us to survive on the savannah. The hair on the top of our head protects us from the part directly exposed to the sun, the rest of our bodies are obliquely exposed to the sun, and have a high melanin content to protect us from the sun's rays. "We have a water- and sodium-wasting cooling system of abundant sweat glands, totally unfit for a dry environment." This is a bit ridiculous. If we were aquatic, we wouldn't need the excessive number of sweat glands that we have. These are only of use when we're in a savannah-type environment, and allow us to cool when running much better than any other savannah dweller. We do not have a "sodium-wasting" system, we sweat excess sodium, and then conserve it, expelling only that sodium we don't need. This is well-demonstrated. "We need much more water than other primates, and have to drink more often than savanna inhabitants, yet we cannot drink large quantities at a time." In fact, we have a unique adaptation to exertion in hot climates: we can lose up to 10 % of our body weight in water, without any effect on performance. Being able to operate at such a huge water deficit is not an adaptation that one would see in an aquatic animal. Dan Lieberman and Tim Noakes have both published extensively on this topic, Noakes' book "Waterlogged" details all the adaptations we have to surviving in a hot, dry climate. We certainly have some adaptations to an aquatic life, but they are inconsequential next to our adaptations to savannah life. Oh, and for omega-3 fats: the ratio we seem to have evolved to need is that found in the bodies of savannah-dwelling ruminants, our main prey animal. Shell middens do not appear in the archeological record until recently, for millions of years we were eating something else... Seth: "We evolved to stand upright to better allow us to survive on the savannah." If the advantages of standing upright on the savannah were so great, why didn't other savannah animals evolve to stand upright? Well, because it doesn't provide an advantage by itself. Walking upright by itself is a huge disadvantage on the savannah because it means you can't travel as fast as a four-legged creature. You're a sitting duck. Only when humans were able to arm themselves could they live on the savannah. Just as humans can now live everywhere.

Daniel Lemire (2013-06-04 15:44:54)

@Tuck If we were aquatic, we wouldn't need the excessive number of sweat glands that we have. To sweat profusely seriously impairs our ability to survive when water is scarce. It seems logical to think that our ancestors were both exposed to hot temperatures and had, simultaneously, access to abundant water throughout the day. The savannah is fine as long as there is always abundant water. The argument that we can lose a lot of water without harm does not convince me of anything: we

have to be able to lose a lot of water because... we do! It would be really strange if we could sweat a lot, by design, but if we could not afford to lose the water... we would be broken. But we still need to replenish the water rather quickly as anyone working out for a few hours knows. The problem, of course, is that if you live by the sea, what do you drink? You can probably find fresh water... but unlike many aquatic mammals we \*need\* a lot of fresh water. This seems like a major inconvenience. Our kidneys do not seem well suited to life by the sea.

Daniel Lemire (2013-06-04 15:53:39)

I see that the article suggests that we ate coconuts for water.

Arndt (2013-06-04 22:25:09)

My own observation is that I digest fish and seafood much better than meat. When I eat meat I can smell and see it some hours later in my stool, even eggs I can smell but after eating fish, shrimp, oysters, squid, etc there is nothing, no smell, it seems to be completely absorbed. As our human ancestors have probably spend time in the water (probably more in rivers than the open sea) and in the savannah (having been rainforest for most of the time) I don't see a conflict that we have adaptations to both environments.

dearieme (2013-06-05 03:19:49)

Why can't we have evolved on the banks of rivers and lakes surrounded by savannah?

Tuck (2013-06-05 07:09:40)

@Seth: "If the advantages of standing upright on the savannah were so great, why didn't other savannah animals evolve to stand upright?" For the same reason other animals didn't evolve human-sized brains, or opposable thumbs. We're unique. "Well, because it doesn't provide an advantage by itself." No trait exists in a vacuum... But standing upright allowed us to develop the traits that make us the most efficient endurance hunter \*on land\*. There are other primates that swim for food. There are no other primates that can run long distances in hot climates, which allows us to run down large animals and kill them without the need for weapons, thus allowing us to become a dominant predator. @Daniel Lemire: "To sweat profusely seriously impairs our ability to survive when water is scarce." It doesn't. It's a short-term cooling process, allowing us to cool faster than an animal that has to pant when it's running. The body adopts other cooling strategies that minimize water loss when it runs low. "But we still need to replenish the water rather quickly as anyone working out for a few hours knows." We can actually go days and days without water, losing massive amounts of body weight, and be perfectly fine upon re-hydrating. There are plenty of hunting societies in African (or Australian) deserts that do well on minimal water. Try putting an animal that is actually adapted to an aquatic life in those conditions, like a hippo, and you'll see what happens to an aquatic mammal. I think the evidence for the aquatic ape theory is pretty sparse, compared to the alternative explanation. This is an excellent primer on Noakes' work: "Waterlogged – A Dogma-Shattering Book?" <http://www.irunfar.com/2012/07/waterlogged-a-dogma-shattering-book.html> Unlike most such works, Noakes' theories have been put in practice in endurance running events. Endurance runners are more at risk from \*too much water\* than from too little. Which makes perfect sense, as we are adapted to hot, dry conditions. Seth: "For the same reason other animals didn't evolve human-sized brains, or opposable thumbs. We're unique." I'm afraid I don't understand how saying "we're unique" explains anything. I believe that lightning doesn't strike twice in the same place for different reasons, so the many ways that humans differ from all other animals must be connected. For example, bipedality and extensive tool use must be connected, in the sense that they have a common cause or one led to the other. To say "we're unique" gives no idea of what the connection is.

Tom (2013-06-05 11:55:40)

The fact that people get sick when they drink huge amounts of water when they are not thirsty has absolutely nothing to do with how we evolved. There are any number of substances that become lethal when over-consumed. What a bizarre argument. Seth: What is over-consumption is shaped by evolution. An animal that lives close to water has less need to store large amounts of water than an animal that doesn't live close to water.

Daniel Lemire (2013-06-05 14:41:28)

@Tuck Better arguments against the aquatic ape theory: 1. We are lousy swimmers by any standard, and without proper training, we are just plain terrible at it. We are probably more likely to get eaten than to eat when swimming in the wild sea. 2. Our children are sure to drown quickly if left unsupervised near water. As for your hypothesis that we are desert animals... That one athlete claims that we can go days without drinking is... frankly, garbage. I once went an entire day without drinking water and I almost collapsed. This is documented. Maybe one particular runner is able to run for days without drinking. Well, he is an oddity. We are more like Zebras... we need to stay near a water hole.

garymar (2013-06-05 15:30:59)

[1]John Hawks> on why anthropologists find the aquatic ape theory unconvincing. Very general, but last part has good links to more detailed criticisms.

1. [http://johnhawks.net/weblog/topics/pseudoscience/aquatic\\_ape\\_theory.html](http://johnhawks.net/weblog/topics/pseudoscience/aquatic_ape_theory.html)

garymar (2013-06-05 15:31:37)

bad tag, sorry!

Tom (2013-06-05 17:34:59)

Seth, I wasn't calling your argument about water consumption bizarre; your point was completely logical. What was bizarre was Tuck's using Tim Noakes' work on hyponatremia to support his point. Hyponatremia is caused when marathoners drink way too much water, reducing serum electrolytes to dangerous levels. Hyponatremia has *nothing* to do with evolution, any more than the fact that we can overeat to the point of throwing up means we evolved to thrive without food.

Tuck (2013-06-06 11:10:40)

"To say "we're unique" gives no idea of what the connection is." True, but your question: "If the advantages of standing upright on the savannah were so great, why didn't other savannah animals evolve to stand upright?" requires a longer answer, even though "we're unique" is sufficient. I didn't want to get sidetracked. :) Standing upright is an advantage in the savannah if you have several other traits. If you don't, it's not. I'd argue that the other traits are; hands that can use tools (which even chimps have, to some extent); a physique that allows running while standing up (chimps cannot for more than a few feet); sweat glands that allow running while standing up for long distances in hot temps; and a large brain that allows us to track prey over long distances even if the prey is out of sight, which allows us to keep the prey moving until it overheats and becomes helpless. No other animal has that unique set of features, and the combination results in a uniquely lethal predator. @Tom: "What was bizarre was Tuck's using Tim Noakes' work on hyponatremia to support his point." It's not bizarre if you're familiar with Noakes' work. Central to Noakes' argument about hyponatremia is the fact that we're well suited to running in a dry climate. It's hard to square that with the aquatic ape hypothesis.

Tuck (2013-06-06 11:17:54)

@Daniel Lemire: "1. We are lousy swimmers by any standard..." Agreed, but if you're arguing against the aquatic ape theory, it's good to present the alternative first. "That one athlete claims that we can go days without drinking is... frankly, garbage." I suggest you go do a little research, then. Familiarize yourself with the evidence. You're clearly not familiar with it now. Noakes has a ton of citations of the research and evidence in his book, start there. He's not "one athlete" btw, he's one of the leading researchers in human exercise physiology, he's written the medical guidelines used for many international endurance running events, and he's also worked with many of the top athletes and endurance events. Next you can look up some of Daniel Lieberman's work on how man evolved as an endurance-running predator in the savannah's of Africa. He knows a thing or two about human evolution. Once you've done that you can come back and we'll have a discussion.

marc verhaegen (2013-06-07 03:21:42)

Thanks a lot, Seth! The poor anti-littoral "arguments" here show that there's no doubt that archaic Homo during the Pleistocene trekked along the coasts & rivers rather than running over savannas: Tuck thought: "We evolved to stand upright to better allow us to survive on the savannah. The hair on the top of our head protects us..." Yes, that's why all savanna mammals stand & run

on 2 legs, and why the bald & bearded men rest in the shadow while the women are running after kudos... :-D He also thought: "If we were aquatic, we wouldn't need the excessive number of sweat glands that we have." ?? AFAWK, only furseals & humans sweat abundantly thermo-actively on land. Sweat = salt + water = scarce in savannas. Enough said. Please inform a bit first: Humans didn't descend from aquatic apes, of course, although our ancestors were too slow & heavy for regular running over open plains as some anthropologists still believe. Instead, Pleistocene Homo populations simply followed the coasts & rivers in Africa & Eurasia (800,000 years ago, they even reached Flores more than 18 km overseas). - google "econiche Homo" - eBook "Was Man more aquatic in the past?" introd. Phillip Tobias <http://www.benthamscience.com/ebooks/9781608052448/index.htm> - guest post at Greg Laden's blog <http://scienceblogs.com/gregladen/2013/01/30/common-misconceptions-and-unproven-assumptions-about-the-aquatic-ape-theory> - <http://greencomet.org/2013/05/26/aquatic-ape-the-theory-evolves/>

## Walking and Learning: GRE Words (2013-06-05 05:00)

Most of [1]my earlier examples of the benefits of walking while studying involved treadmills and learning a foreign language. A Stanford student named Govind writes:

I found I was able to memorize GRE words very effectively while walking [compared to sitting]. It not only made the process much more enjoyable, but since I walked outside (around Oxford [England]), I also was able to associate words with physical cues. The difference between propitiate and propitious is now inextricably linked to Cowley. (I am now a memory palace convert.)

At Berkeley, I once assigned my intro psych students to do self-experiments. One of them measured how many French words she could study before falling asleep. She tried three body positions: sitting at a desk, lying on her side on her bed, lying on her stomach on her bed. She also tried three audio environments: silence, classical music, heavy metal. Best combination: lying on stomach, heavy metal. Worst combination: sitting at desk, silence. This amused me, but I now see that the real lesson of her experiment is that she didn't try walking. It shows how little-known the walking-helps-memorize idea is, even though the effect is easy to notice, as Govind's story shows.

1. <http://blog.sethroberts.net/category/walking-and-learning/>

---

Richie (2013-06-05 09:47:11)

When I was studying for the GRE I would take a vocabulary book with me on my daily hikes. I ended up scoring in the 98th percentile on the verbal section. I'm not sure if memorizing words while hiking increased the quality of my studying. But it was enjoyable enough that it almost definitely increased the quantity of my studying. I would have never been able to sit at home and memorize words for 1-2 hours a day.

Paul (2013-06-06 16:05:09)

I find that at home I can't concentrate enough to listen to a podcast (unless I'm cooking or doing something else that doesn't require the language part of my brain). I'm fine in a car too. It may not be walking so much as having two things going on at the same time. Seth: I see what you mean. Here the improved activity is visual (using Anki) rather than auditory (listening to a podcast). When your eyes are busy (with Anki), it isn't clear what else you can do besides walk. So it isn't clear how to test your explanation. Psychologists usually assume limited capacity - doing X makes it harder to do Y. Of course walking takes no brain power but it's not obvious at all why it should make it easier to do something else (Anki) that does require brain power.

Sentinel (2013-06-18 20:45:46)

Seth: When you write, "Best combination: lying on stomach, heavy metal," did you mean "best for studying" or "best for triggering sleep"? Which combo was best for triggering sleepiness? Seth: Best for studying. In that situation she could study the most words before falling asleep.

### The Rise and Fall of Heart Disease (2013-06-07 05:00)

Heart disease was once the number one killer in rich countries. Maybe it still is. Huge amounts of time and money have gone into trying to reduce it – statins, risk factor measurement (e.g., cholesterol measurement), telling people

to "eat healthy" and exercise more, and so on. Unfortunately for the poor souls who follow the advice (e.g., take statins), the advice givers, such as doctors, never make clear how little they know about what causes heart disease. Maybe they don't realize how little they know.

I encountered an ignorant-without-knowing-it expert after [1]a talk I gave about the effect of butter on brain function. I found that butter improved my brain function (measured by arithmetic speed). I had been eating lots of butter for more than a year. A cardiologist in the audience said I was killing myself. He thought butter caused heart disease. I said that I had experimental data that butter was good for me. Easy to interpret. The notion that butter is bad has come from epidemiological (non-experimental) data, which is hard to interpret. The cardiologist said that the epidemiology has not been misleading. One sign of our correct understanding, he said, is that heart disease has declined. I said there were many possible reasons for the decline.

[2]A 2012 paper called "An epidemic of coronary heart disease" by David Grimes, a British doctor, could hardly make clearer how little we know about the cause of heart disease. Grimes points out that before 1920 heart disease was almost non-existent, that it rose sharply from 1930 to 1970 and since 1970 has declined sharply, at roughly the same rate that it rose. Both the rise and the fall are mysteries, says Grimes, in agreement with what I told the cardiologist. The rise and fall contradict all popular explanations. Heart disease cannot be due to obesity or wealth – both increased substantially at the same time heart disease fell sharply. Nor was the decline due to government intervention:

The decline of CHD deaths in the UK was further described in a UK Government report of 2004, Winning the War on Heart Disease. In this report, the government predictably but undeservedly assumed responsibility for the decline. Clearly, the NHS [National Health Service] in the UK could not have had an international effect [the decline is international].

"There [has been] no obvious effect of statin therapy or other medical intervention," Grimes continues. Yet statins continue to be prescribed in very high amounts and very great expense. The NNT (number of people you need to treat to save one life) is often in the thousands, he noted.

Those who complain about the high cost of health care fatally fail to grasp this enormous ignorance – [3]about many things, not just heart disease – and its consequences. Reducing the cost of health care (reducing the cost of statins, for example) would improve health if cost were the only thing deeply wrong with our health care system. It isn't.

Heart disease follows the rise and fall of the incidence of smoking over that time period.

Michael (2013-06-07 07:48:44)

Take a look at this article and scroll down to the chart of lead levels and time its a pretty good match to the CVD curve. hmm.  
<http://www.motherjones.com/environment/2013/01/lead-crime-link-gasoline>

Russell (2013-06-07 07:55:25)

I've been reading with interest a blog by an economist interested in ancestral health and he has been posting studies showing butter has a negative impact on flow-mediated dilation which he uses as a marker of heart health. Interesting contrasting those studies with your findings of improved brain function and heart exams. <http://www.mattmetzgar.com/2013/05/why-is-butter-bad.html> Seth: As far as I know, it hasn't been established that butter IS bad overall. I think my brain function test can be taken as an overall measure of brain health (because it correlates with several other measures) but I don't think the same can be said for flow-mediated dilation – that it is a good measure of overall heart health.

Nancy Lebovitz (2013-06-07 14:04:46)

Off topic: [1]Lecture and notes about how little is known about the health effects of exercise. Seth: very interesting lecture, I will study it carefully.

1. <http://nancylebov.livejournal.com/579003.html>

Alex Chernavsky (2013-06-07 20:52:09)

About four years ago, I went to a lecture by Dr. Caldwell Esselstyn (cardiologist from the Cleveland Clinic). He argued that all oils & fats are bad for your heart. He advocates an extremely low-fat vegan diet. He showed radiograms showing cardiac arteries before and after his diet. The improvements were substantial. I don't know if he's right or not, and my own diet is not low in fat by any means. But I'm raising this issue because his data was not epidemiological in nature. The cardiac arteries were from the same patient, taken at two different points in time. Here's Esselstyn's site: [http://www.heartattackproof.com/resolving\\_cade.htm](http://www.heartattackproof.com/resolving_cade.htm) He also talked about a test called the Brachial Artery Tourniquet Test, which measures the time it takes for an artery to recover following physical compression of it. Esselstyn claimed that this test can be used to show the harmful effects of eating oils and fats. Seth: Esselstyn gives convincing evidence that his diet is better than what his subjects were eating before. Of course, his diet is a huge change from what they were eating before. I have no idea what part or parts of that change made a difference. Did his subjects improve because they ate less of Chemical X? Did they improve because they ate more of Chemical Y? There are hundreds of Xs and Ys involved. In contrast, my butter experiment changed one thing (butter). Sure, butter has several parts, but it is not a massive change. And I am not making claims about components of butter.

Nancy Lebovitz (2013-06-07 21:14:51)

Seth, thanks. I hope you'll comment or post about how the lecture looks to you. It looks plausible to me, but it's also very much in line with how I'd expect the world to work. Seth: The stuff about HIIT is good and what interests me. The stuff about "adverse effects" is all wrong – the analysis is too simple.

Shep (2013-06-07 23:18:54)

Indeed Jake, the curve of CHD and tobacco consumption is almost identical (ramp up to a peak in the 60s/70s, rapid decline since). It's quite bizarre that Grimes doesn't even mention it in his article

Michael B. (2013-06-08 01:29:16)

People in Tibet are known for a diet high in butter. Maybe we could look at their hearts for evidence? Of course we have to consider that over the millennia there have been adaptations for them to this diet.

dearieme (2013-06-08 10:15:49)

"Indeed Jake, the curve of CHD and tobacco consumption is almost identical (ramp up to a peak in the 60s/70s, rapid decline since)." That suggests to me that it ain't tobacco - if it were I'd expect a lag. If the CHD curve declines just as much for countries where smoking hasn't declined much, then that would be pretty conclusive disproof. Worth a look?

Sam (2013-06-11 12:52:47)

One of the sources that David Grimes cites in his paper is a NHS report with interesting international data. The charts on page 10 in particular. It looks like Ukraine and Russia are in a totally different league in terms of CHD deaths, with 3-4x the incidence per 100,000 compared to the UK. <http://www.chss.org.uk/pdf/education/student/NSF2005.pdf> And according to this Wikipedia chart, Russia and Ukraine have among the highest smoking rates in the world (and the highest

of any countries included in that NHS comparison). [http://en.wikipedia.org/wiki/Prevalence\\_of\\_tobacco\\_consumption#Rates](http://en.wikipedia.org/wiki/Prevalence_of_tobacco_consumption#Rates)

Evelyn M. (2013-06-13 20:44:24)

Thank you for posting this interesting essay, Seth. It reminds me of Rene Dubos who studied tuberculosis incidence carefully and pointed out that while society in general and the medical profession in particular credited the development of antibiotics with the decline in TB, the decline had actually begun well before antibiotics were in widespread use. Seth: I didn't know that, but I see that he makes that point in *The White Plague*, which I will look at.

### Watch Nick Winter Work (2013-06-08 05:42)

On [1]this page Nick Winter, a co-developer of [2]Skritter and [3]Quantified Mind, displays how much work he has done each day (in about a week he will take a long vacation).

To increase productivity he is using what I call [4]percentile feedback. He had [5]great success with it when writing the mobile app for Skritter.

1. <http://www.nickwinter.net/codecombat-stats>

5. <http://blog.sethroberts.net/2012/03/28/nick-winters-big-success-with-percentile-feedback/>

---

### Nick Winter and Percentile Feedback (2013-06-09 08:42)

[1]

How much did [2]percentile feedback help Nick Winter? In 2011, he wanted to finish coding a mobile app for [3]Skritter. This graph shows his daily work on that app. Each point is a different day. The lines are loess fits.

At first, he tried to work on the app but did not make it a priority. Then he made it a priority compared to other things he did. Then he set an explicit goal (a certain number of hours of work each day) and used [4]Beeminder to help reach that goal.

Finally he tried percentile feedback. It helped a lot. His work per day increased about 60 % (to 8.6 hours/day) compared to the previous phase (5.5 hours/day). Using percentile feedback, he finished the app. During the launch, he worked on the app much less.

The data has several interesting features. One is the sudden improvement when percentile feedback started. [5]The same thing happened to me. Another is that it helped him even though he was already making steady progress. A third is that the sudden improvement happened after he had been working on the task a long time (more than six months). Things become easier to do the more we do them but surely this change was complete by the time he started percentile feedback. Apparently it engaged a different source of motivation. Finally, he tried several things before he tried percentile feedback, implying that its value wasn't obvious. It wasn't obvious to me, either. I originally tried it to see what would happen. I didn't have a strong belief it would work.

Above all, this graph shows it's possible to learn from long-term self-measurement and what you learn may not be obvious. People who know little about research sometimes say that randomized double-blind trials are the only convincing way to learn something.

Joan (2013-06-11 15:45:22)

This post led me to find the post about the magic dots, which for me were magic. I have a fairly boring job and lots of annoying things I have to take care of for my family, so it's hard to get going most days. Today I got going right away and stayed on task. I didn't use a stop-watch, just wrote down the time I started, and created the boxes. I started this yesterday afternoon, so this is one and a half days. It seems like getting to fill in little boxes helps me overcome my inner Bartleby.

dearieme (2013-06-10 11:03:01)

That's the usual length of Bee Wilson's weekly column.

Lemmy Caution (2013-06-10 11:46:48)

Educational reform is a scam. <http://www.lawyersgunsmoneyblog.com/2012/10/another-education-reform-sic-fraud> The US school system is pretty good. In the US, students with european ancestry do as well or better as in any european country; students with asian ancestry do as well or better as in any asian country; students with hispanic ancestry do as well or better as in any latin american country; and black students do as well or better as in anywhere. The growth in the number of Hispanic students has made it look like the US schools are rapidly deteriorating though. And, "something must be done". Unfortunately, the only way people get improvements is by 1) cheating or 2) keeping students in school longer. So far, cheating has been the preferred solution.

Zach (2013-06-14 07:29:40)

Wouldn't the second story fall count as evidence that the human genome project and the like are having positive effects right now and demonstrate clear potential for further improvements in quality of life? Perhaps some of this Nobel Prize winning basic research isn't so bad after all.... Seth: The beneficial effect of the human genome project has been very small compared to what was promised and what was spent. The example reinforces that - it illustrates a tiny benefit. And this is a success story.

R. Jones (2013-06-22 23:28:06)

I was looking for a rebuttal of this post : <http://www.sciencebasedmedicine.org/kombucha-a-symbiotic-mix-of-yeast-bacteria-and-the-naturalistic-fallacy/> Seth: Thanks. Yeah, I'll write something about it.

## **The Fate of the Tiananmen Students and the Story of Edward Snowden (2013-06-11 09:16)**

[1]This post by Ron Unz made me wonder: What really happened when student protesters were removed from Tiananmen Square 25 years ago? Unz pointed to [2]a strange website with undated blog posts ([3]mentioned earlier), which [4]claimed that the students were not harmed, in contrast to the usual Western view that many were harmed, even killed. I didn't take the website seriously but I had to admit my ignorance.

I asked several Chinese friends about it. One dared reply. She wrote:

My mom once told me that she was near Beijing when the event happened. She said everything is a mess, no one can go into or out from Beijing. The army is everywhere and people are all in an angry mood, no matter the army (try to pass the possible check so use -) or the citizens. She said the students are innocent, they didn't start the whole thing. And indeed the army was hurt first. But students are young and easy to be incited. Once the army began to take serious method, they didn't care whether you are a student or a mob or a citizen, some innocent students hurt in the turmoil and other students try to gather together to fight back. Then everything began to lose control. After this event, all the students who participate in the sit-in were sent to poor countryside far away and never get a chance to get back to big cities in their whole life. (At that time, all the students are getting job position directly from the government, they don't have options to choose.) My mom told me some female students were sent to countryside and raped by the local people, or have to marry to the local farmers even they have high education.

All the student protesters, according to my friend's mother, "were sent to poor countryside" for the rest of their lives. I hadn't read this anywhere, [5]including Wikipedia. The fate of the protesters was far worse than I had been told by Western media.

My friend's mother could be wrong. Even eyewitnesses can be wrong. But what people actually say, the story they tell, matters infinitely more than the truth.

I am optimistic that the story of Edward Snowden will begin to change how we talk about whistleblowing. Recent stories are not encouraging. [6]Mark Whitacre (Archer Daniels Midland) spent 8 years in prison. That he suffered from bipolar disorder might be taken to mean that only crazy people whistleblow. [7]Jeffrey Wigand (tobacco) was played in a movie by Russell Crowe but went from a \$300,000+/year job to a \$30,000/year job. Bradley Manning faces a very long prison sentence. Julian Assange has been living in the Ecuadorian embassy in London for a year, afraid to leave.

Whereas Edward Snowden, whose leaked information is at least as important, has not yet suffered terrible or even humiliating consequences. Maybe he will live the rest of his life in Iceland – as a hero. He won't just have released enormously useful information, he will have set an encouraging example. That might be his biggest effect on the world.

Tom (2013-06-11 10:44:34)

I hope it works out for him, but I fear it won't. It would've been smarter not to have gone public until he was already physically in Iceland.

dearieme (2013-06-11 13:01:31)

I've seen him accused of being unAmerican. Fair enough: the little bit I saw of him on the telly showed him not to be verbose, sentimental, ignorant or loud. Americans on the telly are rarely like that.

shtove (2013-06-12 02:16:15)

Purpose of the whistle-blown surveillance: <http://www.ritholtz.com/blog/2013/06/big-banks-and-other-corporate-bigwigs-be-nefit-from-illegal-spying/>

Nancy Lebovitz (2013-06-12 10:16:10)

Off-topic: <http://acestoohigh.com/2012/04/23/lincoln-high-school-in-walla-walla-wa-tries-new-approach-to-school-discipline-expulsions-drop-85/> School gets great results by lowering the stress levels of misbehaving students, while still setting boundaries.

### Assorted Links (2013-06-13 06:00)

- [1]Nassim Taleb makes a good point. There is a huge difference between using what you already know (or think you know), which is engineering, and finding out more, which is science. People who know little about science confuse science and engineering, but they do blend into each other, in the sense that science is using what you already know to learn more and engineering is full of uncertainties.
- [2]Association of vegetarian diet and death rate (new study). The vegetarian/non-vegetarian comparison interests me less than the vegetarian/pesco-vegetarian (I call them aquaratarians) comparison, which is less confounded. The pesco-vegetarians lived substantially longer than the vegetarians.
- [3]Levitating Beijingers. What Beijing really looks like.

Jake (2013-06-13 11:51:21)

I think the main reason for the 7th Day Adventists increased lifespan is their frequent use of water fasts.

dearieme (2013-06-13 13:11:14)

Oh I don't know: maybe God just loves them more.

dearieme (2013-06-13 13:13:31)

Now then, Seth, haven't I always sung the praises of fish? Americans would live longer if they cut back their expenditure on dentists and increased it on fish.

Ahrand (2013-06-13 20:11:21)

Now, is it the different amino acid profile of fish or is it the added Omega3 fats and iodine that does it . Because, if its the latter, you can simulate that with supplements...

## Benefits of Brown Noise (2013-06-14 05:00)

Govind M., the Stanford student who wrote me about [1]walking while studying, has written again to say that [2]brown noise (deeper than white noise) makes him "calm and focused". He discovered this while trying to find something to listen to while doing schoolwork:

I tried listening to rain, and that was ok. I know some people try to find places that are really, really quiet and then work there. But that's pretty hard to do. Plus, it seems that the more silent the place, the more distracting individual noises potentially are. So one day I tried brown noise, because it was on the same site as the rain, and I was a fan immediately. I tried white and pink but I found them less calming and a bit too static-y. I use brown noise when I really need to focus. So any "serious" reading, writing, coding, studying, etc. I don't know if there are contexts in which brown noise doesn't help, but it does seem a bit much for responding to emails. . . . [It] makes the outside world melt away.

It also helps him fall asleep. He uses headphones to listen to it. Unfortunately, he said, "everyone that I have told about this thinks I am crazy."

I tried it and quickly became a fan. Brown noise is much more pleasant than white noise. I especially like the Getting Wet preset on [3]this page, which is close to brown noise. It does help me focus. Putting on my noise-cancelling headphones and listening to this is like being instantly transported to a faraway peaceful place. A cabin in the woods. I use it when I am doing something that takes full attention. Unlike podcasts or books, it doesn't interfere with writing. Unlike music, it never becomes boring. (The same piece of music over and over gets boring.) Why isn't something like brown noise piped into waiting rooms, waiting areas, and elevators?

1. <http://blog.sethroberts.net/2013/06/05/walking-and-learning-gre-words/>

2. [http://en.wikipedia.org/wiki/Brownian\\_noise](http://en.wikipedia.org/wiki/Brownian_noise)

3. <http://mynoise.net/NoiseMachines/rainNoiseGenerator.php>

---

Matt (2013-06-14 05:16:51)

I'm also a huge fan of brown noise, especially for going to sleep. I also use it for working sometimes. However the combination of f.lux and brown noise make working past 8 PM almost impossible! I go right to sleep.

Alex Chernavsky (2013-06-14 07:53:45)

Speaking of waiting areas, I'm annoyed that virtually every doctor's office and dentist's office now has a TV mounted on the wall. I used to bring reading material with me when I had an appointment, but I can't read with the TV blaring. Very irritating.

Chuck Currie (2013-06-14 07:58:35)

Wow! I'm stuck on grey...the drips in the foreground could be a little lower, or less constant, but the patter of the rain is exactly what it sounds like hitting our patio umbrella...it's hard to suppress the urge to look out the window (it's a grey morning here, so that adds to the ambiance)...and the sound of the distant storm in the background is one of my all time favorite hunker down, under a blanket with a bowl of popcorn and a book sounds. Cheers

KK (2013-06-14 09:25:28)

I wish you would try and quantify the effect from Brown Noise (on attention, focus, ... whatever). Like you did with Omega-3 and butter. Seth: I'm thinking of measuring how long I work with and without it. Maybe it allows me to work longer before I need to take a break. I may also measure its effect on my sleep.

Jim (2013-06-14 09:47:19)

@Alex, My Dr.'s waiting room TV was playing an (I can only assume) pharma sponsored station that would have short "healthy cooking" clips interspersed between a long series of big pharma ads. I waited 45 minutes, and saw some of the ads four times.

Alex Chernavsky (2013-06-14 10:17:03)

Jim: Big Pharma adding insult to injury. Not only do you have to suffer through the distracting jabbering of the TV, but you're also being assaulted by their pseudoscience.

sa (2013-06-14 14:58:37)

I've played around a bit with various sound generators over the past few months. One is the White Noise app from TMSOFT to help focus, mainly by reducing the impact of background noise. One of its nice features is the ability to mix different noise types, eg I often use blue noise and brown noise together, so you get a blend you like. sox is another useful program ( <http://sox.sourceforge.net/> ) which can be used to generate white noise sound files for use in music players. Also, I recently came across the FocusAtWill website which claims to have music that helps with concentration ( see <https://www.focusatwill.com/science/science-primer/> ) . In my experience it seems to be pretty good for background music while working on a computer - I generally use the UpTempo channel.

Tom (2013-06-14 23:17:37)

I use the TM soft app, too, with a 50/50 mix of waves crashing & brown noise. Incredibly centering.

q (2013-06-15 06:54:26)

brown noise does a good job of unfocusing your ears so you can focus on other things.

Kirk (2013-06-16 12:47:23)

I tried several of the generated noises . . .rain, brown, uptempo . . . they just made me nervous. I'm glad they work for others here, but for me, I prefer either quiet or specific musicians. For example, when cutting code, I'll listen to Sonic Youth. When my goal is to relax, I play Marconi Union.

David199 (2013-06-17 07:12:13)

I found this comment on Wiki interesting: " Its spectral density is inversely proportional to  $f^2$ , meaning it has more energy at lower frequencies . . . the sound is a low roar resembling a waterfall or heavy rainfall." I'm a new father and in one of the books on helping babies sleep, the author recommended using noise like a rainfall; however, he recommended using quality speakers with deep base because the base was very relaxing to children (and adults). He said to mimic what a baby in utero hears, turn on your bath water and fill the tub- now stick your head under the water and listen to the difference in base between running water and the deep tumbling sound you hear while submerged. That's what a baby is used to hearing in utero. I wonder if this brown noise is important because of the deeper base sounds than white noise which can be static-y.

Ivan (2013-06-18 16:21:37)

Pink noise works really well for putting me to sleep when mixed with brown. It's not quite as deep and is somewhere in between brown and white noise in terms of frequency.

nicole (2013-06-21 17:52:49)

i mention this post to my husband, and he brings up this episode of south park. <http://www.southparkstudios.com/clips/15-1766/the-brown-noise>

spacediver (2013-06-24 17:09:16)

Been using brown noise for years courtesy of [www.simplynoise.com](http://www.simplynoise.com)

## **Magic Dots User Experience (Person 1) (2013-06-15 05:00)**

[1]One of my recent posts about anti-procrastination software led a reader named Joan to [2]an earlier post about magic dots, which is a low-tech way of getting work done. Every six minutes of work, you make a dot or line in a certain pattern on a piece of paper. I got the idea from [3]the quasi-reinforcement effect of Neuringer and Chung. Studying pigeons, they found that markers of progress act like rewards. What was amazing was that they got pigeons to work twice as hard (= peck twice as fast) without increasing their salary (= food reward). The dots mark progress.

In [4]her comment, Joan said

This post led me to find the post about the magic dots, which for me [have been] magic. I have a fairly boring job and lots of annoying things I have to take care of for my family, so it's hard to get going most days. Today I got going right away and stayed on task. I didn't use a stop-watch, just wrote down the time I started, and created the boxes. I started this yesterday afternoon, so this is one and a half days.

I asked her for details. She replied:

I have an IT job where I am pretty much self-directed, but one week out of four have to be on-call for production support, which takes up most of the time that week, and I also have to assist the on-call person the other 3 weeks when it's an application I own. Since I spend the on-call week pretty much just monitoring 3 mailboxes, it's very hard to focus on the off weeks, and I find myself reading blogs way too much of the time. Also, some of the production support work is interesting -figuring out what happened and how to fix it, but a lot of it is routine and annoying, like some external server was down, so we have to rerun a job.

I have tried various tools to block the most addictive sites, but am not really supposed to install stuff on my work computer. The percentage thing looked interesting, but it looked like it would be minor project to implement. Then I saw the post about magic dots. I'm a "tactile" learner, which means I like to write stuff on paper, so I thought this would be easy to try and started right away. I was already trying to keep a list and give myself checkmark rewards, without much success.

So far this week has been great - I follow this very loosely. I make a list of activities to accomplish between production support calls, including stretching, etc. and anything that is not something to be done immediately. So things that might not be "work", but that I have to get done that day during the day are on the list, and I fill in between support work with this stuff. I count time spent chatting with co-workers, calls to my mother, calls to the bank, even this email.

The first 2 days were pretty hard. I found myself scanning the list for the least annoying or tiresome tasks, but toward the end of the day I was actually pushing myself to stay and finish a couple of issues that would fit in my time remaining, and empty those in-boxes.

I'm not that focused on filling in the dots [= completing a set of 10] as the day goes on, but after every break I start a new one, and note the time I started.

I have no idea why this works, when nothing else seems to have helped.

I asked what else she had tried. She replied:

I had some success with [5]LeechBlock, but had to remove unauthorized apps [LeechBlock is a Firefox addon] from my desktop and [had to stop] using it to stay off the really addictive sites such as [6]ancestry.com. Work already blocks most social media sites. I tried using the IE site blocking, but having to enter a password didn't seem to deter me.

To try to get motivated and get more done I have:

- Affirmations and resolutions. Fail.
- Tried using a "7 habits" style to do list. Fail.
- Putting little mirrors on my desk. No help.
- Improve another habit and hope for carryover. I tried food monitoring, and spent too much time researching diets. I am keeping up with exercise goals though.
- Looked for support or monitoring sites. Did not find one that seemed like a good fit. Internet addiction forums are mostly about porn or gaming addictions, not [7]ancestry.com or paleo diet blogs.
- I followed a popular "personal productivity" blog for a while, but in the end spent too much time reading the forums. Seems like most of these gurus have always been over-achievers.

Based on statistics I have heard, I'm only a little above average in internet use at work, but some days I'm way over.

Alex Chernavsky (2013-06-16 06:36:21)

I'm going to try the magic dots technique. I don't know if it would help with a couple of big issues I have: I am constantly being interrupted (both at home and at work). And I have a LOT of trouble completing (or, really, even *starting*) projects that have no particular deadline.

garymar (2013-06-16 22:13:33)

I just finished a small job on the computer in 40 minutes using the Magic Dots. But first I wrote an Excel script that beeped every 6 minutes to let me know when to make another mark. I'll try again. I don't know yet if the novelty of the thing is what got me thru or not.

pat (2013-06-17 07:35:50)

I have a similar project and will use the magic dots. I have a legal brief to write and it usually helps me when I am billing by the hour (I am a solo practitioner).

David Johnston (2013-06-17 15:35:12)

I'm 2 hours into using magic dots while wiring up a bunch circuits in a chip, which requires lots of concentration and it appears to be working.

## **Occupational Specialization as Far Back as the Bronze Age (2013-06-16 05:00)**

Linear B is an ancient form of Greek, used around 1500 BC (the Bronze Age) in Mycenaean Greece. Stuff written in Linear B gives us one of our oldest views of human life and can reveal things that other ways of looking at the past (e.g., bones, genes, tools, pottery) cannot. At the end of *The Riddle of the Labyrinth* (2013) by Margalit Fox, a book about how Linear B was deciphered, is a section about what the deciphered tablets turned out to say.

One thing they revealed is considerable occupational specialization. According to Fox (pp. 273-5),

[1]Mycenaeans plied a range of trades. Many tablets reveal the names of occupations . . . metalsmiths . . . textile work . . . tanners . . . leatherworkers . . . priests and priestesses . . . soldiers, rowers, and archers . . . swordmakers and bowmakers, chariot makers and chariot-wheel repairmen . . . goldsmiths and perfumers . . . woodcutters, carpenters, shipbuilders and net makers; fire kindlers and bath attendants; heralds, hunters, herdsman, and beekeepers. . . . bronzesmiths.

Occupational specialization is at the center of [2]my theory of human evolution. The decipherment of Linear B showed that it has existed as far back as we can see. Today there is an enormous amount of occupational specialization, but it also flourished when accumulated knowledge was much less.

The more you see the centrality of occupational specialization to human nature, the more you will see how modern schooling malnourishes almost everyone who undergoes it – which is almost everyone. Human nature takes people at one place and time – such as Mycenaean Greece – and pushes them to become adults who do all sorts of different things (woodcutter, herald, beekeeper . . . ). It takes people who start off the same or almost the same – same place, same food, same weather, similar genes – and creates diversity among them. Modern education tries to do the opposite: Take a diverse set of students and make them the same. One example is *No Child Left Behind*. Another is that in almost every college class, all students are given the same material, the same assignments, and graded on the same one-dimensional scale. We don't need everyone to be the same; in fact, we need exactly the opposite. The more diverse we are, the sooner we will find solutions to pressing problems, because they will be attacked in many different ways.

1. [http://en.wikipedia.org/wiki/Mycenaean\\_Greece](http://en.wikipedia.org/wiki/Mycenaean_Greece)

2. <http://www.scribd.com/doc/61801724/How-Economics-Shaped-Human-Nature-by-Seth-Roberts>

dearieme (2013-06-16 06:58:34)

I can recommend the 1958 "The Decipherment of Linear B" by John Chadwick, who had taken part in that decipherment. The hero of his account is Michael Ventris, an architect by trade who had not gone to university. Ventris was the real thing, a genius, and I don't mean "genius" in the grade-inflated US sense. Chadwick had worked with Ventris and so his portrait of him and his working methods is authoritative. Inside my copy of the book I've found a cutting of a review of a biography of Ventris by Andrew Robinson; the cutting is dated April 2002. "The Man Who Deciphered Linear B: The Story of Michael Ventris" (Thames and Hudson). Here's one quotation from the review "it is a testament to the remarkable level of education available in some schools before the Second World War that Ventris left Stowe (a term early ...) with a degree of fluency in Latin and Greek not matched by most of today's graduates in Classics."

Dena Shunra (2013-06-16 11:00:57)

Professional specialization far predates that. See the Sumerian proverbs from the Oxford ETCSL project: you find professionalized makers of clothing (fullers who make felt, weavers) and scribes and temple workers, and even a hierarchy of disgrace: [1]A disgraced scribe becomes an incantation priest. A disgraced singer becomes a flute-player. A disgraced lamentation priest becomes a piper. A disgraced merchant becomes a con-man. A disgraced carpenter becomes a man of the spindle. A disgraced smith becomes a man of the sickle. A disgraced mason becomes a hod-carrier. [2]catalog of texts - proverbs at the end

1. <http://etcsl.orinst.ox.ac.uk/cgi-bin/etcsl.cgi?text=t.6.1.02&display=Crit&charenc=gcirc&lineid=t6102.p54#t6102.p54>

2. [http://etcsl.orinst.ox.ac.uk/cgi-bin/etcsl.cgi?text=c.6.1\\*&charenc=j](http://etcsl.orinst.ox.ac.uk/cgi-bin/etcsl.cgi?text=c.6.1*&charenc=j)

babar (2013-06-16 17:59:53)

in modern education, not everyone attends the same schools or takes the same classes. Seth: Well, yes, but surely you've heard the term "meritocracy". Those who believe in it inevitably think highly of one-dimensional measures of achievement, such as IQ scores. Somehow merit is one-dimensional.

Tom (2013-06-16 19:18:59)

Nor has everyone heard of hyperbole, either...apparently.

## **Myopia Increases Innovation (2013-06-17 05:42)**

Big public works projects inevitably cost far more than the original budget. I heard a talk about this a few years ago. The speaker gave many examples, including Boston's Big Dig. His explanation was that these projects would not be approved if voters were told the truth. The German newspaper magazine Der Spiegel has just published [1]an interview with several architects responsible for recent German projects with especially large discrepancies between what people were told at the beginning and the unfolding reality - Berlin's new airport, for example. The article's headline calls them "debacles". One architect gives the same explanation as the speaker I heard: "The pure truth doesn't get you far in this business. The opera house in Sydney would never have been approved if they had known how much it would cost from the start."

I disagree. I see the same massive underestimation of time and effort in projects that I do and that my colleagues and friends do, projects we do for ourselves that require no one's approval. I think something will take an hour. It takes five hours. Plainly the world is more complicated than our mental model of it, sure, but there is more to it than that. Someone did a survey of people in Maryland who had been in a car accident so bad they had had to go to the hospital. Within only a year, a large fraction of them (half?) had forgotten about it. When asked if within the last year they had had an accident so bad they were hospitalized, they said no. Apparently we forget difficulties, even extreme ones, really fast. If you forget difficulties, you will underestimate them.

If I had realized how difficult everything would be, I couldn't have done any of it is one explanation, which I've heard

attributed to Gregory Bateson. From [2]Malcolm Gladwell's excellent review in this week's New Yorker of a biography of Albert Hirschman, the economist, I learned that Hirschman – had he realized that this was human nature – would have had a different evolutionary explanation: We underestimate difficulties because this way of thinking increases innovation. Debacle . . . or opportunity?

Difficulty is the mother of invention.

1. <http://www.spiegel.de/international/germany/de-meuron-von-gerkan-and-ingenhoven-on-german-construction-headaches-a-905472.html>

2. [http://www.newyorker.com/arts/critics/books/2013/06/24/130624crbo\\_books\\_gladwell](http://www.newyorker.com/arts/critics/books/2013/06/24/130624crbo_books_gladwell)

---

Franklin Chen (2013-06-17 06:53:34)

Indeed, what would humanity be without the optimism bias? Everything we've done since deviating from other primates has been kind of insanely optimistic. Seth: Maybe there is a compensating bias in the other direction (pessimism bias) because if you are unrealistically optimistic in life-endangering situations, you may die. If I underestimate how long a project will take, nobody dies. If planners underestimate how much an airport will cost, nobody dies.

Janet (2013-06-17 09:46:53)

Do you have a cite for the Maryland car accident study? I study self-report/recall accuracy, and I've never heard of it. I want to add it to my list. Seth: Sorry, I don't. I learned about it from a talk by Elizabeth Loftus, maybe around 1992. I think the talk is online somewhere.

Zubon (2013-06-17 10:15:08)

Without having seen the Maryland study, I note that the standard KABCO injury scale for car crashes has a very broad range for "A," anything from "taken in, checked, and released" to "permanently paralyzed." Police might also code A for cases where someone refused treatment, and comparisons of police and medical reports have shown B injuries that look bad (visible abrasions, any complaint of neck or head trauma) coded as As. Of course people forget things, but if researches simply compared self-reporting to crash reports, they were conflating two types of error. As I said, this is without having seen the study, so it might have taken into account reporting problems.

LemmusLemmus (2013-06-17 13:04:52)

Minor correction: Der Spiegel is a magazine, not a newspaper. On the substantial issue, I found Elizer Yudkowsky's post useful, though too wordy: [http://lesswrong.com/lw/jg/planning\\_fallacy/](http://lesswrong.com/lw/jg/planning_fallacy/)

Alex (2013-06-17 17:03:07)

I think there's a more direct way that evolution favors that optimism bias and amnesia of the negative. Without it there would be hardly any second pregnancies. When I think about it objectively, having children has brought about some of the most grueling hours of my life, with weeks of feeding a newborn round the clock, hours of colicky howling (and that's after pregnancy and childbirth). But those memories feel remote. The highlights feel much more real. Thank you, dopamine! Seth: That used to be my explanation. I can't say I have evidence against it.

SB (2013-06-18 12:48:27)

FYI: <http://www.npr.org/blogs/health/2013/06/18/191279201/3-d-printer-brings-dexterity-to-children-with-no-fingers?uidt=1371584750> #commentBlock An example of innovation coming from outside the establishment. Now, will the establishment embrace it, ignore it or fight to shut it down?

Brock in HK (2013-06-18 18:57:46)

This is the basis for the whole venture capital industry today, and can be seen in many commercial industries at their infancy. Examples: automobiles at the start of the 20th century, dot-coms at the very tail end, plus many in between. Most VC backed companies fail or flounder and only a small few are successful, but when the capital was invested, every company in a VC's portfolio was forecast to have a chance to be a total success. This optimism actually creates much consumer surplus, as in the process of innovation, nobody is sure what exactly will fit the consumer need, so proliferation of ideas and oversupply a) helps identify the best idea and b) helps drive down the price quickly so that more people can benefit from the new invention. Three cheers for myopia! Seth: Your comment reminds me of something I figured out about how to do science: To make progress, it isn't necessary to have a correct explanation of something. Any explanation is helpful, so long as it is testable, because doing the test will be more enlightening than you realize. (Scientists are too pessimistic, engineers too optimistic.) What's important is motivation, not understanding.

Duncan (2013-06-19 14:24:26)

Literal myopia may also be a spur to innovation: Buckminster Fuller's interest in structures is said to have developed early as he concentrated on what he could touch and manipulate, since the world beyond was a bewildering blur, and James Thurber reputedly derived many surreal ideas from his brain's attempts to interpret the fuzzy images his eyes supplied to it.

Kudzu Bob (2013-06-19 22:12:07)

Mario Puzo famously remarked that had he known that The Godfather would be so popular, he would have written it better. Seth: One of the first managing editors of The New Yorker had a saying: "don't get it right, get it written."

## Sunlight and Heart Disease (2013-06-18 22:11)

[1]Vitamin D and Cholesterol: The Importance of the Sun (2009) by David Grimes, a British doctor, contains more than a hundred graphs and tables. Most of the book is about heart disease. Grimes argues that a great deal of heart disease is due to too little Vitamin D, usually due to too little sunlight. I recently blogged about [2]other work by Dr. Grimes – about the rise and fall of heart disease.

Part of the book is about problems with the cholesterol hypothesis (high cholesterol causes heart disease). One study found that in men aged 56-65, there was no relationship between death rate and cholesterol level over the next thirty years, during which almost all of them died (Figure 29.2). There is a positive correlation between death rate and cholesterol level for younger men (aged 31-39). The same pattern is seen with women, except that women 60 years or older show the "wrong" correlation: women in the lowest quartile of cholesterol level have by far the highest death rate (Figure 29.5). A female friend of mine in England, who is almost 60, was recently told by her doctor that her cholesterol is dangerously high.

The book was inspired by Grimes' discovery of a correlation between latitude and heart disease: People who lived further north had more heart disease. This association is clear in the UK, for example (Figure 32.4). Controlling for latitude, he found a correlation between hours of sunshine and heart disease rate (Table 32.3): Towns with more sunshine had less heart disease. No doubt you've heard that dietary fat causes heart disease. In the famous Seven Countries study, there was indeed a strong correlation between percent calories from fat and heart disease death rate (Figure 30.2). You haven't heard that in the same study there was a strong correlation between latitude and dietary

fat intake (Figure 30.8): People in the north ate more fat than people in the south. The fat-heart disease correlation in that study could easily be due to a connection between latitude and heart disease. The correlation between latitude and heart disease, on the other hand, persists when diet is controlled for.

Grimes convinced me that the latitude/sunshine correlation with heart disease reflects something important. It is large, appears in many different contexts, and has resisted explanation via confounds. Maybe sunshine reduces heart disease by increasing Vitamin D, as Grimes argues, or maybe by improving sleep – the more sunshine you get, the deeper (= better) your sleep. Sleep is enormously important in fighting off infection, and a variety of data suggest that heart disease has a microbial aspect. As long-time readers of this blog know, I take Vitamin D3 at a fixed time (8 am) every morning, thereby improving my Vitamin D status and [3]improving my sleep.

Grimes and his book illustrate [4]my insider/outsider rule: To make progress, you need to be close enough to the subject (enough of an insider) to have a good understanding but far enough away (enough of an outsider) to be able to speak the truth. As a doctor, Grimes is close to the study of disease etiology. However, he's a gastroenterologist, not a cardiologist or epidemiologist. This allows him to say whatever he wants about the cause of heart disease. He won't be punished for heretical ideas.

---

Koanic (2013-06-18 23:47:35)

Excellent summary. I find some people have stomach trouble with vit D tablets, and that getting more sunshine works just as well.

Ethan (2013-06-19 05:15:00)

If you haven't come across it before Stephanie Seneff (<http://people.csail.mit.edu/seneff/>) has some interesting theories on vitamin d3 and its relationship w/ cholesterol and sulfur. Seth: No, I hadn't, although I linked to one of Seneff's articles [1]here.

1. <http://blog.sethroberts.net/2012/01/14/assorted-links-154/>

Tom (2013-06-19 13:21:32)

This is further illuminated by the experience of cardiologist William Davis (also author of Wheat Belly), who has found great success reversing arterial calcification with a protocol that includes D3 supplementation until blood levels reach 60-70. This is a link to his greatest circulatory calcification turnaround "success story": <http://www.trackyourplaque.com/forum/topics.aspx?ID=7520> Interestingly, the individual who improved so much is an African American male who upon starting the program had NO measurable Vitamin D in his blood. Yep, ZERO. African Americans are known to be more susceptible to heart disease than whites, and they are also known to produce less D in response to a given level of sunlight. This makes me wonder is another possible confounder of the heart disease epidemic (in addition to latitude) is an increasingly urbanized black and brown population (with concomitant undiagnosed low D3 status) in northern cities. Of course, this issue is risky for a professional scientist to study, as even looking into the matter could end a career. Seth: "increasingly urbanized black and brown population"...the incidence of heart disease is going down, not up. Your possible confounder is changing in the wrong direction.

dearieme (2013-06-19 15:43:08)

"possible confounder of the heart disease epidemic": then why has the epidemic occurred in other countries too?

adamlong (2013-06-20 10:51:53)

Seth: I am a long time reader and huge fan of your blog. Thank you so much for all you bring to the community. I'm particularly interested in understanding these issues related to diet, but at the same time feel the same frustration that-I assume-many others feel because people with credible credentials seem to be taking diametrically opposed positions on issues that are crucial to my day to day decisions regarding my diet. Decisions on questions like, "how often should I eat eggs?" "how much sun should I expose myself too?" A google search on Stephanie Seneff turned up (1) a number of interesting powerpoint presentations and essays but also (2) at least one blog post, from someone who appeared to have relevant background in nutrition, who was extremely critical of her approach and her claims. <http://carbsanity.blogspot.com/2012/03/low-fat-vitd-and-stephanie-seneff.html> Of course, the fact that someone, somewhere has criticized her does not mean she's wrong. But I find myself very frustrated trying to evaluate all of this and would appreciate your take. Seth: I find CarbSane's criticism unconvincing. I do not get alarmed that someone "learned from Gary Taubes". I do not consider it a big deal that Seneff's Ph.d. is in a different area. I don't care whether Seneff's blog has "a feminist angle". I suppose my take is: ignore ad hominem criticism.

Tom (2013-06-21 07:39:18)

Carbsane has said that she herself has no PhD and that her Masters is in Materials Science & Metallurgy. Seth, re: urbanization, I should have added that the 2010 census found that African Americans have subsequently been moving out of urban areas, reversing the earlier concentration: [http://usatoday30.usatoday.com/news/nation/census/2011-05-20-chicago-blacks-exodus\\_n.htm](http://usatoday30.usatoday.com/news/nation/census/2011-05-20-chicago-blacks-exodus_n.htm)

Ian (2013-06-21 22:56:38)

Hi Seth Not sure if you have seen this: Sunshine Could Benefit Health and Prolong Life, Study Suggests <http://www.sciencedaily.com/releases/2013/05/130507195807.htm> The effect appears to be due to increased nitric oxide level and may not be related to vitamin D levels. All the Best

dearieme (2013-06-20 06:23:14)

"the adoption of the vegetarian diet tends to follow the onset of mental disorders": as casual observation suggests.

Michael Flagg (2013-06-20 08:22:55)

Regarding the link to the MS/latitude correlation article, could I get the title? The link sends me to a login page but I don't see a title or author. Thanks. Seth: That's odd. The title is "Latitude is Significantly Associated With the Prevalence of Multiple Sclerosis".

Matt (2013-06-20 08:39:28)

Nikoley's experience with resistant starch seems interesting, I'm going to try that out with green bananas and raw potato starch and see what happens

dearieme (2013-06-20 08:48:41)

There's a well known hypothesis, examined here, that MS was spread into the Faroes by British troops in WWII. (They'd gone there to garrison the island against the German navy, the Danes not having had time to send a garrison.) The argument is that rural people may have little resistance to micro-organisms brought in by the arrival of urban people. When I remember the spelling of the name of the chap who made the hypothesis, I'll post it here. <http://www.ncbi.nlm.nih.gov/pubmed/371519>  
Seth: Very interesting. It is consistent with the latitude finding if the latitude finding is due to better sleep at lower latitudes. Better sleep, more resistance to infection.

dearieme (2013-06-20 08:53:34)

Kinlen: he offered the Faroes example as support when he put forward his hypothesis, aimed first at explaining cancer clusters. [http://en.wikipedia.org/wiki/Leo\\_Kinlen](http://en.wikipedia.org/wiki/Leo_Kinlen)

Paul N (2013-06-20 12:32:14)

Chris M's improvement could also have been (partly) from taurine in the meat. While we can synthesise it, some people are not so good at this. Taurine seems to be important for the brain, though its exact functions are unclear. The b vitamins probably helped too... Seth: Interesting idea, I would like to test it by varying my taurine intake and measuring brain function. I haven't noticed any effect on brain function from changing how much meat I eat (from low to high or high to low...I've never gone to zero). Nor I have noticed any effect of changing my Vitamin B intake. In contrast, changing how much animal fat I eat has had easy-to-notice effects.

Paul N (2013-06-20 20:17:35)

You can buy L-taurine as a supplement. Taurine is also a feature ingredient in Red Bull (don't ask me why, but I'll wager it helps with the energetic feeling) I guess we have a situation where someone with vegan induced nutrient deficiencies will respond well to all sorts of animal foods, but if you are already well nourished with animal nutrient X, more of it won't help. Unless you are one of those who doesn't do well making their own taurine, or converting beta carotene into vitamin A, etc. Seth: Yes, it's very plausible that I already get enough taurine but a vegetarian might not.

Nancy Lebovitz (2013-06-21 05:32:54)

I've heard from a couple of sources that CoQ10 makes statins safer. Do you think there's anything to the idea? Seth: I don't

know anything about this, sorry.

## **Tisano Chocolate Tea and Combining Complex Flavors (2013-06-21 05:00)**

After I interviewed Patrick Pineda about [1]how Tisano Tea began, he gave me several tins of chocolate tea, their main product. Since then, I've had dozens of cups of chocolate tea. It's a good caffeine-free drink, especially with cream.

My main use of chocolate tea, however, has been to improve black tea. Black tea + chocolate tea = great drink, better than any black tea alone or chocolate tea alone. So much better that I have stopped drinking black tea the usual way (without chocolate tea). Even cheap black tea (e.g., Lipton's) plus chocolate tea tastes better than expensive black tea. I think I know why. Black tea (fermented) has a complex flavor, like most fermented foods. Expensive black tea is more complex than cheap black tea, but only a little more. Likewise, chocolate tea has a complex flavor (like chocolate). Combining two sources of substantial complexity produces tea with great complexity – much more than you can get by tweaking one source of complexity (e.g., varying black tea).

Here's a recipe:

1. To 2.0 g of black tea and 0.9 g of chocolate tea add 8 oz of boiling water. Brew 4 minutes.
2. Add cream and sugar to taste.

[2]Peet's tea designers may have reached a similar conclusion. Peet's sells limited-edition teas that are available for only a few months, one at a time. Several months ago the limited-edition tea was Red Cloud Cacao, which combined black tea, chocolate tea, and rooibos. The chocolate tea was from Tisano. I loved it. It sold surprisingly well, I'm told. Their next limited-edition tea, still available, is [3]Anniversary Breakfast Blend. Here's what the tin says:

We seek out small lot teas with unique characters and intriguing flavors . . . Then . . . we set out to make great teas even better . . . We artfully marry the elements of distinctive black teas until we have achieved a well-balanced, extraordinarily aromatic, and flavorful cup.

I told a Peet's customer service person how much I liked the combination of black and chocolate tea. That's funny, she said, the Anniversary Breakfast Blend is made by adding a chocolate mist to black tea. The blended teas are misted with chocolate. The website and the container say nothing about this. My guess is that the tea designers came to the same conclusion as me. Chocolate was so potent they couldn't bear to omit it. But they couldn't simply add chocolate tea to the blend, because that would repeat Red Cloud Cacao, appear formulaic, and spoil the story of "seek[ing] out small lot teas". It would also be obvious: You could look at the tea and see the chocolate. So they used chocolate mist and didn't tell customers. What the tin says is doughnut truth: The whole truth, nothing but the truth, with a hole in the truth.

Complexity is much different than other sources of pleasure in food (salty, sweet, chewy, etc.). [4]My explorations suggest we can detect a lot more complexity that you can get from a single fermented food. But I have yet to encounter a single recipe that combines fermented foods. Most professional recipes produce complexity via many spices, which is labor-intensive (you need to add and adjust all those spices, and worry about their age) and, in my experience, produces no better results than adding one fermented flavoring, such as miso.

[5]Salting tea also seems to improve it.

Kirk (2013-06-21 10:46:27)

Agreed that most recipes fail to use multiple fermented foods. There are a few exceptions, such as the Reuben sandwich, which uses three fermented foods: corned beef, cheese, and sauerkraut. Also those sandwiches made with a true sour-dough bread, cheese, and a fermented meat. I also suspect it is why cheeseburgers are popular: the cheese along with the ketchup or mustard (both of which typically are made with vinegar.) Then there are the complex salads using cheese, fermented meat, and fermented olives, dressed with a vinaigrette. I use combinations of fermented foods all the time in my cooking. I really appreciate you discovering this technique and writing about it. I've read cookbooks for many years and the only one who came close to this idea was the guy who said most soups can be improved by adding cheese. Seth: Good points. I was making lassi yesterday and thought: what should I add? Vinegar? No, I thought, it's already sour. I failed to appreciate the vinegar (e.g., balsamic vinegar) could add complexity.

Kirk (2013-06-22 10:21:47)

It could be that some foods come together at a certain level and further complexity doesn't help. I described before my doubts that adding a fermented food would improve my guacamole, but I haven't run that tasting session yet. As for lassi, the standard additions are one or more of fruit, salt, spices, sweetener. It would be interesting to try adding a sweet white wine, or cold brewed black tea, or chocolate. (I can't add chocolate due to an allergy, but you could try.) Seth: Adding wine to lassi is a good idea, I'll try it. Guacamole is a good test case. If it doesn't benefit from a more complex flavor, that would puzzle me.

Food of the Gods: "Bulletproof" Cocoa (2013-07-15 04:27:29)

Regarding climate change, the following recent research is compelling (to me) and explains the decade long temperature stagnation: <http://uwaterloo.ca/news/news/global-warming-caused-cfcs-not-carbon-dioxide-study-says>

## **Magic Dots: User Experience (Person 2) (2013-06-23 05:52)**

In 2012 I posted about [1]using "magic dots" to get work done. You make a mark on a piece of paper every six minutes you work. The idea derives from [2]the quasi-reinforcement effect of Neuringer and Chung. They found that giving pigeons markers of progress toward food, such as a blackout, doubled how much the pigeons pecked for food – that is, doubled how much they worked.

I found magic dots very helpful. The future will be different from the past was my reaction. (In the future I will get more work done.) So did [3]a reader named Joan. Now [4]a reader named David Johnston tells his experience:

I'm an engineer designing cryptographic digital circuits in microprocessors, which is intellectually challenging but also involves a lot of coding and debugging which requires concentration and attention to detail but is certainly not intellectually challenging. My specialization is random numbers, which even by computer science standards is a very narrow and deep field to specialize in. I don't know of anyone else who does what I do. My work environment is saturated with sources of interruption which very much gets in the way of getting work done. If you think my employer is getting something wrong in creating an effective workplace for engineers, you would be correct. Procrastination is a big issue for me and I've tried various approaches to focus better without great success except for the Japanese music thing described below.

So after reading your article I gave it a try, I set up a timer on my computer (Orzeszek Timer) to beep every six minutes and filled out the dots on each beep.

On my first pass I lasted 2.5 hours before I had a meeting to go to and completed a detailed technical diagram of a circuit I was proposing. The next day I did 5 hours (with a lunch break in between) and was coding up the circuit. I stopped due to a meeting and could have continued. The third day I did not get a chance to focus on code or design, so I managed 0 hours. Then the weekend happened.

This is very much not normal for me. I might do 30 minutes to 1 hour before feeling the need to do something else besides concentrating, like dealing with email or getting a coffee. Getting back to it is not an efficient process since you are typically juggling multiple facts (aka the 'working set') pertinent to the problem and getting back in that frame of mind takes time. This is well a well documented aspect of computer programming, where there is a warm up time before the programmer becomes productive and then the productive period is fragile and easily set back to the start by interruptions.

I intend to keep trying this method and I hope it proves to be effective over longer periods because succeeding at my job is a lot less stressful than not succeeding. Obviously the vanishingly small investment required to try it is a big factor in making it easy to choose to try it.

So my initial reaction is that it works. My sense is that there is something important about mentally breaking up progress into chunks. I certainly do that on long tasks, e.g. a long drive ( I might envision it as passing the 10 %, 20 % etc points as we progress) or recently a game ([5]Ingress - a game you play with a smartphone that requires you get out and walk a lot) where the space between levels doubles. To get to the final level 8 from 7 requires 600,000 points to reach 1.2 million total. Logic would suggest you should just head out and get all the points you can as fast as possible, but that is disheartening because any one day doesn't make a big dent. By setting a goal of 10,000 per day, that gave me a mental and physical framework that was effective. I knew when to keep going (less than 10,000 points achieved) and I knew when to stop (at 10,000 points and probably 2 miles walking). Roughly 60 days later I got to the highest level.

While working on design, the beep in my ear and reaching to draw a dot or line on graph paper was not enough to knock off my concentration, but the continuing for the next six minutes felt like an achievable goal, much like 10,000 points in Ingress felt like an achievable goal each day, whereas choosing to sit and concentrate for five hours is a non starter, much as trying to battle through 600,000 points in Ingress is a non starter.

Possibly unrelated, but maybe not - I have found that I work well listening to Japanese music on headphones (e.g. [6]Happy End or [7]Tokyo Jihen). I haven't a clue what the words are and so it seems to not interrupt my coding state of mind in the same way that English language music does. The cadence (3-6 minutes per song) is not that far off the quasi-reinforcement time of 6 minutes that was suggested on your website. Also it blocks out the blathering of people near me in the office. I presume it being Japanese has nothing to do with its efficacy. It is just a language that hits zero of my language processing neurons. Any language would do if the music was good.

If you find the magic dots don't work for you, I am just as happy to hear about it.

Koanic (2013-06-23 07:29:21)

Agree with everything noted. Except the limitation is doing it at a desk. Do it with a pen on your upper wrist instead. I track major strategic wins towards the next life level on the right wrist, with a short acronym summarizing the current objective. On the right wrist, I have "SOG" which stands for "sh-t" "OK" "good". I make hashes for each performance level throughout the day. The SOG ratings are relative to yesterday's performance. "Good" means better than yesterday's average. So it drives continuous performance improvement, and is an easily viewable "life dashboard" for the day. Then I download to a journal at the end of the day. It gamifies life, which is cool. Seth: Very interesting. You write with pen on your skin? I would think that would be hard to wash off completely. If not what do you write on?

Koanic (2013-06-23 20:26:09)

Yes, with a pen on my skin. No, the bigger problem is that it smudges and fades. So I refresh it. Also writing on the upper wrist results in less ink loss than writing on the top of the hand, which I was doing previously. With the wrist, it only comes off in the shower.

dearieme (2013-06-24 03:19:15)

Ahoy, Seth: re tonsils. <http://www.nejm.org/doi/full/10.1056/NEJMoa1215881>

RyanE (2013-06-24 13:14:22)

Ball point pen comes off easily with a quick spray of hair spray. Mom's 'final net' is what I used to use when growing up and the at-the-time bass fiddle playing infatuation would write things on my hands... :)

David Corbacho (2013-06-26 11:22:27)

This reminds me to David Seah's tracker <http://davidseah.com/blog/node/the-task-progress-tracker/> Have you use them ? Do you think is a good template to use the magic dots system?

## Scrivener for Windows Review (2013-06-24 05:00)

After hearing several people, including [1]James Fallows ("the single best bargain ever offered in the software world"), praise [2]Scrivener, a software program for writing, I tried it again. I had tried it a year ago, but there were so many bugs I quickly stopped. There were fewer bugs this time, but my experience was not good.

The free-trial copy says you can use it for "30 non-consecutive days". I didn't know what that meant. I was told it means "30 separate days before the trial expires – the trial is measured in "days of use", rather than elapsed time since installation". Someone thought that would be clear? I suggest "30 not-necessarily-consecutive days" plus an explanation of what that means.

When I imported material from Microsoft Word – the most common possible import – links were lost. I filed a bug report. I got an answer: "Unfortunately that's the reality of importing: some information can be lost when you move from one file format to another." Well, yes, but how about fixing the bug? I asked. In reply, I was told that Scrivener

for Windows was the work of one person and that the import software was third-party. "We are constantly striving to find new [import software], and to make improvements on our own, where we can," said the spokesperson for Scrivener.

I used Scrivener for about two weeks. Then, trying to put a quotation block in my text, I found that particular formatting is not available. It has been a long time since I came across writing software that did not include quotation blocks. The final straw. I went back to Microsoft Word.

In a way, it's a miracle I lasted two weeks, given the difference in resources invested in Microsoft Word and Scrivener for Windows.

---

Alex Chernavsky (2013-06-24 07:26:09)

What surprises me is the high degree of tolerance that some users exhibit toward crappy software. At my workplace, we use a cloud-based database management system. The software is clunky, poorly designed, slow, and hard to use. The company that makes it is only interested in adding new features, not in fixing problems with the existing features. And yet... many of my co-workers love the program. It makes no sense to me.

Christopher Burd (2013-06-24 09:01:21)

This makes we want to try Scrivener, out of curiosity if nothing else.

Angus (2013-06-24 09:15:50)

I'm a full time freelance writer, and have worked exclusively in Scrivener for Mac for about five years. It doesn't seem buggy at all to me. ESPECIALLY compared to Word for Mac.

Joe Harris (2013-06-24 14:37:32)

Slightly off topic but I highly recommend learning Markdown and a short spell forcing yourself to create documents in it exclusively. Using Markdown you can create documents in any simple text editor and it has the added bonus of discouraging you from using extraneous (and time wasting) formatting.

william counselman (2013-06-25 19:09:31)

Try OpenOffice or LibreOffice free/open source word processors.They have most of the features of MS Word and save files in many formats. Upgrades are always free and you're encouraged to share the program. Versions for Windows, Macintosh and Linux operating system. Works for me. Check it out. Free as in speech and free as in beer.

Bryan (2013-06-26 21:46:11)

I've only used Scrivener (Mac) for one project – a big legal research paper – and I thought it was great. All my work originated in the program, so I didn't have to import anything. Also, I know a number of different writers who swear by the program. Fallows aside, non-techy types seem to love it.

Dario Ciriello (2013-07-04 07:50:46)

I tried it for a couple of days and hated it, but for different reasons. Everyone's process is different, and I tend to the organic and paper notes. Also, I didn't need another learning curve in my life, and Scrivener is both buggy and not entirely intuitive. Last is the import from word issue, which is no problem at all in InDesign or even Wordpress. I'll stick to notebooks and paper.

Kevin McCready (2013-07-04 15:52:15)

You have the word science twice and experiment once in your blog title and you're still with windows??? I switched to linux ages ago and have not looked back for even half a second. It's faster, better, easier and these days has a great community to help with the learning curve. Seth: An R program I need is only available for Windows. I also need to use Windows because my students use it..

Brian (2013-07-07 10:13:39)

Along the lines of Alex Chernavsky's comment, I also noticed, starting in the mid 1980's that many people, rather bizarrely, don't mind buggy software. At the time I thought it was because people who hadn't much computer experience were likely to blame themselves more than the software. In 2013, it seems that explanation is implausible because people have had decades to become familiar with computer use and to better attribute blame. My revised explanation is that buggy software doesn't bother many salaried workers because their salary is in the short-run unaffected by inefficiency. As for Word and Windows, both of which I find quite reliable, I wonder if the fact that parity memory and ECC doesn't seem to be present in the computers most people buy may have something to do with the residual level of dissatisfaction we may be left with. Big programs face more memory error risk. Failures I've encountered in recent years seem less repeatable and so I have revised upward my estimate that they are caused by flipped-bits.

daniel (2013-07-12 23:20:25)

You could try our academic authoring tool Fidus Writer. It's in Beta so still full of bugs. But we certainly try to fix them and value feedback.

Phil Goetz (2013-07-15 12:43:35)

Scrivener is meant for novelists and screenwriters. It's not going to provide a big advantage unless you're making book-sized documents (or trilogies) out of elements that group naturally into scenes and characters. Flipped bits due to ECC are not yet a major cause of bugs. I run large bioinformatics program on a computer without ECC. A typical run requires every bit out of 50,000,000,000 bytes in the files to be correct, and fails about once a month due to a flipped bit. Seth: I agree about Scrivener. I am puzzled that James Fallows, who is not a novelist or screenwriter, likes it so much.

## **Magic Dots: User Experience (Person 3) (2013-06-25 05:00)**

Based on [1]research by Neuringer and Chung, I started marking my work progress by [2]making a mark (such as a dot) every six minutes of work. I did it for difficult tasks, such as writing. Neuringer and Chung found that markers of progress made pigeons peck twice as much. The dots seemed to enable me to work twice as much – e.g., twice as long.

I think a friend came up with the name magic dots. It did seem magic that such a tiny thing – making a dot on a piece of paper – could be so useful. [3]A recent post about procrastination software led a reader named Joan to start

using it. I've already described [4]her experience ("the magic dots have been magic") and [5]someone else's experience here.

Two more people have told me about their experience. I'll describe what one of them said today and what the other one said tomorrow. Alex Chernavsky wrote:

I tried the Magic Dots system yesterday, and I liked it a lot. I ended up with two-and-a-half completed squares. I was more productive than usual. (By the way, have you heard of the [6]Pomodoro technique? It's similar.) I didn't use a stopwatch. I download an iPhone app called [7]Interval Timer, by Delta Works. It's free, but it shows small, unobtrusive ads. I set it to do continuously-repeating six-minute countdowns. The end of each cycle is marked by a short vibration. The iPhone screen stays lit-up the whole time that the application is running, so you can easily check the remaining time. If I remember to glance at the screen, I will make a mark if the application shows a remaining time of less than three minutes. If I forget to check, I make a mark when I hear the vibration. I was home alone most of the day, and I was able to get a lot of work done. I didn't use the technique when I was doing menial chores, like washing dishes. I only used it when I was working at my desk.

Alex also asked several questions:

What happens if you end up getting distracted by a non-productive, time-wasting activity, like checking Facebook? Should you reset the six-minute countdown cycle back to the beginning, or...?

I would just stop the stopwatch, not reset the timer. I would hate to lose the 2 minutes or whatever.

What's the best way to account for unplanned, unintentional changes in focus from one productive activity (e.g., balancing your checkbook) to a different productive activity (e.g., replying to important email messages)?

I don't change anything, as long as I am being productive I keep racking up the dots.

What happens if you need to take a bathroom break or other short break? Should you pause the timer?

No, I count anything necessary, including bathroom breaks and making tea. This is one reason I like the method: getting credit for making tea.

nicole (2013-06-25 17:26:12)

the six minute increments reminds me of the hell my friends who are lawyers working on billable hours live in. they have to account for their work in 6 or 15 minute increments.

Sarah (2013-06-26 02:41:49)

Hi Seth, Since you don't have a twitter account, I'll leave this here: <http://www.plosone.org/article/info:doi/10.1371/journal.pone.0065263> Study showing scientific impact does not increase in similar proportion to grant size. Regards, Sarah

Jim Breed (2013-06-28 10:15:41)

Thanks to Alex C. for the lead on the interval timer. I just downloaded it.

### **Magic Dots: User Experience (Person 4) (2013-06-26 05:00)**

Previous posts about the magic dots method of getting work done are [1]here. Recently, Patrick Dwyer, a solo-practitioner lawyer in Chicago, started using them. He explained how they help:

When I use the magic dots for brief writing it helps me in a few ways. First, it is much less intimidating to set a goal to write for 15 minutes than for 50 hours. Second, it also does not seem so bad to work for just a few more minutes when I am bored or out of ideas rather than wait for that elusive "flow." Third, it gives me an ability to keep a precise account of my time and what I was doing so that I can show the client a specific task when I send the bill. Fourth, after I have made several boxes at the end of a day, it gives me a sense of accomplishment. All these things help me not to procrastinate. There is also something pleasing about drawing the boxes which seems to be more satisfying than merely writing non-graphic sentences or notes about my time.

I agree with all this, but would add that the method was suggested to me by [2]pigeon research in which none of these factors could have mattered (e.g., pigeons do not bill clients). If the pigeon research and the magic dots method really involve the same mechanism – which seems to be true – then that mechanism is remarkably old. According to [3]this, the common ancestor of birds and humans lived 300 million years ago. Maybe it is hard to notice the mechanism because it is buried so deep in our brains.

Animal learning researchers have always said that by studying animals (such as rats and pigeons) we will learn about humans. This example supports that claim. (As does the Shangri-La Diet.) The pigeon research, which had a very counter-intuitive result, led me to try the magic dots method, which seems like it can't possibly work, but did. Yet when this actually happened it was hard to notice. I talked about the pigeon results, which I thought were astonishing, for many years before I realized they might help me.

dearieme (2013-06-27 09:19:21)

I thought that the end of the weight loss article, where the writer made a desperate lunge statin-wise, was unconvincing. Hell, maybe the control group combed their hair more often. Still, it showed how difficult it is to do a properly controlled trial - one has to guess which variables should be matched.

### Heart Disease Epidemic and Latitude Effect: Reconciliation (2013-06-28 05:00)

For the last half century, heart disease has been the most common cause of death in rich countries – more common than cancer, for example. I [1]recently discussed the observation of David Grimes, a British gastroenterologist, that

[2]heart disease has followed an infectious-disease epidemic-like pattern: sharp rise, sharp fall. From 1920 to 1970, heart disease in England increased by a factor of maybe 100; from a very low level to 500 deaths per 100,000 people per year. From 1970 to 2010, it has decreased by a factor of 10. This pattern cannot be explained by any popular idea about heart disease. For example, dietary or exercise or activity changes cannot explain it. They haven't changed the right way (way up, way down) at the right time (peaking in 1970). In spite of this ignorance, I have never heard a health expert express doubt about what causes heart disease. This fits with what I learned when I studied myself. What I learned had little correlation with what experts said.

Before the epidemic paper, Grimes wrote [3]a book about heart disease. It stressed the importance of latitude: heart disease is more common at more extreme latitudes. For example, it is more common in Scotland than the south of England. The same correlation can be seen in many data sets and with other diseases, including influenza, variant Creutzfeldt-Jacob disease, [4]multiple sclerosis, [5]Crohn's disease and [6]other digestive diseases. More extreme latitudes get less sun. Grimes took the importance of latitude to suggest the importance of Vitamin D. Better sleep with more sun is another possible explanation.

The amount of sunlight has changed very little over the last hundred years so it cannot explain the epidemic-like rise and fall of heart disease. I asked Grimes how he reconciled the two sets of findings. He replied:

It took twenty years for me to realize the importance of the sun. I always felt that diet was grossly exaggerated and that victim-blaming was politically and medically convenient - disease was due to the sufferers and it was really up to them to correct their delinquent life-styles. I was brought up and work in the north-west of England, close to Manchester. The population has the shortest life-expectancy in England, Scotland and Northern Ireland even worse. It must be a climate effect. And so on to sunlight. So many parallels from a variety of diseases.

When I wrote my book I was aware of the unexplained decline of CHD deaths and I suggested that the UK Clean Air Act of 1953 might have been the turning point, the effect being after 1970. Cleaning of the air did increase sun exposure but the decline of CHD deaths since 1970 has been so great that there must be more to it than clean air and more sun. At that time I was unaware of the rise of CHD deaths after 1924 and so I was unaware of the obvious epidemic. I now realize that CHD must have been due to an environmental factor, probably biological, and unidentified micro-organism. This is the cause, but the sun, through immune-enhancement, controls the distribution, geographical, social and ethnic. The same applies to many cancers, multiple sclerosis, Crohn's disease (my main area of clinical activity), and several others. I think this reconciles the sun and a biological epidemic.

He has written three related ebooks: [7]Vitamin D: Evolution and Action, [8]Vitamin D: What It Can Do For Your Baby, and [9]You Will Not Die of a Heart Attack.

---

LemmusLemmus (2013-06-28 07:07:54)

Interesting. If I may go OT, do you have any thoughts on this: [http://well.blogs.nytimes.com/2013/06/27/how-carbs-can-trigger-food-cravings/?\\_r=0](http://well.blogs.nytimes.com/2013/06/27/how-carbs-can-trigger-food-cravings/?_r=0)

Three Pipe Problem (2013-06-28 07:08:27)

What is your basis for saying that sunlight has not changed much. Have you ever heard of those who claim "Global Dimming" has been substantial based on long-running "pan evaporation" experiments? Seth: My basis is what I have read about global weather during the 20th century. Sunlight changes can't possibly explain the results Grimes describes (the rise and fall of heart disease by a factor of 10-100, peaking at 1970). I did not know about that Global Dimming stuff, it sounds interesting.

Three Pipe Problem (2013-06-28 09:04:58)

Glancing at the wiki it looks like it has also reversed recently. Seth: Global Dimming, at 4 % or less, cannot explain changes by a factor of 10.

Sam (2013-06-28 10:39:19)

Did you happen to ask Grimes about the effect of smoking on CHD? It seems odd that he apparently disregards tobacco use entirely, given that it is known to be a significant risk factor for heart disease, and that tobacco consumption has varied significantly over time. I'm not saying that Vitamin D doesn't matter, or anything like that, but just that you'd expect to see some discussion of the impact of tobacco. Here's a link to some historical stats on UK tobacco consumption, which peaked in 1945: <http://www.cancerresearchuk.org/cancer-info/cancerstats/types/lung/smoking/long-cancer-and-smoking-statistics#history> Seth: No, I didn't ask him.

Tom (2013-06-28 10:49:44)

I just read his book "You Will Not Die of A Heart Attack." It's terrific, and I'm sure my GP (and most cardiologists, for that matter) have no idea about the facts laid out in it. It's worth the money for the Deaths from CHD chart alone.

Sam (2013-06-28 10:55:20)

Sorry for the double comment, but this paper from BMC Public Health also shows a much less dramatic drop in CHD mortality than Grimes's paper appears to - in part due to the way the data are presented. For the age groups at the greatest risk of CHD, the decline from 1970 to today is more like 50 %, rather than 95 % (or a factor of 10). <http://www.biomedcentral.com/1471-2458/8/148/figure/F1?highres=y> <http://www.biomedcentral.com/1471-2458/8/148/>

Tom (2013-06-28 11:06:49)

Interesting. I'd love to know what Dr. Grimes has to say about the discrepancy.

dearieme (2013-06-28 11:47:56)

Don't put too much weight on the Clean Air Act. According to the enviro writer Lomberg, if you plot the decline of dirt in the air in the UK (or maybe England and Wales) there is no change of slope when the Act came into force. [I have not checked this claim.] On the other hand, there is no doubt that the air got cleaner and cleaner whatever the actual cause. And anyway, maybe the slope would have changed for the worse but for the Act. For example, maybe economics drove industries to replace coal by oil but it needed the Act to force domestic users off coal.

JM (2013-07-01 12:50:45)

I also found his ebook, "You will not die of a heart attack" interesting reading, although it appears to be just a version of his article that was also linked to here (which you can get for free). He doesn't really solve the mystery of what caused this epidemic but does shed a new light on something everyone seems to think they know they cause of. Also, it isn't as close to an end as he implies - I know of two men in their 50's who suffered recent heart attacks, and in neither case was there a clear case of obvious cause. The doctor's just shrugged their shoulders or said their must have been an unknown family history when questioned - so frustrating!

## **Mental Effects of Butter: "My Video-Gaming is Better" (2013-06-29 05:00)**

Based partly on [1]my research, a friend of mine started eating the same amount of butter I do: 4 tablespoons (about 60 g) per day. He described what happened:

I'm noticeably smarter since I started butter. Immediately.

Faster insights, faster foreign language processing, increased creativity, faster at math-in-my-head. My video-gaming ability is better, which partly is a measure of my reaction time. Since I log my creativity similarly to my workouts I can view the increased production.

Started butter properly 3 days ago. Haven't been sleeping well due to workload and digestive issues...yet still my performance keeps [improving]. I suspect it will be yet markedly better again once I get some proper rest.

I am experiencing creativity effects [similar to those] that resulted when I was mindhacking with various [2]racetams along with sublutamine and centrophenoxine. I have not been taking that brain-stack for a month because it was causing digestive problems. Suddenly with butter all the mind-hacking benefits have returned.

1. <http://vimeo.com/14281896>

2. <http://en.wikipedia.org/wiki/Racetam>

---

dustin (2013-06-29 10:50:42)

How do you log creativity / production.

adamdavidlong (2013-06-29 15:48:31)

Seth, I suspect you have covered this before but any thoughts on Dave Asprey's "Bulletproof Coffee" i.e. coffee with grass fed butter + mct oil added. I have been trying it for the last several months. Prior to April of this year, I drank 3 cups of coffee total in the prior 4 decades, but I'm finding I really like this as part of my routine. Seth: I don't know if mct oil has any effect but butter certainly does. I drink black tea every morning...not so different from coffee.

Matteo (2013-07-04 11:31:59)

Do you if any butter is good? I mean, my mother usually buys low cholesterol butter. I still prefer normal butter since as I read from T. Ferriss and others cholesterol is good for Test production. But it would be interesting to know. Seth: I tried several

brands and price points. I never saw a difference. For example, I found no difference between Land o'Lakes and Strauss butter.

Edward (2013-07-19 11:19:00)

I take typing tests and have found that >50g of butter a day improves accuracy from around 97-98 % to 98-100 %, I can type about 87-89 wpm eating anything, but when I consume butter within a few minutes my accuracy and speed jumps miraculously to 90-110 wpm. I did one week of butter and then a one week washout and then replaced butter with 85 % chocolate and the improvements were more substantial than butter, I had never been able to type more than 111 wpm with 100 % accuracy, with about 50g of 85 % chocolate I typed 117 wpm with 100 % accuracy for the first time in my life. 70-75 % chocolate was comparable to butter. The washout period doesn't seem to matter and butter and chocolate combined don't seem to have a compound effect, so in myself chocolate confers what butters seems to and then some.

### **Alternate-Day Fasting Improved My Fasting Blood Sugar (2013-06-30 05:00)**

A few days ago, I gave a talk at a Quantified Self Meetup in San Francisco titled "Why is my blood sugar high?" (PowerPoint [1]here and here). My main point was that alternate-day fasting (eating much less than usual every other day) quickly brought my fasting blood sugar level from the mid-90s to the low 80s, which is where I wanted it. I was unsure how to do this and had tried several things that hadn't worked.

Not in the talk is an explanation of my results in terms of setpoint (blood sugar setpoint, not body fat setpoint). Your body tries to maintain a certain blood sugar level – that's obvious. Not obvious at all is what controls the setpoint. This question is usually ignored – for example, in Wikipedia's [2]blood sugar regulation entry. Maybe Type 2 diabetes occurs because the blood sugar setpoint is too high. If we can find out what environmental events control the setpoint, we will be in a much better position to prevent and reverse Type 2 diabetes (as with obesity).

A few years ago, I discovered that [3]walking an hour per day improved my fasting blood sugar. Does walking lower the setpoint? I didn't ask this question, a curious omission from the author of The Shangri-La Diet. If walking lowered the setpoint, walking every other day might have the same effect as walking every day.

I was pushed toward this line of thought because alternate-day fasting seems to lower the blood-sugar setpoint. After I started alternate-day fasting, it took about three days for my fasting blood sugar to reach a new lower level. After that, it was low every day, not just after fast days. My experience suggests that the blood-sugar setpoint depends on what your blood sugar is. When your blood sugar is high, the setpoint becomes higher; when your blood sugar is low, the setpoint becomes lower. Tim Lundeen had told me something similar to this.

If you tried to lower your fasting blood sugar and succeeded, I hope you will say in the comments how you did this. I tried three things that didn't work: darker bedroom, Vitamin B supplement, and cinnamon. Eating low carb raises fasting blood sugar, [4]according to Paul Jaminet.

sa (2013-06-30 05:46:15)

Could you describe what you eat on the eating / fasting days in more detail ? I'm interested in how you use this along side strategies such as your flaxseed consumption and vitamin D supplementation. I've tried alternate day fasting and have had some success with it in the past for weight reduction. There are lots of different fasting plans - from my reading, the essential element seems to be going for 16+ hours without any food, so you don't completely have to abstain from food for a full day. I like a daily 19/5 schedule personally : skip breakfast , have a late lunch, then a normal dinner, which is pretty easy to stick to. In the 19 hours, I consume only water. Seth: Before I started alternate-day fasting, I ate only one normal meal per day – already coming close to your 19/5 schedule. While doing alternate-day fasting (which I am doing now), I eat normally (for me) on the meal days (low carb, vaguely paleo) and on the fast days I eat butter and flaxseed oil and a few other things, about 700-800 calories. I take Vitamin D3 at 8 am every day.

dearieme (2013-06-30 06:39:25)

Is it the fasting that matters, or having successive days with very different diets? What if, say, I ate only fish on the 'fasting' days, and my normal diet, minus fish, on the 'eating' days? Anyone here want to try that out? Seth: There's lots of research about intermittent fasting in animals, such as rats. In this research, the successive days do not have different diets, in the sense that what is eaten on the fast day (the little that is eaten) is the same sort of food that is eaten on the non-fast days.

Mark Cancellieri (2013-06-30 07:28:09)

I believe that intermittent fasting helps by improving insulin sensitivity. Things like fasting improve the sensitivity of insulin receptors in the muscles, allowing the muscles to take in greater amounts of glucose from the blood stream. That's the problem with insulin resistance in obese people. They are consuming tons of sugar (and carbohydrates), but they can't get the sugar into their muscles because the insulin receptors are not sensitive. All that energy available and they can't get it into their muscles to burn it off. As I understand it, high intensity training (i.e. exercising your muscles until "momentary muscular failure") is also very good for improving receptor sensitivity. When we thoroughly deplete glycogen in our muscles, it triggers our body to improve receptor sensitivity so that we will be better able to quickly restore glycogen levels in the future. I tried doing one 24-hour fast per week, but now I do a daily 16-hour fast (a la Leangains). I do all my eating during an 8-hour "feeding window." This is a reasonable compromise for me. I start eating at 12 noon and stop at 8 PM. My next step is to give up diet soda, which I currently drink outside my feeding window (for the caffeine). They have found that artificial sweeteners also reduce insulin sensitivity. This may be sabotaging my results to a degree. Seth: "Intermittent fasting helps by improving insulin sensitivity." Well, maybe. Why should improving insulin sensitivity change the body-sugar setpoint? It isn't clear why. In the realm of body weight, there is a similar issue. Just because exercise burns calories does not imply it lowers the body fat setpoint. Certain sorts of exercise do lower the body fat setpoint, but that had to be figured out.

Antonio (2013-06-30 10:04:52)

Quick question: Seth, how do you measure you blood sugar levels? Thanks Seth: I use Abbott's Freestyle Lite meters with butterfly test strips. They work well. No pain when I prick myself on my arm. Only a tiny amount of blood is needed. The test strips cost about 50 cents each.

Jerry (2013-06-30 10:24:42)

I have been doing a similar self-experiment for about 3 years now. I have accumulated quite a lot of blood sugar data, and my numbers are similar to yours. My situation and A1c numbers are also similar. I've learned a few things in my experiment, which I'd like to share: 1. Blood sugar meters have terrible reproducibility, but some are better than others. Avoid Reli-On meters altogether. I've had pretty good luck with True-Track meters (and the USB port is very handy for downloading data). Whatever meter you are using, buy a full box of strips, and take 10 or so readings from the same prick. You will see significant variation in the readings. It's expensive, but if you do 40 or so successive readings, you'll be able to calculate the statistical variance of the meter. 2. If you get an unusually high or low reading, take another using the same prick. Take a third. The variance will surprise you. If I were injecting insulin, I'd never trust a single reading. 3. I use the inside tip of my left pinky finger. Least innervation and highest vascularization. 4. A reading when you first wake up will tell you more about liver insulin insensitivity than all the readings you take throughout the day. Mine ranges from 75 to 110. If I'm doing something right, it will be in the

80s. More commonly, it will be in the mid 90s. 5. Exercise helps tremendously. I like to rock climb at the local gym, because it's the only activity I truly enjoy. It's very intense, short duration, and probably not very aerobic (I hate aerobics) but it can get your heart rate up for short bursts. Climbing for an hour after work, fasting afterwards, and then going to bed early usually, but not always, will keep me in the 80s the next morning. 6. As per Jack Kruse's recommendations, wearing blue-blockers after sunset seems to help. (They also work tremendously well for eliminating jet lag.) 7. My fasting blood sugar seems to creep up during allergy season (spring and fall). When I'm sneezing and hacking, the sugar is almost always around 100 rather than 85. (I'm very interested to know if a hookworm infestation will lower this.) 8. Stress definitely raises blood sugar. Both long-term annoying stress and sudden, unexpected stressful situations seem to aggravate it. Mine once shot up from 90 to 157 after I was hit with an unexpected bill from a hotel front desk. 9. Read Dr. Bernstein's book. It is loaded with good information. 10. I've found that cutting back somewhat on protein lowers fasting blood sugar. Fat (lard and/or coconut oil) doesn't seem to have much of an effect., unless large amounts are eaten before bed. That seems to increase liver insulin insensitivity. 11. The most fascinating thing I've discovered is that cold thermogenesis (see Dr. Kruse's blog) really lowers blood sugar quickly and effectively. If mine's over 100 in the morning, I jump into a tub of 50 to 60 degree water and soak for 20 minutes. That reliably drops it to the 70s or low 80s. This effect last anywhere from 90 minutes to 5 hours. From what I've been reading, cold does not cause an insulin release, but rather a release of TXIP. 12. I supplement with Mg and D3. Active liopoic acid often seems to have an effect, but it's hard for me to isolate the cause/effect as of yet. I have not tried alternate day fasting, just reduced eating or skipping dinner, and that definitely seems to help. After reading this post, I will try alternate day fasting.

Joe (2013-06-30 12:45:19)

FYI: Alternate day fasting increases LDL particle size independently of dietary fat content in obese humans  
<http://www.nature.com/ejcn/journal/vaop/ncurrent/abs/ejcn201383a.html>

Mike Coleman (2013-06-30 13:12:25)

As an adjunct, you might also check out this study, which points to benefits of glucose control from regular blood donation. The Wikipedia page on blood donation has a couple more references, including the Finnish study pointing to lower incidence of Type 2 diabetes. <http://www.biomedcentral.com/1741-7015/10/53> As for "set points", maybe it doesn't really change the set point. Maybe it just keeps the system from reaching equilibrium most of the time? In any case, that might be a distinction without a difference—if it works, who really cares why. Seth: That's very interesting about blood donation. In your "maybe it doesn't really change the set point", what is "it"? If by "it" you mean alternate-day fasting, I guess you mean that frequent meals (more frequent than alternate-day fasting) may raise fasting blood sugar not because they change the set point but because they keep the system from reaching equilibrium most of the time. Then my question is what you mean by "equilibrium". "who really cares why?" – I think the history of science shows that theories (which answer "why" questions) are often really helpful. Theories may suggest or motivate new experiments, for example.

August (2013-07-01 09:38:29)

I don't think Jaminet is right about this, but the requirements for keeping fasting blood sugar low via a low carb diet is pretty restrictive and thus most people saying they are low carb are probably cheating enough to cause the problem. I did it for a while after going to the doctor and finding out I had a high fasting blood sugar. It seems to be predicated on what you ate or drank the day (or night) before, and it doesn't necessarily make any kind of sense. For instance, when I found out I had the high fasting blood sugar, I had been experimenting with a tablespoon of honey before bed (improves sleep). Well, the honey had to go, but a chocolate bar with 20g of sugar in the afternoon didn't seem to cause any problems. I was carrying around a jar of ghee at the time to help make calorie requirements. Low carb does make you insulin resistant, and in context, this is a good thing because it keeps the glucose reserved for the brain. So, Jaminet and others are probably seeing blood sugar rising during the time it takes for the body to switch this particular insulin resistance off. Peter did a series on palmitic acid a while back, which is how I was informed of this: <http://high-fat-nutrition.blogspot.com/> I got bored with the whole thing. I ran out of blood test strips and eventually decided I want more muscle. I suppose I should get some more, because I'm certainly eating a lot more carbs. The problem is, I can eat to make the testing look good, but I'm not improving my quality of life when I do that. When I eat and gain muscle, the improved quality of life is noticeable. Seth: Higher blood sugar levels are correlated with greater risk of several major diseases, such as stroke. This is why I believe high fasting blood sugar is a bad thing. I agree

that fasting blood sugar is not the perfect way to measure blood sugar; HbA1c is better. When I started alternate day fasting, I didn't notice any decline in quality of life – if anything it improved because I had more free time.

peter (2013-07-02 07:41:05)

walking shortly after a meal (about 15-20 minutes) which prevents a post-meal spike in blood sugar; and cinnamon. my last blood sugar reading was 87; i also eat a fair amount of avocado and minimize starches/sugars Seth: You found that adding cinnamon made a noticeable difference? I haven't heard that before about avocado.

Char (2013-07-02 13:43:06)

I had wondered if you have tried walking for different amounts of time and frequency after you discovered that it lowered your blood glucose to find the lowest amount for the benefit. And are you still walking while doing alternate day fasting? Seth: Yes, I walked varying amounts. I found I needed to walk about an hour to lower my fasting blood sugar the next morning. Thirty minutes wasn't enough. I am still walking while doing alternate day fasting.

A Reader (2013-07-02 20:55:37)

Is the amount of walking one hour in total throughout the day or does it need to be one continuous hour? Seth: Close to continuous. Maybe 2 30-minute bouts will work. But scattered walking didn't help.

Mike Coleman (2013-07-04 13:14:50)

Replying, yes by "it" I meant ADF. In the model I'm contemplating, "equilibrium" is reached by eating ad libitum every day. Now, if one starts eating ADF instead, does this affect set point? Or does it just pull the system away from equilibrium without affecting set point at all? If I have a helium balloon in my living room, it will naturally rise and stay at the ceiling. But if I bat it downwards regularly—say every three seconds—it will spend no time at all on the ceiling. Is that because my batting somehow affected the tendency of helium balloons to stay on the ceiling? No—it just prevents this equilibrium from occurring. One key question is whether the set point sticks upon discontinuing ADF for a while. If it sticks, even for a month or two, that would be interesting. Regarding "why", I just meant that if ADF really affects longevity, as a practical matter, maybe I should be doing it, whether or not set point is the mechanism. Seth: Alternate-day fasting may or may not change the blood sugar level that the body "defends" (= the setpoint). As far as I can tell, it does change the set point. My experience suggests that the defended level changes in a few days, not a month. The helium balloon analogy does not involve a regulated system. Sorry, I don't understand what you mean by "the model I'm contemplating".

### Does Alternate-Day Fasting Lower HbA1c? (2013-07-02 05:00)

[1] 

This graph shows my HbA1c values in recent years. After a lot of variation, they settled down to 5.8, which was the measurement a month ago. 5.8 isn't terrible – below 6.0 is sometimes called "okay") – but there is room for improvement. In [2]a large 2010 study, average HbA1c was 5.5. The study suggested that a HbA1c of about 5.0 was ideal.

Three weeks ago I started alternate-day fasting (= eating much less than usual every other day) for entirely different reasons. Although people sometimes find alternate-day fasting unpleasant (they get too hungry on the fast days),

I haven't noticed this. I blogged recently that within days of starting, [3]my fasting blood sugar levels greatly improved. Yesterday I got my HbA1c measured again. It was 5.4 – much better. This supports the idea that alternate-day fasting is helping a lot. HbA1c measures glucose in the blood over 8-12 weeks so there could easily be more improvement.

"Whether intermittent fasting can be used as a tool to prevent diabetes in those individuals at high risk or to prevent progression in those recently diagnosed with Type 2 diabetes remains a tantalizing notion," [4]said an author of [5]a recent paper on the subject. My experience suggests that you can easily find out for yourself if intermittent fasting will help. It took only a week to be sure that my fasting blood sugar had improved and only three weeks to have a good idea that my HbA1c has improved. My improvement was almost as fast and clear as what happens when people with a vitamin deficiency are given the vitamin they need.

There are countless ways of doing alternate-day fasting (or, more generally, intermittent fasting). A clinical trial usually tests just one way, which you may not want to copy exactly. My results suggest that blood sugar measurements provide an easy way to tell if your particular version of intermittent fasting is helping.

---

John S. (2013-07-02 15:34:00)

If the green dots are your previous level, they show high variability as well as sudden, precipitous drops. Your current results don't support anything. Seth: Time will tell.

Adam (2013-07-03 04:00:43)

I thought that was a bit curious too. In the end of 2006/beginning of 2007 your HbA1c dropped more than 1 point. What was the interval between those 2 readings & what did you do during that time? Seth: The interval was 3.5 months. I can't remember what I did but probably reduced my high-GI carb intake. The early years of these readings are the first years the service was offered. I was surprised by the high values and probably changed what I ate, but it is also possible that the measurement method improved (e.g., the calibration improved).

Jazi Zilber (2013-07-17 20:48:33)

note that this measure gives an average of the last three months of blood sugar. so it lags.....

jclifton (2013-07-20 07:44:03)

Seth, when doing alternate day fasting, how do you continue eating flax seeds/oil and butter if you're fasting every other day? Seth: I eat them on the fasting days. If you look at alternate-day fasting protocols, they usually include 500 calories or so on the fasting days.

### David Grimes Responds to Comments (2013-07-04 05:00)

In recent posts ([1]here, [2]here, and [3]here), I've described the ideas of David Grimes, a British doctor, about the cause of heart disease. Grimes recently responded to comments on [4]the last post:

First, to develop the latitude theme, that distance from the equator determines risk of heart disease, cancers, multiple sclerosis and others. Four visual pieces of evidence for you.

[5] 

The sunshine map of the UK: We see what would also be the map of multiple sclerosis and CHD in the UK – both diseases most common in the west of Scotland and least common in the south-east of England. Similar pattern of average life expectancy.

Look at cancer incidence in North America for another latitude effect.

[6] 

Then there is breast and colon cancer in Europe:

[7] 

But the [most] important observation of the sun being protective against cardiovascular disease comes from the USA. A latitude effect is present but weak. However a longitude effect is powerful. It works out as an altitude effect – the higher the altitude of residence the lower the risk of death from cardiovascular disease (coronary heart disease + stroke). It is interesting to note the mirror image of the land profile from east to west and the CVD death profile. This can be explained most simply and most plausibly by the higher UV exposure at higher altitudes.

[8] 

[9] 

This is a powerful supplement to the latitude observations in Europe. The [north-south] length of Europe is worth remembering: the north of Scotland is the same latitude as Hudson Bay. In the north of England I live further north than anywhere in China. This means big sun exposure effects.

The size of the disease differences is impressive – e.g., a factor of 2. I think these sunshine correlations are due either to a protective effect of Vitamin D or a protective effect of sleep (more sunshine = better sleep). There's no doubt that sleep quality depends on the amplitude of a circadian rhythm (greater amplitude = better sleep), which in turn depends on the amplitude of the sunlight intensity rhythm, the day-night difference.

dearieme (2013-07-04 06:58:05)

This is excellent stuff, Seth: keep going. Here's my suggestion for someone's research topic: break down the British heart attack rates geographically not according to where people live now, but where they were born (or, even better if practical, where they lived until they were, say, 18). My idea is that if heart attacks depend on some unidentified microorganism you might well pick it up at an early age, long before you are vulnerable to a heart attack. This might be worth doing too for other diseases e.g. M.S. Seth: Thanks! There is a lot of evidence for something happening at a young age, perhaps in the womb, that affects your health much later. The book Mothers, Babies and Health in Later Life by Barker has many examples.

steve (2013-07-04 12:28:15)

Seth, thanks for this post. The altitude correlation is interesting. This is something Ray Peat has written about. He attributes the benefits of altitude to the higher concentration of CO<sub>2</sub> in the air. Here's a link: <http://raypeat.com/articles/aging/altitude-mortality.shtml> Ray writes extensively about the protective benefits of CO<sub>2</sub>. His writings are worth a look, imo. I came across something else interesting regarding the correlation between latitude and MS. It's from Roy Swank, MD. He treated MS with diet and believed that the latitude correlation resulted from those further from the equator consuming a more animal based

diet and thereby more fat. He recommends a low fat diet. [http://www.drmcDougall.com/res\\_swank.html](http://www.drmcDougall.com/res_swank.html) Food for thought. ;-)

Seth: My guess is that radiation hormesis has a lot to do with better health at higher altitudes. There is more radiation at higher altitudes. The radiation activates repair systems.

Nancy Lebovitz (2013-07-04 16:26:46)

[http://www.ted.com/talks/richard\\_weller\\_could\\_the\\_sun\\_be\\_good\\_for\\_your\\_heart.html](http://www.ted.com/talks/richard_weller_could_the_sun_be_good_for_your_heart.html) Sunlight releases nitric oxide precursors that people have in their skin, which probably helps with blood pressure.

David Grimes (2013-07-06 01:39:51)

Observations are real. Then follows conjecture, attempts to explain the observations based on knowledge that we have. Protection by living at a high altitude in the USA requires explanation. Low partial pressure of oxygen has been suggested but does not make sense. Is the partial pressure of CO<sub>2</sub> really greater at high altitude? My school physics makes this unlikely. Is there a plausible mechanism? Does it make sense? I suggest increased sunlight intensity on the basis o: parallels with latitude; UV light being known the cure tuberculosis; UV light and vitamin D enhancing immune mechanisms. There is the recent observation that sunlight exposure has clinical benefit even when the blood level of vitsmin D does not change, hence the suggestion of a mechanism different from vitamin D. Nitric oxide is suggested but this is a very tentative suggestion and far from conclusive. The bottom line is that the sun is beneficial, but there might be mechanisms of benefit additional to vitamin D

### Why Do Magic Dots Work? (2013-07-05 05:00)

[1]

I've posted [2]several times about the use of what I call "magic dots" to get things done. You make a dot or line every six minutes of work. I use the counting method shown above. [3]The effect was first seen in pigeons. [4]A similar

effect was discovered (by accident) in rats.

It works amazingly well. "The magic dots have been magic," said [5]a user named Joan. It would be nice to know why – maybe the effect can be made even stronger. Joan commented in an email:

I have been thinking about why this has worked for me - I think it's that there is an almost immediate "reward", so I get started right away. Since the reward does not have any associations, there's no inner conflict sabotaging it. For instance, I might feel guilty if I ate a jelly bean every 6 minutes, or I might just eat them anyway. I'm not "deprived" if I don't get to add more dots and lines, and I know I can just get back to work and start writing dots again.

Certainly the dots - or the act of making a dot – act as a reward. But why? If I'm writing something, why do the dots have an effect when I can already see my progress by looking at what I've written? I'm already making marks.

The consistency of the marks – the same mark, again and again – may make a difference. Presumably the brain needs to notice a correlation: Writing (or whatever the difficult task is) produces both marks and progress (= a sense of satisfaction). Other activities produce neither. The more identical the marks, the easier to see the correlation. When I write, there is not one consistent mark of progress.

Maybe other people have independently discovered this, without knowing about the pigeon results. Their methods might shed light on what you need to do to get the effect. I don't know of any independent discoveries. The closest thing I can think of is most computer games provide markers of your progress throughout the game, such as level advancement.

Shawn (2013-07-05 06:11:35)

Is Magic Dots more for sedentary work? Yes: work where you remain near a pad of paper.

Conrad (2013-07-05 08:13:51)

Hi Seth, sorry if I'm overthinking this, but I just can't figure out your exact "magic dots" methodology from your posts. Here's my best guess- Is this correct? 1. Set a timer that counts upward from zero. 2. As you're working, occasionally glance over to the timer 3. Whenever the timer has passed a new  $n \cdot 6 - 3$  threshold, add "dots" until you reach "n" dots. 4. If you catch yourself NOT working, throw away the paper and reset the timer. Do this example describe it correctly? Example: Last time I glanced at the clock was at 60 minutes, which means there should be 10 marks on my paper (because  $10 \cdot 6 - 3 = 57$ ). Then at the 64 minute mark I glance over at the clock and add the 11th mark (because  $11 \cdot 6 - 3 = 63$ ). The next time I glance at the clock it's at 77 minutes. At this point  $n=13$  (because  $13 \cdot 6 - 3 = 75$ ) so I make TWO additional marks on the paper to get me up to the correct value for n. Seth: Yes, that's right. I changed a few words

Meegs (2013-07-05 11:33:11)

I've tried and it works. Worked for an hour straight on something I was procrastinating on. I'm using an interval timer app and notepad app on my phone and tablet.

Tom (2013-07-06 04:36:03)

I've been trying it; it works. I've just been making a mark when the timer resets.

John Eels (2013-07-06 04:42:16)

I tried it last night. I had a letter to write. It worked well. My approach deviates from Conrad's. I use a six min countdown on my mobile phone. After six min an alarm rings. I make a dot or line then and set the countdown again. Pieces by pieces I approach the square with the cross. In the end, I had four of these figures and a letter to send. Seth: Your letter took four hours?

Alex Chernavsky (2013-07-06 08:10:21)

I use a free interval timer that I configure to automatically cycle through six-minute countdowns. There is nothing to reset, except if you want to stop the cycling. The app issues a short vibration at the end of each cycle. <https://itunes.apple.com/us/app/interval-timer-for-fitness/id406473568?mt=8>

John Eels (2013-07-07 04:51:28)

Yes, it took four hours. The letter was addressed to a close friend. I disappointed her. I apologized and showed what had happened. Seth: That's a good example.

Caleb C (2013-07-07 20:17:36)

Is there an Android App which is a stopwatch that you can program to vibrate/make noise every six minutes? That seems like it would be ideal and I'd really like find one. You get the reinforcement if you're near where you can make the mark, but if you can't make a mark at the moment it keeps going so you still have your running total for when you can make the dots.

Rob (2013-07-15 01:57:38)

@Alex, I prefer the 30/30 app (<http://3030.binaryhammer.com/>) that comes \*without\* the annoying advertisements the interval timer has. @Caleb – I don't own an Android device, but a quick search showed me that the interval timer @Alex was referring to is available to Android users as well.

Bryan (2013-07-21 20:01:24)

You might also look for a "tabata timer" which is a timer app used to time intervals in a workout.

## **Tsinghua Graduation Memento Statement (2013-07-06 05:00)**

The first class of Tsinghua psychology majors in a half-century is graduating in a few days. (The Tsinghua psychology department was closed in the 1950s – Soviet-style university reorganization – and reopened in 2008.) The seniors asked their professors for statements to be included in a memento book. My contribution:

I remember [1]our first day of class (Frontiers of Psychology). It was my first time teaching in China. It was on a Monday, maybe it was your first class at Tsinghua. Some things surprised me. Moving from students in the front row to students in the back, English ability got worse. Each student said their name. When one student said her Chinese name, everyone laughed. I still do not understand this. This had never happened in my American classes. A student had her picture taken with me. This too never happened in America. There were two graduate students in the class. Both of them volunteered to be teaching

assistants. In America, no graduate students attended my undergraduate classes, and you need to pay them a lot of money to be teaching assistants. (At Tsinghua, that was the only time graduate students came to my class.) The graduate student who became my teaching assistant told you, "Don't say *My English is poor*. Say *My English is on the way*." I can tell you now I disagree. It is confusing to say *My English is on the way*. There is nothing wrong with saying *My English is poor*. I say 英语不好 all the time. We were all so new that we weren't sure when class ended! That was the first thing you made me learn: The length of a class period. I enjoyed having dinner with you. You were less afraid of me than my Berkeley students. I especially remember dinner with 王强, who told me the Chinese side of the debate about the Chinese takeover of Tibet. Most people in America, including professors like me, had no idea there is another side. I had had a big gap in my knowledge and hadn't even realized it. The most important thing I learned from you was how to teach better. The homework you did was very good but I was puzzled how to grade it. From talking with you at dinner and listening to you in class, I could tell that all of you were excellent students. It did not seem like a good idea to make it difficult to get the highest grade, but what was the alternative? This was the puzzle that you pushed me to solve. Eventually I changed how I teach quite a bit, as you may know from talking to students from [2]last year's Frontiers of Psychology. Thank you for that, and may you teach your future teachers as well as you taught me.

Because my students were so good, they made me see the deficiencies in usual teaching methods especially clearly. It really did seem idiotic to take perfectly good work and carefully divide it into piles of best, good, and less good (and give each pile a different grade). Surely there were better uses of my time than making such distinctions and better uses of their time and mental energy than trying to do exactly what I wanted.

When I visited Berkeley to be considered for an assistant professor job, one of the interviews was with graduate students. One of them asked, "Which do you like better, teaching or research?" "Research," I said. They laughed. All Berkeley professors prefer research, but you're supposed to say you like them equally. I was unaware of this. I did like research more, and still do, which is why I am surprised that I talk about teaching so much. I told a friend at lunch recently that it was weird how much I talk about my teaching ideas.

## **Journal of Personal Science: Effect of Meditation on Math Speed (2013-07-08 05:00)**

by [1]Peter Lewis

Background

I've been practicing meditation on and off for years. It doesn't interest me in a spiritual sense; I do it because I think it improves my mental function. However, what I've read suggests there isn't a lot of evidence to support that. For example, [2]John Horgan in Scientific American:

Meditation reportedly reduces stress, anxiety and depression, but it has been linked to increased negative emotions, too. Some studies indicate that meditation makes you hyper-sensitive to external stimuli; others reveal the opposite effect. Brain scans do not yield consistent results, either. For every report of heightened neural activity in the frontal cortex and decreased activity in the left parietal lobe, there exists a contrary result.

From a 2007 [3]meta-analysis of 800+ studies:

Most clinical trials on meditation practices are generally characterized by poor methodological quality with significant threats to validity in every major quality domain assessed.

Most of this research asked questions different than mine. The studies used physical measures like blood pressure, studied complex states like depression and stress, or isolated, low-level "executive functions" like [4]working memory. My question was simpler: Is meditation making me smarter? "Smarter" is a pretty complex thing, so I wanted to start with a broad, intuitive measure. There's a free app called Math Workout ([5]Android, [6]iPhone) that I've been using for years. It has a feature called World Challenge that's similar to what Seth [7]developed to test his own brain

function: it gives you fifty arithmetic problems and measures how fast you solve them. Your time is compared to all other users in the world that day. This competitive element has kept me using it regularly, even though I had no need for better math skills.

## Study Design

I only had about a month, so I decided on a 24-day experiment.

**Measurement.** Every day for the whole experiment, I completed at least four trials with Math Workout: three successive ones in the morning, within an hour of waking up, and at least one later in the day. For each trial, I recorded my time, number of errors and the time of day. Math Workout problems range from  $2+2$  to squares and roots. The first ten or so are always quite easy and they get more difficult after that, but this seems to be a fixed progression, unrelated to your performance. Examples of difficult problems are  $3.7 + 7.3$ ,  $93 + 18$ ,  $14 * 7$ , and  $12^2 + \sqrt{9}$ . If you make a mistake, the screen flashes and you have to try again on the same problem until you get it right. As soon as you answer a problem correctly, the next one appears.

**Treatment.** I used an ABA design. For the first seven days, I just did the math, with no meditation. (I hadn't been meditating at all during the 3-4 weeks before the start of the experiment.) For the next ten days, I meditated for at least ten minutes every morning within an hour of waking, and did the three successive math trials immediately afterward. I did a simple breath-counting meditation, similar to what's described [8]here. The recorded meditations that I gave the other participants were based on Jon Kabat-Zinn's [9]Mindfulness Based Stress Reduction program and also focused on awareness of breathing, though without the counting element. The final seven days were a second baseline period, with no meditation.

Before beginning, I posted about this experiment on Facebook, and I was pleasantly surprised to get eleven other volunteers who were willing to follow the same protocol and share their data with me. I set up online spreadsheets for each participant where they could enter their results. I also emailed them a guided ten-minute meditation in mp3 format. It was a fairly simple breathing meditation, secular and non-denominational.

## Results

Meditation had a small positive effect. During the meditation period, my average time to correctly answer 50 problems was 75 seconds, compared to 81 during the first baseline – a drop of 7 % – and the times also dropped slightly over the ten days (slope of trendline: -0.6 seconds/day). When I stopped meditating, my times trended sharply back up (slope: 1.0 seconds/day) to an average of 78 seconds during the second baseline period. These trends suggest that the effect of meditation increased with time, which is in line with what most meditators would tell you: the longer you do it consistently, the better it works. My error rates were more flat – from 2.1 errors per 50 correct answers in the first baseline period, to 2.2 during the meditation period and 2.5 during the second baseline – and did not display the same internal trends.

(click on the graph for a larger version)

Of the other eleven subjects, six of them stuck with the experiment till the end. Their data was messier, because they were new to the app and there's a big practice effect. Because of this, I was less focused on finding a drop from the first control period to the meditation (which you'd expect anyway from practice) and looking more for an increase in times in the second control period (which you wouldn't expect to see unless the meditation had been helping).

Taking that into account, three of the six subjects seemed to me to display a similar positive effect to mine. Two I'd call inconclusive, and one showed a clear negative effect. ([11]Here is the data for these other subjects.)

#### What I Learned

I found these results encouraging. Like Seth, I take this kind of basic math exercise to be a good proxy for general brain function. Anything that makes me better at it is likely to also improve my performance on other mental tasks. As I mentioned above, I've been using this particular app for years, and my times plateaued long ago, so finding a new factor that produces a noticeable difference is impressive. An obvious concern is that I was trying harder on the days that I meditated. Since it's impossible to "blind" subjects as to whether they've meditated or not, I can't think of a perfect way to correct for this. If meditation does make me faster at math, what are the mechanisms? For example, does it improve my speed at processing arithmetic problems, or my speed of recall at the ones that I knew from memory (e.g. times tables), or my decisiveness once I think I have an answer? It felt like the biggest factor was better focus. I wasn't solving the problems faster so much as cutting down on the fractional seconds of distraction between them.

#### Improvements

It would have helped to have a longer first control period, as Seth and others advised me before I began. I was scheduled to present my results at [12]this conference and at the time it was only a month away, so I decided to make the best of the time I had. Next time I'll have a three- or four-week baseline period, especially if I'm including subjects who haven't meditated before. The single biggest improvement would be to recruit non-meditators to follow the same protocol. Most of the other volunteers, like me, were interested because they were already positively disposed towards meditation as a daily habit. I don't think they liked the idea of baseline periods when they couldn't meditate, and this probably contributed to the dropout rate. (If I'd tried to put any of them in a baseline group that never meditated at all and just did math, I doubt any of that group would have finished.) It might be easier to recruit people who already use this app (or other math games) and get them to meditate than vice versa. That would also reduce the practice effect problem, and the effects of meditation might be stronger in people who are doing it for the first time. More difficult math problems might be a more sensitive measure, since I wouldn't be answering them from memory. Nothing super-complex, just two- or three-digit numbers ( $253 + 178$ ).

I'm planning to repeat this experiment myself at some point, and I'm also interested in aggregating data from others who do something similar, either in sync with me as above, or on your own timeline and protocol. I'd also appreciate suggestions for how to improve the experimental design.

#### Comment by Seth

The easiest way to improve this experiment would be to have longer phases. Usually you should run a phase until your measure stops changing and you have collected plenty of data during a steady state. (What "plenty of data" is depends on the strength of the treatment you are studying. Plenty of data might be 5 points or 20 points.) If it isn't clear how long it will take to reach steady state, deciding in advance the length of a phase is not a good idea.

Another way to improve this experiment would be to do statistical tests that generate p values; this would give a better indication of the strength of the evidence. Because this experiment didn't reach steady states, the best tests are complicated (e.g., comparison of slopes of fitted lines). With steady-state data, these tests are simple (e.g., com-

parison of means).

If you are sophisticated at statistics, you could look for a time-of-day effect (are tests later in the day faster?), a day-of-week effect, and so on. If these effects exist, their removal would make the experiment more sensitive. In my brain-function experiments, I use a small number of problems so that I can adjust for problem difficulty. That isn't possible here.

These comments should not get in the way of noticing that the experiment answered the question Peter wanted to answer. I would follow up these results by studying similar treatments: listening to music for 10 minutes, sitting quietly for 10 minutes, and so on. To learn more about why meditation has an effect. The better you understand that, the better you can use it (make the effect larger, more convenient, and so on).

Erika (2013-07-08 08:35:08)

I am a regular meditator and I have a couple of thoughts that might be helpful. I've had a daily meditation practice for the last 6 years that was initially 15 minutes a day but increased to 2 hours a day (I'm now meditating for 1 hour a day). I practice Zen mediation which is probably quite similar to the breath centered meditation mentioned. - meditation is a skill that is developed. Individuals new to meditation may not see as much benefit if they aren't trying to learn that skill (rather than just thinking during that period of time). Personally, I think this may be part of why some studies on meditation are inconclusive. - meditation takes time. I have personally experienced some dramatic changes because of my meditation practice but only after fairly significant periods of daily, consistent practice. - I would say the real benefits begin to come after 30 minutes of daily practice. For me, there was a clear and noticeable difference about 2 weeks after beginning 30 minutes/day - The biggest improvement came for me when I moved from 30 minutes/day to 1 hour/day. It took about 4 weeks to see that improvement. - 2 hours a day was wonderful. Many of the things that make our lives harder are small day to day anxieties - the 1000 emotional paper cuts of interacting with other people. With this level of practice it is much easier to not take things personally. It's very hard to maintain 2 hours a day. For me, this is what meditation does: - removes some fear of suffering/pain. I find that I procrastinate significantly less because I don't have as much need to avoid those tasks. You might not think that you procrastinate because of suffering/pain but that's what I began to see when I started meditation. - helps with anxiety - helps you see more clearly what you are reacting to. What I would recommend for your experiment: - have another group of experienced meditators and have them increase the daily meditation time (with the minimum being 30 minutes). - have this group run the experiment for at least 2 months - I would have the group try and record their level of procrastination (although it might be hard to measure) Cheers, Erika

gwern (2013-07-08 08:40:06)

Could you post the spreadsheet/data for all 12 subjects? I'd like to analyze it.

Justin Irving (2013-07-10 05:17:03)

Thank you for posting this. Anyone familiar with the emwave2 device? It's a commercial heart rate variability monitor, with desktop software. A biofeedback meditation aid. It would be worthwhile to do a similar experiment, using the HRV monitor as the treatment, instead of 'unguided' meditation. It could tell us something about \*why\* meditation is helpful. I hope I will stay focused this topic long enough to finish a study of my own...

Peter Lewis (2013-07-12 07:40:59)

Erika: Thanks for the detailed reply, it's very helpful and I'll definitely take your recommendations into account for the next time. I'm not sure how long I can realistically get people to meditate a half hour or more every day, but something more rigorous is definitely called for. Gwern (and anyone else): I've now posted the raw data at [www.plewis.info](http://www.plewis.info) (link at the bottom) Justin: haven't heard of the emwave2. I once had a gadget that measured breathing through the oxygen content of your breath, you'd hold your index finger on a sensor ... I think it was called the Stress Eraser or Stress Relaxer? Anyway I found that to be a helpful form of biofeedback for meditation. Heart rate might be a bit more useful but I don't know that either would really tell us "why" it works...

gwern (2013-07-13 19:07:16)

Thanks. Using that Excel data, I've done the analysis and posted it all here: [http://www.gwern.net/Lewis %20meditation](http://www.gwern.net/Lewis%20meditation) Summary:  $p=0.27$  for meditation (but p-values are pretty useless in small studies), and I found practice & Robert's time-of-day effects but not any obvious week-day effects.

What We Are Reading | Quantified SelfQuantified Self (2013-07-14 11:38:21)

[...] Journal of Personal Science: Effect of Meditation on Math Speed by Peter Lewis: Originally presented at our 2013 Quantified Self European Conference, this post details Peter's self-experiment on improving his cognitive abilities through a meditation practice. Peter also has an excellent post on his personal website entitled, What's Driving the Quantified Self Movement? Well worth a read. [...]

## **The History of Human Chromosome Number Reveals Constraints on Professional Scientists (2013-07-09 05:00)**

Why does personal science matter? One reason, as I've said [1]many times, is that personal scientists (who do science to help themselves) are free to speak the truth. Sometimes professional scientists (for whom science is a job) are not.

The history of human chromosome number is a good example. Starting in the 1920s, humans were said to have 48 chromosomes. In fact, the correct number is 46. From the soon-to-be-published book *The Truth in Small Doses* by Clifton Leaf (copy sent me by publisher), which is about cancer research, I learned that in 1955 two Swedish scientists, Tjio and Levan, established the correct number. After their article appeared,

Several researchers wrote [them] to confess that they, too, had spied only forty-six chromosomes but had thrown out the results because they were in conflict with established knowledge.

"In conflict with established knowledge" was euphemism for we were worried what would happen to us.

*The Truth in Small Doses* begins with this story. Leaf's point is that cancer researchers have a similar problem: They too cannot tell the truth, which is that progress against cancer has been poor, in spite of billions of dollars spent on

research.

1. <http://media.sethroberts.net/articles/2010%20The%20unreasonable%20effectiveness%20of%20my%20self-experimentation.pdf>

---

dearieme (2013-07-09 05:38:25)

"progress against cancer has been poor": with the exception, I understand, of useful progress on some childhood cancers. Seth: That's right. Because those cancers are rare, it doesn't do much to change the overall record. The other exception is lung cancer. Lung cancer has gone down a lot since it was figured out that it is caused by smoking. Leaf doesn't mention this.

Tim Ossman (2013-07-09 06:31:21)

How long will it before "Professional Scientists" will admit research which makes people TRULY UNCOMFORTABLE, such as that indicating that humans are hybrids of bonobos and PIGS? <http://www.macroevolution.net/human-origins.html> In our lifetimes?

Alex Chernavsky (2013-07-09 07:53:14)

From Richard Feynman's graduation speech given at Cal Tech in 1974 (as quoted on this [1]Wikipedia page):

We have learned a lot from experience about how to handle some of the ways we fool ourselves. One example: Millikan measured the charge on an electron by an experiment with falling oil drops, and got an answer which we now know not to be quite right. It's a little bit off because he had the incorrect value for the viscosity of air. It's interesting to look at the history of measurements of the charge of an electron, after Millikan. If you plot them as a function of time, you find that one is a little bit bigger than Millikan's, and the next one's a little bit bigger than that, and the next one's a little bit bigger than that, until finally they settle down to a number which is higher. Why didn't they discover the new number was higher right away? It's a thing that scientists are ashamed of - this history - because it's apparent that people did things like this: When they got a number that was too high above Millikan's, they thought something must be wrong - and they would look for and find a reason why something might be wrong. When they got a number close to Millikan's value they didn't look so hard. And so they eliminated the numbers that were too far off, and did other things like that

Seth: Yes, another good example.

1. [http://en.wikipedia.org/wiki/Oil\\_drop\\_experiment](http://en.wikipedia.org/wiki/Oil_drop_experiment)

Daniel Lemire (2013-07-09 09:25:33)

I don't think there is necessarily always a conspiracy in favor of the status quo. People just tends to cling to whatever they have learned about first. It is expensive to change your mind. There is no doubt that "we were worried what would happen to us" is sometimes the right explanation, but it is not always the case. The phenomenon you describe happens even when nobody has a strong incentive to preserve the status quo.

Nile (2013-07-09 11:12:00)

To expand on what Daniel Lemire wrote - Thorson Veblen coined the term "trained incapacity" to refer to the inability of people to see solutions to problems when the solution exists outside the training or educational background of the solution seeker. A story, probably apocryphal, was that Veblen bolted a pipe to a table and then dropped a small ball, like a ping-pong ball, into the pipe. On a nearby table Veblen had laid out some tools, as well as normal amenities - water, light snacks, etc. Veblen then invited some engineers to get the ball out of the pipe. The provided hand tools were (deliberately) inappropriate for the task so the engineers failed. Veblen then asked a farmer to get the ball out of the pipe. The farmer promptly took the water pitcher, poured water into the pipe and the ball floated to the top. I have no doubt that some scientists are afraid to speak the

truth for fear of damaging their reputations but I also have no doubt that some scientists (and politicians, educators, citizens, business people, etc.etc.) simply can not see or accept existing reality because of "trained incapacity" All the more reason to do personal science and "crazy" experiments A good, short explanation of the phenomenon by the late, great Herman Kahn can be found here; [http://www.hudson.org/index.cfm?fuseaction=publication\\_details&id=2219](http://www.hudson.org/index.cfm?fuseaction=publication_details&id=2219) Seth: I agree. That's another reason to support personal science: To open up the investigation of X (e.g., cancer) to people who use tools other than the tools of professional scientists. The story sounds too practical for Veblen.

dearieme (2013-07-09 13:02:28)

The Millikan story is a bit clouded, though, by the fact that he fiddled his numbers anyway (or so I understand).

### **Congratulations, Morex! Shangri-La Diet Success (2013-07-10 05:00)**

The photo on the left was taken summer 2011; the photo on the right was taken June 2013. He lost 75 pounds in 5 months. Morex writes:

All my life I had been the fat guy. I was that kid in school that couldn't run or go out and play because I was too heavy. You know how that is.

My teenage years and all my adult life I had been the fat guy. Until today.

I tried every kind of diet to my knowledge. I exercise since I have memory. But I never could lose enough

weight or maintain the little weight loss I could achieve.

Until I read Freakonomics, which led me to research about Seth and SLD, which led me to these forums and to reading the book.

So last January [January 2013], after reading a little about how SLD works, I decided to give it a go.

He gives details [1]here.

1. <http://boards.sethroberts.net/index.php?topic=8367.0>

---

David (2013-07-10 20:40:18)

That is incredibly impressive. I am happy for the great success he has had. But I wish we knew why it worked so well for him, but not for others. I've tried SLD three times and did not have any significant success. Seth: If you contact me, I'd be happy to try to answer your question: why it worked for him but not for you.

Morex (2013-07-11 08:51:07)

Thank you for posting about my little SLD adventure. All the credit is yours, really. You, sir, are awesome. But now you made me curious. I know what I did, of course, but is there any particular scientific reason why SLD worked with me?

David (2013-07-11 18:28:21)

Morex - When I've tried SLD I have noticed that food often didn't taste as good as it had before and it did feel like I got full a bit faster, but those effects were fairly small and did not amount to any significant appetite suppression. So after a week or so food cravings start to kick in and willpower (to eat less) runs out. From reading your page on the SLD forums, it seems like you experienced noticeable appetite suppression by Day 4 and the effect only got stronger from there. Is that correct? Seth - I've sent you an email.

Morex (2013-07-12 10:51:08)

Hi David. In my experience, yes, food tastes different under SLD. The things you used to like will no longer be appealing and you will develop new tastes. For example, I now love jalapeños and peanuts. I crave for them and I didn't even think about them before SLD. Also, I rarely use spices anymore. I don't need them. Simple food now is so intense that I may use a little pepper here and there. But that's it. So yeah, food tastes a little different. I think it has to be that you are breaking the addiction to always have very strong flavors on your mouth. And yes, you get full REALLY fast after AS kicks in in all its force. Take a look at my journal and you'll see the portions I have nowadays. My AS was good from the beginning. But it took a little more than a month for it to be this huge. I am not an expert, of course, but I always advise to be VERY patient. In a world where we are used to instant gratification, waiting a few weeks might seem a daunting task. Just have your oil or sugar in the amount appropriate to your body and be patient. I had to read the FAQ a few times and the book twice. And follow SLD like a bullet list. Don't stay too far away from the plan. That was my only secret, really. Hope that helps.

delante (2013-07-15 03:04:15)

Re "why it worked for him but not for you" - if there's anything new here, or if its some aspect that most people miss, I'd be interested to read more about it on the blog . Seth: My theory is this. Your weight is controlled by (say) five factors. SLD changes one of them, pushing you toward a lower weight. It is powerful only to the extent that your eating is based on how hungry you are. SLD will appear to fail - no lost weight - when (a) the other factors are pushing your weight upward strongly

enough and (b) hunger has little control over your eating (= you often or usually eat when you're not hungry), which reduces the downward push of SLD.

### Assorted Links (2013-07-11 05:00)

- [1]self-tracking neuroscientist. I have only learned from tracking when I am adventurous – when I change stuff, such as what I eat. I will be curious to see if the same thing happens here. The initial thought when tracking yourself is "keep things constant" so that the data from different days will be more comparable. This makes sense if you are doing an experiment where different days get different treatments. It does not make sense when you are not doing an experiment. This self-tracker doesn't seem to be doing any experiments, so he should allow his life to be messy if he wants to learn more.
- [2]Interview with Renata Adler
- [3]Alternate-day fasting thread at Mark's Daily Apple
- [4]An essay on the effect of immigrants on "economic freedom" (via [5]Marginal Revolution) does not mention the fact that immigrants bring new ideas and skills. This is an example of the way economists usually ignore innovation, which benefits from new ideas and skills. Innovations usually derive from new combinations of things. To open a new business (an instance of economic freedom) it really helps to have a new good or service. New cuisines (immigrants open restaurants) is just the beginning.

Thanks to Dave Lull.

Tim Ossman (2013-07-11 15:07:01)

Interesting link for you: <http://www.bbc.com/future/story/20130710-how-our-organs-sniff-out-smells/all>

Steve Johnson (2013-07-11 15:46:56)

<http://www.isegoria.net/2013/07/why-does-the-lack-of-traffic-rules-work-in-en-gland-but-not-in-haiti/> Yep, immigrants bring loads of new ideas and cuisine is just the beginning.

Dave in Seattle (2013-07-11 23:18:41)

Yes, immigrants, especially from the third world bring a great deal with them. Just off the top of my head, think of all the doctors and medical professionals from India and the former USSR who made incredible innovations in medicare and insurance fraud. The next time the feds make a medicare bust just check out the names-usually an odd assortment of Armenians, Ukrainians, Russians, Russian Jews, Nigerians and South Asians, all working harmoniously to screw over their adopted country and Uncle Sugar. The Chechen terrorists in Boston, the Saudi terrorists on 9/11 and the Fort Hood shooting. In Seattle it seems the Romanian immigrants are in forefront of ATM fraud with incredibly high tech card skimmers. The Chinese and Koreans are

ruthless at human trafficking and prostitution. The illegals from Mexico and Central America are usually the ones clogging your local hospitals ER-those are the good ones, the bad ones of course are members of the ruthless drug gangs now recruiting and operating in the USA because of our insane open borders policies. Did I leave anything out? Antibiotic resistant TB, identity theft, the complete fracturing of society because no one trusts each other anymore with high security gated communities for the rich and the ever diminishing middle classes trying to escape the chaos and bad schools . Suburban and urban sprawl, unsustainable water demands in desert monstrosities like Las Vegas and Phoenix, traffic jams, low wages and massive job competition for native born Americans from the lowest rungs of society. These open borders zealots like Obama, Bush jr., McCain and the tenured professors at George Mason University don't have to deal with this anarchy and the crime they've created. They've got cheap nannies, gardeners, maids, etc. and most importantly they get to feel and look compassionate while they get to denigrate the "nativist rednecks" who are left bewildered as their nation crumbles and best of all the taxpayers get stuck with the bill. Plus a fractured and diverse society is much easier to rule and tyrannize. It was Saudi immigrants who gave us the TSA. Remember that the next time you or your grandmother is harassed and molested by a government agent at the airport. Seth: "Did I leave anything out?" Yes, you did. How recently did you use Google? I used it a few seconds ago. How recently did you eat ethnic food? I ate kimchi 10 hours ago. To give just two examples. You left a lot out. When is the last time you were personally affected by one of the bad effects you describe?

Dave in Seattle (2013-07-12 09:53:56)

Look I like some ethnic food. But all I'm asking for is a little hard headed cost benefit analysis. Or better yet, just for our bettors to ask the citizens of this country if we want to be a multiracial, multilingual, religiously diverse nation of well over 300 million people. We were never asked, it was just shoved down our throats and if you disagreed you were labeled a hateful, racssist. See the now unemployed and likely unemployable Jason Richwine or James Watson, John Derbyshire or Pat Buchanan, well you see where I'm going, certain thoughts are well, Crimethink no matter how scientific or factual they are. I'm affected by it everyday, my once friendly, safe neighborhood that was completely homogeneous thirty years ago is filled with Asian and Hispanic gangs, drive by shootings that literally never happened when I was a kid, happen a few times a year. Doors were left unlocked for the most part, kids played all day without any supervision or their parents worrying about them. Now you'd be nuts to let your kids out your sight in this neighborhood. Parts of Eastern Washington state, which is where my family is from (Oakies) used to be filled with quiet, friendly, little farm towns that are now filled with Central American drug gangs fighting vicious little turf wars with each other. And no these Hispanics aren't picking crops in the fields-their parents did that, the kids are in jail, dealing drugs or if they are women usually on welfare. Look I like Mexicans, I like their food and I've done lots of grunt work with them. I respect hard working people and many illegals are decent and hardworking but they bring a whole host of pathologies with them and to ignore these is just stupid. Also flooding the US with tens of millions of low skilled and barely literate workers when the real unemployment is around 20 % is just cruel to our own citizens who we are supposed to be looking out for. It's cruel to the low skilled workers that used to do those jobs, but nobody will hire them now because they aren't as cheap, subservient and most importantly for the employer dispossable as the illegal/legal immigrants. The Google argument is a strawman, when has the US denied entry to genius immigrants? To equate the parents of Brin and Page or of Tesla and Einstein to the millions of low skilled, barely literate people we are taking in nowadays is disingenuous. Like I mentioned before, Medicare fraud is multi-billion dollar industry and highly intelligent immigrants from low trust nations play a huge role in this fraud. No one wants to take an honest look at how much these immigrants cost our nation. I mean how many more Raj Rajaratnam or Armen Kazarians can this country take. Our country is what 16 trillion dollars in debt and yet we continue to take in super smart crooks from all over the world. And yes I know there are plenty of home grown criminals but do we need to scour the world for more? And as Steve Sailer has written about, why are we importing fraudulent asylum seeking Chechens. Or think about all of crime the Somali immigrants cause in once placid Minnesota? I'm sure Somali cuisine has it's fans but is it worth it? You admire Japan and it's culture, so do I. By your thinking Japan should let in millions of migrants from all over the world. Somalis, Nigerians, Salvadorans, Indians and Pakistanis would make Japan more interesting, with a better choice of markets and restaurants, well perhaps. Other things might change too and as Dennis Mangan has said, "What could go wrong?" Seth: I don't have an opinion about large-scale immigration. I am neither for nor against it. My point is/was that your earlier argument that immigration was overall bad was woefully incomplete. I don't agree that a long list of bad effects of immigration - the fact that immigration does have many bad effects - should determine what any reasonable person should think. I agree that the thought police are far worse than the thinkers they try to suppress. I also think that you need

an assimilation process that works and if you don't you are going to have enormous trouble. That being said, I think of the following: Person A: My GPS keeps breaking! Person B: You have GPS? Americans are lucky that so many people want to come here. There's a reason. It's not that they think we're easy marks. Far from it.

Barbarosa (2013-07-12 17:30:11)

Let's get real here. We need to stop pretending that the immigration we like (japanese sushi chefs or Chinese STEM post-docs, e.g.) has a flying fig to do with what the immigration debate is mostly about – amnesty and eventual citizenship for at least 11 million low-skilled, uneducated Mexican citizens, who sure as Hell will not be founding any software companies or twee tea shops. Mexican immigrants have been in this country for well over a hundred years, and for whatever reason they simply do not converge to white middle-class standards on a number of social metrics. Ergo inviting them in en masse will bring down the National average. We have a good thing going. It's not worth risking for cheap Mexican food. It's really not that complicated. The fact that their presence does not obviously deleteriously effect upper-middle class urban yuppies is altogether unsurprising: we don't live in their neighborhoods, their academically below average children don't go to school or camp with ours, and they're not competing for our high paying jobs. Low skilled immigration will only harm American's will low-skilled jobs. And corporate capitalists (i.e. investors of capital) will benefit from their cheaper labor. Well educated, affluent Libertarians like to delude themselves with the conceit that these displaced workers can just go out and get more education or "retool their skill set" or some other such fairy tale. Half of Americans are necessarily below average. It will be hard enough finding a place for them in a economy where the gains are increasingly redounding to the cognitively gifted.

### **Anesthesia Dolorosa Mirror Cure (2013-07-12 05:55)**

[1]Anesthesia Dolorosa is a very rare condition in which part of the skin that is numb feels pain. It is a side effect of surgery for trigeminal neuralgia. "No effective medical therapy has yet been found," says [2]the Wikipedia entry. Whoever wrote that meant that no entirely effective therapy has been found. Some surgical treatments are helpful some of the time.

In [3]a series of blog posts, an art historian named Beth Taylor-Schott wrote about using a mirror to eliminate her husband's Anesthesia Dolorosa, which was on his face. She got the idea from a New Yorker article by Atul Gawande about V.S. Ramachandra's use of mirror therapy to treat phantom limb pain. I [4]mentioned this years ago but it is worth mentioning again as an example of non-medical-professionals finding a solution to a medical problem much better than anything professionals came up with.

Here's a brief description of what happened:

My brother-in-law sent me [5]an article by Atul Gawande from the June 30th [2008] issue of the New Yorker. Using the information from the article, we came up with a non-reversed mirror therapy to try to reduce David's AD-related pain. . . . We started doing the therapy on the 23rd of July, 2008. Within 2-3 days, his pain was down to zero, and as long as we continued to do the mirror therapy 3-4 times a day, it remained that low. This was the lowest it had been since he had had the sympathetic nerve blocks, and it stayed low for much longer periods of time than it had after the blocks.

Once the pain was stabilized at 0, we started to reduce his Neurontin, first by 400 mgs each time, then once we got to 1200 mg, by 200 mg at a time. Typically, we reduced it every 3-4 days. The first or second day after the Neurontin was reduced, the pain would typically start to go up somewhat, although it rarely went above a 5, and that was under extreme circumstances. But if we kept doing the mirror therapy, it would go back down and remain at zero, so that we could reduce the Neurontin again, and so on.

Today is the 27th of August. David's pain has been under control all day. Tonight, for the first time, he did not take any Neurontin when he went to sleep. As of tomorrow morning, it will have been 36 hours since he has had any Neurontin. . . .

[Details of the treatment] David can look either into the mirror in his hand, or into the reflection of that mirror in the mirror on the wall, and in both of them he sees a non-reversed image of himself (unlike a regular mirror image, in which the image is reversed.) The therapy depends upon the brain not realizing that the images it sees are non-reversed images, but assuming that they are regular, reversed mirror images. . . . standing behind the chair, I would reach around and touch/massage the right side of David's face for the length of the session while he watched in the non-reversed mirrors. Yes, you read that correctly. The affected side is the left, but I would massage the right side, the one that still has feeling. Since David's brain thought it was looking into a mirror, it saw me massaging the left side of the face and so actually experienced sensation in that left side when I was actually touching the right side. In this way, it contradicted the brain's theory that since it was not getting any signals from the nerves, something must be terribly wrong, so that it needed to invent pain signals to alert David to its state.

That ordinary people can do so much better than experts on an enormously important problem (if you have AD) is either wonderful or depressing if you believe, as I do, that this will turn out to be common. I have written to Taylor-Schott to ask what has happened since then.

## **My Heart Watch: Bay Area Health Measurements (2013-07-13 05:00)**

For many years I have used the services of [1]Heart Watch to measure my cholesterol and other health-related things, such as HbA1c. The couple that runs Heart Watch, Sandy and Glen, travels up and down California. I was able to get tested only every three months. Feeling that this was inadequate, just as I did, a man named Karl Corbett recently started a business called [2]My Heart Watch that allows much more frequent tests in the Bay Area, at similar price. My Heart Watch uses the same portable testing devices as Heart Watch.

The Berkeley location is almost across the street from Whole Foods. I signed up online (I was the first person to use their online sign-up service), which was very convenient.

Corbett told me that he greatly improved his cholesterol numbers by changing to [3]a Caldwell-Esselstyn "plant-based diet" that included lots of vegetables, some fruit, no oils, and no animal-based products. (Since the usual oils, such as olive and soybean oil, are plant-based, this is a curious feature. Esselstyn seems to ignore [4]bad effects of cholesterol lowering.) The more often you can test yourself, the more easily you can determine what controls what you're measuring. When you can test yourself often enough to be sure whether a dietary (or other) change has made a difference, you can begin to ignore large clinical trials and their many limitations, which include poor choice of control group, poor statistics, incomplete reporting, biased reporting, publication bias, confoundings, investigator fraud, on and on. They are the fool's-gold standard. If I can determine if [5]alternate-day fasting improves my HbA1c, I can ignore what clinical trials say about it.

Before writing this post I spoke to Corbett about getting discounted testing in return for publicizing My Heart Watch.

4. <http://www.ncbi.nlm.nih.gov/pubmed/2144195>
5. <http://blog.sethroberts.net/2013/07/02/does-alternate-day-fasting-lower-hba1c/>

---

Sean (2013-07-13 05:52:51)

I'm not sure what convinced me of Dr Esselstyn's diet, whether it was the scientific objectivity, the overall website design, or the 'as seen on CNN' logo at the top of the page, but I'm suddenly convinced that SFAs will clog my arteries.

Laura (2013-07-13 07:47:32)

Regarding the study you linked (bad effects of cholesterol lowering)...it seems that cholesterol was lowered in that study by means of medication. The health outcomes might be very different if the same thing were achieved using an Esselstyn-type diet. Seth: I think it is not so simple. Let's say the medicine in that study has two effects: X and cholesterol-lowering. An Esselstyn-type diet has other effects: Y plus cholesterol-lowering. As far as I know, the medicine in that study does not have the bad effects (e.g., increased risk of suicide) unless your cholesterol is low. Which suggests that it has bad effects because it lowers cholesterol. So it is not obvious how an Esselstyn-type diet will affect suicide and other measures of mental health. Were Esselstyn to understand this and try to find the answer ("what effect does my diet have on mental health?") I would respect him. As far as I know, he doesn't. The bad effects of cholesterol-lowering seen in that study and others he dismisses too easily.

dearieme (2013-07-13 11:00:09)

Perhaps your optimal cholesterol level is whatever level your body adopts when you eat a healthy mixed diet. Who knows?

derp (2013-07-13 14:24:27)

It is an interesting piece of self-experimentation and emphasizes how important it is to measure early, often and regularly. You already noted the futility of bringing down the cholesterol content - this is another aspect of self-experimentation: You need to measure outcomes that really do improve that what you want to improve (health in that case) and not some epidemiologically-linked number.

Javed Alam (2013-07-13 22:36:02)

I have used this home Kit to test for total cholesterol, HDL and Triglycerides. [http://www.cardiochek.com/index.php?option=com\\_content&view=article&id=135&Itemid=255](http://www.cardiochek.com/index.php?option=com_content&view=article&id=135&Itemid=255) It works and results match up with the lab results. I don't use it to test blood glucose levels for that I have a different test kit from Bayers. I also use home A1C test kit from Bayers some times. Seth: At first I was excited by the existence of home A1C testing. Then I saw [1]this review.

1. [http://www.amazon.com/review/R1274T1GB88EI7/ref=cm\\_cr\\_dp\\_title?ie=UTF8&ASIN=B004N110GQ&nodeID=3760901&store=hpc](http://www.amazon.com/review/R1274T1GB88EI7/ref=cm_cr_dp_title?ie=UTF8&ASIN=B004N110GQ&nodeID=3760901&store=hpc)

dearieme (2013-07-14 03:10:15)

On second thoughts: is there any worthwhile evidence that such a thing as an optimal cholesterol level exists? (I exempt from this question the poor souls suffering from Familial Hypercholesterolemia.)

dearieme (2013-07-16 13:53:41)

Perhaps I needn't have exempted the poor souls. <http://drmalcolmkendrick.org/2013/07/16/you-are-a-very-black-swan-indeed/>

---

Alex Chernavsky (2013-07-14 08:45:08)

Here's another interesting story from the *New York Times*: "[1]Do Clinical Trials Work?"

1. [http://www.nytimes.com/2013/07/14/opinion/sunday/do-clinical-trials-work.html?\\_r=0](http://www.nytimes.com/2013/07/14/opinion/sunday/do-clinical-trials-work.html?_r=0)

Alex Chernavsky (2013-07-14 09:04:49)

Finland also has a very effective way of treating psychosis – far more effective than the standard practice (in most Western countries) of drugging people into oblivion:

**Open Dialogue Therapy in Western Lapland for Psychotic Patients** In the Western World, Western Lapland in Finland has adopted a form of care for its psychotic patients that has produced astonishingly good long-term outcomes. At the end of two and five years, eighty percent of first-episode psychotic patients in Western Lapland are either employed or back at school. Only about one third of the patients are ever exposed to antipsychotic medications, and only 20 % end up taking the drugs on a continual basis.

From: <http://robertwhitaker.org/robertwhitaker.org/Solutions.html>

Mikael (2013-07-14 10:57:30)

That is an experimental therapy in Western Lapland where hardly any people live at all - not something that is used in all of Finland. Don't get me wrong, I love Finland and am half-Finnish, but things are really not as rosy as painted in the articles here. Finland is just the current stop on the "Scandinavians are so happy" meme train. Seth: I am impressed that Finland is testing such a therapy. Nowhere in America, as far as I know, is it being tested.

Staffan (2013-07-14 11:40:05)

Mikael, most measures of economy, health care, education, crime, corruption etc show that Finland is doing very well. And unlike the rest of Scandinavia Finland doesn't have immigrants patrolling certain suburbs and instructing women on how what clothes to wear, it doesn't have riots, it doesn't have Breivik etc.

The Skeptic (2013-07-14 12:11:21)

re: Mood benefits of fermented food *The study was funded by Danone Research. Mayer has served on the company's scientific advisory board. Three of the study authors (Denis Guyonnet, Sophie Legrain-Raspaud and Beatrice Trotin) are employed by Danone Research and were involved in the planning and execution of the study (providing the products) but had no role in the analysis or interpretation of the results.*

dearieme (2013-07-14 13:30:26)

@Alex: "Some patients did do better on the drug, and indeed, doctors and patients insist that some who take Avastin significantly beat the average." So some must have undershot the average i.e. have had their death brought forward by the Avastin?

Adam (2013-07-14 16:33:28)

Yeah, Finland is quite successful... at robbing the unborn who will be forced to pay for all of this sh! & for their entire lives: <http://www.nationaldebtclocks.org/debtclock/finland>

Evelyn M. (2013-07-17 02:22:49)

With respect to the medical price-fixing going on in the U.S., the author recommends more direct government intervention. To me, it seems from the evidence presented that price-fixing started when the federal government established the Medicare program (which, laughingly, was sold to the public as a way of saving money in the long run by making people healthier the same way the NHS was sold in Britain). Perhaps the simplest solution would be to go back to direct payments from patients to doctors, the way the system worked for hundreds of years, with the understanding that care would be provided to those unable to pay by charitable organizations (which would go back to collecting donations from the public at large instead of taking government fees) and physicians themselves, as a moral responsibility buttressed by the increased respect they would thereby earn from the public and their fellow professionals. Using the Web patients could shop around for general physicians or specialists, knowing up-front what the cost for visits or procedures would be - and having feedback to review from past patients. Hospitals, too, would post their charges up-front, so patients could decide where to go based on price versus perceived or actual quality of services. More attention should also be given by the press and other media to the results of Cochrane Collaboration mega-analyses of clinical trials data which show, for example, that annual physical exams by general practitioners or specialists are worthless (or even result in unnecessary and costly treatment). If people had to rely on their own decision-making, they would consider twice before following "doctor's orders" blindly, as most people do nowadays. Most Medicare patients never inquire what the actual cost of a procedure is, they just want to know how much the co-pay amount would be - and since the physician wants the patient to remain on his books, he usually waives that piddling amount in any case. Seth: Your idea has some very good aspects - and a hospital in Oklahoma has started posting charges up front - but it does not address protect against catastrophic loss. If only one person in 1000 is going to need Expensive Procedure X, how shall X be paid for?

Evelyn M. (2013-07-17 17:55:00)

Thank you for the response, Seth. I don't think we need the government to handle the one person in 1,000 needing expensive procedure X - that is what "saving for a rainy day" is for those of us who can pay their own way, the use of high deductible

insurance for unanticipated drastic events for the majority of the population, or the best use of charitable donations for those who can't cope on their own. We will never have a perfect system, and we will never be able to keep everyone alive forever no matter how much money we spend. Seth: That makes sense – that only insurance with a high deductible should exist because otherwise doctors and hospitals will price-fix. However, I would like to know more about health care in Japan, where health is better than here and health care is much cheaper than here. I don't know why. At Berkeley, at a psychology department meeting, there was a certain problem we needed to solve. *Let's see how other departments handle this*, I said. I was told that such a thing was beneath us, We should be leaders.

Evelyn M. (2013-07-18 12:08:54)

As few Westerners know Japanese, and it seems that few Japanese with English-language skills think Americans are interested in their health system, I fear that we may never have an opportunity to learn how the Japanese medical system compares to ours. My own guess would be that differences in health statistics between countries derive from (1) how the numbers are constructed (the different ways infant mortality is defined, for example) (2) the genetic makeup of the population, (3) the relative healthiness of the environment (levels of pathogens, heat and humidity), and (4) the quality of the health care and medical systems. It is sad to hear that things at Berkeley are as bad as you describe. It must be hard to cope in such an anti-intellectual environment. No wonder you run away to China!

### **Anesthesia Dolorosa Mirror Cure Update (2013-07-15 05:00)**

I [1]recently posted about using a mirror to cure anesthesia dolorosa, a painful skin condition similar to phantom limb pain, which is always caused by surgery. Beth Taylor-Schott, the inventor of the technique, told me what's happened since she last blogged about it:

Since then, David is still pretty much pain free and off Neurontin. Just a twinge now and then that he takes care of with Lidocaine, if anything. Have not had to re-do the therapy or anything like that.

I have been contacted by two researchers in the UK, and as I understand it, they're doing research based on the blog, though I have not heard what their results are. Also, someone in Australia wanted to fly us out to do a demonstration and be at a conference, but I couldn't get enough time off work to make it worth it.

I have heard from people who have read the blog and who want to do the therapy and who have questions, which I always answer, but only a very few of them ever come back to tell me that it's worked, and no one has ever come back to say it hasn't, so I'm not sure what to do with that. I don't really see this as my crusade. I put the blog out there, and I figure the people who are meant to find it will find it. We ourselves only discovered this through a weird series of coincidences, after all.

She explained what she meant by "weird series of coincidences":

It was by no means certain that I would read it. I think it had been sitting in my in-box for three or four months when I went back and read it. That is one coincidence. Another is that I came across it because, given that David had just flatlined twice in the hospital, I was in no shape to do anything BUT clean out my inbox, not something I did at all frequently at the time (like MAYBE once a year or every two years). And then too, I read it at a moment when his cardiologist had just told us that probably David needed to not only go off the stimulants he'd been taking to counteract the Neurontin, but also the Neurontin

itself. His pain was being kept under control in the hospital with injections of Toradol, and there was no way they would let me give him that much when he was at home and not being monitored. So what would we have done if the mirror therapy hadn't worked? He would not only have been non-functional, but in constant, excruciating pain. And yet I did not go into the inbox looking for answers, I went into it to distract myself from the fact that I seemingly had no answers. So the whole thing had a very *deus ex machina* quality to it.

And then there's the fact that I happen to be the kind of person who is resilient enough to actually try something like this despite years of frustration with the condition and our treatment at the hands of the experts. What are the chances that I'd be in a situation like this, especially given the rarity of David's condition? (Last I heard, M, the woman in the piece by Gawande, did not pursue the therapy, even after it was suggested to her.)

In a list of things that made the discovery less likely (e.g., rarely cleans out her inbox) she includes something that made the discovery much more likely, namely "what would we have done if the mirror therapy hadn't worked?" She and her husband were incredibly motivated to make it work. More motivated than professional scientists ever are. This is an enormous advantage of personal science over professional science: the much greater motivation of the personal scientist.

Matt (2013-07-18 06:00:58)

I believe that hernia hospital was discussed in a chapter in one of Atul Gawande's books. I remember that the doctors at the hospital were hired right after they finished their internship – as soon as they are legally allowed to practice medicine. They aren't surgeons or trained in surgery. I remember being struck by the massive waste involved in doctor's education – these hernia surgeons need not to have ever gone to medical school, but they do what they do far better than general surgeons. And – it would be insulting for a general surgeon, who spent four years in medical school, five years in residency, a few years as a fellow somewhere, to only do one specific surgery. And so the system serves physician's egos and pocketbooks far better than it does patients. Seth: Good points. Especially "such extreme specialization is discouraged by the massive amount of education that doctors receive". I think a similar dynamic operates in science: After all that education, to do simple self-experiments would be insulting. Must do expensive research, whether that's what is needed or not.

dearieme (2013-07-18 06:15:02)

There are a lot of livelihoods that depend on popular theories of cardio-vascular diseases.

Paul N (2013-07-18 06:15:10)

I think this sort of change is inevitable, it is just being resisted by the medical community. Look at the model that made McDonalds successful; -they concentrated on preparing variations of just one thing (i.e. burgers), and -they split up the work into single task jobs that could be done by staff with a relatively low level of training (compared to a traditional chef). It is easy to see how a clinic that specialises in just one thing can follow a similar model, and this already exists with many medical service business (pathology, lab testing etc). And, of course, it already exists for cosmetic surgery - many places do this and nothing else. The problem is/has been the front end - the doctors. You have to see a doctor, that costs probably \$100 for a consultation, to get a test that may cost \$20. As we start to see more of these service businesses deal directly with people - no doctors required- the front end monopoly will start to crack. A specialised surgery clinic is a bit more complicated than a pathology lab, but far less so than a hospital. It is also much less bureaucratic, so we will see more innovation happening too.

shtove (2013-07-18 10:17:25)

Never heard of koji salt - thanks for the link. LA Times has an article (your link is paywalled outside US): <http://articles.latimes.com/2012/aug/25/food/la-fo-koji-20120825>

Thomas W (2013-07-18 11:26:02)

Cataract surgery in India is another example of this trend.

Evelyn M. (2013-07-18 12:11:00)

A wonderful collection of links. Many thanks.

kxmoore (2013-07-18 18:12:37)

heart disease and air quality. <http://forums.webmd.com/3/cholesterol-management-exchange/forum/1270>

Shep (2013-07-18 22:50:02)

Grime didn't even mention smoking in his article and this one clearly states the correlation between reduction of smoking and reduction of heart disease. You seem pretty happy to accept some pretty weak evidence in the face of the There are literally hundreds of articles showing the link between smoking and CHD. Any chance you'll be linking to any of those? Seth:

The article says that changes in smoking do not explain changes in heart disease. There is a correlation, yes, but the details contradict the idea that reduction in smoking caused the reduction in heart disease. Did I miss something? The only evidence I could find that smoking causes heart disease is the risk factor stuff – smokers are more likely to have heart disease than non-smokers. Obviously "smoking is unhealthy" and "heart disease is caused by doing unhealthy things" so this correlation by itself I don't find especially persuasive – people who smoke probably do other unhealthy things. Millions of people suffer from heart disease who don't smoke. For all I know smoking has a small effect. Something else has a large effect. The question raised by the article I cite is: what is that "something else"?

Jerry (2013-07-20 07:46:30)

I have cooked with koji before. You can order dried, inoculated koji rice and use it to ferment your own soy sauce, miso, and to make amasake, a very sweet, delicious desert. Homemade amasake (as opposed to the store-bought stuff) is a bit of an acquired taste. Millet amasake is absolutely delicious. However, I am now convinced that these are not particularly healthy foods. I eliminated all of them from my diet a few years ago and I feel noticeably better. These foods are high in glutamate, and I'd rather err on the side of caution by not eating them. Dr. Baylock wrote extensively about this in "Excitotoxins: The Taste that Kills" a book I recommend. It is hard to refute that free glutamate causes brain damage in lab animals. Yes, it's a naturally-occurring taste, and we have sensors all over our alimentary canals for it (which probably evolved for sensing protein levels in ingested food), but I see no point in adding any to food. Seth: I'm pretty sure we can detect protein in food without glutamate detection. I think we like the taste of glutamate so that we will eat more aged/fermented protein – for example, aged meat. Surely you eat aged meat, which has much more glutamate than fresh meat. But I don't disagree with your decision to stop eating all those fermented soy products. No doubt some people get too much glutamate – for example, people who suffer from MSG.

## **How to Detect Dementia (2013-07-19 05:00)**

Dementia is common. You might think that doctors and neuropsychologists would have a good understanding of how to detect it. Judging from [1]a recent New York Times article, they don't. The article is based on a study that found that people who report memory problems not detected by a standard test turn out to be more likely to end up with dementia (measured by a standard test) than those that don't. This isn't surprising; what's more revealing is how people who report memory problems have been treated in the past: their complaints have been dismissed. For example:

Patients like this have long been called "the worried well," said Creighton Phelps, acting chief of the dementias of aging branch of the National Institute on Aging. "People would complain, and we didn't really think it was very valid to take that into account."

Doctors had no idea whether these complaints were valid but rather than admit this ignorance they . . . confabulated. They claimed, based on nothing, that the complaints were not valid. It reminds me of [2]a surgeon telling me that research supported her claim that I needed surgery (for a hard-to-notice hernia). No such research existed. When I asked her what research? she said she would find it. She was bluffing, in other words. That's just one doctor making up evidence. Here it has been a whole group of doctors.

The problem isn't just confabulation. Apparently doctors in this area fail to understand basic principles of measurement. When Patient Y visits Doctor X and complains of memory problems, Doctor X gives Patient Y a series of memory tests. Only if Patient Y scores below normal range does Doctor X think that Patient Y's complaint is "real". For example:

The man complained of memory problems but seemed perfectly normal. No specialist he visited detected any decline. "He insisted that things were changing, but he aced all of our tests," said Rebecca Amariglio,

a neuropsychologist at Brigham and Women's Hospital in Boston.

Amariglio apparently fails to understand that a series of measurements on one person – which is what the man's complaint was based on, comparing himself now to himself in the past – is going to be vastly more sensitive to change than a comparison of one person to other people. A reasonable response to a complaint of memory loss would be: This is hard to detect with a one visit. Let's give you a sensitive test and have you come back in six months to see if you decline more than normal. Judging from the Times article, doctors still haven't figured this out.

Speaking of memory decline, Posit Science still hasn't sent me [3]the data they promised to send me.

Thanks to Alex Chernavsky.

---

dearieme (2013-07-19 06:47:01)

I find myself struggling to remember familiar names. Last week it was "hollyhocks", this week it was - oh bugger, I can't remember. Seth: The more you know the harder it will be to recall one thing correctly – there is more interference from everything else you know. Increasing memory problems with age may or may not be due to memory decline.

Charlie (2013-07-19 10:36:46)

My 94 year old mother has always complained about not being able to remember things, although she remembers lots of things from her childhood. A few years ago she really started complaining and I even noticed she was a little more forgetful. So I took her off her statin meds and started feeding her butter - a pound a week. Her memory is back to where it was when she only thought she couldn't remember. She is also in brighter spirits, more active and engaged. Charlie

Evelyn M. (2013-07-19 11:45:08)

As medical science doesn't know what to do about memory loss, even if physicians acknowledge it is occurring, there is no point in taking that problem to a physician. This should be made common knowledge, just as people should be told that it is useless to visit a physician when you have a cold or the flu. I can no longer keep up with story lines in modern films, but I think that is due to the poor quality of movie production and direction nowadays, not a loss in my own abilities. If I watch a film I haven't seen before dating before the 1970s, I have no trouble whatsoever in following the plot. Also, films in the "good old days" actually let you hear the dialogue - no music hindered the sound of speech, while nowadays dialogue in films is usually overshadowed by loud music and sound effects. I read somewhere that a good test for when a woman is losing her mental capabilities is whether she can still put a complicated meal together. We have proper family dinners every week, and I am able to serve everything on time and cooked correctly, so I'm not too worried about occasional lapses in remembering people's names! First things first.

Alex Chernavsky (2013-07-19 13:45:39)

Evelyn, I think that modern movies and TV shows are far more complicated than they used to be:

During its 44 minutes – a real-time hour, minus 16 minutes for commercials – the episode (of Fox TV show "24") connects the lives of 21 distinct characters, each with a clearly defined "story arc," as the Hollywood jargon has

it: a defined personality with motivations and obstacles and specific relationships with other characters. Nine primary narrative threads wind their way through those 44 minutes, each drawing extensively upon events and information revealed in earlier episodes. Draw a map of all those intersecting plots and personalities, and you get structure that – where formal complexity is concerned – more closely resembles "Middlemarch" than a hit TV drama of years past like "Bonanza." For decades, we've worked under the assumption that mass culture follows a path declining steadily toward lowest-common-denominator standards, presumably because the "masses" want dumb, simple pleasures and big media companies try to give the masses what they want. But as that "24" episode suggests, the exact opposite is happening: the culture is getting more cognitively demanding, not less. To make sense of an episode of "24," you have to integrate far more information than you would have a few decades ago watching a comparable show. Beneath the violence and the ethnic stereotypes, another trend appears: to keep up with entertainment like "24," you have to pay attention, make inferences, track shifting social relationships. This is what I call the Sleeper Curve: the most debased forms of mass diversion – video games and violent television dramas and juvenile sitcoms – turn out to be nutritional after all.

[http://www.nytimes.com/2005/04/24/magazine/24TV.html?\\_r=0](http://www.nytimes.com/2005/04/24/magazine/24TV.html?_r=0)

Evelyn M. (2013-07-19 18:07:47)

Thank you for the comment, Mr. Chernavsky. Happily, "24" was so brilliantly produced and directed (not to mention scripted and acted) that I had absolutely no trouble following it! We are all looking forward to the new season that we've been told will begin in 2014.

Andrew (2013-07-23 06:22:53)

A bit off topic (although a bit related to dementia), but I haven't seen whether you've expressed any views about the fish oil/prostate cancer study. I've been taking omega 3 supplements for some time (both for brain function and cankersores) and a number of people have advised me to stop as a result of the study. I am personally skeptical of the study, but was curious if you have any thoughts. Seth: The study made me glad I take flaxseed oil rather than fish oil. It's epidemiology, usually a bit hard to interpret. I take flaxseed oil because of experimental data I gathered on myself – much better evidence, if I want to know what's good for me.

Kyle Lee (2013-07-23 21:27:20)

1. I think 1 thing with the Fish Oil study is that they looked at 1 factor. Maybe they were pre-disposed to having more health problems which led them to take the fish oil. Also they didn't look at the quality or dosage of the supplements. 2. Seth have you ever experimented with replacing flaxseed oil with fish oil? Seth: Long ago I thought I would try fish oil in place of flaxseed oil but other things have kept getting in the way. The one time I tried fish oil it gave me a headache. I have some in my refrigerator now, however.

## **Butter and Coffee (2013-07-20 05:00)**

In [1]Perfect Coffee at Home, authors Michael Haft and Harrison Suarez, who have started a digital publishing company, say that [2]the Buttermind experiment influenced them to start adding butter to their coffee. In [3]this excerpt, they say that their cholesterol went down 25 points during the period they drank it (their lives changed in many other ways at the same time). At the end they say:

Later, we would learn that Ethiopian warriors had drunk buttered coffee to energize before battle as far back as 600 CE. But that was after we had stopped regularly drinking it. When we transitioned out of the Marine Corps and our days became less frenetic, it just didn't seem as necessary.

The mention of Ethiopian warriors reminds me of how, after discovering that pork fat (from pork belly) improves my sleep, I learned that Mao Tse-Tung praised a certain pork-belly dish (???), calling it "brain food". I don't drink coffee

but I have tried tea with butter. It tasted good, but I didn't like the residue it left on the tea cup. Cream doesn't leave a residue. I haven't noticed that butter gives me energy. The benefits I believe in are better brain function and [4]better sleep. Maybe more calmness.

---

Shawn (2013-07-20 07:11:58)

This is slightly tangential but I ate a couple tablespoons of butter right from the stick and a couple days later developed a couple pimples. I suspect it was from the butter but am not 100 % positive. I have read reports about dairy causing acne. Seth: yes, dairy definitely causes acne in some cases. the effect might go away with more exposure to butter, it's hard to say.

Jim (2013-07-20 09:02:59)

Biohacker Dave Asprey is a proponent of butter (grass fed) with coffee for its purported cognitive benefits. Opinions seem to be split between those having great results, and those who think it is "gross" (e.g., Seth's comment about residue).

Stephen (2013-07-20 09:23:41)

Add me to the list of people you convinced to start drinking buttered coffee. Might be noticing some effects, though I'll report back after a few weeks. As an aside, I really liked your posts on continuous graphical feedback a while back, and I'm thinking about implementing a system like that for myself. So I'd really like to know: - Are you still using your system? - If so, how effective is it now compared to back when you wrote those posts? Seth: I am still using my system, yes. I now use a somewhat better system, an improved version. I couldn't live without it. It is the same effectiveness now as when I wrote those posts. If you are interested in trying it, please contact me and identify yourself as the author of this comment.

David Johnston (2013-07-20 13:18:03)

Why butter and not cream? I drop about 1/3 pint of heavy cream (from allegedly happy cows) in my coffee. It seems to me that cream is just a superset of butter and it pours more easily than butter. Seth: Supposedly butter is made from cream (and only cream), so cream = butter. In practice, it is not so simple. What is sold as "cream" can contain many things and be treated in many ways after the processing point where some cream is turned into butter and some isn't. You make a good point, I should try substituting cream for butter and see what happens.

Charlie (2013-07-20 14:48:14)

First comes milk, then comes cream, then comes butter. Butter is basically the purest form of milk fat - "almost" all the proteins and sugars have been removed, or separated out - when it comes to dairy, it's all about the separation. Butter by volume has twice the amount of fat as cream, and consequently, twice the amount of calories. I prefer the taste of cream in my coffee, so I just eat 2+ tablespoons of butter on a home made coconut bar with my morning coffee. I also eat chocolate butter, which I make, with my afternoon coffee and cream. Cheers

haig (2013-07-20 18:13:15)

Seth, have you seen large differences in effects between animal fat and butter? I drink coffee with coconut oil and am going to experiment with adding either ghee or tallow (yuk I know) for some added fat in the mornings and would like to know which is better or if the differences are negligible. I'm dairy free because of acne and anxiety over raising LDL cholesterol, that is why I'm thinking about incorporating the grass fed tallow. Seth: Yes, I have seen large differences. My arithmetic speed got faster

when I switched from pork fat to butter.

Stephen (2013-07-21 10:28:34)

Seth: That's great to hear. I probably can't use your system (I'm on Linux, and I don't know R), but I just coded up something that does approximately what you described. What were the improvements you added? Seth: A friend and I are making an app that we plan to sell, so I am not anxious to publicize the improvements.

B.B. (2013-07-22 08:01:05)

Is there any advantage for using ghee instead of butter, holding the quality of the cows constant? Seth: I don't know. I should try ghee in place of regular butter.

Charlie (2013-07-23 06:43:22)

Ghee is the last step in the dairy separation chain and is the purest form of milk fat I know of - hard to think of what you could possibly do and what you would be removing once you get to ghee. You can make your own if you have the time and patience. It's also known as drawn butter in the restaurant biz - it's what you get with lobster (should get anyway) - a quality kitchen will have a container of it sitting on the back of the griddle that is used for frying instead of vegetable oil. Cheers

Paul N (2013-07-23 10:46:05)

@ Charlie - you could go one step further in the separation chain, and centrifuge the ghee to separate the short and long chain fats. This is what Weston Price did to create his "high vitamin butter oil", and this is what Green Pastures does (following his procedure) to make their butter oil. However, all of this is a lot of work, and I am quite happy to just eat the butter!

Charlie (2013-07-24 08:41:06)

@ Paul N - You are correct...and I've even taken Green Pastures butter oil - however, because of my already high volume of butter consumption, I'm not sure if it has had any effect. There are some that believe that it helps with tooth/oral health, but so does xylitol, which I also consume, and so does fax seed oil, which I used to consume, and so does reducing your consumption of carbohydrates, especially grains, sugars and fruit, which I did some years ago, so consequently I'm not sure which one, or combination, has actually improved my tooth/oral health...because, it has improved, markedly. I think I should buy stock in Kerrygold... Cheers

haig (2013-07-24 20:37:29)

Thanks Seth. Another question I have, were the gains in mental speed only experienced within a timeframe after eating the butter, or did they carry over throughout the day or week regardless of when you consumed the butter? Did you vary the times that you did your arithmetic tests? Would it be beneficial to eat it before a long day of mental work or is it just important to incorporate it into your diet at any time? Seth: The effects of butter didn't last long - maybe they lasted a day. I took the arithmetic tests at many different times of day. I think it is a good idea, based on my results, to eat butter daily. My experience with flaxseed oil suggests it will have more than one benefit.

- [2] Criticism of Malcolm Gladwell by The Korean, [3] Gladwell's persuasive rebuttal, [4] more from The Korean, [5] more from Gladwell. I thought the work under discussion ("ethnic theory of plane crashes") was the best part of Outliers. Gladwell summarizes it: "That chapter in Outliers is about a series of extraordinary steps taken by Korean Air, in which an institution on the brink of collapse and disgrace turned themselves into one of the best airlines in the world. They did so by bravely confronting the fact that a legacy of their cultural heritage was

frustrating open communication in the cockpit. That is not a slight on Korean culture, or any other high-power distance culture for that matter.”

- More praise for the new TV show [6]Naked and Afraid on the Discovery Channel. It really is riveting.
- [7]Ziploc omelette. Poor man's sous vide.

Thanks to Nicole Harkin.

dearieme (2013-07-21 05:45:21)

“That is not a slight on Korean culture”: but of course it is, if by “slight” he means drawing attention to a shortcoming. It's saying that for a particular purpose Korean culture is dysfunctional. Naturally all cultures are dysfunctional for some purpose or other; indeed for many purposes or other. That's the human condition.

Alex Chernavsky (2013-07-21 07:41:02)

There is some evidence that spraying with DDT is the best solution to the malaria problem in Africa.

As malaria surges once again in Africa, victories are few. But South Africa is beating the disease with a simple remedy: spraying the inside walls of houses in affected regions once a year. Several insecticides can be used, but South Africa has chosen the most effective one. It lasts twice as long as the alternatives. It repels mosquitoes in addition to killing them, which delays the onset of pesticide-resistance. It costs a quarter as much as the next cheapest insecticide. It is DDT.

<http://www.nytimes.com/2004/04/11/magazine/11DDT.html>

Joe (2013-07-21 13:05:22)

Personally, while the omelet “sous vide” sounds like a good idea, I wouldn't try it. Not for BOILING anything. At warm temperatures, yes. Seth: Good point, not a good idea to boil plastic.

kxmoore (2013-07-21 22:36:38)

“Naked and Afraid” is an awesome show. Miles above the spate of other survivalist shows. Sheer genius, makes me want to learn how to start a fire and make shoes from tree bark and find a woman who can chase down and kill an eel with a club. The

show is about more than surviving in a wilderness though.

dearieme (2013-07-22 07:08:53)

"find a woman who can chase down and kill an eel with a club": dead easy. She takes the eel to a club, gets it to annoy the bouncers, and, bingo, it's a Norwegian Blue.

Corruption and hidden failed animal studies results of Glaxo off-shoring drug research to China: <http://www.nytimes.com/2013/07/23/business/global/drug-research-in-china-falls-under-a-cloud.html>

Alex Chernavsky (2013-07-23 07:08:39)

Tom, the problem may be worse in China, but Big Pharma has a long history of committing fraud no matter where they do business. See, for example: <http://projects.propublica.org/graphics/bigpharma>

Tom (2013-07-23 08:38:58)

Wow...really scary.

### **More Magic Dots (2013-07-23 05:00)**

A New Jersey patent attorney named Jim D writes:

I've been using the magic dots as you described, marking a dot or line every six minutes. I use an online timer with an audible tone every six minutes. A portion of my work requires focus, as I have to review, compare and contrast technical documents. I've historically had limited ability to focus for extended periods of time. I've used an online bar graph countdown timer, but even with the visual feedback of the bar graph counting down, the longest I could go without a short break was 20 minutes. I've also tried online Pomodoro timers, with alternating work and break periods, but again, the longest I could go without a break was 20 minutes.

In contrast, by using the magic dots method, I can easily focus for 60 minutes. I've been working for 60 minutes until the box is completed, and then taking a short break before starting another 60 minute box. After a few more weeks, I will see if I can extend the focus length for a longer period of time. (As an aside, I wonder if completing an entire "box" is psychologically important, and, if so, would a 90 minute "box" shape work better than continuing with consecutive 60 minute boxes?).

I don't think finishing a box matters. Sometimes I do, sometimes I don't, it doesn't seem to make a difference. A friend used a much different counting system; it also worked. After years of using six-minute intervals I have started to use five-minute intervals; they don't interfere too much and shorter intervals are likely to be more powerful. I would like to compare different interval lengths but it is a difficult experiment to do.

Nile (2013-07-23 13:06:32)

I've had a very similar experience. Visual graph type feedback doesn't really do much for me but magic dots work fairly well. I found 6 minutes too short and changed the interval to 10 minutes so I now make magic triangles. I started out trying to work an hour at a time but today I managed 2 hours. I seem to be getting better at extending the time worked but... time will tell

Ronald Pottol (2013-07-23 13:37:31)

For a quick cheap OS X timer, put this in a file called magic\_dots.sh `#!/bin/bash # a script to say magic dot every 6 minuts, for ever. for (( ; ; )) do say "magic dot" sleep 360 done` Then type `chmod 755 magic_dots.sh` in the directory the file is in (or open it's properties and make it executable). Then at a terminal, type (or double click on it, I would think) `./magic_dots.sh &` and your computer will say "magic dot" every 6 minutes. To make it stop, close the terminal window it was run from. Or just leave the & off, and close the terminal window. Worst case, reboot.

Tom Myers (2013-07-30 10:47:32)

Nice. To make it double-clickable on a Mac, however, I believe you should call it magic\_dots.command rather than magic\_dots.sh; double-clicking on that should open up a window which you can close to end the process. You ought to be able to make it stop with `killall magic_dots.command` which could also be in a double-clickable stop\_dots.command file; haven't tried. (On Ubuntu, where the "say" command does not exist, I will now use `espeak -v en "magic dot"` for an equivalent script, which does stop with "killall" - thanks!)

## Are Drug Companies Becoming Less Law-Abiding? (2013-07-24 05:00)

Alex Chernavsky drew my attention to [1]a report of the giant fines assessed drug companies for fraudulent marketing. For example,

Merck agreed to pay a fine of [2] \$950 million related to the illegal promotion of the painkiller Vioxx, which was withdrawn from the market in 2004 after studies found the drug increased the risk of heart attacks. The company pled guilty to having promoted Vioxx as a treatment for rheumatoid arthritis before it had been approved for that use. The settlement also resolved allegations that Merck made false or misleading statements about the drug's heart safety to increase sales.

Fines, of course, are supposed to reduce bad behavior. Here are the fines by year:

- 2009: 2 fines
- 2010: 1 fine
- 2011: 1 fine
- 2012: 5 fines

This pattern does not suggest the fines are working. Drug companies, of course, are very big. I would like to see cross-industry comparisons: which industries pay the most in fines per dollar of revenue?

1. <http://projects.propublica.org/graphics/bigpharma>
2. <http://www.justice.gov/opa/pr/2011/November/11-civ-1524.html>

---

Mark (2013-07-24 05:28:59)

Sheesh, this pattern suggests that the fines aren't really being issued... Only 9 fines over 4 years for fraudulent marketing implies to me that their definition of fraudulent is pretty damn weak. "Demonstrated to be safe" is fraudulent in all cases. Seth: I don't know if these are all the fines. I think they are all the giant fines.

Alex Chernavsky (2013-07-24 07:32:30)

In the US, the FDA (Food and Drug Administration) issues a lot of warning letters, typically hundreds every year. [http://en.wikipedia.org/wiki/FDA\\_Warning\\_Letter](http://en.wikipedia.org/wiki/FDA_Warning_Letter)

Wil (2013-07-24 16:57:37)

Seth: These revelations are not new. It is becoming common knowledge that drug development and testing has for years been characterized by conflicts of interest and outright corruption. Marketing practices are particularly egregious. Regulation of the industry is weak to the point of scandal because of long-standing regulatory capture at least as bad as what has occurred in the banking industry. We have essentially the same problem in the broader medical care industry in the USA. The problems are unlikely to be resolved until a way is found to eliminate, or at least temper, the profit motive in these industries.

Wil (2013-07-24 17:19:00)

PS - Readers of your blog concerned about ethics in medicine, pharma and related matters (such as addressed in your post) may be interested in these two blogs by Dr. Howard Brody and Dr. Roy Poses, respectively. <http://brodyhooked.blogspot.com/> Hooked: Ethics, Medicine, and Pharma (Dr. Howard Brody) Updates and Commentary related to HOOKED: ETHICS, THE MEDICAL PROFESSION, AND THE PHARMACEUTICAL INDUSTRY, by Howard Brody, MD, PhD (Rowman and Littlefield, January, 2007) <http://hcrenewal.blogspot.com/> Health Care Renewal (Dr. Roy Poses) Addressing threats to health care's core values, especially those stemming from concentration and abuse of power. Advocating for accountability, integrity, transparency, honesty and ethics in leadership and governance of health care. Regards, Wil

nicole (2013-07-24 18:21:48)

looking at the budget of the FDA for enforcement might also be important. maybe they are not violating the law any more or less than normal, but the FDA has more money for enforcement.

Kyle Lee (2013-07-25 08:36:25)

I've definitely seen this trend going on for a while, it's similar to the banking community. At some point does someone have to go to jail?

## **Researchers Fool Themselves: Water and Cognition (2013-07-25 05:00)**

A [1]recent paper about the effect of water on cognition illustrates a common way that researchers overstate the strength of the evidence, apparently fooling themselves. Psychology researchers at the University of East London and the University of Westminster did an experiment in which subjects didn't drink or eat anything starting at 9 pm and the next morning came to the testing room. All of them were given something to eat, but only half of them were given something to drink. They came in twice. On one week, subjects were given water to drink; on the other week, they weren't given water. Half of the subjects were given water on the first week, half on the second. Then they gave subjects a battery of cognitive tests.

One result makes sense: subjects were faster on a simple reaction time test (press button when you see a light) after being given water, but only if they were thirsty. Apparently thirst slows people down. Maybe it's distracting.

The other result emphasized by the authors doesn't make sense: Water made subjects worse at a task called Intra-Extra Dimensional Set Shift. The task provided two measures (total trials and total errors) but the paper gives results only for total trials. The omission is not explained. (I asked the first author about this by email; she did not explain the omission.) On total trials, subjects given water did worse,  $p = 0.03$ . A surprising result: after persons go without water for quite a while, giving them water makes them worse.

This  $p$  value is not corrected for number of tests done. A table of results shows that 14 different measures were used. There was a main effect of water on two of them. One was the simple reaction time result; the other was the IED Stages Completed (IED = intra/extra dimensional) result. It is likely that the effect of water on simple reaction time was a "true positive" because the effect was influenced by thirst. In contrast, the IED Stages Completed effect wasn't reliably influenced by thirst. Putting the simple reaction time result aside, there are 13  $p$  values for the main effect of water; one is weakly reliable ( $p = 0.03$ ). If you do 20 independent tests, purely by chance one is likely to have  $p < 0.05$  at least once even when there are no true effects. Taken together, there is no good reason to believe that water had main effects aside from the simple reaction time test.

The paper would be a good question for an elementary statistics class ("Question: If 13 tests are independent, and there are no true effects present, how likely will at least one be  $p = 0.03$  or better by chance? Answer:  $1 - (0.97^{13}) = 0.33$ ").

I wrote to the first author (Caroline Edmonds) about this several days ago. My email asked two questions. She replied but failed to answer the question about number of tests. Her answer was written in haste; maybe she will address this question later.

A better analysis would have started by assuming that the 14 measures are unlikely to be independent. It would have done (or used) a factor analysis that condensed the 14 measures into (say) three factors. Then the researchers could ask if water affected each of the three factors. Far fewer tests, far more independent tests, far harder to fool yourself or cherry-pick.

The problem here – many tests, failure to correct for this or do an analysis with far fewer tests – is common but the analysis I suggest is, in experimental psychology papers, very rare. (I've never seen it.) Factor analysis is taught as part of survey psychology (psychology research that uses surveys, such as personality research), not as part of experimental psychology. In the statistics textbooks I've seen, the problem of too many tests and correction for/reduction of number of tests isn't emphasized. Perhaps it is a research methodology example of Gresham's Law: methods that make it easier to find what you want (differences with  $p < 0.05$ ) drive out better methods.

Thanks to Allan Jackson.

1. [http://www.frontiersin.org/Human\\_Neuroscience/10.3389/fnhum.2013.00363/full](http://www.frontiersin.org/Human_Neuroscience/10.3389/fnhum.2013.00363/full)

Alex Chernavsky (2013-07-25 08:24:26)

In my (limited) experience, even people who claim to be experts in statistics often don't know what they're talking about. I remember working on a paper back in graduate school. The lead author was trying to determine whether to use the Kolmogorov-Smirnov test, the Mann-Whitney test, or something else altogether. The people we consulted did not exactly fill us with confidence in their abilities. (Of course, maybe we just asked the wrong people.) Seth: I have never used the Kolmogorov-Smirnov test nor the Mann-Whitney test and expect never to do so.

David Johnston (2013-07-25 09:27:27)

KS is to MW as is sameness of distribution is to sameness of means. KS is very handy in my line of work, MW not so much. Seth: KS is much less sensitive than other tests.

Three Pipe Problem (2013-07-25 09:29:28)

Can you recommend any resources for people who may have a decent math background and know some very basics about statistics and are looking to improve their insight in a time effective manner? Seth: Their insight about what?

Kevin Miller (2013-07-25 09:37:59)

I think a better and, to my mind, more convincing approach, is to require replication. Finding the same effect in two independent samples is pretty powerful. Controls for multiple comparisons are a mixed bag, and some of them can really be too strict. Multiple-experiment papers, which are the norm in most cognitive psychology journals, typically include a replication as part of later experiments, and I find that to be more convincing than statistical controls for multiple comparisons. Of course, neither control for other issues such as non-representative of stimuli or subjects, but such is life in this vale of tears. Seth: The first person not to fool is yourself – preferably without the enormous cost of repeating the experiment. You don't seem to be taking the cost of replication into account. Or maybe you are thinking like a reader rather than as a practitioner. If you have two or three independent tests, the adjustments for multiple comparisons are realistic. You really can set the overall p value to 0.05. Sure, replication is a good idea, too. In multiple experiment papers, nothing is said about experiments that didn't work out – there is no statement like "we are not omitting relevant evidence" – so it is less than obvious what repetition means. Of course, when authors omit relevant evidence they are deceiving others, not themselves. What's interesting about this example is that the researchers appear to have deceived themselves.

Mark (2013-07-25 10:59:12)

Completely agree that replication is key (in experimental studies, that is... Replication is a less reliable tool in non-randomised studies because bias is systematic), and is a much more important consideration than multiple testing. Any "significant" result might be a type 1 error, and a p-value doesn't give any indication how likely that might be. Replication is the only way to rule that out (which is why FDA typically requires at least 2 phase 3 trials).

John Eels (2013-07-25 12:49:37)

@Three Pipe Problem, that's a good question. I'd like to run simple experiments and test for significance. I studied psychology and had courses in statistics. I don't remember much. I'd like to fresh up basic concepts in a playful style: Self experimentation 101 with suggested experiments (week one eat 60g butter daily, week two don't, week three like week one again and so on and test reaction time or whatever concept daily, or connection amount of coffee consumed and self-measured sleep quality, or sleep quality and seeing people in the evening). Stuff gets so much more interesting if it has real life value.

gwern (2013-07-25 21:41:39)

> A better analysis would have started by assuming that the 14 measures are unlikely to be independent. It would have done (or used) a factor analysis that condensed the 14 measures into (say) three factors. Then the researchers could ask if water affected each of the three factors. Far fewer tests, far more independent tests, far harder to fool yourself or cherry-pick. Where would these 3 factors come from? If they're being estimated from the data, without any previous reason to expect particular factorization, and then fed into the tests with the expectation we have reduced our false positive problem, that makes me feel uneasy and wonder how kosher this procedure really is. Incidentally, as far as the Mann-Whitney goes, I've used it twice recently

when I wanted to compare 2 groups but they were blatantly not normally-distributed (in [http://www.gwern.net/Google %20Alerts #it-was-mid-2011](http://www.gwern.net/Google%20Alerts%20it-was-mid-2011) and [http://www.gwern.net/Anchoring #article-effect](http://www.gwern.net/Anchoring%20article-effect)). Normality is common, sure, but so is non-normality; if one never feels the need to use it, perhaps one is simply shoehorning t-tests where they don't belong. Seth: Check out "data transformation" (e.g., log transformation) the next time you encounter non-normal data.

dearieme (2013-07-26 14:39:07)

Those who have followed the trail of crookedness in "Climate Science" would not be too surprised at Nature's response, eh?

David Johnston (2013-07-26 15:53:38)

The law requires open meetings to minute the decisions. I.E. motions made, mover, seconder and outcome. Adding anything else adds to legal risk. If I can get through a HOA meeting (I'm president/chair) without any decisions being made, I consider it a victory. Deciding to not decide is not a decision, or at least doesn't appear in the minutes.

### Chinese Food: China vs America (2013-07-27 05:00)

I skype-chatted with [1]Clarissa Wei, a Chinese-American journalist in Los Angeles whose [2]post about stinky tofu in Los Angeles impressed me.

SR What do you think of Chinese restaurants in America compared to Chinese restaurants in China?

CW It depends on where you're talking about. In broad America, the Chinese food is pretty different from that of China. In places like Los Angeles and pockets of New York... it's much more alike

SR I'm thinking of the best ones in Los Angeles.

CW It's definitely cleaner here that's for sure. In Los Angeles, the food quality is pretty similar. The major difference

would be the price and variety. The selections are also pretty similar. The set-up in American Chinese restaurants is obviously different than the ones in China so that influences things a lot

SR I have never been to a Chinese restaurant in America that resembles a high-end Chinese restaurant in Beijing

CW In Los Angeles – there are a couple high-end Canto restaurants. They typically are your seafood + dim sum banquet types. Lunasia is a great example.

SR What do you mean by the set up?

CW Well in China, a lot of the restaurants are literally hole-in-the-walls. There isn't that much of a standard in terms of being neat and sanitary.

SR There is vastly more range in China, both better and worse

CW In the rural countrysides, it's out of people's homes. But in America, everyone has to have at least some degree of sanitation.

SR Chinese restaurants in China are more playful. Like a toilet restaurant, for example.

CW Very true. Yeah they're opening one of those in LA.

SR Or a restaurant where everyone says hello when you enter and goodbye when you leave

CW There's also a Taiwanese "Hooters" in L.A. A lot of the Taiwanese breakfast eateries in L.A. have that "cutesy" vibe.

SR When you were in China were you in any way disappointed by the Chinese restaurants?

CW I was in China in 2011 for 4 months as part of a study abroad program. I was disappointed mostly because I always got sick.

SR What city?

CW Shanghai. But I travelled to Guilin, Dunhuang, Beijing. I got sick from just the regular restaurants on my street. Some were marketed as higher-end. I lost 10 pounds from throwing up. Mind you, I go to Taiwan yearly and that never happens.

SR The first time I went to China I was sick every 2 days, but after that I was fine.

CW I think my toleration for bacteria is pretty low.

SR I get sick no more often in Beijing than in Berkeley. [But in Beijing I eat Korean and Japanese food mostly.]

CW That's surprising. I was at [3]Donghuamen [a night market selling strange food] in Beijing. Did an article on that

place. But I just felt like throwing up because the streets reeked of trash.

SR The cheap restaurants scare me. They use recycled cooking oil.

CW I think that's changing now with the media coverage on the Chinese food scandals. But in places like Los Angeles..the food is pretty up to par in terms of "authenticity".

SR How was the food in the various Chinese cities besides Shanghai?

CW It was alright. I get turned off when a restaurant is dirty to be honest. But that may just be because of my American upbringing. It really influences how I consume the food and how much I eat of it. When I was in Dunhuang, there was a vendor making daoxiaomian but he kept on coughing over and over. And we watched him make the dish and serve it to us. I felt disgusted but we were starving.

SR What did you think of the food expertise of the Chinese people you met in China?

CW I learned a lot about Chinese food in China from my Chinese teacher. That's when I started to gain in interest in the regional differences. The oyster omelette for example in Xiamen is similar to the one in Taiwan, but crispier and thinner

SR It was very hard to buy a kitchen timer in Beijing because I was told no one uses them when they cook.

CW No one uses fancy gadgets or exact measurements there. It's all passed down and family recipes which is the beauty of it.

SR My students at Tsinghua are more connoisseurs of food than my Berkeley students. A lot more.

CW Food is such a central theme of the Chinese culture. There's a fascination with Western food too. In Shanghai, my first article for CNN was "Top Western Restaurants in Shanghai". I brought my Shanghainese friends along to one of the places – a bagel places – and they were fascinated.

SR I went to the best Korean restaurant I've been to outside Korea in Shanghai.

CW Shanghai has a tradition of really embracing foreign cooking traditions. One of the best fine dining restaurants I've been to was in Shanghai, Mr. and Mrs. Bund.

SR Do people in Shanghai understand how good the food is in Japan?

CW I think so. But a lot of Chinese people really don't have the opportunity to travel abroad. They don't have a feel or the exposure to foreign tastes as much as Americans do. In Taiwan, there's a fascination with the Japanese. Obviously because of the occupation of the Japanese but a lot of the high-end Taiwanese restos are Japanese influenced.

SR Controlling for age who did you think are the more adventurous eaters, Americans or Chinese – I mean the ones you know.

CW Chinese hands down.

SR That's interesting, I always worry that my students won't like this or that. [At least, they draw the line at eating insects.]

CW Just because Chinese cuisine has a variety of meats and offal and "bizarre" parts you know. So they're much more open to try .... snails from France than your average American. Because snails are a Chinese dish too. Also in Chinese culture, you're taught to eat anything and everything that's presented to you. It's rude to refuse.

SR A friend of mine said that Chinese (in practice) is a language of verbs, English is a language of nouns. One of the verbs is "eat". Parents tell children: "eat".

CW Yes. Americans have the luxury of being more picky – look at the whole gluten free, vegan movement in these metropolitan places. If you go into a Chinese restaurant in China and say you're vegetarian – they don't really know how to work with you. Some places will just roll their eyes.

SR After you came back from Shanghai to Los Angeles, how did you view American Chinese restaurants differently? The authentic ones.

CW I appreciated it a lot more. The food here is good and it won't give me food poisoning. Sanitation was like the biggest worry in China. An article recently came out that said the ice from the KFC in China had more bacteria than toilet water.

SR I never go to KFC in China. Now I have been vindicated in that decision

CW The egg tarts there are fantastic. Modeled after the original Macau egg tart recipe apparently.

SR There should be a category: best food in worst restaurant. Also worst food in best restaurant.

CW Chinese restaurants have such extensive menus, it's always easy to find a bad item.

SR I was impressed that Chinese restaurants managed to make mashed potatoes slightly interesting. That's baby food! They added raspberry sauce.

CW Again – fascination with Western food.

Alex Chernavsky (2013-07-27 07:43:43)

That's interesting that Chinese restaurants in China have trouble with the concept of vegan food. In the United States, Asian eateries are probably more vegan-friendly than any other category of restaurant. You can usually order any dish with tofu in it instead of meat. (Sometimes you have to be careful that the dish doesn't include fish sauce, though.)

dearieme (2013-07-27 11:02:42)

I had a delicious Chinese meal in San Francisco in 1966. I was rather surprised, though, that I was the only white face in the restaurant.

## Benefits of Alternate Day Fasting (2013-07-28 05:00)

A friend of mine named Dave saw the BBC program [1]Eat, Fast and Live Longer ten months ago. The program promotes intermittent fasting for better health. It sounded good. Already he often went a day without food. Some Brahmins in South India had eaten this way for millennia – which suggested it made some sense. It wasn't a fad. Alternate day fasting was simpler than the "fast 2 days per week" regimen the TV show ended with. He started alternate day fasting immediately.

It was easy to start. The first day was hard. He had painful stomach cramps, but hunger was not a problem. The second day of fasting was slightly difficult, again because of stomach cramps. By the third day of fasting, there was no problem. He tried eating a small meal (400-500 calories) on fasting days but it just made him hungry. It was easier to not eat at all.

Within two weeks, his head felt clearer, he had more energy, and he felt lighter. Lots of people say the same thing in [2]YouTube videos about the diet. He had more mental energy. Before the diet, he easily became overwhelmed. In spite of a highly technical background (he was a math professor at an Ivy League school), something as simple as writing a computer program would exhaust him. When he tried to tackle a technical problem, he would get overwhelmed, exhausted, and would quickly give up. For example, he has written tens of thousands of lines of computer code. Writing in a language he knew very well, he'd be unable to get beyond 10-15 lines. Within three months of starting the diet, he took an online class (an introductory class about R) and was surprised he could do the work. (He had started the class to take his mind off of family issues he had to deal with. He wanted to do something for himself.) After that, he took two more online classes, about cryptography and about functional programming. He finished them and did well. He was elated.

Several other things started improving. He'd had GERD ("acid reflux"). He had poor digestion at night, would wake up with an "acidic stomach" and burning in the back of his throat and mouth. He'd had this all his life (he's now in his fifties). In his twenties, several health experts told him he had digestive problems. When he started alternate day fasting, he didn't change the time of day that he ate. After two or three months, his GERD entirely went away.

Another improvement was athlete's foot. He'd had it since his mid-twenties. He had it all over his feet, not just the toes. He'd done many things to get rid of it. None of them worked, at least permanently. After two months of alternate day fasting, he noticed improvement. Over the following months his athlete's foot continued to improve. However, three weeks ago he started drinking a half-gallon of yogurt per week. Within two weeks of starting that, his athlete's foot got much worse. Eating much more yogurt was the only dietary change he'd made. The connection (yogurt increased athlete's foot) is plausible because athlete's foot is due to one or more fungi, fungi need sulfur to grow, and yogurt contains a lot of cysteine, which contains sulfur. ([3]A natural therapy site gets it exactly wrong: "Continuing to consume yogurt . . . on a daily basis after the immediate problem has been solved may prevent future outbreaks").

His food allergies started going away. Wheat was the worst. After eating wheat, he got brain fog, agitation (difficulty sitting still), and difficulty focusing. He would start having violent imagery; for example, his dreams will get quite violent. A laboratory test showed that he had astronomical levels of an immune response to gluten peptides. Another food allergy of his was dairy. It caused agitation, difficulty concentrating, and depression (in the sense that you feel like you want to kill yourself). Before he figured this out, there were times he consumed a quart of milk in a short period of time. Half an hour later, he got these three symptoms, including scary depression ("there's no way out"). Now he can consume both wheat and dairy without trouble. His wheat allergy isn't entirely gone but it is much better. He hasn't noticed any allergic reaction to dairy, even large amounts.

He'd had blood sugar problems for a long time. He'd had hypoglycemia since his late twenties. After strenuous exercise, he could come close to passing out. He would eat fruit to keep this from happening. He'd be lying on the floor, drag himself to eat a piece of fruit, and instantly feel better. After a meal, he'd feel tired, then eat something sweet and feel a rush of energy. He had a regular need for sweet things, including dessert. Whenever he had dinner, he'd really want dessert. About eight months after he started alternate day fasting, he realized that his craving for something sweet went away. One day it was present, the next day gone. Instead of feeling tired after a big meal, he felt calm.

He thinks that he must have had a candida infection and his gut is healing. This would explain the allergies going away and the GERD improvement. He hadn't expected these changes. He just started it because it fit his eating patterns and was more regular.

"I've experienced hunger for the first time," he says. If he doesn't eat the morning of a day he's supposed to eat, he feels ravenously hungry – a new experience. A crystal-clear sense of hunger, which is pleasant. It's pleasant to know what hunger is. He takes meals more seriously, because that's the day he's eating. He pays more attention to his food.

I found his experience far more convincing than anything else I'd heard about intermittent fasting. It was sustainable, it was easy, the benefits were unexpected, no ideology was involved, all sorts of things got better. It was as if this was the eating pattern our bodies were built for. My friend's experience led me to try alternate day fasting, [4]as I've said. After a few days my fasting blood sugar substantially improved (from the mid-90s to the mid-80s). Within weeks, my HbA1c went from 5.8 to 5.4. I haven't noticed mental changes but my brain test scores have improved for reasons I cannot yet explain (there are several possible explanations).

None (2013-07-28 06:57:36)

Funny. The title of the show reminded me of the book about grammar by Lynne Truss: "Eats, Shoots & Leaves". I think that the show is "Eat, Fast and Live Longer" and not "Eat Fast and Live Longer". While reading the first paragraph I was trying to figure out why eating fast could be healthful... Thanks for the link. I've been fasting about one day a week. Feels good. Seth: I thought the title was a joke like that but I checked and you're right, there is a comma.

Elizabeth Molin (2013-07-28 07:05:09)

Possibly related: a dermatologist told me to use any topical medication morning and evening, then skip a day completely, and continue to alternate. This keeps one from becoming inured to the medication, he said, and results in optimal effectiveness. Perhaps we should also work every other day, instead of five days a week and then two days off...

Brandon Berg (2013-07-28 07:41:53)

I had had plantar warts for a couple of years prior to starting IF (eating in a four-hour window each night). They cleared up almost immediately. Seth: Quite surprising, but in agreement with what happened to my friend, especially the disappearance of his athlete's foot. [1]The Wikipedia entry for plantar warts says nothing about intermittent fasting.

1. [http://en.wikipedia.org/wiki/Plantar\\_wart](http://en.wikipedia.org/wiki/Plantar_wart)

Nancy Lebovitz (2013-07-28 08:53:25)

<http://chriskresser.com/the-saturated-fat-heart-disease-myth-colonoscopy-heal th-risks-and-intermittent-fasting> Page down to "Does intermittent fasting harm the adrenals?" - the general point is that people who are highly stressed or who seem to be in worse shape (after the first few days) of IF probably shouldn't do it.

dearieme (2013-07-28 10:07:15)

Thank you, Nancy. I was particularly interested in the suggestion that colonoscopies are a bet against the odds.

Steve Johnson (2013-07-28 10:24:29)

*His food allergies started going away. Wheat was the worst. After eating wheat, he got brain fog, agitation (difficulty sitting still), and difficulty focusing.* Why would he keep eating wheat???? What is wrong with people? Seth: After he figured this out, he ate almost no wheat.

Tom (2013-07-28 11:27:52)

It's highly addictive.

Yojik K. (2013-07-28 11:33:16)

Seth, do you suppose that there is any particular benefit to Alternate-Day-Fasting over other IF regimes like the 18:6? Do you know have any intuition for the dynamics of fasting (the longer you fast, the better results? or, is there any optimal time to for a fast? 24 hours? 18? 16?) Seth: I suppose the longer you can fast without discomfort, the better. I can do alternate day fasting forever, it is pleasant rather than unpleasant. I used to eat one meal per day plus snacks. Plainly alternate day fasting is better.

Ash Simmonds (2013-07-29 01:06:04)

@Elizabeth Molin "Perhaps we should also work every other day, instead of five days a week and then two days off..." Exactly what I did back in 2011. I realised I couldn't handle spending all week at work, and I'd also built up enough leave to take 2-3 months holiday. Instead of doing that, I asked my boss if I could just come in M-W-F, he agreed, and I tell you what everything just makes sense when you do it like that. So yeah, picture this - every day that you go to work, you know you have a day off tomorrow. And when it's Friday - you get two! As for eating, I do what I call Intermittent Feasting. Seth: When your "only work MWF" schedule stopped, what happened?

jclifton (2013-07-29 07:06:51)

Hi Seth, I've followed and have been interested in IF and ADF for a year or so and have had mixed results. Just doing some reading/reviewing of the yahoo link you provided and there are a few posts regarding atrial fibrillation and stiff heart disease. Not sure what to make of them, but in general have heard mostly positive things in relation to the heart and fasting. Have a look: [http://xa.yimg.com/kq/groups/15437070/982523391/name/Ahmet\\_JCF\\_16\\_843-853\\_2010\\_IF+mice+cardiac+probs.pdf](http://xa.yimg.com/kq/groups/15437070/982523391/name/Ahmet_JCF_16_843-853_2010_IF+mice+cardiac+probs.pdf) Also, mentioning the heart: <http://www.scientificamerican.com/article.cfm?id=how-intermittent-fasting-might-help-you-live-longer-healthier-life>

Jeff (2013-07-29 14:25:17)

Seth - What do you eat on your fasting days when you're consuming 700 - 800 calories? Seth: Butter, flaxseed oil, and a few other things.

Jeff (2013-07-29 17:50:15)

Seth - Thanks for the details. I've been eating butter, flaxseed oil and home made kefir from all your posts on the health benefits. Any thoughts on the health pros and cons of eating less of these foods or even skipping them completely some days while doing alternative day fasting? Seth: No, I have no relevant experience. I eat butter and flaxseed oil on fast days, for what it's worth. I want to keep brain function constant so that I can study the effect of other things on brain function.

Nina (2013-07-30 15:10:00)

jclifton - from a cursory reading of the first paper, I wasn't clear what the diet comprised. I think food composition does make a difference to heart function. I'm yet to be convinced of the alternate day fasting as the cause-effect factor in atrial fibrillation and stiff heart disease. I used to experience heart palpitations when I followed a low carb diet and had protein shakes with lots of whey protein and leucine. When I reduced the protein powders, the heart was fine. I'm doing a version of shangri la on one meal a day. I've switched from oil to butter (oil fine at first, but in the second week I started to retch) and no heart problems. Nina

Ashish (2013-07-30 19:00:14)

Interesting. I assume he drank water. Did he consume any liquid calories or probiotics (Yakult?) on his fasting days? I'm tempted to try this - spare no detail. Something is missing in the story. He didn't get to be an Ivy League math professor by being confused, exhausted, overwhelmed and depressed all the time. Were his indigestion and tiredness increasing in severity before he started the diet?

Ashish (2013-07-30 19:13:45)

How does exercise fit in with all this fasting?

limette (2013-07-31 16:11:23)

What did he eat on his non-fasting days? I'm curious, because I'm dealing with a candida infection and this account gives me hope. Seth: A later post will answer this in detail, but the short answer is: nothing unusual. He did not change his diet when he switched to alternate day fasting.

PC (2013-08-04 10:31:18)

My story is quite similar - I feel so much better when fasting, with more mental focus. I am more productive and less depressed. I'm assuming I may have candida overgrowth or something.

## What I'm Reading (2013-07-29 05:00)

- Republic of Outsiders: The Power of Amateurs, Dreamers, and Rebels by Alissa Quart
- Brilliant Blunders: From Darwin to Einstein, Colossal Mistakes by Great Scientists that Changed our Understanding of Life and the Universe by Mario Livio
- Fate of the States: The New Geography of American Prosperity by Meredith Whitney
- Americanah by Chimamanda Ngozi Adichie, might set the record for largest value of letters in author's name (21) minus letters in title (10) = 11
- proofreading part of a new book by Edward Jay Epstein, described as a "Kennedy assassination diary"

---

KevinTran (2013-07-30 00:19:13)

Nice post

Kudzu Bob (2013-07-30 00:25:15)

Why do so many contemporary non-fiction writers use colons in their titles? Pressure from publishers? Herd instinct? [1]Even some novelists have begun to do this. The trend bothers me, although for the life of me I cannot say why.

1. <https://www.google.com/search?q=%22a+novel%22+%22amazon%22&ie=utf-8&oe=utf-8&aq=t&rls=org.mozilla:en-US:official&client=firefox-a>

dearieme (2013-07-30 01:37:52)

The trend bothers me: for the life of me I cannot say why. Look, saved a word. How much of punctuation is just habit? I use too many commas, and I don't always edit them out.

### Assorted Links (2013-07-30 05:00)

- [1]The power of the smell of chocolate. I add cacao shells (from [2]Tisano Tea) to the tea when I brew black tea. This adds complexity. 2.5 g of black tea plus 0.9 g of cacao shells.
- [3]Madonna's diet is rather hard. "I am basically dying on this diet. . . . It is so hard to give up all those foods."
- [4]Sous vide basics. "Using extra virgin olive oil results in an off, metallic, blood taste." [5]DIY sous vide, I want to read it to learn how controllers work.
- [6]More about Steve Cooksey and the ADA. The North Carolina branch of the American Dietetics Association attacked Cooksey for making nutrition recommendations on his blog. For free. This post explains why they did such a strange thing. A friend of mine, a nutrition professor at UC Berkeley, gave a Freshman Seminar (unpaid classes with about 10 students) on how to fix a car. Later he got a letter from a dean in the engineering school at Berkeley saying that only engineering professors can teach such a course.

Thanks to Richard Sprague.

## Was Sisyphus in Hell . . . or Heaven? (2013-07-31 05:00)

In third grade, I learned that Sisyphus was condemned to an eternity of pushing a rock up a hill, the rock rolls back down, he pushes it up again, and so on. Why the Greeks told this story I had no idea, and still don't.

I am now moving – from an apartment in the basement of a house to an apartment on the top floor of the same house. I've discovered that in small amounts this is enjoyable. I enjoy carrying stuff up a bunch of stairs. I could do it an hour per day forever – like Sisyphus, except with time off.

Here is the downside of the occupational specialization that distinguishes humans from other species. I don't need to haul stuff upstairs one hour per day. People move stuff for a living. Instead I walk uphill on my treadmill, a imitation activity that does nothing for my upper body. I could move heavy stuff around my apartment, but that's boring. The situation reminds me of the way Japanese schoolchildren clean up their school every day. In small amounts, cleaning is fun. Whoever runs Japanese schools has figured this out and used this fact to everyone's benefit. Blogging is another example. In small amounts, writing and being read is fun. The communication this enables helps everyone. When writing becomes a job, a lot is lost – much less diversity of points of view. Those who write for a living are afraid of losing their jobs, reducing even further what can be said.

This blog is all about the fact that science is still another example. In small amounts, doing science is fun, especially when it has practical benefit (e.g., sleep better). Professional scientists have their place, just as professional movers, janitors, and writers have their place. But people who do science purely for their own ends – just as I move stuff upstairs purely for myself – have their place too. I am not as strong as a professional mover but I make up for it in dozens of ways. Personal scientists don't have the resources (e.g., expensive equipment) of professional scientists, but they make up for it in dozens of ways. Without them, the diversity of ideas that are taken seriously (e.g., tested)

goes way down.

---

Pat McGee (2013-07-31 11:30:21)

Hi Seth, Who did the sculpture? I like it. Pat

Ashish (2013-07-31 15:16:32)

You might be as strong as a professional mover. IIRC, David Sedaris worked as a mover in NYC. Seth: I wish.

dearieme (2013-07-31 22:07:37)

Ahoy, Seth. <http://cardiobrief.org/2013/07/31/european-heart-guidelines-based-on-disgrace-d-research-may-have-caused-thousands-of-deaths/> Seth: Thanks.

## 8.8 August

### The Feet of People Who Never Wear Shoes (2013-08-01 05:00)

In the 1940s, [1]a podiatrist named Samuel Shulman examined the feet of a few thousand Chinese and Indians who never wore shoes. Their feet were in much better shape than the feet of people who wear shoes regularly.

The resulting complete absence of onychocryptosis [ingrown toenail] should serve to prove that proper nail care plus nonrestrictive footwear are all that is necessary to prevent the condition even in the presence of congenital nail malformations that are considered predisposing factors. . . . One hundred and eighteen of those interviewed were rickshaw coolies. Because these men spend very long hours each day on cobblestone or other hard roads pulling their passengers at a run it was of particular interest to survey them. If anything, their feet were more perfect than the others. All of them, however, gave a history of much pain and swelling of the foot and ankle during the first few days of work as a rickshaw puller. But after a rest of two days or a week's more work on their feet, the pain and swelling passed away and never returned again.

Chinese parks often have cobblestone-like paths that are extremely painful to walk on barefoot (for me) but that others (usually old Chinese people) walk on barefoot for health. I was surprised how clearly the pain went away day by day of exposure. [2]A 2005 study showed that four months of walking on cobblestone mats reduced blood pressure and improved balance compared to a group that walked the same amount normally:

Participants [average age about 80 years old] were randomized to a cobblestone mat walking condition (n=54) or regular walking comparison condition (n=54) and participated in 60-minute group exercise sessions three times per week for 16 consecutive weeks.

Measurements: Primary endpoint measures were balance (functional reach, static standing), physical

performance (chair stands, 50-foot walk, Up and Go), and blood pressure (systolic, diastolic). . . .

Results: At the 16-week posttest, differences between the two exercise groups were found for balance measures ( $P=.01$ ), chair stands ( $P<.001$ ), 50-foot walk ( $P=.01$ ), and blood pressure ( $P=.01$ ).

Some of the cobblestone walkers walked barefoot, some wore socks. A hypertension expert, apparently not understanding statistics, [3] said he wanted a larger study. I agree with him when he says that the speed of the improvement is what's most impressive.

Because our ancient ancestors no doubt went barefoot and walked on irregular surfaces, both sets of results – the foot survey and the cobblestone experiment – support conventional paleo theorizing.

I have a cobblestone mat. I tried to walk on it. It was so painful I couldn't get past the initial difficulty. Maybe I will try again.

1. <http://refs.ahcuah.com/papers/shulman.htm>

2. <http://onlinelibrary.wiley.com/doi/10.1111/j.1532-5415.2005.53407.x/abstract>

3. [http://www.cbsnews.com/2100-204\\_162-708479.html?pageNum=1](http://www.cbsnews.com/2100-204_162-708479.html?pageNum=1)

---

Joel W (2013-08-01 06:30:48)

To get yourself accustomed to that pain without full immersion, start by rolling your feet on a lacrosse ball. Lacrosse balls are great for opening up tissue, and they're super cheap. Eventually, you'll get some of the really bad initial knots/fascia broken up and you can start going to the cobblestone.

Tom Passin (2013-08-01 06:38:49)

Trouble is, the abstract doesn't say how \*much\* blood pressure changed, only that the change was statistically significant compared with just walking (the publication is behind a firewall and I didn't want to pay to read the paper itself). We could estimate the minimum effect, though. Let's say that the standard deviation of BP readings is 5 mm, not unlikely based on myself. With 54 participants, the standard error would be about  $5/\sqrt{54}$  or about 0.7 mm. Allowing 3 SD change (2.6 would give  $p = 0.01$ ), that would be about 2 mm. So they probably saw about 2 mm difference in the groups. Not a lot, healthwise. As for the cobblestone mat, I lived for a year in Hawaii and for the last half, I went barefoot a good part of the time. It was painful at first, but eventually I could walk on a coral road carrying a 40-pound load without problems. I could also walk on a hot airport tarmac barefoot in the sun. After I left Hawaii, it took about 2 years for my feet to return to their previous condition. I don't know about blood pressure effects. But I don't think you'll get there with a few minutes a day on the mat. This study had the participants do an hour at a time. That's probably what it takes. Seth: Your calculation of the difference doesn't include the between-group comparison. That would double the minimum effect. I think it is too soon to be sure the blood pressure improvement was "not a lot, healthwise" in the sense of unimportant. The effect might have increased with further exposure. And it seems to point to a way of lowering blood pressure previously unknown or little known that is cheap and safe. Maybe there are other ways to take advantage of the underlying principle. And maybe there are other benefits.

Katie (2013-08-01 07:12:23)

Has anyone ever studied barefoot vs. wearing flip flops? When I'm not working (where I'm a professional and have to wear high heels - ugh), I try to be barefoot or in flip flops (the thinner the sole the better) if I'm out in public as much as possible. All of my older relatives keep saying it's going to ruin my feet, but I've been doing it for about 15 years now and made it through one pregnancy so far and still have no foot pain or problems.

Tam (2013-08-01 16:53:43)

@Katie <http://www.alignedandwell.com/katysays/open-toes-open-hearts/> #sthash.4O03zyvs.dpbs

gwern (2013-08-01 17:51:54)

Thomas: I jailbroke the paper for you at <http://dl.dropboxusercontent.com/u/182368464/2005-li.pdf> Enjoy. Your estimates are on the low end\*, see the table on pg6. Systolic fell by 5.3 mmHg more in the mat walking group, and diastolic fell by 3.19 mmHg more. \* If I had to guess, it might be because you forgot that they should be doing multiple-correction of their p-values, and so the effect size has to be much larger than you assumed in your single-p-value example. In this case, they measured at least 10 end measures and so there's a big adjustment going on.

Katie (2013-08-02 08:47:43)

Thanks, Tam!

Tom Passin (2013-08-02 09:53:13)

"Seth: Your calculation of the difference doesn't include the between-group comparison. That would double the minimum effect. " Actually it would be about  $\sqrt{2}$ . But since I didn't have a good value for the standard deviation, there wasn't any point in getting into more detail. I was just trying to roughly gauge the effect size, based on the info in the abstract. Now that gwern has provided a pointer to the paper, I see that the standard deviation was rather larger than my swag at it (13.5 mm vs 5 mm). Using this higher value and looking for between-group differences, for the 2.6 sigma value (i.e.,  $p = 0.01$ ) you would get about 6.8 mm as the likely difference. From the paper's data, the weighted between-group difference afterwards was 7.06 mm, with a standard error of about 2.4. Pretty close. The change in systolic pressure for the non-cobblestone group was -3.7 mm. So using the cobblestones seems to have lowered the systolic pressure by another 3.4 mm, with about the same standard error as above. If only the abstract had told us enough that we could have assessed the real-world significance without all this estimating! Seth: I agree, the abstract should have made clear the size of the effect.

Tim Beneke (2013-08-02 11:23:52)

FYI: Jiangyin, one of China's richest cities, just down the river a bit from Shanghai, has a sports stadium that seats 30,000 – mostly soccer is played there. There are many amenities, including a large area in the stands where people can walk on cobblestone, or the equivalent, to improve their health. It probably, like acupuncture/acupressure/foot massage, releases endorphins...

Heidi (2013-08-03 00:20:04)

The solution to the cobblestone mat problem is to tell the manufacturer you can't use it, and suggest they make a series of mats leading up to the real thing. They make more money from making it easier to use. This is a common problem with a lot of sports and exercise equipment, the manufacturer always designs it for people who are already fit, and doesn't even try to make things easier for the almost fit but willing.

peter (2013-08-04 12:42:28)

what comes to mind is reflexology, i.e., walking on cobblestone is the same as massaging the bottom of the feet.

A Berg (2013-08-08 06:39:52)

Interesting. I've kind of had a similar experience recently. I've had some difficult to get rid of pain in one of hip joints. Mostly it just hurt slightly to walk. Anat Baniels theory (from her 'Move into life' book) and her methods helped me somewhat. Physiotherapy and chiropractor helped me almost not at all. After 3-4 months with this going a bit up and down, I stopped using sandals/footwear indoor, and just wore socks to see if that would help on the problem. Almost immediately it started to improve. I could better sense my body and try different walking styles and until, I believe, my body rediscovered how to walk

without pain (as I believe Anat Baniel claims it should be able to). Part of the problem I think was tense muscles, and walking barefooted I could better relax my thighs, and recover a natural walk. A few times I have forgotten this, and used sandals, and sometimes I notice some annoyance in the legs again. So I find it quite likely that the bare footedness has helped. But then as I just recall, I guess my experience is just one among many. I believe I have read here last year that running barefooted is better for the knees (as I also discovered after testing it, but I stopped barefoot running because of pain from running on roads).

Alex Chernavsky (2013-08-02 07:28:15)  
From the article about breast-feeding:

Multiple studies have found hospitals and birth centers often sabotage women's efforts. For instance, one-quarter of hospitals and birth centers give at least half of healthy breast-feeding newborns formula, according to the surgeon general's report, and almost three-quarters give breast-feeding mothers "welcome packs" that include formula.

Todd Fletcher (2013-08-02 09:30:40)

All three of my kids were breastfed and not a single one ever had an ear infection. That's something that's almost unheard of (haha).

MJB (2013-08-02 13:50:12)

A brave Baltimore teacher speaks the truth about schools, students "I have taught in the Baltimore public school system for the past two decades. What we need is better students. We have many excellent teachers. I cannot count the number of students who have physically destroyed property in the schools. "They have trashed brand new computers, destroyed exit signs, set multiple fires, destroyed many, many lockers, stolen teachers' school supplies, written their filth on the tops of classroom desks, defecated in the bathrooms and stairwells, assaulted teachers (beyond constantly telling them to perform certain impossible acts upon themselves) and refused to do any homework or class work. <http://washingtonexaminer.com/a-brave-baltimore-teacher-speaks-the-truth-about-t-schools-students/article/2533752>

Tom (2013-08-02 14:06:14)

whoops, sorry about the double post. Seth, interesting post about conflicts of interest among the doctors setting cholesterol targets: <http://drmalcolmkendrick.org/2013/08/02/who-shall-guard-the-guardians/>

aelephant (2013-08-02 16:17:50)

Many Chinese mothers take prescription drugs to STOP lactation so that they can quit breastfeeding. You've heard of the massive formula consumption in China, no doubt. The people around a new mother will also often pressure her to give her baby formula, making her feel that her milk is inadequate in supply or quality. This becomes a self-fulfilling prophecy when the baby is full of formula & loses incentive to feed naturally.

### **Suicidal Gestures at Princeton: A Staggering Increase (2013-08-03 05:00)**

A friend of mine knows a former (retired) head of psychological services at Princeton University. She told him that in the 1970s, there were one or two suicidal gestures per year. Recently, however, there have been one or two per day.

Something is terribly, horribly wrong. Maybe the increase is due to something at Princeton. For example, maybe new dorms are more isolating than the old dorms they replaced. Or maybe the increase has nothing to do with Princeton. For example, maybe the increase is due to antidepressants, much more common now than in the 1970s.

Whatever the cause, it would help all Princeton students, present and future, and probably millions of others, if the problem were made public so that anyone, not just a vanishingly small number of people, could try to solve it. It isn't even clear that anyone is trying to explain/understand/learn from the increase.

Princeton almost surely has records that show the increase. If, as is likely, Princeton administrators never allow the increase to be documented, it will be a tragedy. It is an extraordinary and unprecedented clue about what causes suicidal gestures. Nothing in all mental health epidemiology has found a change by factor of a hundred or more – much less a mysterious huge change.

The increase is an unintended consequence of something else, but what? Because it is so large, there must be something extremely important that most people, or at least Princeton administrators, don't understand about mental health. The answer might involve seeing faces at night. I found that [1]seeing faces in the morning produced an enor-

mous boost in mood and that faces at night had the opposite effect. I cannot say, however, why seeing faces at night would have increased so much from the 1970s to now.

1. <http://escholarship.org/uc/item/2xc2h866/>

---

Three Pipe Problem (2013-08-03 05:43:21)

Seth do you know what the Werther effect is? Perhaps that is why Princeton's administration is not so forthcoming. When publicizing suicide predictably leads to more suicides of a similar nature, the ethical question is a complex one. Seth: Yes, I know about the Werther effect. Given the size of the increase and the amount of suffering implied (including people elsewhere), I don't think that whether to do something about it – to do the utmost possible – is a complex or difficult ethical question. The benefits of figuring out what caused the increase would be enormous.

dearieme (2013-08-03 07:22:49)

Is it possible that they are admitting more students who suspect that they are not up to it? Is there any correlation between suicidal gestures and lack of academic success? How do their figures compare with, say, Yale or Oxford? Seth: Good questions I cannot answer. However, I doubt that admissions changes could produce such a big change

Alex Chernavsky (2013-08-03 12:45:26)

I'm not particularly suprised by the dramatic increase in suicidal gestures. Our society seems to be experiencing an epidemic of mental illness in general. It's interesting to note that PTSD didn't seem to exist for soldiers who underwent traumatic experiences during the American Civil War.

A study just published in the *Journal of Anxiety Disorders* looked at the extensive medical records for soldiers in the American Civil War, whose mortality rate was about 50-80 [times] greater than modern soldiers fighting in Iraq and Afghanistan. In other words, there would have been many more having terrifying experiences but despite the higher rates of trauma and mentions of other mental problems, there is virtually no mention of anything like the intrusive thoughts or flashbacks of PTSD. In a commentary, psychologist Richard McNally makes the point that often these symptoms have to be asked about specifically to be detected, but even so, he too admits that the fact that PTSD-like symptoms virtually make no appearance in hundreds of thousands of medical records suggests that PTSD is unlikely to be a 'universal timeless disorder'. Taking an even longer view, a study published in *Stress and Health* looked at historical accounts of traumatic experiences from antiquity to the 16th century. The researchers found that although psychological trauma has been recognised throughout history, with difficult events potentially leading to mental disorder in some, there were no consistent effects that resembled the classic PTSD syndrome. Various symptoms would be mentioned at various times, some now associated with the modern diagnosis, some not, but it was simply not possible to find 'historical accounts of PTSD'.

<http://mindhacks.com/2012/08/11/a-very-modern-trauma/>

Alex Chernavsky (2013-08-03 13:07:20)

So, to follow-up on my comment above: Investigative reporter Robert Whitaker wrote a book about this huge increase in the incidence of psychiatric disease. Whitaker attributes the epidemic to the toxic effects of psychotropic drugs. The evidence he presents is impressive. The book is fascinating (if disturbing) and is worth a read: [1]*Anatomy of an Epidemic: Magic Bullets, Psychiatric Drugs, and the Astonishing Rise of Mental Illness in America*. Seth: If I remember correctly, nothing in that book came anywhere close to a hundred-fold increase.

1. <http://www.amazon.com/Anatomy-Epidemic-Bullets-Psychiatric-Astonishing/dp/0307452425>

dearieme (2013-08-03 15:20:30)

"PTSD didn't seem to exist for soldiers who underwent traumatic experiences during the American Civil War." Is PTSD the same thing as the "shell shock" of the First World War?

Ashish (2013-08-03 18:03:15)

The selectivity of elite schools is much greater than it was in the 1970s, the pressure is greater (from the cost, and a tougher job marketplace), and the ethnic and socioeconomic composition of students is much different. So while the data this psychologist relates is shocking, I think the meaningful comparison is to contemporary institutions. Of course, universities have no incentive to make this information public.

nansen (2013-08-03 18:21:58)

"The answer might involve seeing faces at night." What about not seeing faces during the day, due to concentration on gadgets?

BRW (2013-08-03 18:44:42)

I think a number of factors could be at play here. One is certainly diet. I'm sure the food served at Princeton has changed quite a bit since the 70's. Another is probably, sunlight exposure. More competitive = more indoor studying. I also think folks are way up on the pill usage and most likely drinking more alcohol. I doubt one factor is at play here.

Alex Chernavsky (2013-08-04 08:56:33)

Seth, with regard to increases in the rates of mental illness, Whitaker argues that the epidemic has hit young people disproportionately hard. Citing US government statistics, Whitaker shows that among children, the rate of disability due to mental illness increased 35-fold between 1987 and 2007. During that same time, adult disability due to mental illness increased by a bit under 4-fold. 35-fold isn't so far removed from the 100-fold increase you described in your blog post. The rates of juvenile bipolar disorder have increased about 40-fold since 1987. Our old friend Dr. Joseph Biederman (about whom [1]you've blogged) is partly (or perhaps *mostly*) responsible for this iatrogenic tragedy.

1. <http://blog.sethroberts.net/2011/07/22/joseph-biederman-and-parents-they-should-be-left-in-a-room-together/>

Tom (2013-08-04 11:12:27)

The demographic makeup of the student bodies of elite universities has also changed considerably in that timeframe. There may be more "tiger mothers" now.

dearieme (2013-08-05 03:59:05)

Hang on, we've all forgotten the obvious question. What proportion are girls?

Christopher Burd (2013-08-05 14:33:33)

There are more suicidal gestures, but are there more suicides?

Tom (2013-08-05 21:37:58)

Good point. According to Wikipedia at least, females make far more "suicidal gestures" than males. But males actually kill themselves far more often than females. Which raises the question of whether the rise in suicidal gestures might be an upbeat sign. :-)

ChristianKI (2013-08-10 04:40:01)

Maybe the psychological counselling got more trustworthy over time so there's better reporting going on. Looking at the number of real suicides would be a much better way to see whether there a real problem going on. Seth: The number of actual suicides might be less sensitive, since there are far fewer of them.

B.B. (2013-08-12 07:05:40)

I will relate a personal observation. I once taught part-time at Wharton in the mid-1980s. In a class midterm exam, an Asian

female student folded during the exam. I took her outside the class and talked to her. She was clearly suffering extreme test anxiety. I told her I would drop the midterm and base her grade on the final, but only if she went to Penn's counseling center to get treatment for test anxiety. The same thing happened on the final. I asked if she had done as I told her. She related that the counseling center was so overwhelmed with students that it could not give her immediate counseling and only offered medication instead. Truly sad. And that was almost 30 years ago. I am sure the situation has gotten worse. Partly, that student's issue were related to familial and ethnic expectations (she told me that), female anxiety, and competitive pressure. Those factors likely increasingly apply to the entire student population at the Ivies.

sa (2013-08-12 14:42:07)

Maybe its due to an increase in the numbers of people infected by a parasite ? [http://www.theatlantic.com/magazine/archive/2012/03/how-your-cat-is-making-you-crazy/308873/?single\\_page=true](http://www.theatlantic.com/magazine/archive/2012/03/how-your-cat-is-making-you-crazy/308873/?single_page=true) "In a 2011 study of 20 European countries, the national suicide rate among women increased in direct proportion to the prevalence of the latent Toxo infection in each nation's female population. "

### **More About Benefits of Alternate Day Fasting (2013-08-04 05:00)**

Last week [1]I blogged about a friend who derived great benefits from alternate-day fasting. There were several reader questions. I put them to my friend:

Q How does exercise fit in with all this fasting?

A I do lyengar yoga every day, about 2 hours.

Q I assume he drank water. Did he consume any liquid calories or probiotics (Yakult?) on his fasting days?

A Yes, water. I replace electrolytes, but that's for other reasons. (I don't regulate electrolytes well.) There may have been 8 or 10 days in the last 9 months when I had a very small amount of food on a fasting day - a little yogurt or a little rice & sauerkraut, maybe. Q What did he eat on non-fasting days? A Breakfast of stir-fry + egg + some fruit & yoghurt & nuts & flax seeds. Maybe I break that into two meals or maybe not. Dinner of ... veggies/rice/chicken or ... something like that. [He didn't change what he ate when he started alternate-day fasting.] Q Something is missing in the story. He didn't get to be an Ivy League math professor by being confused, exhausted, overwhelmed and depressed all the time. Were his indigestion and tiredness increasing in severity before he started the diet? A I was severely ADHD all my life, and collapsed in the early 2000's. I turned out to suffer from heavy metal poisoning: mercury, lead and a little bit of arsenic. I've been detoxing for a number of years with steady improvement. As to how I managed to become an Ivy League math professor, that's not unusual. There are a lot of us. There is a subtype of ADHD called "with hyperfocus". Hyperfocus is a mild form of the Asperger's "little professor" syndrome, in which a person is completely consumed by one subject, at the expense of anything else.

1. <http://blog.sethroberts.net/2013/07/28/effect-of-alternate-day-fasting-on-a-friend/>

---

limette (2013-08-04 12:18:59)

That clinches it for me. Beginning today, I'm starting alternate day fasting. I've had issues with candida since childhood and I want to finally kill it off. Most of the candida diets severely limit food choices and it's been hard to adhere to them.

Thomas Johnson (2013-08-04 12:24:43)

A few questions for you or your friend about the practicality of ADF: \* If you take medications that are supposed to be taken "with food" (which typically means that they are fat-soluble I think) how do you deal with this? \* How do you deal with the social aspect of eating? When your friends invite you to go out for lunch/dinner/drinks with them, do you just order a water? Seth: I'm not taking any medications. When eating with friends, I just eat very little.

Thomas Johnson (2013-08-04 12:28:54)

Also just came across this interesting snippet at <http://www.webmd.com/vitamins-and-supplements/nutrition-vitamins-11/fat-water-nutrient?page=1> Water-soluble nutrients work best when you get them in the proper amounts. When you eat or take more than your body needs, the body adapts by absorbing just what it needs, and then it usually excretes the excess in your urine – but not always. A study in the August 2010 Journal of Nutrition Science and Vitaminology found that urinary excretion of certain vitamins and other nutrients was reduced when study participants fasted.

Adam (2013-08-04 16:07:40)

@Thomas Johnson: Most medications can be taken with or without food, the food slows absorption & can minimize stomach upset. There are only a few that really need to be taken with food. Off the top of my head, I can only think of one & it is an anti-parasite drug that you're probably not taking. What drugs do you take that you think must be taken with food?

John (2013-08-04 18:34:15)

Has it had any effect on body weight?

Ashish (2013-08-04 21:51:34)

Does fasting give him bad breath? That seems to be a common side effect. Aren't bad smells, like the smell of feces, our body's way of telling us that something is wrong - or, in the case of feces, "don't eat this"? (As a practical matter, how does he deal with the fasting-induced halitosis?) Also - I know, so many questions - what is our best understanding of the physiological process by which fasting creates benefits such as loss of bad fat, reduced GERD, etc.? My experience is that missing a meal increases acid reflux, so I hesitate to go all the way. Thanks.

Adam (2013-08-04 23:11:36)

@Ashish: Have a look at [https://en.wikipedia.org/wiki/Stomach\\_acid#Secretion](https://en.wikipedia.org/wiki/Stomach_acid#Secretion). Stomach acid is secreted in response to a meal. No meal = less acid, at least from my reading. Fat loss would be explained by your body dipping into fat stores once all the readily available substrates have been depleted. There are also a lot of hormonal changes that occur in response to fasting.

Thomas Johnson (2013-08-05 13:40:24)

@Adam: I take a zinc supplement daily, which (at least for me) produces significant gastrointestinal upset if not taken with food. See <http://www.livestrong.com/article/30801-effects-taking-zinc-empty-stomach/>

Adam (2013-08-05 18:21:54)

@Thomas Johnson: I see. I think I got a little nausea as well when I tried zinc. You could try splitting the dose up. I found some info that suggests the amount your body absorbs is inversely proportional to the dose you take, so taking smaller doses more frequently would probably benefit you in 2 ways: less stomach upset & a greater percentage absorbed in each dose.

Ken (2013-08-06 14:53:00)

What about drinking coffee on fast days? Encouraged or what that alter the effects of fasting? I would be concerned about low blood sugar making me cranky, but I think black coffee would help compensate. Seth: I drink lots of tea on fast days. Including Choffy, a coffee substitute made with chocolate. I brew it like tea.

Char (2013-08-06 15:02:45)

I found this interesting. I wonder if it's some of the same things going on with alternate day fasting.  
<http://www.dailymail.co.uk/health/article-2385179/I-reversed-diabetes-just-11-days-going-starvation-diet.html>

### **More Evidence Linking Fermentation and Complexity: Wild-Fermented Wine (2013-08-05 05:00)**

I came to believe that we need to eat fermented foods to be healthy partly because this idea solved an evolutionary question: why do we like food that is sour, umami-flavored, and complex? I realized that all three preferences could be explained the same way: All three push us to eat more fermented food. For example, fermented milk (yogurt) is sourer than fresh milk.

Fermentation also increases complexity. An example is miso. I noticed that miso by itself was sufficient flavoring for soup. I had to add quite a few spices to produce the same amount of complexity that miso alone produced – miso was a super-spice.

Wine is a fermented food, of course, but long ago all fermentation was "wild" – it proceeded from whatever fermenting agents were in the air, on people's hands, and so on. Fermentation increased complexity not just because the microbes metabolized the food but because there were many kinds of microbes. Australian winemakers were [1]recently given a lesson in the connection between wild fermentation and complexity:

We were tasting two glasses of pinot noir, blind, and the questions were: is there any difference between them? If so, how are they different?

Glass One was full purple-red in colour and smelled fresh and fruity, delightfully primary, with a bright raspberry aroma that was almost like bubble gum. It was pristinely clean, delicate, light on the palate and charming, but ultimately rather simple.

Glass Two had a darker colour and blacker fruit aromas, more complex and mysterious. Similarly, in the mouth it was fuller-bodied, richer and deeper, with greater textural interest, fleshier and denser, with more tannin. A beautiful wine, too, but much more profound and captivating than Glass One.

Winemaker David Bicknell then announced to the gathering [of winemakers] that the only difference between the wines was that Glass One had been fermented with a pure yeast strain and Glass Two had undergone a wild ferment. That means no yeast had been added: the juice had been fermented by whatever yeast strains happened to be in the air at the time.

"Both wines were picked from the same Upper Yarra Valley vineyard on the same day, and everything in the winemaking was the same except the yeast," announced Bicknell, who is the winemaker at Oakridge. The class was asked to try to pick the wild ferment and say which wine they preferred. The great majority nominated the correct glass, and liked it more. There was nothing wrong with Glass One: it was simply that Glass Two was better - every way you looked at it.

The "class" was a wild-yeast workshop at the recent Australian Wine Industry Technical Conference in Sydney. The "students" consisted mainly of experienced winemakers. . . . The environment, especially the air, contains hundreds of thousands of strains of yeast, most of which occur naturally. The species present depend on what flowers, fruits, trees and grasses are in that locality. Recent New Zealand research has shown that yeasts are territorial, and the species present vary according to the place. . . .

Pairs of Hardys' Eileen Hardy chardonnay and Mount Pleasant Hunter chardonnay, all 2013 vintage, one of each "wild" and the other seeded with cultured yeast, showed more permutations of character. With Mount Pleasant, the wild wine was cloudy in appearance, and quite stinky, but also showed density of flavour and richness, while the regular wine was good but not as interesting. The winemakers seemed to think the stinky one would clean up after a period of lees-stirring.

Of the Hardys wines, the regular ferment looked bright and clear in the glass, and was pristinely clean, intense and lively, with a spring water-like lightness of texture. The wild ferment was cloudy, smelled of cashews, bread, smoky oak, sulfides and spices, but the real difference was in the mouth. Its texture was far more rich and dense, fleshy and rounded, smooth and harmonious.

Eileen Hardy winemaker Tom Newton said he believed the sulfides were related to the wine's greater textural density. Indeed, all winemakers I've quizzed who practise wild fermentation believe it gives their wines greater length of palate and improved texture as well as extra flavour complexity.

Even riesling responds to this "rougier than usual handling". Kerri Thompson's wild-ferment Clare Valley riesling was a graphic illustration. Served beside a conventional Clare riesling, which was a perfectly good wine in its way, her KT Pazzo Riesling 2013 was turbid (not clear) and smelled of apple, pear, yeast and a hint of nuttiness from time spent in old barrels. It was a more expressive, more textural and more layered wine than the conventional one. It's on sale soon at \$29.

And perhaps the most beautiful, exotic, fascinating wine of the day was Cullen's Kevin John Chardonnay 2011. . . . Biodynamically grown and wild fermented, it's a pioneer and benchmark of the genre. It's so complex it's difficult to describe, although honey and oak and what I call "balsamic" (like the smell of balsamic vinegar, without the vinegar or sweetness) aromas are all involved, welded to a razor-sharp, crisply tart, long and linear palate structure.

Will Australia become the new California? Decades ago, California winemakers figured out how to make wines that were the equal of French wines. No doubt French winemaking had stagnated. Australian winemakers have just been taught how to make much better wines for the same price. As far as I know, Californian and French winemakers have yet to learn this lesson.

Wine is a very old food. One remarkable thing about this demonstration is how long it took – how long it took to learn this lesson. Sure, we like hand-made this and artisanal that, but in so many ways we prize uniformity, no more so than in our educational system, to which we entrust the most precious thing we have: our children. Who are treated by that system in a factory-like way, in the sense that all children in a class get the same teaching materials and are given the same tests. I have yet to hear an education theorist say that the best education produces diversity not uniformity. When I let my students' underlying diversity be expressed (for example, in what they chose to learn), teaching became much easier. Win-win. Essentially what the winemakers are figuring out: When you let the natural variation of yeasts be expressed, making great wine becomes much easier.

---

dearieme (2013-08-05 07:42:31)

Allow me to recommend a birthday present wine I got from my daughter: Assyrtiko 2012 Wild Ferment from the Gaia estate, Santorini. Yum, yum.

Nina (2013-08-05 10:40:32)

In Europe there's a big natural wine movement. Georgia in the Caucasus has a long tradition of natural wines. <http://www.youtube.com/watch?v=Zh9AcMFTvUM>

Tom Passin (2013-08-05 17:21:54)

I bake bread, mostly sourdough. I use a long fermentation time - usually 12 - 16 hours. It's well known in the baking business that longer fermentation times lead to more flavor. Some of that is just time hydrated (wet) aside from any fermentation, but fermentation also plays a big role. I did an experiment in which I used a pinch of conventional yeast to make one batch of dough, and my regular sourdough culture for another. The recipes were adjusted to have the same overall amounts of flour and water, and the pinch of yeast was selected to give about the same fermentation time as the sourdough batch would take. The result was that both batches fermented, handled, and baked essentially the same as each other. The sourdough bread clearly had better and more complex flavor. I'd done the same kind of thing before, with similar results, but this time I made sure that the recipes and fermentation times were the same so as to get a more controlled comparison. In developing a sourdough culture, it's often said that you get wild yeast from the air. That may be so on occasion, but I have reasons (I won't go into here) for thinking that most of the yeast arrives with the flour you use to create the sourdough culture. Eventually the culture stabilizes with a mixture of yeast and lactic and acetic acid bacteria. It's the mix of all three that gives the fine sourdough quality - the complexity that Seth talks about.

dearieme (2013-08-06 02:47:10)

Ahoy, Seth. News from the Old England Journal of Medicine: <http://www.dailymail.co.uk/health/article-2385179/I-reversed-diabetes-just-11-days-going-starvation-diet.html>

Loweeel (2013-08-06 12:11:11)

Seth, apparently there isn't really any such thing as a true "wild yeast" fermentation. Rather, when they've actually looked into it, regardless of what yeast starts off, they're all out-competed in fairly short order by dominant commercial wine-specific yeast strains. <http://fermentationwineblog.com/2013/08/wild-yeast-fermentation-theres-no-such-thing/> Seth: The article fails to explain why the supposedly wild fermentation wines tasted much better in the Australian taste test.

## **Cream Cheese Improves Brain Function (2013-08-07 05:00)**

Last night I had dinner with a friend in a restaurant. We chatted with a couple sitting next to us. They asked what I did research about. "Food and the brain," I said. "What foods make the brain work best." They asked for an example. "[1]Butter," I said. The woman smiled. "That's great news! Butter is delicious." As they left, the woman said, "I feel like I've learned some really interesting things."

I agree, great news - partly because butter is delicious. Yet it fits what we already know. It's been known since the 1920's that a high-fat ("ketogenic") diet can ameliorate childhood epilepsy. I suppose it's called "ketogenic diet" to avoid the term high-fat - or to sound more "scientific". It's an unfortunate name because why the diet helps is unclear. "Although many hypotheses have been put forward to explain how the ketogenic diet works, it remains a mystery," [2]says Wikipedia.

Another example of dairy fat improving brain function comes from [3] a little girl with a rare genetic disease:

A 3-year-old girl, . . . thanks to a diet of cream cheese, gained the ability to speak despite a disease that [had] left her mute from birth.

Fields Taylor, from Melton Mowbray in Leicestershire, was born with the incurable genetic disease Glut 1 Deficiency that caused a lack of glucose to flow to her brain. Today, Taylor's diet of four containers of the cream cheese per week gives her a voice. . . . "The amount of Philadelphia [cream cheese] she goes through is mad but worth it. It really has been our saving grace. She loves the stuff and piles it on crackers," The Mirror quoted her mother Stevie as saying. "The first time I heard Fields say 'Mum' it was just wonderful." . . . Glut 1 affects just 26 people in the U.K.

Thanks to Tom George.

---

Charlie (2013-08-07 09:01:06)

Unfortunately, all commercial produced cream cheese in the US contains one or more of the dreaded "gums" - guar, xanthan or carob bean - none of which I can tolerate. Fortunately, the European versions, do not - creme fraiche, mascarpone, etc., also quark and farmer cheese. Cheers

Jonathan Shewchuk (2013-08-07 23:36:20)

"Ketogenic" implies more than just high fat, doesn't it? The carb intake must also be low enough for the body to go into ketosis. Also, it seems to me that "ketogenic" diets for epilepsy are often more restrictive than ketogenic diets for weight loss or endurance sports, because some epileptics have to severely restrict their protein intake as well to avoid seizures. Seth: Then "high-fat low-carb diet" would have been a good name. The trouble with "ketogenic diet" is that it implies that the diet works because it produces ketosis. That could easily be wrong.

Paul N (2013-08-09 08:25:54)

I'm not sure that "high carb low fat" is accurate either. If the diet is improving brain function in people with impaired brain glucose metabolism, it is almost certainly because of ketones - the brain cannot process fatty acids/triglycerides. But this does not necessarily require it to be low carb, either. Eat coconut oil and/or medium chain triglycerides, and your body produces ketones even when you are still eating plenty of carbs. There is the well known case of [1] Dr Mary Newport, who treated her husband's alzheimers by adding coconut oil to his oatmeal, and saw improvements in days. This would not have been an LCHF diet, nor even "ketogenic" by the normal definition, but it does produce ketones and did improve his brain function. I'll guess, and it's just a guess, that the epileptics have to avoid certain types of proteins that have high glutamate content - as glutamate excites neurons, while ketones produce GABA to inhibit them. It's easy to see there's lots more to be learnt in this area, and also easy to see that since ketones/MCT's/coconut oil are not drugs nor patentable, there isn't much money being devoted to research on them. Given Seth's results with butter, I'm sure butyric acid helps the brain too, though likely in a different way, since it produces improvements that coconut oil doesn't.

1. <http://www.tampabay.com/news/health/spring-hill-couple-inspires-research-into-coconut-oil-for-alzheimers/2124596>

## Alternate Day Fasting: Not For Everyone? (2013-08-08 05:00)

I've been doing [1]alternate day fasting for about two months. I find it very easy. In several ways it's easier than eating every day:

- save time
- save money
- less constrained on eating days
- a little more hungry than usual on fasting days (up to a point hunger is pleasant – when the Shangri-La Diet wiped out all my hunger, I didn't like it)
- sense of accomplishment when I wake up after a fasting day (I did it)
- food tastes better

Maybe my friends are unusually tolerant but I have yet to encounter a serious negative. Yesterday, a fasting day, I happily watched a friend eat dinner. I had two bites out of curiosity. I saw nothing to suggest it made her uncomfortable I wasn't eating.

However, a different friend has told me that alternate day fasting made her sick. She did it for about three months, felt worse and worse, and finally stopped. She believes it works less well for women than for men. I suspect a heavy exercise routine (she ran a lot) made alternate day fasting more difficult. But there is also the best-selling book [2]The FastDiet. It has two authors, a man (Michael Mosely, a doctor) and a woman (Mimi Spencer, a journalist). The book contains a remarkably short and remarkably unenthusiastic description of Spencer's experience with intermittent fasting. Maybe it didn't agree with her, either.

1. <http://blog.sethroberts.net/category/health/intermittent-fasting/>

2. <http://thefastdiet.co.uk/>

---

Jim (2013-08-08 06:14:34)

There are many comments on various paleo blogs indicating that intermittent fasting is more difficult and less beneficial for women.

Charlie (2013-08-08 06:16:36)

I have seen several discussions on "paleo" blogs that suggest fasting - intermittent, alternate day, whatever - isn't always good for women, and some suggest it's never good. Cheers

None (2013-08-08 07:05:12)

I fast one or two days a week. I like it so far. I feel better and with more energy the next day. I don't exactly feel great on fast days. I don't think that I could do two consecutive days, much less alternate days. I can't run much on the days I fast. It feels like it would be too much stress on my body. By the way, the 5:2 authors don't always recommend fasting two consecutive days. And don't forget that they define fasting days as days in which men are advised to consume 600 calories and women 500. That's very different from alternate day fasting with no (or few) calories on fasting days.

Rlen (2013-08-08 08:53:02)

I tried 5:2 for a couple of weeks. Initially I did great, but after maybe 6 weeks my stomach started protesting. Violently! I switched back to normal eating and it took me about 2 months before the stomach got back to normal. (I had the impression that too much nightshade plants in my diet caused the upset) I will try 5:2 again as I really like the concept and I do want to know if this was just a one time fluke or not.

Jazi Zilber (2013-08-08 11:49:03)

I believe its individual. For me, fasting has been terrible for awhile. I simply could not stand it. Not psychologically - physically. It would drain my energy and make me sick. then it changed. now i can fast. For a very long time, I was unable to fall asleep without having eaten some time before sleep.

CC (2013-08-08 13:15:45)

When I investigated alternate day fasting several years ago, I discovered that 1) not enough investigation had gone on that explored the differences male vs female physiology made on the effects of fasting, and 2) what findings were available re: female fasting weren't so good. It makes sense; during times of scarcity, it's harder on a female body (and on the developing fetus) to be pregnant. Negative changes in women appeared to be more pronounced and possibly linked to hormonal balance. We do know that, under a certain body weight, fertility can be affected and menses can be delayed or halted. Anecdotal evidence in some of the fasting forums I read also seemed to also point to fasting being unhealthy and not beneficial for some women (though some of those poor women would try repeatedly, experience the same negative results and feel that they were failing). The potential benefits (possibly mainly experienced by males) didn't sound worth the potential risks, to me.

Todd (2013-08-08 14:21:54)

As someone who has worked with a lot of performance athletes, attempting to fast while training for performance can put down a beating on the adrenals. Women are indeed more susceptible to dysfunction in the adrenal/thyroid/ovary axis. Not to say that fasting can't be done for performance athletes, but it usually needs to be a very resilient person with a good understanding of how to fuel during their non-fasting periods. Fasting may also exacerbate adrenal and thyroid issues in people just interested in health and fitness, so, for someone who's already started down some paths of hormonal issues, fasting can dig their hole a bit deeper. Again, not to say that it can't be done or that it's not beneficial, just some folks are way more susceptible to downregulating their thyroid and screwing up their cortisol curve.

Rob (2013-08-09 17:28:41)

Here is Mimi Spencer's experience with the Fast Diet (page 9): "In the months that I wrote the Times feature, I have remained a convert. An evangelist, actually. I'm still "on" the Fast Diet, but I barely notice it. At the outset, I weighed 132 pounds. At five feet, seven inches, my BMI was an OK 21.4. Today, as I write, I weigh 119 pounds, with a BMI of 19.4. That's a weight off. I feel light, lean, and alive. Fasting has become part of my weekly life, something I do automatically without stressing about it. Six months in, I have more energy, more bounce, clearer skin, a great zest for life." Accounting for British understatement, and overlooking the excessive comma usage, I would say that is a strong endorsement. Seth: One paragraph...in a whole book? What about lab results? What about blood sugar? What about examples of feeling "light, lean, and alive"? Did she recommend the diet to anyone else? This isn't my idea of enthusiasm.

Ashish (2013-08-09 23:20:00)

It's 11:17pm. I haven't eaten all day. I suspect that the cooking and eating time saved was replaced by time spent, especially as the day wore on, fantasizing about my next meal, and Googling recipes for breakfast. No euphoria yet. Seth: I think the "conditioned hunger" goes away but the saved time does not.

## The Truth in Small Doses: Interview with Clifton Leaf (Part 1 of 2) (2013-08-09 05:00)

I found a lot to like and agree with in *The Truth in Small Doses: Why We're Losing the War on Cancer – and How to Win It* by Clifton Leaf, published recently. It grew out of a 2004 article in *Fortune* in which Leaf described poor results from cancer research and said that cancer researchers work under a system that "rewards academic achievement and publication over all else" – in particular, over "genuine breakthroughs." I did not agree, however, with his recommendations for improvement, which seemed to reflect the same thinking that got us here. It reminded me of President Obama putting in charge of fixing the economy the people who messed it up. However, Leaf had spent a lot of time on the book, and obviously cared deeply, and had freedom of speech (he doesn't have to worry about offending anyone, as far as I can tell) so I wondered how he would defend his point of view.

Here is Part 1 of an interview in which Leaf answered written questions.

SR Let me begin by saying I think the part of the book that describes the problem – little progress in reducing cancer – is excellent. You do a good job of contrasting the amount of time and money spent with progress actually made and pointing out that the system seems designed to produce papers rather than progress. What I found puzzling is the part about how to do better. That's what I want to ask you about.

In the Acknowledgements, you say Andy Grove said "a few perfect words" that helped shape your thesis. What were those words?

CL "It's like a Greek tragedy. Everybody plays his individual part to perfection, everybody does what's right by his own life, and the total just doesn't work." Andy had come to a meeting at *Fortune*, mostly just to chat. I can't remember what the main topic of conversation was, but when I asked him a question about progress in the war on cancer, he said the above. (I quote this in the 2004 piece I wrote for *Fortune*.)

SR You praise Michael Sporn. His great contribution, you say, is an emphasis on prevention. I have a hard time seeing this as much of a contribution. The notion that "an ounce of prevention is worth a pound of cure" is ancient. What progress has Sporn made in the prevention of anything?

CL Would it be alright, Seth, if before I answer the question, I bring us back to what I said in the book? Because I think the point I was trying to make – successfully or not (and I'm guessing you would conclude "not" here) – is more nuanced than "an ounce of prevention is worth a pound of cure."

Here's what I see as the key passage regarding Dr. Sporn (pgs. 133-135):

For all his contributions to biology, biochemistry, and pharmacology, though, Sporn is still better known for something else. Rather than any one molecular discovery, it is an idea. The notion is so straightforward—so damned obvious, really—that it is easy to forget how revolutionary it was when he first proposed it in the mid-1970s: cancer, Sporn contended, could (and should) be chemically stopped, slowed, or reversed in its earliest preinvasive stages.

That was it. That was the whole radical idea.

Sporn was not the first to propose such an idea. Lee Wattenberg at the University of Minnesota had suggested the strategy in 1966 to little response. But Sporn refined it, pushed it, and branded it: To distinguish such intervention from the standard form of cancer treatment, chemotherapy—a therapy that sadly comes too late for roughly a third of patients to be therapeutic—he coined the term chemopreven-

tion in 1976.

The name stuck.

On first reading, the concept might seem no more than a truism. But to grasp the importance of chemoprevention, one has first to dislodge the mind-set that has long reigned over the field of oncology: that cancer is a disease state. “One has cancer or one doesn’t.” Such a view, indeed, is central to the current practice of cancer medicine: oncologists today discover the event of cancer in a patient and respond—typically, quite urgently. This thinking is shared by patients, the FDA, drug developers, and health insurers (who decide what to pay for). This is the default view of cancer.

And, to Sporn, it is dead wrong. Cancer is not an event or a “state” of any kind. The disease does not suddenly come into being with a discovered lump on the mammogram. It does not begin with the microscopic lesion found on the chest X-ray. Nor when the physician lowers his or her voice and tells the patient, “I’m sorry. The pathology report came back positive. . . . You have cancer.”

Nor does the disease begin, says Sporn, when the medical textbooks say it does: when the first neoplastic cell breaks through the “basement membrane,” the meshwork layers of collagen and other proteins that separate compartments of bodily tissue. In such traditional thinking, it matters little whether a cell, or population of cells, has become immortalized through mutation. Or how irregular or jumbled the group might look under the microscope. Or how otherwise disturbed their genomes are. As long as none of the clones have breached the basement membrane, the pathology is not (yet) considered “cancer.”

For more than a century, this barrier has been the semantic line that separates the fearsome “invader” from the merely “abnormal.” It is the Rubicon of cancer diagnosis. From the standpoint of disease mechanics, the rationale is easy to understand, because just beyond this fibrous gateway are fast-moving channels (the blood and lymphatic vessels) that can conceivably transport a predatory cell, or cells, to any terrain in the body. Busting through the basement is therefore a seeming leap past the point of no return, a signal that a local disturbance is potentially emerging into a disseminating mob.\*

But while invasion may define so-called clinical cancer for legions of first-year medical students, it is by no means the start of the pathology. Cancer is not any one act; it is a process. It begins with the first hints of subversion in the normal differentiation of a cell—with the first disruption of communication between that cell and its immediate environment. There is, perhaps, no precise moment of conception in this regard, no universally accepted beginning—which makes delineating the process that much harder. But most, if not all, types of “cancer” have their own somewhat recognizable stages of evolution along the route to clinically apparent disease.

“Saying it’s not cancer until the cells are through the basement membrane,” says Sporn, “is like saying the barn isn’t on fire until there are bright red flames coming out of the roof. It’s absolute nonsense!”

(Sorry for that long excerpt.) I think that Dr. Sporn’s greatest contribution was to reframe cancer as a continually evolving, dynamic process — carcinogenesis — rather than an event or state of being. And it was one that, conceivably at least, we could interrupt — and interrupt earlier than at the point at which it was clinically manifested. This was distinct from early detection, which, while effective to some extent and in some cancers, was both detecting cancers too late and “catching” many lesions that weren’t likely to develop any further (or didn’t really exist to begin with), adding to the already-great cancer burden.

There was a potential, said Sporn, to intervene in a way that might stop developing cancers in their tracks, and yet would not necessarily have to add to the burden of cancer overtreatment.

As I spend most of Chapter 7 discussing, there are enormous barriers to pulling this off—and I did my best to lay out the challenges. But I do believe that this is the way to go in the end.

SR You praise Kathy Giusti for her effect on multiple myeloma research. I couldn't find the part where that research ("a worthy model for cancer research that can serve as a guidepost for the future . . . that teaches everything there is to teach about the power of collaborative science", p. 260) came up with something useful.

CL Seth, sorry this again may be me not being very clear in my writing. I apologize for that. But the lines you cite actually are intended to set up the Burkitt story in the following chapter. It was Burkitt's effort against the mysterious African lymphoma, that remains, in my view, "a worthy model for cancer research..."

SR You praise Burkitt's epidemiology. How did that epidemiology help find out that Burkitt's lymphoma responds to certain drugs? I couldn't see a connection.

CL Good question. I think Burkitt's very old-fashioned epidemiological investigation identified a widespread, terrible cancer that had been seen many times, but not noticed for what it was. It helped narrow down who was getting this cancer and—at least in a broad, geographical sense—why. But it wasn't epidemiology that helped discover that this lymphoma was responsive to certain drugs—that was trial and error. As with the case of Farber and ALL [acute lymphocytic leukemia], many today would blanch at the primitive experimental protocols that tested these toxic drugs in children. But with an extraordinarily aggressive tumor that was killing these kids in weeks, Burkitt felt he had to try *something*. Again, that's not epidemiology, but it is an understanding of the urgency of this disease that we can, perhaps, learn from.

[End of Part 1 of 2]

---

Mark (2013-08-09 07:02:18)

Seth, thanks! This is wonderful. And you've just sold one copy of this book. That said, and I'm not criticizing your reading, but I totally agree with this blurb regarding Sporn. Of course, this is out of the greater context of the book, as well, so maybe I'll be similarly concerned when I read it (I take the view that most of the preventive epidemiology stuff is pretty much bunk).

Rlen (2013-08-09 07:53:45)

Nicolas Taleb has something to say about the medical system as well in his most recent book "Antifragility". In short, he thinks that the current system does not do enough experimentation and tries to much to design a solution. This makes it open to downside (failure) but closes it to upside (unexpected discoveries). Seth: My view is the current system makes science into a job. Jobs demand steady results. There can be no taking chances, no long periods of failure. But good science – in contrast to assembly line science – demands exactly that. That is a blend of what Taleb and Leaf say.

dearieme (2013-08-09 15:53:32)

Somewhere on the web I saw words to the effect of "Cancer is a thousand diseases with a common symptom." I wish people would repeat that rather than the ludicrous "The War on Cancer". "Jobs demand steady results. There can be no taking chances, no long periods of failure." Yes, but why? Who imported this daft mindset into science? After all it's not the mindset that dominates, for example, oil exploration, where periods of failure are accepted as part of the the cost of big successes. Seth: People who aren't scientists asked for it and scientists agreed. Inherent in the notion of job is trade with people with other jobs. People with other jobs (e.g., legislators, parents, journalists, etc.) give scientists money, attention, and so on and want something in return. Such as visible progress. Scientists themselves don't point out how deeply science is screwed up by

emphasis on short-term progress (Stockholm Syndrome?), so it is unsurprising that outsiders don't see it.

## **The Truth in Small Doses: Interview with Clifton Leaf (Part 2 of 2) (2013-08-10 05:00)**

[1]Part 1 of this interview about Leaf's book *The Truth in Small Doses: Why We're Losing the War on Cancer – and How to Win It* was posted yesterday.

SR You say we should “let scientists learn as they go”. For example, reduce the need for grant proposals to require tests of hypotheses. I agree. I think most scientists know very little about how to generate plausible ideas. If they were allowed to try to do this, as you propose, they would learn how to do it. However, I failed to find evidence in your book that a “let scientists learn as they go” strategy works better (leaving aside Burkitt). Did I miss something?

CL Honestly, I don't think we know yet that such a strategy would work. What we have in the way of evidence is a historical control (to some extent, we did try this approach in pediatric cancers in the 1940s through the 1960s) and a comparator arm (the current system) that so far has been shown to be ineffective.

As I tried to show in the book, the process now isn't working. And much of what doesn't work is what we've added in the way of bad management. Start with a lengthy, arduous, grants applications process that squelches innovative ideas, that funds barely 10 percent of a highly trained corps of academic scientists and demoralizes the rest, and that rewards the same applicants (and types of proposals) over and over despite little success or accountability. This isn't the natural state of science. We BUILT that. We created it through bad management and lousy systems.

Same for where we are in drug development. We've set up clinical trials rules that force developers to spend years ramping up expensive human studies to test for statistical significance, even when the vast majority of the time, the question being asked is of little clinical significance. The human cost of this is enormous, as so many have acknowledged.

With regard to basic research, one has only to talk to young researchers (and examine the funding data) to see how badly skewed the grants process has become. As difficult (and sometimes inhospitable) as science has always been, it has never been THIS hard for a young scientist to follow up on questions that he or she thinks are important. In 1980, more than 40 percent of major research grants went to investigators under 40; today it's less than 10 percent. For anyone asking provocative, novel questions (those that the study section doesn't “already know the answer to,” as the saying goes), the odds of funding are even worse.

So, while I can't say for sure that an alternative system would be better, I believe that given the current state of affairs, taking a leap into the unknown might be worth it.

SR I came across nothing about how it was discovered that smoking causes lung cancer. Why not? I would have thought we can learn a lot from how this discovery was made.

CL I wish I had spent more time on smoking. I mention it a few times in the book. In discussing Hoffman (pg. 34, and footnote, pg. 317), I say:

He also found more evidence to support the connection of “chronic irritation” from smoking with the rise in cancers of the mouth and throat. “The relation of smoking to cancer of the buccal [oral] cavity,” he wrote, “is apparently so well established as not to admit of even a question of doubt.” (By 1931, he would draw an unequivocal link between smoking and lung cancer—a connection it would take the surgeon general an additional three decades to accept.)

And I make a few other brief allusions to smoking throughout the book. But you're right, I gave this preventable scourge short shrift. Part of why I didn't spend more time on smoking was that I felt its role in cancer was well known, and by now, well accepted. Another reason (though I won't claim it's an excusable one) is that Robert Weinberg did such a masterful job of talking about this discovery in "Racing to the Beginning of the Road," which I consider to be the single best book on cancer.

I do talk about Weinberg's book in my own, but I should have singled out his chapter on the discovery of this link (titled "Smoke and Mirrors"), which is as much a story of science as it is a story of scientific culture.

SR Overall you say little about epidemiology. You write about Burkitt but the value of his epidemiology is unclear. Epidemiology has found many times that there are big differences in cancer rates between different places (with different lifestyles). This suggests that something about lifestyle has a big effect on cancer rates. This seems to me a very useful clue about how to prevent cancer. Why do you say nothing about this line of research (lifestyle epidemiology)?

CL Seth, again, I agree. I don't spend enough time discussing the role that good epidemiology can play in cancer prevention. In truth, I had an additional chapter on the subject, which began by discussing decades of epidemiological work linking the herbicide 2-4-D with various cancers, particularly with prostate cancer in the wheat-growing states of the American west (Montana, the Dakotas and Minnesota). I ended up cutting the chapter in an effort to make the book a bit shorter (and perhaps faster). But maybe that was a mistake.

For what's it worth, I do believe that epidemiology is an extremely valuable tool for cancer prevention.

[End of Part 2 of 2]

1. <http://blog.sethroberts.net/2013/08/09/the-truth-in-small-doses-interview-with-clifton-leaf-part-1-of-2/>

---

sa (2013-08-10 14:28:42)

Regarding the "lengthy, arduous, grants applications process that squelches innovative ideas", another avenue in the future may be crowdfunding. People have been known to fund interesting ideas on Kickstarter.com, such as the Pebble smart watch and Star Citizen, the computer game, to the tune of \$10 million and \$15 million respectively, which are staggering amounts. There is a niche for someone who figures out a way to bring together people who suffer from diseases, or people just interested in donating to a specific area of research, with researchers doing innovative research in those areas. microryza.com is one website which looks like its tackling this as it lets people put their research projects up and gather funds from backers, and update them with results. There's a need for caution in this kind of crowdfunding to prevent scams etc. However its also exciting from the prospect of using the net to gather together people who, say, suffer from a particular condition and have in depth knowledge about it, to fund the scientists working on it directly.

## **Smoking and Cancer (2013-08-11 05:00)**

In his interview with me about The Truth in Small Doses ([1]Part 1, [2]Part 2), Clifton Leaf praised Racing to the Beginning of the Road (1996) by Robert Weinberg. "A masterful job . . . the single best book on cancer," wrote Leaf. In an

email, he continued:

In Chapter 3 of "Racing to the Beginning of the Road," Weinberg goes through much of the early epidemiological work linking tobacco to smoking (John Hill, Percivall Pott, Katsusaburo Yamagiwa, Richard Doll), but then focuses on the story of Ernst Wynder, who just happens to be one of Weinberg's cousins. [As a medical student, Wynder found a strong correlation between smoking and lung cancer.] Building on his own prior epidemiological work, and that of many others, Wynder actually built an experimental "smoking machine" at the Sloan-Kettering Institute in New York in the early 1950s. The machine collected the tar from cigarette smoke (and later, the condensate from the smoke) and Wynder used those to produce skin cancers in mice and rabbits. But the amazing part of the story is what happened later...with Wynder's bosses at Sloan-Kettering and with one of the legendary figures in cancer research, Clarence Cook Little. I don't want to give the story away. (If you have the time, you really would love reading the book.) But it's one of the most damning stories of scientific interference I've read.

Wynder met a lot of opposition. His superiors at Sloan-Kettering required that his papers be okayed by his boss, who disagreed with his conclusions. Clarence Cook Little, according to Weinberg, made the following arguments:

The greater rates of lung cancer in smokers only gave evidence of a correlation, but hardly proved a causal connection. One's credulity had to be strained to accept the ability of a single agent [he means smoking] to cause lung cancer along with so many other diseases including bronchitis, emphysema, coronary artery disease, and a variety of cancers of the mouth, pharynx, esophagus, bladder and kidney. After all, many of these diseases existed long before people started smoking.

A little masterpiece of foolishness . . . and more reason to never ever say correlation does not equal causation. Little was at one point [3]President of the University of Michigan. Later he worked for the tobacco industry. It wasn't just Little. Weinberg says that Wynder's colleagues complained about his "statistical analyses and experimental protocols, which they found to be less than rigorous."

Weinberg says little about epidemiology in the rest of the book – which, to be fair, is about the laboratory study of cancer. At the very end of the book, he writes:

We learned much about how cancer begins; it is no longer a mystery. We will surely learn more . . . but the major answers already rest firmly in our hands. . . . No, we have still not found the cure. But after so long, we know where to look.

The claim that "we know where to look" is not supported by examples. And Weinberg says nothing about prevention.

Weinberg's book reminded me of a new-music concert I attended at the Brooklyn Academy of Music. Hard to listen to (non-melodic, etc.) like lots of new non-popular music. I didn't enjoy it, but surely the composer did – this was fascinating. *How did it happen?* I wondered. Weinberg describes a great deal of research that has so far produced little practical benefit. Weinberg, it seems, has managed to avoid being bothered by this – if he even notices it. How did this happen?

I don't think it's "bad" or wrong or undesirable to do science with no practical benefit, just as I don't complain about "unlistenable" music. Plenty of "useless" science has ultimately proved useful, but the transition from useless to useful can take hundreds of years, which is why there must be "scaffolding," sources of support other than practicality.

This is why scientists use the word *elegant* so much. Their enjoyment of "elegance" is scaffolding. Long before "useless" science, there was "useless" decoration (and nowadays there is "unlistenable" music). Thorstein Veblen showed no sign of understanding that the "waste" he mocked made possible exploration of the unknown, which is necessary for progress. (By supporting artisans, such as the artisans who make decorations, we support their research.) What is undesirable is when someone (like Wynder) manages to do something useful, to foolishly criticize it, as Little and Wynder's colleagues did.

## **"Hunger is a Necessary Nutrient" (Ancestral Health Symposium 2013) (2013-08-16 03:49)**

Nassim Taleb said this or something close to it on the first day of the Ancestral Health Symposium in Atlanta, which was yesterday. Danielle Fong told me something similar last week: We should use all of our metabolic pathways. Of course it is hard to know what metabolic pathways you are using. In contrast, Taleb's point – not original with him, but a new way (at least to me) of summarizing research – is easily applied.

What I know overwhelmingly supports Taleb's point. 1. When I did the Shangri-La Diet the first time, I was stunned how little hunger I felt. This wasn't bad – presumably my set point had been too high, lack of hunger reflected the dropping set point, it was good to know how to lower the set point – but it was dreary, not feeling hunger. It was as if life had gone from color to black and white. Something was missing. 2. Data supporting the health benefits of intermittent fasting, which produces more hunger than the control condition. 3. [1]The experience of my friend who had great benefits from alternate-day fasting. He told me he had never felt hunger before, at least of that magnitude. A great increase in hunger, in other words, happened at exactly the same time as a great improvement in health.

Obviously Taleb is talking about hunger caused by lack of food, rather than hunger caused by learned association (if you eat at noon every day you will become hungry at noon, if you eat every time you enter Store X, you will be come hungry when you enter Store X, the existence of this effect is why they are called appetizers). The Shangri-La Diet reduces your set point but only if your set point controls when/how much you eat is this going to make a difference. So to lose weight you need to do two things: 1. Lower your set point. 2. Lower your weight to your set point. While SLD certainly does #1, it does not do #2. You can make sure your weight is near your set point if you feel strong hunger if you don't eat for a while.

Taleb's comment suggests focussing on the outcome of fasting, rather than on its duration or frequency. Instead of fasting every other day (or whatever), fast until you feel strong hunger. How often you need to do this, how strong the hunger should be, are questions to answer via trial and error.

1. <http://blog.sethroberts.net/2013/07/28/effect-of-alternate-day-fasting-on-a-friend/>

---

Charlie (2013-08-16 08:49:34)

"Hunger is a necessary nutrient." "...fast until you feel strong hunger." Life is simple...so many try to make it complicated. Complication is profitable to those who create the complication. KISS (keep it simple stupid) was quite popular for a while...no profit there...so it has been discarded. Thanks Seth... Cheers

Morex (2013-08-16 09:08:59)

I get the point of this post, but at least for me at this time, things are a little different. Under SLD I have no problem feeling no hunger at all. As a matter of fact, it's liberating. I spent too many years being slave to never ending hunger, that SLD is breathing room. I stopped having oil about 2 months ago, but appetite suppression is still very strong. I'm in control of what I eat and much more mindful of the times I HAVE to eat to keep going. This allows me room to focus on other things in life. I have been experimenting with intermittent fasting these past weeks and it's really nice not to be hungry like hell while doing it.

Alex Chernavsky (2013-08-16 12:09:53)

So besides hunger, what of other "metabolic pathways" – thirst, lust, sleepiness, desire for companionship, etc.? Should we use those, as well?

fi (2013-08-16 15:02:04)

Seth, could you explain how a changing set point works when dieting? I am also doing the alternate day diet and have experienced some fasting days with little or no hunger and then some fasting days with extreme hunger. I have also found that weight loss is not linear, rather, at least lately, it comes in sudden several pound drops along with multiple days of no weight loss at all, or rarely mild gains, despite following the same daily alternating fast/eat pattern. I assumed it was water weight, weight of food eaten the previous day etc, but I don't think that can fully explain it. What causes set point to lower and how long does that process take? Thanks. Seth: Your set point will go down when you reduce the strength of smell-calorie associations in what you eat – that is my short and possibly incomprehensible explanation. For a longer explanation, please see The Shangri-La Diet. Your setpoint is always changing, at least according to my theory, sometimes going up, sometimes going down. When the downs outweigh the ups, the overall trend is down. I don't worry about the day to day stuff, I cannot explain it. It is the week by week trends that matter.

Brock in HK (2013-08-17 01:30:19)

Ironically, NNT also said that you can provide confirmatory quotes from authorities supporting both sides of any position, which makes the proposition of quoting him as an authority on something quite "meta". That doesn't mean that his quote is wrong, only that just because he said it doesn't make it true. Fortunately, you provide some data points from which to draw some inferences, rather than just relying on his quote. The joys of NNT! He makes thinking about most things more interesting. Seth: There's a lot of data supporting what he said, he is far from the first person to say it. He just said it the best.

Tom (2013-08-17 13:23:22)

So many Americans today don't know what hunger actually is. The processed food supply is designed to raise the set point and create hunger rather than to satiate. It's like we're all drinking salt water to quench our thirst. From my experience fasting when you are above your set point feels good. Your body is trying to get your weight down to the set point weight. When I break a fast with the lower set point I become extremely satisfied from a healthy meal that might be only 300-400 calories. That's after going most of the day on very little calories. It's like your body forgets what food is.

Adam (2013-08-17 17:36:36)

I've found a hard weightlifting workout in the evening will make me ravenously hungry the next morning. Since I only lift every other day, I tend to eat breakfast every other day as well.

v (2013-08-19 05:17:04)

NNT talks about the importance of variability within a certain range (ala his comment about being exposed to differing temperatures). he left out a key point which is corollary to this: knowing what your range of variability is, is not always obvious, and you can hurt yourself seriously by going over your range. for example, I believe that NNT suffered significant injuries from over-exercising. on the de vany site, there was discussion over my head about 'signal to noise' ratio and how going over a certain range created too much 'noise'. also, de vany himself has exercised over his range as now at around 75 he had to get a knee and hip replacement. I have had problems finding a proper range of carbs. I did not know I was glucose intolerant until recently, as my weight, A1c, and fasting glucose were all within normal levels. it was only when my husband bought a glucose meter and I started testing my post prandial blood sugar for fun that I realized my blood sugar rises to diabetic levels eating a bagel or a bowl of oatmeal or lots of blueberries. testing using 23andme revealed my beta cells do not produce enough insulin early on (phase 1 response). I may already have some damage as I have intermittent tingling on the soles of my feet, gum recession, etc, all of which are associated (not exclusively) with high blood sugar. both my parents have diabetes. at this point I control my blood sugar by eating a stricter form of paleo which involves no fruit (except when temptation overcomes me), and I stop eating at least 5 hours before bed whereas I used to snack a lot before bed time. so range of variability is an important topic that I hope we can address in more detail.

v (2013-08-19 05:30:36)

I forgot to mention that I have been paleo since 2009, but was eating an looser version (basically fruit whenever I wanted). after 3 months of paleo, I had lost 15 % of my body weight, which I have maintained until now. however, after the first year, my A1c went from 5.9 to 5.6. I expected a bigger drop having cut out milk, grains, legumes, and all junk food. I have recently become stricter with my carb intake, and my A1c is 5.3, although my weight is basically the same. so weigh loss does not track directly with improvements in blood sugar levels. I wonder how many others eating paleo may have undiscovered glucose intolerance. my heuristic is if someone in your family has diabetes, buy a cheap meter from Wal-Mart and start testing you 1 and 2 hour post prandial blood sugar levels. at 1 hour, blood sugar must be below 140 at a bare minimum. I believe the national group of American endocrinologists (I forget the official name) says post prandial blood sugar should be below 140 at all times, as being at 140 and above for extended periods leads to organ damage. i think fasting blood sugar needs to be under 100 at a bare minimum.

### **Correlation of Body and Soul (Ancestral Health Symposium 2013) (2013-08-17 05:00)**

Geoffrey Miller, speaking at the Ancestral Health Symposium, said that every mental disorder impairs your sense of humor, so sense of humor is a good marker for overall brain function. It's a fascinating point: what is the evolutionary reason that humor exists? Miller says it helps in mate choice. We select people in many ways (spouse, lover, business partner, friend, student, teacher, etc.). Maybe sense of humor is a general signal of health.

At the first Ancestral Health Symposium, Tucker Max noted that the attendees looked much better – healthier – than usual. It was a good point. Almost no one was fat, for example. And a large fraction of them became interested in paleo because of their own poor health, which paleo helped with. At this year's symposium, I've noticed that the attendees strike me as in unusually good mental health, in the sense that I find everyone easy to talk to. For example, I had an interesting talk with a woman about "unschooling". (I realized from what she said that non-traditional schooling is close to common sense when it is done with kids who are doing badly in school Why repeat what isn't working? My experience suggests it also helps kids who have done well in school. Where it is non-intuitive. If something is working, why change it?) Likewise, all of the questions after talks are polite, none are too long, none are grandstanding.

---

none (2013-08-17 07:39:28)

Actually, I don't agree with the premise. One person comes to mind: Woody Allen.

dearieme (2013-08-17 11:44:51)

There's a question I've wondered about since childhood. How does one know that a joke has been made even if one has not seen the joke? By "one" I mean an ordinary, well-adjusted person. Would the same question be valid for a psychopath?

BenSix (2013-08-18 04:14:48)

"Actually, I don't agree with the premise. One person comes to mind: Woody Allen." Humour is a good sign of *intelligence*, perhaps, but not of emotional stability. One could add Peter Sellers, Spike Milligan, Peter Cook, Lenny Bruce, Richard Prior, Rodney Dangerfield, Tony Hancock and Kenneth Williams, and that's just a drop in an ocean of misery.

Kas Thomas (2013-08-21 10:58:15)

Some of the best comedians are seriously disturbed individuals. (I feel certain this has been the subject of many a suitably boring Ph.D. thesis.) Nevertheless, studies have shown that women do seek a "good sense of humor" in mates, so there is both reproductive and survival value, I think, in one's ability to find humor in things. It's a tricky area, though. Finding inappropriate humor in things is not unknown in schizophrenia. Norman Cousins famously tried to tie sense-of-humor to reduced mortality. It would be interesting to know if any recent work has been done in this area. Sounds like a great area for future blogs.

Sylvie- Hollywoodhomestead.com (2013-08-27 11:01:20)

Nice chatting with you at AHS Seth! You might be interested in this post I wrote about unschooling: <http://www.hollywoodhomestead.com/what-is-unschooling/>

### **Unhelpful Answers (Ancestral Health Symposium 2013) (2013-08-18 05:00)**

At the Ancestral Health Symposium, I went to a talk about food and the brain, a great interest of mine. The speaker said that flaxseed oil was ineffective because only a small fraction (5 %) gets converted into DHA – a common claim.

During the question period, I objected.

Seth I found that after I ate some flaxseed oil capsules, my balance improved. Apparently flaxseed oil improved my brain function. This disagrees with what you said.

Speaker Everyone's different.

A man in the audience said what I observed might have been a placebo effect. I said that couldn't be true because the effect was a surprise. He disagreed. (The next day, in the lunch line, he spoke to a friend about getting in a kerfuffle with "an emeritus professor who wasn't used to being disagreed with.") I spoke to the speaker again:

Seth Is it possible that flaxseed oil is converted to DHA at a higher rate than you said?

Speaker Anything's possible.

This reminded me of a public lecture by Danny Kahneman at UC Berkeley. During the question period, a man, who appeared to have some kind of impairment, asked a question that was hard to understand. Kahneman gave a very brief answer, something like "No."

Afterwards, a woman came over to me. Maybe flaxseed oil reduced inflammation, she said. Given that the brain is very high in omega-3, and so is flaxseed oil, this struck me as unlikely. I said I didn't like how my question had been answered. I've been there, she said. Other members of her family were doctors, she said. She would object to what they said and they would respond in a dismissive way.

The speaker is/was a doctor. Her talk consisted of repeating what she had read, apparently. The possibility that something she read was wrong . . . well, anything's possible.

---

dearieme (2013-08-18 05:04:33)

"Everyone's different." "Anything's possible." What a convenient philosophy. Mind you, the Second Law of Thermodynamics rules out the second one. Seth: I could have said "If everyone's different, why do you believe what you just told us will help anyone?"

Rachael (2013-08-18 06:16:11)

Both of those answers were dodges to avoid engaging with you. It was very dismissive and unhelpful.

LemmusLemmus (2013-08-18 07:00:36)

"Anything's possible" seems like the perfect answer to questions that start with "Is it possible that . . ." Questions like that should be forbidden.

Alex Chernavsky (2013-08-18 07:39:51)

Any sort of gathering tends to include at least one abrasive, opinionated loud-mouth.

None (2013-08-18 10:20:28)

But both could be right. Let's pretend for a second that the speaker was talking about the results of a carefully done experiment. The outcome of the experiment applies \*on average\*. We rely on groups being comparable (exchangeable, conditionally independent from potential outcomes, etc) when making inferences about treatment effects. However, person i, let's call him Seth, may very well react completely different than person j. Yes, anything is possible but the experiment demonstrated that on average some stuff is more possible than other. An experiment is not answering the question of what is the causal effect for i or j or any of the persons individually. Treatment heterogeneity is an important aspect of experiments. Seth: I wouldn't say "both could be right". She said that flaxseed oil was a poor way to get omega-3 to the brain. I found it worked fine. I believe flaxseed oil is better than fish oil because it produces a steadier flow of long-chain omega-3. The short-chain omega-3 in flaxseed oil is slowly converted to long-chain omega-3. whereas the long-chain omega-3 in fish oil produces a spike in long-chain omega-3. That spike might be why fish oil gave me a headache the one time I tried it.

Alex Chernavsky (2013-08-18 16:29:23)

When I started taking flaxseed oil, it gave me headaches for the first couple of weeks. I was almost going to discontinue taking it. The headaches went away, but I still get indigestion from it once every ten days or so.

Jonathan Shewchuk (2013-08-18 21:13:00)

Seth, I guess you haven't done the experiment to see if DHA would improve your balance equally much as flaxseed oil? It would be interesting to know. If you could do it without getting headaches. Metacomment: I sense that most medical scientists are in denial about how difficult and complex their own fields are. They are deeply invested in there being easily discoverable, clearcut answers, and they greatly underestimate how little they know and how complicated the real answers are. (It's not hard to understand why a career in science might ultimately make a person delude themselves this way.)

Sam (2013-08-18 23:38:40)

I wonder if you might have gotten better reactions if you used questions instead of claims (both for the speaker as for the placebo-man). To ask them how their explanation fits into your results. For the speaker even simple questions like "How have you verified that Flaxseed oil is useless (or is this just a theoretical opinion)?" might work.

v (2013-08-19 05:00:55)

fish oil makes my already heavy periods even heavier. for that reason, I cannot take it. ground flax seed does not have that affect on my periods. is this because the concentration of omega 3s in the ground flaxseed that my body absorbs is much less than that of the fish oil? it is a possibility.

Dr. Dumbfounded (2013-08-19 10:03:03)

I imagine that at least some of the following probably went through the speaker's head after your question: 1. How exactly did you conclude your "balance" was better? Is this something you test in some consistent manner every morning? With as nebulous a term as "balance", an operational definition is a must, particularly when presenting the subject in a scientific forum. 2. How do you know it was the flax seed oil? Is every day of your life completely identical so that the only variable that changed was the consumption of the oil the night before? In a similar vein, since you had no expectation of any effect on your balance (as per your "refutation" of a placebo effect), I think we can safely conclude this wasn't a prospective trial, but a retrospective review of your prior day's activities. Why on earth did you single out the flax seed oil as the cause of your improvement??? This is one of the main reasons retrospective analyses are considered low quality evidence. Your sample size of 1 doesn't help the case much either I'm afraid. Do you understand the purpose of controlled experiments? 3. Balance is a widely distributed function and is dependent on the integrity of multiple bodily systems (musculoskeletal, muscle spindle, peripheral nerves, inner ear/semicircular canals, cardiovascular, vestibulocochlear nerve, vestibular nucleus, visual system, etc.), not all of which exist in the brain. Thus, "improved balance" does in no way equate to "improved brain function" (once again, "brain function" is a bit nebulous a term for an academic venue). In clinical practice, the most common causes of balance disruption are related to hypovolemia, inner ear disorders, and peripheral neuropathy, none of which are "brain functions." 4. Even if your balance did improve, and even if we were to concede (quite charitably!) that it was related to the flax seed oil you consumed the night before, why would we automatically conclude that conversion of flax seed oil to DHA was the responsible mechanism??? 5. Are you high? Did those words really just come out of your mouth?! Who let you in here??? And on and on and on.... Suffice to say that there are many many layers of problems with your statement. And taken apart, the odds that the sentence "my balance was better one morning due to consumption of flax seed oil the night prior thanks to enhanced production of DHA" is true is roughly 86 gazillion to one. Hence the response "anything's possible." I think you owe her a huge thank you. Seth: I carefully measured my balance. I carefully confirmed that flaxseed oil was the cause of the improvement. I found that flaxseed oil improved other measures of brain function. As for whether conversion of the omega-3 in flaxseed to DHA was responsible, can you propose a plausible alternative? When your patients or friends or family say something that disagrees with what you believe, how do you respond?

john (2013-08-19 14:04:57)

And there has been some discussion about the oxidation potential of some fish oils, pre-capsulation, in the factories, whereas flax seed oil can be ground and consumed quickly under the recipients control.

JeffR (2013-08-20 15:23:03)

Dr. Dumbfounded makes many great points and I would hope Seth would think more fully about this.

Erik (2013-08-23 21:26:18)

I used to have horrible earwax problems. My ears would clog up and I couldn't hear. I read on the internet somewhere that omega-3 could help. I took some capsules of fish oil, and it went to work immediately. I could actually hear my ears unclogging. I wasn't testing my balance at the time, but I'm certain that if I was, it would have improved dramatically. Since then, I lost a lot of weight and I don't have the earwax problems anymore. I believe this is in part due to reduced inflammation, and eating more nutrient-dense foods. Anyway, it seems likely that several of the answers you've received might be on to something. It very well could be that the flax seed oil is anti-inflammatory and improved your balance by opening up your ear canals. If that's true, it's also possible that it opened up other tubes in your body, such as the blood vessels in your brain. So it might have led to improved brain function, and it might have led to better balance, but the fact that you had better balance might not be due specifically to better brain function. I do believe that your general question is valid. There are millions of healthy, intelligent human beings on the planet who have never let an oily fish get anywhere near their mouth. So, while oily fish might be a

very concentrated source of omega-3, it's certainly possible or even likely that the body can get sufficient amounts by other means. Personally, I sense that sometimes, your body is better off with a less potent form of a nutrient. Polar Bear liver, for example, is such a potent source of vitamin A that eating it can kill you. The vitamin A found in vegetables, on the other hand, is weaker, less potent. Your body has to convert it to a usable form. So, it probably takes what it actually needs and ditches the rest.

Dallas Hartwig (2013-08-25 08:56:13)

I happened to attend the presentation you are referring to, and heard both your questions and the responses offered. I actually thought that the speaker did an excellent job of responding to your personal experience, given that it seems, at least at first, to disagree with much of what the current published research would suggest about the usefulness of flaxseed as an omega-3 source. The speaker could not discount your personal experience, and was not the one that suggested that your experience may have been placebo-influenced (that was a loudmouthed attendee). The speaker, instead, chose to acknowledge your experience, but was unwilling to pit your personal experience against the majority of the published research in a fight to the death, a decision that I respect and appreciate. As the speaker noted, there can be a large degree of interindividual variability, and your experience does not invalidate the published data, nor vice versa. By phrasing your question in the "is it possible?" format, the speaker had two possible answers: yes or no. If she chose no, she'd be invalidating your perspective and shrugging off n=1 data as well as speaking with an unwarranted scientific hubris, which I suspect we all would be disappointed with as a response. If the speaker said yes, which they did, they were simply acknowledging that your personal experience AND the published data could be correct, as they are not mutually exclusive and may share a common mechanism other than just EPA and DHA concentration at the cell membrane level. I respect the answer supplied, and wonder what possible response would have pleased you more. Seth: When I said "is it possible that . . . " I meant "what about the possibility that . . . " That the speaker would take the question literally did not occur to me. If the speaker had tried to be helpful in her answer, that would have pleased me more. For example, she could have explained the basis for what she'd said. Why she believes it.

JohnG (2013-09-10 08:17:28)

I've noticed this effect in many areas of scientific investigation (nutrition, global warming, etc). Perhaps this phenomenon is caused by a natural human trait to strive to understand and categorize something unexplained. Then, once what was a mystery is first categorized by someone (whether that categorization is correct or not), it is no where near as fun to attempt to duplicate/reaffirm/confirm that categorization than it is to come up with a whole new categorization. So, that first categorization is just left unconfirmed and is just used by others in attempting to find other new categorizations. Just a crazy thought :)

## **Economic Stagnation and Recent College Graduates (2013-08-19 05:00)**

In [1]an excellent article about the college-loan "bubble" – the government has made it easy for students to get loans that a large fraction of them will repay only with great difficulty – Matt Taibbi writes:

We're doing the worst thing people can do: lying to our young. Nobody, not even this president, who was swept to victory in large part by the raw enthusiasm of college kids, has the stones to tell the truth: that a lot of them will end up being pawns in a predatory con game designed to extract the equivalent of home-mortgage commitment from 17-year-olds dreaming of impossible careers as nautical archaeologists or orchestra conductors.

I agree with Taibbi's big point – college students are being very badly treated – but I would summarize it differently. The worst thing older people can do to young people is construct an economy that has no place for them. Humans are the only animal that specializes. We learn a specialized skill and use it throughout our life to make a living. Not allowing someone to do this is not allowing them to be human.

Due to lack of innovation, too few jobs are being created. New jobs in new industries doing new things are jobs for which young people are especially well-suited. The problem with stagnation – stagnation in new goods and services – is (a) problems stack up unsolved and (b) jobs especially suitable for recent entrants to the job market aren't created.

Failing to provide college students decent jobs is Horrible Thing #1. Burdening them with a great deal of debt before they enter a stagnant economy is Horrible Thing #2. I have [2]blogged many times about Horrible Thing #3: Not helping students learn and develop their individual skills.

---

dearieme (2013-08-19 05:20:26)

"We're doing the worst thing people can do: lying to our young." Golly, he can't know much about history if he thinks that's the worst people can do.

Tom (2013-08-19 10:38:04)

The quote is valid read in the context of the article, which is available free.

Christopher Burd (2013-08-19 12:12:18)

Presumably a large portion of these loans will never be repaid, despite the absurd regulation that prevents education debt from being discharged through bankruptcy. An intelligent government would be planning to wind them down in an orderly way, while also correcting the misallocation of resources in (and, possibly, to) the education sector.

Alex Chernavsky (2013-08-19 12:57:44)

This article says that 514 schools have default rates that are higher than their graduation rates: <http://www.takepart.com/article/2013/07/08/student-loan-default-rates-rise-graduation-rates> This article from *The Atlantic* cites government figures to claim that the overall default rate on federal student loans is currently 12.8 %, although a much higher percentage of borrowers are in deferment or forbearance. <http://www.theatlantic.com/business/archive/2013/08/our-student-loan-system-is-broken-and-these-new-statistics-prove-it/278453/>

dearieme (2013-08-19 15:36:45)

"The quote is valid read in the context of the article": do you mean that the article is hysterical and hyperbolic and the quotation is in line with that? It always seems to me a kind of intellectual bad manners to rant and rave about a serious problem that needs calm analysis. Still, I suppose there's a living in it.

Tom (2013-08-19 15:56:21)

I actually agree with Seth that the article is excellent. In any event, Matt Taibbi's career has gone pretty well so far.

Craig (2013-08-19 18:43:16)

I'm not sure how we go about providing college students with jobs. Scott Sumner would emphasize stable NGDP growth, and I agree, but I don't think that is what Seth is talking about. What jobs develop seems to me a pretty emergent property, rather resistant to design from above. There is a lack of feedback in our current system. See Bryan Caplan Launching the Innovation Renaissance [by Alex Tabarrok] (STEM majors haven't increased in 20 years, but Psychology majors have increased tremendously). Still my biggest issue is that I'm not sure how we are supposed to create jobs for graduates. Software and

globalization have eliminated many of the jobs that used to need an intelligent, generally educated person. Seth: You create good jobs for recent college graduates by innovation – creation of new goods and services and new ways of providing old goods and services. The world has plenty of problems to solve. For example, two recent college graduates have started a company that produces biodegradable replacements for styrofoam.

Michael (2013-08-20 05:53:11)

I agree with a lot of the sentiment here but I would say horrible thing no1 is neoliberal capitalism (possibly capitalism in general). When capitalism enshrines profit making as a priority (not job creation or innovation), and innovation isn't really being piqued by capitalism (instead sabotage of human industry, potential is), what happens is less jobs are created, and we see the sort of thing that is happening in the US re tertiary students now. Arguably we don't need new goods and services'. Infinite growth/ the endless pursuit of 'innovation (innovative ways to rationalise to increase rates of profit in times of increasing resource scarcity) aren't necessarily needed. Why can't uncertainty be embraced, not pushed away in discomfort because we focus on endless 'progression' to ever greater ways of profit making and limiting people's potential... Seth: "why can't uncertainty be embraced" – such as uncertainty whether your child will get autism? I don't agree. I agree that new goods and services are not all we need to solve existing problems.

Melissa (2013-08-20 06:44:56)

Matt Tiabbi did a tremendous job exposing the sickening truth about our largest banking institutions during the financial crisis, and I welcome him tackling student debt. The time for calm analysis in this country has come and gone. Considering the fact that what passes for journalism in this country is a mixture of lies, equivocation, and propaganda, I think Tiabbi's unique style is refreshing while being extremely informative. His research is impeccable, and he does an excellent job putting the puzzle pieces together for the masses. Intellectual bad manners? Try being a new graduate with student debt and no prospects, and maybe you will be thankful for the journalist willing to employ some hyperbole and hysteria in exposing how this country treats it's youth. Having a son who graduated in 2009 (magna cum laude from an excellent institution) I can't even begin to tell you how emotionally wrenching it is to realize that no one will give you a chance because you have no experience. The amount of wasted human capital out there is staggering, and the fact that our government does nothing to correct it while profiting off of it is obscene.

Evelyn M. (2013-08-20 21:54:33)

As an old fogey, it seems to me that some chickens have come home to roost. I recall an eminent economist speaking out of turn at the time when vast numbers of women were entering the workforce in this country in the 1970s and 80s. I asked him where all these jobs had come from and what effect this fundamental change in the job market would have. He reminded me of the law of supply and demand, saying that the eager new workers were willing to take much lower salaries than men, so men's salaries had already stagnated. Indeed, he said, the future appeared grim for men who expected that they would be the sole breadwinners for their families, and that eventually women, too, would begin to realize that with the cost of childcare and housecleaning services, the additional wages they were bringing to the family were not really very much. I believe we've all seen that work out as he predicted. And of course the law of supply and demand applies to educational degrees as well. If only five percent of 25 year-olds have college degrees, having such a degree has meaning, if 95 percent hold such a diploma, it is virtually meaningless. Add to that the loss of jobs as the economy changed from manufacturing to service - with many people thrown out of work as factories closed and automation increased - and it seems to me that were we to return to the pre-1970 norm of one breadwinner per family there would be virtually no unemployment. What we have today are more than two people applying for each job available. It would be a wrenching experience to revert to what used to be the norm, but facing reality is better than denying it. And I'm not saying that in every case it would be the mother that would stay at home - we have learned that some women are excellent professionals - and if so then their husbands could manage the household and children, and look for a part-time position. And think, if we could return to a situation in which most children were raised in intact families, with one parent being a mainstay in the home, how much happier our children would be. . . But, such are the musings of an old fogey sitting at her computer. Seth: I agree with you. The change is already happening in an unanticipated way: Many people work from home. And more people are self-employed. Those are jobs halfway between homemaker and company man.

Arndt (2013-09-06 11:03:53)

College students have already spent 10 years in public schools, isn't it enough time to find out your talents? Public school seems like a big failure, college even more. Get a job, get payed for learning skills and finding out your vocation and go to university only if unavoidable for your profession and if you know exactly what you want to get out of you studies. In the end capitalism is not about profits or the economy but about a moral philosophy, that one do not initiate force against a person and his property and that producer and consumer can exchange freely goods and services. Capitalism does not care if you make a profit on your ventures, but most producers do as if you put more resource in your production than you get out you end up broke. Innovation is only beneficial if it reduces cost (consumption of resources), increases the benefit of produces or satisfy new needs. The problem in the west is over consumption, we consume more than we produce and financed it with dept. This dept can't be repayed unless people reduce their lifestyle and produce more and start saving.

## **Women and Body Fat (Ancestral Health Symposium 2013) (2013-08-20 05:00)**

One of the best talks at the 2013 Ancestral Health Symposium was by Will Lassek, a retired doctor. Here's the abstract:

One puzzle is why human males have such a strong preference for women with hourglass figures and low weights that can compromise fertility. The second is why slender young women typically have about one third of their weight in body fat, more than bears starting to hibernate, and why human infants are also very fat. Finally, why do women typically gain another twenty pounds or more during their reproductive years? The answer may lie in the roles that fat plays in providing essential fatty acids needed for the growth of a very large brain and in regulating overall fetal growth.

His answer to the first question was that death during childbirth was a serious danger. Women of lower weight give birth to babies with smaller heads – less likely to cause death. Wider hips means a larger birth canal. Women gain weight after their first birth because their birth canal is wider – the optimal baby size has gone up. A variety of data supported these ideas. Lessek's answer to the first question is quite different than [1]what evolutionary psychologists have said.

1. <http://www.ncbi.nlm.nih.gov/pubmed/16818094>

---

dearieme (2013-08-20 05:35:45)

"One puzzle is why human males have such a strong preference for women with hourglass figures and low weights that can compromise fertility." Does he assume that this is a long-standing preference or does he view it as a fashion for the last century or so?

dearieme (2013-08-20 05:37:48)

Actually, reflecting on the slender-to-the-point-of-anorexia models of the present, maybe I should be asking whether the hourglass figure has gone out of fashion in the last few decades.

RAD (2013-08-20 07:26:11)

None of the discussion addresses the question "why human infants are also fat". Was it addressed in the talk? I'd also like to add that the human male preference for an hourglass figure may be independent of the reproductive benefits. The hourglass figure may be a signal of femaleness. As a counter example, human males may have a preference for narrower jaws as a

signal of femaleness and jaw width is probably independent of reproductive health. Seth: The "sign of femaleness" idea is interesting. There is also a preference for neoteny which leads to curious correlations. For example, female models have unusually baby-like faces.

Paleophil (2013-08-20 17:40:39)

"One puzzle is why human males have such a strong preference for women with hourglass figures and low weights that can compromise fertility." It has not always been so and even today is not so everywhere: > Stone Age female (possible fertility) "Venus figurines" are mostly "obese" (for example, see the famous Venus of Willendorf) > female steatopygia was traditionally valued by African Bushmen (fka "Hottentots") and is similar to the aforementioned figurines, though not quite the same > ancient fertility goddess images were usually "fat" > there are/were traditional bride fattening practices and/or male preferences for "thicker" women in traditional societies in Africa, the Caribbean, and among African Americans, Hispanics, and perhaps others > Research suggests that skinniness is overrated, healthwise, and body fat excessively demonized: "Overweight people 'live longer' study claims," <http://www.nursingtimes.net/nursing-practice/clinical-zones/public-health/overweight-people-live-longer-study-claims/5053341.article> > there is a human bias to assume that what is prevalent today has always been so and is perfectly natural, and it is often wrong "Those who have big legs and fat body, like arms too..., they look pretty when they wear grass skirts." - Kitavan woman, Tribal Wives Kitava television show, <http://www.youtube.com/watch?v=OPfeXlwFW Rg> "I don't want no woman with no skinny legs" - Joe Tex

Paleophil (2013-08-21 04:29:20)

The Dr.'s name is spelled Lassek, for those interested in Googling him. He said "If you really want a low waist-hip ratio, you almost have to be skinny." <http://www.pghcitypaper.com/pittsburgh/a-conversation-with-william-lassek/Content?oid=1339427> That may be overemphasizing thinness. Groups in which women's hips are naturally larger could have larger waists and achieve the same ratio and healthy body fat deposition to the hips and buttocks is another factor, not just thinness. I recall reading in the past that male preferences in at least one study were less about a small waist or thinness than waist/hip ratio at any body weight. Women were still seen as attractive even if they had larger waists as long as the preferred ratio was there. Also, there is apparently conflicting evidence even on WHR: <http://psychsciencenotes.blogspot.com/2010/09/brief-rant-about-waist-to-hip-ratio.html> Wouldn't smaller heads also mean smaller brains and be a somewhat offsetting evolutionary disadvantage? Seth: Thanks for the correction. Heads grow. A smaller head in the beginning implies a smaller head only for a period of time. But, yeah, there are certainly trade-offs.

Mariana (2013-08-21 19:49:10)

Have you noticed how the answer is not an answer at all? If indeed there is a good reason for why women are fatter (and isn't there always?) then why do men find it unattractive? My personal guess is that a strong torso usually means a strong body all over, and that having hard abs and all over strength are more common among people who are less fat and more active. When you're healthy and energetic - and fertile - you don't want to stay put in a chair doing nothing all day, getting fatter and weaker. Back in the days when even great beauties were fatter than today's top models those same beauties also wore quite tight corsets that artificially emulate the look of a strong torso: straight back, narrow waist, flat stomach.

Evelyn M. (2013-08-22 06:11:16)

Very thin women, due to anorexia, starvation, or excessive exercise, lose the ability to menstruate and thus become infertile. Our bodies are smarter than we are, therefore men who listen to their bodies gravitate toward women with a reasonable amount of fat deposits in their breasts and hips.

## First Effects of Intermittent Fasting (2013-08-21 05:00)

Jeff Winkler described his first weeks of intermittent fasting:

Annual physical July 2nd [2013], HDL 46, cholesterol 243, LDL 177. Doc pushing for statins. I've been taking 5000 IU D3, some zinc, eating vaguely low carb. Had a kid a couple years ago. Watched Eat Fast, Live Longer. Was blown away.

Decided to try intermittent fasting and use \$500 USB ultrasound device ([1]BodyMetrix) for feedback. Conclusions after three weeks:

- It's not hard. I'm eating within an 8-hour window. Usually try to eat first food at 9 AM, close the window 8 hours after. I'm hardly ever hungry. Now it's like "oh, it's 9, guess I should eat". I'm not eating specially or restricting my intake.
- Losing weight. About 237->231 in 20 days.

For me, the novelty was his BodyMetrix data (mm of subcutaneous fat). Here it is:

[2]  This shows fat loss from the thigh and waist; the chest measurements vary too much to see a trend. The BodyMetrix data and the weight data (237->231) confirm each other. He also used an Omron measurement device that uses impedance to measure body fat. You hold it in your hands. Its data were too noisy to conclude anything. All in all, Winkler's scale did a good job of detecting weight loss, the BodyMetrix device added a bit (confirmed the weight loss was due at least partly to fat loss), and the Omron device added nothing. The BodyMetrix device is advertised with the claim "no embarrassing pinching" but I'm sure pinching (with calipers) to measure skinfold thickness would have been more accurate.

2. <http://blog.sethroberts.net/wp-content/uploads/2013/08/winkler.png>

---

Sentinel (2013-08-21 09:41:16)

Seth, what happened to the very interesting links you had posted this AM (re kvas, teetotaling, etc.)? Seth: I posted them too early. They will re-appear tomorrow.

Greg (2013-08-25 05:51:34)

Wow! I'm fascinated by the BodyMetrix device. It looks like it can also do 2D imaging. Have you played around with that? I also wonder if it can do any sort of cardiovascular imaging (e.g. heart or carotid arteries). I'm guessing they are not FDA approved for that and therefore can't talk about it. BodyMetrix says the device can distinguish between superficial and deep visceral fat. Have you looked into that? It would be very nice to see whether different diets favor loss of one vs. the other. Seth: I've never used BodyMetrix device. This data does not make me want to, either

Jeff Winkler (2013-08-27 14:19:00)

Have not tried reading the scans, but you could... example images at <http://www.fitnessassist.com/blog/bodymetrix-ultrasound-body-composition/>. I've been using waist measurement as a proxy for visceral fat. This fellow - <http://bjorngranum.com/intermittent-fasting-end-of-20-day-challenge-with-measurements-and-summary> (a trainer) gets more consistent results than I... see the video @3:57; very little variation. I'm sure there's a practice effect with either calipers or the bodymetrix. Not so simple as stepping on a scale.

### Assorted Links (2013-08-22 05:00)

- [1]The increasing popularity of kvas. "We ferment with ginger and, I believe, longer than other people - for seven to 10 days."

- [2]Giving up wine (and other alcohol) for a month. Before this he drank 2 glasses of wine/day.
- [3]Wellness Mart (in California) makes it easy to get basic medical tests. " In California, you are required to have an order from a doctor for blood tests, but WellnessMart, MD stores all have medical doctors on staff. Our doctors allow their license to be used for basic screening tests because there are some things that really shouldn't be that difficult to find out.

If you don't have a doctor's order and you want to run tests that aren't a part of our standard screening packages, you will be charged a MD Consultation Fee of \$25. Our doctor will help you to put together a panel that will accomplish the goals you are looking to accomplish. If the doctor determines that it is not appropriate for you to run the tests you want to run at WellnessMart, MD there will be no charges."

- [4]Riding a bike while learning Polish. It helps.

Thanks to Casey Manion and Adam Clemens.

shtove (2013-08-22 11:22:20)

The wine article had an interesting reference to gut bacteria and the vagus nerve - Emily Deans covered it last year: <http://evolutionarypsychiatry.blogspot.co.uk/2012/01/more-evidence-for-gut-brain-connection.html>

Kirk (2013-08-23 09:05:23)

J.D. Moyer noticed "a slight resurgence in asthma symptoms" during his experiment (40 Days Without Booze). I wonder if it's due to a reduction in fermented food (alcohol). He could experiment with drinking lassi instead of alcohol to see if he observes the same suppression of asthma symptoms.

dearieme (2013-08-23 16:27:01)

here's a self-experimenter <http://chiefio.wordpress.com/2013/08/20/of-spots-bugs-and-toxins/>

peter (2013-08-24 12:24:12)

re the article on giving up alcohol, the author notes that his asthma worsened; i understand that alcohol dilates blood vessels; i noticed that when i drank as little as a tablespoon of vodka that i seemed to breathe easier. It may be that alcohol dilates lung sacs.

## **Stagnation in Psychiatry (2013-08-23 05:00)**

[1]A recent New York Times article lays it out:

Fully 1 in 5 Americans take at least one psychiatric medication. Yet when it comes to mental health, we are facing a crisis in drug innovation. . . . Even though 25 percent of Americans suffer from a diagnosable mental illness in any year, there are few signs of innovation from the major drug makers.

The author has no understanding of the stagnation, yet is opinionated:

The simple answer [to what is causing the stagnation] is that we don't yet understand the fundamental cause of most psychiatric disorders [what does "fundamental cause" mean? – Seth], in part because the brain is uniquely difficult to study; you can't just biopsy the brain and analyze it. That is why scientists have had great trouble identifying new targets for psychiatric drugs.

The great increase in depression has an environmental cause. Meaning that depressed brains (aside from the effects of depression) are the same as non-depressed brains. Someone who knows that would not talk about biopsying the brain.

You come to a room with a door. If you don't know how a door works, you are going to do a lot of damage getting inside. That is modern psychiatry. I described a new explanation for depression in [2]this article (see Example 2).

Thanks to Alex Chernavsky.

1. [http://www.nytimes.com/2013/08/20/health/a-dry-pipeline-for-psychiatric-drugs.html?\\_r=1&](http://www.nytimes.com/2013/08/20/health/a-dry-pipeline-for-psychiatric-drugs.html?_r=1&)

2. <http://www.escholarship.org/uc/item/2xc2h866>

---

dearieme (2013-08-23 05:24:08)

"when it comes to mental health, we are facing a crisis in drug innovation": the first clause there is redundant.

Alex Chernavsky (2013-08-23 06:51:24)

I think the great increase in depression probably has multiple causes, one of which is quite ironic. Antidepressant drugs probably cause depression (or, at least, exacerbate it). See, for example: [1]"Now Antidepressant-Induced Chronic Depression Has a Name: Tardive Dysphoria"

1. <http://www.psychologytoday.com/blog/mad-in-america/201106/now-antidepressant-induced-chronic-depression-has-a-name-tardive-dysphoria>

elduderino (2013-08-23 10:55:50)

We also have a lot of stagnation in other areas of medicine. The advances are minimally incremental and, because of industrial interests, the effects are overstated. Take statins for example. The sad truth is that we had little revolution since vaccination and antibiotics. Seth: I agree. Also the bad effects are understated. And antibiotics are questionable: the bad effects could easily outweigh the good effects.

Steve Greenleaf (2013-08-23 11:02:44)

Seth, Have you read Leah Greenfeld's Mind, Modernity, Madness? I haven't yet, but I've read a bit of it plus her blogs, which provide the main thesis. It seems very similar to the lines along which you are thinking, although she comes at the issue as an anthropologist & political scientist (and perforce, as a historian). A compelling & fascinating topic.

Alex Chernavsky (2013-08-24 07:22:45)

@Steve Greenleaf, the book you referenced certainly looks interesting, but wow! \$34.05 for just the Kindle edition! <http://www.amazon.com/Mind-Modernity-Madness-Culture-Experience/dp/0674072766>

john (2013-08-26 09:59:23)

Hi, Seth, I'd just like to recommend you this reading: <http://www.theverge.com/2013/8/21/4595712/gut-feelings-the-future-of-psychiatry-may-be-inside-your-stomach> Hope you find it useful. Cheers!

## Wild-Fermented Wine and the Ecology of Knowledge (2013-08-24 05:00)

I learned about [1]wild-fermented wine from Shana Reade, who teaches wine sellers about wine. She works for a New York wine distributor called [2]Empire Merchants.

Before the 1950s, almost all wines were made with wild ferments. Only then did cultured (store-bought) yeasts start to be used on a large scale. The new wines surely tasted worse, but it was the era of TV dinners. The first cultured yeasts were especially popular in Australia, where less tradition blocked their adoption.

Nowadays wild-fermented wines are made in many places, including California, France and Germany. They are more expensive than cultured-yeast wines but you can buy one as cheaply as \$15. Wild yeast is free, but the overall process is more costly because it needs more space and time. When you do wild fermentation, you put out vats of wine open to the air. The vat-to-vat variability goes way up and some vats will have to be thrown out. Wild fermentation also varies much more in how long it takes. Wineries rarely harvest all their grapes at once. With cultured yeasts, but not wild yeasts, they can be sure that one batch will finish before the next batch arrives.

Scientists have found that the yeasts in wild-fermented wines have thicker cell walls than the yeasts in cultured-yeast wines. This is an example of the general observation that microbes (and other living things) grown by man have fewer functioning genes and metabolic pathways (such as the metabolic pathways that build cell walls) than the wild type. Wild yeast, of course, has a more stressful and variable environment than cultured yeast. Cultured yeast loses functioning genes over generations because it does not encounter the problem they solve. There is no selection against deleterious mutations. Because wild yeast has more functioning pathways, it produces more metabolic byproducts, making a more complex flavor. This is a tangible version of the idea that [3]we should use all our metabolic pathways. (A better version is use as many metabolic pathways as possible – fermented foods help with that.) So wild fermentation is (a) more diverse in terms of strains of yeast than cultured yeast and (b) individual strains of wild yeast have more functional metabolic pathways than individual strains of cultured yeast. (Cultured wine yeast starter includes several strains of yeast.)

The ecology of knowledge isn't simple. Cultured-yeast wines (in the 1950s) were made possible by earlier wild-fermented wines. With cultured yeasts you can do wine experiments you could never do with wild yeasts, thereby learning how to make better wine in general. Today's wild-yeast wines benefit from that knowledge. They also benefit from a mass market created by cheap (cultured-yeast) wine. An ecosystem that includes both sorts of wine spreads much further and produces much better wine than an ecosystem that includes only one sort of wine.

Personal science is like cultured-yeast wine in the sense that it allows far more experiments. Personal scientists can do experiments that professional scientists would find almost impossible. (For example, the effect of [4]standing 8 hours/day on sleep.) A scientific ecosystem that includes both personal and professional science is going to solve problems far better than an ecosystem with only one of them.

More broadly, the story of wild-fermented wines illustrates how you need complexity and optimality – not just one of them – to solve actual problems (in contrast to artificial ones). Wild yeasts are complex, but not optimal; cultured yeasts are optimal but not complex.

A well-functioning system produces both complexity and optimality. This not-very-difficult idea is almost ab-

sent from modern thought. In nutrition, economics and education, for example, there has been almost no study of how to produce complexity.

Nutrition scientists have had little interest in fermented foods, which increase our inner complexity. Yes, as nutritionists say, we need good amounts of a long list of nutrients and micronutrients (optimality). In addition, however, we need inner complexity to solve actual problems, such as digesting food and fighting off pathogens. You can't make a list of all the metabolic pathways we need to be healthy – it might be in the hundreds of thousands. You'd never learn our need for complexity from any nutrition book, as far as I can tell.

The science of economics revolves around optimality (e.g., most profit). I believe the current stagnation of the American economy is partly due to the poor understanding of economists of how to produce economic complexity. If they don't know, neither will anyone else. Interest groups, rich and poor, have no interest in complexity. (Illustrating The Stupidity of Crowds. The Wisdom of Crowds is about optimality.) All sorts of policies are too narrowly evaluated. Their effect on optimality is assessed (*how will this affect growth of GDP? or how will this affect percent unemployed?*), but not their effect on complexity.

As for education, it is a good idea to push students to be better (push them toward optimality, e.g., be better at math). But a single-minded emphasis on optimality (e.g., No Child Left Behind), with no value placed on complexity, is a disaster.

dearieme (2013-08-24 05:25:35)

I do hope you tried the Greek one I recommended.

dearieme (2013-08-24 11:52:08)

They need the income, the Greeks.

Kaleberg (2013-08-24 21:15:25)

I read that one theory about the rising alcohol levels in wine is that local wild yeasts have been selected for sulfur resistance by the sulfur based process used to halt fermentation. I wonder how close to the old yeasts these modern wild yeasts are.

Elizabeth Stott (2013-08-25 03:30:33)

Fascinating. Interfering with any dynamic system will cause a back reaction and has the potential for instability. Something neglected by interfering politicians who think things they don't like can be 'fixed' ... I liked your comments on 'optimality and complexity'. It allows us to focus on an argument more effectively. On a tangent - I am curious as to how humans - with our biological dependence on complex systems of micro-organisms - will cope in space. Will the exported microbes develop new strategies for living in space? And will returning astronauts struggle to cope with the terrestrial environment?

## Showers and the Ecology of Knowledge (2013-08-25 05:00)

In [1]a recent post, I said a well-functioning system will produce both optimality and complexity. I meant important systems like our bodies, economies, and formal education. If you look at [2]the nutrition advice provided by the United States Department of Agriculture – the food pyramid, the food plate, the recommended daily allowances, and the associated reports – you will find nothing that increases the complexity of metabolism inside our bodies (in particular, the diversity of metabolic pathways). The advice is all optimality – for example, the best amounts of various micronutrients. The people behind the USDA advice, reflecting the thinking of the best nutrition scientists in the world, utterly fail to grasp the importance of complexity. Half of nutrition research – or more than half, since the topic has been so neglected – should be about how to increase internal complexity. In practice, almost none of it is. It's obvious, I think, that the microbes within us are very important for health. They are mostly in our intestines and must be heavily influenced by what we eat. How did they get there? How can their number be increased? How can their diversity be increased?

The absence is especially striking because the point is so simple. To solve actual problems, you need both optimality and complexity. Showers – what we use to take a shower – provide an example. You want to adjust the water temperature. If you try to do this while taking a shower, it can be hard because of the delay between changing the hot/cold water proportions and feeling the effects. It is better to use the bathtub (lower) tap to set the temperature (measuring it with your wrist) and only after you've optimized the temperature, shift the water to the shower head. The bathtub tap produces simple output (a single stream of water) that is easy to optimize. The shower head produces more complex output that is harder to optimize but does a better job of washing (an actual problem). You need both bathtub tap (for optimization) and shower head (for complexity) to do a good job solving the problem. Likewise, we need both an understanding of necessary nutrients (Vitamin A, etc.), which can be optimized, and an understanding of microbes, which cannot be optimized but can be made more complex, to make good decisions about what food to eat. Ordinary food is the hardware, you might say; and microbes are the software.

Jake (2013-08-25 08:16:08)

You call for complexity in nutrition. Art DeVaney and Nassim Taleb call for chaos in nutrition. I think it is the same thing. Who knows what combination of nutrients the body needs? When I go to a salad bar, I try to put in my bowl 11-13 different vegetables. I like the idea of complexity, you should write more about it. Seth: In nutrition, complexity is a matter of enzymes: more enzymes, more complexity. It's like having more books in a library. I'm not sure what chaos is in this situation. I wouldn't say that a larger library is more chaotic than a smaller one.

Antonio (2013-08-25 18:01:43)

Hi Seth, how are you? I have a question related to your previous post on pork belly but I am not sure where to ask. I am interested in the benefits of the animal fat and hence I would like to try your recipe with pork belly and miso soup. Yet, I could not find it while searching over your blog. Thanks. Seth: I just cooked the pork belly and added it to miso soup. That's all.

## Organic Pollutants Associated With Diabetes (2013-08-26 05:00)

Everyone knows that diabetes is associated with obesity, probably because obesity causes diabetes. However, thin people also become diabetic. A clue to why is provided by the correlation between diabetes and what are called "persistent organic pollutants" (POPs). POPs are man-made organic compounds, usually pesticides, such as polychlorinated dibenzo-p-dioxins and polychlorinated dibenzofurans.

[1]A 2006 study using NHANES (National Health and Nutrition Examination Survey 1999–2002) data found very strong associations between levels of these chemicals and diabetes. For example, a risk ratio of 30. These associations persisted even when the data was stratified in all sorts of ways. The scariest result came from people who had BMI < 25. Looking only at such people, those above the 90th percentile for amount of POPs had 16 times the risk of diabetes as those below the 25th percentile. Here is something associated with thin people getting diabetes.

Does the association exist because POPs cause diabetes? You might argue that POP exposure is correlated with poverty (poor people are more exposed), poor people exercise less than rich people, and lack of exercise causes diabetes. However, Agent Orange exposure among soldiers is associated with diabetes. That is unlikely to be due to confounding with poverty or lack of exercise.

Everyone has these chemicals in their body, but almost no one knows how much. I don't know if I'm in the 10th percentile or the 90th percentile. If I'm in the 90th percentile, what can I do about it? A good place for self-measurement and tracking.

dearieme (2013-08-26 05:36:22)

"A 2006 study ...": seven years - so who's tried it out on rats and so on?

Tom (2013-08-26 15:52:52)

Scotchgard stain & fire protection is another key source. If you have furniture or carpeting that was manufactured before 2002 you're exposed to it on a daily basis. [http://en.wikipedia.org/wiki/Perfluorooctanesulfonic\\_acid](http://en.wikipedia.org/wiki/Perfluorooctanesulfonic_acid)

Tom (2013-08-26 18:58:08)

Just remembered that fire retardants in furniture skyrocketed (nationwide) due to a 1975 California regulation. <http://www.sfgate.com/health/article/Flame-retardant-free-furniture-rare-costly-4299274.php>

Ief (2013-08-27 06:47:09)

I will make an old question (just curious what people in this blog think). Why the property man made ads a lot to how much we should suspect a chemical? If unnatural is the answer then what about all the chemicals that occur in the nature but are new to humans (you encounter them whether or not you do any type of "paleo-eating") . To this chemicals there is much more exposure. Bruce ames for example had similar thoughts

## Dutch University Fires Unnamed Researcher (2013-08-27 05:00)

If you [1]google "Ranjit Chandra" (a famous Canadian nutrition researcher), the second result is [2]this page, created by me, which lists many articles about a scandal that Saul Sternberg and I did a lot to uncover. We pointed out that

several details of one of Chandra's papers were impossible. I did not create the page to harm Chandra, but it does: For the rest of his life, anyone curious about him will find out about the scandal. It is a scarlet letter with capital S and capital L.

I suspect this is why Leiden University recently [3]fired a scientist without naming him/her.

Leiden University Medical Centre (LUMC) has fired an employee who has committed fraud in the collection of research data. An internal inquiry showed that the employee deliberately manipulated laboratory research. The employee has confessed and accepted the dismissal. Additionally, the LUMC withdraws two scientific publications by this employee. The fraud was discovered by immediate colleagues at the Rheumatology Department.

A deal was struck. The employee won't contest the firing, the medical center won't name the employee in the press release. The employee didn't want the scandal to follow him/her for the rest of their life.

I disagree with this deal. As a result of the employee's fabrication, a clinical trial was started in which sick people ingested or had injected a powerful drug. The university claims no one was hurt ("It is clear that at no time a dangerous situation has arisen for patients"). I have no idea if anyone was hurt, but the potential for damage was great. Last night a friend told me about a Traditional Chinese Medicine drug that a friend of hers took. It worked for years and then one day stopped working. It came from China. It turned out the Chinese manufacturer had run out of the crucial ingredient and had substituted an animal tranquilizer. Her friend was really damaged by this. Chandra's data might have caused people to take too many vitamins.

The medical center employees who handled this case (presumably very high up in medical center administration) treated the rest of us – who deserve to be warned about the fabricator – not so differently than the fabricator did: as people who don't matter. Who don't deserve protection.

More [4]A comment at Retraction Watch says the anonymity is Dutch tradition: "The names of the people are not published so that these people have a chance of rebuilding their lives in the future. In the Netherlands even people who have committed serious crimes do not have their full name or photo published in the press."

dearieme (2013-08-27 05:06:17)

And without the name of the evil-doer, there will be far less publicity for the case and therefore for Leiden University.

Nancy Lebovitz (2013-08-27 05:54:29)

Off topic: <http://www.npr.org/blogs/thesalt/2013/08/22/209844877/reviving-an-heirloom-co rn-that-packs-more-flavor-and-nutrition> Article mentions complex flavors as valuable.

Alex Chernavsky (2013-08-27 07:31:47)

It's hard to keep this kind of stuff secret, especially these days. *Nature* is reporting that the person is name [1]Annemie Schuerwegh:

**Research fraud** A researcher at Leiden University Medical Center in the Netherlands has been fired for committing scientific fraud, the centre announced on 14 August. Annemie Schuerwegh, who worked in the rheumatology department, admitted manipulating data included in a study published in *Proceedings of the National Academy of Sciences* in 2010, says a report from the centre. She went into the laboratory outside office hours and added mouse antibodies to tubes of human blood samples. The centre will withdraw the article and another paper, and has halted a clinical trial based in part on the fraudulent data.

<http://www.nature.com/news/seven-days-16-22-august-2013-1.13575>

1. <https://www.google.com/search?source=ig&rlz=&q=%22Annemie+Schuerwegh%22>

gwern (2013-08-27 16:37:19)

And by insisting on full retribution and perpetually tarring the culprit, one raises the stakes and guarantees the culprit will fight the accusations tooth-and-nail and never clearly admit guilt or lay out what was falsified. It may be satisfying to destroy their ability to 'rebuild their lives in the future', but there are consequences to total warfare and some of those may be unintended. There are reasons lawyer & doctor confidentiality extend to crimes; another good example is how felony murder laws encourage additional murders - if you're already going to jail for life for committing an armed robbery, you might as well kill the clerk so he can't testify later. The Bloody Code was repealed for good reason. So the question is: do you want vengeance, or do you want to make the world a better place?

Ashish (2013-08-27 17:55:30)

@gwern: Naming the perp is not about "vengeance." It is about ensuring that they do not get to repeat the identical misdeed again and again and again. The example of pedophile priests comes to mind. You make a good point about mandatory sentencing laws - I know of no easy answer.

## Autoimmune Disorder Improved With Fermented Food (2013-08-28 05:00)

From [1]a recent story in the Santa Cruz Sentinel:

[Kelly] Dearie turned to fermented foods in a moment of despair.

Her husband Charlie, who suffered from an autoimmune disorder that attacked his platelets, was told by doctors that he needed a spleen removal and a hip replacement. That would mean Charlie, an active 32-year-old man, would never be able to run or mountain bike again. . . .

The family decided to seek an alternative, and consulted Santa Cruz clinical health coach Craig Lane from Health Alkemy. . . . He checked Charlie's temperature, blood pressure and lab results, and listened to Charlie talk about his diet, sleep and exercise. Instead of the surgeries, Lane recommended some dietary changes such as taking out coffee, wheat and sugar, and adding beet kvass, a traditional Russian fermented tonic.

Within three weeks, his platelet numbers were almost normal. Within two years he was running again,

said Dearie. . . . Inspired by her husband's healing, Dearie opened Creative Cultures and sells the beet kvass.

---

Alex Chernavsky (2013-08-28 06:24:29)

OK, but maybe it was the absence of coffee, wheat, and/or sugar. Seth: Yes, that's a fair question, I should have stressed that.

Charlie (2013-08-28 06:58:00)

Ditto Alex...how do we know? I for one, cannot seem to tolerate fermented foods, no matter the type or how much I like them, and I do like them - they give me horrible heart burn. So, I'm sticking with feeding a limited, but robust, gut flora, instead of a weaker diverse, multicultural variety. Cheers

Paul N (2013-08-28 07:41:02)

I think it was likely both. Getting rid of the wheat and sugar certainly removes the major gut irritants and contributors to disordered gut flora, but the fermented stuff helps provide the right flora to restore balance. Add to that that beet kvass has a long standing reputation as a blood cleanser, and I'd say it was both. There are some clinical studies looking at beetroot, and its [1]blood pressure reducing effects. The lactic and other acids from fermentation (and probably a good dose of B vitamins too) almost certainly help.

1. <http://www.ncbi.nlm.nih.gov/pubmed/22414688>

Tuck (2013-08-28 10:58:07)

Wheat is one of the only plants we know of that is a known cause of auto-immune reactions. (Poison Ivy being the other one, but no-one eats that.) Wheat-caused autoimmune diseases are known to affect every tissue in the body. I think it's a pretty safe bet therefore that removing wheat was the trigger for his improvement, and not the beet juice...

Ross (2013-08-31 08:40:06)

Does fermenting wheat via a traditional sourdough process remove the auto-immune issue?

libfree (2013-08-29 09:50:30)

Seth, What are your thoughts on fermented meats? If we eat fermented vegetables and dairy, shouldn't we be letting our meats ferment? Seth: I try to eat fermented meats. For example, prosciutto, aged salami. Cremenelli salami is especially good.

dearieme (2013-08-29 10:15:56)

"doses of whey protein significantly reduced post-prandial blood sugar levels": I hate the dishonesty of that sort of statement. Seth: What is the dishonesty?

Valerie (2013-08-29 20:15:52)

Whey protein in cheese? From my understanding, most of the whey is removed from cheese. Except for a few cheeses (like Ricotta), shouldn't cheese be especially low in whey protein?

dearieme (2013-08-30 08:12:38)

Seth: What is the dishonesty? The use of "significantly" - which the layman will interpret as 'substantially' - when the original result is "statistically significant", a quite different concept. (To be fair, I don't know whether this article is guilty of that crime, but if it isn't it's damn near unique.) Seth: The reduction is large, see <http://www.nutritionj.com/content/11/1/83/figure/F1>. Certainly "significant" in the sense of important. The authors are guilty of not making that clear.

Charlie (2013-08-30 17:05:20)

I don't see how using whey protein to raise your insulin level is beneficial long term. I believe, reducing your carbohydrate load would be much more beneficial; short term and long term. Seth: The whey protein lowered insulin level, see <http://www.nutritionj.com/content/11/1/83/figure/F1>.

Jon (2013-09-03 07:21:26)

Seth, I believe you misread figure F1 with respect to insulin levels. Figure 1B shows insulin levels as a function of time for the different meals, and the whey protein level is higher than all the others for most of the post-prandial period. Figure 1C shows the insulin index of the meals (in light bars.) Again, the whey protein meal shows the highest level. Finally, quoting from the paper itself: The insulin iAUC following human milk, bovine milk and casein was similar to that seen with WWB. In contrast, the whey meal exhibited higher insulin iAUC 0-120 min, than the WWB ( $p < 0.05$ ). Additionally, the whey meal resulted in an elevated insulin response (iAUC 0-120 min) also when compared with data for casein and human milk. Seth: Thanks for the correction. Yes, I said lowered insulin when I meant lowered blood sugar.

Jeff Winkler (2013-09-03 07:34:17)

Great talk from Jana Beck. Here are higher-resolution graphs - <http://janabeck.com/blog/2012/10/12/lessons-learned-from->

100/ Her blog posts about beeminder are also very good. Talk about closing the goals-data-behavior loop!

## Rewarding Criticism Put Nicely Produced Long-Lasting Change (2013-08-30 05:00)

[1]Eliezer Yudkowsky, I'm told, used to be a not-nice critic. The problem was his delivery: "blunt, harsh, not sufficiently tempered by praise for praiseworthy things" (Alicorn Finley). However, this changed about a year ago, when Anna Salamon and Alicorn Finley decided to try to train him to be nicer. Alicorn describes it like this:

Me, Eliezer, Anna, and Michael Blume were all sitting in my and Michael's room (where we lived two houses ago) working on, I think it was, a rationality kata [= way of doing things], and we were producing examples and critiquing each other. Eliezer sometimes critiqued in a motivation-draining way, so we started offering him M &Ms when he put things more nicely. (We also claimed M &Ms when we accomplished small increments of what we were working on.)

Eliezer added:

Some updates on that story. M &M's didn't work when I tried to reward myself with them later, and I suspect several key points:

- 1) The smiles/approval from the (highly respected) friends feeding me the M &Ms probably counted for more than the taste sensation.
- 2) Being overweight, M &Ms on their own would be associated with shame/guilt/horror/wishing I never had to eat again etc.
- 3) Others have also reported food rewards not working. One person says that food rewards worked for them after they ensured that they were hungry and could only eat via food rewards.
- 4) I suspect that the basic reinforcement pattern will only work for me if I reward above-average performance or improvement in performance (positive slope) rather than trying to reward constant performance, because only this makes me feel that the reward is really 'deserved'.

Also:

- Andrew Critch advises that 'step zero' in this process is to make sure that you have good internal agreement on wanting the change before rewarding movements in the direction of the change
- The Center for Applied Rationality (CFAR) has some experience learning to teach this.
- CFAR has excellent workshops but not much published/online material. A good mainstream book is [2]Don't Shoot the Dog by Karen Pryor.

I like this example because the change was long-lasting and important.

1. [http://en.wikipedia.org/wiki/Eliezer\\_Yudkowsky](http://en.wikipedia.org/wiki/Eliezer_Yudkowsky)

2. <http://www.amazon.com/Dont-Shoot-Dog-Teaching-Training/dp/1860542387>

---

Alex Chernavsky (2013-08-30 06:48:00)

See also: "[1]What Shamu Taught Me About a Happy Marriage" The author uses animal-training techniques to address her husband's annoying behaviors.

The central lesson I learned from exotic animal trainers is that I should reward behavior I like and ignore behavior I don't. After all, you don't get a sea lion to balance a ball on the end of its nose by nagging. The same goes for the American husband. Back in Maine, I began thanking Scott if he threw one dirty shirt into the hamper. If he threw in two, I'd kiss him. Meanwhile, I would step over any soiled clothes on the floor without one sharp word, though I did sometimes kick them under the bed. But as he basked in my appreciation, the piles became smaller. I was using what trainers call "approximations," rewarding the small steps toward learning a whole new behavior. You can't expect a baboon to learn to flip on command in one session, just as you can't expect an American husband to begin regularly picking up his dirty socks by praising him once for picking up a single sock. With the baboon you first reward a hop, then a bigger hop, then an even bigger hop. With Scott the husband, I began to praise every small act every time: if he drove just a mile an hour slower, tossed one pair of shorts into the hamper, or was on time for anything.

1. [http://www.nytimes.com/2006/06/25/fashion/25love.html?pagewanted=all&\\_r=1&](http://www.nytimes.com/2006/06/25/fashion/25love.html?pagewanted=all&_r=1&)

Dragan (2013-08-30 11:27:37)

Alex, I like that example. Presumably this would be less effective if the person being trained had no affection for the trainer. But even more I wonder how well it would have worked if the trainer (wife) did not love the trainee (husband). Seth, I came across your blog about a month ago and somehow ended up reading through most of it. I believe I learned quite a bit. To me, most interesting topics I've read about here are: the Shangri-La "Diet" (ahead of its time), development of skill in context of human evolution, Jane Jacobs as a thinker on all sorts of things, self-experimentation as part of a new literacy, most of your thoughts on statistics (e.g., against uncritical "Correlation is not causation"). There's more, I'm sure. Thanks for sharing.

### **Criticism of My View of Education: My Answer (2013-08-31 05:00)**

My criticism of college education can be boiled down to this: It is too much one-size-fits-all. It takes too little account of differences between students. Those differences are no accident. They reflect the fact that a good economy needs to produce many different things. [1]Human nature has been shaped to provide exactly that.

Bryan Caplan [2]posted about this, and one reader (Tim of Angle) replied:

Roberts is criticizing colleges for not doing something that they aren't really trying to do. . . . Our educational model is built around hiring teachers who are (supposedly) good at thing X and paying them to train other people to do thing X. Nobody claims that the way the teacher does thing X is the only way to do thing X, nor even the best way to do thing X; what colleges do claim is that the way the teacher does thing X is a successful way to do thing X, and it hopes that the teacher can train students to do thing X competently at least the way the teacher does thing X.

I was discussing undergraduate education at Berkeley. Berkeley professors are hired mainly based on their ability to do research. Undergraduate classes are not about training researchers (= the next generation of professors at research universities, such as Berkeley); that's what graduate school is for.

In most Berkeley undergraduate classes, professors aren't teaching students to "do" anything, at least anything that

most of us would recognize as "doing". (Engineering, art, architecture, foreign language and perhaps statistics classes are exceptions.) In most classes, students are introduced to an important fraction of an academic field. In a social psychology class, for example, they learn about social psychology research. The class is not about how to do social psychology. It is about what has been done and what has been learned. If the class consisted entirely of students who wanted to become psychology professors, that would be fine. In fact, only a small fraction of Berkeley psychology majors (5 %?) go to graduate school in psychology. The students in most Berkeley classes (outside of the more vocational areas, such as engineering) will go on to do many different jobs. Few in any class will become professors.

I think one theory of higher education is close to what Tim of Angle says. The practice, at least at elite universities such as Berkeley, is quite different.

A different theory of higher education revolves around signalling. College performance provides a useful signal to future employers, that's why it exists in present form. At Berkeley, I never heard this motivation (will this provide a good signal to employers?) brought up in discussions about grading or anything else. It's utterly clear, on the other hand, that where you go to college (Harvard versus College of Marin) is indeed a powerful signal to employers and, yes, if you can go to Prestigious College X, you really should. How many "axes of excellence" there should be – how many separate categories or dimensions we should use to rank colleges – is a different discussion.

1. <http://media.sethroberts.net/articles/2011-04-08%20How%20Economics%20Shaped%20Human%20Nature.pdf>

2. [http://econlog.econlib.org/archives/2011/12/seth\\_roberts\\_on.html](http://econlog.econlib.org/archives/2011/12/seth_roberts_on.html)

---

dearieme (2013-08-31 06:24:44)

"In most Berkeley undergraduate classes, professors aren't teaching students to "do" anything, at least anything that most of us would recognize as "doing"." And yet you ain't learning Chemistry if you are not doing a lab class where you - not you and a partner - do organic syntheses, quantitative analysis, and so forth. Doing is an essential part of learning in many disciplines. Even the mild mathematician must "do" problem after problem until he has internalised theory and practice sufficiently to solve problems skilfully.

Dragan (2013-08-31 16:33:13)

"Engineering, art, architecture, foreign language and perhaps statistics classes are exceptions." Seth, it would be interesting to hear why you called out those particular disciplines as exceptions (to "most classes"). Also, "In a social psychology class, for example, they learn about social psychology research. The class is not about how to do social psychology. It is about what has been done and what has been learned. If the class consisted entirely of students who wanted to become psychology professors, that would be fine." Seth: Yes, it's not black and white. In most classes, you learn knowledge. In a small number of classes, you learn skills. In many engineering classes you build something. In most foreign language classes, you learn to speak and read the language. In (studio) art classes you make art. And so on. It's not black and white because in chemistry and physics classes there are often labs, in geology classes you may go on field trips and learn to identify rocks, an animal learning class may have a lab, and so on. This seems contradictory. If a class consisted "entirely of students who wanted to become psychology professors," then wouldn't we want it to actually be about "how to do social psychology" rather than merely about "what has been done" already? After all, students who want to be psychology professors need to learn how to do psychology. My sense is that students in a typical undergraduate class (and K-12) aren't learning how to "do" the disciplines, but rather how to do some related busywork. I certainly didn't get to "do" much real mathematics before graduate-level courses. Maybe this is not that different from what you're saying. Seth: I agree with you. I wouldn't call the usual curriculum "busywork" but I agree that it is quite different than "real math", "how to do social psychology" and so on. There is a busywork element of most classes in the sense that the content is relatively convenient for the pro-

fessor to teach. Easier to lecture about what social psychologists have learned than to teach a social psychology lab, for example.

## 8.9 September

### The Irrelevance of Grass-Fed Beef (Ancestral Health Symposium 2013) (2013-09-01 05:00)

*Grass-fed beef is better than ordinary (grain-fed) beef because it has a better omega-3/omega-6 ratio.* I've heard this a thousand times. It's true. Grass has more omega-3 than grain, which is high in omega-6. But it is misleading. For practical purposes, grass-fed and grain-fed beef are the same in terms of omega-3 and omega-6.

[1]Peter Ballerstedt made this point in his talk at the recent Ancestral Health Symposium. He showed this slide, based on research by Susan Burkett.[2] 

This shows the amount of omega-3 and omega-6 in one serving of various foods. The amounts in grass- and grain-fed beef are small relative to other foods most people eat. People who have said *eat grass-fed beef*, such as [3]Michael Pollan, should have been saying *eat less chicken*. When I started eating grass-fed instead of grain-fed beef, I noticed no differences, which agrees with this analysis.

---

Nancy Lebovitz (2013-08-28 00:20:21)

Good thing I eat grass-fed beef (at least some of the time) because it tastes better. Seth: I agree, it tastes better.

Beth@WeightMaven (2013-09-01 06:16:23)

I don't know that I would have called grass-fed beef "irrelevant" because the absolute amount of o3 is small. Eating grass-fed beef for o3 or because of the o3/o6 ratio is not useful, as you point out above. But eating grass-fed beef for other reasons can be downright relevant. For example, grass-fed cows aren't typically given the hormones or antibiotics given to feedlot cows. That matters to me! Seth: I am unsure why I should care about the hormones or the antibiotics. I'm not saying you're wrong, just that the evidence behind your view is unclear.

rif (2013-09-01 11:58:23)

I am confused. Surely, a rib-eye steak is a kind of beef?

Joe (2013-09-01 12:05:16)

Why no comparison of grass-fed rib-eye to grain-fed rib-eye? Hmmmmm.

Joe (2013-09-01 12:40:12)

Why no comparison of grass-fed rib-eye to grain-fed rib-eye? Or to strip steak, etc? What's so different about ground beef???

Justin Irving (2013-09-01 13:26:26)

Wow. This is news to me. Thanks for sharing, raises many questions. I was under the impression that grass fed \*and finished\* beef was fairly comparable to wild salmon in O3. I wonder if the data in this chart are for store bought GFB (usually grain finished) or if it was fully grass finished (usually only available through order or local markets). The other advantage of grass fed beef is alleged fat soluble vitamins, which are presumably good. As far as Beth's comment above, my fear is that antibiotics and the estrogen used to fatten cows bioaccumulates and then jacks the human endocrine system and gut bacteria when eaten. I look forward to hearing what the GFB people have to say.

Michael George (2013-09-01 14:28:30)

It looks to me like this is playing with statistics again, and I'm surprised you fell for it, Seth. Is this chart comparing the fat? Or the meat? If I take a ounce of fish fat and an ounce of beef fat – the amount of omega-3's should be comparable, right? The problem, in my mind, is that today people aren't eating the fat with their beef. You can't even buy a cut of beef with the fat still all around it. When I was a kid eating at grandma's and we got a steak or pork chop, there was a ring of fat around it. It was so good! And I'm believing that when our ancestors ate their beef, it had a bunch of fat hanging off it. But today, I don't see people eating the fat with their beef. In fact, I have to buy beef fat separately to add to my meals. Now, I'm under the impression that if I eat the fat with the lean meat, that I'm getting the omega-3's that are necessary. What do you think?

Angelyne (2013-09-01 14:40:19)

I would say that the omega-6/omega-3 content of grass fed beef is irrelevant to the decision to buy grass-fed beef. Ruminants haven't evolved to eat massive quantities of grains, it makes them sick. You end up eating meat from what is essentially a sick cow. But even more important, If you eat a grass fed cow, you are are eating meat produced from animals that exist within their natural context, or as close as you can get with agriculture and husbandry. When properly managed, the animal is outside, in the sunshine, eating what it evolved to eat. The animal/grass coexist and need each other. As apex predators we feed on the cow, which is also part of the circle. When you take a cow to a feeding lot, you break that circle. You feed them something they aren't designed to eat, something that is grown elsewhere at great environmental cost. The manure they produce no longer feeds the soil, but now becomes a pollutant. The water must be piped in from elsewhere, depleting water tables. The cow is now yet another environmental burden in an unsustainable system. That's why I eat grass-fed meat.  
<http://www.pbs.org/wgbh/pages/frontline/shows/meat/interviews/pollan.html>

Bert (2013-09-01 23:12:50)

From where I come from, grass-fed is typically cheaper. O3/6 content notwithstanding, I guess, if I'm to eat what I should, then the stuff that I eat should eat what it's supposed to, too. :)

Antonio (2013-09-02 12:09:45)

"I would say that the omega-6/omega-3 content of grass fed beef is irrelevant to the decision to buy grass-fed beef" I could not agree more. omega6/omega3 ratios is not the only think that matter for our health ...

Tom (2013-09-02 13:06:23)

Thanks for this post, Seth. With all the hype that has grown up around the grassfed beef industry, that chart is nothing short of shocking. Talking about higher Omega 3s lets ranchers benefit from healthfulness perceptions without actually making any health claims. There's no FDA litigation risk if the healthfulness is merely presumed by starry-eyed consumers. I do wish there were an entry on that chart for so-called "Omega 3" eggs. I imagine it would reveal a similar scam.

Kim Øyhus, physicist (2013-09-03 04:54:10)

There are real differences, because when I eat farmed fish, I get rashes or something similar, and after eating wild fish, it disappears. The difference is quite large. Seth: Interesting. I avoid farmed salmon, try to always eat wild salmon.

Kyle (2013-09-05 10:06:24)

It would be nice to compare a grass-fed ribeye to grainfed. Also it would be very interesting to look at the ratio in grain fed dairy verse grass-fed (particularly butter).

David Johnston (2013-09-06 17:26:58)

For me, the grass fed thing was always more about the cow than the O3/O6 ratio.

JohnG (2013-09-10 08:04:25)

The old government nutrition database site would give omega 3 and omega 6 numbers on quite a few items. If I remember correctly, the ribeye numbers were similar between grainfed and grassfed beef with the grassfed ribeye numbers being lower overall for both omega 6 and omega 3. The ratios weren't that much different for any cut of meat I checked. For some cuts, grassfed faired better on the ratio number; and in other cuts it was the other way around. You can look at Loren Cordain's own numbers (<http://thepaleodiet.com/published-research-about-the-paleo-diet/>) and see for yourself that the argument for eating grassfed because it has a better ratio is meaningless. This doesn't negate the possibility, which Angelyne brought up, that there's something else in play when animals are fed outside their normal diet (such as the fact that the ratio of palmitic saturated fatty acid goes up in comparison to stearic acid in grainfed beef and what significance that may hold).

Ed (2013-09-25 12:26:43)

Grass fed vs Grain fed. Grain fed is akin to fattening the cattle up. Literally. The higher fat content of grain fed cattle would be concentrated with omega 6 as opposed to omega 3. Not too mention that cattle have evolved to consume grass, not grain. As far as the increased hormones and its effect on livestock. There have been scientific studies that show a correlation between the hormones and increased negative health effects in humans. A quick Google search will turn up some scientific articles.

sharon (2013-09-25 18:23:01)

Grass fed is kinder to cows.

## **What is College For? (2013-09-03 05:00)**

David Brooks, the New York Times columnist, [1]tries to answer this question:

Are universities [he means undergraduate education] mostly sorting devices to separate smart and hard-working high school students from their less-able fellows so that employers can more easily identify them? Are universities factories for the dissemination of job skills? Are universities mostly boot camps for adulthood, where young people learn how to drink moderately, fornicate meaningfully and hand things in on time? My own stab at an answer would be that universities are places where young people acquire two sorts of knowledge, what the philosopher Michael Oakeshott called technical knowledge and practical knowledge.

My answer: Almost all college students want to figure out what job to choose. The answer will depend on what they do well, what they enjoy, and will have a big effect on the rest of their life. The better the answer, the more successful and happy they will be. For them, that is above all what college is for.

This doesn't even occur to Brooks as a possibility. I suppose professors like this state of affairs (a smart person – Brooks – can't even think of this). If no one mentions it, they are that much further from having to consider it. Trying to help students reach this goal means giving up power. The more a college helps students learn what they enjoy and what they are good at, the less professors can do exactly what they want.

There is nothing terrible about college classes. I don't say that this or that humanities course is "useless". The trouble is lack of balance: too many normal classes, too few "classes" that explicitly help students to learn about the world of work and how they might fit into it. Only a few colleges – often low-prestige "trade schools" – do much to help students learn about possible jobs, what they enjoy, and what they are good at.

Judging by how Berkeley courses are taught – they do little to help students decide what job to do, unless they are seriously considering being a professor – most professors have little or no interest in helping students this way. I suspect, however, they don't know what they might gain from doing so. At Berkeley I taught a class called Psychology and the Real World whose goal was exactly that: help students find their way (a particular problem for psychology majors, few of whom go to graduate school in psychology). They could do almost anything, so long as it was off-campus. It was little work for me and the students learned a lot. I enjoyed seeing them begin to find their way. This is what I think isn't obvious to professors: the more you help students learn what they want to learn, the easier and more satisfying it is for you.

1. <http://www.nytimes.com/2013/04/05/opinion/Brooks-The-Practical-University.html?hp&r=1&>

---

Alex Chernavsky (2013-09-03 09:38:55)

And, speaking of education, apparently the US Government is starting to run randomized controlled trials to test the effectiveness of various educational approaches or techniques: "[1]Guesses and Hype Give Way to Data in Study of Education"

1. <http://www.nytimes.com/2013/09/03/science/applying-new-rigor-in-studying-education.html>

Dragan (2013-09-04 16:36:43)

Alex, From the article you linked, opening paragraph: "What works in science and math education? Until recently, there had been few solid answers — just guesses and hunches, marketing hype and extrapolations from small pilot studies." It's true that there have been few solid answers. It's false that this is because education researchers have been only "extrapolating from small pilot studies." Even a cursory google search (or better yet, looking in ERIC) will find large scale experiments dating back 30+ years. Overwhelmingly, findings have been that stuff you think should matter doesn't. For example, both group-based and lecture-based teaching can work... or might not. As the article even mentions, it's not unusual to call What Works Clearinghouse "What Doesn't Work Clearinghouse." My guess? People are different. There aren't going to any "solid" answers of the sort until this fact is recognized. Medicine doesn't work the same for everyone, why should education?

Dragan (2013-09-04 16:52:24)

Seth, I like your general thinking on college education. You may as well extend it to parts of K-12. One of the wisest, smartest people I know finished only 4 years of school. It taught him how to read and write, do arithmetic, read maps, and a bit of history. That was enough. Sure, "modern age requires more than that" but it's not like modern (US) education does a particularly good job teaching more than that. Personally, I can't remember almost anything from grades 7-10 other than a bit of Latin, some basic geometry, and a few books I read and liked. I'm sure there's more I learned, but I'm equally sure it wasn't terribly important. At least in grades 11 and 12 I read mostly enjoyable books and studied Calculus, though I'm sure many of my classmates cared for neither.

Robert (2013-09-06 13:36:38)

Seth, I agree with much of what you said regarding the current nature of education. I'm an undergraduate student and am worrying about the same things you mentioned at the beginning of your posts: what is my desired career path and what do I need to do in order to live my desired future. Most of the classes I've taken for my majors (Human Biology and Cognitive Science) haven't helped me acquire the skills I'll need in the real world and perhaps that's due to teachers not caring about the students' needs and wishes. Since high school, I've kept a folder on my computer titled "Continued Education," which contains much of what I've read on my own in order to provide myself with the education that I really want (i.e. one that improves the skills I want to master). So far, my self-directed education may have been as valuable as the formal education I've received so far-it's a little depressing. Anyway, I'll stop ranting. Thanks for the insight. Robert

Griff (2013-09-06 18:32:48)

I am not sure if I have a well formed thought on this. I think college is for different things for different people. I for instance liked math and knowing how things worked. I would have preferred a math degree, but when I asked the guidance counselor what I could do with that, she said "You could be a math teacher." Given the school I went to, it was a huge de-motivator. When I asked my father, he said "Engineers have to be good at math and they get paid well at the shipyard." As a result, I went to engineering school. It was brutal at first, but when I made it to the more specialized courses, I really enjoyed it. In addition, the courses I chose were heavy on math, e.g. fields and control systems. I liked Psychology as well, but when I suggested switching, my father, who generously paid for my education asked "Are you going to pay for that?" In his own estimation, he didn't think it would give me the best livelihood. I went on to be an engineer, but surprisingly the engineering part of my career was very short. I quickly moved into project management, then management, consulting, and ultimately executive management. There is always a technical edge to what I do and I find I rely on the methodical, analytical, and systems-thinking mindset I learned from engineering, but it is far from true engineering work and I definitely miss the math. (Financials are dull, and I have taken every opportunity to make it interesting through statistics and modeling, but that is still not enough). I think there are at least two groups of people in college. The ones that do it for a love of learning and pursuing an interest, and the ones that are convinced (either on their own or from parental pressure) that it is a necessity. Also, the selection of major can either be by interest or expected financial return. You may be smart enough to be a doctor, lawyer, engineer or software developer, but it doesn't mean you should be one. I think this is why there are so many disappointing doctors, lawyers, engineers and software developers (I believe it is Paul Graham that said there is a logarithmic difference in the productivity or value of software developers, I would assume the same in other knowledge workers). They may be smart, and they may have done very well in college, but that doesn't translate to performance at work or happiness at work. It was interesting at the shipyard. Those with above a 3.0 started as a GS-7 and those with below 3.0 GPA started as a GS-5. Their own statistics showed that GS-5 reached a GS-12 faster on average than the GS-7. The reason wasn't known, but the theories included that GS-5's didn't walk around like prima donna's and got down to working. Not sure if I concur, but it is true that many of the engineer's felt that some things were just beneath them. I don't think a diploma means much more than some level of commitment to a body of knowledge. I wouldn't say commitment to a profession, as only a subset of what is learned is used in the profession. Also, I don't think a college degree should mean much more than a head start in many pursuits. I had worked with many technicians that were at least my equal if not my better. Most of the best had a deep seated interest and many had engineering related hobbies, e.g. ham radio, designing audio amplifiers, etc. My own father had no degree, but is an adept problem solver in addition to being very gifted in working with his hands. He worked his way up from an apprentice pipe-fitter to the highest position possible in the shipyard before retiring. As an apprentice, he was given the opportunity to go to college, but having tried it decided that he preferred working and making overtime to support the family (and pay off his house in seven years). I think the idea that everyone has to go to college is a mistake, and I think companies do themselves a disservice on passing on people that a) don't have a degree or b) don't have a degree in the desired specialty. Of the two best project managers I ever employed, one had no degree and one had a biology degree (we were a technical/engineering organization). One of my favorite interview questions is to ask people what they enjoy doing in their free time. My best employees free-time activity is very similar to their work activity. The sys admins have racks of servers and networking gear in their basements. The developers are tinkering with mobile apps, setting up home music servers, trying out new technologies, etc. Griff Seth: I agree about the free time question. I write this blog in my free time...and it is about the same stuff I do research about.

Hazel Meade (2013-09-17 10:28:34)

When I was in high school I was taught that I should already have decided what I wanted to study by the time I got to college. Obviously college is much more beneficial to kids if they arrive with a major already decided, and a lot of it will end up being wasted time if not. STEM majors in particular depend heavily on the first two years of math and science core courses for the second two years where the real coursework begins. If you aren't already taking the core STEM classes in Freshman year, by sophomore year, you'll have forgotten much of your high school math and it will be nearly impossible to catch up. I can't see much value in spending thousands of dollars a year "finding yourself" by taking random electives. You're supposed to be doing that in high school. Seth: "Finding yourself" is more profitably accomplished by doing internships, which better teach what this or that job would be like. If you are advocating for a gap year, I agree with you.

Hazel Meade (2013-09-17 14:48:49)

I'm not a fan of gap years. I think enriching the high schools with more interesting electives would be the better plan. Let junior and senior year high school students pick more of their own classes and offer a variety of '101' type humanities along with AP math and science. Econ 101, Psych 101, Poly Sci, World History, etc. could all be taught senior year of high school. Seth: I think you overestimate what a high school (more interesting electives) can teach relative to what the rest of the world (gap year) can teach.

Assorted links (2013-09-18 09:18:09)

[...] 5. The Seth Roberts theory of what college should be for, but too often isn't. [...]

Paul (2013-09-18 10:19:14)

Students are very different. I've had students who came in knowing exactly what they wanted to do, others the opposite, older students who needed a degree to get promoted.... What strikes me is how college education is being homogenized - one size fits all and we just have to find the magic bullet seems to be the implicit philosophy now. Seth: I agree. And not just college education.

zbicyclist (2013-09-18 21:52:48)

I don't mean this as a criticism of Seth, who's trying to improve things, but part of this was called in the olden days "working your way through college". That's what's a lot different now. My father in law could work his way through Northwestern (late 1930's). I could work my way through Missouri as a commuter student (late 1960s, tuition \$1250 - that's \$1250 total for four years). Now what you can earn by working 16 hours a week or so doesn't make much of a dent in even a state school's tuition, so perhaps there are fewer students working (or feeling that working while going to college is an important part of their financial/educational process, as opposed to a bit of spending money).

Kelly Smith (2013-09-19 09:07:08)

Great post Seth, I agree that most of the dialogue is missing this critical part of the college purchase. Mentoring, coaching, counseling...whatever you call it, this was definitely something I was looking for from my undergrad education, and like many people, I ended up finding it outside of the "system." It sounds like your psych and the real world course is similar to point #4 in the "University 2.0" concept. I'd love to learn more about your experience with this type of education, and I welcome any feedback on the straw man concept. <http://www.squidoo.com/university-2-0>

Seth Roberts (2013-09-19 14:07:34)

My Psychology and the Real World class is easy to describe: 1. Students found their own internships/volunteer work. I didn't have to do anything or push them. Only students with something in mind took the class - about 12 of them. 2. During class, we discussed what they had learned recently from what they were doing. This required no preparation on my part. So the class was extremely easy to teach, if "teach" is the right word. 3. After the class, some students said it was a great class and they had learned more from it than any other class they had taken. I think I gave all of them A's. They wrote a short paper about what they'd learned.

Karen (2013-09-19 15:00:27)

The ridiculous part of the education system is that we shouldn't have to wait until college to be given the opportunity to find out what we like and are good at. Most of us have no idea how to even begin to answer this question because we have been sitting in a classroom being told what to learn and how to learn it for almost a decade and a half before we are even presented with any kind of choice concerning our education. Forced curriculum does nothing to help kids find their individual talents and interests. This is why I am homeschooling my children. My 11 and 9 year old sons are already well on their way to choosing their future career paths because they are allowed a say in how their education unfolds. Self-directed curriculum is a far better way in which to learn how to set goals and achieve them and when they get to college they will know exactly why they are there and what they need to do to get where they want to go.

## Assorted Links (2013-09-04 05:00)

- [1]fruit and diabetes. Blueberries good, cantaloupe bad.
- [2]R most popular language for "analytics/data mining/data science work" among survey respondents. I wish I could describe the respondents, but I can only say they are people who might call what they do "data mining" or "data science". In addition, the use of R is growing. Most psychology departments teach SPSS or Matlab.
- [3]Thomas Frank criticizes universities, undergraduate education in particular. "An educational publisher wrote to me [asking] to reprint an essay of mine [that is freely available]. . . . The low, low price that students were to pay for this textbook: \$75.95."

1. <http://www.bmj.com/content/347/bmj.f5001?etoc=>

dearieme (2013-09-04 13:23:25)

Astonishing - an apple a day keeps the doctor away. I hope it applies also to British apples, which are more - how to phrase this delicately - flavoursome than American. Unfortunately the blueberries on sale in Britain are tasteless. If anyone thinks he can frighten me off our home-grown strawberries he is sadly delusional.

dearieme (2013-09-04 13:32:19)

"Thomas Frank criticizes universities" Forgive me for repeating myself but Dissolution of the Monasteries.

Mark (2013-09-04 17:28:21)

More bunk out of Harvard... How many different questions can they ask of this same data set (with no adjustments for multiplicity)?

AI (2013-09-04 20:49:48)

wow. i'm surprised. cantaloupes aren't even that good.

dearieme (2013-09-05 13:53:46)

Ahoy, Seth. <http://www.independent.co.uk/news/science/gut-bacteria-could-be-behind-why-so-me-identical-people-are-fatter-than-others-8800808.html>

Zach H (2013-09-05 19:05:52)

Cantaloupe is cheap. Blueberries are expensive. This is likely significant. Also, dearieme: the apples in American grocery stores may not be tasty, but I assure you a bit of effort uncovers delicious apples, many of varieties unavailable in the UK. Seth: Interesting point about cost. Maybe blueberries are better than cantaloupe because they are more likely to supply a nutrient we are not already getting (because, due to price, we are eating fewer blueberry-like foods than cantaloupe-like foods).

Mark (2013-09-06 03:09:51)

Or maybe people who can afford to eat more blueberries can also afford to take many other steps to protect their health. If you have access to the actual paper, just look at the comparison across fruit quartiles in Table 1. All \*measured\* health behaviours (smoking, drinking, exercise, vitamins) increase monotonically across the quintiles, and it's remarkably consistent across the 3 cohorts. Simply put, the people who ate most fruit, on average, were inherently healthier, and that just cannot be controlled for using a statistical model. The same has been true of the previous BIG RESULTS to come out of this Harvard group using

these very same data. Walter Willet is a hack. Seth: Good point about confounding. However, I don't agree "that just cannot be controlled for" – why not? Why not control for smoking, for example?

Mark (2013-09-06 06:57:56)

Because controlling for all "known" confounders does not necessarily reduce the net confounding bias. That is, bias could very well be increased by controlling for things like this... this is very easy to demonstrate through simulations. "Smoking" (as much as that measures the same thing across people) can be controlled for, but not all of the other health related decisions that go along with it.

David Johnston (2013-09-06 17:07:40)

So the Blueberry-Kefirgurt I eat turns out to be healthy. 1) Ferment 20 %/80 % Kefir/Heavy cream mixture for 3-4 days at room temp until very thick and tangy. Cool in a fridge. 2) Stir in blueberries. 3) Eat. Seth: Good idea.

David Johnston (2013-09-06 17:14:42)

R is a horrible language. The more I use it the more I appreciate Python. But sometimes you need a manova and R's got all the stat functions.

disgruntledphd (2013-09-08 05:02:34)

Seth, while most psychology departments teach SPSS/Matlab/Excel (seriously), the use of R in psychology has been growing for a while. Also, lots of data science questions are merely repacked psychology datasets (certainly those relating to advertising and/or social networks). Anecdotally, I have noticed quite a large movement towards R even in my department, where no-one knew what it was when I started using it three year ago.

Stephen Marsh (Ethesis) (2013-09-08 15:45:58)

BTW. <http://www.telegraph.co.uk/earth/environment/climatechange/10294082/Global-warming-No-actually-were-cooling-claim-scientists.html>

lemmy caution (2013-09-16 10:44:50)

I eat a pound of frozen blueberries a night. A two pound bag costs \$10. I am not even going to pretend that that much blueberries is good for you. It does not seem to be all that bad for me though.

## **Magnesium and Rectum Healing (2013-09-05 05:00)**

After I posted a link to [1]an article about magnesium deficiency ("50 studies suggest that magnesium deficiency is killing us"), a reader who wishes to be anonymous looked into it.

After reading your post about magnesium oil, I read up on it, and thought I'd try it. I didn't notice any difference, but I have a report. In my reading, I came across stories of people who sprayed the oil on wounds.

I have a recurring minor irritation that, when it occurs, usually takes weeks to heal. Passing a large stool can cause small tears in the rectum, so small they don't even bleed but nonetheless can be felt. If another stool, even a regular-sized one, passes before the tears heal, they are painfully re-opened, though not re-opened fully. The pain is not severe but is, frankly, a pain in the \*\*\*. In my case it usually takes weeks for the tears to completely heal.

I was a couple weeks into this cycle when my bottle of magnesium oil arrived. I had read that it promotes healing and some people spray it on wounds. So I sprayed it on my irritated area once a day for three days, and on the third day when I passed a stool there was no pain! Never before had it healed so quickly, and I've had this problem at least once a year for over ten years.

I'm impressed. This resembles a theory making an unlikely prediction that turns out to be true. Other examples of magnesium benefits are [2]here and [3]here. Maybe magnesium will improve my sleep. That should be easy to test.

1. <http://www.dumblittleman.com/2013/08/50-studies-suggest-that-magnesium.html#more>

3. <http://blog.sethroberts.net/2008/06/23/scott-adams-magnesium-and-knee-pain/>

---

anon (2013-09-05 05:45:59)

Has this guy tried anything else? Maybe magnesium isn't the key ingredient, maybe any number of different lotions would work.

dearieme (2013-09-05 05:52:49)

We live in a hard water area so there's presumably lots of Ca (certainly) and Mg (possibly) in the water. Perhaps I should phone the Water Company and enquire.

Vic (2013-09-05 07:32:37)

Seth, isn't your sleep quality already at 99+/100? How will you detect any additional improvement? Seth: When I wake up I rate how rested I feel on a scale from 0 to 100 %. On this scale, the difference between 99 % and 100 % is easy to notice – even though it may not seem like much. I think what I am rating is how much remains of something, where 100 % = none. Maybe it is easier to see why 1 % and 0 % can be easy to distinguish.

Tim Beneke (2013-09-05 10:49:00)

FYI: One common treatment for hemorrhoids is to take a bath in epsom salt water; epsom salts are high in magnesium... I've twice now floated in a sensory deprivation room in 10 inches of water saturated with epsom salts – I wonder how much the calming exuberance I and others feel during and afterwards is tied to the absorption of magnesium...

gwern (2013-09-05 16:02:17)

> Maybe magnesium will improve my sleep. That should be easy to test. I look forward to the analysis. As it happens, I've already started randomized & blinded consumption of 800mg magnesium citrate, and sleep will be one of the endpoints.

magnesium (2013-09-12 18:23:31)

People's experiences with magnesium seem to vary. Some claim it helps them sleep, others say it keeps them up. When I first used magnesium (200mg/d), on day four I slept longer/deeper than I had in years. But the effect wore off and my sleep returned to "baseline". I tried increasing the dose (400mg/d), but it made my sleep worse. At 400mg/d I also developed diarrhea.

## **A Little-Noticed Male/Female Difference: Pressure to Conform (2013-09-06 05:00)**

In *Americanah*, Chimamanda Adichie's new novel, she writes (p. 240):

Ojiugo wore orange lipstick and ripped jeans, spoke bluntly, and smoked in public, provoking vicious gossip and dislike from other girls, not because she did those things but because she dared to without having lived abroad, or having a foreign parent, those qualities that would have made them forgive her lack of conformity.

Here is another example, from [1] a profile of Claire Danes:

She changed schools twice, "fleeing one mean girl only to find another incarnation of that same girl in the next school." She was targeted for her looks, her nerdy curiosity, her refusal to conform.

My impression is that these examples illustrate a large male/female difference: Women will commonly criticize another woman for lack of conformity (unless somehow "earned"); men are much less likely to criticize another man this way. When women do it, it is called being catty. There is no equivalent term when men do it – presumably because no one invents a term for something that doesn't happen.

I have never seen this mentioned in the literature on male/female differences (nor in Sheryl Sandberg's *Lean In*). It isn't easy to explain. Could it be learned? Well, in my experience girls are under more pressure to "act a certain way" than boys (Japan is an example), but I can't explain that, either, nor can I see why that would translate to women putting pressure on other women to conform.

One reason this tendency is hard to explain is its effect on leadership. Putting pressure on other women to conform makes it harder for women to become leaders – leadership is the opposite of conformity. Making it harder for women to be leaders makes it easier for men to be leaders. It is hard to see how this particular effect (there are many others) benefits women.

1. [http://www.newyorker.com/reporting/2013/09/09/130909fa\\_fact\\_lahr?currentPage=all](http://www.newyorker.com/reporting/2013/09/09/130909fa_fact_lahr?currentPage=all)

---

Tom (2013-09-06 05:42:00)

I predict that you will be attacked for expressing this idea. :-)

MikeW (2013-09-06 06:02:23)

"I have never seen this mentioned in the literature" As I recall, something like this is mentioned in John Gray's *Men are from Mars, Women are from Venus*. I don't know if Gray ever uses the term "conformity", but he does talk about women needing approval and validation, while we men frankly don't give a damn. By the way, I never bought into Gray's premise. To me it's an insulting stereotype to assume that when a woman talks about a problem, she needs a hug, not a solution. Of course, that may explain why I'm still single... Seth: I haven't read Gray's book. However, needing approval is quite different than disliking non-conformity of other women. The two things – needing approval and disliking non-conformity of other women – do both act in the same direction, to increase conformity.

dearieme (2013-09-06 06:06:53)

Is it an aspect of the fact - if fact it be - that women are less differentiated than men? I know that the standard deviation of IQ among women is smaller than among men. Are there any other quantitative psychological or physiological traits that show that pattern?

Three Pipe Problem (2013-09-06 07:16:28)

dearieme I was reminded of exactly the same thing. Seth, I love the way you pick out new/under-represented ideas and share them. Thanks so much for the time you invest in this blog.

Leslie (2013-09-06 07:43:03)

Perhaps it's more a difference between males and females in how non-conformity is punished and what sort of things are punished. As an example, any queer person will tell you there is pressure to conform from both males and females, but you get threats of violence, actual violence, "corrective rape", and sometimes even murder, from men. The comedian Louis CK has a joke about this difference of physical vs emotional violence between men and women; 'a man will cut off your arm, but a woman will s\*\*\* in your heart'. Of course, you also have "gas lighting" (using lies to make a woman doubt her memory,/perception/sanity), but that's not male on male abuse. I think there is more pressure on women to conform from both men and women. Seth: "More pressure on women to conform from both men and women". That would be a good study. For example, if someone wears an unusual colored shirt, is there a difference in response depending on whether the wearer is male or female?

Leslie (2013-09-06 08:25:37)

Here's a relevant study... <http://blogs.wsj.com/atwork/2013/02/22/conflict-at-the-office-women-and-the-catty-trap/> "The subjects, both male and female, consistently viewed the conflict between the two women in the most negative light." If men are being critical, then they are blunt and honest, if women are critical, then they are catty or b\*tchy. Seth: Well, yes, since there is no male equivalent of "catty" when men criticize other men it follows that different words would be used to describe that criticism. I don't see how that sheds light on whether there is a male/female difference here.

Melissa (2013-09-06 09:04:29)

I think you are missing something here. The people expecting women to comply and exerting that pressure are other women too, in other-words this can be seen as BOTH female oppression AND female leadership.

Ouis (2013-09-06 09:04:50)

I do think that there is some gender bias in the assumption that men don't do this. I am a psychologist and have treated way too many men who were bullied as adolescents because they didn't conform. They were dumped in trashcans, locked in lockers, and beaten up. Gay men are often beaten to death for their differences. That being said, I do wonder with females if there is some evolutionary pressure to conform so as not to attract attention to the female group in general. Someone who stands out as a female may attract dangerous attention to the female "tribe." There may be other competition pressures as well (the female who stands out may attract the alpha ape. Anyhoo, it is all theorizing, but the idea that only females do this too each other is plain wrong. Seth: The idea is that females do it more.

Nancy Lebovitz (2013-09-06 10:18:48)

Men's clothing in Western Civ tends to be much less varied than women's- I don't know if there are other cultures where this isn't the case. Is it pressure to conform or something else?

Tim Beneke (2013-09-06 10:20:04)

Generally, gender researchers in recent decades find that girls and women display more relational violence – malicious gossip, hurtful insults, etc.; while boys and men are more physically violent. "Pressure to conform" probably is tied to this...

Elizabeth Molin (2013-09-06 12:08:15)

dearieme, women are physiologically MORE differentiated than men—we don't pee through the opening we use for sex.

Shawn (2013-09-06 15:41:19)

Could this be a legacy of polygyny type relationships where many women had to share one man? Then they all had to be cooperative (i.e. on the same page) to enhance reproductive fitness?

dearieme (2013-09-07 03:10:01)

"but the idea that only females do this too each other is plain wrong. Seth: The idea is that females do it more." Why do some people find it so hard to grasp any argument about averages? It's as if you said that men are on average taller than women and some chump said 'but my mum's taller than my dad'.

Steve Johnson (2013-09-07 03:36:37)

"Why do some people find it so hard to grasp any argument about averages?" Understanding averages when talking about people leads to crimethink. People are just being responsible and engaging in crimestop.

nile (2013-09-07 11:32:34)

A long, long time ago... a woman who was 8 or 9 months pregnant would have had a difficult time surviving on her own. Not impossible but more difficult. A 9 month pregnant female can't run as fast, climb as fast, jump as high and so on. Chances for survival are enhanced if she is in a community of non-pregnant females and perhaps a few males hanging around because of the sexual availability of the non-pregnant females. If that is the case, then conforming is the most rational strategy - being non-conforming risks ouster. Being non-conforming is an implicit, and sometimes explicit, judgement against the group

Ashish (2013-09-07 14:16:56)

There is a theory that women evolved gossip (and cattiness) as a way to connect with each other during those long days at home while the men were out hunting. As a man, it's easy to interpret gossiping and cattiness as pressure from other women to conform. That's a male-brain interpretation and assumption which may not be true. Perhaps women understand that this cattiness is just cultural, just a way to connect, and do not hear the words (from other women) as literal pressure to conform. I.e. they roll with the verbal punches - they don't take this kind of criticism (from other women) as seriously as a man would. I am neither a woman nor an evolutionary scholar, but I've heard a similar explanations from multiple sources.

Christopher Burd (2013-09-07 22:54:44)

*To me it's an insulting stereotype to assume that when a women talks about a problem, she needs a hug, not a solution.* My personal experience tells me you are wrong: very, very wrong. Instinctually, I agree with you, but I am wrong too.

dearieme (2013-09-08 02:38:45)

"dearieme, women are physiologically MORE differentiated than men—we don't pee through the opening we use for sex." We weren't discussing the plumbing.

Staffan (2013-09-08 04:43:03)

dearieme said, "Are there any other quantitative psychological or physiological traits that show that pattern?" <http://www.sciencedirect.com/science/article/pii/S0092656612001730> <http://staffanspersonalityblog.wordpress.com/?s=men+have+more+varied+personalities>

dearieme (2013-09-08 05:28:54)

Thank you, Staffan.

Elizabeth Molin (2013-09-08 07:41:52)

Sorry, dearieme; I assumed that your use of the word "physiology" covered everything physical, including the plumbing.

KD (2013-09-08 19:20:15)

I'd imagine that it has something to do with sex and mating. The two examples both show women knocking back a rival's reproductive advantages- one for good looks and the other for extra ornamentation. It's pretty obvious that women's looks play a far larger role in finding a mate than mens'. So it makes sense that women would look to hamstring women who have a leg up in that game. It's the same with women who sleep around, they're 'cheating' and the women will be more viscous

than the men policing it. Men don't have a great deal of trouble falling in line behind and supporting somebody they genuinely respect- the captain of the football team type doesn't have a lot of guys gossiping about how he shouldn't show off his bench press. It's a cliché but it's true that the people who 'hate the football team' are the ones dressed in black and smoking behind the library. The other socially dominate types are mostly happy to be along for the ride with their leader. There are occasional power struggles, but when they're over most men are happy to fall into line behind the winner without taking little shots over and over. It's all averages with exceptions, but that largely conforms to my experiences. Looking at real life is a lot more interesting than positing how things ought to be.

ken (2013-09-08 22:11:39)

I wonder if it is part of establishing the pecking order. Perhaps men are quicker to threaten or use violence to establish social dominance, and therefore might use size to determine pecking order nonverbally. If women are slower to threaten or use violence, then superiority must be established using other means.

lemmy caution (2013-09-16 10:36:59)

In bands of hunter gathers, there are strong pressures on men to conform to an egalitarian ethos. Since this is ultimately enforced by violence, a lot of this is weeded out when the state gets a monopoly on violence. Pressures for women to conform are not generally enforced by violence so they are more likely to stick around/ be rediscovered under civilization.

### **Deirdre McCloskey and Me (2013-09-07 05:00)**

In [1]an appreciation of Ronald Coase, I came across [2]an article by Deirdre McCloskey, the economist. It reminded me of our back and forth emails in 2007 about her and Lynn Conway's treatment of [3]Michael Bailey, who had written a book they hated. I reread the emails and found them still interesting, especially McCloskey's claim that she and Conway have/had no special power. Is there a variant of sophistry that refers to self-deception? You can read [4]the whole correspondence, [5]McCloskey's version, which omits my final email, or [6]my version ("McCloskey and Me: A Back-and-Forth", plus plenty of context – my article starts on p. 117 of the 139 pp).

Thank god she and [7]Conway failed to end Bailey's career. The Man Who Would Be Queen ([8]pdf) – about male homosexuals and cross-dressers – remains the best psychology book I have ever read. Last year I assigned my Tsinghua students to read a third of it (any third they wanted). One student said it was so good she read the whole thing.

8. <http://faculty.wcas.northwestern.edu/JMichael-Bailey/TMWBBQ.pdf>

dearieme (2013-09-07 15:17:12)

Admit it, Seth, you had "cattiness" in mind. Seth: No, the opposite. A puzzle about autogynephilic transsexuals is their hyper-masculine behavior. In various ways (e.g., job choice) they appear more masculine than the average man.

Christopher Burd (2013-09-07 22:45:02)

Disgracefully, the Globe and Mail assigned McCloskey to review Bailey's book. I'm glad he's managed to continue his career, but if I'm not mistaken, he never wrote his planned book on "autogynephiliac" transsexuals - TMWWBQ focusses on the effeminate type, doesn't it? If so, that's a loss, especially with transsexual issues being so much in the news. Seth: TMWWBQ covers autogynephilic (non-homosexual) transsexuals. I presume that is why Conway and McCloskey hated it.

## **Dangerous Noise and "Doctors Hurt You" (2013-09-08 05:00)**

I have a friend with life-altering hyperacusis, a hearing problem where ordinary sounds can cause pain. It started after she worked in a noisy workplace for three years.

"People are always told about things they should do for good health: eat right, exercise, wear sunscreen, don't smoke," said my friend. "But they are almost never warned about loud noise, and if they are, it's only about hearing loss far off in the future." Her healthcare philosophy is doctors hurt you, which she finds so self-evident that she can barely explain why she believes it.

Her husband has hyperacusis, too, even worse than hers. His came from too many rock concerts. He sought medical treatment for a disorder that even Google has barely heard of, and now takes a staggering amount of pain medicine. His philosophy, at least historically, has been doctors help you. She has done her best to keep him away from doctors, but there is no doubt that, through a combination of bad advice and bad treatment, doctors have made his health much worse. (The pain medicines do reduce pain – but much of his pain was caused by doctors.) Judging by his and her experience, doctors hurt you is more accurate.

I am writing this in the loudest Starbucks I have ever been in, in New York City. (I have been in hundreds of Starbucks.) Three employees have told me they cannot control the volume of the music. Even with my Bose noise-cancelling headphones, it is too loud. I must find somewhere else. A friend who used to work at Starbucks disputes their claim that they cannot control the volume. She says the content of the music is set by corporate but the volume is controllable at individual stores. A customer at the loud Starbucks told me he thought the employees made the music so loud to drive customers away.

Exhibit 1 in the argument that doctors hurt you is [1]tonsillectomies, probably the most common operation ever. Your tonsils are part of your immune system – removing them makes as much sense as removing part of your brain. Tonsillectomies remained common long after it was clear that tonsils were part of the immune system. Perhaps doctors didn't understand high school biology? Or they didn't care? Either answer suggests that doctors should be avoided.

1. <http://boingboing.net/2012/01/10/tonsillectomy-confidential-do.html>

---

dearieme (2013-09-08 05:26:26)

The idea that nobody warns you about the health risk of loud noise seems pretty silly to me. Indeed, why would you need warning? If you shrink away from it, what more do you need to know?

PeterC (2013-09-08 06:51:00)

Why not visit some of NYC's wonderful independent cafes, for generally better coffee and less ear-splitting?

Judy B (2013-09-08 08:08:56)

The damage that can be done by over exposure to loud sounds has long been known! That is why the guys guiding planes on the ground at airports wear noise blocking ear phones. Too many were losing their hearing. For years, ENT's have also been warning of the damage to the inner ear from loud music, including the popular ear buds. Unfortunately the warnings have fallen on deaf ears (pun intended).

Alex Chernavsky (2013-09-08 11:05:26)

What's odd to me is that I know a fair number of people who are in their 40s and 50s and who have attended lots of loud rock concerts over the years, and continue to do so. I have not noticed any hearing loss in them. I'm also mystified by stories such as this one: <http://www2.canada.com/ottawacitizen/news/story.html?id=2768201f-b809-4b9a-bdd6-a091929e7149&p=2>

The festival's loudest performance came during KISS – the band apparently hit a high of 136 dB before an NCC official insisted that the sound engineer turn it down.

That performance by KISS is rumored to be one of the loudest, ever. I wonder how the concert-goers (especially the ones right near the stage) escaped serious, permanent damage to their hearing.

Joanna (2013-09-08 11:20:13)

I often wonder how much damage is done every day to the hearing of the (usually immigrant) lawn care workers in my (and many US neighborhoods) who use large very noisy mowers and leaf blowers every day without any noticeable ear protection. If I find the noise level a problem and I am inside my house how much is it affecting them?

AI (2013-09-08 13:02:22)

What percentage of 1960's era pediatric surgeons could even bear the emotional and ethical burden of knowing that they had irreparably damaged the immune systems of thousands of children? (Not to mention the lawsuits.) The belief in the validity of such surgeries must remain intact until those doctors have passed away.

George (2013-09-08 14:41:51)

Which NYC Starbucks Seth? Seth: In Chelsea on 8th Ave, I think. Or maybe 7th Ave? Something like that. A small narrow one.

Tom (2013-09-08 15:06:05)

Al, as the son of a surgeon, I can tell you that surgeons simply don't believe studies associating their livelihood with bad outcomes.

Nancy Lebovitz (2013-09-08 15:07:33)

Hypotheses: the employees at the very loud Starbucks had a boss who insisted on the high volume music or they liked the loud music themselves. If you care that much, it would be interesting to contact higher level management.

Marc Richard (2013-09-08 16:49:03)

I don't know how bouncers and bartenders at clubs don't become deaf in a week. I can barely stand one night out at those places and my ears are ringing for days! Also, concert venues are some of the worst offenders. The kids standing in front of the speakers have no clue what they're doing to their ears.

Ross (2013-09-08 17:55:30)

This is an excursus, but I had Bose noise-canceling headphones for years and then I tried simple firearm surpressing earmuffs. The [1]Peltor Optime 105 Earmuff is vastly better at reducing noise and I can wear them all day while I'm working at my job as a programmer. I switched to them after reading [2]Peopleware which cited some study that found that creative leaps in programming are frequently missed if you listen to music while programming.

2. [http://www.amazon.com/Peopleware-Productive-Projects-Teams-Edition/dp/0321934113/ref=sr\\_1\\_1?ie=UTF8&qid=1378688033&sr=8-1&keywords=people+ware](http://www.amazon.com/Peopleware-Productive-Projects-Teams-Edition/dp/0321934113/ref=sr_1_1?ie=UTF8&qid=1378688033&sr=8-1&keywords=people+ware)

TomGinTX (2013-09-08 19:11:52)

Ross, thanks for the tip.

Sameer (2013-09-08 19:34:02)

Thank you so much Ross! I have been looking for a suggestion on that note.

Kirk (2013-09-09 21:13:11)

Another thanks to Ross for the tip. I offer two recent and relevant stories. Recently my wife and I flew to California on a Saturday, leaving at 11:50 AM. Apparently most Midwestern vacationers start drinking before a noon flight and continue drinking during the flight. The volume in the plane rose higher and higher as the drunks yelled at each other and four babies cried. I finally tore pieces of paper napkin and stuffed the wads in my ears. The other story happened at my physician's office several weeks ago. I had gone in for a yearly physical. They do the paperwork thing and then have you wait outside the doctor's office. Unfortunately for me, a 60 inch TV screen mounted above the admissions window blared the sound to some reality TV show about building gignormous back yard decks. The sound drove me further and further away, until I was standing in the hall and peeking around the corner as I waited for the nurse come retrieve me. It's not that I dislike loud music. My favorite band for years was Sonic Youth.

Alex Chernavsky (2013-09-10 04:20:11)

Doctors and dentists used to have quiet waiting rooms, where you could sit and read a book. No more. Every waiting room now seems to have a large, loud TV mounted on the wall. I wonder if the majority of patients think that this is a good thing.

Jerry (2013-09-14 09:33:01)

"Exhibit 1 in the argument that doctors hurt you is tonsillectomies, probably the most common operation ever." How about circumcision? I'm talking about routine infant circumcision (currently performed mostly on unconsenting newborn males in the US). Is that not far more common than tonsillectomy? Does it not cause far greater harm? Seth: Yes, it is far more common. "Does it not cause far greater harm?" That's not clear at all. Why do you think this?

Susan (2013-09-16 07:34:45)

I have for a long time been sensitive to loud sound. In the 80's I walked out of a Billy Idol concert because it was killing my ears. I often ask coffee shops and restaurants to reduce the volume, and although they don't like it and friends are sometimes embarrassed I do not feel guilty at all. One friend wore cotton in his ears for many years and I have taken up the practice. He is a musician and so am I, so to reduce stress and keep good pitch, I took up his practice. Be prepared for people asking you if there is something is wrong with your ears. Take care of yourself, don't be afraid to ask for what you want. Think outside the box!

lemmy caution (2013-09-16 10:20:22)

I go to a lot of loud concerts and have tinnitus. Doctors warn people about loud noise all the time. There seems to be a psychological component to people who are disturbed by ear disorders. The more you focus on the problem, the bigger the problem becomes. This habituation therapy seems to work for hyperacusis as well: [http://en.wikipedia.org/wiki/Tinnitus\\_retraining\\_therapy](http://en.wikipedia.org/wiki/Tinnitus_retraining_therapy)

## More About Magic Dots (2013-09-09 05:00)

Govind M., the Stanford grad student [1]who recommended brown noise, has good things to say about magic dots:

I have been using magic dots for about two months now and they work. I have no idea why they work – maybe it's the reinforcement – but they do. I enjoy making them and for me, I have to finish them. I use 9 min/mark for 90 min intervals, which also provides a very easy way to track time. A four box day is enormously productive, though the fourth box typically gets torpedoed by a meeting or something.

One of the advantages of magic dots is that instead of setting down an intimidating 90-minute chunk of time, my mental horizon is shortened to the next 9 minutes. After that, the box takes over. So in situations in which (1) it is difficult to get started and (2) I want to add structure to the day, I use magic dots.

I asked, "When you are using the magic dots, do you work for longer periods of time before taking a break?" Govind said:

Yes. However, it is possible that goal gets shifted from "be focused and attentive and not goofing off on facebook" to "work long enough make 10 marks on a piece of paper." It makes it easier to start and to continue on working.

I too find that magic dots make it easier to start work. I think this happens because the task in front of me (getting work done) seems more doable.

---

Dena Shunra (2013-09-09 10:07:28)

I think the dots and paying attention to making them at fixed intervals distract the uppermost layer of consciousness, the one that otherwise distracts me. I find that some kinds of music achieve this for me, but not reliably. Dots distract that layer of consciousness reliably. When that part's taken care of, it's a lot easier for me to get into a "flow" state - because my own mind is not getting in my way. Another trick that works well for me is counting things - it seems to keep the same mental function too busy to distract me. N=1 of course. Seth: That's an interesting analysis. I'm not sure what you mean by "counting things". What things, for example? When do you count them? How does it help?

Dena Shunra (2013-09-10 07:55:04)

Any counting works for distraction: birds passing by my window; words translated per time unit (15 minutes is good); occurrences of the letter q in my text; typos (times I have to use the backspace). For what it's worth, counting things helps distract that layer of consciousness when I'm trying to go to sleep, as well. Not sheep (I don't have any handy), but reviewing

places I've seen and counting the number of roadbumps in a parking lot, or of branches in a tree work really well. My working explanation of this, which I came to while trying to build a model to describe my work, is that there are "deeper" processing layers (which I need to access professionally, so I can translate units of meaning rather than merely words) that get very distracted by the constant chatter of the top layer (which keeps wanting to talk to me, in words; that massively gets in the way of translating someone else's words). Even deeper layers help get me over conceptual roadblocks (translating metaphors is fun, but tricky); distracting the layers that get between me and \*them\* requires more sensory involvement (going for a walk, for example).

vs (2013-09-10 10:02:03)

I combined magic dots with Govind's recommendation for brown noise. This helps the time pass while working. It also seems to help me work longer hours. Thanks to Seth and Govind for these helpful productivity hacks. On iTunes and I downloaded "Brown Noise Loop" from the album "White Noise Loops for Sleep" by the artist "Sounds for Life". (I find this mp3 more pleasant than the free brown noise mp3s I found online.) Brown Noise Loop is 9:30. I play it on low-volume on repeat. It fades out at the end, so without looking at the time I know about 10 minutes have past. I mark a dot. Then after five dots, or 50 minutes, I take a 10 minute break. I make a pattern like the five side of dice. The hourly breaks came from Cal Newport, and his book "How to Become a Straight-A Student". Breaks between five to fifteen minutes on the hour seem to help extend the period of time people work. Newport wrote this book while completing his PHD at MIT. It's helpful not just for students but also "knowledge workers"- those that read, write, and research in their work.

## **The Blindness of Scientists: The Problem isn't False Positives, It's Undetected Positives (2013-09-10 05:00)**

Suppose you have a car that can only turn right. Someone says, Your car turns right too much. You might wonder why they don't see the bigger problem (can't turn left).

This happens in science today. People complain about how well the car turns right, failing to notice (or at least say) it can't turn left. Just as a car should turn both right and left, scientists should be able to (a) test ideas and (b) generate ideas worth testing. Tests are expensive. To be worth the cost of testing, an idea needs a certain plausibility. In my experience, few scientists have clear ideas about how to generate ideas plausible enough to test. The topic is not covered in any statistics text I have seen – the same books that spend many pages on to how to test ideas.

Apparently not noticing the bigger problem, scientists sometimes complain that this or that finding "fails to replicate". My former colleague Danny Kahneman is [1]an example. He complained that priming effects were not replicating. Implicit in a complaint that Finding X fails to replicate is a complaint about testing. If you complain that X fails to replicate, you are saying that something was wrong with the tests that established X. There is a connection between replication failure and failure to generate ideas worth testing. If you cannot generate new ideas, you are forced to test old ideas. You cannot test an old idea exactly – that would be boring/repetitive. So you give an old idea a slight tweak and test the variation. For example, someone has shown that X is true in North America. You ask if X is true in South America. You hope you haven't tweaked X too much. No idea is true everywhere, except maybe in physics, so as this process continues – it goes on for decades – the tested ideas gradually become less true and the experimental effects get weaker. This is what happened in the priming experiments that Kahneman complained about. At the core of priming – the priming effects studied 30 years ago – is a true phenomenon. After reading "doctor" it becomes easier to decide that "nurse" is a word, for example. This was followed by 30 years of drift away from word recognition. Not knowing how to generate new ideas worth testing, social psychologists have ended up studying weak effects (recent priming effects) that are random walks away from strong effects (old priming effects). The weak effects cannot bear the professional weight (people's careers rest on them) they are asked to carry and sometimes collapse ("failure to replicate"). Sheena Iyengar, a Columbia Business School professor and social psychologist, got a major award ([2]best dissertation) for and wrote [3]a book about a new effect that has turned out to be [4]very close to non-existent. Inability to generate ideas – to understand how to do so – means that what appear to be new ideas (not just variations

of old ideas) are more likely to be mistakes. I have no idea whether Iyengar's original effect was true or not. I am sure, however, that it was weak and made little sense.

Statistics textbooks ignore the problem. They say nothing about how to generate ideas worth testing. I haven't asked statisticians about this, but they might respond in one of two ways: 1. That's someone else's problem. Statistics is about what to do with data after you gather it. That makes as much sense as teaching someone how to land a plane but not how to take off. 2. That's what exploratory data analysis is for. If I said "Exploratory data analysis can only identify effects of factors that the researcher decided to vary or track. Which is expensive. What about other factors?" they'd be baffled, I believe. In my experience, exploratory data analysis = full analysis of your data. (Many people do only a small fraction, such as 10 %, of all reasonable analyses of their data.) Full analysis is better than partial analysis, but calling it a way to find new ideas fails to understand that professional scientists study the same factors over and over.

I suppose many scientists feel the gap acutely. I did. I became interested in self-experimentation most of all because it generated new ideas at a much higher rate (per year) than my professional experiments with rats. I had no idea why, at first, but as it kept happening – my self-experimentation [5] generated one new idea after another. I came to believe that by accident I was doing something "right". I was doing something that fit a general rule of how to generate ideas, even though I didn't know what the general rule was.

T

he sciences I know about (psychology and nutrition) have great trouble coming up with new ideas. The paleo movement is a response to stagnation in the field of nutrition. The Shangri-La Diet shows what a new idea looks like in the area of weight control. The failure of nutritionists to study fermented foods is ongoing. Stagnation in psychology can be seen in the fact that antidepressants remain heavily prescribed, many years after the introduction of Prozac ([6] my work on morning faces and mood suggests a much different approach), lack of change in treatments for bipolar disorder over the last 50 years (again, my morning-faces work suggests another approach), and in the failure of social psychologists to discover any big new effects in the last ten years.

Here is the secret to idea generation: Cheaper tests. To find ideas plausible enough to be worth testing with Test X, you need a way of testing ideas that is cheaper than Test X. The cheaper your test, the larger the region of cause-effect space you can explore. Let's say Test Y is cheaper than Test X. With Test Y, you can explore more of cause-effect space than you can explore with Test X. In the region unexplored by Test X, you can find points (cause-effect relationships) that pass Test Y. They are worth testing with Test X. My self-experimentation generated new ideas worth testing with more expensive tests because it was much cheaper than existing tests. Via self-experimentation, I could test many ideas too implausible or too expensive to be tested conventionally. Even cheaper than a self-experiment was simply monitoring myself – tracking my sleep, for example. Again and again, this generated ideas worth testing via self-experimentation. I did what all scientists should do: use cheaper tests to generate ideas worth testing with more expensive tests.

August (2013-09-10 06:15:40)

Cheaper tests are good, unless the cheaper tests are computer models. We need cheaper real world tests. Didn't you post a long time ago about the error rate of DNA computer models? I learned about the dubious nature of computer modeling via the intersection of politics and climatology. Seth: Computer models aren't tests of theories, they are theories.

Tom (2013-09-10 08:50:13)

A good illustration of your point: <http://well.blogs.nytimes.com/2013/09/10/myths-surround-breakfast-and-weight/>

kxmoore (2013-09-10 09:00:42)

i wonder if this test is replicable. The implications are huge considering the explosion of obesity and it's related health effects. <http://www.ncbi.nlm.nih.gov/pubmed/22863169>

Wil B (2013-09-10 09:13:37)

Experience has shown, I believe, that this is a particularly glaring problem in the context of drug testing and development in the pharmaceutical industry. Much of this is surely brought about by conflicts of interest (and a certain amount of corruption) which are endemic in this exceedingly profit-driven industry. Another issue is the common disregard of true scientific method (Popper anyone?) in the planning and conduct of testing because so much of the "testing" is done with profits in mind. Shouldn't the object (protocol) for whatever is being tested be to disprove a particular hypothesis, rather than allowing biases to creep in so that a certain desired result can be realized and money can be made? A failure to disprove a hypothesis would be much more honest and convincing, wouldn't it? Seth: If "profit" includes career advancement, salary increase, grant renewal, and so on, I think about 100 % of testing is done with profit in mind. Almost always some results are more profitable than the others.

Kim Øyhus, physicist (2013-09-10 23:38:20)

Tests confirming a theory, will give less and less confirmation for more and more work. Tests falsifying a theory, are much more efficient. This means that cheap good scientific results will consist of lots of partially confirmed theories, with lots more falsified theories discarded. Seth: "Tests falsifying a theory are much more efficient." Hmm. You don't have a choice. You can't choose whether your test will support or falsify your theory. That depends on the results. However, I do think that tests of ideas of intermediate plausibility produce more information – more shift in belief – than tests of ideas that are very high or very low in plausibility. But that's just the average shift in belief. More interesting is what the distributions look like.

August (2013-09-11 09:30:24)

I agree, but they are 'testing' against computer models and presenting the results as evidence to the public. I've even heard of it locally, in biochem. My coworker's former boss was doing research into proteins related to cancer. They kept trying to get him to test against computer models. They closed his lab down eventually, and he had to go work as someone else's assistant.

Wil B (2013-09-12 08:31:28)

Seth said (re the scientific approach of attempting to disprove a hypothesis vs. trying to prove the hypothesis): You don't have a choice. You can't choose whether your test will support or falsify your theory. That depends on the results. Perhaps we are discussing different categories and goals of "testing." Staying with the category of drug development and testing for purposes of illustration, let's say a company's hypothesis is that compound X, being developed in a laboratory, is generally effective to treat Y disease in humans and will not have any bad side effects. Employing the usual testing methods, a study group of investigators administers compound X to human subjects with disease Y to see if the compound cures (or ameliorates) the disease. If a significant number of the subjects are cured (or get better) after taking the compound, and do not appear to suffer debilitating side effects, the hypothesis is "proven," the results are positive, and the company will make a lot of money selling it to patients with disease Y. But can we be certain that the testing and record keeping was conducted honestly and without bias in advance; i.e., free of undue influence and a strong desire to reach a certain result? Wouldn't it be better to at least have a

separate, independent arm of the study (if for no other reason than to keep the results-oriented group of investigators honest) examining and tracking the same test subjects and maintaining their own data with the opposite "goal" of falsifying the first group's finding? If the latter group fails in its effort to falsify the first group's results, that's fine because the company (and the FDA) could have much more confidence that the compound will, in fact, be a safe and efficacious product. In this instance the failure to falsify was in reality a positive result! In this context, which method of drug development, testing (and perhaps ultimate approval) would most doctors and end users prefer? Wil B.

### **"The Cause of Ulcers is Bacteria" Makes as Much Sense as "The Cause of Car Accidents is Cars"** (2013-09-11 05:00)

If I were to look at you, and say, in a serious tone of voice, "The cause of car accidents is cars", you'd think I'm nuts. It's not a useful statement. Yet many medical and science experts – including the people who award the Nobel Prize in Physiology or Medicine – believe it is helpful to say "the cause of ulcers is bacteria". The two statements are similar because only a small percentage of cars get in accidents and only a small percentage of people infected with *H. pylori*, the bacterium that supposedly "causes ulcers", get ulcers. A helpful investigation of what causes ulcers would figure out the crucial difference(s) between those infected with *H. pylori* who don't get ulcers (almost all) and those who do (very few).

I recently encountered the "the cause of ulcers is bacteria" twice in one day. Once in [1]a book review by John Timpane:

Barry Marshall, who discovered what causes stomach ulcers, played fast, loose, and messy with his methods and data. He was right, and got the right answer, and now we know.

(Timpane is right about the "fast, loose, and messy" part. Marshall ingested a large number of *H. pylori*. He failed get an ulcer – and claimed the outcome supported his view that *H. pylori* causes ulcers.) And once in The New Yorker, in [2]a long article about the benefits of microbes, especially *H. pylori*, by Michael Specter:

In 1982, to the astonishment of the medical world, two scientists, Barry Marshall and J. Robin Warren, discovered that *H. pylori* is the principal cause of gastritis and peptic ulcers.

Should I expect science journalists to understand causality? Maybe not. But it is interesting that the people who award the Nobel Prize in Medicine and "the medical world" do not understand it.

2. [http://www.newyorker.com/reporting/2012/10/22/121022fa\\_fact\\_specter](http://www.newyorker.com/reporting/2012/10/22/121022fa_fact_specter)

---

Mark (2013-09-11 07:58:56)

I agree, and think that another good analogy would be saying that having no Y chromosome is a cause of pregnancy.

Nancy Lebovitz (2013-09-11 09:49:38)

"Ulcers are caused by bacteria" is still an improvement over "ulcers are caused by stress and/or spicy food". Seth: That's not clear. Maybe 99 % of everyone is infected with *H. pylori* and, of those infected, only those exposed to stress develop ulcers. If so, the old thinking ("ulcers are caused by stress") was better than the new thinking ("ulcers are caused by bacteria").

RAD (2013-09-11 10:02:24)

Seth, I'm grasping to understand your logic. As I understand it, the causality is *H. pylori* Infection -> Chronic Gastritis -> Gastric Ulcers -> Gastric Cancer. Prior to Barry Marshall the presumed causation was Stress -> Gastric Ulcers. Marshall did not get ulcers after his experiment but he immediately had symptoms of chronic gastritis. Are you saying there is no causation between *H. pylori* and chronic gastritis or are you saying that you would like to see more qualifiers when people discuss the association between the PRESENCE of *H. pylori* and chronic gastritis (which I think is low)? Seth: I don't know if ordinary amounts of *H. pylori* cause gastritis (Marshall ingested an unusually large amount), nor do I know what fraction of gastritis cases are associated with *H. pylori*. So I can't answer your question.

Alex Chernavsky (2013-09-11 10:23:37)

Seth, is there an article or a paper that – in your view – accurately describes the etiology of ulcers? I'm asking because I'm not clear about your specific objections to the *H. pylori* hypothesis. Seth: I don't know of one. As far as I can tell, the etiology is almost completely unknown. Most people have *H. pylori* infection. Almost no one gets ulcers. Why do some people with *H. pylori* infection get ulcers? Very little is known about this. My objection to the *H. pylori* hypothesis is that it has confused a lot of people. A lot of people think it is well-understood what causes ulcers. That's not true.

Nancy Lebovitz (2013-09-11 11:18:03)

I think Seth's point is that there hasn't been further investigation into what some people are get serious *h. pylori* infections and others don't.

K Daniel (2013-09-12 00:43:10)

If, as you proclaim, ulcers are NOT caused by bacteria then why does the now standard treatment for ulcers (a two-combination course of antibiotics) "cure" ulcers in the vast majority of cases? What, in your opinion, is causing the ulcers that are "cured" by the antibiotics? If you can't answer that question then I have a new theme: Seth's blog is related to science the same way that creationism is related to evolution. Seth: Ulcers supposedly cured by antibiotics come back very frequently. In your haste to say something derogatory, you seem to not have fully understood my comment. I don't claim to know what distinguishes people infected with *H. pylori* who don't get ulcers (almost everyone) and those infected with *H. pylori* who do get ulcers (a tiny fraction).

dearieme (2013-09-12 03:29:59)

"what distinguishes people infected with *H. pylori* who don't get ulcers (almost everyone) and those infected with *H. pylori* who do get ulcers (a tiny fraction)": that's a very good point, and one that I hadn't appreciated. Why on earth hasn't it been investigated properly?

GB (2013-09-12 04:10:43)

Hi Seth, Apologies for the change of topic, but I don't know how else to contact you. I'm keen to buy Shangri La diet on my kindle, and I know there's a version available for sale. But as soon as I log into my Amazon account, I'm no longer offered the opportunity to buy it. It's like the kindle version no longer exists, only the physical hard cover and paperback versions are available to me. I'm in Australia, and suspect the book is not offered there for some sort of licencing reason. Are you aware of this? Many people Down Under could use your book these days. Thanks for your scientific contribution and great blog.

Mark (2013-09-12 08:18:26)

Do antibiotics actually "cure" the ulcer, or do they just help to meliorate the symptoms? These are two vastly different things. Perhaps *H. pylori* simply exacerbate the symptoms (e.g., by causing irritation or inflammation), so antibiotics appear to "help" the ulcer (but in fact they're doing no such thing). The bottom line, as Seth pointed out, is that if *H. pylori* is the "cause" of

ulcers, then how can the majority of the world's population be infected but very few actually have ulcers? This is all very similar to the whole "high cholesterol causes heart disease" myth.

JM (2013-09-12 12:33:06)

Based on a number of things I have read about H. pylori and ulcers, my personal thoughts are that if almost all of us carry the bacteria then those who do get ulcers it is because the bug has found a weakness in their natural defenses and used it to attack the stomach lining - whether that weakness is caused by stress, diet or something else hasn't been determined. Also found this article very interesting - a small study found a link between the presence of H. pylori and atrial fibrillation of the heart. At the end of the article there is the statement "H. pylori is a very resilient bacterium and has properties that enable it to escape detection by the immune system" <http://www.sciencedaily.com/releases/2005/06/050616062204.htm>

### **Dragon vs. Dragon: Same Name, Different Genus? (2013-09-12 05:00)**

In a discussion of dragonfruit (common in China), a Chinese friend pointed out that Chinese dragons and Western dragons are quite different. I was surprised, I hadn't noticed this. My friend was right:

There are two distinct cultural traditions of dragons: the [1]European dragon, derived from European folk traditions and ultimately related to Greek and Middle Eastern mythologies, and the [2]Chinese dragon, with counterparts in Japan, Korea and other East Asian countries.

[3]says Wikipedia. Why two different imaginary animals would be quite similar isn't obvious.

1. [http://en.wikipedia.org/wiki/European\\_dragon](http://en.wikipedia.org/wiki/European_dragon)
2. [http://en.wikipedia.org/wiki/Chinese\\_dragon](http://en.wikipedia.org/wiki/Chinese_dragon)
3. <http://en.wikipedia.org/wiki/Dragon>

---

Richard Sprague (2013-09-12 07:10:18)

This is just an artifact of language, and how somebody a long time ago decided that the proper translation of "Qilin" is "Dragon". They could have easily decided to simply call it a "Qilin". This is similar to how the word "Typhoon" just means "Hurricane in the Pacific". (or more precisely, "tropical cyclone". I bet that whatever similarity there is between the two imaginary animals is a recent development: before East-West contact, they could have been totally different long ago.

Three Pipe Problem (2013-09-12 07:56:38)

Watch "Symbols of an Alien Sky" and you will understand where the dragon myths came from and what they have in common.

Three Pipe Problem (2013-09-12 09:52:14)

P.S. It's not about aliens.

Brandon Berg (2013-09-12 09:57:07)

They're not all that similar. Chinese dragons are essentially flying snakes, whereas western dragons have four legs, large wings,

and torsos. All they have in common are flying, being reptilian and breathing fire. (Actually, do Chinese dragons do that?) Note also that Chinese "lions" are not all that similar to real lions, and in Japanese the real giraffe is named after a very different mythological creature, the kirin.

kxmoore (2013-09-12 10:54:56)

it has been proposed that dragon myths evolved from exposure to dinosaur fossils. would explain cross-cultural similarities.

shtove (2013-09-12 12:04:43)

Lions in medieval heraldry were actually leopards. And the giraffe is camelopardalis. Dragon is from dracus, which means ia. water snake, which gives us Dracula. Mwahahahaa.

dearieme (2013-09-12 12:06:14)

I've seen the claim that the Welsh dragon was introduced to the Romano-Britons by Sarmatian cavalry units of the Roman Army. [http://en.wikipedia.org/wiki/Welsh\\_Dragon](http://en.wikipedia.org/wiki/Welsh_Dragon) The Sarmatians seem to have come from an area that stretched as far east as the Caspian.

Florinescu Eduard (2013-09-12 12:38:01)

How would an animal look if you would found its bones. Do you think our civilizations is the only one digging or finding dinosaur bones. Maybe they project the shadow of their civilization on this reconstructed unidentified animal.

Florinescu Eduard (2013-09-12 12:44:03)

@kxmoore Just now I saw your comment I thought about this but didn't found this speculation in literature, can you give me a reference where you found this mentioned.

David (2013-09-12 12:51:49)

The Chinese dragon is based on the appearance of biggish asteroid impacts, the atmospheric trail in particular.

Tim Beneke (2013-09-12 13:06:25)

I'm told by a Chinese friend that, for the Chinese, the dragon is always serious. This came as a surprise since I always saw dragons as at times, light and sources of amusement...

kxmoore (2013-09-12 19:54:07)

Florinescu see "the first fossil hunters" by Mayer [http://en.wikipedia.org/wiki/Adrienne\\_Mayor](http://en.wikipedia.org/wiki/Adrienne_Mayor) #Fossil\_Legends\_of\_the\_First\_Americans\_282005.29

## **Hobbyist Science vs. Professional Science vs. Personal Science (2013-09-13 05:00)**

In [1]a TED talk, Paula Scher, a graphic designer, told how a hobby of painting maps turned into something like a job.

I was up in my country house, and for some reason, I began painting these very big, very involved, laborious, complicated maps . . . They would take me about six months initially, but then I started getting faster at it. Here's the United States. Every single city of the United States is on here. . . . One of my favorites was this painting I did of Florida after the 2000 election that has the election results rolling around in the water. . . . Somebody . . . saw the paintings and recommended them to a gallery, and I had a first show about two-and-a-half years ago, and I showed these paintings that I'm showing you now. . . . They sold quickly, and became rather popular. . . . The gallery wanted me to have another show in two years,

which meant that I really had to paint these paintings much faster than I had ever done them. . . . I was no longer at play. I was actually in this solemn landscape of fulfilling an expectation for a show, which is not where I started.

A hobby turned into a job. This has happened countless times – I believe [2]all jobs started as hobbies.

One hobby that turned into a job is science. The first scientists were hobbyists – for example, Darwin and Mendel. The success of hobbyist scientists led to the creation of full-time jobs that included doing science – professors of science at universities. When science became a job, something was gained (professionals had more time per day, money, training, institutional support, collegial support, and prestige than hobbyists) and something was lost (professionals had less freedom than hobbyists). Professionals could do many things hobbyists could not, but the reverse was also true: hobbyists could do many things professionals could not. For example, they could work on a question for ten years without publishing anything (Mendel, Darwin) and entertain highly heretical ideas (Darwin). Professionals needed steady output and dared not offend, for fear of losing their job.

[3]My personal science (personal science = using science to help yourself) is another step in this history. I combined the freedom of hobbyists with the knowledge, skills and resources of professionals. I can do whatever self-experiments I want and test whatever ideas I want. Yet I also have professional levels of training, knowledge, skill, and (to some extent) equipment provided by my job as a psychology professor, Berkeley library access, the Internet, free software, and cheap computers. To these two elements – the freedom of hobbyists, the resources of professionals – my personal science added a third element not found in hobbyist or professional science: the motivation of a person with a problem. I wanted better health. My personal science helped me get it. In the beginning, I wanted to sleep better, lose weight, have less acne, and be in a better mood. Later, I discovered new ways [4]to improve my brain function and blood sugar. Just combining the freedom of hobbyists with the resources of professionals, personal science would probably be a big improvement. Adding better motivation suggests that personal science is even more likely to improve our lives by learning what professional scientists haven't learned. The combination of professional science and personal science will be far more powerful (= more useful) than professional science alone.

I've seen this in my own life, over and over, and I predict it will eventually be true for everyone. Learning how to control one's own health – how to sleep well, for example – is non-trivial knowledge.

Nancy Lebovitz (2013-09-13 06:15:54)

I've been thinking that publication schedules for news and magazines have a similar ill effect to what you describe for science. If you have to keep filling a certain amount of space or time with "information", you're going to be either puffing up small amounts of information or missing important stuff, probably both. Admittedly, since resources are limited, missing important things is inevitable, but having to puff up relatively minor things wastes resources.

Tom (2013-09-13 10:04:45)

Empowering personal scientists would also probably be far faster and efficient than haranguing kids to go into science majors (which might result in more cheap lab techs and teaching assistants in ten or fifteen years, but not necessarily more

breakthrough discoveries.) One thing might help propel personal science is a series of contests, at about 1/100th the scale (or less) of the SpaceX prize. Contests might recognize things like the annual best breakthrough in... - micro power production - fermented food production - bee keeping - backyard mulching - gray water repurposing/usage - low-water landscaping - inexpensive micro-apartment design - inexpensive, supportive senior living design - safer/easier/more effective/higher compliance exercise methodologies to preserve muscle mass in seniors ...etc. The prizes would probably not even need to be financial to be effective. And I can't think of a better coordinating point than The Journal of Personal Science (nor a better coordinator than you, Seth.)

Seth Roberts (2013-09-13 10:05:55)

I agree. And there are many things – some of them true – that professional journalists can't say for fear of losing their jobs.

Bobby Levin (2013-09-13 10:55:20)

Seth: I certainly agree with what you have written, but one thing that concerns me is whether our short term successes could be deceptive. For example, could the ingestion of significant amounts of say butter cause long term health issues that would only be discovered when it is too late. Or could taking a certain nutritional, have short term benefits and longer term consequences.

Seth Roberts (2013-09-13 11:27:08)

The history of pharmaceutical drugs says yes, this is a possibility. Many drugs with short-term benefits have turned out to have long-term costs that weren't made clear. Likewise, the bias of "evidence-based medicine" (which pays great attention to the benefits of treatments, and almost no attention to their costs) also suggests this is a serious problem with professional medical research. When you study yourself, I think there is less bias and better monitoring. You can detect bad effects sooner.

### **Eric Kandel Sheds Light On Who Wins Nobel Prizes (2013-09-14 05:00)**

The most interesting thing about the Nobel Prize in Medicine is its predictable irrelevance to major health problems. Year after year, the prize-winning work has failed to reduce heart disease, cancer, depression, stroke, diabetes, schizophrenia, and so on. Another interesting thing about the Nobel Prize in Medicine is that Eric Kandel, a Columbia Medical School professor, managed to win one. In 1986, a book called *Explorers of the Black Box: The Search for the Cellular Basis of Memory* by Susan Allport told how Kandel tried to take credit for other people's discoveries. Not a pretty picture. Yet in 2000 he won a Nobel Prize for those or very similar discoveries. Did Allport exaggerate? Did her sources deceive her? Did Kandel – contrary to what Allport's book seems to say – deserve a Nobel Prize?

I can't answer these questions. However, a [1]recent article by Kandel ("A New Science of Mind") in the New York Times sheds light on how well he understands medicine and neuroscience. Not well, it turns out. He writes:

We are nowhere near understanding [psychiatric disorders] as well as we understand disorders of the liver or the heart.

Actually, our understanding of liver and heart disorders is close to zero, matching our understanding of psychiatric disorders. If we had some understanding of heart disease, for example, we would know why heart disease is much rarer in Japan than in the United States.

Kandel goes on to say "the prefrontal cortex . . . is the seat of executive function and self-esteem." The self-esteem claim is apparently based on [2]this study. Okay, people with low self-esteem may be more sensitive to feedback than people with high self-esteem. That one region in the brain exhibits such a difference doesn't show it is "the seat of self-esteem" – whatever that means. Perhaps other regions also show such an effect. It would make as much sense

(none) to say the prefrontal cortex is "the seat of feedback". In addition, Kandel apparently fails to realize how often these imaging studies yield false positives. One imaging study is not enough to conclude anything.

Kandel makes a big deal of [3]one particular study:

In a recent study of people with depression, Professor Mayberg gave each person one of two types of treatment: cognitive behavioral therapy, a form of psychotherapy that trains people to view their feelings in more positive terms, or an antidepressant medication. She found that people who started with below-average baseline activity in the right anterior insula responded well to cognitive behavioral therapy, but not to the antidepressant. People with above-average activity responded to the antidepressant, but not to cognitive behavioral therapy. Thus, Professor Mayberg found that she could predict [emphasis added] a depressed person's response to specific treatments from the baseline activity in the right anterior insula.

Mayberg looked at many brain areas (how many is unclear from the abstract). Maybe 30 areas. From those 30 areas, she picked the region that best discriminated responses to the two types of therapy. This means little. If you look at enough brain regions, you will always find one that, purely by chance, discriminates rather well. Mayberg did not show that the particular region she emphasized (the right anterior insula) has any predictive power. She did not do a second study to make sure her results were not pure chance. The abstract emphasizes this ("if verified with prospective testing . . ."). Contrary to Kandel, Mayberg correctly predicted nothing.

Mayberg's study could not be weaker, yet Kandel places great weight on it.

These results show us four very important things about the biology of mental disorders. First, the neural circuits disturbed by psychiatric disorders are likely to be very complex. [The results, which are relatively simple, do not show this.]

Second, we can identify specific, measurable markers of a mental disorder, and those biomarkers can predict the outcome of two different treatments: psychotherapy and medication. [Biomarker means biological correlate. The study was not about biological correlates of depression. It was about predictors of treatment response. Those predictors were measured before treatment, when all subjects were depressed. They were not measured after treatment.]

Third, psychotherapy is a biological treatment, a brain therapy. It produces lasting, detectable physical changes in our brain, much as learning does. [In Mayberg's study, "brain glucose metabolism was measured with positron emission tomography prior to treatment." As I said, it wasn't measured after treatment, so the study could not provide evidence that psychotherapy changed the brain.]

And fourth, the effects of psychotherapy can be studied empirically. [We already knew this. There have been thousands of empirical studies of psychotherapy.]

What a mess.

The article goes on to say impenetrable stuff like this:

This new science of mind is based on the principle that our mind and our brain are inseparable. The brain is a complex biological organ possessing immense computational capability: it constructs our sensory experience, regulates our thoughts and emotions, and controls our actions. . . . Our mind is a set of

operations carried out by our brain. The same principle of unity applies to mental disorders. In years to come [emphasis added] this increased understanding of the physical workings of our brain will provide us with important insight into brain disorders, whether psychiatric or neurological. But if we persevere, it will do even more: it will give us new insights into who we are as human beings.

This is in the grand Nobel Prize in Medicine tradition. The honored work, we are told by the press release, will be terribly useful in the future, although it was done twenty years ago and so far hasn't been useful at all.

I asked Kandel for comment. He did not reply. Whether Kandel's understanding was ever better than this, I don't know.

---

Tim (2013-09-14 06:07:46)

I saw him on Charlie Rose not so long ago spouting bogus left-brain / right-brain nonsense, and other back-of-the-cereal-box neuroscience "facts." Disturbing. I couldn't figure out why he would do that...Maybe he really is that ignorant?

dearieme (2013-09-14 09:41:30)

"to those who, during the preceding year, shall have conferred the greatest benefit on mankind" is a more demanding requirement than "might some day, if the wind is set fair, conceivably contribute to some invention or discovery that perhaps does benefit mankind". Just another case of grade inflation.

Seth Roberts (2013-09-14 10:43:10)

No doubt he is ignorant of psychotherapy research. There's been a lot of it, as I said.

David (2013-09-14 11:04:49)

You say he won an unshared Nobel prize. Not true. He shared the prize with Arvid Carlsson and Paul Greengard. Seth: Thanks for the correction.

slourfet (2013-09-16 06:30:30)

"Actually, our understanding of liver and heart disorders is close to zero, matching our understanding of psychiatric disorders. If we had some understanding of heart disease, for example, we would know why heart disease is much rarer in Japan than in the United States." Close to zero? Really? Do you not think you might be overstating, just a little? What would you say constituted 2 % understanding? Or 5 % understanding? More relevant, "Third, psychotherapy is a biological treatment, a brain therapy. It produces lasting, detectable physical changes in our brain, much as learning does."... As I said, it wasn't measured after treatment, so the study could not provide evidence that psychotherapy changed the brain Writing this sentence has changed my brain. The only interesting claim is "we can identify specific, measurable markers of a mental disorder, and those biomarkers can predict the outcome of two different treatments: psychotherapy and medication" but I agree the evidence doesn't support it.

KevinH (2013-09-20 15:35:11)

Not to promote Kandel, but there is still a large difference in our understanding of the relevant problems. Given a single person we can still say 'you have heart disease, that means you have plaque in location A and it means that if left untreated that you will have an X % chance of undergoing a heart attack, however if we treat it with drug B, you have a Y(>10) % chance of success'. We can't do anything quite like that for psychological diseases. It is all 'do you meet 3 of the 5 criteria', with very poorly understood mechanism, and very low success rates of treatment. Seth: The cause of heart disease is very poorly understood. Kandel may think it is due to cholesterol.

KevinH (2013-09-20 15:52:46)

oops, I apologize but I actually only read before the fold when i posted then read the rest.... however, the argument only gets stronger relying only on your own writing after the fold. No one is arguing about the fact that the heart is the thing that pumps blood through the circulatory system, but as you rightly point out, we have only the weakest claims to understand what 'the prefrontal cortex' or any other region is doing. Also, if your main point of the piece is that the Nobel prize in medicine doesn't strongly effect day-to-day life, you are so wrong you should rethink everything you know. The last three prizes have been handed out for: stem cells, understanding the immune system, and in-vitro fertilization. All fields that are having concrete effects today for real people. 2 years before Kandel, the award was given for nitric oxide; knowledge which is now used routinely in heart surgery and to help keep patients alive after a heart attack. So, when you say "Year after year, the prize-winning work has failed to reduce heart disease" what exactly do you think you mean?

Seth Roberts (2013-09-21 00:57:41)

How did the stem cell research affect everyday life? How did the immune system research affect everyday life?

### **Drawing a Line Where No Line Was Needed: GQ Editor Defends Hugo Boss (2013-09-15 05:00)**

The comedian Russell Brand, [1]at a GQ awards show in London, "joked" – according to Brand, it was a joke – that the sponsor of the event, Hugo Boss, clothed the Nazis. Fine. More interesting to me was something that happened later. [2]According to Brand, the following conversation took place:

GQ editor Dylan Jones What you did was very offensive to Hugo Boss.

Brand What Hugo Boss did was very offensive to the Jews.

Sure, Jones was upset. But nothing in his job description requires him to defend Hugo Boss. Especially in the least nuanced possible way. In contrast to Brand's criticism of Boss, which makes Brand look good, Jones's criticism of Brand, if it has any effect at all (probably not), makes Jones look foolish. He did not make his remark out of carefully-calibrated self-interest.

Jones's comment interests me because now and then something in my head pushes me to do two things I know are unwise:

1. Tell someone else what to do when there is no reason to think they want my advice.
2. Simplify a complicated situation.

Jones did both things. I try to resist – try to say nothing – but am not always successful. Maybe Desire #1 is why professors are fond of teaching what they call "critical thinking" – it allows them to indulge Desire #1. On the face of it, [3]appreciative thinking – especially nuanced appreciation – seems at least as important, but I have never heard a

professor say he teaches that.

1. <http://www.hollywoodreporter.com/news/russell-brand-writes-op-ed-629416?>
2. <http://www.dailymail.co.uk/news/article-2420733/It-wasnt-intended--destroy-Russell-Brand-hits-offensive-Nazi-jibes-GQ-Award-sponsors-Hugo-Boss--admits-ruined-illusion-sophistication.html>
3. <http://blog.sethroberts.net/2008/12/12/whats-appreciative-thinking/>

---

Melissa (2013-09-15 09:25:07)

Two things I am constantly tempted to do as well. Have (finally) figured out why the first is ill-advised. And, now that I think about it, the second often blows up in my face as well. But, if possible, would love your perspective on why this is. Seth: If I understand you, you're asking: why is it ill-advised to simplify a complex situation? I'm not sure I understand, but I'll say this: It leaves you badly prepared when things go wrong. Things go wrong more often than you expect. It also leads to overinvestment. You think you understand something, you don't, you lose your investment.

Nancy Lebovitz (2013-09-15 11:20:05)

A while ago, I improved my life by adding what I called the cheerleader function: if anything was important enough for me to be annoyed when it went badly, it was important enough for me to be pleased when it went well.

dearieme (2013-09-15 11:25:47)

Well I think that Shakespeare and Rembrandt and Mozart and Beethoven are jolly good. So there.

Ashish (2013-09-15 13:28:44)

@Nancy: Beautiful! I think I will borrow that.

Seth Roberts (2013-09-15 13:43:09)

"I think that Shakespeare and Rembrandt and Mozart and Beethoven are jolly good." I agree, to some extent literature classes help you enjoy/appreciate literature, art history classes help you enjoy/appreciate art, and certain music classes help you appreciate/enjoy music. Science classes help you understand science, which is surely necessary to appreciate/enjoy it. At Berkeley, at least, I didn't come across professors who said they did this explicitly, although maybe this just means I didn't talk to the professor who taught introductory music. I attended art classes hoping they would help me appreciate art. They didn't – that was quite clear. Nancy, I like that idea. I find that seeing the positive side (seeing the good) is more challenging and less boring than seeing the negative side (seeing the bad).

Kirk (2013-09-15 14:26:04)

One of the things I keep reminding myself, as a parent of young adults in their twenties, is that they don't want my advice unless they specifically ask for it. Drats. I have all kinds of useful advice going to waste. As for GQ's Mr. Jones, my assumption when I first read that Daily Mail article written by Mr. Brand was that the editor was trying to save his own career. The award given to Mr. Brand was "the 'oracle' award at the GQ Men of the Year Awards". Somebody at GQ, possibly Mr. Jones himself, approved that award. And Hugo presumably is a major advertiser . . . look at the photo of the comedian standing in front of a fashion background stamped with GQ and HUGO. I found Mr. Brand's Daily Mail article to be interesting and amusing. Then I watched the video and found the performance obnoxious.

Alex (2013-09-15 15:14:09)

I love your notion of appreciative thinking. I hope you'll mention it more often. You have interesting insights on meta-cognition.

kxmoore (2013-09-15 20:05:48)

i post again russell brand lacerating msm noodles <http://www.youtube.com/watch?v=ADJhErmJuoQ>

kxmoore (2013-09-15 22:58:30)

nice blog on writing about science <http://ksj.mit.edu/tracker/2013/09/my-st-orify-mike-daiseys-responses-my-tra>

Nile (2013-09-16 05:08:00)

#1 made me laugh. I have often said about myself "God put me on earth to tell other people how to live their lives" I too have found this unwise but I am constantly tempted.

Nancy Lebovitz (2013-09-16 07:16:31)

Kirk, you could put your advice online in the hope that it will find its way to people who want it.

Kirk (2013-09-16 19:41:52)

@Nancy, Well, I was kind of continuing a family joke. My mother used to complain she had lots of unused advice left over after my brother and I became adults. My reaction to that impulse (to provide unsolicited advice) is instead to make an effort to ask interesting questions. I think this circles back to one of Seth's original observations, which is that people don't care for unsolicited advice when it is said directly to their face. On the other hand, people love to prospect for gold. We enjoy the thrill of the hunt and the pleasure of an unusual success. Which is why many of us read Seth's blog. He introduces new concepts we might want to experiment with. One final observation. I find that the blog writers who end their posts by soliciting opinions gather interesting comment strings, such as the posts by Kevin Drum and Rod Dreher. Seth: Thanks for the suggestion.

## Teaching Academic Writing: My Plan (Part 1 of 2) (2013-09-16 05:00)

This semester at Tsinghua – which begins this week – I am going to teach Academic Writing in English. The class is in the Psychology Department. It hasn't met yet; I suppose all of my students will be psychology majors. In this post I am describe my plan for teaching it; future posts will describe what actually happened.

Last year I taught a class called Frontiers of Psychology. [1]I discovered that I could teach the class without grading. I never gave grades (nor tests), yet the students did lots of work (the assignment completion rate was about 99.9 %) and apparently learned a lot. Behind my removal of grading was my belief that long ago people learned everything without grading. Maybe I can use those ancient sources of motivation, rather than fear of a bad grade or desire for a good grade. The details of the course centered on three principles: 1. Customization. As much as possible, I tried to allow each student to learn what they wanted to learn. For example, they had a very wide choice of final project. 2. Doing. "The best way to learn is to do" (Paul Halmos) – so students did as much as possible. For example, they did experiments. 3. Telling. Students told the rest of the class about what they had read or done. I gave plenty of feedback but it was always spoken. For example, after each class presentation I pointed out something I liked and something that could have been better.

It was like the discovery of anesthesia. All of sudden, no pain. No difficult grading decisions. No written comments (explaining the grades), which I wondered if the recipient would understand. The class was a pure pleasure to teach. For the students, no longer did they need to worry about getting a bad (or less than perfect) grade.

Can I repeat this with a much different class? At the same time I taught Frontiers of Psychology, I also taught Academic Writing in English for the first time. It was pass/fail, so I didn't grade there, either, but I wasn't happy with how it went. (I didn't want to teach it again . . . but, a month ago, I learned I am teaching it again.) This time I am going to take what I learned from my Frontiers of Psychology experience and try to create a better class.

In the next post I will describe my overall plan. Throughout the semester I will post about how well my plan is working. Supposedly "[2]no battle plan survives contact with the enemy" but my Frontiers of Psychology plan worked fine. I didn't change it at all. Maybe my Academic Writing plan will work, maybe it won't.

[3]Movie directing and teaching.

3. <http://blog.sethroberts.net/2013/01/28/movie-directing-and-teaching/>

---

Dragan (2013-09-19 21:09:31)

Surely you know that it wasn't Halmos who invented or even coined the learning-by-doing educational approach! Actually, since you're in China, it'd be interesting to see whether this "I hear and I forget. I see and I remember. I do and I understand." or this "Tell me, and I will forget. Show me, and I may remember. Involve me, and I will understand." are actual honest-to-goodness Chinese proverbs in common use.

## Teaching Academic Writing: My Plan (Part 2 of 2) (2013-09-17 05:00)

To review, [1]I am teaching Academic Writing this semester. I want to motivate learning using forces other than grades. Here is my plan.

On the first day of class, I'll say: Don't take this class unless there is some piece of writing you want to do. This class will be all about me helping you write whatever you want. Most of the students will want help writing a personal statement for graduate school applications. I'll tell them there needs to be something else they want to write. Without that the class will be a waste of time.

For the first class – the course meets for 1.5 hours once/week – I'll talk about writing a personal statement.

After that, the general plan will be:

1. I meet with students after class (in the same place) for however long they want, maybe 5-20 minutes. They choose the duration. During these meetings, they show me what they've written. I read it and tell them how they can improve it.
2. During the next class, each student who met with me will give a talk lasting the same length of time as our meeting. For example, if we met for 5 minutes, the talk will last 5 minutes. The talk will be about what I said. After each talk I'll give feedback.

3. In addition, students who meet with me will add my advice to a shared document (e.g., Google Docs).

4. Each week, one student will be assigned to spend a certain length of time (30 minutes) improving the shared document. For example, making it clearer or better organized. The next class they will give a brief talk saying what they did. Again, I will give feedback.

This accomplishes several things: 1. Customization. Each student can write whatever they want. 2. Doing. They actually write "real" material (in contrast to writing assignments). What they choose to write will probably be stuff like a paper for another class but at least it isn't a writing assignment. 3. Telling. They will tell other students what they have learned.

Attractive elements of the plan for me include the fact that I never lecture and never grade. I never need to guess what the students need help with. I learn what they need help with by looking at what they've written. Even though there are no grades or teacher-imposed deadlines, I give lots of feedback – it really is challenging. Attractive elements of the plan for students are that there is flexibility, they can write whatever they want, they never have to take notes (yet there is a written record to refer to), and they are pushed to understand the material in a non-competitive way.

If a student doesn't pay attention in class – the presentations when other students tell what I told them — he risks having me make the same comment on his writing I made earlier on someone else's. Then he would have to tell other students that I made that same comment. The other students wouldn't like that; it wastes their time. So there is pressure to pay attention. If you miss it during class, you can study the shared document.

More English is not my students' native language, although they are quite good at it. I think that they are more likely to understand another student say X (in English) than when I say X (in English) because the student's English will be closer to their English ability. I might use words they don't know. This is a problem in America, too (professor knows a lot more than his or her students) but it is especially clear here. My point is that this is a good feature of having students give class presentations about what I told them, rather than me telling the class directly, which might seem better. If a presenter makes a mistake, I will fix it.

1. <http://blog.sethroberts.net/2013/09/16/teaching-academic-writing-my-plan-part-1-of-2/>

---

Mark (2013-09-17 06:29:20)

Seth, This is really awesome. I hope it works out and can't wait to hear how it works out. Seth: Thanks, Mark. I really have no idea what will happen.

Alex Chernavsky (2013-09-17 12:18:39)

Just curious if the administration at Tsinghua University gives you freedom to teach your classes in whatever way you see fit, and how that level of freedom compares to American universities. Seth: so far so good at Tsinghua...At Berkeley, professors complained that I gave students too much freedom.

Dragan (2013-09-19 20:42:22)

That sounds great. I'd enjoy taking your class. Two thoughts I had reading this... 1. This sounds like a difficult course to teach

well. (Much more difficult than a straight-up lecture/assignment class.) 2. "If a student doesn't pay attention in class — the presentations when other students tell what I told them — he risks having me make the same comment on his writing I made earlier on someone else's. Then he would have to tell other students that I made that same comment. The other students wouldn't like that; it wastes their time. So there is pressure to pay attention." Consider it a hunch, but this will happen. Probably more than once. And it's probably not a bad thing, either. If it happens, it probably means that you're dealing with something that's difficult for your students. In that case, it won't be wasting everyone's time! Anyway, I look forward to hearing about how the course plays out.

## Foreign Language Learning Tips (2013-09-18 05:00)

After I said that I was having trouble learning Chinese, my friend [1]Carl Willat made several interesting suggestions:

My ideas are pretty simple, and I don't know if they'll work for you but I'm thinking back on what helped me the most when I was learning Italian. Maybe they will strike you as obvious, or what you're already doing. I'll spell them out here anyway, and please just ignore anything that seems useless. I apologize in advance.

The big one, reading out loud and having someone correct your pronunciation, probably won't work as well when you're dealing with those Chinese characters instead of words in a recognizable alphabet. But the underlying concept, learning the way a child learns, might have other applications. This was Roberta Niccacci's approach and it worked incredibly well for me. She said pronunciation comes before comprehension. I read books out loud to her and my pronunciation got to be very good, though I didn't understand much of what I was reading. After three or four books I could read like an Italian newscaster. "Keep doing this and you will wake up speaking Italian," she said, and that's what it felt like.

I found that in Italian I was developing little islands of solid comprehension in different areas of the language. As I learned more and these areas grew they eventually started to connect with each other. That's when I felt like I was starting to become fluent. Children don't have big vocabularies when they're learning to talk at first, but what they do know they know really solidly. When I was in Italy with Matt he saw a woman call her dog, saying "Vieni qua!" and the dog obeyed. "That little dog knows more Italian than I do," Matt said. It was a joke but the concept was right. The dog only knew a couple of words but knew them really well.

One thing I recommend is having phrases in Chinese that you repeat over and over until you know them so well they sound like English to your brain. These would be phrases that come up in daily life all the time. Probably you're doing this already, right? Because undoubtedly there are things you have to say in Chinese all the time just to get by. It's almost feels like you're learning English synonyms or slang, instead of taking on a whole gigantic language. It helps if you have someone to help you make sure you're pronouncing these phrases perfectly, so you're absolutely confident in them. Same with the Chinese ideograms; get the basic ones really solidly before adding new ones.

Then, talking to yourself. At one point I started talking to myself in Italian, like all the time, both out loud and in my head. I wasn't self-conscious because nobody was listening. I just kept up a constant jabbering. Even if what I was saying to myself wasn't very sophisticated, I was doing a pretty good job of talking like an Italian child who talks to himself. Talking to myself seemed to make me start thinking (and dreaming) in Italian.

As far as memorizing Chinese characters, if I were going to do it I would use the same kind of memory systems I use to memorize a deck of cards or a shopping list of hundreds of items: those mnemonic and associative devices like in the Harry Lorayne books on memory. Lorayne is a memory expert and magician who would do these stunts like remembering everybody's name in a big audience. I think he's got something on memorizing Chinese characters, maybe like what this guy is doing:

<http://www.fluentin3months.com/chinese-vocab/>

When we were learning Italian Matt and I both got this children's book called First Thousand Words in Italian, which had colorful, labeled cartoon drawings of various objects. To this day I see some of those pictures in my mind when I think of certain Italian words. The pictures helped a lot, but we also used those crazy memory tricks from Harry Lorayne. A radiator is "il termosifone" in Italian, which we remembered with the similar-sounding phrase, "they're mostly phony". You know, in San Francisco a lot of apartments have old steam radiators that don't work anymore, so they're mostly phony. I don't know if this method strikes you as too ridiculous, but it sure worked.

Matt and I both ended up with a pretty solid 1000-word Italian vocabulary very early in the game. This was also a lot of fun because when I was talking to Italians even though my knowledge of the language was obviously rudimentary, I nevertheless knew a lot of obscure words I shouldn't have known at that stage. They would be astounded when I came up with the right word for sawdust, spiderweb, rain gutter or puddle. I was talking to Roberta and her Mother one time and I wanted to dig a hole to plant tomatoes and I asked them if they had a shovel, using the word "vanga". They burst out laughing because I had asked for a very particular kind of shovel, more like a flat bladed spade, instead of the more generic "pala". It was just like the way adults laugh when a small child comes up with the right word unexpectedly.

Movies with subtitles. English movies with Chinese subtitles, Chinese movies with English subtitles, or Chinese movies with Chinese subtitles. Especially movies you've seen before so you know the plot and have a vague idea what's being said. Reading and hearing at the same time seems to help your brain get some traction. This works like a refresher course for me in French or Italian, and is especially good for colloquial stuff that's not in the books. I watched some of these movies over and over.

Songs. At one point I worked on my French with French songs from the 1930's. Once again, singing songs meant repeating phrases, and memorizing long passages. You get in the rhythm of the language too. You're keeping it going so you can't really do it in a halting way. In Italian, though, I could never find many songs I liked. I spent one trip to Paris mostly tracking down sheet music to some of those old songs, to solve certain mysteries with the lyrics, and so that I could play them on piano. Having a mission or an errand like that always seems to make travel more enjoyable.

And Bridget swears by the Pimsleur method. She checks the CDs out of the library. She learned a lot of German that way before going to Germany, and was working on Vietnamese briefly so she could talk to our housekeeper a bit. When she was learning Italian the first thing she did was change her language preference to Italian on Facebook. Then every time she went on Facebook which, was quite a lot, she had to do a lot of translating in her mind. She picked it up fast, but she's also really good with languages.

bjk (2013-09-18 08:45:20)

Most of my twitter feed is in french and german, forces me to read short bites of french and german, plus I occasionally click on the articles. Good practice.

Richard Sprague (2013-09-18 10:05:08)

I second the recommendation about songs. A sappy love song usually has easy-to-understand lyrics and phrases that are useful even if you're not in love. (e.g. "if you don't love me, then X" is easy to replace with a different verbs). It helps that the catchiness of a pop beat is a good way to pass time on mundane tasks (e.g. commuting or exercising). Two that I like for Chinese are 周杰伦 (or anything from 周杰伦 and 蔡依林) (google for the lyrics, or ask any of your students to set you up with QQ Music so you can listen as much as you like).

Sentinel (2013-09-18 10:09:07)

Many good ideas in there! Including bjk's. I think that the Heisig method (either the "Remembering the Kanji" book for Japanese or "Remembering the Hanzi" book for Mandarin) does just what he discusses - it might be the ultimate way to systematically employ mnemonic tricks to memorize the meaning of 2000+ characters in a short period of time. Seth: The Heisig method is good, I agree. But in isolation, I have found, it is worthless. For me, at least, it has to be connected with something more social or pleasant - something motivational.

garymar (2013-09-18 14:34:33)

...little islands of solid comprehension... [that] grew [until] they eventually started to connect.

My experience exactly. Of course, with all these isolated areas of comprehension, I would often steer the conversation to a place where I could use them! May have made people think I was a bit OCD at the time. I've used Pimsleur to good effect with Mandarin. Got a solid pronunciation foundation.

Adam (2013-09-18 16:23:09)

Personally, I feel like I need different levels of difficulty depending on my energy level. If I'm highly motivated, I'll try to have a conversation with a Chinese coworker. If I'm less motivated, maybe something passive like watching Chinese TV. If I'm tired, sometimes even passive sources are frustrating because they're too fast & my comprehension is low. At these times, something even more passive, like watching an English TV show with Chinese subtitles & my finger on the pause button works really well. This way I'm not lost as far as what is going on in the show, but I'm still exposed to Chinese & picking up new vocab words.

Robbo (2013-09-19 07:07:09)

I am about 30 months into studying Swedish. At the same time I have been doing some freelance teaching of English, so I have experienced both sides of the desk. I endorse your friend's point about reading aloud. Some of the most productive classroom time I have spent has been students reading aloud and the teacher helping them improve their accent (consonants, vowels, stress, and tone). I try to read something every day in 'study mode', which means use an online dictionary to look up words and expressions I don't understand, and a notebook to write down those I think may be useful. Just the act of writing them down helps them to stick in the mind. I started off using 'easy-read' materials prepared specially for learners, now I use 'good' authors - not excessively literary but writers of clear and expressive Swedish. I also try to write a little Swedish every day (I have a Swedish blog for this). Writing, to me, is a good way to build the active vocabulary and stock of expressions you need to exercise the highest skill, which in my view is to talk fluently, expressively, and correctly in back-and-forth conversation. Where a blog scores over class exercises is that it is my choice what I write and how and when I write it. Of course choosing my own subjects means I am interested and want to do them justice. To do this I have to learn new words and expressions, and by using them they become part of my active vocabulary. I am looking to engage someone to help me by listening to me read aloud and correcting my accent, and reading my blog and correcting my grammatical and word-selection errors.

GB (2013-09-19 07:24:38)

Agree with Carl and garymar. I'm near fluent at comprehending everything a German-speaking waiter would say to me in a bar or restaurant, and yet completely lost at the immigration or tax office. 'Islands of solid comprehension', great concept.

Josh Manley (2013-09-19 07:59:32)

Fantastic post Seth. I enjoy these highly informative, practical posts very much. Thanks for sharing.

Seth Roberts (2013-09-19 13:52:25)

"I enjoy these highly informative, practical posts": Thanks, I try to imitate Tim Ferriss.

Sentinel (2013-09-19 14:45:34)

Seth, I agree that Heisig in isolation may not be effective because it's not inherently interesting. I use [kanji.koohii.com](http://kanji.koohii.com) to study Heisig; it uses online flashcards (you can set up an account for free) which makes Heisig into something more like an interactive video game. (You can share and vote on the memorization tricks everyone has created. I also add the pronunciations to the electronic flash cards, creating deeper "islands of solid comprehension.") Matching what you suggested, I read a lot of manga [only titles I enjoy] and this is my reward for learning all the Heisig kanji.

nicole (2013-09-19 17:48:53)

a friend once told me the easiest way to learn a language is to take a lover. so true. :)

Robbo (2013-09-19 22:04:09)

In the spirit of 'Quantified Self', how does one measure ones own progress in learning a language ? Subjectively I feel I stay still for a while, then something happens that makes me aware that I now am significantly improved from x weeks previously, although in between there was no sensation of daily progress. With a yardstick of some kind, even very imprecise, it would be possible to test different tactics and find out what worked best. Without one, it's a matter of guesswork and subjectivity. Any ideas ?

Adam (2013-09-20 00:09:00)

Anki is one easy way to track your language progress. I have 1539 mature cards in my most recent Mandarin Chinese deck, which means I've probably memorized something like 500 new vocabulary words in the last 7 months. There are some free sites out there that will estimate your vocabulary by having you read an article in the target language & mark the words you don't recognize. For listening & speaking, you'll probably need a partner of some sort, although you might be able to record yourself & compare it to previous recordings.

Jan Rendek (2013-09-21 10:22:22)

I'm a translator/interpreter for Slovak-English living in a non-English speaking country so I'm not speaking English very often. But to be a good interpreter, one has to speak English often. I noticed that I have a warm-up period of app. 10-20 minutes into the job. So next time, I just read an English text for 1/2 hour before a job and voila, the warm-up period was zero :) I'm also reading English texts aloud whenever possible. Did not hurt so far :-)

Ulrike Rettig (2013-10-03 18:26:11)

Great post, with good practical ideas! I especially like the suggestion of reading aloud. I read aloud in French every day. But I'm not at all a beginner, I read aloud as a preparation for speaking (just as Jan Rendek says). One of my best reading experiences was reading a long bed-time story in French to a four-year- old French girl who kept asking questions and making comments. I noticed the next day my French came more easily than usual. I've started a new language, and also found - like Robbo - that I seem to hit a plateau for quite a while, and then suddenly, I make a leap ahead. It must be the way our brain processes language.

## What Goes Unsaid: Self-Serving Health Research (2013-09-19 05:00)

"The realization that the world is often quite different from what is presented in our leading newspapers and magazines is not an easy conclusion for most educated Americans to accept," [1]writes Ron Unz. He's right. He provides several examples of the difference between reality and what we are told. In finance, there are Bernie Madoff and Enron. Huge frauds are supposed to be detected. In geopolitics, there is the Iraq War. Saddam Hussein's Baathists and al-Quada were enemies. Invading Iraq because of 9/11 made as much sense as attacking "China in retaliation for Pearl Harbor" – a point rarely made before the war. In these cases, the national media wasn't factually wrong. No one said Madoff *wasn't* running a Ponzi scheme. The problem is that something important wasn't said. No one said Madoff was running a Ponzi scheme.

This is how the best journalists (e.g., at The New Yorker and the New York Times) get it wrong – so wrong that "best" may be the wrong word. In the case of health, what is omitted from the usual coverage has great consequences. Health journalists fail to point out the self-serving nature of health research, the way it helps researchers at the expense of the rest of us.

The recent Health issue of the New York Times Magazine has an example. [2]An article by Peggy Orenstein about breast cancer, meant to be critical of current practice, goes on and on about how screening has not had the promised payoff. As has been widely noted. What Orenstein fails to understand is that the total emphasis on screening was a terrible mistake to begin with. Before screening was tried, it was hard to know whether it would fail or succeed; it was worth trying, absolutely. But it was always entirely possible that it would fail – as it has. A better research program would have split the funds 50/50 between screening and lifestyle-focused prevention research.

The United States has [3]the highest breast cancer incidence (age-adjusted) rates in the world – about 120 per 100,000 women, in contrast to 20-30 per 100,000 women in poor countries. This implies that lifestyle changes can produce big improvements. Orenstein doesn't say this. She fails to ask why the Komen Foundation has totally emphasized cure ("race for the cure") over prevention due to lifestyle change. In a long piece, here is all she says about lifestyle-focused prevention:

Many [scientists and advocates] brought up the meager funding for work on prevention. In February, for instance, a Congressional panel made up of advocates, scientists and government officials called for increasing the share of resources spent studying environmental links to breast cancer. They defined the term liberally to include behaviors like alcohol consumption, exposure to chemicals, radiation and socioeconomic disparities.

Nothing about how the "meager funding" was and is a huge mistake. Xenia Jardin of Boing Boing called Orenstein's article "[4]a hell of a piece". Fran Visco, the president of the National Breast Cancer Coalition, [5]praised Orenstein's piece and wrote about preventing breast research via a vaccine. Jardin and Visco, like Orenstein, failed to see the elephant in the room.

Almost all breast-cancer research money has gone to medical school professors (most of whom are men). They don't do lifestyle research, which is low-tech. They do high-tech cure research. Breast cancer screening, which is high-tech, agrees with their overall focus. High-tech research wins Nobel Prizes, low-tech research does not. For example, those who discovered that smoking causes lung cancer never got a Nobel Prize. Health journalists, most of whom are women, apparently fail to see and definitely fail to write how they (and all women) are harmed by this allocation of research effort. The allocation helps the careers of the researchers (medical school professors); it hurts anyone who might get breast cancer.

---

Alex Chernavsky (2013-09-19 07:17:27)

I think one possible reason for the lack of research on preventive measures is that the researchers may figure that the lifestyle changes would turn out to be measures that would be unpalatable to the general public (things like eating less processed food, drinking less alcohol, exercising more, etc.) and hence would not gain widespread acceptance.

Steve Johnson (2013-09-19 09:21:39)

What Alex said but even more so because it's a women's cancer and women react angrily and emotionally to the idea that anything is their fault. Pop culture example from an episode of Sex and the City: Samantha: I don't understand how this happened to me. Dr: It could be genetics, but since there's no breast cancer in your family, it could be a variety of factors, - diet, lifestyle choices. Samantha: - Lifestyle choices? Dr: Some studies have shown women who haven't had children have an increased chance of getting it. Samantha: I see. So I brought this on myself? Dr: No, I'm just giving you the basic... Samantha: I think we're done here. Dr: Maybe I wasn't clear. Samantha: Give me my chart. I'm going to find some woman doctor, some hot woman doctor who understands what this is all about. Yes, it's fiction but it's popular fiction and this is not the only place where you'll hear that same attitude. A cure fits much better into the mental model of the world that women tend towards - if something is wrong it's someone else's job to figure out how to fix it.

Toddy Cat (2013-09-19 10:27:55)

Of course, one of the reasons that "lifestyle modification" has gotten a bad rap over the last fifty years is that so much of the advice was either oversimplified or just flat-out wrong. In fact, one could make the argument that smoking is almost the only thing that the "public Health" community has gotten right in the last fifty years - that's an exaggeration, but not much of one. So naturally, people are a bit skeptical that this time, the authorities finally have it right. And God forbid that that advice might offend someone's ideological prejudices, as seen above.

Nancy Lebovitz (2013-09-19 11:07:09)

It might be pollutants rather than lifestyle. What about \*really\* self-interested medical research? That is, research on a problem the researcher or a loved one of the researcher has?

dearieme (2013-09-19 12:14:08)

"The United States has the highest breast cancer incidence (age-adjusted) rates in the world — about 120 per 100,000 women, in contrast to 20-30 per 100,000 women in poor countries": seek and ye shall find. Screening is bound to put up the number of cases diagnosed, isn't it? It may extend nary a life, but at least it'll find tumours, however small or slow-growing. Also <http://drmalcolmkendrick.org/2013/09/19/deadly-medicines-and-organised-crime-how-big-pharma-has-corrupted-healthcare/> #comments

Jay (2013-09-19 13:28:10)

Hi Seth, I think a big part of the incidence of Breast Cancer might have something to do with the populations of individuals who carry harmful mutations of BRCA1 & 2, in particular, Ashkenazi Jews. From the cancer.gov web site: 1. How much does having a BRCA1 or BRCA2 gene mutation increase a woman's risk of breast and ovarian cancer? A woman's lifetime risk of developing breast and/or ovarian cancer is greatly increased if she inherits a harmful mutation in BRCA1 or BRCA2. Breast cancer: About 12

percent of women in the general population will develop breast cancer sometime during their lives (4). By contrast, according to the most recent estimates, 55 to 65 percent of women who inherit a harmful BRCA1 mutation and around 45 percent of women who inherit a harmful BRCA2 mutation will develop breast cancer by age 70 years (5, 6). 2. Are mutations in BRCA1 and BRCA2 more common in certain racial/ethnic populations than others? Yes. People of Ashkenazi Jewish descent have a higher prevalence of harmful BRCA1 and BRCA2 mutations than people in the general population. Other ethnic and geographic populations around the world, such as the Norwegian, Dutch, and Icelandic peoples, also have higher prevalences of specific harmful BRCA1 and BRCA2 mutations.

Seth Roberts (2013-09-19 13:45:11)

To finish the BRCA argument you need to say how common the two mutations (BRCA1 and BRCA2) are, so we can get some idea of what fraction of breast cancer cases they are involved in.

Seth Roberts (2013-09-19 13:47:14)

I meant "lifestyle" to include all sorts of environmental changes, including pollutants. Maybe lifestyle was the wrong word. Pollutants can be avoided – I try to avoid them in Beijing – just as lifestyle can be changed.

Seth Roberts (2013-09-19 13:50:31)

Public health researchers have also been right about the contribution of low folate to birth defects. I believe that epidemiologists will turn out to be right about the connection between poor sleep and depression – a very important clue to what causes depression. Also about selenium and cancer. However, I agree, there is vast room for improvement.

JM (2013-09-19 13:56:58)

Wow, Steve, way to accuse an entire gender of being angry and emotional when confronted with a devastating diagnoses - I think that probably applies to a lot of people (men and women) who are told they have a possibly fatal illness. And using Sex and the City as an example doesn't really help your argument.

Nancy Lebovitz (2013-09-19 22:43:22)

Jay, there are about 5 million Jews in the US out of a total population of about 300 million– I don't think that's enough to affect the breast cancer stats much. Here's a weird one: cancer rates are *\*positively\** correlated with income. [http://www.who.int/gho/ncd/mortality\\_morbidity/cancer\\_text/en/](http://www.who.int/gho/ncd/mortality_morbidity/cancer_text/en/) More longevity? More diagnosis? Something quite mysterious? Map of states: <http://www.cdc.gov/cancer/breast/statistics/state.htm> Unfortunately, most maps are by country– this strikes me as fairly useless. Seth, what do you do to avoid pollutants in China? Seth: I heavily filter the air in my apartment.

Jay (2013-09-23 15:02:48)

Hi Seth, sorry I left that part out. From: <http://www.jewishgenetics.org/?q=content/ashkenazi-jews-and-brca1-and-brca2> "Various studies have examined the ethnic distribution of BRCA1 and BRCA2 mutations associated with breast and ovarian cancer. Three mutations in these genes (185delAG and 5382insC in BRCA1 and 6174delT in BRCA2) occur at an increased incidence in the Ashkenazi Jewish population, estimated at 2.5 % (or 1 in 40), compared to less than 1 % in the general population." As for the number of Jews, the 5 million number may seem low, but I don't think that number includes the population who may be descendants of Jews (and thus more likely to carry at least part of the genetic profile associated with the cultural group) yet not qualify as technically "Jewish". I count myself as part of this group.

Jeff Winkler (2013-09-24 03:35:19)

Speaking of life-style modification... Sanjiv Shah improved sleep quality by (Boston QS: <http://www.youtube.com/watch?v=VDQ0TPxHn0Q>) by blocking blue light at night. Blue light blocks melatonin production. He reduced sleep latency and increased deep sleep – measured by a Zeo and Fitbit. Shift work in nurses for more than 30 years has a breast cancer risk ratio of 1.36 - <http://www.ncbi.nlm.nih.gov/pubmed/11604480?dopt=Abstract> Profoundly blind women have a 50 % reduction in breast cancer - <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2363754/> It would make sense that income upregulates electronics such as tablets, lowering melatonin production with late-night use.

## Teeth Clenching Can Release Too Much Mercury (2013-09-20 05:00)

IFRAME: [1][http://www.youtube.com/embed/DcSO8gWB0Z0?feature=player\\_detailpage](http://www.youtube.com/embed/DcSO8gWB0Z0?feature=player_detailpage)

Recently the Berkeley City Council heard testimony about a proposed ban on mercury amalgam dental fillings. A young man named D— M—, shown in the video, told the Council that he had grown up in Berkeley and had gotten mercury amalgam fillings from local dentists. They did not tell him the fillings were dangerous. He attended Berkeley High, Harvard, and finally the clinical psychology program at UC Berkeley – which I know is extremely hard to get into, as he says. They accept about 1 in 500 applicants.

In 2007, three years into the program, he started clenching his teeth. He began to have problems resembling mercury poisoning, such as fatigue and poor concentration. He had to leave the psychology program. Hair tests showed large amounts of mercury. He did not eat unusual amounts of fish, so it's likely that his fillings were the source of the mercury. By 2012, he could no longer work and pay rent.

I had no idea that teeth clenching and mercury fillings were so dangerous together. A few years ago, I found, to my surprise, that [2]removal of mercury fillings improved my score on the reaction time test I use to measure brain function. At first, I had thought the improvement had other causes. Only when I tested these causes and found no supporting evidence did I look further and discover the improvement had started exactly when I got my fillings removed. After I discovered this, I looked around for other evidence that mercury fillings were dangerous. To my surprise (again), my evidence seemed more persuasive than anything I found. M—'s story is much scarier than mine and supports my conclusion that mercury fillings are dangerous.

Had M— been using my reaction-time test day after day, he might have discovered deterioration on that test before he noticed other problems. The test might have provided early warning. I hadn't noticed problems with concentration or fatigue, yet when my fillings were removed I got better on my test. Had M— noticed the problem earlier, he might have figured out the cause earlier.

If you don't monitor yourself as I do – and almost no one does – you are trusting your dentist, your doctor, your food providers, and so on, to be well-informed and truthful about the safety of their products. If the problems aren't obvious, there is plenty of reason for them to put their hands over their eyes and say "I don't want to know" about problems with their products. Drug companies have often hidden the dangers of their products and surgeons have hidden the dangers of their procedures. Few people grasp that "evidence-based medicine", with [3]its disregard of bad side effects, is biased in favor of doctors. ([4]Ben "Bad Science" Goldacre is a prominent example of someone who fails to understand this.) If you monitor yourself you are less at the mercy of other people's poor science, lies, and motivations that conflict with finding and telling the truth.

1. [http://www.youtube.com/embed/DcSO8gWB0Z0?feature=player\\_detailpage](http://www.youtube.com/embed/DcSO8gWB0Z0?feature=player_detailpage)

2. <http://blog.sethroberts.net/2011/06/26/damage-due-to-mercury-revealed-by-brain-test/>

3. <http://boingboing.net/2012/01/10/tonsillectomy-confidential-do.html>

4. <http://www.badsience.net/>

Mark (2013-09-20 07:57:17)

I'm so glad to see you take Goldacre to task on this, I completely agree. I remember when I was reading Bad Science that there was this footnote acknowledging that, in truth, no drugs could ever be determined to be safe for everybody but that one would essentially be wasting their time worrying about that (or something to that effect). I remember being like "What?!?", and quickly jotting a note in the margin. The fact that randomized trials cannot actually "demonstrate" any drug to be safe is missed by most (it's statistically and logically impossible to show that something is no different than placebo, which is essentially what "demonstrated to be safe" means).

Mark (2013-09-20 07:59:37)

I should also say that I think Bad Science is by and large a decent book... Goldacre just doesn't always seem to understand that absence of evidence is not evidence of absence.

Alex Chernavsky (2013-09-20 08:55:07)

Jay S. Cohen wrote an interesting book called, [1]*Overdosed. He makes the point that there is a large amount of variability in how individuals respond to drugs. Pharmaceutical companies don't want to admit that this variability exists – because, at the very least, it complicates dosing issues. Cohen advocates "start low, go slow" when starting a drug regimen. (I think the book is out of print now, but used copies are still available.)*

1. <http://www.amazon.com/Over-Dose-Jay-S-Cohen/dp/158542370X>

Alex Chernavsky (2013-09-20 08:55:58)

Sorry, the book is actually titled, *Over Dose: The Case Against the Drug Companies*.

Seth Roberts (2013-09-20 14:31:04)

Mark, did you mean Bad Pharma (rather than Bad Science)? Bad Pharma is Goldacre's recent book, Bad Science is an older book. I agree, Bad Pharma is a decent book. I hope that someday Goldacre will realize there are big problems with the rest of medicine as well, problems less obvious than high prices.

dearieme (2013-09-20 15:10:13)

For years I've joked that Americans' lifespan is shorter than (for example) most West Europeans' because Americans spend far too much time at the dentists. Correlation and cause?

Sentinel (2013-09-20 15:41:47)

At least according to Joseph Mercola articles sympathetic to "biological dentistry" or "holistic dentistry", removing mercury amalgam fillings has its own set of dangers (release of large amounts of mercury into the body all at once)! In addition to monitoring one's symptoms of mercury poisoning (a la Seth), I wonder if there is a way to also monitor the extent of the increase or decrease of mercury in the body after removing the filling. Scary....

Open2 (2013-09-20 17:07:14)

Supposedly, MTHFR variants can affect a person's ability to detox mercury and other heavy metals.

D.R. (2013-09-21 03:51:08)

Regarding amalgam removal, you may want to look at IAOMT's web site, where they have information describing safe removal procedures: <http://iaomt.org/safe-removal-amalgam-fillings/>

Seth Roberts (2013-09-21 15:57:22)

"Safe amalgam removal". I monitored myself before and after the amalgam removal and saw no change. This shows that the amalgam removal had been done safely.

Dan OBeirne (2013-09-29 11:13:29)

Nice article. We all know Mercury is a dangerous b/c it is a neurotoxic. What you may not know is that it is lipophilic so it stores likes to store itself in fat stores. Since the human brain has a lot of fat the Hg can go there. "Silver dental fillings" contain up to 50 % Hg. Of course this does not affect everyone as we all have different toxic sensitivities. This is also influenced by your total toxic load This is a treatment that dates back to around the time of the US Civil War. Dentist I know, tell me the fear among the ADA seems to be big lawsuits like Tobacco & Asbestos IF the truth came out

Dan OBeirne (2013-09-29 11:14:47)

Here is some scientific research. For example, a peer-review study published in 2005 by the Freiburg University Institute for Environmental Medicine found that "mercury from dental amalgam may lead to nephrotoxicity [kidney poisoning], neurobehavioural changes, autoimmunity [autoimmune disease], oxidative stress, autism, skin and mucosa alterations or non-specific symptoms and complaints,"

Dan OBeirne (2013-09-29 11:20:48)

Proper removal of dental amalgams is VITAL. One of the best is the Huggins Protocol and is based on the pioneering work of Hal Huggins, DDS, MS, a leading figure in the world of biological, or holistic, dentistry. Also find info here: [www.toxicteeth.org](http://www.toxicteeth.org) best from Spain

### **"Sitting is the New Smoking" (2013-09-21 05:00)**

I learned this phrase ("sitting is the new smoking") from Galen Cranz, with whom I taught [1]a class called Office of the Future in 2001. We agreed that sitting was bad. I believed that sitting was bad because I discovered that [2]if I stood a great deal, I slept better. A [3]recent review:

A study published in the journal Diabetologia in November 2012 analyzed the results of 18 studies with a total of nearly 800,000 participants. When comparing people who spent the most time sitting with those who spent the least time, researchers found increases in the risks of diabetes (112 %), cardiovascular events (147 %), death from cardiovascular causes (90 %) and death from all causes (49 %).

I wonder whether any effect of sitting would remain after adjustment for quality of sleep. Maybe those who sat less slept better, as I did. Epidemiologists haven't yet grasped the importance of sleep – part of an overall failure to realize that the immune system matters. Whether or not you sleep well is surely as important as whether or not you smoke. [4]Here is a study that connects poor sleep and heart disease.

At a recent conference, I foolishly sat a lot more than usual. Maybe I sat for 7 hours two days in a row. After the first day I woke up with a minor muscle spasm in my lower back that went away. After the second day, I woke up with a really bad muscle spasm in my lower back and could barely move most of the day. Maybe my sitting muscles are weaker than other people's. Maybe eating more sugar than usual (sugar is inflammatory) and less flaxseed than usual (flaxseed is anti-inflammatory) also contributed to the problem.

---

Kristian Dupont (2013-09-21 06:16:52)

A physiotherapist I had once said "the body was made for walking and lying down, not for standing and sitting". It works better in Danish because it rhymes but the phrase still stuck with me, to the point where I am considering trying out treadmills for my desk..

q (2013-09-21 06:24:05)

i think one would have trouble teasing out cause and effect here. (if you have a metabolic issue you'd probably spend less time on your feet because it would be less pleasant.)

vgm (2013-09-21 14:01:47)

Your lower back issue could be a result of shortened hip flexors (as a result of sitting) + not bracing your core/keeping neutral spine, therefore hanging out on your lower back/discs. See mobilitwod for much more.

r (2013-09-21 14:04:52)

Seth, One of my favorite books is Pete Egoscue's "Health through Motion", linking posture and health. Sitting is bad, but even when people move, they're repetitively using the same muscles over and over. They don't get the variety of movement needed to maintain the entire muscular system. The result is some muscles go dormant, while others do extra work they weren't designed to do to pick up the slack. These muscle imbalances shift the skeletal system out of alignment, posture deteriorates, and overall health declines. The book teaches how to analyze posture, and how to re-engage dormant muscles. Egoscue also fits into your theme of outsiders vs experts. He's contended that some things like cartilage loss can be stopped and repaired naturally once the muscular system is rebalanced (<http://bepainfreeforlife.com/2010/01/26/the-body-is-amazing/>). Even things like digestion and sleep improve when posture is improved.

Seth Roberts (2013-09-21 15:01:19)

I find lounging – between sitting and lying down – works fine. Weight is spread out, like lying down, but eyes face forward, like sitting.

Is sitting the new smoking? | peakmemory (2013-09-22 06:17:44)

[...] Seth Roberts makes the case. [...]

lemmy caution (2013-09-23 11:11:52)

Avoiding sitting down is one health tip that I believe works but that I will never follow.

Brandon Berg (2013-09-25 05:31:57)

It's also possible that the casual effect goes the other way. I would expect high blood sugar to wake you up, so maybe the effects of standing on sleep quality are mediated by glucose control.

Ollie (2013-10-06 19:30:02)

Thanks for sharing your thoughts about harmful side effects. Regards

---

Steve Hansen (2013-09-22 07:31:47)

I'm a bit dubious about the "toxic plant killed Chris McCandless" story. This article has a very different take: <http://foragersharvest.com/into-the-wild-and-other-poisonous-plant-fables/>

Anders (2013-09-22 09:10:36)

here's a climate model you may like.... [http://www.coyoteblog.com/coyote\\_blog/2013/09/update-on-my-climate-model-spoiler-its-doing-a-lot-better-than-the-pros.html](http://www.coyoteblog.com/coyote_blog/2013/09/update-on-my-climate-model-spoiler-its-doing-a-lot-better-than-the-pros.html)

Alex Chernavsky (2013-09-22 09:53:25)

Steve, thanks for posting that. Krakauer could be partially right, in the sense that the beta-ODAP in the seeds (if, indeed, it's even present) could have been the final straw that broke McCandless's back. I wonder if anyone involved in this subject has ever attempted to eat a substantial amount of those wild-potato seeds in one sitting.

Tom (2013-09-22 13:55:43)

*the beta-ODAP in the seeds (if, indeed, it's even present)* It's present. <http://www.christophermccandless.info/Ronald-Hamilton/ronald-hamilton-intothe-wild6.html> I wonder if anyone involved in this subject has ever attempted to eat a substantial amount of those wild-potato seeds in one sitting. After reading the Hamilton article, I hope not.

Jim (2013-09-22 15:03:39)

Steve, I don't see a date on the post you cite to, but I think it addresses Krakauer's 1st and 2nd explanations, while the (very recent) article pointed to by Seth is directed to Krakauer's 3rd (and he thinks final) explanation.

Tom (2013-09-22 15:48:34)

Indeed. The certitude of the Forager's Harvest article plays very differently after reading the Hamilton piece.

spacenookie (2013-09-22 17:15:12)

The Forager's Harvest piece does a nice job of showing that McCandless could have/would have just plain starved to death and

that Krakauer has been pushing poisoning theories for the last 20 years that he now admits were wrong. If you look at the following articles, it adds a little more to the controversy. <http://www.alaskadispatch.com/article/20130917/krakauers-wild-theory-mccandle-ss-gives-short-shrift-science> <http://www.alaskadispatch.com/article/20130919/jon-krakauer-responds-what-killed-chris-mccandle-esp-the-comments-of-the-second-article-where-krakauer-and-clausen-go-back-and-forth>.

Adam (2013-09-22 17:18:51)

Alzheimer's is "Type 3 Diabetes" so this is not surprising. <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2769828/>

## **Does Intermittent Fasting Improve Repair Processes? (2013-09-23 05:00)**

After I [1]blogged about benefits of alternate-day fasting, a software engineer named Brandon Berg [2]commented:

I had had plantar warts for a couple of years prior to starting IF (eating in a four-hour window each night). They cleared up almost immediately.

I had never heard about this effect of fasting. And the [3]Wikipedia entry on plantar warts said nothing about this. I asked Brandon for details.

When and where did this happen?

I was working full time while also attending college with a 12-hour schedule or so. That may or may not be relevant; I was under a lot of stress, both in terms of the pressure to serve both masters, and the sleep I sacrificed to make it happen. So that may have contributed to my development of the warts. I actually don't remember whether I developed them before or after I went back to school, but I was definitely in school when they went away. I was 23 when they disappeared, and I lived in Seattle at the time. This was back in 2004, so I'm a bit fuzzy on the details.

Did you have any idea what had caused the warts?

Presumably a viral infection, since that's what causes warts, isn't it? I did a lot of walking around barefoot when I lived with my parents before going off to college in 1998; maybe I was infected then, and carried the virus asymptotically until the stress triggered the development of the warts? But again, I don't remember whether they were there when I went back to school.

Had you tried other ways of getting rid of the plantar warts?

I might have tried apple cider vinegar on a select few. I distinctly remember that working for a wart on my thumb, but the ones on my feet were too numerous to treat them all that way. I never saw a doctor about them, since I always figured they'd just go away sooner or later, and they didn't bother me that much.

Why did you do the intermittent fasting?

This was back when the studies about IF extending lifespan in mice first started hitting the media. Or the first time I was aware of them, anyway. Living longer sounded good to me.

Did you expect it to affect your plantar warts?

I had no particular expectation that it would affect the warts.

How did others react to the fact that the IF got rid of the plantar warts?

I lived alone, so I never really told anyone else about them. I've mentioned this to a couple of people in passing, but don't recall any notable reaction, other than "Oh, that's interesting," or something similar.

How fast did they clear up? (= what does "almost immediately" mean?)

I don't remember, exactly. It was definitely within a month. I checked my email archives and see that in 2008 I said that it took less than a week. I remember mentioning this to a friend on ICQ back when it happened, and I \*may\* still have the logs from that on a hard drive in my closet, but I currently have no way to access it since I just moved to Tokyo and only have a notebook with no eSATA port, and I'm not planning on getting a desktop until I find a permanent apartment. Sorry I can't be more precise here. Obviously the probability that it was a coincidence is much lower if they cleared up in a week than if they cleared up in a month.

How do you explain their disappearance?

I'm not sure. It's entirely possible that they'd run their course and it was just their time to go. My pet theory is autophagy: Starved for protein, my body started scavenging for expendable tissue and resorbed the warts. There were two small wart-like growths—one on my thumbprint and one on my nose—that persisted for years afterwards, so it's definitely not a surefire cure.

On a related note—and this also may be purely coincidental—the last two times I've felt a cold coming on, I tried to combat it with a full-day fast, on the theory that this would ramp up my cellular resistance to oxidative stress and reduce the severity of my symptoms. In both cases, I did have a much less severe cold than I usually do, with symptoms reduced to a more or less negligible level by the next day, where I usually get 3-5 days of moderately severe symptoms.

jclifton (2013-09-23 09:23:10)

hi Seth, speaking of fast, any updates on your ADF routine? Still a success? Glycated hemoglobin trending down or has that stabilized at pre-fasting levels? Seth: I'm in China now where it is hard for me to get HbA1c measurements I trust. It is still a success in other ways: easy, losing weight, saving time. The discipline it requires – not much, but some – is somehow pleasant, like physical exercise.

Kirk (2013-09-23 12:05:27)

Paul Jaminet discusses what is happening at length in chapter 40 of the book titled Perfect Health Diet. The key concept is autophagy.

vgm (2013-09-23 13:56:38)

This may have happened to me as well. I had a plantar's wart on my foot for a few years. Around the time I stopped eating breakfast in the morning, it disappeared inexplicably and in definitely less than three weeks.

Jonathan Shewchuk (2013-09-23 18:30:07)

Dr. Michael Eades has a good blog post about how ketosis causes cells to recycle junk proteins at <http://www.proteinpower.com/drmike/ketones-and-ketosis/ketosis-cleans-our-cells/>.

Kirk (2013-09-24 06:25:54)

Robert Chuckrow reports that a cyst he had had for decades disappeared during a long fast. His article on fasting can be found at <http://chuckrowtaichi.com/Fasting.html>.

Jenny (2013-09-25 10:03:08)

I was given a different method for getting rid of warts - plantar and on my hand. Cover the wart with a bit of banana skin - soft side inside. tape in place for a few hours. After about 24 hours, the centre of the wart dies and goes black. Wash/ scrub this off. If necessary repeat. Usually 2 treatments clears them, and only once have I had to do 3 - that was a very deep wart. I have got rid of several, on several different occasions. Somebody said what do you do with the banana? Might as well eat it! I think this must be a chemical reaction affecting the wart. Seth: that's fascinating. I wonder how it was discovered.

JM (2013-09-25 13:56:38)

Have never heard of the banana skin cure for warts - very interesting. Also, if fasting reduces aspects of blood sugar, and warts are caused by a virus, maybe the virus needs sugar (in some form) which plummets in the system when fasting and without enough it dies.

Seth Roberts (2013-09-25 14:32:04)

"maybe the virus needs sugar (in some form) which plummets in the system when fasting and without enough it dies." Blood sugar goes down when fasting to 80 or so. Fasting probably produces dozens of changes. Maybe even hundreds of changes.

### **Chinese versus American Math Education (2013-09-24 05:00)**

When she was in eighth grade, a Chinese friend of mine moved from Shanghai to upstate New York. (Her dad worked for General Electric.) In New York, she discovered she'd already learned eighth-grade math - in fourth grade. Her new school moved her to tenth grade math. It was still material she'd already had, but less absurdly easy.

If 80 % of American parents knew this, would they abide it? Or would they decide that something is terribly wrong? Now, of course, almost no American parent knows this.

---

Jim (2013-09-24 08:34:25)

The Chinese students may have a higher aptitude for math that allows for a steeper learning curve than American students could tolerate. In my town, even the American born Chinese students seem to have a relatively high aptitude for math. This is evident even at early grade levels (kindergarten, first grade) where I assume differences in parental emphasis on education would not yet have a great effect.

Jon Orloff (2013-09-24 09:00:04)

Do you suppose that learning a particular language at an early age predisposes one for certain activities? Such as Chinese or Russian for math and German or English for physics?

Wilkins (2013-09-24 09:04:45)

"If 80 % of American parents knew this... " . Then nothing would change at all. Parents already know that American kids lag many other nations in math & science. It's been a loud, consistent theme in the U.S. media for decades. yawn Secondly, "parents" are typically unable to analyze & understand the core deficiencies of the American K-12 school system. They are direct products of that miseducation system, and have been heavily indoctrinated by that very same "system" to accept it as is. The fundamental dysfunctional, and despotic nature of compulsory mass schooling is truly invisible to most Americans. Thirdly, parents have zero practical power/authority to improve that education system. Parental power was lost long ago to legions of government education administrators, bureaucrats, and NEA lemmings. Real power has consolidated at the distant

state and Federal bureaucracies. Imagined parental-power over the vast calcified government school empire is extremely naive.

AI (2013-09-24 09:25:11)

I once heard a math professor at a very large and well known university with a very strong math department say that, by the age of 12, most children have the necessary brain development to understand basic calculus. I've always wondered if that was true, and I'm curious if anyone else has any comments about it. In some countries, all high school students are required to take calculus in order to graduate. So, it seems that by the age of 18 many (most? all?) people have the ability to comprehend math at that level. There's always the sneaking suspicion in US schools that we just aren't teaching math properly/assigning enough homework problems/exercising the students' minds/providing enough body armor/etc.

Alex Chernavsky (2013-09-24 09:26:00)

See also: "[1]Is High Self-Esteem Bad For Math Education?" I like the George Carlin quote at the end of the blog post.

1. <http://scienceblogs.com/evolutionblog/2010/09/08/is-high-self-esteem-bad-for-ma/>

Amanda (2013-09-24 11:46:42)

Malcom Gladwell claims that language differences also play a role: <http://gladwell.com/rice-paddies-and-math-tests/>

Roger Sweeny (2013-09-24 12:32:22)

College professors are some of the least self-aware people I have ever encountered. That math professor is full of sh\*t. My experience teaching high school students is that at the age of 12 many of them don't have the brain development to understand basic algebra, let alone calculus. There is a big intellectual leap between "what do you have to subtract from 12 to get 7?" and "12 - X = 7; what is X?" It is a leap that some people (like "a math professor at a very large and well known university with a very strong math department") make easily, so easily they don't even realize it is a leap. I don't know how many countries require passing calculus to graduate high school. If they are honest in their testing (a very big if), then nowhere near 100 % of their 18 year olds are getting high school diplomas. Math doesn't come easy to lots of people in the USA. Even if we're "teaching math properly/assigning enough homework problems/exercising the students' minds," lots of them won't "get it." Education Realist has an interesting post on, "The myth of 'they weren't ever taught ...'" <http://educationrealist.wordpress.com/2012/07/01/the-myth-of-they-werent-ever-taught/>

GB (2013-09-24 12:32:55)

Malcolm Gladwell outlined some interesting theories on this in Outliers. His ideas sound plausible, but I have no idea if they're valid: [http://chineseculture.about.com/b/2008/12/16/why-are-chinese-better-at-math.h tm](http://chineseculture.about.com/b/2008/12/16/why-are-chinese-better-at-math.htm)

jon (2013-09-24 12:42:50)

Robinson (of the Robinson Curriculum) had his kids teach themselves math from second grade on (among other subjects). They would finish calculus between the ages of 14 and 17. Although I don't necessarily agree with all of Robinson's methods it shows that people are very capable. Government schooling is a waste of time, even private schools. Best just to home educate if possible.

Seth Roberts (2013-09-24 13:10:18)

"Imagined parental-power over the vast calcified government school empire is extremely naive." I didn't say that - that parents have control over the "school empire". I don't know what would happen if parents had a better idea of how bad American education is relative to other countries that also engage in "despotic . . . compulsory mass schooling". (My anecdote at least suggests that compulsory mass schooling is not the only problem.) I am much less sure than you that the answer is obvious. I think recent history supports your claim of powerlessness. Michelle Rhee, Diane Ravitch, Geoffrey Canada - none of them derived power from parents. But I also think most parents don't understand how far America is behind other countries.

Lew (2013-09-24 13:36:58)

My 15-yr old son is doing AP Calculus along with some of his high school friends of the same age. I think he could have handled it a 2-3 years ago. He's on the same curriculum path his 2 older brothers took. And our family isn't even Asian.

S.M. (2013-09-24 14:06:49)

"I don't know how many countries require passing calculus to graduate high school. If they are honest in their testing (a very big if), then nowhere near 100 % of their 18 year olds are getting high school diplomas." "The Chinese students may have a higher aptitude for math that allows for a steeper learning curve than American students could tolerate. In my town, even the American born Chinese students seem to have a relatively high aptitude for math." I have counter-examples for both of these statements. I am an Eastern European - schooled there up to finishing high school. We did high-level calculus in grades 10-12 and most students were pretty good at it. Most of them were white. I don't think you have to be Chinese (or Asian) in order to understand it. Most Eastern European countries have similar math courses in high school and do high level math for grades 5-8. Testing is fair. I don't know much about Western Europe. I went to college in the US. In my first year I was taking differential equations and doing fine while most American peers were seniors. Eastern European friends that moved to the US during high-school often mentioned how their math and science classes were "so easy" because they did that material 4-5 years previously. I don't have direct experience with this but tend to agree. I'm not blaming parent involvement or teacher or anything. I have a distinct feeling that US education was on par with most European schools in terms of difficulty (pre-undergraduate) but schools started to focus on standardized tests and what not and started to "teach to the test". The SAT only has very basic math in it. The GRE also deals with pretty basic math. I got really high scores in both on first try without years of standardized testing experience or preparation. I am in no way a genius; most of my high school classmates probably would have scored similarly. P.S. Something that might contribute to this - Eastern European students tend to "specialize" before high school. Some of them go the math/science route, and take exams to get into those courses, and follow a mainly science curriculum, others do art/music and all that implies, and others do humanities. The students themselves have to discover their aptitudes and needs and apply for the route to match. Most humanities students only take basic math and are never expected to take calculus for their final graduation exam for example. While science route students have to and their work is mostly centered around scientific subjects. Maybe that focus has something to do with it? Seth: Good comment. Including correct use of "steep learning curve", which is rare.

dearieme (2013-09-24 15:48:04)

"I have a distinct feeling that US education was on par with most European schools in terms of difficulty (pre-undergraduate)": no. I can remember the debates in Britain in the late sixties when the Forces of Progress were determined on "comprehensivisation" in the secondary schools. "We want to copy the US" they said. Their opponents howled with anguish: everyone with experience of sending children to American schools seemed to leap into the fray, dismissing American standards as hopelessly undemanding. It was, such people said, the Germans and French from whom we should learn about secondary schooling - it was only at graduate school level that we needed to learn from the US. I've spent most of my career in good universities and everything I and my colleagues have seen - on academic leave, on teaching American visiting students, and so on - says that the Forces of Conservatism were right in the sixties. Indeed, in spite of decades of the dragging down of British standards, American schoolchildren still manage to be more poorly prepared for undergraduate studies, it seems. Nor is the problem remotely confined to STEM subjects: colleagues have reported the problem to be worse in languages, with Americans expecting to work from translations into English rather than reading in the original tongue. The fact that few Americans seem to know much history or geography is also remarked on. The tragedy of all this is that the American exchange undergraduates that I've taught have been clever, unusually keen to learn and very hardworking. By God they've been let down by the schools, and it would seem to have been a problem for generations. Seth: I agree with all this. The mere fact that it has to be said is one sign of how poorly Americans grasp how badly their education system works, compared to many other places. Why education reformers don't pound this - American kids much more poorly educated than other rich countries's kids - into us is a question I can't even begin to answer.

Education Realist (2013-09-24 15:54:28)

"If 80 % of American parents knew this, would they abide it?" Of course. They know it now. How is you think most parents

aren't completely aware of this fact? But of course, by "American parents" you mean suburban, probably white, parents. Asian parents living in this country are well aware. That's why many of them came here, to avoid the hyper-competitive atmosphere back in China and Korea—and it's why most of them pay for hagwons over here. But then, it's only a tiny fraction of "American parents" that delude themselves into thinking that students could be learning more, if only we bothered to teach it to them—or that the brightest kids are suffering by not learning material they could have learned in 4th grade in 8th. Cheating is rampant in China, and while they cover rote material quite well, it's very obvious that they aren't encouraging their kids to think critically. So distrust what you hear that "most" Chinese students are doing, because "most" of them cheat. And those who aren't cheating are desperately memorizing. That's why the Chinese have largely taken over the top 20 % of most elite US universities without having even begun to start taking over the country. And many, but not most, American parents know all that, too. Especially the ones who live next to lots of Chinese, Koreans, and Indians (who cheat, too). Some overstatement in this comment, but nowhere near as much as in your single "most American parents", so we're even. Seth: "They know it now". They do? They know education in other countries is better as measured by standardized tests – and some of them wonder whether the test scores coming out of China (comparing Chinese students to students in other countries) can be trusted. I don't trust them. I don't think most parents know concrete examples like this one. This example cannot be explained by cheating.

S.M. (2013-09-24 16:02:26)

dearieme - you might be right. I was basing my assumption on my professors' stories and impressions. I don't know how it was in the past. The more modern trend of standardizing everything certainly doesn't help. I have a similar experience of American undergraduates - they are quite clever, hardworking and keen on learning. My friends and I used to envy them on their "fun" experience with school. For us it was a very formal environment; American students pre-undergrad get to have more fun. We didn't have a well-stocked chemistry lab, so we did very few experiments and many more paper and pencil problem sets. My American friends did many more experiments. I guess the answer might be somewhere in the middle? I do appreciate Seth's continuous efforts towards finding better ways of learning.

Nancy Lebovitz (2013-09-24 16:49:54)

I'm reminded of an NPR piece I heard a while ago– it claimed that elementary math in American schools is based on a theory that it should be dabbled at repeatedly in the hope that students will eventually pick it up, rather than thoroughly understanding a concept and then moving on.

Adam (2013-09-24 16:54:59)

This probably has something to do with Chinese education being completely focused on their college entry exam, the 高考. Chinese education emphasizes rote memorization above everything else, which I imagine is useful in math. They don't learn how to derive the answers, they just memorize which equation to use for which problem and that's that. While Chinese are able to do well in certain areas based on all of this, it doesn't foster creativity and Chinese children's lives are Hell compared to American children. After school they go to after school school and continue memorizing material for the next test. Very few of them play sports or have time to "just be kids". I remember when I was a kid I would go out in the forest behind my house after school & just play around, build forts & stuff for hours at a time. They say "time in nature" is highly correlated with empathy. Aside from creativity, another thing greatly lacking in Chinese culture is empathy. Don't get me wrong, this seems like a scathing rant about Chinese. I'm married to a Chinese woman & have lived here for 3 years. I do like aspects of China, but the price their kids pay to be "good at math" & to pass a stupid test is not worth it.

as (2013-09-24 18:09:59)

I don't understand what they get for all this. I can use myself as an example though I'm not Chinese. I spent a lot of time on math growing up. All I could really do, however, is solve a given type of math problem fast. And then, over time, I'd probably forget the lesson that I'd learned. I was also part of the math competition team. I didn't really do anything useful or interesting with the math I learned. I didn't use it to solve any real world problems. I don't really use any of the math I learned at my job. In fact, when I look back on it, I wish I'd spent less time on math. I took way too many classes. I wish I'd looked ahead to figure out how much math I'd need later on in life and only done that.

Jim B (2013-09-24 19:04:01)

A co-worker from China told me that the reason they are better than us at math is that they teach their kids to count on their fingers. We have been using the fingermath method to homeschool our kids. <http://www.amazon.com/The-Complete-Book-Fingermath-Scientific/dp/0070376808> The book was meant to be a textbook (in the 70's?), but it never caught on. It is essentially a "finger abacus". Right hand is ones, left is 10's, thumbs are units of 5. You teach the kids how to transition (once you put all four fingers down, you pop them up and put down your thumb – thumb and four fingers down, then you pop them up and put down a finger on your left hand). They are the ultimate math manipulative. My daughter is starting second grade math. All the topics are redundant - carrying? It is obvious with finger math. Borrowing? Obvious. Having the numbers written horizontally instead of vertically? No need to rewrite. Moving on to multiplication–skip counting by 5s? By 10s? No need to drill, just show it to her. If all or most Chinese learn like this, a chunk of our basic math program is redundant. On top of that, the Chinese kids would probably have a better "number sense", and less math anxiety.

Seth Roberts (2013-09-24 19:39:39)

"I don't understand what they get for all this." That's a good question. I was good at math as a kid. Now it's helpful with statistics, which I use all the time. Many psychology professors seem afraid of statistics. This is a huge problem for them because they often let other people analyze their data. It inevitably gets analyzed badly but they are unaware of this. Chinese students who get a perfect score on the math GRE, as many do, find it easier to go to graduate school in America. I think math ability makes engineering more of a possible job. A friend of mine at Berkeley wanted to be a doctor. She changed her mind after her first science class. Maybe better math would have helped.

S.M. (2013-09-25 02:59:17)

I often asked myself what will I do with all that math/science I took as I child. And trust me it was a lot. Often times we would skip sports class and do math. As a child I did find it sometimes useless. From what I can tell so far it's that it does "shape" your brain somehow. People who take the math/science route from my country have some aptitude in it, but for the most part, they end up at the end of it all thinking in a more analytic manner. It was very easy for us to pick up new science subjects in college, or to get good at programming fast, because of the way our brains were "re-wired". Even in our current jobs it's much easier for us to grasp certain scientific subjects or understand things that seem to baffle the humanities folk. We're not doing math exactly, but I am pretty sure we are using those connections that we formed in the past. I don't have any scientific proof of this, it's more of an observation. Wish somebody could do a study at some point to look at how school shapes your mind :)

Kirk (2013-09-25 10:30:42)

I had to take 20 hours of advanced math for my computer science degree, earning high grades in each class. In my work, I used a little bit of set theory but no other math concepts. So from my personal experience, I'm not convinced that America would be a better place if all kids learned more math. The Computer Science department grew out of the Math department. It was obvious they forced all those required math hours just to keep their math department employed. I am more worried about two related issues, both of which I have seen happen to kids I know. (By kids, I mean I knew them when they were friends of my children when young and now they're grown up and in their twenties.) The first: why are so many boys failing in school? The second: why do so many smart girls choose unemployable degrees?

Dragan (2013-09-25 10:48:58)

Seth, I'm curious as to the value of taking algebra by 4th grade? In my own socialist/"Communist" country (not China), 4th grade included Geometry and Algebra content–stuff beyond anything most US students learn till high school. I thought this was great, because I loved mathematics. But other kids, those who didn't love mathematics, didn't think it was so great. They fell behind pretty quickly. Then again, this was a system that did not try to educate all of its students. So it didn't matter if some kids were held back for a while because they couldn't master linear equations by 5th grade. China, I understand, is more similar to this than United States (where we try to educate every child). Given that most students simply do not need this knowledge, what is the value of this type of education? To produce "useful" citizens? If it's product is me, I have to tell you, I'm not particularly "useful"–my pure mathematics degree isn't really gonna help me do anything useful.

Dragan (2013-09-25 11:10:27)

One more thought. It seems that Seth and most of the commentators are aware of some international comparison studies I am not when they draw the conclusion that "most parents don't understand how far America is behind other countries." I guess I don't either! The standard, which I take to be TIMSS, shows U.S. 4th and 8th graders are doing fine, on average. Could be better, yes, but a far cry from what media and politicians tell us. For example, many people I talk to seem shocked to learn that we do better than Germany. In fact... In 8th grade, the 11 education systems with average mathematics scores above the U.S. score were (South) Korea, Singapore, Chinese Taipei (Taiwan), Hong Kong-CHN, Japan, Massachusetts-USA, Minnesota-USA, the Russian Federation, North Carolina-USA, Quebec-CAN, and Indiana-USA. Note that 4 of those 11 were states in the US! The countries which do outscore us are very different than the United States. Education-focused culture, homogeneous, and/or not interested in educating the bottom 20 % of students. Given that United States cooperatively downplays the importance of education, is heterogeneous, and attempts to educate all students, I genuinely don't see how we're so far behind as many here assume.

Education Realist (2013-09-25 11:38:49)

"This example cannot be explained by cheating." No. It could possibly be explained by rote learning. It could also simply be that your friend's daughter was smart. By no means does it mean that the Chinese are that much more advanced than we are. And most parents would know, I hope, not to think one concrete example was evidence of what's going on in a huge country like China.

Seth Roberts (2013-09-25 13:19:33)

"It could also simply be that your friend's daughter was smart. By no means does it mean that the Chinese are that much more advanced than we are." I will find out if my friend was in a special school or class.

Roger Sweeny (2013-09-25 19:09:41)

S.M., I think you may be agreeing with me. I said, "I don't know how many countries require passing calculus to graduate high school. If they are honest in their testing (a very big if), then nowhere near 100 % of their 18 year olds are getting high school diplomas." You said that your fellow students took calculus but they had specialized before they entered high school and the non-science specialists didn't take calculus. I don't doubt that some high school students can handle calculus. Even some 14 year olds can (e.g., the kids you mentioned). However, most American 17 year olds simply cannot. And I feel fairly sure that there is nowhere in the world where close to 100 % can.

Carlos (2013-09-26 00:13:45)

It is not only the Chinese children. I am from Spain and was an exchange student in Iowa where I did the 11th grade. Math was really easy for me because I had already learnt everything they were teaching two years before. But it was not only math, the same happened with Physics and Chemistry where I got the best grades of my class without even trying for the same reason, everything they were teaching I had already learnt before.

### **"Trying to Confuse You": Pluses and Minuses of the Professorial Value System (2013-09-25 05:00)**

A Chinese friend of mine is a chemistry major. In one of her classes, the textbook was so hard to understand she said the authors are "trying to confuse you." They use difficult words, for example. A Berkeley art history major told me much the same thing. In her reading assignments, she said, the writers couldn't write a sentence without a few big words. They were trying to impress readers, she believed.

Yes, professors write badly – in these two cases, the writing seemed actively bad. Thorstein Veblen wrote a whole book about showing off (The Theory of the Leisure Class). One chapter was about professors. They show off, said Veblen, by doing research with no practical application and by writing obscurely. Obscure writing is showing off because, like useless research, it shows you don't have to care what other people think ("it carries a pointed suggestion

of the industrial exemption of the speaker”).

Veblen said little about the costs and benefits of the behavior he described, beyond calling it wasteful. I say the opposite – not wasteful at all. When, long ago, people bought “useless” (“deadweight loss”) gifts or “useless” hood ornaments or decorated buildings with “useless” ornamentation or performed “useless” rituals and ceremonies that require special products (e.g., special clothes), they subsidized skilled artisans. For a long time, that was incredibly important. Research by skilled artisans led to better tools, the creation of metals, and so on. Helping those artisans make a living supported (increased) research in material science. Pushing people toward “useless” research was valuable because it diversified the research being done – there are many ways to be useless, just as you can misspell a word more ways than you can spell it correctly. The most important discoveries, such as electricity, would not have been made if everyone tried to do research with obvious application. Allowing professors to use big words and write badly is a small price to pay for the valuable “useless” research they perform.

-----

Ad

I use Grammarly for [1]proofreading because . . . well, just because.

-----

There is an unrecognized problem with this, however. If you get one group of people to do “useless” research by turning things upside down so that useless is seen as better than useful (professors value “pure” research over “applied” research), it becomes very hard for them to do useful research. For a long time, practically all important research was material science research – how to control the material world. When something useful was discovered via “useless” research, the knowledge could be transferred to everyone else, who had normal values (useful is better than useless). Everyone else went on to use the knowledge in profitable ways – to make better knives, for example. This system (the results of “useless” research are used by other people to make a profit) gave us the world we live in, a world of wonderful products. The products on offer are staggering in their diversity, low cost, and general excellence. The hard drive on my laptop, the clothes I wear, for example.

Against this brilliant control of materials we can put our amazing lack of control of our bodies. A large fraction of Americans sleep poorly. Nothing (such as street noise) is making them sleep badly; they just don’t know how to sleep well. Depression is a huge problem, obesity is a huge problem (in America), and so on. It isn’t just ordinary people. Sleep experts don’t know how to improve sleep, weight control experts don’t know how to lose weight, psychiatrists don’t know how to prevent depression, and so on. Closely related to this is our health care system. It is dominated by doctors, who often use a peculiar and self-serving reasoning I call [2]doctor logic. When I was a graduate student, my dermatologist was surprised when I measured my acne to see if the treatments he prescribed actually worked. It was a new idea to him. An influential Stanford psychiatrist named David Burns, whose famous book has sold millions of copies, [3]has not yet figured out it would be a good idea to measure daily the mood of his patients. (Other psychiatrists are even worse.)

Why are we so smart about materials and so stupid about health – which is far more important? I think it is because the whole system evolved to push our economy forward via advances in material science. For hundreds of thousands of years, that is where improvement was possible: better stuff, such as better tools. The same “habits of mind” (as Veblen would say) and research system has managed to produce plenty of “useless” knowledge outside of material science. This knowledge can be translated into useful discoveries, as I have done ([4]new ways to sleep better, lose weight, be in a better mood, and so on), but these discoveries don’t lead to products, at least not in obvious ways. Control of our bodies is quite different than making something physical. My first interesting self-experimental

discovery was that eating breakfast made my sleep worse. That's very useful, but not at all profitable – there is no obvious associated product. For professors, a problem with my discovery is that it's useful. (Another problem is that it's small.) For everyone else, a problem is that it isn't profitable. The system that worked so well for material science breaks down when it comes to health science.

Yet the fact that you are reading this suggests, at least to me, that a big change is coming.

Glen Raphael (2013-09-25 10:00:39)

The link to "has not yet figured out" is broken.

Seth Roberts (2013-09-25 13:43:56)

I have fixed the broken link ... however it linked to a post that has not yet appeared so the fixed link will be a little puzzling. It now links to evidence for the statement.

Alex Chernavsky (2013-09-25 19:02:23)

See also, "Postmodernism Disrobed", by Richard Dawkins. Here's a sample:

Suppose you are an intellectual impostor with nothing to say, but with strong ambitions to succeed in academic life, collect a coterie of reverent disciples and have students around the world anoint your pages with respectful yellow highlighter. What kind of literary style would you cultivate? Not a lucid one, surely, for clarity would expose your lack of content. The chances are that you would produce something like the following: "We can clearly see that there is no bi-univocal correspondence between linear signifying links or archi-writing, depending on the author, and this multireferential, multi-dimensional machinic catalysis. The symmetry of scale, the transversality, the pathic non-discursive character of their expansion: all these dimensions remove us from the logic of the excluded middle and reinforce us in our dismissal of the ontological binarism we criticised previously."

<http://old.richarddawkins.net/articles/824>

shtove (2013-09-26 13:26:18)

@ Alex. I recall reading a passage in Jacques Lacan - he wrote something like: "I am deliberately making this hard to follow because otherwise it would not be worth writing". Years ago, never been able to track it down with google. Seth: yeah, that's a nice summing up.

shtove (2013-09-26 13:44:22)

ps. the postmodernism generator mentioned in Dawkins doesn't seem to work anymore, but the archive on the website also has a section for generated adolescent poetry: <http://www.elsewhere.org/hbzpoetry/>

## Queen Late (2013-09-26 05:00)

When a Chinese friend of mine was in first grade, she was habitually late for school. Usually about ten minutes. Her mom took her to school on a bike. One day she was 20 minutes late. The door was closed. My friend opened the door. "May I come in?" she asked the teacher. The teacher came to the door. She took my friend to the front of the class. "Here is Queen Late (???)", she said.

Everyone laughed, including my friend. She thought it was a funny thing to say, not mean. The name stuck. Many years later, she was called Queen Late by those who knew her in primary school. Her teacher was not a great wit. Other students at other schools were called the same thing. It was/is a standard joke.

Sometimes I think Chinese have, on average, a better sense of humor than Americans, but who really knows? A more interesting contrast is how lateness is handled. At UC Berkeley, about 20 years ago, I attended a large lecture class (Poli Sci 3, Comparative Politics) taught by Ken Jowitt, a political science professor. Jowitt was considered an excellent lecturer, which was why I was there, but he was also famous for being hard on students who came in late. When I was there, a student came in late. Jowitt interrupted what he was saying to point out the offender and said something derogatory. I don't remember what Jowitt said but I do remember thinking – as someone who also taught large lecture classes where students came in late – that he was making a mountain, an unattractive mountain, out of a molehill. It didn't occur to me to wonder how he could have dealt with the problem in a way that made everyone laugh.

---

Kitty (2013-09-26 13:12:16)

I had several professors in college who disrupted the class far more with their offense at latecomers than did the tardy students themselves. One actually stopped talking, walked to the door, yanked in the late students physically, slammed the door and yelled that no one else was to be let in (it was unclear as to who was to enforce this). It made us all very uncomfortable not just for the remainder of the class, but for the rest of the semester. We tell new members to my book club that we start at 7:00, or 7:15 if you are on "Donna time," obviously named for a member who is chronically late. Also not particularly witty, but amusing to us nonetheless.

dearieme (2013-09-26 13:12:23)

"Sometimes I think Chinese have, on average, a better sense of humor than Americans, ...": what's the opposite of 'fishing for compliments'? Seth: Uh, "fishing for insults"?

Alex Chernavsky (2013-09-26 19:23:55)

My ex-roommate from college entered the New York State Police Academy after graduation. He told me that one of the cadets had a habit of falling asleep at inappropriate times. Eventually, the instructors called the whole class for an assembly in the auditorium. Then they made the sleepy student move his bed from his dorm room to the stage. He then had to get into his bed and "sleep" in front of his classmates.

d-day (2013-09-26 23:42:24)

When I was in law school, a professor intensely disliked lateness. During the first week, a student came in just a few seconds after the start of class, she humiliated him by demanding, in front of the whole class, to know the answer to the question. There was, of course, no question, and the poor guy was so embarrassed while she browbeat him that the rest of the students were very uncomfortable on his behalf. Finally she said "the answer is 'yes.' Now go sit down." Which I learned after the fact, since I walked in a minute after that. I tried to slip into my chair unnoticed but she demanded to know the answer to the (nonexistent) question. I said "yes"—thinking, hey, I've got a 50/50 shot!—and sat down. The entire class burst into applause, the teacher blushed purple, and then told me to leave her class and pick up my law degree on the way out because I didn't need her class. I had no idea what was going on, but the class continued laughing so and I stayed put. It was a cool moment—how often do 100 people clap for a display of bravado—and a really, really uncomfortable semester. Unfortunately, I wasn't able to learn the lesson enough to cure my chronic lateness, which continues 12 years later despite some occasionally awful consequences. I've tried setting alarms and timers and keeping records of how long things take, but the answer is always "10 minutes more than you think." I wish you had a not-being-late hack that worked as well as brown noise and magic dots. Seth: I try to get everywhere 10 minutes early. I end up getting there a few minutes early.

dearieme (2013-09-27 02:36:54)

"Seth: Uh, "fishing for insults"?" I was hoping that there was an idiom. Latecomers: I never minded in the least someone who quietly entered by a rear door and sat down without disturbing her classmates. People who entered late by a front door and started to walk across the room between me and the class would find themselves ushered out and advised on the whereabouts of the back door. If they ever tried it a second time I'd usher them out, explain that they were in danger of being reported to a disciplinary officer, and tell them to fuck off. That worked. Seth: That's reasonable. The student Jowitt made an example of had entered quietly through a back door. No one would have noticed if Jowitt hadn't made a fuss. Maybe the idiom you are looking for is "making a mountain out of a molehill". In Jowitt's case, it wasn't even a molehill.

Sentinel (2013-09-27 09:24:10)

Seth, I wonder if you have an opinion on Dr. John Sarno and his theory of Tension Myoneural Syndrome (TMS, the idea that much physical pain, especially back and neck pain, is caused by a mindbody disorder whereby the mind represses unconscious rage by creating a physical distraction through the autimmune system via reducing the flow of blood to certain muscles). The reason I mention it is that he surmises that tinnitus could also be a similar mindbody disorder, controllable (like TMS) through a process of becoming aware of the rage-oriented contents of the unconscious. I had considerable success in eliminating back, neck and wrist pain through application of his methods. Though I did not set out to eliminate my tinnitus through his method, the tinnitus (years long and very annoying) totally went away around the same time. Regards,

JM (2013-09-27 13:50:57)

Regarding tinnitus, my husband recently gave up taking statin drugs, one reason was because they gave him tinnitus - which would start after he took a dose and gradually fade (he was taking a dose every other day before he gave it up completely). It was only one of many side effects that bothered him but one I had never heard of before. And this was on a fairly low dose.

CC (2013-09-27 15:29:01)

Sentinel, I'm not sure if you saw this but the 20/20 report on Dr. Sarno was awesome: <http://www.youtube.com/watch?v=vsR4wydiIBI>

Sentinel (2013-09-27 15:44:12)

CC, thank you. I actually HAVE seen that! Sarno notably did experimentation on himself in the course of developing his theories.

Nancy Lebovitz (2013-09-27 19:25:07)

I manage my tinnitus (right ear) by running my attention down a muscle on the right side of my neck for a few minutes. Unfortunately, it doesn't work if I try to notice the moment when the tinnitus disappears, but there's a reliable correlation between doing the relaxation technique and the tinnitus going away for weeks or months. Being able to manage something that's supposed to be incurable contributes to my cynicism about medicine- this doesn't mean I think all tinnitus has the same cause or the same cure. I don't have a history of exposure to loud sounds, for example. My tinnitus seems to be correlated with worrying about money.

Kitty (2013-09-27 23:48:44)

I can't wait to read the book about Matthew Shepard. If you like reading "everybody got it wrong" books, I highly recommend [i]Columbine[/i] by Dave Cullen. If you haven't, everything you thought you knew about the murders is wrong.

Jim (2013-09-28 11:09:36)

Seth, I think I cured my tinnitus with the low carb, high fat diet that I used to fix type 2 diabetes. My ears used to ring fairly loudly, especially at night and sometimes also had a low frequency throbbing in my right ear. The right ear problem is gone

and I now go for days without hearing any higher frequency ringing. I knew from random blog reading that LCHF works for lots of people on diabetes but I haven't seen anything on tinnitus. It probably took 3-6 months before I realized this helped and it could be that I was still tweaking my diet and something specific did it. For example I got more careful about lowering omega-6 fats which I've read is related to inflammation levels. In any event, it's interesting that a generally irreversible, serious condition is fixed.

Leftblank (2013-10-02 07:59:05)

Seth, Watching this video makes me think flavor scientists have reverse-engineered the SLD to create the Doritos Locos Taco for Taco Bell. <http://www.nytimes.com/2013/10/02/dining/the-nacho-dorito.html> There is a reference to an effort to avoid adding a specific flavor to trigger satiety, and an attempt to prolong the odor so that more hunger is triggered. It almost makes you think these scientists know exactly how to thwart efforts at appetite control.

## **Progress in Psychiatry and Psychotherapy: The Half-Full Glass (2013-09-28 05:00)**

[1]Here is an excellent introduction to cognitive-behavioral therapy (CBT) for depression, centering on a Stanford psychiatrist named David Burns. I was especially interested in this:

[Burns] currently draws from at least 15 schools of therapy, calling his methodology TEAM—for testing, empathy, agenda setting and methods. . . . Testing means requiring that patients complete a short mood survey before and after each therapy session. In Chicago, Burns asks how many of the therapists [in the audience] do this. Only three [out of 100] raise their hands. Then how can they know if their patients are making progress? Burns asks. How would they feel if their own doctors didn't take their blood pressure during each check-up?

Burns says that in the 1970s at Penn [where he learned about CBT], "They didn't measure because there was no expectation that there would be a significant change in a single session or even over a course of months." Forty years later, it's shocking that so little attention is paid to measuring whether therapy makes a difference. . . . "Therapists falsely believe that their impression or gut instinct about what the patient is feeling is accurate," says May [a Stanford-educated Bay Area psychiatrist], when in fact their accuracy is very low.

When I was a graduate student, I started measuring my acne. One day I told my dermatologist what I'd found. "Why did you do that?" he asked. He really didn't know. Many years later, an influential psychiatrist – Burns, whose *Feeling Good* book, a popularization of CBT, has sold millions of copies – tells therapists to give patients a mood survey. That's progress.

But it is also a testament to the backward thinking of doctors and therapists that Burns didn't tell his audience:

- have patients fill out a mood survey every day
- graph the results

Even more advanced:

- use the mood scores to measure the effects of different treatments

Three cheap safe things. It is obvious they would help patients. Apparently Burns doesn't do these things with his own patients, even though his own therapy (TEAM) stresses "testing" and "methods". It's 2013. Not only do psychiatrists

and therapists not do these things, they don't even think of doing them. I seem to be the first to suggest them.

Thanks to Alex Chernavsky.

Alex Chernavsky (2013-09-28 09:44:53)

Here's another interesting article about psychotherapy. Science writer John Horgan discusses the "Dodo Effect":

"Dodo" refers to an episode in Lewis Carroll's fable *Alice's Adventures in Wonderland* in which Alice and other characters wash up onto an island. There they encounter a dodo bird who persuades them to race around the island. The dodo finally announces that the race is over and proclaims, "Everyone has won, and all must have prizes!" Over the last few decades, the psychologist Lester Luborsky of the University of Pennsylvania tested the dodo effect by comparing different psychotherapies, including psychoanalysis, cognitive-behavioral therapy and interpersonal therapy. His research confirmed that all methods are equally helpful to patients. [...] Other prominent researchers—notably Jerome Frank, a psychiatrist at Johns Hopkins—realized that the dodo effect undermined the validity of all psychotherapies. Frank's own research corroborated the dodo effect. In one study, he and colleagues provided depressed patients with three treatments: weekly individual therapy, weekly group therapy and minimal individual therapy, which consisted of just one half-hour session every two weeks. "To our astonishment and chagrin, patients in all three conditions showed the same average relief of symptoms," Frank wrote...

See: "[1]Cybertherapy, placebos and the dodo effect: Why psychotherapies never get better"

Franz (2013-10-04 03:49:09)

Filling out short mood surveys is pretty common when using CBT in the NHS in the UK, and I'm assuming pretty much anywhere that funders want to see effectiveness data (e.g. 42nd Street in Manchester near where I live which is a charity providing free counselling for young people). My experience of private therapists/counsellors is that they tend not to, though. Seth: Are the mood surveys daily? Or just when you come to offices for therapy? My guess is the latter.

### **"Science is the Belief in the Ignorance of Experts" – Richard Feynman (2013-09-29 05:00)**

"Science is the belief in the ignorance of experts," said the physicist Richard Feynman [1] in a 1966 talk to high-school science teachers. I think he meant science is the belief in the fallibility of experts. In the talk, he says science education should be about data – how to gather data to test ideas and get new ideas – not about conclusions ("the earth revolves around the sun"). And it should be about pointing out that experts are often wrong. I agree with all this.

However, I think the underlying idea – what Feynman seems to be saying – is simply wrong. Did Darwin come up with his ideas because he believed experts (the Pope?) were wrong? Of course not. Did Mendel do his pea experiments because he didn't trust experts? Again, of course not. Darwin and Mendel's work showed that the experts

were wrong but that's not why they did it. Nor do scientists today do their work for that reason. Scientists are themselves experts. Do they do science to reveal their own ignorance? No, that's blatantly wrong. If science is the belief in the ignorance of experts, and X is the belief in the ignorance of scientists, what is X? Our entire economy is based on expertise. I buy my car from experts in making cars, buy my bread from bread-making experts, and so on. The success of our economy teaches us we can rely on experts. Why should high-school science teachers say otherwise? If we can rely on experts, and science rests on the assumption that we can't, why do we need scientists? Is Feynman saying experts are wrong 1 % of the time, and that's why we need science?

I think what Feynman actually meant (but didn't say clearly) is science protects us against self-serving experts. If you want to talk about the protection-against-experts function of science, the heart of the matter isn't that experts are ignorant or fallible. It is that experts, including scientists, are self-serving. The less certainty in an area, the more experts in that area slant or distort the truth to benefit themselves. They exaggerate their understanding, for instance. A drug company understates bad side effects. (Calling this "ignorance" is too kind.) This is common, non-obvious, and worth teaching high-school students. Science journalists, who are grown ups and should know better, often [2]completely ignore this. So do other journalists. Science (data collection) is unexpectedly powerful because experts are wrong more often than a naive person would guess. The simplest data collection is to ask for an example.

When [3]Genius by James Gleick (a biography of Feynman) was published, I said it should have been titled Genius Manqué. This puzzled my friends. Feynman was a genius, I said, but lots of geniuses have had a bigger effect on the world. I heard Feynman himself describe how he came to invent Feynman diagrams. One day, when he was a graduate student. his advisor, John Wheeler, phoned him. "Dick," he said, "do you know why all electrons have the same charge? Because they're the same electron." One electron moves forward and backward in time creating all the electrons we observe. Feynman diagrams came from this idea. The Feynman Lectures on Physics were a big improvement over standard physics books – more emotional, more vivid, more thought-provoking – but contain far too little about data, in my opinion. Feynman failed to do what he told high school teachers to do.

We need two different science classes. | Ordinary Times (2013-09-29 07:45:53)

[...] There is another definition of science though. And it is antithetical to the body-of-knowledge definition. Richard Feynman's description of it follows: (Also see Seth Roberts.) [...]

dearieme (2013-09-29 07:47:00)

"science education should be about data – not about conclusions" He did enjoy saying silly things to tease the scientific bourgeoisie. I suppose the proposition that science education should be about data, and conjectures, and hypotheses, and theories, and conclusions, and refutations, and scientific history, and .... was just too humdrum to say.

Bob (2013-09-29 08:15:11)

I think Feynman just fundamentally did not trust experts, authority, teachers, other scientists, etc. He was an extreme case. On his chalkboard at the time of his death he had written "What I cannot create I do not understand" and "Know how to solve every problem that has been solved". He felt the need to derive everything for himself. Heck, he didn't even trust dentists. He thought brushing your teeth was superstition. Seth: Yet he bought meat from meat experts, clothes from clothes experts, electricity from electricity experts, and so on. He flew on planes flown by flying experts. He trusted them with his money and

safety. I suppose if I had said this to him he would have said something like "expertise expands to fill areas of ignorance."

Alex (2013-09-30 06:25:13)

I read somewhere that the explanation for higher HbA1c is Low Carb -> Lower Blood Glucose -> Longer RBC lifespan -> Higher HbA1c

Jon (2013-09-30 10:13:43)

Here is an article explaining why HbA1c levels may be elevated by a low-carb diet, even if blood glucose levels are not: <http://chriskresser.com/why-hemoglobin-a1c-is-not-a-reliable-marker>

kxmoore (2013-09-30 21:14:26)

Pomerantz's experiment showed little change most health markers between a low and high carb diet. His carbs came

mostly from white rice and he eschewed gluten so I infer he ate little if any powdered carbs. It would be very interesting to see a follow-up experiment replacing the rice with bread to see if results correlated with this study: <http://www.ncbi.nlm.nih.gov/pubmed/22863169>

dearieme (2013-10-01 14:12:12)

"little change most health markers between a low and high carb diet": humph. Eat a mixed diet that includes plenty of fish, and a modicum of wine and beer. That's probably the way to bet.

Greg (2013-10-01 16:05:15)

Hi, thanks for the interest in my talk. I agree a1c is not a terribly reliable marker. I just reported it because the low carb advocates all said it was supposed to go up and it didn't. I wouldn't put much faith in that mouse study. For example, the C57BL/6N mice they used are known to get fat on a high fat diet. This doesn't usually happen to humans who eat high fat diets, so I'm a bit mystified why this mouse is considered a standard animal model for human obesity. I don't really pay much attention to animal studies any more unless the model they are using has been validated to be an accurate in humans (which is virtually never the case). I would not be surprised if bread had a different effect than rice – for one, it is much lower in water content, which likely affects the rate at which you can eat and digest it (the fact that rice is hard to eat fast may be one reason why it seems healthier than other carbs). Although I'm not gluten sensitive as far as I can tell, I don't eat much bread, so I'm not likely to try this experiment with bread. If you do though please let us know what happens.

### "A Debt-Ceiling Breach Would be Very, Very, Very Bad" (2013-10-01 05:00)

At the end of [1]an article by Kevin Roose in New York about the effects of a debt-ceiling breach:

The bottom line: A debt-ceiling breach would be very, very, very bad.

Keep in mind that these are all hypothetical scenarios. Reality could be better, or much worse. The truth is that while we sort of know what a government shutdown would look like (since it's happened in the past), we have no idea what chaos a debt-ceiling breach could bring. If, in a month, we reach the X Date, run out of money, and are stuck in political stalemate, we'll be entering truly uncharted waters. And we'll be dealing our already-fragile economy what could amount to a knockout blow.

This is an example of something common: Someone who has never correctly predicted anything (in this case, Roose) telling the rest of us what will happen with certainty. If Roose is repeating what experts told him, he should have said who, and their track record. Roose is far from the only person making scary predictions without any evidence he can do better than chance. [2]Here is another example by Derek Thompson in The Atlantic.

The same thing happens with climate change, except that it is models, not people, making predictions. Models that have never predicted climate correctly – for example, none predicted the current pause in warming – are assumed to predict climate correctly. We are supposed to be really alarmed by their predictions. This makes no sense, but there it is. Hal Pashler and I [3]wrote about this problem in psychology.

A third example is the 2008 financial crisis. People who failed to predict the crisis were put in charge of fixing it. By failing to predict the crisis, they showed they didn't understand what caused it. It is transparently unwise to have your car fixed by someone who doesn't understand how cars work, but that's what happened. Only Nassim Taleb seems to have emphasized this. We expect scary predictions based on nothing from religious leaders – that's where the word apocalypse comes from. From journalists and the experts they rely on, not so attractive.

I don't know what will happen if there is a debt-ceiling breach. But at least I don't claim to ("very very very bad"). And at least I am aware of a possibility that Roose (and presumably the experts he consulted) don't seem to have thought of. A system is badly designed if a relatively-likely event (debt-ceiling breach) can cause disaster – as Roose claims. The apocalyptic possibilities give those in control of whether that event happens (e.g., Republican leaders in Congress) too much power – the power to scare credulous people. If there is a breach, we will find out what happens. If a poorly-built system falls down, it will be much easier to build a better one. Roose and other doom-sayers fail to see there are plausible arguments on both sides.

Brock in HK (2013-10-01 07:50:59)

The climate models are written by people, so it's still basically people making the predictions. It just sounds more official to say "the model says". The model says what the people who built the model want it to say. And with many models, it's GIGO.

kasy fiskalne warszawa (2013-10-01 08:41:36)

If a poorly-built system falls down, it will be much easier to build a better one.

B.B. (2013-10-02 09:13:16)

While I agree with some of what you say, not all. (1) We can know from experience and history how to treat diseases or financial crises even if we don't fully understand fundamentals. Science is never-ending. In that sense, there is always more to learn, which means we are all, always, ignorant about everything. (2) I can fail to predict earthquakes, but still can know how to send emergency relief to cities hurt by them. I can fail to predict a bout of the flu, but still know how to treat symptoms. I can fail to predict financial crises, but still can know how to respond to one. (3) History has plenty of examples of default on sovereign debt. Books of case histories have been written. We can see how Greece is doing right now. We can look at recent decades in Argentina. We can look at Russia in 1998. But there has not been a default on sovereign debt by a reserve currency ever that I know of, perhaps with the exception of the collapse of the Roman Empire. It is like playing Russian roulette: better not to test the hypothesis outside of a laboratory. (4) If someone with a bad record of making predictions warns you not to step in a bear trap, it might be wise to listen.

Seth Roberts (2013-10-02 16:37:39)

"I can fail to predict earthquakes, but still can know how to send emergency relief to cities hurt by them. I can fail to predict a bout of the flu, but still know how to treat symptoms. I can fail to predict financial crises, but still can know how to respond to one." You are arguing because you know how to send emergency relief and treat flu symptoms you know how to respond to a financial crisis? I hope not. 1. Earthquakes. We don't know what causes them, don't pretend to. 2. Flu. Do you know how to reduce how often you get the flu in the future? Probably not. Yet that would be a good idea. In

addition to treating symptoms. 3. Financial crisis. Surely it would be a good idea to reduce the chances of later crises. People who failed to predict the 2008 crisis are not good choices for doing this. I was talking about reducing risk, not treating symptoms.

## **How Things Begin: Duke Check (2013-10-02 05:00)**

Ed Rickards, a retired lawyer and journalist, writes [1]Duke Check, a blog about Duke University, which I enjoy reading even though I have no connection with Duke. It emphasizes scandals and bad governance but also [2]praises. He started it in 2009. There have been plenty of scandals since then, including [3]the Anil Potti cancer research fraud.

I recently asked him a few questions.

Why did you start Duke Check?

I started DukeCheck – originally Duke Fact Checker – because of a lack of transparency and accountability on the part of the school's administration. You may want to review [4]this Chronicle profile, especially the comments from the late law professor John (Jack) Johnston, about the need for such a column and my goals. I want to provide stakeholders in Duke – students, parents, faculty, alumni, workers, everyone – with the information so that they can participate and have their thoughts count. I really do not care if they agree with me or not, just so long as they step forward.

After you graduated from Duke, did you have further association with the school (e.g., worked there)?

I graduated from Duke 1963 and Duke Law 1966. No, I never worked for Duke or had any relationship other than alum. I continued to stay in touch, I wrote various letters about my feelings, but the internet is what opened it all up. and made it possible for me to write my blog from either NY (where I used to live) or Coconut Grove (dead of the winter). I have recently closed up NY and live near Princeton NJ . . . on a golf course which is a big switch.

Have you ever been a professional writer?

After brief flirtation with the law, and a job in private equity that was totally boring, I returned to my first love, Journalism, which attracted me while I was in college, and also during the summers when I worked for a local daily newspaper in my hometown. I have worked at the Associated Press, ABC, CBS and NBC, so I have been all around!

[This makes Duke Check a super-hobby – combining the freedom of a hobby with the skills of a professional. This blog, too, is a super-hobby.]

Duke has just opened a campus in China, in [5]Kunshan, which is near Shanghai. The campus is called Duke Kunshan University (DKU). Does the DKU story point to/illustrate any general lesson(s)?

The DKU story will end with an empty campus in Kunshan. Many colleges have hit brick walls with their international adventures and this will be another. 15 years ago, Duke was gung-ho to open in Frankfurt; our president at

the time, Nan Keohane, held an international news conference linked by satellite with reporters asking questions in Durham, NY, and Frankfurt. Six years, \$15 to 20 million later, it died.

Duke should pursue international opportunities; but trying to export bricks and mortar to China will not fly. For one thing, academic freedom is a very strong tradition at Duke, and no Chinese leader will tolerate it. The new campus cannot teach nor allow religious services. We were founded by Quakers and Methodists.

We also see our administration going overboard on finances. At a time when money is tight, unbelievably tight, we're exporting green like mad. The numbers do not add up: number of students, amount we can charge them. This may well be the first thing to implode, academic freedom the 2nd.

### **JFK Assassination Diary by Edward Jay Epstein (2013-10-03 01:02)**

Edward Jay Epstein has just published a new book called *The JFK Assassination Diary* based on the diary he kept when he wrote *Inquest*. It is available on [1]Kindle, Nook and as an iTunes ebook. It will soon be available in paperback.

He wrote me about it:

As you know I was the only person to interview the Warren Commission as well as its staff and liaisons with the intelligence services. I did these interviews as an undergraduate at Cornell with no credentials as a journalist, scholar, or author. My interviews also produced a revelation that shook the journalistic establishment, which had been blithely reporting until the publication of my book *Inquest* that the Commission had left no stone unturned in an exhaustive investigation. In fact, as I showed, it was a brief, sporadic, and incomplete investigation. Indeed one in which the senior staff lawyer in charge of the crime scene investigation quit after two days, and the young lawyer who took his place, Arlen Specter, was never able to view the single most crucial piece of evidence – the autopsy photographs. The Commission was never able to obtain them, nor other pieces of evidence, because Robert Kennedy blocked it. For the same reason, the Commission was not provided with any information about a parallel plot to kill Castro in 1963. The Commission could not connect dots to which it was denied access.

I had no problem getting this information. Many of the young lawyers on the staff were furious with the way the investigation had been handled and the time pressure imposed on them. So they gave me FBI reports, payroll records and their memos, without me even asking. This raises a question. As these

lawyers and Commission members were not bound by any secrecy agreement, as amazing as that might seem nowadays, why had not journalists from major news organizations sought the same information from them? After all, in 1963, the Kennedy assassination was the crime of the century. Fifty years later, I still cannot answer this question.

A very good question. Why weren't journalists from major news organizations more . . . enterprising? It is [2]another variation on The Emperor's New Clothes, where a Cornell undergraduate manages to see what many much more experienced and credentialed experts failed to see, or avoided seeing. I would answer Epstein's question like this: The experts were disinterested in gathering evidence that might contradict their world view. That world view included a belief in the competence of exceedingly important government commissions. They didn't want to gather evidence that might make them uncomfortable. I see this every year at Nobel Prize time. No journalist ever questions the claims in the press releases that accompany the prizes.

dearieme (2013-10-03 03:09:58)

Normally I pay no heed to JFK assassination yarns, but I saw one the other day that raised a wry smile. The proposition was that when JFK was first shot, the car behind jolted and a secret service man aboard accidentally fired a shot which was the one that removed much of Kennedy's head. The wry smile was caused by the thought that many of the claimed inconsistencies in the evidence might be explained not by a huge conspiracy, but by a simple accident. On the who gains principle, LBJ must be the main suspect. On the principle of cuckolded men seeking revenge, the field is too large to contemplate. As for why journalists are not inquisitive, the answer is probably the same as for why dogs lick their balls.

Mark Sanders (2013-10-03 11:06:43)

Related to this is how some investigations refuse to consider eye-witness evidence. My vague memory after all these years is that people heard bullets coming from a different direction than from the window where Oswald was. This testimony was discounted. But here are two other incidents where this happened: 1. The airplane that blew up in the sky over the south shore of Long Island back in (I think) the early 90's. Many eyewitnesses on the beaches said they saw something flying in the sky hit the airplane. This included ex-military people who knew what a missile looked like in the air. All of these testimonies were discarded in the investigation because they obviously didn't know what they were looking at. I remember a ridiculous animation put on TV by the government that tried to explain that the aircraft just broke in half somehow on its own. What was funny was that parts of their explanation apparently conflicted with the laws of gravity and other scientific basics. 2. Again in the 90s I think, an American ship shot down an Iranian civilian airplane, killing many people. The electronic equipment on the ship somehow convinced the commander that it was a military plane and had to be shot down because of where it was and how it was maneuvering. However, sailors on the ship were able to use their own eyes to tell that it was a civilian airplane.

## **The Willat Effect With Gin (2013-10-03 05:00)**

[1]The Willat Effect – named for [2]Carl Willat, whose limoncello comparison tasting made me notice it – may happen when you experience two similar versions of one thing close together. (For example, sip one limoncello and then sip another.) The differences between them become clearer, of course. The Willat Effect is the less obvious hedonic

change: suddenly the differences matter. Suddenly one version is more pleasant, the other less pleasant. The hedonic changes are large enough to change how I spend money (I buy the better version more, the worse version less). I believe this effect turns people into connoisseurs.

I recently noticed the Willat Effect with gin. As part of a project to buy every type of not-too-expensive alcohol in a nearby liquor store, I bought a bottle of Bombay Sapphire London Dry Gin. I neither like nor dislike gin, it was just something they sold I hadn't tried. It was medium-priced (about \$20). I liked it okay.

I returned to the liquor store. This time I bought two brands of London dry gin: Tanqueray (about \$20) and Greenall's Special (about \$15). At home I tasted them side by side. The Tanqueray was much better, I noticed right away. It was softer, more rounded, and had floral overtones absent from the Greenall's. Where was the Bombay Sapphire gin on these dimensions? Did it have floral overtones? I had no idea. Now I was curious. One close comparison shifted my buying habits in two ways: (a) I want to make more of these comparisons. I want to try every brand of gin in the liquor store to see if the cheaper brands tasted worse. (b) Apart from these comparisons, I will never buy inferior gin again.

The Willat Effect happens only if the two things being compared are neither too similar nor too dissimilar. Perhaps differently-priced versions of London dry gin are roughly the right distance apart and are a convenient way to demonstrate the effect. It's easy to get different versions of London dry gin.

The effect interests me because it is (a) practical (a source of enjoyment), (b) a subtle comment on intellectuals (who complain about our "consumerist" society) and economics (I look forward to an economist's explanation of connoisseurship), and (c) it supports [3]my theory of human evolution, which says connoisseurs came to exist because they promote technological innovation. Connoisseurs make it easier for the most skilled craftsmen – the ones most likely to innovate – to make a living.

dearieme (2013-10-03 07:08:47)

Also worth trying (in addition to Gordon's, of course) are Adnam's First Rate Gin Original Bombay Dry Gin Oxley Cold Distilled London Dry Gin. I'm sure there are other contenders: you could have some pleasant evenings ahead.

griff (2013-10-03 17:51:37)

I had a similar experience with Vodka. A friend of mine started a distillery in Maryland and my former boss had invested in or sat on the board of another distillery. We decided to sit down and compare. This is interesting, as the whole point of vodka is to not have a taste. Nevertheless, there was a distinct smoothness or "roundness" to one of them. The other was sharp and had an odd burnt wood flavor. Also interesting, but not related. My friend explained that he chose vodka as his first product given a) it isn't really supposed to have a taste, just use good water, good grains, ferment and filter. b) it is the best start up liquor for a distillery as there is no aging process. Therefore, you get a quick return on investment.

Joe Harris (2013-10-08 05:13:53)

I couldn't pass up the opportunity to recommend Hendrick's Scottish gin. This is the king of gins in my view. They use cucumber in it's production and it's best enjoyed with a slice of cucumber in place of the usual slice of lime. Hmm, is it too early for gin? ;)

Paul (2013-10-09 08:46:32)

Boodles! The finest gin of our, or any, era. Beefeater's is pretty good too.

## **The "Disgusting" Foods I Eat (2013-10-04 05:00)**

In [1]a review of Anna Reid's new book, Leningrad: Tragedy of a City Under Siege, I learned that one of the calorie sources that starving Leningraders came to eat was:

'macaroni' made from flax seed for cattle

To which I say: Damn. The implication is that, before the famine, "flax seed for cattle", which is roughly the same as flax seed, was considered unfit for human consumption. Only when starving did Leningraders stoop to eat it. I can buy flax seed in Beijing. But not easily.

The triangle is complete. I have now learned that the main things I care about in my diet, which I go to great lengths to eat every day, are all considered "disgusting" by a large number of people:

1. Flax seed. It is the best source of omega-3 I have found. I eat ground flax seeds every day. Flaxseed oil goes bad too easily.
2. Butter. Perhaps the most reviled food in America, at least by nutritionists. A cardiologist once told me, "You're killing yourself" by eating it.
3. Fermented foods. Many fermented foods are considered disgusting – after all, they are little different than spoiled foods.

1. <http://www.dailymail.co.uk/home/books/article-2032706/BEYOND-HORROR-They-ate-cats-sawdust-wallpaper-paste--babies-Leningrads-agony-Nazis-tried-starve-submission-LENINGRAD-TRAGEDY-OF-A-CITY-UNDER-SIEGE-1941-44-BY-ANNA-REID.html>

---

Kevin Miller (2013-10-04 05:15:39)

Flaxseed oil freezes well and thaws quickly. I take small plastic bottles of I think 4 ounces of flaxseed oil, which makes a quick and convenient lunch, particularly when traveling.

dearieme (2013-10-04 06:25:46)

If they don't eat butter, what on earth do they have on their croissants? Or on their peas or boiled potatoes? A mysterious people, the Americans. Seth: Americans use all sorts of butter substitutes, especially margarine. Fancy restaurants serve olive oil in place of butter. In one expensive Berkeley restaurant, I was unable to get butter.

GeoffD (2013-10-04 07:12:10)

I take 360 calories of butter and mct oil for breakfast every morning in my coffee. Delish. I've never been leaner, healthier, more energized or happier in my life. Here's to butter. I'll get my omega 3's in salmon though...

Alex Chernavsky (2013-10-04 07:57:19)

Dearieme - this is what I use in place of butter: <http://www.smartbalance.com/products/buttery-spread/smart-balance-buttery-spread-flax>

Tom (2013-10-04 09:43:00)

Alex, you know that that product is mostly soybean oil, right?

Alex Chernavsky (2013-10-04 10:52:16)

Tom: no, I didn't know that. But it doesn't matter much, because I'm not a heavy user of that margarine.

Antonio (2013-10-04 12:03:30)

"Flax seed. It is the best source of omega-3 I have found" What about chia seeds?

JM (2013-10-04 14:19:48)

Dearieme - No we Americans aren't mysterious - despite being told for decades that cholesterol is bad for us butter is sold in every supermarket (so people do buy and use it!) And most restaurants I frequent put butter on the table these days next to the bread basket and not margarine. The real problem is that most restaurants in the kitchen are using mostly cheap vegetable oils, like soybean oil, as does most processed foods - and I bet if you look around the shelves of supermarkets and restaurant kitchens of Europe and other countries you will see a lot of the same thing. It's a cost issue.

Seth Roberts (2013-10-04 14:20:44)

"what about chia seeds?" Too hard to get. But you might be right - maybe they would be better in some way that would outweigh the increased difficulty of getting them.

Nancy Lebovitz (2013-10-04 18:21:10)

Butter is in a different category- it's a guilty pleasure rather than something like liver that a lot of people are repulsed by.

dearieme (2013-10-05 12:01:00)

Good news, JM. I see that the possibility that butter and its kin are not mass murderers is leaking into the media. <http://blogs.telegraph.co.uk/news/damian-thompson/100239917/is-this-the-real-identity-of-the-heart-disease-serial-killer/>

Jeff (2013-10-05 13:35:10)

Seth - How much ground flax seed do you eat each day? Are you consuming it plain or mixed in something else? Thanks.

Seth Roberts (2013-10-05 14:19:40)

I eat 60 g of ground flaxseed each day. I divide it into two 30 g portions. Eat each portion with yogurt and fermented rice and some flavoring.

dearieme (2013-10-06 13:41:32)

Beef Stroganoff: first my wife fries the mushrooms in butter and then takes them out and puts them aside to keep warm. Then she melts more butter in the frying pan and adds the fat and any gristle she's cut off the meat. When all that has melded together, in goes the beef. When that's ready she adds the warm mushrooms. Then she deglazes the pan with some brandy and finally she adds the cream. She serves on rice, with peas. We feel no need to add butter to our peas for this meal.

Jeff (2013-10-07 14:54:34)

Seth - Why do you divide your dose of flaxseeds? Are you still eating it taste free? Seth: 60 g was a lot to eat at once. Also divided dosing is likely to produce a steadier supply to the brain. No I don't eat it nose-clipped. I get plenty of smell-free calories from the butter I eat.

Ross (2013-10-08 08:11:21)

Professor Roberts, I too have been struggling with trying to figure out how to get flaxseed into my diet. I was buying flaxseed oil, but it is expensive in the long run and I don't know how to test if it is rancid since flaxseed oil doesn't seem to taste so great from any producer. I bought a Piteba oil extractor, but I have failed to make that system work. My wife put in the amount of flaxseed needed to give everyone who eats two pieces of sourdough bread the 60 g and it wasn't very tasty. Can you enumerate the practical ways you ingest flaxseed? What is your yogurt/fermented rice recipe? Do you have any other recipes? Thanks for your blog. - Ross

Seth Roberts (2013-10-08 14:16:32)

yes, flaxseed oil is expensive. And must be kept cold. I grind the flaxseeds with a blender. Takes seconds. I store them at room temperature. I eat them with yogurt (without sugar), sweetener, and flavoring. Flaxseed: 30 g. Yogurt: yogurt I make myself. No sweetener. More sour than store-bought yogurt. About 3 spoonfuls. Sweetener: Xylitol, honey, or something else. Recently I've been using "Japanese yogurt" (a sweetened store-bought yogurt that seems to be different from other yogurt) and fermented rice, which is sold in Chinese food stores. Flavoring: a small amount (1 tablespoon?) of wine, whisky, tequila, etc.

Jeff (2013-10-09 03:49:41)

Seth - Thanks for answering all my questions. How much taste free butter are you currently ingesting?

Texan99 (2013-10-12 09:14:00)

I haven't touched margarine since I moved out of my parent's house decades ago. Never understood why people would eat it when they can get butter. Lots of food can be easily fermented at home, from yogurt to dill pickles. Even leaving the beans to soak in water overnight causes a bit of fermentation to start, and cuts down on flatulence.

joseph (2013-10-14 14:25:48)

" I get plenty of smell-free calories from the butter I eat." In your book which i have you list Extra light Olive Oil, and Sugar Water, as smell free calories which works with the SLD Diet, so butter can be added? then it must be eaten by itself otherwise the attending foods will add smell, what else is smell free? flax seed oil does have some smell, ground seeds maybe not?

Seth Roberts (2013-10-14 15:18:56)

I eat butter wearing nose clips. Nose clips remove smell. Any food is smell-less calories when eaten nose-clipped.

xap (2013-10-15 00:34:20)

I, for one, would love to see a longish post titled something like "What I ate this week." to get a better overall idea of what you eat, when and how. You mention specific topics in the posts, and clarifications in the comments, but it would be great to get a broader overview. As for swimming type nose clips, I have found them somewhat loose (even when wearing two) but came across a post (somewhere in the forums I think) about using spirometry nose clips which have suited me much better since I switched to them.

## TV Shows I Like (2013-10-05 05:00)

Something compels me to tell you the TV shows I really like. In no special order:

1. [1]The Fall. Gillian Anderson is an out-of-town detective called in to solve a string of murders. On Netflix.
2. Mom. Humor with a sad undercurrent (this show) is much better than less-layered humor (The Big Bang Theory, by the same people).
3. Nashville. As good as Thelma and Louise (by the same person), but longer.
4. Downton Abbey . No show portrays kindness better.
5. Survivor. Current season (Blood versus Water), in which returning players playing against their loved ones, might be the best ever.
6. The Mindy Project. The wittiest TV show. (Hello Ladies is good.)
7. Masters of Sex. About Masters and Johnson. Early personal science – sex mystified Masters.
8. Homeland. The first episode makes me think this season will be even better than the first.
9. Peaky Blinders. About a Birmingham crime family post World War I.
10. Mad Men (between seasons).
11. Episodes (between seasons). Matt LeBlanc plays Matt LeBlanc. Very funny.
12. Separated at Birth (between seasons).
13. The Fosters (between seasons). About a foster family.
14. Veep (between seasons). My favorite show – well, either this or Downton Abbey or Nashville.

1. [http://en.wikipedia.org/wiki/The\\_Fall\\_\(TV\\_series\)](http://en.wikipedia.org/wiki/The_Fall_(TV_series))

---

Alex Chernavsky (2013-10-05 05:32:30)

I generally don't like television dramas (never liked *The Sopranos* or *Mad Men*, for example). But I've recently started watching *Breaking Bad* (via Netflix), and I'm very impressed with the acting, writing, and directing. It's head and shoulders above your typical TV drama.

dustin (2013-10-05 08:41:37)

@alex chernavsky If you didn't like the sopranos but you do like breaking bad, you might give The Wire a try. Don't be put off by it being a cop show. I'm not generally a fan, but this was in a different category.

kxmoore (2013-10-05 22:11:20)

naked and afraid is the only show i look for Seth: Yeah, I like that too.

vgm (2013-10-06 22:39:23)

I cannot recommend The Thick of It highly enough. Veep is a spinoff of TTOI. Both are created by Ianucci, but I think TTOI is much better. Seth: TTOI was great. I like Veep even more, maybe because Serena (Veep) is even better done than Malcolm (TTOI).

Texan99 (2013-10-12 09:09:38)  
I'm enjoying "Revolution."

### Signaling and Higher Education: Email With Bryan Caplan (2013-10-06 05:00)

I recently emailed back and forth with Bryan Caplan about [1]a signaling view of higher education, which Bryan elaborates in [2]these slides. I wrote to him:

Having looked at your slides, I would say we pretty much agree. I think employers have little control over the content of college education and, as you say, use quality of college because it works better than IQ tests and the like – as you say.

Perhaps we also agree that just as British aristocrats have a lot less power now than they did 200 years ago – the message of Downton Abbey – so are American college professors slowly losing power. MOOCs are one example, blogs are another. Parents and professors are quite happy with the current system, students and employers are not, and they are gaining power. That is my theory, anyway.

I think a signaling explanation does a very good job of explaining why sense of humor matters so much, [3]especially in mate choice. Sense of humor = Nature's IQ test. Sense of humor signals problem solving ability, which really matters but is hard to measure directly. I used to think that we have two basic tasks in life, manipulating things and manipulating other people (long ago nobody was depressed, etc.) and they were really different.

---

DA (2013-10-06 10:48:28)

One surprising result of this phenomenon is that major businesses seem to invest comparatively little in higher education. It would not be difficult for Microsoft or Apple to start a college dedicated to teaching the skills that their pipeline demands. However, outside of some relatively small gifts to engineering, business and comp sci departments, they seem mostly content with outsourcing under the current model.

Roger Sweeny (2013-10-06 16:42:53)

Microsoft or Apple could start colleges but 1) students can't be sure they won't get fired or want to take a job elsewhere so they will want a curriculum which is fairly general, 2) Anglo-American law prohibits Apple or Microsoft from making an enforceable agreement: we will pay for you to attend and you agree to work for us for 7 years.

Dennis Mangan (2013-10-06 17:20:36)

Employers don't use college instead of IQ tests because that's better, but because using IQ tests is all but illegal. Disparate impact, and all that.

LemmusLemmus (2013-10-07 06:26:48)

"Employers don't use college instead of IQ tests because that's better, but because using IQ tests is all but illegal. Disparate impact, and all that." Sure. The world ends at the borders of the USA.

Andy (2013-10-07 06:54:03)

I had a pint of Erdinger(hefe) that had sat in a poorly maintained keg in a bar in Wan Chai for so long that it had gone pleasantly sour. I had drank proper Belgian lambics before and it was so close, that I actually just finished the beer without complaining and appreciated that a lambic in Hong Kong would have cost me alot more, if I could even find one!

garymar (2013-10-07 14:27:43)

"Furthermore, the clay pot has properties such as biodegradability, rotproofness and vertebration which are all critical elements for storing Kimchi for a prolonged period."

I pride myself on having an ample vocabulary but am stumped by the word "vertebration". The pot has vertebra? Now that I think about it, it could be "ventilation". Rotproofness also was troubling - how could it be rotproof and biodegradable *at the same time*? But I think they mean "anti-fungal" here.

garymar (2013-10-07 14:32:36)

Spoke too soon! Here's what Wikipedia says about Onggi pots:

Vertebration Onggi has one strong advantage over other containers: it is not affected by use or natural phenomena. In fact, onggi can withstand exposure to strong sunshine and rain for a long time.

Well, that clears that up!

Portlander (2013-10-07 20:40:13)

I believe the moral should be choose your Willat Effect wisely.

### **The Emperor's New Clothes and the New York Times Paywall (2013-10-08 05:00)**

A few years ago I blogged about three books I called [1]The Emperor's New Clothes trilogy. Each book described a situation in which, from a certain point of view, powerful people – our supposed leaders – "walked around naked", that is, did things absurd to the naked eye, like the Emperor in the story. As in the story, many people, including experts, said nothing.

After reading about [2]the fate of the *Washington Post*, I thought of the *New York Times* paywall, which can be avoided (i.e., defeated) by using what Chrome calls "incognito mode". (Firefox has a similar mode.) I didn't know this until recently; some of my friends didn't know it. One of them carefully rationed the Times articles she read. I wonder how the long the ignorance will last. The Times is an extremely important institution. In the many long discussions at the *Times* about the paywall, no one mentioned this?

1. <http://blog.sethroberts.net/2010/04/27/the-emperors-new-clothes-trilogy/>

2. [http://www.washingtonpost.com/business/as-jeff-bezos-prepares-to-take-over-a-look-at-forces-that-shaped-the-washington-post-sale/2013/09/27/11c7d01a-2622-11e3-ad0d-b7c8d2a594b9\\_print.html](http://www.washingtonpost.com/business/as-jeff-bezos-prepares-to-take-over-a-look-at-forces-that-shaped-the-washington-post-sale/2013/09/27/11c7d01a-2622-11e3-ad0d-b7c8d2a594b9_print.html)

---

Shawn (2013-10-08 05:42:39)

The paywall can also be defeated by doing a search for the article's title.

Alex Chernavsky (2013-10-08 05:45:23)

According to this blog post, the *New York Times* spent something like \$40 million developing their paywall: <http://blogs.law.harvard.edu/phlg/2011/03/28/how-did-the-new-york-times-manage-to-spend-40-million-on-its-pay-wall/>

Mark (2013-10-08 08:25:54)

You can also avoid the NYT paywall by going in through a simple google search... that is, search for the title of the article and click the link.

Three Pipe Problem (2013-10-08 09:58:23)

I find that sometimes to avoid the paywall I have to do a Google search, but rather than clicking on the main NYT article to click someone who has blogged it and follow the link from there.

Alex Chernavsky (2013-10-08 10:00:51)

There is some speculation that the *New York Times* purposely made it easy to circumvent the paywall. That way, people who care about convenience and who have the money will pay the subscription fee. People who are poor and/or tech-savvy can still read the content (and the *Times* still gets ad revenue from those viewers). Now, having said that, it's still a mystery why it should cost a staggering \$40 million to put up the paywall. In a related matter, see this interesting story about the truly outrageous amounts of money that New York City government is spending to create a customized human resources system: "[1]For Bloomberg, Waste Mars Another Digital Project"

Soon after becoming mayor, Michael R. Bloomberg announced a plan to modernize the computer system that handles personnel information for New York City's vast work force. The \$66 million project was to be one of

the signature technological innovations of his tenure. Nine years later, his administration has already spent \$363 million — and the work is far from done. The administration has pressed ahead despite repeated warnings that the project is deeply troubled, according to a review of thousands of pages of city records, as well as dozens of interviews with officials and private contractors. The administration's own internal monitors regularly filed reports detailing chronic mismanagement, cost overruns and rampant waste. "It was a runaway project," said Raj Agarwal, a city official who managed the early stages of the new system before resigning in frustration over what he saw as the administration's incompetence.

1. [http://www.nytimes.com/2011/09/24/nyregion/bloombergs-computer-project-for-personnel-data-leads-to-waste.html?pagewanted=all&\\_r=0](http://www.nytimes.com/2011/09/24/nyregion/bloombergs-computer-project-for-personnel-data-leads-to-waste.html?pagewanted=all&_r=0)

Jim (2013-10-08 10:15:19)

I always thought they made the firewall leaky on purpose.... It is a fine balancing act, clamp down too much and readers go elsewhere (and google can't index articles), give too much away and no one pays. They probably have some idea how many people are reading for free, and if it gets out of hand, will tighten a bit. (There are other well know workarounds, I won't mention them here).

Alex (2013-10-08 12:16:21)

The Washington Post's paywall can be circumvented by going incognito as well. I am sure both institutions are well aware of this, but have wisely opted to allow it. As Alex C. points out, they are still getting ad revenue from page views of people who go to the trouble of going incognito, google searching, or following links from social media (those don't count, either). They maximize revenue when they make it inconvenient, not impossible, to read without subscribing. I saw the downside of the tight paywall with the Wall Street Journal. I had a free account from my time at Dow Jones, which published WSJ. There were writers I enjoyed following. But if I read something interesting that I wanted to share with friends and family, I had to include the text in my email, because they couldn't get to it. It also wouldn't be worth blogging about, because most people couldn't get to it. I didn't see how much that affected my reading priorities until one day I realized that I hadn't checked the Wall Street Journal in months.

Tom (2013-10-08 17:39:24)

I hadn't known about the incognito mode hack; I've just been hitting the 'stop loading' button on the browser before the blocking javascript can load.

Bando (2013-10-09 09:44:59)

Another way to get around is to use different browsers—you get 10 free articles per browser.

## **Does Chicken Extract Improve Brain Function? (2013-10-09 05:00)**

[1]An article in the latest Nutrition Journal says that a "proprietary" extract of chicken meat, called CMI-168, improved brain function. From the abstract:

Normal, healthy subjects were supplemented with either placebo or CMI-168 for 6 weeks. The subjects were given a series of cognitive tests to examine their levels of cognitive functioning at the beginning and end of supplementation, as well as two weeks after termination of supplementation. The combination of these tests, namely Digit Span Backwards, Letter-Number Sequencing, and the Rey Auditory Verbal Learning Test (RAVLT), was used to assess the subjects' attention and working memory. . . . Subjects supplemented with CMI-168 showed significantly ( $p < 0.01$ ) better performance in all cognitive tests after 6 weeks' supplementation compared to [placebo] and [their] superior performance was maintained even 2 weeks after termination of supplementation.

This is the first time I've heard that something in chicken improves brain function. The abstract understates the

4766

strength of the evidence;  $p < 0.001$  (not 0.01) in almost all relevant comparisons.

However, several details make me question the claim.

1. Two of the five authors work for the company that sells the chicken extract.

2. The subject recruitment makes no sense. "A total of 46 healthy male and female subjects aged between 35 and 65 years were recruited either as walk-in or referred from their general practitioners for counseling for life-style related issues." Walk-in? "Life-style related issues"? "Counseling"? I have never heard of such things in this context. Nothing is said about payment or the fraction of people who declined to participate.

3. Vague statistics. I cannot tell if pre-treatment scores were used to make the treatment scores more sensitive. Someone who does better than average before treatment is likely to do better than average after treatment – you want to adjust for that.

4. No apparent learning effect. Subjects in the placebo group did not clearly improve from test to test. There is usually a big learning effect with such tests. Nothing is said about learning effects.

5. Vague supporting evidence. "Anecdotal evidence has long associated EOC [essence of chicken] with improving cognitive performance, especially related to learning and memory, as well as executive function," says the paper. It provides no documentation of this evidence.

6. Uniformly positive results. The paper emphasizes results from nine different tests of brain function. All showed significant improvement at the same  $p$  value ( $p < 0.001$ ). When I used four different tests to measure the brain effects of flaxseed oil, different tests had widely different sensitivities.

I haven't been able to find anything supporting the idea that chicken meat (or extract) improves memory other than what this company says.

I asked a Chinese friend about this; she too had never heard this claim.

[2]The company behind this (Brand's) is more than a hundred years old, and essence of chicken has been their main product. In spite of my doubts, however, I would still like to test the product to see what effect it has on my reaction-time measure of brain function.

Strangely enough, after writing this post weeks ago, I noticed by accident that duck seemed to improve my brain function. I was stunned – as I said, I had never heard such a thing. I'll describe the data later.

1. <http://www.nutritionj.com/content/12/1/121>

2. <http://www.brandsworld.us/en/home/index.php>

---

dearieme (2013-10-09 06:02:53)

Duck: now you're talking. My beloved does a lovely smoked duck salad in the summer, and roast duck in the winter. Though I see that we're going to kick off the roasts season with Guinea Fowl - presumably because there's still ample tarragon in the garden. Ah bliss.

Alex Chernavsky (2013-10-09 07:00:36)

Seth, on a related subject, have you heard anything from Eri Gentry? I was hoping that her [1]Buttermind experiment would be the first of many such crowd-sourced studies, but the whole thing has apparently petered out. Seems a shame. It would be nice to have a group of people who could be called upon to test claims such as the one about the chicken extract. Seth: Yeah, I agree. I haven't heard anything from Eri Gentry lately.

1. <http://blog.sethroberts.net/2011/01/29/the-buttermind-experiment/>

Alex (2013-10-09 09:45:02)

Dearieme, your comments often make me hungry. Your beloved needs to start a food blog.

Staffan (2013-10-10 03:50:20)

If they really had something they would use a large sample, let independent researchers do the study, use an ordinary IQ test and follow up after at least six months or even a year to show that the effect could be permanent. Ergo they have zipppo. Seth: IQ tests are not designed for repeated testing. The stronger the effect, the smaller the sample they would need. My research suggests the improvement lasts about a day. I suspect they don't know whether their extract works, even though it does.

dearieme (2013-10-10 06:22:06)

"Your beloved needs to start a food blog." As a birthday present I plan to sign her up for a course on smoking food, held amongst the beauties of the Lake District. Amn't I good to her? On a marginally more serious note, how about duck eggs, Seth?

Seth Roberts (2013-10-10 16:35:39)

I've eaten fermented duck eggs many times. Never noticed improvement on my brain test.

Brandon Berg (2013-10-10 05:57:59)

Eh. Not that big a deal. A typical Japanese grocery store will have on the order of 20-30 natto options, usually around 1-3 yen per gram. From the packaging, this appears to be exactly the same stuff sold in stores. I've heard that modern natto is usually made with a bacterial monoculture and it's less nutritious than wild-fermented natto. I've been meaning to look for a restaurant that has traditional straw-fermented natto, but haven't gotten around to it yet.

## Association of Sleep and Chronic Illness (2013-10-11 05:00)

[1]A recent PatientsLikeMe survey found a strong correlation between chronic illness and poor sleep. Here are the most interesting results:

PatientsLikeMe survey respondents in the U.S. (n=3,284) . . . are almost nine times more likely to [have] insomnia than the general adult population. . . . PatientsLikeMe members with health conditions experience [each] of the four symptoms of insomnia [= trouble falling asleep, trouble staying asleep, early awakening, and waking up not rested] at twice the rate of the general adult population.

This supports my view that bad sleep causes illness. The correlations could have plausibly been the other way (better sleep among survey respondents). People sleep more when sick. Whatever makes sick people sleep more might also make them fall asleep faster and wake up less often.

If I slept poorly, I would move heaven and earth to sleep better. (But would never take sleeping pills.) I sleep well, actually, but I still track my sleep and do various experiments to see if I can improve it. For example, recently I was puzzled why I was sleeping less well in Berkeley than in Beijing. One possibility was that my Beijing bedroom was darker than my Berkeley bedroom, even though my Berkeley bedroom was quite dark (e.g., no light from a street lamp). I made my Berkeley bedroom even darker and found my sleep improved. It really was cause and effect. When I made my Berkeley bedroom lighter, my sleep got worse.

My enormous concern with sleep – nothing matters more for health – seems to put me in a tiny minority. Even sleep researchers don't say bad sleep causes sickness. However, [2]Robb Wolf agrees with me. He has said, "If someone sleeps poorly it is hard to keep them alive. If someone sleeps well, it is hard to kill them" – a good way of putting it. At the recent Ancestral Health Symposium in Atlanta, I asked him where he got this. He said it was based on his experience, meaning his experience working with other people.

My view is heavily based on my experience of my own health. [3]Exactly when I greatly improved my sleep, I greatly improved my health. I stopped getting obvious colds. The people around me continued to get them. I hadn't expected this. In the research literature I found plenty of support for the idea that better sleep causes better health. An example is that poorer health during the winter seems to be due to less light, not the cold. I am sure morning sunlight improves sleep. Vitamin D has been associated with dozens of measures of health (more Vitamin D, better health). This too may reflect the underlying causality better sleep → better health because sunlight increases Vitamin D and improves sleep. That morning Vitamin D improves sleep ([4]Tara Grant's great discovery) be important here. Epidemiologists should always measure sleep the way they always measure smoking. Now they almost never do.

Thanks to Richard Sprague.

More "Even sleep researchers don't say that bad sleep causes illness" – that's wrong. Here's [5]an example:

Yet there's strong evidence that lost sleep is a serious matter. The Sleep in America polls and several large studies have linked sleep deficits with poor work performance, driving accidents, relationship problems, and mood problems like anger and depression. A growing list of health risks has been documented in recent studies, too. Heart disease, diabetes, and obesity have all been linked with chronic sleep loss. "People just don't realize how important sleep is, and what the health consequences are of not getting a good night's sleep on a regular basis," Hunt tells WebMD. "Sleep is just as important for overall health as diet and exercise."

I should have said sleep researchers don't connect good sleep with good immune function, which this quote illustrates.

David (2013-10-11 07:00:44)

Not that I doubt the importance of sleep, but in this case couldn't the causation easily go the other way: if you're chronically ill, that illness interferes with your ability to sleep?

Char (2013-10-11 08:44:48)

Here Stephan Guyenet discusses sleep and obesity. He mentions Dan's Plan (<http://www.dansplan.com/blog/index.php>) where it's been discussed also. I find this interesting.

Char (2013-10-11 09:05:12)

Whoops! Forgot the link to Stephan Guyenet's blog: <http://wholehealthsource.blogspot.com/2013/10/sleep-and-genetic-obesity-risk.html>

Michael (2013-10-11 12:50:47)

Seth, I think you are correct that bad sleep causes illness. However, that people sleep more when sick, is imo generally true more so for acute than chronic disease. I believe that in chronic disease one may find oneself in a vicious cycle: poor sleep contributes to the chronic condition, the chronic condition in turn (e.g., through pain) contributes to poor sleep. A very tough proposition.

Alex Chernavsky (2013-10-11 17:27:46)

"Even sleep researchers don't say bad sleep causes sickness." About five years ago, I attended a lecture by Cornell psychologist [1]James Maas. He did point out various ill effects of sleep deprivation, although he seemed to focus mainly on people who voluntarily deprive themselves of adequate sleep.

1. [http://cornellalumnimagazine.com/index.php?option=com\\_content&task=view&id=1307&Itemid=9](http://cornellalumnimagazine.com/index.php?option=com_content&task=view&id=1307&Itemid=9)

Stu (2013-10-11 21:08:09)

Most days I wake up feeling more tired than when I went to bed the night before, however I find that if I take up to a tablespoon of raw honey immediately before bed I almost always wake up feeling totally refreshed. I've suffered from low energy, brain fog, fatigue and sore muscles for years and I tried eliminating food groups (dairy, grains, nightshades, etc) but that didn't fix the problems (although wheat has been problematic) but taking the honey did. I usually sleep without any problems that I'm aware of even if I awaken feeling unrefreshed I will still sleep through the night and won't awaken early or whatever, but the crucial thing is I feel rested when I wake up, if I get that right I can even eat bad food and feel good all day. I've tried coconut oil and coconut oil combined with honey but they didn't work. I've also noticed caffeine later in the day and chocolate have a huge impact on this. There are a lot of factors that come in to play so the honey thing doesn't always work, but it can make a big difference. I think the fructose helps replenish liver glycogen which may help me get more deep sleep but I don't know for certain

Seth Roberts (2013-10-12 01:55:52)

That's fascinating. You write: "I've also noticed caffeine later in the day and chocolate have a huge impact on this." Could you elaborate? Huge impact in what way?

Seth Roberts (2013-10-12 02:02:32)

Yes, Maas does say this. This is from a Cornell press release about a book by Maas:

The book also includes two tests to help the reader determine how well they sleep, the costs of sleep loss and research findings that link poor sleep with colds, flu, unhealthy skin, weight gain, diabetes, heart disease and cancer, as well as stress, anxiety and depression.

Stu (2013-10-12 04:56:57)

I've noticed a while ago that for some reason if I drank coke with dinner I always felt terrible the next day and didn't sleep well even though I would avoid sugar most of the time. I thought it was the sugar that gave me hangover like symptoms and unrefreshed sleep, but I had done 'carb back loading' with heaps of sugary foods and junk and slept well after, but if I drank coke I didn't feel refreshed the next day. After a while I realised it might be the caffeine. Also I noticed that the honey wasn't as effective if I had caffeine in the afternoon or evening. Alcohol seems to effect sleep also for me - it helps me sleep but I don't wake up feeling refreshed. It's so hard to get everything right. Recently I tried drinking one cup of tea at 10am and no caffeine after, I found that I felt terrible in the middle of the afternoon but that night I had really vivid dreams, two of the dreams that night were flying dreams which was cool. I think eating chocolate after dinner kind of messes things up also, but a glass of milk without chocolate has similar effects to honey. But it gives me acne... I've even got to the point where I think that flossing before bed and brushing my teeth improves my sleep but that's just ridiculous! The honey and caffeine thing makes sense but the oral hygiene thing is probably a bit far fetched. I do have a lot of light exposure though in the evening so I haven't really dealt with that as a factor. I'm also a little worried that the honey might raise my set point so I don't always do it, plus I think it isn't as effective if you do it everyday for some reason.

Stu (2013-10-12 05:19:10)

Also I forgot to mention: refreshed sleep = low (normal) appetite the next day and fasting is easy, unrefreshed sleep = insatiable (unsatisfied appetite) the next day/can't stop thinking about food!

Vic (2013-10-12 08:47:48)

Seth, how important to your sleep are sleep position (back, stomach, side) and mattress firmness? Seth: I don't pay attention to any of that. Sometimes I wonder what effect it would have if I slept on the floor but I haven't found out.

nansen (2013-10-13 17:25:51)

How exactly do you make your Berkeley bedroom even darker? Have you considered wearing a sleep mask, or do you still want the dawn light to get through?

Jeff Winkler (2013-10-14 13:48:55)

Confirmatory study and a cheap DIY intervention- Michael Mosley (of Eat Fast) participated in a study where they changed sleep from 6.5 to 7.5 hr, and did blood draws for quick feedback. A summary is at <http://www.bbc.co.uk/news/magazine-24444634>. Think the meat is in the video, but it's region-blocked :( - (Seven) volunteers were randomly allocated to two groups. One group was asked to sleep for six-and-a-half hours a night, the other got seven-and-a-half hours. After a week the researchers took blood tests and the volunteers were asked to switch sleep patterns. The group that had been sleeping six-and-a-half hours got an extra hour, the other group slept an hour less. ... the most interesting results came from the blood tests that were run. Dr Simon Archer and his team at Surrey University were particularly interested in looking at the genes that were switched on or off in our volunteers by changes in the amount that we had made them sleep. "We found that overall there were around 500 genes that were affected," Archer explained. "Some which were going up, and some which were going down." What they discovered is that when the volunteers cut back from seven-and-a-half to six-and-a-half hours' sleep a night, genes that are associated with processes like inflammation, immune response and response to stress became more active. The team also

saw increases in the activity of genes associated with diabetes and risk of cancer. The reverse happened when the volunteers added an hour of sleep. ===== Improving sleep quality by blocking blue light @night. Seth, what color were the lights in your Berkley bedroom? Sanjiv Shah - Sleep and Tinted Goggles - Boston QS - <http://vimeo.com/64204620> Reduced sleep latency, more deep sleep (per Zeo). Works for me, and the glasses are \$9. No-brainer.

Seth Roberts (2013-10-14 13:54:08)

I made my Berkeley bedroom darker by lowering the blinds. In Beijing I hang big towels over the windows. Yes, I have considered wearing a sleep mask. It's something I plan to try. I don't worry about dawn light while asleep any more since I wake up before dawn.

Stu (2013-10-14 15:22:10)

I was under the impression that sleep cycles followed a 90 minute ultradian rhythm... If that's the case then 7.5 hours sleep would be ideal as you would awake towards the end of the cycle whereas people sleeping 6.5 hours would be awoken in the middle of the cycle. Perhaps that could be something to consider, maybe 6 hours would be better than 6.5 hours

### **A High School Teacher Learns About Teaching (2013-10-12 05:00)**

While reading a [1]blog post about teaching high school math, this caught my attention:

I tend to stay pretty focused on teaching; rarely do I give A Talk. Today . . . I made an exception.

[teacher] "What is it you think I want?"

[student] "You want me to shut up." . . .

[teacher] "Why?"

[student] "Because it's your job!"

[teacher] "Because I want everyone to pass this class."

The class's sudden silence [made me realize] that my remark had [had] an impact. . . .

I adopt my students' values and goals, rather than insist they adopt mine. [emphasis added. To be sure, this is an overstatement – the truth is teacher/student compromise – but you get the point.] The kids were shocked into silence [because] they realized that my most heartfelt goal was to pass everyone in the class. I learned a key lesson I still use every time I meet a new class [–] make it clear I want to help them achieve their goals, which usually involve surviving the class.

I was unclear what the "key lesson" was so – I have edited the quote to make it clearer – so I asked the teacher blogger, who replied

The key lesson is *explicitly state that I adopt my students' values and goals, rather than insist they adopt mine*. My students's awareness that I want to give them value as they define it is essential to creating the classroom environment I want.

When I began working full time as a public school teacher [after years doing test prep], I had much tougher kids [than in test prep], and my classes were not as comfortable as I was used to. It was the emptiness or worse, hostility, I got from enough of the students that bothered me. I enjoyed teaching. But I felt something missing around the edges that I'd always felt-expected-from my classrooms, and I couldn't even really spell out what was lacking—not gone, just not universal. I didn't know why.

So in that moment [when I told my students that my goal was to help them reach their goals] I realized that one of my greatest teaching strengths was completely under the radar [= not noticed] not only to the toughest of my public school students, but to \*me\*. Many of my toughest public school students, the ones that had tracking bracelets or a long history of suspensions or just three years of repeated failures—hell, not only didn't they realize that I wanted them to achieve their academic goals, they didn't realize they HAD academic goals, since no one had ever told them that just "passing the class" was an allowable goal. I'd never realized how essential that understanding was to the rapport and engagement I had with kids until I experienced teaching without it.

I've only rarely experienced that alienation or hostility since [I learned to be explicit about my priorities]. I still have to be tough and snarl and yell. But now my public school classes give me the same sense of affinity, of understanding, that my test-prep classes did.

All or almost all teachers want their kids to do well. But teachers usually define "doing well" by their own ruler, and set their goals higher than is realistic—and so are often disappointed. I think most people [including high school teachers] don't understand the degree to which high school students feel their choices in school are completely out of their control. They can't choose most classes, they are "helped" by giving them more of the classes they hate (double math periods for strugglers).

This supports my view that teaching is much easier when you try to help students reach their goals than when you try to get them to reach your goals. Few teachers I know have figured this out – at best, they get to different students learn differently and stop. I think it's the beginning of wisdom about teaching. I eventually found, after years of experimentation, that (a) my students's goals overlapped mine well enough to be acceptable to onlookers and (b) their innate desire to reach those goals was strong enough that [2]there was no need to grade them.

1. <http://educationrealist.wordpress.com/2013/07/21/who-i-am-as-a-teacher/>

2. <http://blog.sethroberts.net/2013/01/26/my-ideas-about-teaching-put-into-practice/>

---

Texan99 (2013-10-12 08:59:11)

I enjoyed a story arc in "The Wire" in which a teacher got kids interested in math by showing them how an understanding of probability could earn them money at playing craps.

Rollins (2013-10-12 14:58:25)

Seems rather a tale of an egocentric teacher publicly praising himself for his supposed selfless devotion to his students values and goals. Many student, especially Elijah, quite understandably hated high school math... and wanted out of this teacher's classroom. The teacher had exactly zero empathy and support for that clearly stated 'value'. Instead, the teacher proclaimed his own 'teacher-value' to the class – "everyone to pass this class" ... even if they don't ever like or understand algebra... and that somehow this algebra-classroom-experience would most certainly improve their lives ever after. In fact, algebra & geometry are of no practical use to most people in their entire personal lives. Most American K-12 "education" is merely social ritual. The students correctly assessed they were wasting their time in that algebra classroom. But the teacher-bureaucrat could only

see the arbitrary syllabus and daily disciplining of his captive audience... while arrogantly pretending to be empowering the values of his students.

Roger Sweeny (2013-10-13 07:34:14)

Rollins, you are absolutely right that "algebra & geometry are of no practical use to most people in their entire personal lives" and that in that sense the students "were wasting their time in that algebra classroom." However, in terms of getting a credential, you are absolutely wrong. They need to pass algebra to graduate and they need a high school diploma to get considered for many, many jobs—even if the job has nothing to do with algebra. The American legal system allows, even encourages, that. Education Realist's students don't want to be shut out of the "good jobs." ER knows all this. Don't hate the player; hate the game.

Education Realist (2013-10-13 08:01:30)

Thanks, Roger. Rollins, you wound me! I hate reading self-congratulatory teachers. I was doing exactly the opposite of that. I was explaining my priorities in the context of a debate of reform vs. traditional math (I ascribe to neither camp). Seth asked me to elaborate in email, and I stressed several times that I didn't want to sound like a pompous teacher doing some narcissistic backpatting. But the reality is that most math teachers believe, passionately, in their subject. They believe that the solution to the achievement gap is to raise standards, work hard, and love math. Education reformers also believe that the problem is low standards, that all kids could learn math if they had good teachers. I am explaining a priority set that is quite different. Seth asked me to elaborate on one particular piece of that. It's pretty ludicrous to paint me as a teacher who believes in arbitrary curriculum standards, since I regularly post that I do exactly the opposite.

Rollins (2013-10-15 10:46:59)

" It's pretty ludicrous to paint me as a teacher who believes in arbitrary curriculum standards..." ' All curriculum/syllabus standards are arbitrary & subjective everywhere and always. It is impossible for them to be otherwise. Inability to grasp this basic fact leads to huge conceptual errors in "education", "teaching", "student status", "values", "priority sets", "math", "science", "history", etc, etc. There are a million subjects that 'could' be taught in high-school, with a vast array of possible learning methods. Even the 'need' for a teacher is totally arbitrary, as are despotic truancy laws depriving students of basic human liberty. No matter how valuable somebody believes a subject may be— there are only 24 hours in a day, and an arbitrary decision to teach one subject (algebra ?) is also a decision NOT to teach a million other subjects. Most high-school and college curricula and teaching methods have barely changed since medieval times. The denizens of the educational-establishment can not see the big picture and have an extremely narrow view of "education reform" and student values/choices/freedoms.

## **Why We Need Diverse Fermented Foods (2013-10-13 05:00)**

I found [1]this comment from Art Ayers deep in a discussion on his excellent blog [2]Cooling Inflammation:

Probiotic fermenting bacteria only work in the upper part of the gut, not in the colon. The anaerobic bacteria that work in the colon must be slowly acquired by persistent eating of diverse veggies to provide diverse polysaccharides and uncooked veggies to provide the bacteria.

I agree and disagree. It's an excellent point that the bacteria near the stomach are quite different from the bacteria deep in the colon. So you need different sources of each. I don't know what "probiotic fermenting bacteria" are (I was under the impression that all bacteria "ferment"), but, yeah, bacteria that live on lactose (e.g., in yogurt) are going to be quite different than bacteria that live on more complex sugars that are digested more slowly than lactose and thus pass further into the intestine.

To me, this explains why I like vegetables. I have no trouble avoiding fruit, bread, rice, pasta, and so on, but I hate meals without vegetables. Why? This line of thought suggests it is because they supply complex polysaccharides

needed for deep-colon health. As Ayers implies, you wouldn't need a lot. This line of thought suggests how you or nutrition scientists can decide what fermented foods to eat (some for each part of the digestive system).

I disagree about raw vegetables. Like most people, I don't like raw vegetables. I like the crunchiness but the taste is too weak. That most people are like me is suggested by the fact that raw vegetables are almost never eaten without dip or dressing (which add fat and flavor) or something done to make them more palatable (e.g., sugar and liquid from tomatoes). If raw vegetables were important, even necessary, for health, the fact that they are hard to eat would make no evolutionary sense.

I do like pickled/fermented vegetables of all sorts, such as kimchi and sauerkraut. I believe they are a far better source of the bacteria you need than raw vegetables (they have far more of the bacteria that grow on raw vegetables than ordinary raw vegetables).

1. <http://www.blogger.com/comment.g?blogID=196334975274806517&postID=3161635954700370250>

2. <http://coolinginflammation.blogspot.com/>

---

xap (2013-10-13 05:26:27)

A fascinating example of bacterial interactions within humans is something I was reading earlier about studies from the early 20th century about tuberculosis and its possible anti-tumor effects. This led to the novel but effective idea of using the BCG vaccine to treat bladder cancer. [http://community.advanceweb.com/blogs/al\\_1/archive/2009/07/13/an-immunotherapy-success-story-bcg-and-bladder-cancer.aspx](http://community.advanceweb.com/blogs/al_1/archive/2009/07/13/an-immunotherapy-success-story-bcg-and-bladder-cancer.aspx)

kxmoore (2013-10-13 08:30:30)

have you tried making kefir Seth? ridiculously easy with much more probiotics than yogurt. also easy to store/put to sleep. Seth: I have made kefir. It was not ridiculously easy, although maybe I was doing something wrong. Do I need kefir grains? I don't know. Do you use kefir grains? If so where did you get them?

kxmoore (2013-10-14 00:13:20)

how i have made kefir for 7 years: 1 put kefir grains and milk and or coconut milk in jar 2 place jar in dark place for 18 -24 hours 3 strain and refrigerate liquid. go back to step 1 you can get grains mailed from numerous sites(ebay) for under \$10 or even free. get live milk grains. if u ever pass thru nyc i'll give you some as a small thanx for your wonderful site. this guy is the kefir master. he ferments veggies with kefir. <http://users.sa.chariot.net.au/dna/kefirpage.html>

### **Omega-3: More Evidence of Brain Benefit (2013-10-14 05:00)**

[1]From the Wall Street Journal:

In a study to be released Tuesday, participants with low levels of omega-3 fatty acids in their blood had slightly smaller brains and scored lower on memory and cognitive tests than people with higher blood levels of omega-3s. The changes [that is, the differences] in the brain were equivalent to about two years of normal brain aging, says the study's lead author.

As this article recommends, I used to eat plenty of fish. But I still noticed a dramatic improvement in my balance and cognitive abilities when I started taking flaxseed oil. The best amount seemed to be 2-3 tablespoons/day. Fish wasn't supplying close to the optimum amount of omega-3. One comment on the article was

The only proper response to this article should be, "Duh."

I disagree. A better response is to ask How much room for improvement is there?

1. [http://online.wsj.com/article/SB10001424052970204653604577249192836516880.html?mod=health\\_newsreel](http://online.wsj.com/article/SB10001424052970204653604577249192836516880.html?mod=health_newsreel)

---

Nick (2013-10-14 05:41:07)

You like flax, but it's a source of ALA, not EPA/DHA. <http://examine.com/faq/can-i-eat-flax-seeds-instead-of-fish-or-fish-oil-for-omega-3s.html> Flax is healthy, but I don't think it can offer the same benefits of fish, contrary to what your anecdote suggests.

David199 (2013-10-14 09:59:23)

I'm also curious why he uses flax oil and not fish oil directly.

Ron (2013-10-14 11:57:23)

Seth, Seems to me what would be clarifying/useful is if you were to try and switch out the flaxseed oil for an equal amount of fish-derived omega 3's (ie, EPA/DHA from fish oil). The purpose being that you would then know if it were a general omega 3 dosing effect, or specifically an alpha-linolenic acid effect. Seth: Others have found similar effects using other forms of omega-3.

Brian (2013-10-14 12:44:59)

Seth posited a neurological benefit. Nick, you posted a link about its efficacy in providing a cardiovascular benefit. Further, the abstracts for the later studies at your link, e.g. regarding vegan consumption, dealt with quantities of flaxseed that are approximately no more than 1/8 of what Seth consumes.

JRM (2013-10-14 14:31:25)

What percentage of calories per day are you consuming as omega 6? Omega 3? Seth: Omega-6: Not much. 3 %? That's just a guess. Sometimes I eat nuts. I avoid vegetable oils, nut oils, and so on. Omega-3: 10 %? Again, these are just guesses.

Valerie (2013-10-16 19:30:29)

I tried eating ground flax seeds regularly on two different occasions. Both time, I ended the experiment because I was getting bruises. I mean that tiny bump in anything gave me a bruise. Carrying a heavy box in my hand gave me bruises on both forearms. I even got bruises I could not explain. It seemed dangerous to continue. Did anyone else encounter that problem? Does it mean something? Is there a solution?

Seth Roberts (2013-10-16 19:39:11)

Increased bruising from flaxseeds: I think this is due to an increase in clotting time, a well-known effect of flaxseed oil and perhaps fish oil. Too-long clotting time certainly is dangerous – the danger is of a stroke. I eat ground flaxseed because it has substantial easy to notice benefits (e.g., pink gums instead of reddish gums). If I were in your position, I would start with a tiny dose and increase it. At the first sign of bruising, I would reduce the dose to a dose that doesn't cause bruising. I would also try to find out if my clotting time (without flaxseeds) was unusually long.

Sentinel (2013-10-15 06:09:22)

Seth, I was intrigued to learn that there are also people online who claim that methods based on Dr. John Sarno's theories about Tension Myoneural Syndrome (TMS), can be used to combat insomnia.

Ief (2013-10-15 06:40:04)

4 years ago I also got rid of back pain by reading John-Sarno's book, the mind body prescription. When I started reading this blog I was wondering how it is possible Sarno's thoughts for pain hasn't caught Seth Roberts attention (since other meaningful heresies related to medicine had).

Brian Toomey (2013-10-15 09:38:21)

Hi Seth, I'll vouch for Sarno. I've given the book to at least a dozen people who were considering back surgery and/or in serious pain and it worked in all cases. He comes from a psychodynamic perspective (repressed narcissistic rage is a key construct) that might be over theorizing. As I read him, he is essentially working on an ethical way to elicit the placebo effect transparently. I recommend this book to anyone with back pain or anything else that might be psychodynamic (which is lots).

Le (2013-10-15 13:29:11)

After reading Sarnos book I got rid of lower pelvis chronic pain and carpal syndrome that were with me for some years (I went to all the traditional doctors and tried all the usual treatments with zero success). At the time and even now it looked like a miracle as I went from pain to no pain in one week. And I am a very objective and scientific oriented person.

Staffan (2013-10-16 03:52:08)

Not that I don't appreciate omega 3 (it was actually this blog that got me hooked on it) but this sounds a bit dubious. Parents of low intelligence (and low reading skills) are probably less informed about omega 3 so IQ becomes a confounding variable.

### **Coffee Experiments: Suggestions for Improvement (2013-10-16 05:00)**

Seth Brown, a "data scientist" with a Ph.D. in computational genomics, has done several experiments [1] about the best way to make coffee. In one, he compared other people's burr grinders to his blade grinder. There was no clear difference in taste. In another, an Aeropress apparently produced better-tasting coffee than drip extraction. He hasn't found other factors that matter. If I drank coffee, I'd be happy to know these things.

If I were teaching how to do experiments, his work would be a good case study. I'd have my students read it and suggest improvements. The contrast between his data analysis (sophisticated) and experimental design (unsophisticated) is striking, maybe because he has no background in experimentation.

Here's what I would have done differently:

1. Study my reactions, not the reactions of guests. He had house guests rate the coffee he made. Yet he brews coffee for himself much more often than for others – at least, he gives that impression. Since his main customer is himself, it wasn't clear why other people's opinions are more important than his opinion. Maybe he read somewhere that blinding is good and thought it would be easier to achieve if other people did the ratings. He could have rated coffee he made himself blinded. Put stickers on the bottom of identical cups, shuffle the cups. However, since he will usually make coffee unblinded (he will know how he made it), it isn't clear that blinding is good.
2. No "control" experiments. In a "control" experiment, he asked guests which of two identically-made cups of coffee was better. He doesn't say what he learned from this – apparently nothing.
3. Simultaneous presentation. He gave guests two cups of coffee made differently and asked which they preferred. Apparently he gave them one cup at a time. Simultaneous presentation, allowing them to go back and forth, would have allowed much better discrimination. Maybe the two types of grinder differed but his experiment was too noisy to detect this.

In a footnote he wrote:

Ideally, I would have liked to use better control conditions [he appears to realize that there was something wrong with his control experiment – SR], larger sample sizes, more thorough subject randomization [I have no idea what this means; his designs are within-subject. In within-subject experiments, subjects are not randomized – SR], and a more consistent testing environment.

All of these changes would have made his experiments more difficult. Maybe he has internalized the rule harder is better.

The beginning of wisdom about science is roughly the opposite: do the simplest easiest thing that will tell you something. We always know less than we think, so make as few assumptions and as little investment as possible. The easier your experiment, the less you will lose if you make a wrong assumption. The smaller your sample size, the more resources (time, money, subjects, energy) you will have left over for other experiments. Bunsen's experiments would have been easier if he had studied himself. By studying others, he made an untested assumption that they resembled him.

I've done dozens of tea experiments in which I compared tea brewed two different ways. The main things I've learned, besides best brew times and best amounts of tea to use, are: 1. Rinse tea before brewing. It eliminates a kind of dirty taste. 2. Combine [2]chocolate tea and black tea. The combination is better than either alone. 3. A little bit of salt helps.

1. <http://www.drBunsen.org/coffee-experiments/>

2. <http://tisano.com/>

---

Tobi (2013-10-16 05:47:09)

It's a pity that he has not tried to rate the response of his subjects, or himself for that matter, for each coffee brewed. For example, in the case of Grinders we are not told by how much one was preferred to the other. Perhaps some people really really like coffee from one grinder over another, while others barely notice the difference.

dearieme (2013-10-16 07:04:11)

"A little bit of salt helps." Also with coffee - hat tip to my father (who also recommended pepper on strawberries - that works too). Anyway: experimentation. I'm disinclined to make much of data-hammering done by someone who didn't have the sense to attend to #s 1, 2 & 3. Seth: You raise a good question: why don't I try pepper in my tea? and if it doesn't help, why not? I found #2 (meaningless control experiment) especially surprising in someone who works with data for a living and has a Ph.D. related to science. Yet I was impressed he computed a Bayes factor for his evidence.

Matthew (2013-10-16 09:05:02)

I never did rigorous experiments with coffee making, but I paid close attention to the factors which I had read made for better quality. Achieving particular effects repeatably is hard, because there are so many factors that interact. I roast my own coffee, use a decent burr grinder, and have brewed using the Aeropress, French press, vacuum brewer, and the old faithful pour-over cone. Even with these investments into quality and repeatability, the results can vary noticeably from brew to brew. What I have been able to determine to my own satisfaction is the primary importance of these factors, in order: \* age of roast. Younger than 2 days is inferior, older than 10 days becomes stale. \* proper water temperature. Over 205 F and you start to get bitter; under 195 and you get sour. \* quality of the beans. The green beans from sweetmarias.com, for instance, are substantially better than those my father purchases from some cheaper website. \* burr grinder. When using freshly roasted coffee of high quality, I found an immense difference between the coffee produced from a cheap grinder (whether whirly-blade or a mill) and an expensive burr grinder.

Robin Barooah (2013-10-16 09:20:31)

The major flaw seems to be in not controlling for other variables that could be dominating the effects of the variables he is measuring. In particular, he mentions nothing about water temperature. If he's using boiling water, he'll produce acidic coffee regardless of grind size and method. Another mistake he seems to be making, at least in the write up, is to treat the factors as independent. A burr grinder is recommended because it produces grinds of a roughly consistent size rather than a wide distribution of sizes. If you use a whirling grinder and a pour over filter then the coffee tends to form into a sludge and the

water remains in contact with the coffee for much longer than if you'd used a burr grinder. This is a large effect and easily measured with stopwatches. The aeropress works by forcing water through the coffee in a fixed time period using mechanical pressure, so the effect of grind consistency is much less than it would be for almost any other method. I think it's a good idea to test the flavor produced by varying different elements of the coffee making process, but the process is a delicate one with many factors. Ignoring that will just produce results that don't generalize. It would be a far better better to start by learning how to make an \*excellent\* cup of coffee, and then testing variables from there, to see which elements are unnecessary.

Kirk (2013-10-16 09:41:16)

I was puzzled by his use of statistical analysis. In a personal experiment like this, I think a simple bar graph works. Which brings up a related issue which I have been thinking about. How do you represent a number of steps of a tasting experiment? For example, with side-by-side tastings of tea, there are multiple variables: the tea, the amount, temperature, washed vs. unwashed. Start by fixing the type of tea, the water temperature, and the amount of tea. Compare washed vs. unwashed and washed wins, which is easy to visualize because it is a binary decision. Next step compares amounts. Suppose the larger amount tastes better, but is that amount optimal? Which requires tastings of amounts both smaller and larger than the first winner, and that step repeats until an optimal amount has been determined for that particular tea. Start the next step which compares water temperature, which also results in multiple tastings. Have you seen a good visualization of this type of experimentation?

Brian Toomey (2013-10-16 09:42:03)

Seth, I was surprised that you didn't mention the scoring. If I am reading it right he took what could have been a rich/sensitive recording (how much do you like this 0-100) and reduced it to a binary (which do you prefer A/B). Any reason why you didn't mention that? Am I missing something? Seth: No you're right. A better measure of preference would have helped. If you are comparing two cups of coffee, I'm not sure you want to ask separately for each cup "how much do you like this 0-100?" I think you want to ask about degrees of preference: slight, somewhat, etc., and assign numbers to them (e.g., slight = 10, somewhat = 20, etc.). I've never seen that done but it's a good idea.

Alex Chernavsky (2013-10-16 10:27:32)

Kirk, I think that conjoint analysis addresses some of the issues you raise with regard to multiple variables that all influence decision-making. [http://en.wikipedia.org/wiki/Conjoint\\_analysis\\_%28marketing%29](http://en.wikipedia.org/wiki/Conjoint_analysis_%28marketing%29)

Tobi (2013-10-16 11:53:50)

@Brian I made a similar remark, but I see my comment must have gotten lost in the system. Seth: Comments must be approved the first time you comment. So the first time you comment what you write will not immediately appear.

Seth Roberts (2013-10-16 14:27:34)

You mention a bunch of different factors that might be studied (= varied). There are dozens more, such as how much salt to add, how much sweetener (and which sweetener), hardness of water, on and on. Although you speak of "steps" there is no obvious order to how you should test each of the factors. No I haven't seen any visualization. It's more basic experimentation than a type of experimentation. Fisher, the statistician, used tea comparison experiments to illustrate basic principles. "A woman says she can tell whether the cream was added before or after the tea..."

Seth Roberts (2013-10-16 14:39:32)

"It would be far better to start by learning how to make an \*excellent\* cup of coffee, and then testing variables from there, to see which elements are unnecessary." that's a very good point. That's definitely what I do if I find something. First get the effect over and over then gradually see what is essential. For example, suppose Food X improves brain test scores. First show that beyond doubt then slowly vary Food X – 1. try different brands, 2. try closely related types of Food X, and so on.

Kirk (2013-10-16 17:08:40)

I've been drinking and comparing teas for many, many years. When I order samples of tea, I set up an NCAA-basketball-bracket for the initial taste-offs. The results usually are obvious between tea A and B, C and D, and so on. Sometimes there's little difference so I carry both teas to the next round. Eventually I end up at the final round where I do the final taste-off. There isn't always a clear winner. At any rate, along the way I've been making notes about the losers, such as 'harsh edge' or 'good but very average'. These help me when I record the results in a spreadsheet. For tea, I use a ranking from 1 to 5 (where 5 is best). I list 60 entries in my spreadsheet now. (I purchased them from the same company over many years). 4 teas sit at the 5 ranking. For recipes I use a 1 to 10 ranking. Anything 5 or below goes in the trashcan. A 6 is edible but will never be cooked again. A 7 could be eaten once a month, an 8 several times a month, a 9 once a week, and 10's are too good. (Think creme brulee). Most people probably don't want to see the step-by-step analysis of a taste-off, especially when a particular case is being refined, as in the example of a particular tea: how much, what temp, how long, etc. Most people want a recipe. They curate their recipe experts by choosing a particular cookbook. However, in this case (the blog posting on how to make coffee) lots of people were interested because many people have run their own coffee experiments and found other variables to be influential. To answer my own question, I speculate that a story-line illustrated with simple bar graphs at each step would help others run similar taste-off experiments. Or, more likely, they'll say, "Hey, you missed THESE critical variables."

Seth Roberts (2013-10-16 19:08:59)

Kirk, after your earlier comment about tea buying and comparing, I bought about 20 samples from Upton. It didn't work - I didn't like any of them. Part of the problem might have been that I couldn't figure out the best way to brew them - the sample wasn't enough tea to test the possibilities and the suggested brewing instructions I disagreed with.

Valerie (2013-10-16 20:05:17)

I agree with your third suggestion: tasting side by side, back and forth, is much more sensitive. However, for the your first and second points, I disagree: 1- Maybe he was not trying to establish which coffee he likes better, but how to make the best coffee. 2- He seems to try to figure out the noise in the rating. An example might help clarify what I mean. I measure my blood pressure every morning. The daily variations can be large (10, 20, even 30 mmHg). That seems to mean my blood pressure varies wildly from one day to the next. But no! If I measure my blood pressure several times the same morning (about 2 minutes apart, keeping conditions stable) I get the same kind of variations. Thus, the daily variations are just noise. Without some control measurements (in my case, several measures the same morning), I would not have reached the right conclusion.

Seth Roberts (2013-10-16 20:53:39)

He wasn't using ratings. He was just asking people which of two coffees they like better. I still fail to see what he learned from having people compare two identical coffees. He might have learned from that comparison that people tend to prefer the first presented to the second presented, but he didn't say anything like that. He said nothing about the possibility of order effects.

JRM (2013-10-17 09:32:23)

I surprised he didn't test cold brew coffee. The bitterness in coffee is from larger alkaloid molecules which diffuse less at lower temperatures. The result is a sweeter coffee.

Seth Roberts (2013-10-17 16:12:28)

"cold brew coffee". thank you for mentioning that. I recently discovered that cold brew tea is a lot better than regular brew, just like you say, much less bitter. I discovered this in Berkeley but I'm now in Beijing, where I forgot it until you mentioned this.

Tam (2013-10-18 11:47:12)

An anecdote for WBV: my parents have one of these in their physical therapist/personal training studio. One day my little cousin and aunt visited. My cousin was 4 at the time and has very noticeable ADHD. He was running around like a crazy kid does, plopped down on the machine, my mother turned it on, and he immediately calmed down. It was like a light switch had been turned OFF. He was calm and serene with a pleasant smile on his face. The effect only lasted as long as the machine was vibrating. It was quite remarkable. My mother has also used it successfully for a patient with MS that was told by his doctor that he "would never" ride a bike. He rode a bike soon after that. I think it has demonstrated interesting effects on the brain. Personally, I think it feels fabulous and use it for stretching often.

## Omega-3 and Omega-6 in Common Foods and My Consumption (2013-10-18 05:00)

Here is a graph ([2]source) of the omega-3 and omega-6 content of common foods. Although walnuts are relatively high in omega-3, they are much higher in omega-6. This may be why eating them reduced the performance of my lab assistants on a brain test.

When I'm in China, I eat 60 g/day of ground flaxseed. According to this graph, this provides 1.2 g/day omega-3, far more than I would get from any ordinary diet. For example, eating lots of fish would provide much less. I chose this amount based on [3]balance and brain speed results. Flaxseed is hard to get in Beijing. Surely I am the biggest consumer in the China. I am pretty sure I am the only person ever to have optimized my intake. The best amount turned out to be surprisingly high. "We recommend one to two tablespoons [per day]," says [4]a website that sells flaxseed. High consumption of omega-3 should protect me against bad effects of omega-6. For example, when I eat peanuts (high in omega-6), my brain test scores don't change.

[5]Experts say flaxseed is a poor source of omega-3 because it provides short-chain omega-3 whereas the brain needs long-chain omega-3. My results – plenty of brain benefit from flaxseed – suggest this is wrong. The experiments that measured short-chain-to-long-chain conversion did not take account of the effect of experience on enzyme production. If you eat more of a certain food, your body will produce more of the enzymes that digest it. The subjects in the conversion experiments may have had little experience. If your long-chain omega-3 supply is limited by what enzymes can produce, you will get a steadier supply of long-chain omega-3 from enzymatic production than you will from eating the same amount all at once. For this reason dietary short-chain omega-3 could easily be a better source of long-chain omega-3 than dietary long-chain omega-3 itself.

Pat McGee (2013-10-18 07:01:09)

Hi Seth, 1) When I clicked on the link for "balance and brain speed results", I got an errors that seemed to say "Access denied".

2) The HealthyFlax.com web site seems to only promote flax, not sell it. If they do sell it, I couldn't find a link.

Nick (2013-10-18 09:28:39)

The last paragraph on enzymes is interesting. Do you have any references? Seth: It's basic biochemistry. Look at the experiments for which Françoise Jacob won a Nobel Prize: [http://www.nobelprize.org/nobel\\_prizes/medicine/laureates/1965/](http://www.nobelprize.org/nobel_prizes/medicine/laureates/1965/)

Portlander (2013-10-18 10:40:43)

Apologies if you've mentioned this previously, but in what manner do you consume 60g of flax meal a day? Straight, mixed in yogurt, w/ pb & j??? Ok, that last one might be self-defeating :-), but I have 3 kids I have to deal with supplement. I've been giving them mega-EPA fish oil caps for a couple years now. They make a marked difference in my oldest's behavior ( & in my wife's mood back when she was breast feeding), but they are not without concerns. I'm not sure on how much is hype and how much is truth as to the molecular distillation vs. tri-glyceride & EPA vs. DHA forms. There's an enormous difference in cost among the types. So, all in all, I think I'd prefer a good whole food source if we can reasonably work it into our daily diet. OT: Its very hard to beat the convenience of a little magic pill. I can see why pharma is able to do so well for itself. Seth: I eat the ground flaxseed mixed with yogurt. Recently I've gone down to 30 g flaxseeds per day...I'm not sure which is better.

Tuck (2013-10-18 12:50:31)

"High consumption of omega-3 should protect me against bad effects of omega-6. For example, when I eat peanuts (high in omega-6), my brain test scores don't change." From what I've read, it's pretty clear that excess o-6 largely blocks conversion of alpha-linolenic acid (ALA) to long-chain o-3. Consuming more ALA doesn't alter that. But regardless, I wouldn't expect one day of o-6 consumption to have a significant effect on o-3 composition of membranes in the brain (which is why long-chain o-3 is required). If the conversion of ALA to long-chain o-3 is what's driving your increased mental capacity... There is another explanation, however, for your experience. ALA is converted to ketones preferentially over o-6 fatty acids, and ketones are a preferred fuel for the brain. Ketogenic diets, as I'm sure you're aware, are used to treat and cure several brain malfunctions, such as epilepsy. "For example, the oxidation of alpha-linolenic acid is twice that of linoleic acid or oleic acid. Therefore, alpha-linolenic acid and linoleic acid are the most ketogenic fatty acids and enriching a highfat diet with those compounds increases its ketogenic potential. This is the reason that a diet high in flaxseed oil (which contains 60 % of alpha-linolenic acid) is more ketogenic and offers more seizure protection than those using other dietary sources of ketones, at least in animal models (Likhodii et al., 2000)." "Assessing ketosis: Approaches and pitfalls" <http://onlinelibrary.wiley.com/doi/10.1111/j.1528-1167.2008.01826.x/pdf> Increased mental clarity and acuity is one of the benefits many cite from ketogenic diets, so this may be why you benefit from consuming a lot of flax-seed.

Seth Roberts (2013-10-18 16:22:15)

"Increased mental clarity and acuity is one of the benefits many cite from ketogenic diets, so this may be why you benefit from consuming a lot of flax-seed." Based on this explanation, what would you predict?

Seth Roberts (2013-10-18 17:00:47)

For the balance and brain speed results, go here: <http://blog.sethroberts.net/wp-content/uploads/2012/09/2012-09-24-The-Growth-of-Personal-Science-Implications-For-Statistics.pdf> something is strange about the embedded link.

JRM (2013-10-19 00:24:33)

Check units. The chart gives more than 2 grams of omega 3 per 10 grams for flaxseed. 60 grams would be maybe 13 grams of omega 3 per day. This says flaxseed oil is 53 % omega 3 <http://nutritiondata.self.com/facts/fats-and-oils/7554/2>

Tuck (2013-10-19 15:56:40)

"Based on this explanation, what would you predict?" I'd expect that any other source of dietary ketones would have similar effects (such as coconut or MCT oil). As would, after an adaptation period, a ketogenic diet. I've done this myself of late, and now associate carb consumption with fuzzy-headedness. I've not done the self-testing that you've done, however. Seth: Thanks. The Buttermind Experiment included a coconut oil condition. People who ate coconut oil did not become faster at arithmetic. I don't know of any evidence that coconut oil improves brain function. That supports the idea that it is the omega-3, not the ketones.

BRW (2013-10-20 07:03:15)

Seth, do you worry at all about toxicity and peroxidative stress?

Tuck (2013-10-20 08:41:56)

"The Buttermind Experiment..." I was thinking that butter might actually be better, if you get high-quality butter. Butter contains butyric acid (named for butter) which is metabolized in beta-hydroxybutyrate, the primary ketone fuel source of the body. Coconut oil contains medium-chain triglycerides, which are also metabolized into ketones. The evidence I've seen for mental improvement is limited to those with Alzheimer's and a specific genetic marker (that predisposes to Alzheimer's): "Study of the ketogenic agent AC-1202 in mild to moderate Alzheimer's disease: a randomized, double-blind, placebo-controlled, multicenter trial." <http://www.ncbi.nlm.nih.gov/pubmed/19664276>

Shane (2013-10-20 11:54:58)

I've read your theory on why flax O3 is not an inferior form of O3 several times, but do not recall reading accounts of self-experimentation pitting flax O3 vs. more putatively bioavailable sources of O3, like any of the various fish oils. Have you done self-experimentation of this kind? If not, why not? Seth: Two reasons. 1. Busy studying less obvious things that seem to change brain function. 2. Problem of mercury in fish oil. The source of omega-3 is a kind of interaction (the omega-3 effect may vary with source), whereas there are still plenty of main effects to study.

Shane (2013-10-20 12:01:14)

To be slightly more explicit, the other day, in a post, you said this: "As this article recommends, I used to eat plenty of fish. But I still noticed a dramatic improvement in my balance and cognitive abilities when I started taking flaxseed oil. The best amount seemed to be 2-3 tablespoons/day. Fish wasn't supplying close to the optimum amount of omega-3." So you point out that, through self-experimentation, you've found that taking a titanic amount of ground flax meal ("the biggest consumer in China.") produces good results. So in your experiments you kept increasing flax O3 dosing until it produced efficacious results. Did you attempt a similar thing with fish oil, only to find there was no effective dosage that could do for you what flax oil did? Seth: No, I haven't tried fish oil extensively. When I first started talking about the benefits of flaxseed oil on mental tasks, others tried fish oil and found similar results. No doubt fish oil works. There is nothing weird about getting omega-3 from plants, all of which contain small amounts of it. Lots of people flourish without eating seafood – see Weston Price. I have never heard that people need to get their omega-3 from fish.

Peter (2013-10-21 07:58:07)

Chia seeds, any opinions?

## My Theory of Human Evolution: Obsessive-Compulsive Disorder (2013-10-18 05:00)

From Entertainment Weekly:

EW: Are you religious?

Jodie Foster: No. I'm an atheist. But I absolutely love religions and the rituals.

Perhaps everyone enjoys rituals. (Even [1]scientists.) It's a curious enjoyment because rituals are arbitrary and without useful result. No other species has rituals. One sign of the pleasure we derive from rituals is obsessive-compulsive disorder (OCD). OCD takes many forms; one is excessive dependence on rituals, such as a need to do certain things, such as counting, tapping, or aligning, so often that it seriously interferes with being productive. The BBC program [2]Am I Normal? did an excellent [3]episode on OCD (no longer available). If you think of OCD (some forms) as addiction to rituals, the capacity of rituals to provide pleasure – or at least reduce anxiety – is clear.

Why do we enjoy rituals? I've already written about [4]Christmas. Rituals and ceremonies, like Christmas and other gift-giving holidays, are a growth medium for fine craftsmanship. They encourage desire for fancy things – Christmas cards, special food, music, art, the special tools used in Japanese tea ceremonies.

(Maybe the word fancy was invented to describe just these things, it fits so well.)

They help support the highly-skilled artists and artisans who are advancing the state of their art. You can read my whole theory of human evolution [5]here.

---

Nancy Lebovitz (2013-10-18 05:54:08)

The difference is that people with OCD don't like their rituals, but people mostly do like religious rituals.

Eric (2013-10-18 06:03:43)

The great evolutionary advantage that humans evolved was intelligence. Understanding the world implies that we will be successful, while being confused implies that we will be in trouble. Rituals simplify a complex world. You don't have to worry about what to do. If you follow the ritual you will be guaranteed success. For information processors in a complicated world this is an oasis of calm.

Allen K. (2013-10-18 07:05:53)

Maybe "superstitious behavior" is too different from your definition of "ritual", but here goes anyway. I've heard of experiments with birds in which they would be rewarded randomly at various rates. If you do it too often or too rarely, they don't change their behavior. But if it's around 1/4 of the time, then they start to guess "something I did got me a reward", and they train themselves to do weird things (which, of course, get them the reward 1/4 of the time), such as stand on one leg. The punchline is that baseball players hit the ball about 1/4 of the time. Seth: B. F. Skinner wrote a paper about "superstition" in pigeons that was later shown to be all wrong (by [1]Staddon and Simmelhag). The 1/4 stuff I've never heard before and animal learning is

my professional field.

1. <http://garfield.library.upenn.edu/classics1981/A1981LF07000001.pdf>

David (2013-10-18 07:15:45)

Humans are not the only animal who perform rituals. My dog will not lie down to sleep without first spinning around 3 times before plopping down into her chosen spot for a snooze. It's a consistent behavior she's exhibited since she was a puppy. It's like she's screwing herself into place to be more snug before nodding off. I once had a cat who had a very set routine for cleaning herself. She ALWAYS cleaned her entire right arm before licking anything else. Always. Seth: Okay, let me restrict the term "ritual" to stuff that is transmitted from one person/animal to another.

Tom Passin (2013-10-18 07:51:27)

Actually, animals do seem to get OCD - <http://www.veterinarypracticenews.com/vet-practice-news-columns/pet-projects/obsessive-compulsive-disorder-in-animals.aspx>

Tom Passin (2013-10-18 08:13:42)

Now I'm enjoying your linked paper on human evolution and trade/specialization. But again, you say that only humans do X - this time, trade - and there is evidence that some animals do trade. E.g., [http://www2.gsu.edu/~wwwexa/news/archive/2009/09\\_0610-tradingbehavior.html](http://www2.gsu.edu/~wwwexa/news/archive/2009/09_0610-tradingbehavior.html) In general, a lot of people who said that "only humans do x" have found that some animals also do the it, even if in simplified and attenuated form. That would suggest that the evolution of X would have been easier because there was a pre-existing starting point for evolution to work on. Seth: The link isn't much support for the idea that animals trade:

Georgia State's Sarah Brosnan, assistant professor of psychology, and research scientist Michael Beran conducted a study to see if chimpanzees spontaneously bartered foods among each other, using tokens which represented those foods. While results indicated that the animals were cognitively able to understand trade, without enforcement from human experimenters, trade disappeared.

Joe (2013-10-18 13:21:24)

"Humans are not the only animal who perform rituals." I agree! See: MATING rituals, for example. Seth: Good point. I should have said humans are the only animals with learned rituals.

Maureen (2013-10-18 15:44:04)

As Joe says - just look at animals when the hormones are pumping! My interest in this evolutionary aspect of rituals is how it plays into that whole can of worms of people getting obese and then trying to fight their way out of it. I've been teaching a series of mindfulness habits and after having a quick browse through your main article, it occurred to me whether I'm just getting people involved in mindfulness or just giving them another ritual to follow? Would you see mindfulness types of training as a case of one unhealthy ritual (scoffing too much food or starving and binging) with a slightly more healthy one of being aware of your hunger and nipping it in the bud. I can see I'm going to have to dig deeper into your work.

Staffan (2013-10-19 04:41:30)

Like Nancy pointed out, OCD is not an addiction. I have subclinical OCD and I'd gladly be rid of it. Lack of anxiety (which is as good as it gets) is not addictive. If I was to give it an evolutionary explanation I'd say those who worried about having bolted their dwelling properly before going to bed had a slightly higher survival rate than others. Seth: "bolted their dwelling"? Locks were invented recently. OCD takes many forms. In one case, a person with OCD did not feel comfortable unless everything in his house was coated with a fine layer of confectioner's sugar.

Seth Roberts (2013-10-19 13:31:39)

"People with OCD don't like their rituals." I agree, that's an important difference.

Andrew (2013-10-20 18:29:02)

For what it's worth, I don't really like special rituals. I generally find them boring. Even brushing my teeth at night is something I have to take extra pains to get myself to do. I may have (undiagnosed) ADHD, which might have something to do with it. I've heard of various psychological benefits to rituals, so it would be nice to enjoy them.

dearieme (2013-10-19 07:53:33)

"Duke can keep a student's grades secret — available only to a few administrators": this is a feature of American life that I don't understand. My university results were published in the newspapers. Is it just another example of American talk of free speech and freedom of the press being baloney?

as (2013-10-20 16:58:41)

The removal of wisdom teeth also affects the aesthetics of your face. With my family, there was a noticeable difference for the worse after the wisdom teeth were taken out. The cheeks have this sunken look.

### Harry Shearer Used My Joke (2013-10-20 19:32)

I haven't seen This is Spinal Tap but I am a big fan of Harry Shearer's [1]Le Show, a weekly podcast. For the last few months, one segment has been about the misuse of so: People use it to start sentences that aren't about consequences ("So we were standing there minding our own business. . . ."). I wrote Shearer to say he should change the name from Le Show to Le So. Not long after that, he ended the so segment with "here on Le So".

1. <http://harryshearer.com/le-show/>

---

thnidu (2013-10-24 18:33:50)

That's been an opening for jokes for years. "So a blogger, a podcaster, and a linguist walk into a bar..."

## **Our Need for Morning Faces: Does Isolation Cause Delusions? (2013-10-21 05:00)**

In 1995, I discovered that [1]seeing faces in the morning raised my mood the next day. For example, seeing faces Monday morning improved my mood on Tuesday (but not Monday). Study of the effect suggested we have a face-sensitive oscillator that controls mood and sleep. The oscillator needs morning-face exposure to work properly – faces "push" the oscillator as you would push a swing. Long ago, this oscillator synchronized the mood and sleep of people who lived together. The synchronization helped them cooperate. It is much easier to work with a happy person than an unhappy person and, of course, much easier to work with someone awake than someone asleep.

My results suggested you need to see morning faces on the order of 30 minutes to get a big effect. The faces need to be similar to what you'd see in a conversation. Looking at people on the subway doesn't count. Nowadays, as far as I can tell, hardly anyone gets the right input. In extreme cases, this causes depression, poor sleep, bipolar disorder, and anxiety disorders. What else might it cause?

A friend, whom I'll call Ben, recently told me something that sheds light on this. Three years ago he was a graduate student at Columbia. He lived in a basement apartment, with no sunlight. It was between semesters. He had no regular contact with anyone. He was depressed. Then things got worse: He became delusional. He started thinking that every conversation he heard was about him. "Everything I heard or saw was directed at me," he said. There was a boiler in the room next to his apartment. He believed it was a nuclear reactor.

Although Ben was isolated in terms of seeing other people, he had non-visual contact with people online. He told them about his strange thoughts. Some thought he had a problem, some didn't. Some thought he sounded mystical. He felt physical discomfort – a "pulling inside". His heart seemed to be beating differently. He called his parents. They were so alarmed that they contacted someone they knew in New York. Eventually an ambulance arrived at Ben's apartment and took him to a mental hospital. At the hospital, he told them he thought he was dead. After a day or so at the hospital, on a locked ward, he felt much better. However, he wasn't allowed to leave for two weeks because the doctors didn't know what was wrong with him.

After leaving the hospital he took a break from graduate school and went to stay with his parents. He saw a psychiatrist and was prescribed [2]Risperdal (an antipsychotic) and Depakote (for mania).

The pattern is okay during semester (when he sees others on campus), sick between semesters (when he doesn't see others), okay in locked ward (when he sees others). Bipolar disorder sometimes includes delusions during mania, so the association of disordered internal rhythms and delusions is not new. But why should disordered internal rhythms cause delusions – in this case, paranoid ones? One possibility is that it is beneficial to be paranoid in the middle of the night. If someone wakes you up, you will wake up thinking they tried to wake you up, which will make you especially mad. The madder you are, the less likely they will do it again. I argued that the irritability associated with depression is beneficial in the middle of the night for just this reason: It protects sleep. If someone wakes you up you

will get mad at them. This explanation predicts a circadian rhythm in paranoia, increasing in the evening. However, I'm not sure this explains why he thought a boiler in the next room was a nuclear reactor.

1. <http://www.escholarship.org/uc/item/2xc2h866>

2. <http://en.wikipedia.org/wiki/Risperidone>

---

gwern (2013-10-21 08:12:52)

> However, I'm not sure this explains why he thought a boiler in the next room was a nuclear reactor. Excluding the obvious like schizophrenia (happens a lot in age brackets like grad students'), maybe sleep deprivation? Associated with hallucinations, and if he was in the basement using a computer, he could be deprived without realizing it.

Sentinel (2013-10-21 09:41:45)

Seth, I understand your theory that seeing faces improves mood the next day, but what is the connection between seeing faces and sleep? (Thanks!)

CC (2013-10-21 09:49:13)

"The faces need to be similar to what you'd see in a conversation. Looking at people on the subway doesn't count." Wait, why not? We're all standing pretty close together on the subway. Seth: What you see needs to be very close to what you see during an ordinary conversation.

Seth Roberts (2013-10-22 04:22:57)

The connection between seeing faces & sleep: Seeing faces in the morning improves sleep, as far as I can tell.

Nancy Lebovitz (2013-10-22 08:29:40)

It seems to me that "Can Isolation Cause Hallucinations?" would be a more accurate title. Seth: Hallucinations is when you see things. But maybe "delusions" is too weak.

Nancy Lebovitz (2013-10-23 13:35:48)

Sorry, I should have proofread before I posted. What I meant was "Can Isolation Cause Delusions?", with the change intended to imply that isolation might cause delusions rather than that it reliably does cause delusions. Seth: I agree, that's a good change.

thnidu (2013-10-24 18:32:09)

CC ( & Seth): I grew up in NYC. On the subway you may be only 6 inches from someone else's face, \*but you're not looking at it\*. We deliberately avoid the appearance of social contact, because being that close normally implies intimacy. And even if we are looking straight at a person's face in the subway, we still normally don't treat the sight / eye-contact as we were conversing with that person. We have our shells up. I would not be a bit surprised if that made a major difference in the psychological effects.

## Mo Ibrahim: How I Became a Teacher (2013-10-22 05:00)

I met [1]Mo Ibrahim, a high school teacher in New York, because of his Behind the Approval Matrix blog, [2]which I admired. [3]I interviewed him about his [4]I Got Uggs! blog. Recently he has become interested in finding out if [5]my ideas about teaching can help him teach better. This is the first in a series of posts by him about that.

I went to college at Chicago State University, a commuter school in Chicago. I started in the late 1980s. I considered a career as a teacher when I was there, but changed my mind after I visited the education department and learned about the student teaching requirement, which seemed like a drag. Later I visited the premed office.

Mostly I studied biology and

graduated with a degree in Independent Studies. By graduation, I had been accepted at University of Illinois School of Medicine, in Chicago.

I started there in 1995. The summer before I enrolled, I had been verbally promised a whopping three scholarships. One was from my State Representative, the other two from a non-profit organization that helps African-Americans get into medical school. I did get the scholarship from the State of Illinois, which covered my tuition. However, I never got the other scholarships, which meant that my living expenses weren't covered. Between the time of the verbal promise and my enrollment, the organization had started a policy of only giving scholarships to students in the second and later years of medical school. Too many African-American students dropped out in the first year; the foundation reasoned it was wasting its money.

At the medical school's financial aid office, I was informed that my only option was to take out a loan. This was something I had sworn I would never do. I'm Muslim; interest-based loans are against Islamic law. Despite being told that it was virtually impossible to be a medical student and work, I got a job during the graveyard shift at a seedy hotel on the North Side. I avoided drinking coffee to stay awake because I didn't want to go to the bathroom and compete with the rats for a stall. Without coffee, I fell asleep. I was only there a week. A tenant who owed the hotel over \$1,000 moved out while I was asleep. I was immediately fired. Three months later, I withdrew from medical school. I couldn't afford it.

My first real job after medical school was in the medical records office at St. Francis Hospital. A co-worker was taking a computer repair class at a community center and suggested that I join him. I didn't take the class, but I purchased a used computer, some computer repair books, and studied for the A+ Certified Computer Repair Technician exam. I passed the exam on the first attempt and got a job making five times what I was making at the hospital. I did computer repair and network engineering for five years. Unfortunately, the work seemed to be drying up. I started at \$100/hour but after five years was making \$9/hour. Toward the end of the five years, my wife and I took a vacation in New York City. In the subway, I noticed an advertisement for the New York City Teaching Fellows (NYCTF) Program. I liked the idea of being a teacher because of the job stability and the idea of giving back to the minority community. NYCTF automatically puts you in an "underprivileged" school. The deadline for applying to the program was quickly approaching and I filled in the online application as soon as I returned to Chicago.

I was invited back to New York for an interview. After I taught a sample lesson and did group and one-on-one interviews, I was accepted into the 2004 NYCTF program. That summer I enrolled in a Master's degree program in Education at the City College of New York. I also got a job teaching at an underprivileged high school near Columbus Circle. Ten years later, I am still trying to determine the best way to teach my students.

nicole (2013-10-22 18:46:19)

the link in the original "behind the approval matrix" now links to some customer matrix website. Seth: thanks, I've fixed it.

Dragan (2013-10-23 12:08:19)

It's always interesting to consider the type of training we give USA teachers—especially those who have the hardest positions (in this case, "underprivileged" schools)—in comparison to the type of training given to teachers in, say, Japan or Finland.

### **Walking Meetings Much Better than Seated Meetings (2013-10-23 05:00)**

In [1]an interview about his new book The JFK Assassination Diary, Edward Jay Epstein was asked how he, a Cornell undergraduate, managed to talk to the people who did the research behind the Warren Commission Report. "It was a different age," he said. "People actually communicated by sitting across a desk from one another and talking." When I heard this, I was amused. I had just discovered that it was much better to meet with students walking than seated. What Epstein considered the good old-fashioned way (seated meetings) was to me the crazy new-fangled way.

As I've blogged, this semester I am teaching [2]a class about academic writing. I am trying to apply my no grading/no lecturing method that [3]worked well last year in a much different class (Frontiers of Psychology). In the writing class, my plan was/is to meet with students one-on-one right after class, in the same room. They choose the meeting length. During the meeting they show me what they've written and I make comments. During the next class they give a brief talk (e.g., 10 minutes) in which they tell the rest of the students what I told them. The course is much easier to teach than usual: no lecture, no grading, no written comments. Yet the students get as much one-on-one feedback as they want. I think spoken (face to face) comments are much better than written ones because they allow the recipient to ask questions.

Right now we covering how to write a personal statement for graduate school applications. The first set of after-class meetings was a week ago. The class has 12 students. Five signed up for meetings, 10-15 minutes each, an hour total. At the end of the hour I was tired. It was hard to concentrate that long. I went home and rested.

The class meets once/week. I thought of my discovery it was [4]much easier to study Chinese while walking than while sitting (more [5]here). While sitting I got exhausted after 10 minutes. While walking (on a treadmill), I could easily study 40 minutes. Jeremy Howard discovered the same thing. He put it like this:

[On a treadmill] I can [study Chinese] for an hour. Normally if I'm just sitting down I can just do it 20 minutes. . . . And at the end of that hour I was ready to do something else. Whereas at the end of 20 minutes, normally I'd be totally ready for a rest.

This gave me the idea of meeting with my students while walking. I've done walking interviews many times – for example, with job candidates and fellowship applicants. I didn't like sitting for long periods of time and I hoped that walking would reduce their anxiety. It seemed to work.

During the next class, I announced the change: Bring a printed copy of your work (while walking I could not read a computer screen). I said they didn't need a printed copy today, just in the future.

After that class, I had four meetings. In three cases, the student did not have a printed copy so I started with the one student who did. I was pleasantly surprised that the other three students had made printed copies of their work by the time of their meeting so I did all four meetings walking.

What a difference! The meetings felt like no work at all. At the end of them, I felt refreshed. Yet their details (who, when, what, how long, etc.) were very close to what had left me tired a week earlier.

Maybe in the future offices and meeting rooms will have side by side treadmills and you project what you want to look at together on the wall. [6]Another advocate of walking meetings is [7]Nilofer Merchant. She says she listens better, mobile phones are less distracting, and the mood is better.

Humans [8]evolved to specialize and trade. Specialized knowledge needed to be passed down, so we must, under the right circumstances, enjoy teaching, just as a healthy diet must taste good.

Phil (2013-10-23 09:35:19)

Thought you might find this interesting - easy way to try a standing desk: <http://gregschlom.com/post/4555981908/standing-desk> That with a little bit of training for proper standing posture might help a lot of people be more comfortable and productive.

Phil (2013-10-23 09:37:36)

Also - and this is totally unrelated, but I just thought of it - have you ever read *\_Self-Help Without the Hype\_* by Robert Epstein? It's a book that strongly encourages self-experimentation. Seth: Thanks for the recommendation. I haven't seen it.

garymar (2013-10-23 15:27:53)

"People actually communicated by sitting across a desk from one another and talking." I think what he's trying to say here is, "instead of tweeting each other." Emphasis being on face-to-face communication.

dearieme (2013-10-23 18:24:50)

"meet with students one-on-one ...During the meeting they show me what they've written and I make comments." Welcome to Oxford.

Nancy Lebovitz (2013-10-24 05:29:37)

For some reason, I can't see the comments on this post. Clicking on the recent comments links doesn't work either. Any thoughts about how you'd accommodate people for whom walking is difficult or impossible? People with radically different walking speeds? Seth: If someone can't walk, I would meet with them without walking.

Jill (2013-10-24 11:24:14)

"I think spoken (face to face) comments are much better than written ones because they allow the recipient to ask questions." For me personally, I don't think this would be the case. For one, my mental processing seems slower/less robust with oral communication. (Though my hearing tests fine, I sometimes have trouble deciphering words that I hear, vs words that I see.) For another, I like to have a hard copy to refer back to. I think it's worth keeping in mind that you may have some students for whom this is true, and maybe adapt the format to support different learning styles if the need arises. Seth: I suspect my 100 spoken words would be more helpful than my 10 written words. Writing is much harder than speaking, especially handwriting (typing is easier than handwriting). After they talk to me, my students make a written summary of what I tell them – so that is a hard copy.

Cleanthes (2013-10-26 17:42:20)

Hmm, walking about while teaching... How Aristotelian. All that was old is new again.

Joe (2013-10-24 13:31:15)

There were some sweets, but they were limited to seasonal fruits, perhaps for a few weeks of the year. Perhaps some sugar cane, which was simply sucked on, not processed and added to every food. Paleo-style desserts are at least as tasty as sugar-laden sweets. The sweetness comes from things like stevia, xylitol, honey, dates, fruits, and maple syrup. For example, I

can make you some chocolate avocado brownies that you will never be able to tell from regular old brownies. You would never know they were made from avocados if I didn't tell you beforehand. And they contain ZERO sugar!

lemmy caution (2013-10-24 16:32:09)

Honey is pure sugar. It is hunter gatherers favorite food. Paleo guys should just eat fruit. "Order Without Law" is a good book. Seth: Honey is 20 % water.

Joe (2013-10-25 13:11:02)

Yes, honey is sugar. But then, so are ALL carbohydrates! Used judiciously, say, for infrequent baking, it's no big deal. Since baking, per se, is emphatically not paleo, neither would using fruit be paleo. But Loren Cordain, the Godfather of paleo, says that the 80-20 rule is probably good enough. Eat strictly paleo 80 % of the time, and bend the rules a bit the other 20 % of the time. Which is what I do. Nota bene: From a strictly paleo point of view, eating a little honey once in a great while is probably better for you than eating fruit everyday, because hunter/gatherers couldn't possibly have had fruit available to them all year long. It's a seasonal item.

### **Saturated Fat and Heart Attacks (2013-10-25 05:00)**

After I discovered that [1]butter made me faster at arithmetic, I started eating half a stick (66 g) of butter per day. After a talk about it, a cardiologist in the audience said I was killing myself. I said that the evidence that butter improved my brain function was much clearer than the evidence that butter causes heart disease. The cardiologist couldn't debate this; he seemed to have no idea of the evidence.

Shortly before I discovered the butter/arithmetic connection, I had a heart scan (a tomographic x-ray) from which is computed an Agaston score, a measure of calcification of your blood vessels. The Agaston score is a good predictor of whether you will have a heart attack. The higher your score, the greater the probability. My score put me close to the median for my age. A year later – after eating lots of butter every day during that year – I got a second scan. Most people get about 25 % worse each year. My second scan showed regression (= improvement). It was 40 % better (less) than expected (a 25 % increase). A big increase in butter consumption was the only aspect of my diet that I consciously changed between Scan 1 and Scan 2.

The improvement I observed, however surprising, was consistent with [2]a 2004 study that measured narrowing of the arteries as a function of diet. About 200 women were studied for three years. There were three main findings. 1. The more saturated fat, the less narrowing. Women in the highest quartile of saturated fat intake didn't have, on average, any narrowing. 2. The more polyunsaturated fat, the more narrowing. 3. The more carbohydrate, the more narrowing. Of all the nutrients examined, only saturated fat clearly reduced narrowing. Exactly the opposite of what we've been told.

As [3]this article explains, the original idea that fat causes heart disease came from Ancel Keys, who omitted most of the available data from his data set. When all the data were considered, there was no connection between fat intake and heart disease. There has never been convincing evidence that saturated fat causes heart disease, but somehow this hasn't stopped the vast majority of doctors and nutrition experts from repeating what they've been told.

---

Nick (2013-10-25 05:41:32)

Eating butter is still a silly idea because it's bereft of nutrients.

Peter Andrews (2013-10-25 06:02:45)

Very nice half hour Australian TV show about the lack of evidence for cholesterol/saturated fat hypothesis just aired October 24, 2013. <http://www.abc.net.au/catalyst/heartofthematter/>

Richard A. (2013-10-25 06:30:50)

Real butter has all kinds of trace nutrients in it that are missing from margarine.

Tuck (2013-10-25 06:46:22)

"Eating butter is still a silly idea because it's bereft of nutrients." That's wrong. <http://nutritiondata.self.com/facts/custom/2244512/2>

Mark (2013-10-25 08:29:42)

"Eating butter is still a silly idea because it's bereft of nutrients." Well, it's obviously not bereft of nutrients because it's loaded with saturated fat (besides the link Tuck provides).... which is kind of the point. Second, Seth has found that it made him faster at arithmetic. How is that silly?

Alex Chernavsky (2013-10-25 11:28:23)

See also this article from the *Los Angeles Times*: "[1]Time to end the war against saturated fat?"

1. <http://www.latimes.com/science/sciencenow/la-sci-saturated-fat-20131022,0,2193813.story>

Joe (2013-10-25 13:18:49)

It's nice to see the tide finally turning regarding saturated fats. I eat a lot of it, and I've never been healthier. Want a really silly idea? Eating margarine!

emini\_guy (2013-10-25 15:38:10)

See also this: <http://shine.yahoo.com/healthy-living/does-butter-still-deserve-a-bad-rap-controversial-doc-says-no-002203701.html>

David (2013-10-25 19:44:07)

Seth, have you considered doing similar experiments with eggs (and especially with eggs from chickens that eat bugs and grass instead of just corn)? Eggs are criticized for having lots of fat/cholesterol, but certainly humans and their ancestors have been eating eggs whenever they could find them. It's hard to believe that we didn't evolve to take advantage of such a great source of energy and nutrients. Seth: I have never noticed any brain benefit from eating eggs. I haven't specifically done an experiment.

qhfgva (2013-10-25 21:23:55)

I was curious what the vegan response to this article would be and posted a comment here: <https://plus.google.com/u/0/104628657784485387851/posts/DR178fSBY6M> I don't know enough about this paper to know if his response is fair or not. As a butter eater I'd certainly \*like\* to believe that the 2004 paper referenced above is not misleading.

Heidi (2013-10-25 21:34:46)

The study used questionnaires, and apparently the unsaturated fat was vegetable oil used for cooking. In other words, these polyunsaturated fats were mostly nasties, not high quality polyunsaturated oils such as flax oil, etc. I think the study would have been even better if they had asked the participants to use only certain oils, not soy and corn, which they then used to fry up something equally toxic, no doubt. My real question would be, if one cooks with ghee and coconut oil, and only uses high

quality polyunsaturated oil without heating it, would they get better results? I'm betting my own health that ... yes.

Audrey (2013-10-26 12:55:19)

Seth, I wonder if you have ever tested if zinc supplementation has any effects on you. <http://itsthewooo.blogspot.com/2013/10/zinc-omg-cico-is-stupid-and-useless.html>  
<http://www.ncbi.nlm.nih.gov/pubmed/22549093>

Seth Roberts (2013-10-27 00:25:56)

Have I studied zinc? I think I took it a few times and noticed no difference. Not sure.

Nick (2013-10-27 05:51:10)

Can't believe everyone got on the defensive about my comment on butter. It has a bit of vitamin A and perhaps some K2, that's it. Relative to other foods, that's nothing. If you eat, say, ground beef, (saturated fat in it too) you get lots of nutrients that tag along. Does this comment section just latch to whatever Seth preaches like its gospel?

Brock in HK (2013-10-27 07:12:04)

Nick - Can't believe you made a short, ill-informed comment on this blog, which focuses on presenting evidence from the result of (usually self-) experiments. If you had even a few facts to support your initial assertion, you might have started a debate rather than receiving a scolding. Still not quite there with your comment. Can you disprove that Seth benefited from his consumption of butter? That might be a more productive avenue.

Joe (2013-10-27 08:58:55)

"Can't believe everyone got on the defensive about my comment on butter." Really? Even when you make comments like this: "Eating butter is still a silly idea because it's bereft of nutrients" The 20 Health Benefits of Real Butter: [http://bodyecology.com/articles/benefits\\_of\\_real\\_butter.php#.Um013hAnX8k](http://bodyecology.com/articles/benefits_of_real_butter.php#.Um013hAnX8k) 7 Reasons Why Butter is Good For You: <http://authoritynutrition.com/7-reasons-why-butter-is-good-for-you/> Does that really sound "silly" to you? Really?

Nick (2013-10-27 09:46:15)

Butter isn't unhealthy, at least in moderation. I just think there's better options. For butter's saturated fat and CLA, eat fatty red meat. For the K2 and vitamin A, eat beef liver and eggs yolks. For the butyrate, optimize your gut microbiome and eat plant fiber (especially resistant starch). My gripe is that these posts lead people to eat multiple sticks of butter a day, thinking it's healthy. Beyond moderation (e.g. a little added to meals for flavor), it's just a pile of calories without that much added nutrition.

Nick (2013-10-27 09:47:05)

I'm also not knocking Seth's self-experiments. I think they're really cool!

Joe (2013-10-27 13:04:49)

"My gripe is that these posts lead people to eat multiple sticks of butter a day," Why? You yourself said to "eat fatty red meat." Would that automatically lead people to eat several pounds of red meat a day? Ditto for liver, egg yolks, etc. Really? "thinking it's healthy." But it is healthy! When eaten in NORMALLY consumed amounts. "(e.g. a little added to meals for flavor)" Who suggested otherwise? I eat grass-fed butter, red meat, beef liver, and eggs, among other things. Plant fiber is over-rated. IMO (including resistant starch), but I nevertheless eat some each day, mostly in the form of nutritionally dense veggies (e.g. kale). Nothing "silly" about it.

Eric Anderson (2013-10-28 02:20:37)

From this web site: Is Butter Healthy? Butyric Acid Benefits So today I want to start by addressing butyric acid (also known as butyrate). Butter is the richest dietary source of butyric acid (3-4 %), a short-chain fatty acid which is proving to be highly beneficial. Butyric Acid and Metabolic Health A very interesting study demonstrated the benefits of butyric acid in mice. Researchers found that feeding these mice butyric acid could reverse several harmful metabolic affects. The mice

who received butyric acid in their diet were leaner and did not have a tendency to overeat. They also had lower cholesterol, triglyceride and fasting insulin levels—all pointing to better metabolic health and a decreased risk of developing metabolic syndrome. Butyric Acid and Gut Health The gut actually uses butyric acid as an energy source. Butyric acid has been shown to benefit those with gut disorders like ulcerative colitis and Crohn's disease. That's because this short-chain fatty acid helps restore the integrity of the gut lining while also reducing inflammation. Butyric Acid and Cancer Studies have demonstrated that butyric acid has the ability to cause cancer cells to mature into normal cells. This is a unique property, since most anti-cancer substances either kill the cancer cell or cause it to kill itself. Butyric acid, however, appears to preserve the life of the cell by normalizing its function. <http://www.livingthenourishedlife.com/2010/10/is-butter-healthy-part-one-butyric-acid> Is Butter Healthy? In the end, the degree of health-giving properties in any given food is dependent upon an individual's tolerance or dietary needs. In other words, your mileage may vary. But after today's post and as we continue to explore butter's health benefits, I hope that we can end the tirade on this traditional fat and learn to appreciate what butter has to offer.

Brock in HK (2013-10-28 06:50:40)

I'm curious as to a) how many people Nick knows that are eating multiple sticks of butter as a result of posts like this; and b) how many people are negatively impacted in the various health dimensions as a result of eating all those sticks of butter. I posted a request over at [butterovereatersanonymous.org](http://butterovereatersanonymous.org) to see if anyone would volunteer data, but got no joy. Seth: Why the negative bias? Why don't you also ask how many people are positively impacted?

Audrey (2013-10-28 20:09:21)

I think Brock is actually teasing Nick's dogmatism rather than being negative toward butter. In any event, there's no such thing as [butterovereatersanonymous.org](http://butterovereatersanonymous.org).

Brock in HK (2013-10-29 18:22:35)

Big, big ;) to Audrey. I better go park the url for future use! My rhetorical curiosity was grounded in the truth: I think the answer to a) is that very few people are eating tons of butter to the exclusion of other nutrient dense foods such as liver, grass fed beef, vegetables, etc., as a result of posts by Seth or anyone else with similar n>=1 evidence (see Dave Asprey, et. al.). Seth - I think people are actually positively impacted by higher butter consumption than the standard American diet and I (n=1) count myself among them. I think the answer to b) is that of those that would qualify in condition a, an even smaller subset of people are negatively impacted in various health dimensions by the consumption of butter in those much larger quantities. As someone who eats a lot of butter, I was just being Silly.

Brad (2013-11-01 05:42:02)

@Nick, I read similar thoughts about butter all the time. The flaw in many people's thinking is that butter is not nutrient dense compared to other foods because of how they are defining "nutrients", primarily as vitamins and minerals and ignoring the fact that the fatty acids, the actual fat itself, *is* nutrients. It is nutritional and it does have positive impacts to health - therefore by definition is nutrients - regardless of the old, outdated, definition provided by the biased/inept FDA and USDA. Two other logical points... This article and MANY others and related studies support that butter has positive health impact and by association is nutrient dense. Secondly, most people would agree that whole milk, particularly raw/un-pasturized, is a very healthy food. If you don't agree, then just begone as I don't have time to debate with morons. Now, what is butter other than the extraction of most of the lactose and protein from milk? It's basically the concentrated fat and other contents. Is it unhealthy merely because it lacks protein? No! Is unhealthy because it lacks lactose? Quite the opposite. People are just trying to rationalize an irrational fear of eating fat. They think eating fat is bad because it's highly caloric and so make up all this crap to justify not eating much of it. The problem is not the fat or calories, it's that people don't f'ing move enough! (exercise).

jon (2013-11-02 18:19:23)

I fry almost everything in either vegetable oil or butter. My last checkup about 1 month ago suggests that I am in perfect health. Don't believe the hype. <http://wilmington-wedding-dj.com/>

David Johnston (2013-11-04 15:03:30)

Being not afraid of butter is a huge convenience in the kitchen. When I make an omelette, I start with a couple of huge blobs of butter, enough to cover the whole pan bottom to a depth of a couple of mm. Then the omelette slides around easily, cooks evenly, tastes good and has more butter in it. I think there is something to eating fat for breakfast, irrespective of the type of fat. Things you might do if you follow the Seth plan is to drink flax oil, or chow down half a stick of butter. A common thread is that people tend to do this in the morning, because the most practical place and time to do it is in the morning while you are near your fridge. I find that a fat breakfast lasts me until dinner. So you've gone from a fast overnight to a 0 carb breakfast that is highly caloric that you don't break until dinnertime. Without any evidence to back it up, I suggest that continuing a carb fast by eating fat for breakfast is different (in terms of outcome) to eating wheaties for breakfast and having the fat in the evening. I don't have wheaties in the house, so I can't test this hypothesis. Sign's of change? Many of my coworkers brought in to work excess confectionary from Halloween, attempting to offload it on others. I don't remember that in the past. Perhaps the message on sugar is being received more broadly than before.

### **Walking Meeting Update (2013-10-26 05:00)**

In [1]a recent post, I described how much easier it was to meet with students while walking than while sitting. The content of the meetings stayed the same. I met with them after my Academic Writing class to help them with their writing.

I asked my students what they thought of these meetings. They had three complaints:

1. I walked too fast.
2. It wasn't so easy to avoid bicycles and listen to me at the same time.
3. It was cold.

I told them that I found the meetings less tiring. They did not notice this.

I considered walking inside the teaching building but it turned out to be too dark. Instead, we walked outside the building in a nearly-deserted alley (solving Complaint #2). I walked more slowly (colving Complaint #1). I couldn't do anything about Complaint #3.

The students could choose the length of the meetings. Last week all five of them chose 15 minutes. After 1 hour and 15 minutes of walking meetings, I felt entirely refreshed. As if I had done no work at all.

1. <http://blog.sethroberts.net/2013/10/23/walking-meetings-much-better-than-seated-meetings/>

---

Dragan (2013-10-26 12:01:29)

Seems interesting that they did not notice a difference in fatigue. Could be the gift of being in one's early 20s perhaps. Also correct me if I'm wrong but they are taking notes, walking and talking. That's challenging. Seth: They don't take notes.

Michael (2013-10-26 12:49:16)

> Seems interesting that they did not notice a difference in fatigue. > Could be the gift of being in one's early 20s perhaps. If I understand the situation correctly, then we're comparing 1 hour and 15 minutes of meetings (Seth) to 15 minutes (student). It seems to me that the shorter duration (i.e. less tiring) could well explain why the students didn't notice much of a difference between walking and sitting meetings.

## Learning English: Walking versus Sitting (2013-10-27 05:00)

A Chinese friend of mine learned about my discovery that it was [1]much easier to study Chinese while walking on a treadmill than sitting. This led her to buy a treadmill. She began to study English (e.g., GRE vocabulary words) while walking on the treadmill. "It worked very well," she told me. She found that if she studied words while walking, she could remember them four days later. If she studied them sitting down, she could remember them only a day later. With Anki, the default settings assume you can only remember what you've studied for a day – the first time you learn a word, you will be tested a day later.

This reminds me of Allen Neuringer's finding of [2]better memory for material learned while moving, but the size of the effect my friend observed is still shocking. If you can remember words four times longer before you need to review them, you can learn four times as fast. The effect that [3]Jeremy Howard and I observed was of similar size. We could only study 10 minutes sitting down but could easily study for 40 minutes or more while walking.

2. <http://web.reed.edu/psychology/docs/SelfExperimentation.pdf>

3. <http://quantifiedself.com/2012/05/jeremy-howard-on-language-acquisition-performance/>

---

q (2013-10-27 07:08:42)

what's even better is stopping and walking and stopping and walking etc. Seth: That's interesting. When you compared straight walking with stopping and walking and stopping and walking, what was the difference between them?

dearieme (2013-10-27 08:21:36)

Learning to read a language is a different problem from learning to speak one. I'd have hoped that all the audio technology available for the last thirty years would have made it easier to learn to speak English than it was for me to learn to speak French. But has it? I wonder sometimes, hearing the pretty bad attempts at speaking English from people at conferences. Anyway, is your Chinese chum concentrating on the written or spoken word? Seth: written word.

Sentinel (2013-10-27 09:37:00)

Seth, I study Japanese vocabulary and kanji while walking (Anki mobile, or my Japanese dictionary flash cards app), but even more so while standing on the subway. Standing and walking both seem to correlate with better retention.

David (2013-10-27 15:13:01)

What a huge effect! If it turns out that big, it will be a wonder that it hadn't been noted before, or taken advantage of by government organizations training employees in foreign languages. It makes me think of two things: one is I remember some teachers claim that adding student motions to teaching really helps the learning. The other is that kids learning (1st) language are most likely walking around at the time, not sitting at a desk. In motion would be the environment more typical to natural language learning. Also, Steve Jobs was famous for having important meetings with people while on a walk.

Adam (2013-10-27 16:49:32)

I haven't tested retention, but I don't do well studying standing in place. Walking is fine, but standing is stressful for some reason. I usually do my daily reviews sitting or reclining on a sofa. I remember reading somewhere that in psychological research they use "doing math while standing in place" as a reliable method of inducing stress.

Seth Roberts on learning while walking | peakmemory (2013-10-29 05:47:12)

[...] Another interesting post by Seth Roberts about the effects of walking on studying: [...]

JM (2013-10-29 12:14:40)

The probiotic studied is very interesting, it is a specific strain of *Lactobacillus Reuteri* which is apparently being studied and marketed by a Canadian company. It was recently granted FDA approval to be sold in the US under the product name CardioViva. (I assume it has already been sold in other countries but I don't know under what names.) It was shown in two published trials to reduce not only LDL cholesterol but also CRP. After reading about it I purchased some and decided to do my own experiment to see if it lowers cholesterol. (Mine isn't particularly high but I'm not doing anything else to try and affect it so thought it would be interesting.) My husband is also trying it, he hasn't been able to tolerate statins and should lower his LDL some so we'll see.

Arndt (2013-11-19 22:14:32)

### **Doctor's Data Sues Stephen Barrett of Quackwatch (2013-10-29 05:00)**

In 2010, [1]Doctor's Data, an Illinois clinical lab, sued Stephen Barrett, who runs Quackwatch, for making false and misleading statements about them. The lawsuit is still in progress. I am glad they sued. As far as I can tell, Quackwatch does contain false and misleading statements.

I've gotten about fifteen hair tests – whenever I get my hair cut – from Doctor's Data. The test measures about forty elements, such as mercury, tin, and selenium. One test costs about \$60. One reason I test my hair is curiosity – who knows what I might learn? Another is concern about heavy metal exposure due to living in Beijing. In [2]a post updated in 2010, Barrett called hair tests "a cardinal sign of quackery". I have no idea whether there is any truth to Barrett's argument but I am sure he is too confident I am wasting my money. [3]My own data suggest Barrett is wrong about the safety of mercury amalgam fillings. He believes that all safety concerns about those fillings are wrong. I found that when I had some of mine removed, my brain test scores improved starting exactly at the time of removal. We live in a world where all doctors – conventional and alternative – know almost nothing about the cause of almost any major health problem (heart disease, depression, obesity, and so on). Barrett shows no sign of understanding this. He is too sure that people who disagree with him are wrong.

Doctor's Data is far from perfect. Their hair tests have three serious weaknesses:

1. The information they provide customers like me comes without any information that would allow me to judge the error of measurement. I had to send in two samples from the same haircut to get some idea.
2. The measurements they give come with comparisons to a group of supposedly normal people ("reference range") but those people are not described, making it hard or impossible to interpret these comparisons.
3. They do not report calibration results. I would like to make comparisons across tests – e.g., from a test done this month to a test done six months ago. However, I have no idea about the stability of their equipment.

Many clinical labs have these problems.

On the other hand, the information their hair test provides is far from worthless, as far as I can tell. It is hard to learn anything from one test due to the problems I mention (e.g., if a value is high it might be measurement error) but repeated testing is more interesting. If a value suddenly gets worse for several tests, that suggests a problem. Any pattern in your results might tell you something useful.

If Doctor's Data hair tests are worthless, this would be easy to show. Get two samples of hair (at the same time) from each of ten people. Get all 20 samples tested. If there is no correlation between the two samples, the test is probably worthless. No one, including Barrett, has provided such evidence.

You can learn details of the lawsuit, which Tim Bolen is sure Barrett will lose, from [4]Bolen's website. I have enjoyed reading about it – for example, [5]this complaint about Barrett's lawyer's time-consuming method of discovery. Every story needs a villain.

---

Michael F (2013-10-29 07:02:41)

Interesting use of the hair samples. At one time, Doctor's Data had a service where you could get your toenails analyzed via neutron activation analysis (NAA). The toenails are typically less contaminated by external contamination (i.e. the selenium as active ingredient in dandruff shampoos, dirt under your fingernails from gardening, etc.) You might inquire to see if they could offer that as an alternative to hair sampling. There is published literature available on NAA of toe nails and other samples that provides (limited in my opinion) guidelines for certain heavy metals and some correlations to disease (i.e. selenium and prostate cancer).

Nate (2013-10-29 07:12:56)

My impression of quack watch is the same. He seems to take the view that anything outside of "standard practice" is quackery. It seems as if his website should be very helpful-but it is not. I am a clinical pathologist. On your #3, the lab should be doing calibration studies on any test they report results on. In my lab, we occasionally get requests for documentation of those studies-which we gladly provide. Just call them and tell them your concerns, and ask for documentation of their controls and proficiency testing over the past several months.

David (2013-10-29 12:33:32)

It would also be interesting to have them test hair that is new and closest to the scalp, vs hair that has been cut off in a trim. You'd think the later would have more contaminants from shampoo, etc. Of course, maybe that is the procedure, I'm only assuming the ends are analyzed based on the comment you made about sending it in at each haircut.

gwern (2013-10-29 15:38:05)

So, what \*have\* you learned from the hair tests? Mercury levels seems like an obvious thing to learn, but I don't recall you ever mentioning it in your mentions of the fillings.

Stephen Barrett, M.D. (2013-10-29 17:28:28)

Two studies have been done in which identical hair samples were sent to multiple laboratories. If you would like copies, e-mail me. Tim Bolen has very little understanding of what is happening in Doctor's Data's suit against me. He often expresses excitement are about things he imagines that happen not to be true.

D.R. (2013-10-30 20:51:35)

Yes, stephen but what you really want is multiple samples sent to the \_same \_ laboratory. That's why the studies you mention are a whitewash. But then, you probably don't care.

Alex (2013-11-01 07:42:08)

I have no dog in Quackwatch v. Doctor's Data fight, but the Bolen site you linked to seems like a heaping helping of crazy. I clicked on a couple of links covering topics I'm familiar with-not a lot of connection with reality. But if you were wondering whether octagenarian magician and skeptic James Randi might be gay, this is the place to confirm it. A lot. Seth: I agree, Bolen's ideas are ridiculous and his treatment of Randi is shameful. But he provides useful links to legal documents.

Katie H (2013-11-12 14:37:16)

You are forgetting the difference between reliability, accuracy, and validity. If two tests from the same person yield the same result, then you have a reliable test. But it may not be accurate (the report may have said "12" both times but the true result is "70") nor valid (it may have said 12 both times, and 12 is correct, but there are 12 ducks and the report said it counted chickens). Seth: Where am I forgetting the difference between reliability accuracy and validity?

Economics is either footnotes to Smith and Ricardo, or it is wrong.

MJB (2013-10-30 11:11:53)

Why I Jumped Off The Ivory Tower What makes me pessimistic about my own university and public universities in the United States in general is that their inability to adapt isn't due simply to bad leadership or an unfavorable economy. It's based on structural features that are self-reinforcing. Poor leadership drawn from huge corporations, an incentive structure that favors narrow specialization, and a hostility to potentially disruptive research, all reinforce each other. Those of us whose interests don't fit into that structure have some difficult decisions to make. <http://zacharyernst.blogspot.com/2013/10/why-i-jumped-out-of-ivory-tower.html>

Ashish (2013-11-01 18:30:56)

Behavioral Economics is still tied to reality. Dan Ariely's class at Coursera is magnificent.

## 8.11 November

### Back Pain Cured by Sarno's Ideas (2013-11-02 05:00)

Two years ago, a professor of decision science wrote me to say that [1]Vitamin D3 in the morning greatly improved his sleep. Recently he wrote again:

Once again you have dramatically improved my life through your blog.

In [2]this Assorted Links post you offered:

The back pain of a friend of mine, which had lasted 20 years and was getting worse, went away when he followed [3]this doctor's advice

I read the link about Dr. Sarno and went to Amazon to check out his book, "Healing Back Pain". 700 reviews with a 4.5 star rating. I spent two hours reading the reviews. Person after person saying, "my back is better" and nobody really described what the book had them do. I bought it two weeks ago.

In a nutshell, Sarno says that this type of back pain is caused by oxygen deprivation of some back muscles/tendons, and that the mind has does this as a defense mechanism so I don't have to confront my subconscious anger.

I don't have to pinpoint the source of my anger. I don't have to come to grips with it and stop being angry. I just have to acknowledge the anger. That's it. I read half the book in one sitting. I thought, this is crazy, but it has 700 4+ stars at Amazon. Maybe it does work.

My wife and I have two cars. One of them is a small Saturn. I hate it. It hurts my back to get in or out of it, and if I drive for more than five minutes I have to squirm to keep the back pain under control. Last week I took the Saturn for two half hour drives with only one wince of pain. Today I took it to the gym (a five minute drive) but it didn't hurt to get in or out.

In the morning, to get out of bed, I have to roll over and swing my legs out toward the floor and then prop myself up into a sitting position. At least, that's how I've done it for the past year. This week, I just sat up in bed with no pain. Every morning.

I am still a bit weak in the lower back, after more than a year of restricted physical activity. But this is amazing.

[4]Interview with Sarno on *Larry King Live* (1999).

---

Jerry (2013-11-02 13:53:14)

Very interesting! I occasionally get lower back pain. It comes and goes. It is probably exacerbated by my bad (but comfortable) habit of laying on the floor on my stomach when I read, surf the internet, or do programming. You mentioned lack of oxygen. I started taking HBOT treatments a few weeks ago, and have not had any pain since, even though I've been spending more time laying down. (I also noticed that my blood sugar readings tend to be lower after an HBOT treatment.)

Glen Raphael (2013-11-02 21:09:33)

Apparently for Sarno's treatment to work, you have to believe in it - he claims to have a really high success rate among people who do. But the problem with the claim "you have to believe in this for it to work" is that causality could go either way. The reverse story would be: "people for whom this doesn't seem to work are highly unlikely to believe in it."

Sentinel (2013-11-03 08:12:47)

I was treated according to the Sarno method under his successor, Dr. Ira Rashbaum in NYC. (Sarno is retired.) Though I have long had some back pain, the reason I went was unexplainable wrist pain; this excruciating pain (could not use my hand, could not fall asleep) would come every few weeks and last a couple of days. It happened a total of about 20 times. After studying the materials Dr. Rashbaum gave me, the wrist pain never came back. Sarno does not claim to know the full mechanism of this sort of pain, but explained it as the way the mind is structured (several different brain parts trying to work together) at this point in our evolution. Something in the brain decides to initiate this process, he said, in order to prevent deeply repressed anger from bursting into our conscious mind, since such a "bursting" is seen as a danger by some part of the brain; it is done via the autonomic nervous system, which can, he said, slightly but quickly impair oxygen flow to the muscles, nerves, tendons; Sarno says that this slight change can cause intense pain. (He also suggested that fibromyalgia and other ailments could be caused by this same mechanism.) He wrote that there are also medical studies showing evidence of mild oxygen deprivation in the nuclei of muscle cells of patients with back pain. I recommend "The Mindbody Prescription," his later and more fully realized book on this so-called "TMS" theory. Glen, regarding the idea of having to have "belief" in the method, this is indeed a problem for some patients. I sort of got past it by resolving to be as open-minded as one can be, which I think is enough.

Alex Chernavsky (2013-11-03 09:36:35)

I don't know much about Sarno, but I'm puzzled by the disparity between the seeming wackiness of his ideas (on the one hand) and the large number of people who experienced positive results (on the other hand). I wonder if Sarno's methods work for reasons *other* than the ones he postulates.

john (2013-11-03 10:05:44)

Well oxygen deprivation could be considered a general cause to almost any issue, sort of like inflammation. Mark Sisson has mentioned a study about stress perception and blood vessel dilation vs constriction—maybe that is at work here.

dearieme (2013-11-03 17:35:19)

Does using oxygen for a few days cure back pain? If not, why not?

CC (2013-11-03 20:30:52)

Does anyone think Sarno's ideas could be used for someone with hypersomnia?

Sentinel (2013-11-04 05:36:47)

CC, I know it is not the same thing, but Sarno addresses chronic fatigue syndrome in "The Mindbody Prescription" as a possible "equivalent" of this same ("TMS") syndrome, so I think it's possible that he also thought that about hypersomnia. He pointed out that people with hypersomnia have many of the same psychological attributes (excessive guilt and perfectionism, feelings of worthlessness, etc.) as people with the psychogenic back pain that are the main target of his work.

Russ (2013-11-04 08:44:21)

Certain behavioral treatments for chronic pain focus on reinforcing the occurrence of "non-pain behavior" and extinguishing the occurrence of "pain behavior." Some studies, I believe, have also shown that people who go through this procedure not only act as though they experience less pain but also report that they subjectively do experience less pain. A major aspect of Sarno's approach is that one should act as though one is not suffering from chronic pain. That, to me, seems a more likely cause for the improvement than outdated Freudian notions about repressed rage. The clever thing about this approach is that it suggest that simply giving people instructions to act as though they are not in pain may be, in some cases, be an effective treatment for pain.

James (2013-11-04 12:50:08)

I'm pretty sceptical about a lot of things, but reading Sarno's book helped me to eliminate lower back pain/sciatica a few years ago. The only drawback is that since then I've wasted time trying to use his method to get rid of ailments which have turned out \*not\* to have psychological origins.

CC (2013-11-05 10:33:57)

Thanks, Sentinel. I'm not sure if I should advise my hypersomniac friend to go to Sarno's successor's office for an appt or start by reading his book. But it's very encouraging that he addressed CFS.

Sentinel (2013-11-11 08:44:05)

CC, if your friend is interested in seeing the doc, note that he is heavily booked so better to contact him sooner rather than later. I think it's common to just read the book, and perhaps see the doc if condition persists. But this might be more relevant if the patient wants to rule out a physical medical condition that might be causing the pain.

CC (2013-11-14 10:29:07)

Thanks again, Sentinel.

## **Meat as Health Food, Food Preference as Wisdom (2013-11-03 05:00)**

A Chinese friend of mine had a cold. After a few weeks, she was still sick. I suggested she eat meat – it would provide the amino acids needed to make antibodies. She did want to eat meat, she said, but her mom thought that meat was bad for a sick person – an idea from Traditional Chinese Medicine, I guess.

Yesterday I had a desire to eat meat. That was odd; I didn't usually feel that way. I ate all the meat in the refrigerator (slices of cured meat) but it wasn't much. I ate three eggs. That, too, was odd – usually one egg is plenty. In the evening, I distinctly wanted more meat but decided against going out to get some. This morning I woke up with the flu. I could tell by the joint pain. So that's what joint pain is, I thought. I'd read about flu and [1]written about it, but, before this morning, cannot remember having it. How is the flu different from a cold? I once tried to find out. I might not have come down with today's case of the flu were it not for two events: yesterday's decision not to eat meat; and, the day before, running into a friend who had just left the house after being home-bound for four days with the flu. He shook my hand twice.

Humans (including me) are exceedingly gullible; my evolutionary explanation is that this makes us easier to lead. Gullibility – we believe something just because an authority says it – is cement. It keeps members of a group together. Better that 10 people do one thing (e.g., live in one place) than ten things, in many cases. Pointless to waste time on unresolvable and divisive arguments. Doctors, both Western and Eastern, take advantage of our gullibility. [2]As my friend says, "doctors hurt you" because they tell you to do something different from what you want to do (e.g., eat meat). What you want to do is actual wisdom. We've been shaped by evolution to want to do what is good for us and what we want to eat is a giant clue to what we should eat. In nutrition research, this line of thinking, which

is called dietary self-selection research, is nearly moribund, in spite of [3]a great 1939 article about what happened when young children ate what they wanted. The idea that we want to eat what we should eat is what first led me to think [4]we need to eat fermented foods to be healthy. Fermented foods, much more than other foods, satisfy our desire for sour, umami-flavored and complex-flavored foods. For example, it is easy to produce complexity via fermentation; it is hard to produce it in other ways.

As for my flu, I went to the store and got pork and duck. By evening I felt much better.

---

Frankr (2013-11-03 06:13:24)

What if we want to eat sugars & starches, beer & drugs because of the good effects? Clearly all but arguably beer is unhealthy.

Sam (2013-11-03 06:57:48)

Seth, I agree with you based upon yours and my own experiences. But I am confused that If we are hard wired to crave what we 'need' - we should stop craving when that is 'not needed'...??? Then what about constant craving of sweet things that leads to excess sugar consumption.?

Allen K. (2013-11-03 08:53:58)

That 1939 article is indeed great!

Angelyne (2013-11-03 09:12:39)

Where does the craving for carbs enter with this this idea. I often crave chocolate, especially milk chocolate. I do no crave dark chocolate. It's very distinct. If I pick up a milk chocolate bar, I will feel compelled to finish it, especially if I had a glass of wine or two and my inhibitions are lowered. It's very difficult for me to put it aside. (My husband has this rule that chocolate should be shared equally, damn him :) Yet, I'll have no difficulty ignoring a bar of dark chocolate. So I'm clearly craving sugar, not some other component of chocolate. Apart from chocolate, which is the only "bad" thing that I allow myself, for the most part, I'll crave vegetables. I don't remember ever craving meat of any sort. I think if it was up to my natural inclinations (and judging from the past), I'd eat a SAD diet based on grains, vegetables, milk products and some meat, eggs and fish.

Frankr (2013-11-03 10:56:13)

I should say that in general I think it makes a lot of sense to listen to your body when it comes to what your food urges are...

Alrenous (2013-11-03 13:05:05)

Angelyne, First, coffee drinkers crave caffeine. Imagine a child who had a cuppa with every meal. What do you think would happen to the resulting adult if they tried to switch to decaf? Were you raised on starches, like everyone else? Second, discard any biases against introspection. Look at your craving for sugar in detail. I've had cravings for salt, fat, vegetables, meat, and sometimes particular foods, which I can compare it to. Is the sugar craving the same kind of craving? Is the satisfaction the same? Can you tell the difference?

dearieme (2013-11-03 17:33:05)

Of all the vitamins, the best are the "B" vitamins i.e. beer and bacon.

Seth Roberts (2013-11-03 17:33:09)

"what about constant craving of sweet things that leads to excess sugar consumption?" glad you asked...see my next post.

Seth Roberts (2013-11-03 17:38:57)

"What if we want to eat sugars & starches, beer & drugs because of the good effects?" 1. I think a lot of addiction comes from people wanting to feel better when they feel bad. Comfort foods are a small example. If you got rid of depression, I think addiction would become much less of a problem. 2. I think the view that sugar is unhealthy is too simple. See my next post. Lots of people have bad results on a low-carb diet – the notion that starches are unhealthy is also too simple. Paul Jaminet, for example, had bad results on a low-carb diet.

Seth Roberts (2013-11-03 17:44:19)

"It makes a lot of sense to listen to your body when it comes to what your food urges are..." I agree, and I am also saying something else: It isn't obvious what those cravings mean. It isn't obvious why we crave X or Y. And if we try to figure out why, we may learn something useful. Sugar is a good example. Some people crave it. Well, why? I don't think the answer is obvious at all. Until yesterday I had no idea that craving meat more than usual meant I was in danger of getting sick. I had never heard anyone say that. The discussion about meat was at a superficial level: some people (e.g., vegetarians) said meat was bad, others (e.g., paleo) said it was good. These views and the supporting evidence did not help me understand why desire for meat might go up or down.

Brandon Berg (2013-11-04 04:19:18)

Taking into account the fact that many of the foods available today were not available in the distant past, it seems likely that we may crave certain tastes as a proxy for nutrients that have historically been coupled with those tastes. For example, a craving for sugar may actually be due to a need for nutrients found in fruits, such as potassium or vitamin C. Seth: Interesting idea. But, if so, why do sweet things not taste good when we are hungry? (Which is why dessert is separate and comes at the end of the meal.)

Frankr (2013-11-04 05:48:29)

I think a good rule of thumb is, eat paleo foods that you CRAVE (I am including some starches here because I think some types were around). We should not listen to what we CRAVE when it comes to desires for substances that were not around in the paleo era because our body did not have a chance to evolve a craving or distain for them.

Frankr (2013-11-04 05:52:27)

One other thing that the mainstream is not talking about is ancestral foods based off of ancestry. The ideal diet for a typical NE Asian person may be different from the ideal diet for a Sub-Saharan African or N. European.

Wil (2013-11-04 10:54:55)

This appears to be a very complex topic. But it at least seems clear that the addictive nature of certain foods (and/or components thereof) that are damaging can also drive food cravings. For example, carbohydrates in general are addictive as anyone who has tried (and even succeeded) in transitioning to a life style of carb restriction can testify. There has been quite a lot of writing about the topic of the negative effects of certain carbohydrates on humans; such as by Drs. Michael & Mary Dann Eades, Dr. William Davis, Drs. Phinney & Volek, Gary Taubes and, more recently, Dr. David Perlmutter. Dr. Perlmutter, for example, approaches the issue from his perspective as a neurologist (e.g. damaging brain effects from gluten) and Dr. Davis from his perspective as a cardiologist (e.g. the gliadin protein of wheat which can penetrate the blood/brain barrier and lead to autoimmune diseases). All well worth reading and supported by scientific references.

Seth Roberts (2013-11-04 15:12:13)

"There has been quite a lot of writing about the topic of the negative effects of certain carbohydrates on humans; such as by Drs. Michael & Mary Dann Eades, Dr. William Davis, Drs. Phinney & Volek, Gary Taubes and, more recently, Dr. David Perlmutter." Have any of them explained why evolution has shaped us to like the taste of something that is bad for us?

Seth Roberts (2013-11-04 15:13:17)

"We should not listen to what we CRAVE when it comes to desires for substances that were not around in the paleo era because our body did not have a chance to evolve a craving or distain for them." I think we should figure out why we crave them.

Jason (2013-11-04 17:36:57)

Trusting our appetite is important, but our body may also crave proxy foods that don't fulfill the underlying nutritional deficiency. People who chew ice are iron deficient. Chewing the ice does nothing to treat this anemia, but they still have an appetite for ice caused by a lack of iron. An impulse to eat meat when we are on the verge of sickness does not necessarily mean that meat improves flu resistance. It could be a crossed signal, just like iron anemic pagophagia. Seth: "It could be a crossed signal". The connection between desire for meat and sickness makes a lot of sense: Antibodies are made of amino acids, meat is made of amino acids. Unlike ice and iron deficiency. Crunching ice is a modern substitute for crunching bones, bone marrow is iron rich.

Jason (2013-11-04 17:56:21)

When I started taking an iron supplement, my compulsive desire to eat large quantities of Mexican cole slaw (basically fresh raw cabbage in vinegar) and other crunchy things went away. Before the iron pill, I spent a year incorporating raw cabbage into all kinds of meals, and frequenting a specific taqueria that had a salsa bar with free slaw that I would put inside my burrito. Then, just as quickly, I improved my iron intake and the desire for and love of raw cabbage were completely gone. Based on that experience, when I later felt an intense desire to eat an unripe green tomato, I assumed the cause was a nutritional deficiency, but not necessarily one that an unripe tomato would fix. I had never eaten a green tomato, but the desire to eat one was very strong and clear in my mind. I decided to take a fancy multi-vitamin for children that had a small amount of lots of vitamins, minerals, and herbs in it. I also decided to eat some unripe tomatoes, because why not? The desire went away after a week. For many years I ate no candy or really junk food of any kind. This year I started eating candy when I craved it. Sometimes I very much want to eat a pound of Skittles, and other times I have absolutely no desire for candy, and take little pleasure in it if I eat some anyway. I assume, like my cabbage and tomato experiences, that the Skittles are a proxy for some underlying nutritional need, but unless it's a need for pure carbs, I doubt the Skittles treat that need. My personal instinct is that there is something about the fruit flavoring that is appealing. I only crave fruity candy. Even though I use cocoa and eat dark chocolate, I never crave chocolate.

Stu (2013-11-04 18:36:03)

I agree that food cravings are telling us something, it's just not always obvious. In the study Seth referenced they stated that 'meals were often combinations of foods that were strange indeed to us, and would have been a dietitian's nightmare - for example, a breakfast of a pint of orange juice and liver'. Orange juice and liver are seeming unrelated yet they both contain very high amounts of vitamin C, perhaps that child was deficient in vitamin C and instinctually new to eat those foods. When I ate zero starches and sugary foods I developed tennis elbow which wouldn't heal, had poor sleep, was tired and suffered brain fog and fatigue. And all I wanted was to eat starchy foods. I read Paul Jaminet's book and started eating starches and sugary plant foods again and those problems are now a thing of the past. My instinct were probably right all along, I just needed to eat 'real' foods rather than processed ones

Wil (2013-11-06 11:16:49)

Referring to several authors mentioned above Seth said: "Have any of them explained why evolution has shaped us to like the taste of something that is bad for us?" Seth, that's a valid question. My answer is that I don't think any of the referenced authors have addressed this question explicitly. However, my own view is that it's unlikely that evolution is solely or even mainly responsible for our bad eating habits, but rather societal drivers such as, for example, the marketing of packaged food products with messages that bombard all of us daily on TV, the Internet, and in print media. It seems clear that children are

particularly susceptible to this kind of advertising and bad nutrition habits are the result, extending well into adulthood. A number of the referenced authors have also discussed the fact that many such products have one or more components that are addictive. To the extent this may be true, the suspicion is that some packaged (junk?) food companies are not only well aware of it, but have adopted this as a business model in order to grow sales.

Brandon Berg (2013-11-07 01:12:42)

"But, if so, why do sweet things not taste good when we are hungry? (Which is why dessert is separate and comes at the end of the meal.)" I dispute the premise, or at least its universality. Sweet things taste just fine to me when I'm hungry. I think people usually eat dessert last because sweet things blunt the appetite for more substantial foods but not vice-versa. "Don't eat that—it'll spoil your appetite" vs. [??????](#) Seth: Look at the experiments on the question done by Elizabeth Capaldi (although I am afraid they are hard to get ahold of). "But not vice-versa"...okay, what explains the asymmetry? My argument doesn't depend on the assumption you question. It is obvious that we eat dessert after meals, which raises the questions: 1. why after? 2. why are heavily-sweet things, such as pie and pudding, segregated?

## **Does Bedtime Honey Improve Sleep? Nine Reasons to Think So (2013-11-05 05:00)**

[1]Stuart King, an Australian musician in his thirties, recently [2]commented:

Most days I wake up feeling more tired than when I went to bed the night before, however I find that if I take up to a tablespoon [15 ml] of raw honey immediately before bed I almost always wake up feeling totally refreshed. I've suffered from low energy, brain fog, fatigue and sore muscles for years. I tried eliminating food groups (dairy, grains, nightshades, etc) but that didn't fix the problems (although wheat has been problematic) but taking the honey did. I usually sleep without any problems that I'm aware of – even if I awaken feeling unrefreshed I will still sleep through the night and won't awaken early or whatever, but the crucial thing is I feel rested when I wake up, if I get that right I can even eat bad food and feel good all day. I tried coconut oil and coconut oil combined with honey but they didn't work.

I hadn't heard that before. I searched "health benefits of honey" but didn't find it. A [3]Wikipedia entry about the health benefits of honey doesn't mention it. In China, many people think honey is a health food, yet a Chinese friend of mine, who eats honey daily, hadn't heard this. The uses of honey in Traditional Chinese Medicine [4]lie elsewhere. Honey as sleep aid is briefly mentioned (with a question mark: "Key to a restful night's sleep?") in [5]The Honey Prescription (2010).

Many say or assume something quite different. According to [6]Dr. Mercola, to sleep well "avoid before-bed snacks, particularly grains and sugars". [7]A Huffington Post writer says, "You already know which edibles to avoid before bedtime – namely, alcohol, coffee and sugary desserts." Honey is half fructose, which UCSF professor of pediatrics [8]Robert Lustig calls "poison". [9]Lustig says fructose is "one of the most egregious [= worst] components of the western diet, directly contributing to heart disease and diabetes, and associated with cancer and dementia." [10]John Yudkin, a well-known nutrition professor, wrote books about the harm done by sucrose. He considered [11]fructose even worse. Nutrition researchers rarely study time of day effects. For example, nutritional epidemiologists ask what you've eaten but don't ask when.

I found a bit of evidence supporting what Stuart found – namely, two comments [12]here:

Just started honey and vinegar hot drink 2 weeks ago. Am amazed at the increased quality of sleep and relief of night time pain. Thought I was imagining it so did not have my drink one night. Didn't sleep and

was racked with pain again all night. . . [my recipe:] 2 tbsp apple cider vinegar and 1 tbsp honey with 1 cup hot water.

Honey knocks me out and I actually wake up in the morning feeling refreshed and ready for the day—amazing. I've been using the honey for a few months now. The difference has been "night and day!"

In addition, [13]a 2007 study found that honey at bedtime was slightly better than no treatment at reducing the symptoms of coughing children. [14]A 2010 study and [15]a 2012 study found the same thing.

I asked Stuart how he discovered that honey improved his sleep. He replied:

I read [16]something that Tim Ferriss said about having a small snack before bed [Ferriss advises protein and fat, not honey – Seth], I think he mentioned that unrefreshed sleep was due to low blood sugar. At the time I was doing [17]carb back loading (I've since stopped that as carb restriction gave me problems). I would have a snack before bed but it didn't always work. I think the small fructose amount in honey was what helped, starches didn't always help. I did some research and came across your blog and Dave Asprey's blogs on sleep, [18]Dave mentioned raw honey. He encouraged people to take MCT oil with the honey to stay ketogenic, I tried coconut oil with the honey instead but it didn't work. If anything it made my sleep worse with stomach cramps. I think there is an amount where benefits end, I think anywhere between a teaspoon or a tablespoon is about right. . . . The first time I did it I couldn't believe it, I felt so good the next day.

He added later:

I have noticed that if I eat a lot of sugar during the day (soft drinks, desserts and so forth) then I don't feel refreshed [when I wake up] regardless of the honey. Perhaps there's something about honey that helps regulate blood sugar. I think it works better on an empty stomach/lightly fasted. So if you had dinner at 7 pm you might not eat anything after and take the honey at 9 or 10. In the past I've had a late dinner then maybe some dessert or fruit in the following hours, then added the honey just after and I don't think it worked as well. When I first tried it I used commercially available heated honey and it worked great. I've tried 2 tablespoons, but I don't think that worked any better than one and sometimes as little as 1 teaspoon is enough.

In summary, three people reported great improvement in sleep from honey at bedtime. Stuart found several other things: 1. If he ate a lot of sugar during the day, the effect went away. 2. Other carbs didn't work. 3. An empty stomach was important. 4. Effective doses ranged from 1 teaspoon to 1 tablespoon.

I believe Stuart has discovered something very important. My belief rests on several things:

1. Repetition. I started eating honey (1 tablespoon) at bedtime. My sleep (much better than Stuart's to begin with) clearly improved, even with 1 teaspoon. I felt more rested when I awoke and more rested throughout the day. The improvement happened night after night. One evening I didn't eat the honey on an empty stomach. The improvement didn't happen, just as Stuart would have predicted. I told a friend about it. He took 1 tablespoon at bedtime. His sleep immediately improved by a large amount. He stopped waking up in the middle of the night and stopped needing a nap in the afternoon. Another friend has tried it once (so far). "When I woke up the next morning," she wrote, "I'd realised I'd slept all the way through the night without waking up in the early morning (a nice change) but had a terrible case of the jitters (a not-so-nice change)." A third friend tried it twice. She slept better the first night but not the second. Maybe she failed to eat it on an empty stomach or had too many sweets during the day.

2. Strength increase. As soon as I started the honey, I got stronger – a complete surprise. For years I have done one-legged standing to exhaustion several times per day because [19]it improves my sleep. To reach exhaustion sooner, I stand on one bent leg. Recently I've been doing it four times per day (right leg twice, left leg twice). For a year, I've averaged about 3 minutes to exhaustion. After I started the honey, the length of time until exhaustion quickly increased. Here are the measurements:

[20]

Each point is a different day; each is the average of the two durations for the first right and first left leg standing of the day. The 2013 tick marks the start of 2013. Nothing changed except the honey. The strength increase was also clear in other ways. In Beijing, I live on the sixth floor of a walk up. It became noticeably easier to climb the six flights of stairs.

The strength increase astonished me. The dietary change was tiny, did not happen before exercise, and involved a safe widely-available food (in contrast to the drugs athletes use, such as steroids). I believe better sleep increased muscle growth. I predict that taking the honey at other times, such as in the morning, would not have the same effect. My earlier observations that [21]lots of standing and one-legged standing improve sleep make more plausible causality in the opposite direction: something that improves sleep will increase muscle growth.

When I described my strength increase to Stuart, he replied:

I have noticed that when I do the honey, my weight goes up over the next week or two, perhaps by 400-500 grams [yet] my waist doesn't increase (I measure it with a tape measure) even after a few weeks. I also have been sure that I noticed rapid muscular growth around my chest, shoulders and arms, similar to what I have noticed when going hard at the gym after a few months off. I kind of assumed that maybe I had more stored muscle glycogen from the honey, but had also considered that improved sleep as you said was the reason.

3. Evolutionary explanation. It has been a mystery why evolution shaped us to like sweetness so much. [22]Israel Ramirez (whose research led to the Shangri-La Diet) pointed out that [23]the usual explanation (sugar is a source of energy) makes no sense. If it's because sugars provide energy, why don't potatoes and rice taste just as good? They

don't. Nutritionists lump sugars with other carbohydrates, thereby ignoring the puzzle. No anti-sugar advocate – not Yudkin, Lustig or anyone else – has provided a good explanation of why evolution shaped us to like the taste of a "poison".

There are several related puzzles. Why are meals divided into main course and dessert? In other words, why do we eat the sweet part separate and later? If we like sugars because they provide energy, this makes no sense. If sugars are simply carbs, this makes no sense – we eat plenty of carbs during the main course. The separation of dessert and main course, if it reflects brain mechanisms, must mean that sugars are quite different than other carbs. Somehow we benefit from this division. A few people, in particular Elizabeth Capaldi, an experimental psychologist, have figured out that [24]sweet food tastes worse if we are hungry (enough). This is why dessert comes after the rest of the meal. Yet other carbohydrates do not taste worse. Stuart pointed out something else along these lines, which I had not heard before but which is clearly true: We eat dessert much more after dinner than after lunch.

Stuart's observations explain these mysteries. All four observations (liking for sweetness, separation of main course and dessert, sweet things taste bad when hungry, dessert after dinner but not lunch) make sense if we have evolved mechanisms to push us to eat sweet foods near bedtime. Long ago, these foods would have mainly been fruit. Because sleep is so important for health, there would be powerful selection for anything that improved sleep.

4. Basic physiology. The brain runs on glucose. In my brain tests, sugar drinks, cupcakes, and other sugar-rich foods make an obvious difference 30 minutes to 2 hours later. (I get faster.) And the brain controls sleep, an enormously complicated and time-sensitive process. Too little blood sugar during sleep could easily disrupt sleep.

5. Basic nutrition. Honey is half glucose, half fructose. When you eat it, the glucose enters the blood quickly and would supply glucose to the brain in the first half of the night. In contrast, the fructose turns into glucose and enters the blood slowly (fructose has a low glycemic index). This would supply glucose to the brain in the second half of the night. [25]Many fruits, such as bananas, figs, and grapes, have a similar composition (similar amounts of fructose and glucose). Most fruits have plenty of fructose and glucose. A 50/50 glucose/fructose mixture makes honey near the start of sleep a good source of blood glucose over an extended period without food. Notice that you need both – glucose and fructose – in roughly equal amounts to get a roughly steady supply over six or seven hours.

6. Basic engineering. When you are asleep, there can be no "course correction". You must subsist for the next six or so hours without any behavioral help, such as drinking water when thirsty. So it makes design sense to do something shortly before sleep that will provide a relatively steady supply of glucose throughout the night ("time-release"). That won't be a lot of glucose at once. You need a food that is a mix of sugars.

7. Support for general idea. A few weeks ago a woman told me that when she ate very low-carb her sleep suffered, so she ate more carbs and her sleep got better. This supports the general idea behind what Stuart found – that the brain needs a certain amount of glucose to work well during sleep and it is best if it gets at least some of it from carbohydrate.

8. Explanation of correlation of sugar and bad health. Why is sugar consumption often correlated with poor health? This is easy to explain: sugar at the wrong time is the problem. Too much sugar during the day interferes with the bedtime benefit (and may also interfere with sleep in general). Stuart found exactly this: Eating lots of sugary foods during the day disturbed his sleep and eliminated the honey effect ("if I eat a lot of sugar during the day . . . then I don't feel refreshed [when I wake up] regardless of the honey"). Too much sugar during the day could make it harder to get optimal glucose levels during the night. For example, too much sugar during the day might raise insulin levels, causing too-low blood sugar at night and/or causing a fructose/glucose mixture eaten at bedtime to be digested too quickly. Anything that harms sleep will increase disease. Good health, good sleep and good immune function are closely connected. An example of the evidence is that [26]shift workers get more cancer than non-shift workers.

9. [27]Reichenbach's Common Cause Principle, in my paraphrase, is lightning doesn't strike twice in one place for different reasons. If two rare events might have the same cause, they probably do. In this case, lightning has struck three times in one place. 1. Huge sleep improvement from tiny dietary change. 2. Huge strength improvement from tiny dietary change far from time of exercise. 3. Evolutionary explanation of why sugars taste good, why dessert exists and follows the main course, and so on. Before this, no one has come close to a plausible evolutionary explanation. The absence of an explanation is remarkable because two of the phenomena – sweetness tastes good, sweets are eaten separately after the rest of the meal – are so obvious.

I believe Stuart's discovery is important for two other reasons that might not impress anyone else. One is similarities with my earlier work. First, I've found other "cross-over" interactions with time of day, where something helpful at one time is harmful at another time. [28]Vitamin D in the morning improves sleep, Vitamin D at night harms sleep. Morning faces improve mood, evening faces harm mood. Second, wondering why we like sour, umami and complex flavors was the first thing to suggest to me that [29]we need to eat plenty of fermented food to be healthy. Many facts later, I'm sure this is true. Finally, [30]evolutionary reasoning has helped me find several new experimental effects (morning faces, Shangri-La Diet, flaxseed oil, standing and sleep).

Finally, Stuart's discovery explains something puzzling I'd noticed repeatedly for years. Now and then I slept unusually well. I'd wonder why – how was yesterday different from usual? – and see that the only unusual thing was that I'd had dinner at a friend's house. At the times, I guessed that seeing faces in the evening was somehow improving my sleep. This did not make sense in terms of my morning faces work, but a connection between social contact and sleep was well-established. Now I realize that dinner at a friend's house is one of the few times I eat dessert. A friend told me that when his partner has dinner parties, she serves dessert long after the main course.

[31]This report suggests that different honeys may differ in important ways.

I told a Dutch friend about this. She said it was common in Holland to have milk and honey at bedtime, although she herself didn't do this. I asked why. No clear reason, she said. An excuse to have something sweet? Could this be why the Dutch are so tall? [32]Children grow when asleep. Better sleep, more growth. My strength increase suggests what a big effect this could be.

[33]More posts about honey and sleep.

michael (2013-11-05 05:21:06)

I first heard about this from Dave Asprey... his explanation is "During the night, your brain uses a lot of energy. One efficient form of brain energy comes from sugar stored in your liver, called liver glycogen. Your brain taps your liver glycogen before hitting your muscle glycogen (stored sugar in your muscles), so having a little extra sugar before bed can help your brain function better at night. Raw honey is preferentially used to stock liver glycogen, so it is used first for brain function. Raw honey is 22 % better at making liver glycogen than the cooked, conventional stuff you're likely to find at the supermarket. Taken without protein, a small amount of honey will raise blood glucose while you sleep too. I was skeptical of this trick when I first heard about it in The Honey Revolution, but I found it does work well as long as you don't combine it with protein." /michael Seth: I don't follow the logic of this sentence: "Your brain taps your liver glycogen before hitting your muscle glycogen (stored sugar in your muscles), so having a little extra sugar before bed can help your brain function better at night."

dearieme (2013-11-05 06:08:42)

If glucose/fructose is the answer, surely a cup of weak tea with sucrose would do just as well? (It's what my mother did and she slept like a log. Though her evening nip of whisky might have helped too.) We tend to eat our honey at breakfast: perhaps I should try it last thing at night instead.

dearieme (2013-11-05 06:11:22)

"she serves dessert long after the main course": ah yes - dessert before or after cheese? Or cheese instead of dessert? Or savoury dessert instead of sweet dessert? Tricky territory, this.

T. J. Allen (2013-11-05 06:36:06)

I have noticed a great improvement in sleep from consumption of 1 tablespoon of resistant starch (for example, resistant potato starch) before bed. For a while I was using a teaspoon of Diamond XPC before bed and noticed a similar improvement

in sleep quality.

Sam (2013-11-05 07:16:54)

Looking back... for years, We gave our younger son honey and milk at bedtime as a naturopath told us it was good for his recurring cold. He grew up to be 6'2" vs his older brother who is 5'10" and both parents under 5'10". Correlation.. Causation.. I don't know. But this blog post is fascinating..! Thanks Seth.

Three Pipe Problem (2013-11-05 07:18:53)

'No anti-sugar advocate — not Yudkin, Lustig or anyone else — has provided a good explanation of why evolution shaped us to like the taste of a "poison".' I recall someone, cannot remember who, making the argument that certain amino acids are actually quite sweet tasting. I remember this person challenged readers to taste plain unsweetened protein powder with a clean palette, which I remember doing, and thinking it was indeed quite sweet. I don't think this a huge factor as we obviously seem to have a protein-specific hunger. Just thought it was worth a mention. Great post, looking forward to trying this.

August (2013-11-05 07:31:01)

There's also a book called the Honey Revolution: Restoring the Health of Future Generations. I tried this and it worked, but then my fasting blood sugar numbers got high, so I stopped. Since then I may have fixed the blood sugar issue- when I remember to check my numbers are normal now that I workout, so I may be able to do the honey again.

Charlie Currie (2013-11-05 08:17:48)

I tried the honey at night after hearing Dave Asprey mention it a couple of years ago...horrible acid reflux ensued about an hour after falling asleep. Fructose before bed equals heart burn for me...I prefer my Ice cream in the late afternoon...cold, dry rice cereal (like rice chex) as a between dinner and bedtime snack works for me like honey seems to work for others. I've never been a "sweets" person, preferring bread and butter over donuts (however, I don't eat bread anymore either)...weird, huh... Cheers Charlie

Tom Passin (2013-11-05 09:02:49)

Fructose does not primarily metabolize into glucose; much of it goes into glycogen, but the reactions seem to be rather complex. According to the 1st edition of The Perfect Health Diet by the Jaminets, a small amount of fructose seems to help the liver manage blood glucose levels, and some fructose helps restore depleted glycogen levels in the liver and maybe muscles. But only a small amount. The Jaminets recommend 100 calories/day as the most to ingest. Also, fructose promotes fat retention and weight gain. If the effects Seth is talking about are specifically honey-related (as it seems), then it must be something else in the honey, because table sugar and the sugar in most fruits is about 50-50 glucose-fructose. Anyway, most of us take in way too much fructose in the prepared foods we eat. If the effects are stronger with raw honey (unclear from what Seth has posted here), then they may be related to anti-microbial properties of raw honey which would be degraded by the pasteurization of most honey. Also I've read that most commercial honey is blended with a lot of high-fructose corn syrup. So it would seem best to try this with locally produced, preferably raw honey. Here's a report of new research which finds that the liver's metabolism of fructose is much more complex than previously realized - <http://www.sciencedaily.com/releases/2008/12/081209221742.htm>

Paul (2013-11-05 09:19:51)

I get the impression from reading this that the honey doesn't need to be raw. I think I'll start experimenting tonight with "regular" honey and see if it works. If not I'll source some raw and see if that makes a difference. Might also be worth trying with some of the fruits you mentioned to help isolate the mechanism. I quite like grapes, so that might be a good one to try.

Bruce (2013-11-05 09:22:37)

Be sure to avoid ultra-filtered honey (which removes all the pollen, etc) and chinese honey, which often has heavy metals and/or antibiotics in it. Often the two are the same, as pollen is the only way to determine the geographic origin of honey.

Susan (2013-11-05 09:28:51)

Question for you: Did you conduct your self experiment using local honey? I am asking that question since I am a beekeeper. I will be starting the experiment on myself tonight. Thank you.

AI (2013-11-05 10:29:05)

Thanks for the interesting article. This is not directly related to sleep, but there have been a number of articles making their way around the internet about the problematic international trade in honey. These articles state that some honey is contaminated with heavy metals and/or antibiotics which are not allowed in the US. Also, some honey is so heavily filtered that no pollen remains, which is important because without pollen, it's not possible to track its origin. Finally, some "honey" isn't honey at all. Here's an example of such an article: <http://www.foodsafetynews.com/2011/11/tests-show-most-store-honey-isnt-honey/#.UnkpKvkqiNI> Cheers.

Seth Roberts (2013-11-05 12:06:13)

"Did you conduct your self experiment using local honey?" No I used Australian honey. I am in China and don't trust Chinese honey. I also have honey from Canada and from a French company that is "a blend of EC and non-EC honey".

Seth Roberts (2013-11-05 12:09:38)

"If the effects are stronger with raw honey (unclear from what Seth has posted here)..." Raw vs cooked honey made no difference to Stuart. I am using cooked honey. So are my friends that have tried it. Long ago I suspect the effect came from fruit, not honey, although that's just a guess.

Seth Roberts (2013-11-05 12:14:08)

"He grew up to be 6'2" vs his older brother who is 5'10" and both parents under 5'10"." Four inches is close to the difference between the Dutch and their neighbors. [1]<http://www.dailymail.co.uk/health/article-2441250/Average-BMI-Artist-compares-sizes-men-various-countries.html>

1. <http://www.dailymail.co.uk/health/article-2441250/Average-BMI-Artist-compares-sizes-men-various-countries.html>

Heidi 555 (2013-11-05 12:30:45)

There's a book called The Hibernation Diet that is about talking a spoonful of honey before bed. As I recall the diet claimed it would help you to sleep well, lose weight, and build muscle. <http://www.amazon.com/The-Hibernation-Diet-Mike-McInnes/dp/0285637371> I tried it for a month (pre SLD) and it didn't work for me - I gained 3 pounds. I wrote about it on this thread here: <http://boards.sethroberts.net/index.php?topic=6285.msg68506> #msg68506 Seth: gaining muscle and losing weight are not compatible...but I have definitely gained muscle and slept well.

Bee (2013-11-05 14:02:56)

Very interesting post. Not sure if this is related, but as a type one diabetic, I can tell you that it very hard to sleep with low blood sugar. I'm sure mine goes lower in the night than a normal person, as mine can get down to 40-50 at times from taking too much insulin or a hard workout day. A normal person is usually around 70-80 throughout the day, unless it's after a meal. Also, the lower the blood sugar, the more lucid my dreams. Maybe because I'm not sleeping as soundly. I don't know. Just thought that I'd add this.

Stuart King (2013-11-05 16:11:15)

When I first tried the honey I used an organic, but lightly heated variety which worked very well. After switching to raw local honey it didn't work as well. I'm trying different varieties, according to this study conducted by the Australian Government <https://rirdc.infoservices.com.au/downloads/05-027> different varieties of honey have different glycemic indexes ranging from low to high. In the outcomes they say 'The results of this study showed that different honeys could have significantly different effects on blood glucose and insulin levels, due to differences in their sugar content and physical form, and should not all be classified as one type of food for people with diabetes.' This information may be more important than whether

the honey is raw or not. If the honey increases fasting blood sugar or gives you reflux then perhaps try a different variety to see if there's a difference? I'm also curious about whether sucrose would work however honey (unlike table sugar) is a natural food and has antimicrobial, antibacterial and anti fungal properties, can kill pathogens and candida, prevents biofilm formation, (see here <https://rirdc.infoservices.com.au/downloads/09-180>) has prebiotic properties promoting the growth of beneficial microbes in the intestine and also has antioxidants. (<https://rirdc.infoservices.com.au/downloads/09-179> and also <https://rirdc.infoservices.com.au/downloads/05-040>). It appears that honey, much like fruit, has many other benefits to eating it in small quantities (it seems our preference for sweet things after meals takes care of this anyway). I can't see how table sugar would be beneficial compared to honey or fruit but it still may improve sleep.

dearieme (2013-11-05 16:15:22)

Re Susan's point: we routinely eat two sorts of honey, both sparingly (i) Local, and (ii) Manuka honey from New Zealand. Our most recent experiment was honey from Pitcairn Island: we found it in a drawer; presumably it was an old Christmas present.

Adam (2013-11-05 17:08:01)

J. Stanton recently looked at some studies comparing Sucrose (pure sugar) to Honey & Protein: <http://www.gnolls.org/3559/calorie-cage-match-sugar-sucrose-vs-protein-and-honey-there-is-no-such-thing-as-a-calorie-part-vi/> There must be something else in Honey aside from the Sugar. Quoting: J Food Sci. 2007 Apr;72(3):S224-9. The effect of honey compared to sucrose, mixed sugars, and a sugar-free diet on weight gain in young rats. Chepulis LM. "Overall percentage weight gain was significantly lower in honey-fed rats than those fed sucrose or mixed sugars, despite a similar food intake." And... "Weight gains were comparable for rats fed honey and a sugar free diet although food intake was significantly higher in honey-fed rats."

Israel Ramirez (2013-11-05 19:45:32)

Honey is a very complicated substance, containing lots of substances in varying amounts, depending on what kind of plant the bee harvested. <http://www.beesource.com/resources/usda/honey-composition-and-properties/> I wonder whether any beneficial effects might be due to the micro components rather than sugars. When I was a child, my family took great stock in honey as a treatment for the common cold but I had trouble eating it on account of the overly sweet taste.

Dennis Mangan (2013-11-05 21:30:07)

I think evolution shaped us to like a 'poison' like sugar is the same as for cocaine or porn, both of which humans have a taste for - they're all supernormal stimuli. Seth: With porn, it is clear what's going on. Obviously sexual arousal/pleasure via vision was helpful in certain situations. So with sugar what is the corresponding beneficial situation? The answer is not obvious. With cocaine it is not clear what is going on - what the beneficial situation is, for example. Nor what the paleo equivalent was. What paleo event triggered the same neural pathways as cocaine? I have no idea. However, leaving aside cocaine, I think you're right: the implicit assumption of many people is that we just have too much sugar now. This fails to answer the question of why we like sweetness at all (or why dessert is separate). I'm saying it's not the amount so much as the time of day.

dearieme (2013-11-06 03:29:17)

A young friend was recently on his first business trip to the US. He found two of the main courses he was served in restaurants inedibly sweet. He rejected them: I hope he was quick-witted enough to find a diplomatic excuse for his hosts.

Seth Roberts (2013-11-06 04:56:37)

"I wonder whether any beneficial effects [of honey] might be due to the micro components rather than sugars." I doubt it, for two reasons. One is that, if so, our liking for sweetness and the institution of dessert would remain mysteries. This is the lightning doesn't strike twice in one place for different reasons argument. The other reason is that something hugely important (sleep) was massively improved. Something as major as sleep is unlikely to be massively improved by a tiny part of the diet. It would be like building something essential for life that depends heavily on a tiny hard-to-get part. Sure, we require micronutrients (such as vitamins) for many things. But the vitamins we need are not hard to get and deplete very slowly. It is really hard to get scurvy, for example.

Nancy Lebovitz (2013-11-06 05:00:19)

[1]Dessert is not universal. However, the evidence from experience was interesting enough that I tried honey last night. It didn't make any difference, which I guess isn't too surprising. My sleep problem seems to be driven by hot flashes. I wake up (feeling alert), have a hot flash, and it takes me a while to get back to sleep. I believe that the pre-hot flash state includes a gradual increase of body temperature which takes me out of sleep. There may be adrenalin/cortisol involved, too. The whole cycle (which also happen during the day includes feeling tired/distracted before a hot flash (something I wouldn't notice when I'm asleep.) Anyway, I'll keep trying the honey for a while. Who knows? I might get the strength increase. Seth: If you already get a fructose/glucose mixture near bedtime (how near is unclear. one hour? two hours? three hours?) more of it is unlikely to help.

1. <http://nancylebov.dreamwidth.org/1023540.html?thread=3966260#cmt3966260s>

Nancy Lebovitz (2013-11-06 05:05:54)

Not sure if this is relevant to cocaine, but coca leaf (the source of cocaine) is a staple for people living in the high mountains-life is hard and they need the extra energy. I'd love to see whether coca would help people off a cocaine addiction or even be a useful drug like caffeine, but the experiment isn't legal and I guess coca isn't expensive enough to be worth smuggling.

GeoffD (2013-11-06 05:58:28)

Seth, Thank you for the best blog on the internet. Seth: Thanks! That's a lot of blogs.

Three Pipe Problem (2013-11-06 07:47:33)

"The other reason is that something hugely important (sleep) was massively improved. Something as major as sleep is unlikely to be massively improved by a tiny part of the diet." Milligrams of melatonin can massively improve sleep, and it's found in foods.

Sue (2013-11-06 11:23:58)

I have hypoglycemia and horrible insomnia. I have tried manuka honey before bed but did not see results; however I can concur with Stuarts discovery that a day of low sugar/low refined carbs will guarantee me a good nights rest as opposed to waking up after only a few hours of sleep and not being able to get back to sleep until sunrise. I find I sleep best with light dinner and sleep even better if Im a little hungry before retiring. I do feel like my insomnia is related to blood sugar problems (possibly caused by weak adrenals). Before discovering the diet connection a snack of cheese and fruit before helped a lot but was not any where near as successful as low sugar/low refined carb diet. Another thing that seem critical for me is potassium supplementation. I use about 1/8 tsp of nu-salt and that ensures me refreshing sleep. Too much and Im groggy the next day. My husband who gave up coffee and was looking for a replacement for mental acuity discovered that a spoonful of honey works just as well without the side effects I am curious as to what brand/type of honey you are taking Seth? I would like to try another source of honey. Andrew-how did you solve your blood sugar problems? Thanks Seth: I have been using [1]a blend of Australian honeys from Leabrook Farms (in Australia).

1. [http://www.springgullyfoods.com.au/leabrook\\_farms](http://www.springgullyfoods.com.au/leabrook_farms)

Meets (2013-11-06 11:57:51)

I tried this last night, and it worked. I had a deep sleep and woke up refreshed, which doesn't happen often. I've been eating a lot of honey, but mainly in the morning and afternoon with coffee or yogurt. Occasionally I would sleep well and not know why. Maybe those were the days I had honey with yogurt before going to bed, which I occasionally would do.

Inquisitive Raven (2013-11-06 11:59:52)

Hi, I'm a type 2 diabetic and I'd like to talk about blood sugar. There is a known phenomenon of [1]elevated fasting blood sugar that seems to be related to the long period of no food that people undergo when they sleep. Basically, as I understand it, when blood sugar drops sufficiently at night, the liver releases glucose into the bloodstream. In non-diabetics, the insulin response keeps it from getting too high, but in diabetics, the result is elevated morning blood sugar. There's an alternate

explanation in the linked article, but whatever the reason, I've found that taking a small amount of carbohydrates before bedtime seems to prevent it. What I haven't done is test whether the form of the carbohydrate matters, nor have I figured out the optimum dosage though I suspect that it's between ten and twenty grams. According to the [2]USDA nutrition database, honey has about six grams of sugar/tsp, so 2-4 tsps is about the right dose. I get the 10-20 gram figure from the fact that the recommended dose for treating a hypoglycemic emergency is 15 grams of glucose and, well, trying to avoid spurious precision.

Alex Chernavsky (2013-11-06 12:24:44)

Save-the-sugar-for-dessert might be a modern invention:

Were we to attend a 16th century court banquet in France or England, the food would seem strange indeed to anyone accustomed to traditional Western cooking. Dishes might include blancmange—a thick puree of rice and chicken moistened with milk from ground almonds, then sprinkled with **sugar** and fried pork fat. Roast suckling pig might be accompanied by a cameline sauce, a side dish made of sour grape juice thickened with bread crumbs, **ground raisins** and crushed almonds, and spiced with cinnamon and cloves. Other offerings might consist of fava beans cooked in meat stock and sprinkled with chopped mint or quince paste, a sweetmeat of quinces and **sugar or honey**. And to wash it all down, we would probably drink hypocras, a mulled red wine seasoned with ground ginger, cinnamon, cloves and **sugar**. [...] Before 1650, the elite classes throughout the Islamic and Christian worlds from Delhi to London shared pretty much the same diet: thick purees, lots of spices, **sweet** and sour sauces, cooked vegetables, and warmed wines. **Sugar was ubiquitous as a seasoning in savory dishes.**

(Emphasis added.) From: "Birth of the Modern Diet", by Rachel Laudan. *Scientific American*, Aug. 2000. [http://www.rachellaudan.com/wp-content/uploads/2007/08/birth\\_of\\_the\\_modern\\_diet.pdf](http://www.rachellaudan.com/wp-content/uploads/2007/08/birth_of_the_modern_diet.pdf)

Seth Roberts (2013-11-06 15:36:24)

"Save-the-sugar-for-dessert might be a modern invention". There are plenty of modern instances where main courses have small amounts of sugar. Sushi rice has a small amount of sugar. Korean marinades have small amounts of sugar. Cranberry sauce, sweet and sour sauce and pomegranate sauce are modern. And so on. So sugar is certainly used in main courses, but is it new to have dishes that are mainly sweet (dessert) separated from the rest of the meal? The quotation doesn't show something that we would today call a dessert served at the same time as main courses. Elizabeth Capaldi's experiments that show that sweetness is less pleasant when we are hungry don't depend – one hopes – on when they were done.

Seth Roberts (2013-11-06 18:08:16)

"Milligrams of melatonin can massively improve sleep, and it's found in foods." But not in milligram amounts. Much less. Here is the amount of melatonin in various foods that are HIGH in melatonin: <http://www.thehealersjournal.com/2013/04/08/foods-high-in-melatonin/> You would almost never get enough melatonin from food to improve your sleep. Because melatonin is found in food in such small amounts, it is very unlikely that we need melatonin in our food for optimal sleep. However, your comments makes me curious what effect it will have. I have some lying around.

Nancy Lebovitz (2013-11-07 06:04:53)

Second night, I got a definite improvement in sleep– I only woke up once rather than the usual more times than I can remember. I still don't believe in evolutionary arguments, especially if they're supposed to apply to the whole human race. There are foods which are healthy for most people, but debilitating or deadly for some. There are the usual reasons for why childbirth is risky, but some women (for some births?) have a reasonably easy time of it. Why haven't the traits which make childbirth risky been bred out, or at least made much more rare? I believe strongly in experimentation and observation, and I can live with evolutionary theories being used to check on which experiments are worth trying.

Seth Roberts (2013-11-07 06:41:44)

"Why haven't the traits which make childbirth risky been bred out, or at least made much more rare?" at the last Ancestral Health Symposium, a doctor named Will Lassek made exactly that argument: that certain easy-to-notice things evolved because they made childbirth less risky. His talk was titled "Why Women Need Fat: Three Evolutionary Puzzles". His answers to these puzzles were quite different than the usual answers.

Kelly B (2013-11-07 08:56:16)

Another hot-flash sufferer weighing in; I have exactly the same issue that Nancy reported - an increase in body temperature sometime during the night that wakes me up (thinking it's morning, sometimes at 10:30 pm) in order to have a hot flash. I tried the honey last night for the first time - just 1 tsp. I've been eating very low-carb lately, so no sugar throughout the day at all. I had a hard time getting to sleep initially, and I did wake up for a hot flash at 2 am, and at first, I didn't think it was working. However, when I woke up for the day (unfortunately, about an hour earlier than I wanted to - probably a hangover from the time change this past weekend), I felt an incredible sense of well-being. Normally, I wake up with aching hip joints and feeling pretty ugh, but not this morning. My sense is that the sleep was "richer" - I can't describe what was different, but it seemed different in quality from my normal sleep in the way that heavy cream is different from skim milk. I'm very interested in the strength and muscle mass improvements, although I do realize that I just totally blew the opportunity to set up a control. Still not going to stop.

David199 (2013-11-07 21:20:43)

So a few years ago i stumbled on this thread on the Crossfit Forum. Guys/Girls who were normally strict about their diet found that eating ice cream before bed was causing them to lose weight. The thread is 56 pages and spans 7 yrs of comments. I have not read it all but it appears they never considered the brain/liver combination in regards to sleep. They also didn't seem to put together that it needed to be done before bed and just thought it was something in the ice cream alone. Who could blame them? Most of them would have strict diets during the day and then ice cream before bed - in line with Stuarts observations except it was ice cream vs honey. Comments like this from one poster (on page 51) make me think its a similar phenomenon affecting sleep: "When I'm at college, my sleeping pattern is . . . I don't get much sleep. When I eat breyer's there, the next day my WODs [workouts of the day] feel great. However when I go home and get alot of sleep, the ice cream does nothing and I feel better eating real food." And comments like this on page 45, point out that sugar seems to be an important part of the equation: "Oddly, I almost always PR [set a personal record] the next day after eating a bowl or two of ice cream. If I go overboard on pasta or something the night before, I am usually burned out halfway through a respectable length metcon [metabolic conditioning workout] (20 minutes), but with ice cream it doesn't matter what the WOD is, I always feel and perform better." <http://board.crossfit.com/showthread.php?t=20754>

Seth Roberts (2013-11-08 01:22:38)

"So a few years ago i stumbled on this thread on the Crossfit Forum. Guys/Girls who were normally strict about their diet found that eating ice cream before bed was causing them to lose weight. . . Most of them would have strict diets during the day and then ice cream before bed - in line with Stuart's observations except it was ice cream vs honey." That's fascinating. Not just the results - the benefits of the bedtime ice cream - but also the fact that their will power somehow gave out near bedtime. Their willpower went down or the sweets became more attractive or both. I've heard many times about willpower going down in the evening - I can't remember for what. I wonder if it goes down for sweets (less able to avoid them) more than other things, such as cigarettes and liquor. People binge in the evening much more than at other times of day. It is paradoxical that willpower goes down in the evening because in the evening we should do less of stuff...because we need to do nothing in order to fall asleep. In this case less willpower = more tendency to do something. I find that in the evening it is harder to do almost everything.

David (2013-11-08 01:56:18)

Incredible. Something so simple triples your leg endurance. This is the most epic Seth Roberts discovery to date! And to think a honey-sweetened creme brûlée can now be considered a health food to improve strength and endurance, give better sleep thus overall health, boggles the mind.

Louise (2013-11-08 03:34:25)

Regarding the height of dutch people in relation to milk and honey at bedtime. Perhaps it is as simple as better sleep equals better hormone production. Human growth hormone in particular is produced when we sleep. I've had far too much carbohydrate and sugar today to try it tonight but will definitely try tomorrow evening. In general I have noticed that if I eat fairly low carb during the day and then have a small but carbohydrate rich meal for dinner (such as a vegetable and legume curry with half a cup of white rice) I sleep well and wake feeling both relaxed and refreshed the next morning.

Louise (2013-11-08 03:39:00)

I forgot to add - traditionally honey is considered to help the body retain fluid, helping people sleep through the whole night without needing to pee. Whether it's true or not I don't know. Perhaps some people who normally need to get up during the night to pee could report back here if it made any difference.

Guy (2013-11-08 06:29:02)

Well I tried it last night and I have two things to say; first, it seemed to work as I woke up feeling more refreshed and second, technicolor dreams!!

David199 (2013-11-08 07:39:34)

Louise, I'm currently being treated for insomnia- waking up in the middle of the night, usually around 4am. I always need to go to the bathroom. The honey is helping me sleep better but I'm still awake to go to the bathroom even though I drink almost no fluids after 4pm. I have bought the Hibernation Diet book and searched the web for information while I wait for it to arrive. There is very little information other than the following FAQ with the author ([www.hibernationdiet.blogspot.com](http://www.hibernationdiet.blogspot.com)). His short view is that honey nourishes the liver (and you need fructose to open the liver up to store glucose - this could be a reason why we crave sweets), which provides a steady stream of glucose to the brain during the "8-hour fast" while you sleep. When the brain is "happy", you sleep deeply and the rest of the body burns fat as it rebuilds. If the liver does not have sufficient stores of glucose, the brain signals for stress hormones to kick in and take or make glucose from outside the liver to nourish the brain. These stress hormones (like adrenaline and cortisol) compete with rest and shift the body away from a primary fat metabolism. This is the paradox of eating sugar to burn fat (like the Crossfit guys did) This of providing for the brain during sleep (and the crossfit ice cream thread) are making me rethink how we eat and sleep. We've always been taught not to eat at night. Most people eat around 7pm, go to bed at 11pm and wake around 6-7am. This means we are doing a 12-hour fast each night. During the day we eat several times and people complain of fatigue, esp after lunch. Seems odd that we know we get tired after a big meal (think Thanksgiving) and yet we've set up our day to eat heavily when we want to be active and to fast while we are trying to rest.

Kirk (2013-11-08 10:45:02)

David999, I solved my waking-up-to-pee-often problem by adding iodine. I take one fourth of a 3mg tablet once a day in the morning. Seth, I experimented the last three nights with honey-before-bedtime. My recent typical sleep pattern is an initial 3 hours, wake lightly, then 3 sessions of 1.5 hours each. Sometimes I wake up strongly at 4am at which time I'll either change sleep locations, splash cold water on my arms and face, and/or hold standing meditation for 15 minutes, before attempting sleep again.) Night 1: 1 t honey, slept deeply 4 hours, lightly for another 3 hours Night 2: 1 t honey, no change in sleep habits (both my wife and I were cold that night so perhaps we kept waking each other up) Night 3: 1.5 t honey, slept deeply for 5 hours, woke up strongly, stayed awake for half an hour, then slept another 2 hours I plan to increase the dose to 2 teaspoons tonight.

David199 (2013-11-08 11:16:45)

Kirk, any idea why the iodine helps stop the urge to urinate in the middle of the night?

guv (2013-11-08 15:08:23)

on the dessert/ice cream subject, I found a quote attributed to Ray Peat here, <http://www.dannyroddy.com/main/2011/12/2-9/ray-peats-brain-building-a-foundati-on-for-better-understandi.html> that reads, "During the night all of the hormones of stress and inflammation rise, and the ice cream decreases them enough for you to stay asleep, but they still rise" purportedly (from the Danny Roddy site again), Peat likes/uses low fat Haagen Dazs (one without any gums or fillers).

Stuart King (2013-11-08 16:41:07)

Lower will power in the evening might be a result of decision fatigue or ego depletion, which seem to have a direct correlation with blood glucose levels [http://www.nytimes.com/2011/08/21/magazine/do-you-suffer-from-decision-fatigue.html?pagewanted=all&\\_r=0](http://www.nytimes.com/2011/08/21/magazine/do-you-suffer-from-decision-fatigue.html?pagewanted=all&_r=0) <http://www.forbes.com/sites/trustedadvisor/2012/05/22/keep-those-glucose-levels-up/>

Kirk (2013-11-08 17:51:21)

David199, Why does iodine reduce the urge for night-time urination? In my case, I rarely eat manufactured food or at restaurants. This means I am also not ingesting the salt added during manufacturing. Most salt has iodine added to it (see Iodised Salt entry at Wikipedia). But I don't like the taste of iodized salt, therefore, once I stopped eating potato chips and tortilla chips, I probably slowly got deficient in iodine. My hunch is that after a while my body was doing whatever it could to recycle the little iodine it had and not lose it via urination, and whatever process it used to recycle the iodine made the body want to urgently remove the waste. But that's a layman's viewpoint, probably wrong. All I know is that at some point I added iodine based upon supplement recommendations by the Jaminets, then after noticing the good effects, it didn't take long to narrow the cause to the iodine. It's the only supplement I've taken where I have noticed a result.

Seth Roberts (2013-11-08 17:55:28)

That's a good point. These willpower/ego-depletion/blood glucose studies support my views in several ways: that glucose is crucial for brain function, that low glucose leads to bad function, and that glucose levels depend greatly on both food and amount of mental activity. The alternative is that blood glucose regulation is so powerful and precise that blood glucose is not something we need to worry about. Like body temperature.

guv (2013-11-08 17:59:24)

i read another reason for the need to get up & pee during the night, could be due to a deficiency of sodium in your diet.

Brian (2013-11-09 19:24:54)

In the books "The Iodine Crisis" by Lynne Farrow and/or "Iodine: why you need it, why you can't live without it" by David Brownstein it was mentioned that iodine supplementation can reduce the need to get up and pee during the night. I don't recall if it was said why it works. If you buy Brownstein's book do so from his website to make sure you get the current edition. I think I still have a little local raw honey left in my cupboard. I'm going to try this tonight.

Shane (2013-11-09 22:35:37)

Hmm interesting. Who would have thought that honey before sleep would help! If only it didn't need to be done on an empty stomach I'd give it a try. (I find eating before bed has me sleeping a lot better for some reason.) Seth: I'm sure the "on an empty stomach" part is not exactly right - that some foods in some amounts are okay. I am tempted to try thin crackers - eating the honey on thin crackers.

Robnonstop (2013-11-10 08:04:49)

I was told by a chef: The idea of dessert at the end comes from the French. Europeans had sugary meals, and drinks (everything served at once) like other cultures do but when kings got fat, lost their teeth etc. their doctors decided to BAN those who produce the desserts into a separate, smaller kitchen and only allow a little bit of sweet food at the very end of the meal. What royals do is fancy, so everyone adopted this order. Seth: Interesting. Here is another answer: <http://www.quora.com/Desserts/Why-and-when-did-desserts-become-the-last-course-of-a-meal>

Robnonstop (2013-11-10 08:08:34)

On why we get up at night: Apparently adults in rural areas without electricity always get up at night. It's supposed to be that way. You have to go to bed when it gets dark though. When traveling in rural areas in Asia, I noticed people were often awake around midnight, sleeping before and afterwards. This TED talk makes the same claim but without any explanation: <http://youtu.be/-Z-vyLHi2us>

Christina (2013-11-10 10:39:26)

I'm confused by why there's confusion around the evolutionary desire for extremely sweet things. Lots of sugar = lots of glucose = higher spike in blood glucose and ability to do whatever we need to do with renewed energy. Why is it more complicated than that? Seth: Sugar is a low density form of energy. Fat is almost twice as dense. It is unclear that there is an evolutionary desire for "extremely sweet things" separate from a preference for sweetness. The Paleolithic world did not have a lot of extremely sweet things, so perhaps we like extremely sweet things because we like sweet things. High blood sugar is damaging (diabetes), why would we develop a preference for foods that damaged us? If extremely sweet things are so good for us, why do we get sick of them so quickly? (Sweets are generally small.)

Seth Roberts (2013-11-10 14:17:51)

"Apparently adults in rural areas without electricity always get up at night. It's supposed to be that way." I've heard this many times: "It's supposed to be this way." I am less sure. How do the people who say this know what paleolithic sleep was like? Maybe rural people always get up at night because they don't get enough sunlight in the morning, or enough exercise or enough X - there are dozens of possible X's. To be sure that sleep is supposed to be this way we'd need to know all the variables that have a big effect on sleep and then set all of them to their paleolithic values, and see what happens. The people who make the "supposed to be this way" claim don't seem to understand this.

Chuck (2013-11-10 15:35:37)

In Honey's Unknown Benefits By Lindsey Duncan, ND, CN he states..."Improved sleep and relaxation: Honey can promote relaxation and help ease you to sleep at night. The natural sugar found in honey raises our insulin slightly and allows tryptophan, the compound famous for making us sleepy after eating turkey at Thanksgiving, to enter our brains more easily. Taking a spoonful of honey before bed can help you get restful sleep."

Darrin (2013-11-10 15:47:38)

hi all, i am trying to work out how important the Type of Honey is in this instance (for improving sleep)... i have found two local honeys, both are Raw & Organic. Both are 100 % Australian honey (i am in Aus). & am trying to decide which one to buy first (i'll buy the 2nd if 1st choice 'fails'), here's how they differ; Option A: honey is a dark colour & runny (i seem remember reading that the higher fructose honeys can be runnier than the lower fructose honeys). Option B: honey is light colour & a lot thicker than option A (possibly with some minor crystallisation). label also reads that this honey "retains small quantities of propolis and pollen". Both honeys were at the same temperature, same shop/shelf. Although both honeys are raw & organic, i wonder if option B may have the least processing, due to the mention of propolis and pollen. so which do you think i should buy first for this sleep experiment & why... is runnier better, is higher fructose better (although i do not know the actual fructose contents), is inclusion of some propolis and pollen good or bad, etc, Thanks for any feedback/comments/help Seth: I don't know. That is a really hard question.

Seth Roberts (2013-11-10 17:52:52)

"The natural sugar found in honey raises our insulin slightly and allows tryptophan, the compound famous for making us sleepy after eating turkey at Thanksgiving, to enter our brains more easily." Tryptophan has been found to reduce sleep latency - the time it takes to fall asleep after you turn off the lights and try to fall asleep. I don't care much about sleep latency since I usually fall asleep quickly. That being said, it's possible that the honey has caused me to fall asleep more quickly. Last night it seems like I fell asleep in a few seconds.

Darrin (2013-11-10 18:08:33)

Hi Stuart, you said, "When I first tried the honey I used an organic, but lightly heated variety which worked very well. After switching to raw local honey it didn't work as well. I'm trying different varieties..." I am in Australia as well, which particular honey have you found that works best for you so far? & i'll see if i can find it. &/or have you found a difference between say, thick/light colour honey versus runny/dark colour honey...which one worked best for you? thx

Stuart King (2013-11-10 19:20:11)

Hi Darrin, the honey I first used and have found to be effective since is available at Coles in a 1kg glass jar and is called pure harvest organics - organic honey. I emailed them and they said it is an iron bark variety from Queensland. It is heated to 45 degrees Celsius. They have a variety that looks exactly the same in the health food store but it says raw, however on the side of the jar it still says its heated so I don't know what's going on there. It's consistency is more runny and it isn't as dark as the raw variety I use in my tea (which has a much better flavour). The interesting thing is that the raw local variety of honey I was using which wasn't working as well is also iron bark. Maybe the heating process increases the glycemic index of the honeys. It is thicker and darker. My understanding is that the more pollen and particles there are in the honey, the better the quality. This report (<https://rirdc.infoservices.com.au/downloads/05-027>) gives details on the amounts of fructose versus other sugars in different varieties of Australian honey. Iron bark and other pure floral varieties were low GI yet blends were moderate to high GI. Seth posted that he is using a blend, which I haven't tried yet, I'm testing different honeys to see the effects and quantifying the data.

Darrin (2013-11-10 21:44:09)

Thanks Stuart, regarding "...the more pollen and particles there are in the honey, the better the quality", this could be true & could be 'healthier' as well, but whether either of those things is a factor for improving sleep is another matter. Just looking at the info on the pureharvest/coles honey you mention, which can be found here, <http://shop.coles.com.au/online/national/pureharvest-honey-organic> As this honey is not listed on the pureharvest web site, i am guessing this must be a 'supermarket' version. I've noticed something else on some honey labels which may be relevant here, most honeys label the carb content as all or nearly all sugars, usually 80+ grams per 100g. But a few list sugars as a lesser percentage of carbs, ie. with the coles/pureharvest linked above, sugars 73.6g, carbs 82.4g. & another one i just saw in the local coles express, coles brand 500g organic honey, sugars 69.4g, carbs 87.9g. This could be something to track when testing which honeys work for you.

Christina (2013-11-11 00:01:15)

IRT your comment: Seth: Sugar is a low density form of energy. Fat is almost twice as dense. It is unclear that there is an evolutionary desire for "extremely sweet things" separate from a preference for sweetness. The Paleolithic world did not have a lot of extremely sweet things, so perhaps we like extremely sweet things because we like sweet things. High blood sugar is damaging (diabetes), why would we develop a preference for foods that damaged us? If extremely sweet things are so good for us, why do we get sick of them so quickly? (Sweets are generally small.) — Right, but could it be a speed thing? If you're a zebra about to run briefly from its prey, you'd be better off having a Twix bar than a steak. Lots of things - in larger quantities than "needed" - can end up being bad for us, right? Excessive porn, excessive exercise, excessive sugar. The problem here is that our pleasure system is hard to modulate perfectly, not that there can't possibly be an evolutionary reason for liking refined sugars. Also, I don't think excessively sweet things are necessarily "good for us" beyond serving their purpose in the short term. The fact that we get sick of them is = to people (mostly) no longer being interested in sex post-orgasm, right? Really trying to think through where the confusion is coming from, sorry if I'm being ignorant. Seth: My point wasn't that X or Y was the case, it was that there was nothing simple or obvious about the answer to the question of why we like sweet foods.

Stuart King (2013-11-11 01:17:20)

Darrin yes that is the honey I was referring to. I suspect that labelling of sugar content only refers to the glucose, fructose and sucrose contents of honey. There are at least 12 disaccharides in honey in addition to fructose and glucose - sucrose, maltose, isomaltose, nigerose, turanose, maltulose, leucrose, kojibiose, neotrehalase, gentiobiose, laminaribiose and isomaltulose. My guess is this is where the extra carbs are from.

Stuart King (2013-11-11 01:27:24)

Here's an interesting story about someone who went without artificial light for a month and fell into a bimodal sleep pattern  
<http://jdmoyer.com/2010/03/04/sleep-experiment-a-month-with-no-artificial-light/>

Nancy Lebovitz (2013-11-11 05:52:35)

I ran into an example of sugar being good for me. Friday I felt really drained, even though I'd had a reasonable amount of sleep and eaten as much as I wanted of low glycemic and fairly high-fat food. Towards the end of the day I had a piece of Texas sheet cake (white flour, sugar, Crisco, and applesauce). The world snapped into focus, and a friend said it was the first time she'd seen my eyes open all day. It would seem that keeping myself fed properly is more complicated than I thought.

Eric (2013-11-11 07:17:20)

RE: Evolution and sugar. Glucose can provide a temporary substitute for rest in that it can help restore executive functioning for people that are cognitively fatigued. Since hunting can be a high vigilance activity, and therefore one that can fatigue executive functioning this suggests one possibility. [http://www.psych.utah.edu/psych4130/Kaplan\\_and\\_Berman2010.pdf](http://www.psych.utah.edu/psych4130/Kaplan_and_Berman2010.pdf)

David199 (2013-11-11 08:07:33)

Chuck Says: In Honey's Unknown Benefits By Lindsey Duncan, he states..." The natural sugar found in honey raises our insulin slightly and allows tryptophan, the compound famous for making us sleepy after eating turkey at Thanksgiving, to enter our brains more easily." Chuck, supposedly insulin pushes tryptophan into the brain, which becomes serotonin which becomes melatonin and melatonin moderates insulin which is why eating sugar before bed doesn't cause blood sugar swings or fat gain. Melatonin also helps with HGH pulsing which is beneficial. However, I don't understand the idea of "natural sugar." Honey is a mixture of glucose and fructose. Sucrose is a 50/50 mixture of glucose and fructose. The only difference is that while the two monosaccharides are in free form in honey, sucrose holds the fructose and glucose together with a glycosidic bond which is quickly broken during digestion. Does anyone know if "natural sugar" and sucrose are really that different in terms of how the body metabolizes them? (I do realize that honey has several other beneficial compounds. I'm specifically referring to the "natural sugar" argument.) As to why we prefer sweet foods, my guess is that it has to do with proper liver uptake of glucose, since fructose plays a role in activating glucokinase which is involved in glycogen synthesis. Either way, our taste for sweetness must serve some evolutionary purpose in terms of the doses someone would get from fruit and honey ingestion. It's very difficult to overeat on those foods. I think drinking a 24 oz Mountain Dew perverts our inborn taste for sweetness.

Nancy Lebovitz (2013-11-11 08:15:15)

More evidence about the non-universality of dessert: <http://thoughtcatalog.com/michael-koh/2013/11/16-people-on-things-they-couldn-t-believe-about-america-until-they-moved-here/> Not dessert as in sweet foods, but as in the specific course eaten after dinner. It doesn't exist. Guyanese people eat dinner and then that's it. I remember going to my American friend's house and being shocked that people in real life actually ate dessert. Seth: Dessert is rare in China, where I live much of the year. But the Chinese people near me eat lots of sweets, especially at night. I see this any evening I walk down the street.

David199 (2013-11-11 08:27:24)

Eric, my only issue with your link to the research on glucose is that it doesn't explain why we enjoy things that are sweet. Starch is pure glucose and yet it's not sweet. All sweetness in nature, honey and fruit, contain fructose. Potatoes taste great, but are not sweet. Actually, potatoes only taste good with either adding fat or sugar. Seth, in your original post you discuss why we separate sweetness (dessert) from the rest of the meal. But I would question that assumption. Let's say we are having a simple dinner of meat and a sweet potato. Many people would put some sugar on their meat (steak sauce, BBQ sauce, etc) and would add brown sugar to their sweet potato. Can anyone deny that BBQ tastes better with sugary sauce or that sweet potatoes taste better with brown sugar? Sugar is the third ingredient in most ketchups. Most breakfast cereals have added sugar - even the "healthy" ones. (Kellogg's All-Bran lists sugar as the second ingredient) And I dare anyone to eat a bowl of oatmeal without putting something in it to sweeten it. We simply like the taste of sweet and sweet = fructose.

How to Manufacture the Best Night of Sleep in Your Life ‹ Healthy Naturally Club (2013-11-11 12:33:55)

[...] a tablespoon of honey, preferably raw, right before bed. Seth Roberts has shown through rigorous self-experimentation how it might very well improve sleep, perhaps by keeping [...]

Victor (2013-11-11 15:54:22)

This is a very interesting documentary ("Lights Out") on the effect of electric light at night on the natural production of melatonin. <http://www.cbc.ca/player/Shows/ID/2313199682/> After watching it, I bought a pair of the type of glasses recommended (cheaper safety glasses off of amazon) and used them religiously for 1 month. I noticed significant improvement after 3 nights which continued for the full month of use. For the next month I stopped using them and found reduced quality of sleep after 2 weeks. Before watching the documentary I had had very poor broken sleeps from doing the nighttime parenting of our 2yr old and 1 yr old. Now that winter is approaching I am using them again at night and again noticing the sleep improvements. I think that this is well worth watching and trying it out for yourself. I will be trying the honey now as well, and watching for changes in sleep quality, dreaming and strength changes. Thanks all for the insights Seth: Funny coincidence. A few days ago I wrote a post about the use of the glasses you are using. I agree with what you say. The post will appear very soon.

Robnonstop (2013-11-11 18:10:00)

"I've heard this many times: "It's supposed to be this way." I am less sure. How do the people who say this know what paleolithic sleep was like? Maybe rural people always get up at night because they don't get enough sunlight in the morning, or enough exercise or enough X — there are dozens of possible X's." Not sure what you mean by that. The results from rural areas were only relevant because they fit with what scientists observed in unrelated tribal cultures. The logical conclusion is that it's the standard and that artificial light and lifestyles change sleeping behavior. Of course our artificial unbroken sleep might be better but if your argument is that in rural areas people just don't get enough sleep (for some mysterious reason), why would that not also apply to early humans? Waking up at night has many benefits, survival and reproduction being the most obvious. Also worth noting is that there is no point in having 100 % identical behavior and preference among members of a tribe. Someone has to not like berries, in case they are poisoned, someone has to not sleep at a certain time, in case there is an attack etc.

Vincent Colombo (2013-11-12 08:20:26)

I started taking honey before bed two days ago, after reading this article. Both days I noticed that I had increased dream activity, or at least more awareness of my dreams. They also seemed much more vivid, but this may just be the difference between not really remembering/being aware of my dreams and now at least remembering that I did have dreams. Anyway, the first day I tried this I didn't think it helped, and in fact I felt I may have even woken up more and slept less. The second day (last night) I also felt like I had woken up more during the course of the night, and again felt like I had more frequent and more vivid dreams. However, after being up for a short period of time I started to realize how good I felt overall. Perhaps my body simply needs to adjust from my many years of restless sleep to the more restful sleep that I may now be experiencing. The results are interesting enough that I will continue the experiment and see how it goes. This idea and conversation reminds me of something someone told me years ago. They mentioned they drank something they referred to as "silver tea" before bed, which helped them sleep. Silver tea was simply warm milk with a small amount of sugar dissolved in it. I tried it once or twice when younger, and it did actually seem to help me sleep.

Sara L (2013-11-12 12:32:59)

Really interesting, I will try it. Also, I would like to add something a friend recommended me about honey. I don't know how extended it is, but he recommended, to prevent muscle stiffness (I am not sure it's the proper name, in spanish is "agujetas") , to eat one teaspoon of honey before exercising. As I workout very randomly, I usually had muscle stiffness the first days I worked out, but with the honey I never had it again. I guess having the proper amount of sugars available to the muscle during the whole workout keeps it from anaerobic activity.

Melanie C (2013-11-12 23:00:57)

Here's my guess on our inborn love of sweetness – it's about milk. Human breast milk contains a significant amount of sugar in

the form of lactose. Traditionally, children were nursed until at least age three (still the case in current hunter-gatherer tribes.) An inborn taste for sweet is a big survival advantage for kids – they'll nurse more and get lots of calories from all the sugar and fat in milk. Maybe adult enjoyment of the sweet taste is just a leftover from childhood?

Seth Roberts (2013-11-12 23:33:38)

"An inborn taste for sweet is a big survival advantage for kids — they'll nurse more and get lots of calories from all the sugar and fat in milk." good point. this may be why kids like sweets so much more than adults.

Tim Lundeen (2013-11-21 13:03:43)

I'm curious whether a mix of glucose/fructose would have the same effect as honey. If so, this would confirm that the micro components of honey are not important. Sucrose causes more inflammation than honey, so wouldn't expect it to be as effective. Also, contaminants in the sucrose/fructose mix could cause it to be less effective, whereas organic honey presumably has much lower levels.

Fructose - The Natural Born Killer. Fact Or Fiction. | Get Real Living (2013-11-24 19:23:42)

[...] Interestingly, there are studies that show a tablespoon of raw honey can aid in better sleep. This is due to honey being half glucose and half fructose; glucose enters the blood quickly, supplying the brain in the first half of the night, with fructose turning into glucose (provided you haven't gorged on sugar throughout your day) slowly, meaning your body has a steady supply of energy the entire night. Read more here. [...]

Dinis Correia (2013-11-25 06:35:32)

I'm from Portugal and milk with honey is one of the common recommendations for a good night's sleep (not been drinking milk for some time now, but my mother did this when I was a kid).

julia (2013-11-27 07:50:53)

Sounds plausible. The only obvious issue is tooth decay. Are you brushing your teeth after eating/drinking the honey? Seth: yes, I brush my teeth after consuming the honey.

Crystal (2013-11-29 16:28:45)

Fascinating discussion. I just started trialling it last night, and although I did get up mid-sleep (usual pattern) I noticed the zoe this morning was showing solid blocks of light and rem sleep minus the short waking spikes I normally have, with a higher than normal proportion of REM to deep sleep (1.5:1 vs normal 1:1). I should also note that I'm recovering from stress-related problems including insomnia, but am not medicated. I probably should have waited, since yesterday was also the first day of doing a new exercise program (aquarobics) but I was interested in the strength side as well so thought it might be a good combo to try. Having been hobbling around like a really old woman most of yesterday with muscle ache from the session, I was surprised to wake this morning and find virtually no muscle ache left - maybe the drink helped with processing lactic acid? There was also a significant drop on the scales this morning. Admittedly, I would have expected that with the levels of exercise

yesterday but while under the high stress situation I've had over 3 months of sustained and spiked calorie deficits which failed to show any results on the scales. Maybe there's a reason people head for sweet foods under stress? Re: the children growing overnight, there's some interesting research I came across over a year back now, so I can't remember where, that talks about how children's tastebuds are geared towards sweet over savoury, to the point of aversion to some savoury tastes - on a personal level I know I hated some things that I later became almost addicted to, eg avocado & coffee. This dovetails in nicely with the sleep/ growth hypothesis, I would think. Stuart, having experimented on going raw vegan, the 'raw' but heated honey may be because there's a definition of 'raw' that includes anything not heated above 105 degrees F, approximately (the exact figure varies, but the highest I've seen was 108). The idea being that the raw diet retains health properties because it doesn't kill off the enzymes in food through heating, so anything not heated above the point where they start to die off gets considered 'raw'. (We won't go into whether sustained low temperature heating via dehydrator a la 'gourmet raw' recipes also kills them, that's a whole other can of worms). Thanks Seth. You always give me food for thought ;-) Seth: That's a good point about children and growth. Yes, maybe that explains their sweet tooth. To make sure their brains have enough sugar when they are asleep.

Matt Dippl (2013-12-03 16:43:19)

I have the suspicion that this ritual before bed time might have a beneficial effect on gut flora for some people. Honey in a way is a prebiotic food that could feed beneficial bacteria. This could explain the weight and muscle gain because of improved nutrient absorption due to a well functioning gut. The well being in the morning could be due to improved neuro transmitter renewal again through better nutrient absorption. I will see if I can find some data and research on my hypotheses. Great article!

Michael (2013-12-04 10:07:22)

Hello Seth, the famous German Doctor Strunz (best selling author and doctor for preventive medicine) gives the following explanation: It is because of tryptophan! This amino acid competes with 6 or 7 other amino acids for the brain receptors. If you take sugar, the insulin sends the other amino acids to your muscles so that tryptophan gets to your brain. And will likely have still enough amino acids in your blood pool when going to sleep.

Seth Roberts (2013-12-04 11:01:05)

"It is because of tryptophan!" where does Doctor Strunz say this? I'll be surprised if he has any supporting evidence. Tryptophan does make people sleepy, but the honey improves sleep throughout the night, in a big way. I have never heard of tryptophan doing that - for example, improving how rested you feel in the morning. Nor do tryptophan-rich foods improve how rested you feel in the morning, as far as I know.

Annie Kolatkar (2013-12-04 16:31:53)

A human's first food is breastmilk which is incredibly sweet. All infants need sugars to fuel their impressive growth within the first year until they get transitioned to solids. Lactose is in great abundance in breastmilk because it is so easy for the infant gut to break down into two basic sugar molecules which are used for forming other items and energy. The brain is wired to encourage breast feeding. The actions of latching, sucking, swallowing trigger all kinds of brain responses and the reward is more milk in the mother as demands increase. We are hardwired for the taste of sweet. If you remove lactose from an infant's formula, the infant will not thrive. No other sugar comes close to lactose in the first year. There really is no substitute. And breastmilk usually puts a baby to sleep. Feeding is a lot of work and the growth of an infant is mind blowing. Fast forward to sugar when a baby is older. A connection between good feelings and having energy has been present since birth and is now in association with the taste of sweet. It is just a suggestion, but if you wish to look deeper into why we might be wired for sweet, I'd start there. (PS: I'm the mother of two!) And RS is fascinating to me. My 5yo daughter with Down syndrome instinctively eats cold starch. She has never been constipated which is typical of kids with DS. We raised her for 4 years on beef bone broth with lots of lactose and veggies. She is in great shape! Will check back for more info on RS. Thanks!

Annie Kolatkar (2013-12-04 16:35:14)

Sorry, I wrote "info on RS" but it is the honey research I am interested in since my daughter is not a great sleeper. It was the RS that led me here to your site. Too many browser windows open at the bottom of blog and not enough sleep! :-D

## Assorted Links (2013-11-07 05:00)

- [1]Genetics less important than claimed...again and again. The article's html name says "human genetics successes and failures" but the article is almost all about failure.
- [2]Why I left (tenured) academia. "We shouldn't expect [a college president] whose experience is in leading gigantic, dominant corporations to create an environment that rewards original, interdisciplinary, potentially disruptive research. Their previous success (such as it is) is from operating in an inherently conservative environment, running an organization that thrives in the *status quo*." It isn't just the college president. That such people are chosen as college presidents shows how little people at the top understand or value innovation.
- [3]Monitor Me. BBC TV show about high-tech self-monitoring. My self-monitoring is mostly low-tech, except for brain tests done with a laptop. My experience is that I needed to do everything right – good understanding of previous research, good experimental design, good measurement, good data analysis – to make progress. [4]A talk by Larry Smarr, one of the people in the BBC show, supports this. Smarr has colon inflammation. His design, measurement and data analysis are excellent. However, he chose to test treatments (antibiotics, steroids) known to be poor. They didn't solve the problem. It would have been wiser to try to figure what in the environment might be causing the problem. It certainly wasn't not eating enough antibiotics.
- [5]Fecal self-banking

Elizabeth Molin (2013-11-07 08:14:51)

Of tangential interest perhaps: I was recently moved to reread Frank Herbert's *Dune*, where I ran across the following: "Kynes knew that highly organized research is guaranteed to produce nothing new." The copyright of the book is 1965. Interesting that a science fiction writer had an insight back then that still escapes researchers today, nearly 50 years later... (And how scary to realize that that book is nearly 50 years old!)

dearieme (2013-11-07 13:32:51)

Ahoy, Seth. <http://www.independent.co.uk/life-style/health-and-families/health-news/preventing-flu-scientists-find-bacteria-in-japanese-pickled-turnips-which-could-boost-immune-system-8924768.html>

Seth Roberts (2013-11-07 16:00:05)

thanks, I just finished an Assorted Links post that includes a link to this research.

Seth Roberts (2013-11-07 16:22:10)

"Kynes knew that highly organized research is guaranteed to produce nothing new." I wouldn't go that far. I have learned very useful things from highly organized research. For example, 1. A big time use survey found that Americans stayed up an

hour later than people in 12 other countries. Also Americans watched TV an hour later. This suggested to me that TV could substitute for human contact in the control of when we sleep – a crucial step toward discovering the effect of morning faces on mood. 2. A big survey found that people who have insomnia are much more likely to get depressed in the following years than people who don't have insomnia. This too helped me discover the effect of morning faces on mood. I disagree that highly organized research can't find something new; what is more true is that the researchers who do such research are unable to take advantage of the new information. They are too wedded to certain methods, theories and so on, that worked well in the old ecosystem – the one that doesn't contain the new information.

Elizabeth Molin (2013-11-08 07:59:53)

Thanks for the more nuanced take. I was thinking of "highly organized" in the sense of hierarchical, the research being controlled "from on high," I guess.

### **Why Fashion Evolved (2013-11-09 05:00)**

[1]My theory of human evolution says that fashion (changing preferences for well-made goods) evolved so that artists – the innovators of long ago – would not do the same thing over and over. In [2]an excellent interview, music producer T Bone Burnett says something similar:

I don't believe in crowdsourcing [for artists] because you'll end up doing the same thing over and over again. People tend to want artists to do the same thing, and it is incumbent upon artists to do something that the audience doesn't want – yet.

I've had a hard time finding interesting work by economists on the causes of innovation. It isn't just institutional structures ("extractive" versus "inclusive"), as Acemoglu and Robinson say in *Why Nations Fail*. (Better title: *One Reason Nations Fail*.) An exception is Nathan Rosenberg, an emeritus professor at Stanford, for example [3]this paper about aircraft design.

---

dearieme (2013-11-10 08:04:35)

Long ago I worked at a university with a famously good medical school. I asked what sorts of dexterity tests were applied to the candidates for admission. "None." I suppose that the ancient test of tossing 'em a cricket ball and seeing if they could catch it was viewed as infra dig. Seth: This reminds me of when I asked a Berkeley professor of epidemiology about his upcoming introduction to epidemiology class. "Do you cover what causes immune function to get better or worse?" No, he said.

Nancy Lebovitz (2013-11-10 20:38:58)

Catching a cricket ball may or may not be relevant– as far as I can tell, there are many kinds of dexterity. I became a good calligrapher rather easily, but throwing and catching are my strong points.

Greg (2013-11-11 06:01:41)

The Japanese pickle microbe study was conducted by a food company with a probiotics business. Yet somehow the authors declare "no competing financial interests."

Zach H (2013-11-11 07:10:34)

Seth, have you seen this article? <http://www.nytimes.com/2013/11/10/business/the-co-villains-behind-obesitys-rise.html?src=me&ref=general> Have you considered the possibility that the Shangri-La diet works by modifying gut flora? Seth: No. the appetite reduction is very fast, too fast to involve modification of gut flora.

Seth Roberts (2013-11-11 15:04:01)

"The Japanese pickle microbe study was conducted by a food company with a probiotics business. Yet somehow the authors declare "no competing financial interests." good point.

Nancy Lebovitz (2013-11-11 16:56:15)

Typo: I meant to say that throwing and catching are NOT my strong points.

## **How to Write (and Teach): Tell a Story (2013-11-11 05:00)**

[1]A Lifehacker post by Leo Widrich said you should tell a story instead of giving a Powerpoint presentation with bullet points. Widrich did not make his point using stories. He made the written equivalent of a Powerpoint presentation. He wasn't trying to be funny – at least, not that I could tell.

This semester I'm teaching a class on Academic Writing. Yesterday's class marked the switch from personal statements to other sorts of writing. I decided to mark the transition with a lecture. I had just one piece of advice for my students: tell a story. For fun, and to avoid the oddity of Widrich's presentation, I decided to make my point two ways: without and with stories.

The without-stories presentation was obvious. I wrote "Tell a Story" on the board and gave several reasons why it was a good idea.

The with-stories presentation was not obvious. I told several stories:

1. The morning of the class, I was listening to [2]a C-SPAN podcast – an interview of S. Lochlann Jain, a Stanford professor of anthropology who had written a book about cancer. She herself had had cancer. The interviewer asked: When you got the diagnosis, what did you need? It was a good question. But Jain did not answer it. Instead, she pontificated for a few minutes. It was unfortunate. That answer was like the rest of the interview (she pontificated a lot) and I soon turned it off. She could have told a story, I told my students, but she didn't. And she lost me.

2. I came to understand the power of stories while teaching introductory psychology. My classes were large, hundreds of students. I discovered that to get their attention all I needed to do was tell a story. Within seconds, they would start to pay attention. The lecture hall would become quiet. If I stopped telling a story, I would start to lose them. I could see their eyes wander. That's how I came to teach all my classes: tell one story after another. One of my students told me I was "the professor who tells stories".

3. One day I was in the biology building on the Berkeley campus. It contains many small classrooms. From the outside, you can hear what the instructor is saying. I listened to five classes. In none of them was the teacher telling a story. Apparently most Berkeley professors hadn't figured out this basic principle.

4. I attended [3]a high school graduation in Los Angeles. Very expensive private school. There were six speakers, four students, a teacher, and the headmaster. No one told any stories. I was astonished. It's really hard to be a graduation speaker. This simple rule (tell stories) makes it much easier. None of them knew it. I was especially

surprised that the headmaster, who speaks at graduation every year, failed to understand this. Failing to tell stories in this situation is like choosing to crawl when you could walk.

5. A remarkable thing about stories is that anyone can tell one – or not tell one. The weakest person can tell a story, the most powerful person can fail to tell one. When President Obama was elected, it was very uncertain whether he would be a good President. He had so little experience. [4]I used his inauguration speech to guess how good he would be. If he understood politics, he would tell stories; if he didn't, he wouldn't. In fact, he didn't. Five years later, my low expectations [5]have been borne out. Chinese politicians, as far as I can tell, are not clearly better than President Obama. At the beginning of a student talent show at Tsinghua, a Tsinghua administrator gave a short and boring speech. He too failed to tell stories.

I said it made sense that we pay attention to stories much more than to other things. Stories are fundamentally honest. They contain evidence. If you draw a conclusion, fine – your evidence for that conclusion is clear. You are not overstating your case. Without evidence, anyone can say anything. I also said it is to your benefit to tell a story rather than argue or reason or pontificate. You will appear modest and considerate.

I asked my students to compare the two ways (without and with stories) I had made the same point. There were three possible answers: 1. without stories better. 2. equal. 3. with stories better. Their votes:

without stories better: 1 vote

equal: 2 votes

with stories better: 6 votes.

My students said they had not been taught this. Their teachers – in high school and at Tsinghua – did/do not teach this way nor had they made the general point I was making.

Thanks to Dave Lull.

pond (2013-11-11 07:01:07)

In the last years of her life, my mother told stories, but I always considered it a mark of her mental decline. For example, I wanted her to get to the point and tell me, "John called and invited us to eat out with them." Instead she told a story: "The phone rang, and when I answered it, John said Hello, and I said, Well we haven't heard from you in a long time, and he said he was sorry, but they had been very busy. Anyway, he said that when they got home today, the dog ... [shortened here for your patience] ... and so they were going to eat out. Wow I said, that was awful. Well, he said, would you folks like to come

with us? It's our treat." Maybe I could say this was a bad story, bad storytelling. But I always thought this was the way her mind worked then, that she could not logically sum up a point, but had to reconstruct every moment, starting at an early time, and proceeding blow by blow chronologically until finally reaching the point - the reason why she was telling us this.

dearieme (2013-11-11 12:44:52)

I once started a seminar with "I want to tell you a story". Many of the research students in the audience stirred uncomfortably. Golly, research students en masse are a woefully conservative, unimaginative lot. To generalise: among the brightest undergraduates, those who do not go on to research tend to be a more impressive mob. Is that your experience? Seth: I don't know. At Berkeley almost none of my students went on to do research. At Tsinghua, almost all the students do. It's also true that my Tsinghua students are more impressive than my Berkeley students but there are a hundred other differences between them.

jtw (2013-11-11 18:39:44)

Seth, could you give an example of how you taught technical material (as in your introductory psychology classes) by telling stories? I get the principle but not the practice.

Alex (2013-11-11 18:46:51)

Wow, that's a helpful insight. In order to make good choices about my mini-me kid's homeschool education, I've been examining what I know and how I learned it, versus the stuff I forgot right after finals. I studied computer science, but almost everything I learned for my major came from the textbooks and projects. The class lectures added so little. I also got a minor in philosophy, for the hell of it. I remember far more of the lectures in philosophy classes, though the subject was intrinsically less interesting to me than computer science. I've been trying to figure out why, and I think you just nailed it. Philosophy class lectures were often built on stories. Computer science lectures tended to be bullet-point presentations of textbook content. I'd figured out on my own that I should emphasize hands-on projects over repetitive drills. But you've added two valuable insights to my teaching: walk instead of sitting, and tell stories. Thanks! Seth: hands-on projects need to be built on something else, I think. I tell my students stories before I assign hands-on projects.

Seth Roberts (2013-11-11 22:06:12)

"Seth, could you give an example of how you taught technical material (as in your introductory psychology classes) by telling stories? I get the principle but not the practice." I teach technical material, I suppose you would say, when I teach statistics. I tell stories about data analyses I have done. The situation, the question, the data, the analysis, the conclusion. In introductory psychology, I might tell the story of how the researcher came to do a certain piece of research, then describe the research. Or a story that illustrates the broad point made by the research.

Portlander (2013-11-11 23:41:45)

My kids attend a Waldorf school. The pedagogy is incredibly story-centric. (I've been calling it narrative-based.) Even basic math is introduced as a narrative where each operator given a name for a character corresponding to what the operator does: gather/add, give-away/subtract, share/divide. I forget what multiply does. I do remember place value is introduced as a narrative of a boy picking up stones on a river bank. The stones are picked up one-by-one, but he can only hold nine stones in his hands. No matter how careful the boy is, whenever he picks up a tenth stone he drops one. So he puts the nine, plus one more, into a pouch. But he only has room for nine pouches on his belt. So when his belt gets full, he takes all the pouches from his belt, plus one more, and puts them into a basket. In turn the baskets get very heavy. So heavy that he can only hold nine of them at a time. So nine baskets, plus one more, all go into a cart. Teachers also light a candle before telling the stories. That really focuses the children's attention. You can hear a pin drop in a classroom of 25 first graders. I've heard from my wife that on days she is picking up my daughter from 1/2 day kindergarten, my 3 y.o. son insists on stopping and listening to the first grade's story if when they walk by the door is left open and the candle is lit. He just stops and quietly listens in from the hallway. Seth, you might want to give the candle thing a try. ;) Seth: That's great! I agree, how can I try the candle idea? Somehow the whole story thing is missing from Teach Like a Champion, a distillation of the best teaching techniques from schools across America. Even though Waldorf schools do it, which I didn't know. I will say, however, that I believe in telling true stories. Maybe that is much harder with young children.

Portlander (2013-11-11 23:47:23)

BTW, which do you remember better: that the arithmetic operators are anthropomorphized, or that place value is introduced through a story about a boy picking up stones? :)

Alex Chernavsky (2013-11-12 05:12:23)

MBA courses typically use a lot of stories (called "cases") . Typically, the cases describe some real-life quandary that was faced by a business organization in the past. The students have to analyze the material in the case and come up with a recommended course of action. Harvard publishes a lot of these cases.

dearieme (2013-11-12 07:05:44)

There's a yarn about a young academic saying to an experienced hand "the students want me to illustrate my lectures with practical examples. What would you do in my shoes?" Answer: "I'd show them some." The original point of the joke was that young academics often lack any store of practical examples. But I'll add to it that I used often to tell stories as my way of presenting practical examples. Of course a dim, earnest student may demand to know whether this story will help him pass his exam: only near retirement is it wise to punch him on the snoot.

RicciM (2013-11-12 11:37:00)

Raconteur stories as learning ? "I hear and I forget. I see and I believe. I do and I understand." – K'ung Fu-tzu

Seth Roberts (2013-11-12 12:38:26)

"I hear and I forget. I see and I believe. I do and I understand." Yeah, how come stories aren't in there? The old saying really misses something. You do not hear a story and forget. Quite the opposite.

dearieme (2013-11-12 13:45:47)

Well, if it's Kung Fu versus Homer, Homer wins.

Portlander (2013-11-12 14:46:30)

**[H]ow can I try the candle idea?** I think the point of the candle is to help with the signal to noise ratio in elementary classrooms. And by noise, I'm not talking about cacophony, ;) rather instructional noise. When the teacher lights the candle she is emphasizing that the next 10-20 minutes are going to be nothing but signal. The sub-text is "pay attention, because this is new and it's going to be on the final." Obviously if she lit a candelabra every morning and let it burn through the day it would not have the same effect. As for trying it out, I think you could light a candle at some point in your lecture. Perhaps 1/2 the time at the beginning, and half the time at 1/2 way point. Then measure if students show more interest, either through follow-up discussion questions or project work or answering test questions correctly on candle topics vs. non-candle topics. If specific points within a lecture is too arbitrary, you could also try it on completely different days. I think, though, for it to work, you can't let on that you're doing it arbitrarily as a way to "trick" the students into paying extra attention. The point of the candle is you are out-of-band communicating to them the impending presence of an atypical SNR. Well, that's my hypothesis anyway. I could be wrong. :) Seth: The notion of signalling stuff so that the body or brain can get ready to receive it is a good one. It is the whole idea behind classical (Pavlovian) conditioning. I completely agree this is a good way to teach young children. Yet it is still unclear to me how this would work in a college class.

Jenny (2013-11-14 10:32:45)

I was interested in your story telling - and then realised that the economics book I was reading - "Bet the Farm" was being told as a story. Brilliant - it enabled me to a) finish it and b) remember a lot of it. If it had been told as dry economics, I doubt if I would have got through it.

Jenny (2013-11-14 10:40:26)

Re K'ung Fu-tzu, if you can 'do', it is even better. The Shetland fiddler, Tom Anderson used to teach kids to play tunes. But he

would play them tunes to dance to for several days - and then teach them the tune (by ear) which they could then easily play because they 'knew' the tune.

Arndt (2013-11-19 09:21:21)

People seem to be less resistant towards examples and arguments if they are presented in a 3rd person perspective rather in a 1st or 2nd person, like if somebody does xy versus if I / you do xy. The words I and you seem to turn on an emotional resistance in people and they don't think about what is said. I think story telling uses the 3rd person perspective.

### **Orange Glasses at Night Improve Sleep (2013-11-12 05:00)**

After I discovered that [1]morning faces improved my mood, I tried to maximize the effect - determine the the best time, distance, size, and so on. One evening I went to a screening (Taxicab Confessions) at the UC Berkeley journalism school. It started about 7:30 pm and lasted about two hours. Over the next few days, I discovered that the morning-faces effect was gone. It took a few weeks to return.

The problem, I realized, was the room lighting. The auditorium, like almost all campus rooms, was lit with fluorescent lamps. Maybe they were off during the film (one hour?) but they were on before and after. Fluorescent light, in contrast to incandescent light, contains lots of blue. The faces effect, I knew, depended on a sunlight-sensitive oscillator, which determined a critical period during which faces made a difference. That oscillator was much more sensitive to blue light than red light. If that oscillator wasn't working properly - e.g., its amplitude was too low - the faces effect disappeared. Normally I never experienced fluorescent light at night. There were no fluorescent lights in my apartment, including the bathroom. Cafes, restaurants, my friends' living rooms, and so on - all incandescent light. Incandescent light has very little blue.

I hadn't realized that ordinary fluorescent exposure could cause trouble, but now I did. After that realization, for many years I avoided fluorescent light at night (= after 8 pm). To get home from San Francisco in the evening, I took a cab to avoid fluorescent light on BART. No fluorescent-lit restaurants for dinner, no late-night supermarkets or drug stores. It was bearable, but not pleasant. Except for the Berkeley campus, where students were getting messed up by evenings in libraries, the city of Berkeley was innocuous, but big cities, such as New York with their late hours and heavy subway use, were terrible, exposing residents to lots of fluorescent light at night. Depression [2]may be more common in urban areas than rural areas.

Eventually I realized I could solve the problem with "blue-blocker" glasses - i.e., orange-tinted glasses - that block blue light. (I use [3]these, \$7.) Now I could live normally, except for looking funny now and then. I wore the orange glasses a few minutes last night in a 7-11. Concerned about blue light from LED screens, I also wear them between 9 pm and 5 am when looking at a computer screen. Although compact fluorescents (replacing ordinary light bulbs) have come along, and incandescent lights may be outlawed, my apartment is still all incandescent. The light from compact fluorescents [4]has a lot of blue. Because I had no doubt that fluorescent light at night was bad because of the blue light, I never bothered to measure the effect of the blue-blocker glasses. This might have been a mistake.

Last June, at an evening meeting in under fluorescent lights, an Oakland woman saw me wearing orange glasses. She'd read about them on [5]my blog. Sixty years old, she'd had poor sleep for decades. "It was a quick and easy thing I could try," she told me. "Not a supplement or med." She already took many of these.

The first evening, she put on the glasses at 8 pm. She'd had a lot of energy when she put them on, but 15 minutes later she fell asleep. She only slept for 30 minutes, but the incident suggested great promise. She got into a routine where she put them on when she got home, usually between 8 and 10 pm. The results:

All summer long, I slept better than I have slept in my entire life with these glasses. I haven't had sleep problems until the last couple of weeks. Most nights I sleep through the night. If I get up, it's to go to the bathroom and I quickly go back to sleep. Completely unknown to me in the last couple of decades.

In other words, they helped a lot. It used to take her about an hour to fall asleep. She would take 3 tryptophan pills (= 2.5 g of tryptophan) at bedtime, and then 3 more every 20 minutes she was awake. She ended up taking 6-9 every night. After she started using the orange glasses, she continued the tryptophan but found almost never took 20 minutes or more to fall asleep.

Is she unusually sensitive to blue light? Does she get more blue light at night than the rest of us? Is it a placebo effect? Her house is full of compact fluorescents (she used to work on energy policy) and she spends a lot of time in front of a big (26-inch) computer monitor and a 46-inch TV. They may make things worse, but none of the three (compact fluorescents, big computer monitor, big TV) was around decades ago, when her sleep was also bad. The effects may go beyond blue-light elimination ("when I put them on my world is relaxed," she said) but the notion that this is a placebo effect is contradicted by the many things she tried that didn't help, not to mention the many experiments showing that blue light affects circadian rhythms.

I'd heard vaguely of sleep improvements. For example, [6]Chris Kresser wrote "I've had many patients swear by these goggles". Chris himself, however, rarely used them unless he was looking at electronic devices (like me). "If I notice that my sleep is starting to get funky, I'll wear them," he wrote, but otherwise not. I knew that I got the faces effect - which was huge - without needing to wear them at night, so I had assumed that ordinary (incandescent) evening light was harmless. However, this story, because the effect is so large, makes me question that assumption. I will try wearing them in the evening even when I am not looking at a computer screen.

[7]Orange glasses improve sleep in a naturalistic experiment compared to other glasses. Subjects put on the glasses three hours before going to sleep.

---

GeoffD (2013-11-12 05:56:49)

I've worn them for about 4 months now. They go on every night at 8:30. I'm sound asleep by 10:00. I sleep like a rock straight through. I had a 3 am wake up every night for at least the 3 full years prior to using the goggles. I read every night on an iPad before bed. The benefit to the blue blocking is huge. Seth: That's good to hear. I've been using them at all times recently, instead of just when looking at computer screens.

Frankr (2013-11-12 06:02:16)

This is interesting news. I will try it out. Have you ever tried drinking a cup of milk a few hours before sleeping. I recommend it. I sleep better when I do that.

Xav (2013-11-12 06:56:02)

There's a very popular piece of free software called f.lux ( <http://justgetflux.com> ) which subtly changes your computer display so that it matches the time of day. Lots of programmers have mentioned on various forums I read that it helps with sleep.

dearieme (2013-11-12 06:59:47)

We still use incandescents, having stocked up before the light bulb Nazis' deadlines. In my office (before I retired) I kept the overhead fluorescents off as much as possible and worked with desk lamps. How about LED lights: do they have any ill effects? Seth: I too kept my office lights (fluorescent) off as much as possible.

ChrisB (2013-11-12 07:43:22)

I get this effect from using "flux" on my Mac. This app turns the screen to a red cast at sunset, I go to the strongest setting of tungsten. It takes 15-20 minutes of web browsing in bed and I irresistably fall asleep. Been doing this for over a year. My evolutionary explanation - humans sitting around the campfire at night, safe to go to sleep...

MaxPower (2013-11-12 07:59:59)

Hi Seth, For a couple of years now I've using a computer program called "f.lux" which auto adjusts the color temperature of your computer screen based on time of day and latitude/longitude coordinates. I find it incredibly helpful since I often work on my computer at night.

Brian Toomey (2013-11-12 08:01:34)

Hi Seth, I've been using prescription orange glasses recently. I had bought cheap ones to wear over my prescription lenses. They helped my sleep, but the dual set of lens was annoying so I was very inconsistent with them. I have low blue light light bulbs in my house and have been putting them on at around 5pm and falling asleep around 11pm and sleeping better than ever before. I've only been doing this for 2 weeks, but I am very confident that they are improving my sleep. Seth: I didn't know about low blue light bulbs...how interesting!

Alex (2013-11-12 08:20:49)

Dearieme, regular LED bulbs are also more blue than incandescent bulbs. But you can buy LED bulbs that allow you to adjust the color. At home we are trying Philips Hue LED bulbs, which can be timed to shift colors on a schedule controlled from an iPad. We skew blue in the morning, bright white most of the day, orange at dusk, then red in the evening. The Hue system is spendy, \$200 for three bulbs and a controller. There are also fairly inexpensive (about \$20) LED bulbs that can be manually changed to different colors throughout the day via a little remote control. We started off with one over our kitchen table, and we liked it enough to try out the Hue bulbs. Seth: That's great news. For everyone. I have been very worried that the new LED bulbs will be too blue. I didn't know about adjustable ones.

David (2013-11-12 09:00:50)

There's a free software project out there called f.lux\* that changes the color temperature of your computer screen over the course of the day. It adjusts based on your geographical location and time of day, so it can make the display redder as soon as the sun goes down outside. I've got my laptop set up to switch between 6400K during the daytime and 2300K (dim incandescent range) once the sun goes down. I don't have much data on the effects yet. Although I have noticed that since I've started using f.lux I haven't been on any code-until-3-AM benders. \*<http://justgetflux.com/>

John Kojis (2013-11-12 10:03:12)

I had read about this and got some cheap orange/yellow motorcycle glasses that were bifocals, perfect for evening screens with my older eyes. These worked well, I got sleepy an hour after I put them on, and in a way that I didn't want to fight with to

stay awake. I then decided to spring for a more expensive pair from lowbluelight.com, and they worked even better, perhaps placebo I thought since they cost 5 times as much. I compared the two in looking at a pure blue nightlight I had taken out of the bathroom, and the cheap ones blocked 90 % of the light, made it look brown. When I put on the expensive ones, I had to check to see if the light was on, there was no light at all- I was shocked by the difference. I have no connection to the low blue light people, though they were very helpful on the phone.

Sam (2013-11-12 11:36:05)

For computer monitors there is a program that runs in the background and automatically removes blue at dusk - F.lux - try it.

Seth Roberts (2013-11-12 12:39:47)

"For computer monitors there is a program that runs in the background and automatically removes blue at dusk - F.lux - try it." I did try it. I saw no difference. Whereas orange goggles do seem to make a difference.

Sentinel (2013-11-12 13:34:12)

I use Shades (free download) instead of f.lux. It allows you to make the screen really, really red or amber, etc. (you can choose your tint color from a color palette; the screen ends up darker overall than with f.lux, and 'blue' more or less disappears from your field of vision). Note that if you run f.lux and Shades simultaneously in order to get some uber-effect, the screen starts flickering spasmodically.

Richie (2013-11-12 14:18:38)

When I first started using f.lux several years ago, the program was only able to reduce the color temperature to 2700k, which is equivalent to an incandescent light bulb. At this setting I think it still emitted too much blue light to be effective. However, the recent f.lux update now allows for a color temperature as low as 1200k, which emits less blue light than a match flame. I find this setting to be as effective as wearing orange glasses. Stephan Guyenet had a similar experience with the new f.lux update that he shared in a recent post: [http://www.dansplan.com/blog/2476-f-lux-a-free-computer-program-that-may-impr](http://www.dansplan.com/blog/2476-f-lux-a-free-computer-program-that-may-improve-your-sleep) ove-your-sleep Seth: That's good to know. I used it several years, haven't tried the new version.

vgm (2013-11-12 14:53:40)

My understanding is that blue light inhibits the production of melatonin via the pineal gland. I have been reading to an orange light bulb that I bought on Amazon before going to bed. It seems to be effective, but I do not know if it is real or placebo.

Richard Sprague (2013-11-12 16:18:24)

My quick look at those low-blue light bulbs make me think they must be ordinary orange color bulbs, similar to what you put outside in order to have light without mosquitoes. Come to think of it, maybe that's why those mosquito lights work: insects are attracted to blue lights because it stimulates the same thing it stimulates in our brains.

Justin Irving (2013-11-12 20:55:03)

Seth, I've been using the similar (Uvex S1933X) glasses for about three months. Everything you've written is in line with my experience. I put them on when the sun sets and have them on for the rest of the night (unless I go out that is). Along with honey before bed and magnesium tablets, this has me sleeping like a dog (this is good). I've also switched to wearing Gunnar Optiks brand computer glasses at work, to hopefully cut down on excess blue light from the fluorescent lights and the monitors. I recommend these as well for people who have to work on computers all day.

I've solved everything. | Koanic Soul (2013-11-12 23:15:45)

Theragingwalrus (2013-11-13 14:48:11)

Short wavelengths and melatonin production suppression is old news, but is there also a reason to wear orange glasses if you take melatonin tablets? From looking at models of human circadian rhythm on pubmed, there's still a lot of question marks, so science doesn't seem to have found the answer, but maybe a commenter can fill us in here?

Seth Roberts (2013-11-13 17:25:55)

"is there also a reason to wear orange glasses if you take melatonin tablets?" Yes. Because orange glasses probably come closer than melatonin tablets to reproducing the long-ago environment that shaped our sleep/wake system. Long ago humans got very little blue light at night – like what happens when you wear orange glasses. Long-ago humans did not ingest lots of melatonin. With orange glasses, it is much more obvious what the best dose is likely to be (no blue light at all). With melatonin, it isn't easy to figure out the best dose. But there is no need to lean on theory, you can just try them. It might be easier to take melatonin tablets, I don't know.

[...] Orange Glasses at Night Improve Sleep [...]

the Revision Division (2013-11-15 07:59:27)

[...] IMPROVE YOUR SLEEP with orange glasses. [...]

Suzanne (2013-11-18 07:09:43)

Seth thanks for the post and all the comments from readers. I've made a variation as I was too impatient to wait for my glasses: <http://suzanneloomscreativity.blogspot.co.uk/2013/11/working-with-insomnia-4.html>

## **More About Sleep and Honey: One Teaspoon (2013-11-13 05:00)**

[1]One of the comments on [2]my honey-improves-sleep post deserves emphasis:

I tried the honey last night for the first time – just 1 tsp. I've been eating very low-carb lately, so no sugar throughout the day at all. . . . When I woke up for the day . . . I felt an incredible sense of well-being. Normally, I wake up with aching hip joints and feeling pretty ugh, but not this morning. My sense is that the sleep was "richer" . . . in the way that heavy cream is different from skim milk.

I asked the commenter for an update. She replied:

I'm still seeing improved sleep. Last night, I think I slept for 8 hours straight, or darn near, which has only been possible with an Advil-PM over the past 6 months or so. One of the notable changes in my sleep is vivid dreams. I recalled them pretty clearly the first night, less so since then; I just know that I've been dreaming. I am using approximately 1 teaspoon of honey, taken on the way to bed. Since starting it, I have taken extra care to avoid sugar and starch during the day, as well. I plan to continue it indefinitely.

I too found that one teaspoon of honey made a clear difference, as did Stuart King, who described the effect. I've been taking one tablespoon to be sure to get the greatest possible benefit; eventually I will test smaller amounts.

I don't know of another case where one teaspoon of an ordinary food produces a big improvement. One teaspoon (5 ml) of orange juice has about 2.5 mg of Vitamin C. The daily requirement of Vitamin C is about 80 mg/day. (Whether you should take much more, [3]as some say, is quite unclear.) If you get less than 10 mg/day for a long time, [4]you'll

get scurvy. According to [5]this table, the common foods highest in Vitamin C, such as orange peel, have about 1 mg/g. One teaspoon of honey is 7 g, so from 7 g of a common food high in Vitamin C you'd get 7 mg of Vitamin C. And keep in mind that scurvy is very rare, but bad sleep is common. Which makes the effect of one teaspoon of honey even more striking.

---

Keimpe (2013-11-13 05:27:28)

One practical question (I don't know if it's been asked before, I haven't read the comments to earlier related posts yet): when do you brush your teeth? Before or after taking the honey? Seth: I brush my teeth in the morning.

Keimpe (2013-11-13 06:47:52)

In the morning!? With a self-quantified reason? Because I figure in the evening would be a better moment: you brush away the stuff you accumulated during the day so the bacteria won't do you harm at night. Seth: I haven't compared evening versus morning tooth-brushing. Maybe I should, you're right. I have noticed that tooth brushing wakes me up, but the effect doesn't last long.

Keimpe (2013-11-13 06:51:52)

Having said that (feel free to merge my multiple comments into one) I have read that sugar (and therefore honey as well) is not the main culprit of caries, because it is actually a preservative (that's why marmalade lasts so long) so it would be illogical to assume that it causes caries. It might even protect your teeth! Mind you, I'm not volunteering to try this at home.

Matt (2013-11-13 07:25:02)

Do you plan on testing comparable amounts of white table sugar? It would be interesting if there was something about the honey that was better for sleep than sugar. But it seems almost inconceivable that's the case. Also, I've always wanted you to test an equal amount of beef tallow in place of butter to see if it has any effect on your arithmetic speed. The fats composition should be mostly the same, except that butter will have significantly more butyrate and 6 and 8 carbon fatty acids. The micronutrient content would be different as well, with butter having a significant amounts of some vitamins like A and D. Seth: Testing sugar is a good idea. Beef tallow is hard to get, not so clear why I should test it. Pork fat was worse than butter.

GB (2013-11-13 07:37:04)

Seth, have you tried the honey with a nose-clamp? I'm wondering whether the taste buds are an important indicator to the brain, or whether just the presence of glucose/fructose is enough without the taste effect. Seth: No, I haven't tried that. Good idea.

Rudy (2013-11-13 07:37:45)

Does it need to be raw honey? Are people getting the sleep effect from every kind of honey?

Keimpe (2013-11-13 07:51:33)

Why should Seth do all the testing? Come on guys (and gals), let's get to it. Matt, you take the sugar, GB, good luck with the nose-clamp. Me, I'll do my first (dark and raw) honey experiment tonight. Results first thing in the morning please, right after a solid tooth brushing session :-)

Chris Sturdy (2013-11-13 08:15:26)

I often eat raw local honey, often mixed with some sunflower seed butter, before bed. If I try to read a novel after this, I often find myself nodding off very quickly. Seth: Maybe I fall asleep faster now that I eat honey before bedtime...but maybe not. It isn't obvious, whereas the improvements in how rested I feel in the morning and strength are obvious. I am trying to figure out if honey affects how fast I fall asleep.

Gaspard (2013-11-13 08:59:32)

A possible explanation is that people on lowish carb sometimes have disrupted sleep related to ketosis, and the carbs remove the underlying stress caused by slight ketosis to enable the body to rest. This is from Dr Eades in 2009: "Sometimes for some people being in mild ketosis interferes with sleep, especially falling asleep. For those people (including myself) I often recommend a little herbal tea WITH sugar or honey before bedtime. The teaspoon of sugar or honey adds about 5 grams of carbs, which isn't a whole lot, but is usually enough to shut down ketone production for long enough to allow sleep." Scroll halfway down this page: <http://www.proteinpower.com/drmike/low-carb-diets/why-is-low-carb-harder-the-second-time-around/>

Charlie Currie (2013-11-13 10:01:18)

Over at Richard Nikoley's blog, Free the Animal, he has a running series on resistant starch, which is primarily about blood glucose control. However, one of the unexpected and pleasant effects (affects? I can never get that right) of consuming resistant starch, primarily in the form of unaltered potato starch, is improved sleep along with vivid, technicolor dreams. There has yet to be any discussion of honey at bed time.

Joe (2013-11-13 13:07:26)

Read this book, Seth: Kiss Your Dentist Goodbye, by Ellie Phillips, DDS. Hunch: You'll never eat honey before going to bed again. Not without brushing, etc., afterwards. And again in the morning. Seth: That's strange, I have read it. Before I realized that honey improves sleep. I guess I'll read it again, I agree that you have a good suggestion.

Seth Roberts (2013-11-13 14:11:12)

Eades: "Sometimes for some people being in mild ketosis interferes with sleep, especially falling asleep. For those people (including myself) I often recommend a little herbal tea WITH sugar or honey before bedtime. The teaspoon of sugar or honey adds about 5 grams of carbs, which isn't a whole lot, but is usually enough to shut down ketone production for long enough to allow sleep." I had no trouble falling asleep, yet I found that a teaspoon of honey made a big difference.

Seth Roberts (2013-11-13 14:15:25)

"Does it need to be raw honey?" No. I haven't tried raw honey.

Joseph Cohen (2013-11-13 14:38:14)

After a few months in ketosis I too found that my sleep length and quality diminished. Last night I ate potato before bed and for the first time since starting a ketogenic diet I slept soundly, had vivid dreams, and recovered libido. Perhaps the potato is having the same effect of the sugar in honey.

CC (2013-11-13 15:30:04)

Am I missing something here, or are we all supposed to brush our teeth before bed AND in the morning? Seth: I don't know. I need to reread Tell Your Dentist Goodbye.

Bruce (2013-11-13 16:32:59)

I've had no trouble falling asleep since I started taking Vitamin D in the morning. I started a tablespoon of honey a week ago, and the effect was instantaneous. My sleep now is almost luxurious, and I am waking up more rested. I take the honey, brush my teeth (and floss), rinse with my healthy-teeth mouth rinse, and then go to bed.

Matt (2013-11-13 17:19:03)

My thinking with testing tallow versus butter is that you could perhaps narrow down the specific cause of the effect. Is it just more saturated fat, or something that is specific to butter? Given that butter is better than pork fat (which has plenty of saturated fat), it seems likely that it is specific to butter. If it's specific to butter, then it seems likely that it's due to the SCFSA in butter (lots of butyrate, and some 6- and 8-carbon fatty acids). And since coconut oil has lots of 8-carbon fatty acids but no butyric acid and doesn't produce the effect, I think that it's likely that the effect you notice is due largely to the butyric acid in butter. Tallow is a good experiment here because if you get similar performance to butter then that would be good evidence that pork fat is worse than beef fat because something in the composition (probably the high polyunsaturated fat) is worse for your brain than the beef fat composition. If tallow is similar to pork fat, then it would be evidence that something in the composition of the dairy fat specifically (likely the butyrate in my opinion, maybe the vitamin A) is what is of particular benefit.

Darrin (2013-11-13 19:52:18)

Hi Bruce, Are you still taking the Vitamin D in the morning (as well as the honey before bed)?

Pj (2013-11-13 23:46:12)

Hi Seth Were you aware that consuming sweets later in the day improves response to light therapy for seasonal affective disorder? This seems like it could be related to consuming honey at night. You can find the paper in Psychiatry research 46: 107-117. The authors are Kurt Kriiuchi, AnnaWirz-Justice, and Peter Graw. Seth: No, I didn't know about this. Fascinating.

Louise (2013-11-14 04:04:17)

Well I've had a teaspoon of honey up to an hour before bed for the last three nights. It has not helped me get to sleep quicker, but I am finding that I wake up earlier. I can only assume this means my sleep has been deeper. I have also had some fairly odd dreams. It is quite rare for me to remember dreams. I also seem to be losing weight and have changed nothing else in my diet or daily routine.

Keimpe (2013-11-14 04:04:51)

Tried a teaspoon of honey last night with no effect. But I must say I had friends over, so I had several beers, and since alcohol always makes me sleep deeper but shorter (and the sleep seems of lesser quality), this was not a good night to test it. But I felt obliged to do it and report back here after my comments yesterday. I'll report back again when there's something to report. Oh, Seth, and if you're planning on re-reading "Kiss your dentist goodbye", you may want to pick up "Cure tooth decay" by Ramiel Nagel as well. Seth: I can't say 1 teaspoon is the best possible dose. The best dose might depend on body weight. If you are uncertain whether there is any effect, you should use a larger dose, such as 1 tablespoon, so that if there is no change it is unlikely that the dose was too small.

Jeff Winkler (2013-11-14 04:34:23)

If anyone has a Zeo, would be interested in deep/REM sleep measurement. I'll check if mine's still working. When I was using the Zeo heavily, was always amazed how inaccurate my subjective impressions of sleep quality/wakeups were.

GeoffD (2013-11-14 05:46:23)

I'm 172 5'11". Dose of 1 teaspoon raw organic. 50 % improvement in sleep quality. I currently also use blue blocking goggles from 8:30 pm on. I also sleep on a grounded sheet. Only one night in, but I'm optimistic. Sleep is the key to health.

GeoffD (2013-11-14 05:49:17)

Note: I mixed it with a teaspoon of coconut oil to blunt the insulin effect. I have done coconut oil alone before bed with no noticeable effect.

Seth Roberts (2013-11-14 07:01:47)

"When I was using the Zeo heavily, was always amazed how inaccurate my subjective impressions of sleep quality/wakeups were." Did you consider the possibility that it was the Zeo that was wrong, not your subjective impressions?

Joe (2013-11-14 09:38:22)

"Am I missing something here, or are we all supposed to brush our teeth before bed AND in the morning?" Only if you want to keep your teeth! And it's not enough to just "brush." You need to use the right kind of brush, use the right kind of mouthwash, maintain the proper PH level, eliminate harmful bacteria, etc. You'll notice the difference IMMEDIATELY. And since dental health is so important for HEART health, maintaining proper dental health can literally save your life.

Paul (2013-11-14 11:10:26)

I don't know if this brushing mouthwash thing is true. My gums seem better when I only brush once a day. I get less bleeding with gums and no soreness. I also eat fermented foods and not much sugar. I think there's something to Seth's bacterial space competition theory. If brushing and mouthwash, etc is so necessary, how do you explain the excellent oral health of pre-agricultural remains? [http://www.npr.org/blogs/health/2013/02/24/172688806/ancient-chompers-were-he](http://www.npr.org/blogs/health/2013/02/24/172688806/ancient-chompers-were-healthier-than-ours?ft=1&f=1001) althier-than-ours?ft=1 &f=1001 Hell, my cat doesn't need to brush his teeth and they're all perfectly white. I feed him a 100 % animal meat/organ diet. I'm also not sure that good dental health CAUSES good heart health. Bleeding gums and heart disease are common side effects of chronic inflammation. Brushing your teeth doesn't fix inflammation, though.

Reply to Darrin (2013-11-14 11:11:28)

Darrin asked me a question (below). Yes, I am taking 4000 IU of Vitamin D every morning, and have been since summer of 2012. (I started at 10000 IU and worked my way down to 4000. If I only take 2000 my sleep suffers.) I have been taking the honey for over a week. >Hi Bruce, >Are you still taking the Vitamin D in the morning (as well as the honey before >bed)?

Joe (2013-11-14 12:07:26)

"I get less bleeding with gums and no soreness." You'll get ZERO bleeding gums, and no soreness whatsoever. And no infections. "how do you explain the excellent oral health of pre-agricultural remains?" They didn't eat what you (probably) eat, especially all the sugar and carbs. "I'm also not sure that good dental health CAUSES good heart health. Bleeding gums and heart disease are common side effects of chronic inflammation. Brushing your teeth doesn't fix inflammation, though." Poor dental health creates bacteria in your blood. If that bacteria reaches your heart, there go your heart valves. E.g., endocarditis. <http://www.mayoclinic.com/health/endocarditis/DS00409> You've basically got it backwards, my friend. Bleeding (infected) gums can cause chronic inflammation. Even stress can, in the form of cortisol. Another good book to read is: The Great Cholesterol Con: The Truth About What Really Causes Heart Disease and How to Avoid It, by Dr. Malcomb Kendrick <http://www.amazon.com/The-Great-Cholesterol-Con-Disease/dp/1844546101>

Stuart King (2013-11-14 14:59:01)

GeoffD, I found that combining the honey with coconut oil didn't seem to work as well. I did it for similar reasons to you. It might be worth considering that you want that quick insulin spike and temporary rise in blood sugar from the honey. Adding a fat possibly changes things a bit. But test it and see what happens, I kind of like the idea of trying to combine other foods for a better effect.

Paul (2013-11-14 16:20:32)

"You'll get ZERO bleeding gums, and no soreness whatsoever. And no infections." Well, like I said, it gets worse the more I brush. My personal experience is different than your expectations. I also don't eat sugar (except this honey experiment and the occasional fruit) or grains. In fact the only thing I've really found that gets rid of my gums bleeding is proper omega 3 to omega 6 ratio. Anyway this is rather tangential to the subject at hand. I've found that I sleep better with honey, but I'm waking up sooner. I don't feel any less refreshed, maybe a bit more refreshed in fact. Just strange to be waking up at 5am.

GeoffD (2013-11-15 07:21:52)

Stuart King, I tried 1.25 tsp raw organic last night without the coconut oil. A good, not great night of sleep. I did go to bed an hour later. I'll try again tonight and for 7 days sans oil.

Allen K. (2013-11-15 10:01:44)

To Keimpe above thinking about sugar as a preservative, in marmalade: there it's acting as a desiccant, sucking the water out of bacteria by osmosis. Same principle as salted meat. It's not going to achieve that in your mouth.

Joe (2013-11-15 11:37:46)

"Well, like I said, it gets worse the more I brush." That's because your gums are INFECTED. Until you deal with that, they'll continue to bleed.

Seth Roberts (2013-11-15 13:17:56)

"I've found that I sleep better with honey, but I'm waking up sooner." I found that a lot of standing had the same effect. I woke up sooner but slept better.

Darrin (2013-11-19 01:27:10)

recalling your penchant for flaxseed Seth & the current talk of Honey, thought this may appeal to you, just saw some honey called OmegaHoney, it's Honey blended with 100 % natural cold pressed flaxseed oil, here's a photo of the front label, [http://www.naturesblend.com.au/components/com\\_virtuemart/shop\\_image/product/945921b210f5f0b247afde8bc3-281c53.jpg](http://www.naturesblend.com.au/components/com_virtuemart/shop_image/product/945921b210f5f0b247afde8bc3-281c53.jpg)

Evan (2013-11-20 08:02:33)

I've been doing this for about a week and a half now, taking 1.5tsp of honey 45-60 minutes before bed. I've noticed two things so far. One, my feeling after my morning workouts improved. This is subjective; I don't have any hard strength or endurance numbers to back up any improvement yet. The second is more objective: after about a week (didn't start happening right away), I have regularly started waking about an hour before I usually do, and when I wake, my body feels like it's ready to get up. The only reason I go back to sleep is because I check the clock and it's 3:30am. Next thing on the list is to shift my bedtime so I early wake at a less obscene hour and watch my performance to see if the early waking is because honey is improving or disrupting my sleep.

Suzie (2013-11-21 02:08:17)

I am interested about the orange glasses. Where can you get one? have anyone tried it? those it work? Computer, TV, fluoro lights are bad for sleep. I will try the honey. I also do EFT in bed ( emotional freedom technique) sometimes it helps. I have an active mind and keeps chatting when I am trying to sleep. Seth: I got my oranges glasses from amazon.com. You might try getting plenty of sunlight, like an hour, in the morning. That might slow down your active mind at night.

## **How to Write a Personal Statement or Statement of Purpose (2013-11-14 05:00)**

At Tsinghua this semester I am teaching academic writing. Almost all the students are seniors and almost all of them are applying to graduate school, so I spent several weeks on how to write a personal statement. Each student wrote a draft. I read each draft and made suggestions in one-on-one meetings. The students wrote down my suggestion, and these summaries were compiled into the following guide.

Tips on writing sentences and paragraphs

Never use many **big words**! Especially don't use two big words in a sentence.

Make the sentence shorter and clearer. e.g. "I've set my career determination to..." is better replaced by "My career determination is..."

Use less space (simple and short sentences) on things people know and more on things they don't know. E.g. you

might want to list the statistical courses taken to emphasize your data skill. However, it's better idea that you write more about some experience when statistical method is successfully used.

Make it clear. Especially don't begin with something complicated and confusing. Stand in the professors' shoes and figure out a better way to get through.

Put the main interest in first paragraph. E.g. I'm interested in cognitive neuroscience, so I need put it at the first paragraph and make it obviously.

Put the topic sentence at the beginning of the paragraph. E.g. I should put the main ideas of every paragraph at the first sentence to make it clear. My first research experiment, I should point out I learned cognitive science by practical experiment.

Saying things more directly for people to get points. Example: I wanted to tell the readers why I had more interests in one specific field in psychology than others, but I did not mention this intention in the first place and only began with saying that some experience interested or not interested me, which might make the readers confused.

Things you should write about

Write things that have personal flavor, things that are unique. E.g. quoting from Einstein to illustrate love for cognitive science is not that unique, since everyone heard about them before.

Write about interesting experiences, rather than normal and boring things. Or write about experience that make you come up with some interesting thoughts.

Figure out what experience is important for your application. E.g. I want to apply to a Ph.D program in educational psychology, then my voluntary teaching experience is equally important as research experience. I should write more about it.

Add a good story or something original. Example: I mentioned my little brother in my PS and wanted to point out that it was him who made me get interested in education, yet it lacks some original experience in this part.

What really happened is more important than what supposed to happen. Better write on past achievement than babble about plans.

Explain the relationship between two events more clearly. E.g. explain the causal relationship: why something happened make you fall for psychology? Give specific reasons.

Usually use chronological order. Example: In the opening paragraph, I firstly said that I had studied psychology for three years blah blah, and then wrote what I once desired to be in high school, which is not in a chronological order.

Show important time. E.g. I did my second research in my first year, it was a early time. So, I need make it obvious.

Show the level of a prize. E.g. I won the Second Prize of the competition and I should show the difficulties of this prize.

Tell about yourself, rather than talk about the university.

Introduce yourself at first. E.g. I start with a sentence by a famous police officer but it has nothing to do with me.

Show your desire for the program. E.g. UCL's program is the one I want to apply for most, so I could say "UCL program is my first choice because of ... "

In short, distinguish yourself from other applications by writing things interesting and convincing in a coherent way.

Things that better not appear

Don't write ~~something professors are familiar with~~, write something they don't know but in a way they can understand.

Don't write ~~something sounds unlikely~~.

Don't say ~~negative things~~. E.g. do not say 'I wasn't interested in psychology at first', for it is obviously negative and should be prevented.

Don't write about ~~anything irrelevant~~. e.g. Don't write about your second major in economics if it's irrelevant to your goal in application. (In this case, writing about economics may convey that you are good at math!)

~~"One of my more unusual"~~ is not interesting. Go for "one of my best"

Tips on writing about researches

Explain why you are interested in your research topic.

If collaborate with someone in a research, refer to them.

When talking about a research, the results and achievements are important.

No use referring to ~~what you didn't do~~ for a research! (E.g. I didn't do the literature research in my first psychology experiment. Although I didn't do the literature research, and I didn't know if others do it, the research is still meaningful and I came up with the idea by myself.)

Tell story in a powerful and persuasive way. E.g., I wrote about the story of my first voluntary teaching in local elementary school in Beijing. To make the story more convincing, I should write about more details, like how often I went there, how many students there were, what subjects I was teaching, the reactions of the students. Etc.

---

## LEDs: Indoor Lighting of the Future (2013-11-15 05:00)

In response to [1]my post about wearing orange goggles at night, a reader of this blog writes:

Philips Hue: [www.meethue.com](http://www.meethue.com)

The [2]starter pack includes three bulbs and a controller. One small drawback is that the bulb returns to white when you cut the power. It's annoying to have to repeatedly reset a smart device. The bulbs are well-made, and the light quality is very good across the colors. It will be a great system when they get the price down and refine the controls.

[3]Random LED multicolor bulbs on Amazon

These have varied in quality. One cycled rapidly through the colors (in demo mode) whenever you turned it on, rather than defaulting to white—great fun when your kid likes to flick the lights. One had poor color balance between the red, green, and blue LEDs, so the blended colors came out wrong. Some were great. Having the little remote control nearby was convenient, as long as a kid didn't lose it. These don't put out a lot of lumens, especially in single-LED colors, but that worked fine for us. The bulbs are much lower quality than the Philips Hue, but the low price makes them a good starting point.

1. <http://blog.sethroberts.net/2013/11/12/orange-glasses-at-night-improve-sleep/>

2. <http://www.amazon.com/Philips-431643-Personal-Wireless-Frustration/dp/B00BSN8DN4/>

3. [http://www.amazon.com/s/ref=nb\\_sb\\_ss\\_i\\_2\\_9?url=search-alias%3Daps&field-keywords=led%20multicolor%20bulb&sprefix=led+multi%2Caps%2C253](http://www.amazon.com/s/ref=nb_sb_ss_i_2_9?url=search-alias%3Daps&field-keywords=led%20multicolor%20bulb&sprefix=led+multi%2Caps%2C253)

---

Jeff Winkler (2013-11-15 05:20:06)

It's cool that Philips is building these bulbs and paying for studies... though those are pretty fancy/expensive. This podcast with Richard Hansler (PHD, 42 years at GE Lighting) is good - <http://notjustpaleo.com/podcast-30-dr-ri-chard-hansler-lights-influence-cancer-sleep-obesity-depression/> I've ordered Bulbrite orange bulbs - [http://www.amazon.com/gp/product/B000COZ92S/ref=oh\\_details\\_o00\\_s00\\_i01?ie=UTF8&psc=1](http://www.amazon.com/gp/product/B000COZ92S/ref=oh_details_o00_s00_i01?ie=UTF8&psc=1) for our two-year old's room for storytime. 2 bucks each. The reviews say the 100 watt are enough to read by. Hopefully that'll reduce his sleep latency.

dearieme (2013-11-15 07:28:10)

"our two-year old's room for storytime": I remember that. She'd jump up and start trampolining. We eventually had to give up storytime.

Brad (2013-11-15 10:58:45)

There's also a computer program called f.lux, available for most operating systems and even mobile devices, that automatically adjusts the color temperature of your displays with the sunrise/sunset cycle at your location - adding significant red to displays in the evening to reduce this kind of circadian disruption. The latest version works even with those Phillips bulbs.

Reanna (2013-11-16 13:28:34)

Maybe I'm missing something here, but what about an orange lamp shade? Seth: it's not easy to put orange lamp shades on all of the lights in one's house...and you only need the orange light at night.

Alex (2013-11-17 08:46:15)

Brad, thanks for pointing out that I can use f.lux to control Hue lights. I didn't notice that in the May release notes, since I wasn't using Hue at the time. I use f.lux on all my computers, and I love it. Reanna, it wouldn't be enough to have a typical cylindrical lampshade in orange. Light with blue spectrum would still be emitted at the top and bottom. The goal is to avoid night-time exposure to blue spectrum, which is absent from orange light, rather than to increase your exposure to orange

spectrum.

### **Honey, Sleep and Reddit (2013-11-16 05:00)**

Looking at traffic to this blog, I found [1]a discussion on Reddit, in the Paleo subreddit, of [2]my sleep-honey post. "I'm too stupid to know who's wrong," said one person. Someone else, not the original poster, said:

I'm not on a paleo diet by any means, but I've been taking teaspoons of raw honey before I go to bed this past week strictly because I like the taste. What I have found is a noticeable change in my sleeping. I always wake up with more energy.... regardless if I wake up a couple of times in the night or if I get a full night's sleep. I'm generally a poor sleeper in that I wake up several times in the night. After taking the honey this past week, I have found out that I wake up less or even get a full night's sleep. For example, last night I got a teaspoon of honey before bed, and I got an uninterrupted 6 and a half hours of sleep. I woke up so refreshed this morning, I got up and exercised for the first time in so long. I generally exercise in the afternoons because it takes me a bit for me to actually wake up, but I just felt so rested this morning. I noticed these changes lately, but it took this article for me to realize it might be [due to] the honey.

Again, notice that [3]one teaspoon of honey made a noticeable difference. His or her belated realization is like what happened to me. As I said in the original post, now and then I'd sleep really well. It seemed to be correlated with dinner at other people's houses. I'd sleep better than usual after those dinners. It hadn't occurred to me until [4]Stuart King told me about his honey experience that those dinners were almost the only times I ate dessert.

Person 2 commented:

I tried it last night and noticed an immediate difference this morning.

Person 3 commented:

Tried the honey thing. While I usually wake up feeling like there is a mammoth sitting on top of me, today I woke up not totally refreshed, but without the mammoth, definitely a good feeling

dearieme (2013-11-16 06:54:06)

Ahoy, Seth. You were talking about gin a while ago; I have here something you must be sure to mention to anyone who you expect to buy you a present for Christmas. Just be sure that they'll understand that they must actually give it to you in time for Advent. <http://www.masterofmalt.com/gin/drinks-by-the-dram/the-ginvent-calendar-gin/>

Paul (2013-11-16 07:35:41)

I tested out skipping the honey last night. Even 1 day without it was enough to make the sleep quality worse. Good stuff here.

ChrisB (2013-11-16 08:40:25)

If you noticed even on morning's after eating dessert for dinner at friend's house, then it implies this isn't restricted to honey. Fortunately for me I have lots of honey around, and it is working for me as well, even if I sleep on a cramped couch I wake up feeling refreshed.

Darin (2013-11-16 09:34:11)

I've been using a tablespoon of honey before bed all week since reading the previous posts. The results have been surprising. I'm sleeping an hour less (6 instead of 7) but feel much, much better in the morning. It's as if the quality of sleep is improved so I need less. I'm convinced.

Matteo (2013-11-16 09:42:36)

I'm two days into honey experiment. I didn't sleep as good as usual the last two nights (I usually sleep quite well), but I think it's unrelated to honey. I've been testing my strength with one set of push-ups to failure. Baseline: 14. Too bad I've established the baseline on just one value, as I was eager to start the experiment. Anyway first day with honey: 16 push-ups. 2nd day: 19. I think it's too impressive to be solely due to the training effect. I'll keep you updated on my progress Seth: Here's how you can do the experiment. 1. Take honey every day. Do one set of pushups to exhaustion every day. You will level off quite soon...maybe at 30 pushups, who knows? 2. after it is clear that you have levelled off, change just one thing: stop taking the honey. don't change anything else. Question: what happens to the pushups? My prediction: the number of pushups you will be able to do will decline.

gwern (2013-11-16 11:24:45)

> I tried it last night and noticed an immediate difference this morning. > Even 1 day without it was enough to make the sleep quality worse. Good stuff > I have lots of honey around, and it is working for me as well > I'm two days into honey experiment. I didn't sleep as good as usual the last two nights (I usually sleep quite well), but I think it's unrelated to honey. It's not often one is gifted with such a clear demonstration of selection bias.

Nancy Lebovitz (2013-11-16 12:12:52)

It seems to work for me- there's a clear difference in the number of times I wake up in the night (once or twice vs. too many to count). I haven't done a careful check by not taking honey to see what happens. I suppose you'd double blind it by putting honey or something else of about the same weight in opaque capsules? I don't necessarily try to go to sleep immediately after taking honey. I note that Seth's desserts with friends were probably a while before he went to sleep.

gwern (2013-11-16 12:57:24)

> I suppose you'd double blind it by putting honey or something else of about the same weight in opaque capsules? Yes. Ideally it'd be a similar density and viscosity too - you wouldn't want to put in an equal weight of lead, because it will move around and feel differently. So maybe molasses? The other non-obvious thing is that while making the capsules, you're probably going to get traces of honey on the capsules, so you need to mix together the control and experimental capsules so they're all equally sticky/honey-y. I had to do this with my vitamin D capsules because the oil got on the outside.

Alex Chernavsky (2013-11-16 13:52:21)

Does the honey only work if you take it on an empty stomach? I usually eat a substantial snack not long before going to bed.

Matteo (2013-11-16 14:23:45)

Gwern, Thank you for showing us how one can brilliantly complicate simple things. If someone wants to test for placebo, he can put the honey in a tea or in hot water. Or not put it. And cover the taste with vinegar for instance, as mentioned in a post on this blog. And if one lives alone one can put stickers on the two cups, and then cover the stickers, and in the morning

unveil which one one did drink. Seth: To make the two drinks (with and without honey) equally sweet you should add artificial sweetener, such as Splenda, to the one without honey. You will need to adjust the amount of Splenda to equate the sweetness. If you also add a complex vinegar to both I think it will become very hard to distinguish them. However, I am sure it is not a placebo effect, because a placebo would not have caused me to suddenly become stronger. And I have tried many things to improve my sleep that failed to do so.

ChrisB (2013-11-16 15:00:34)

Gwern, let me give you more context before you throw up selection bias. I have 10 pounds of honey laying around intended for making mead which is unlikely to happen. So for the first time in a year I started using it for real, the tsp's before bed. And there is a noticable difference on waking in the morning. True its not double-blind placebo, merely unscientific and N=1, but that is seems to work for me is all that really matters.

Nancy Lebovitz (2013-11-16 16:13:24)

Pre-sleep honey doesn't taste nearly as good as I'd expect, and I normally like honey. I'm not sure whether it's a matter of intent or timing or what. Anyone else notice something of the sort? Seth: I don't have any trouble eating the honey but I agree it is much less tasty than usual, when I use it to sweeten stuff. That may be a clue that the effect is larger if the honey is eaten earlier. Or maybe it should be eaten with a little bit of something else (yogurt?). Or maybe it is simply the strong concentration that makes it less tasty.

Seth Roberts (2013-11-16 17:53:46)

"Does the honey only work if you take it on an empty stomach?" This is what Stuart noticed. My experience agrees with his. If I eat other food at the same time – cheese, Yakult – the effect disappears or at least gets much smaller. On the other hand, the Dutch have honey & milk at bedtime and I seriously suggest this may be why they are so tall.

Seth Roberts (2013-11-16 17:56:34)

"I don't necessarily try to go to sleep immediately after taking honey. I note that Seth's desserts with friends were probably a while before he went to sleep." I haven't studied it, but I think you can take the honey a few hours before bedtime and it will still work. However, it might not work if between taking the honey & bedtime you did something that depleted your blood of glucose, such as (a) eat something (which increases insulin) or (b) exercise.

Vladimir Heiskanen (2013-11-17 00:33:30)

Hello from Finland! I've been a reader of your blog for a few years, and I especially have enjoyed your writings on circadian rhythm, and motivation (magic dots, brown/rain noise). I have also tried Shangri-La diet (with sucrose water) but it didn't feel right for me. Gonna possibly try later again. This time I would ask whether you'd like to read an article written by me. In my article, I present some research showing that both red and near-infrared light have direct health benefits on tissues and they could be effectively used for many diseases. Red light and near-infrared could possibly explain daylight's positive health effects even better than vitamin D. My article was published in 180DegreeHealth, and it contains more than 100 scientific references: <http://180degreehealth.com/2013/11/red-light-and-near-infrared-radiation-powerful-healing-tools-youve-never-heard-of/>

dearieme (2013-11-17 06:11:00)

We've recently tried Cretan honey on Cretan cheese. (A persuasive stallholder at a village market gave us a sample and thereby made a sale.) It's delicious, even though neither is anything special on its own. How it would do as a pre-bed snack I don't know. I suppose it's a pricier version of a staple of my hill-walking days: honey and cheese sandwiches. Seth: I found that when I ate the honey with cheese it didn't work.

Kirsten (2013-11-17 13:12:58)

Interested in the comments on the honey method—and seeing patterns with something I've personally been working on. For the last year, I've been taking a natural approach to heal thyroid issues (which can be done while taking thyroid medication—best of both worlds, then.) The approach includes a focus on healing the gut (lots of good animal fats, bone broth, lots of probiotics,

avoidances of grains and other food that irritates the gut) and correcting gut dysbiosis and/or vitamin/mineral deficiencies that come from not absorbing your food well. It's not a permanent diet, but a healing diet that you can gradually ease out of. Various conditions can go hand in hand with a wonky thyroid: most people with Hashimotos or hypothyroid issues will also have compromised adrenals—the theory is, when the thyroid is compromised, the body has a diminished engine and the adrenals start working double time to make up. First, they produce too much cortisol; then they get burned out and produce too little. This can be measured with a 24-hour saliva cortisol test to see what your cortisol is like at various times of the day. Without getting too far into the weeds, there's a theory out there that uses T3 (thyroid hormone) therapy to help support and heal the adrenals. The theory is: The body needs the greatest amount of cortisol when waking up, to start the day. Like every other cell in the body, the adrenals have T3 receptors and need thyroid hormone. In a normal body, the body will start producing cortisol about four hours before waking up, so that the body has the fuel it needs to wake up and start the day. Therefore, if you change your T3 dosing so that you wake up two hours (or so) before your alarm and take your first thyroid medicine dose, then go back to sleep, the body will be better supported in producing the cortisol you need to start your day. This is a simplification—there's a guy named Paul Robinson who has written a whole book on the method. Anyway: I've been doing the CT3M for about 4 weeks, and the difference is remarkable—and very much like what you're describing. People worry about getting back to sleep after the dose; Paul says that not only are you likely to fall asleep, that sleep is likely to be deeper and more restful than the sleep that came before it. This has definitely been my experience. And in the four weeks I have weaned off of glandular adrenal support and now wake up refreshed and well-slept. In fact, it makes me realize that for pretty much as long as I can remember, I've been waking up with a slight feeling of jet lag, a pinch somewhere internally. Way back when my naturopath gave me the 24-hour cortisol test and talked to me about my adrenals, she suggested a small protein snack before bed to support them. Separately, I know people who have tried gelatin dissolved in hot water. On body building boards, there are a lot of comments that the gelatin trick will result in significantly increased fat loss...which I believe you would say is possible true because they are getting better and more restful sleep. Anyway, I always enjoy your blog because your observations tend to intersect with the things I'm working on and trying. I may try the honey trick next, and see if that affects the amount of the a.m. T3 dose I need to feel rested.

peter (2013-11-17 17:28:05)

i've had a similar experience, i.e., better sleep and more energy. Intuitively i sense that the effect will wear off in the same way the beneficial affects of medicine wear off. I'd be interested in where others will notice a wearing off etc.

Seth Roberts (2013-11-18 03:41:04)

"Intuitively i sense that the effect will wear off in the same way the beneficial affects of medicine wear off. " I doubt very much that the effect will wear off. No more than the ability of Vitamin C to prevent scurvy wears off. I believe this effect is why we have been shaped by evolution to want dessert after meals rather than before and eat dessert after dinner more than after lunch.

Simon (2013-11-19 02:52:04)

So it seems that, based on Seth's evolutionary argument for sweet things after dinner, and his experience with dessert at friends' houses, it's not honey in particular that confers these benefits but rather anything that's sweet. Has anybody experimented with this idea? I'm going to test it by eating a date before bedtime instead of the honey, as it seems to provide the same amount of total sugar [1], although the fructose:sucrose ratio of honey is 22 times higher than that of dates. Can anybody think of an objective, quantitative test for assessing how well one has slept? [1] <http://www.wolframalpha.com/input/?i=%28sugar+in+2+teaspoons+honey%29+%2F+%28sugar+in+1+date%29> [2] <http://www.wolframalpha.com/input/?i=%28fructose+in+1g+honey%29+%2F+%28sucrose+in+1g+honey%29+%29+%2F+%28fructose+in+1+date%29+%2F+%28sucrose+in+1+date%29%29> Seth: Yes, it would be nice to have an objective quantitative test for assessing how well one has slept. How many times you wake up is a good measure – the more you wake up, the worse your sleep. That's objective and quantitative. How long it takes to fall asleep is another measure.

David199 (2013-11-19 11:08:44)

". . . it's not honey in particular that confers these benefits but rather anything that's sweet. Has anybody experimented with this idea?" One theory of why it works is that honey 1) provides an insulin spike which pushes tryptophan into the brain which becomes serotonin which becomes melatonin and 2) honey nourishes the liver which provides a steady stream of glucose to

the brain during sleep which allows the brain to keep stress hormones low. Honey has a roughly equal ratio of glucose and fructose which is important since fructose liberates glucokinase which allows the liver to store glucose. Fruits should be similar. Sucrose (table sugar) is 50/50 glucose/fructose but unlike honey, the sucrose and fructose are bound by a glycosidic bond which is broken down in digestion; however, the theory is that this changes the absorption of sucrose making it less healthy (it spikes insulin faster and the fructose is delayed in opening up the liver). HFCS is a more complicated beast. Milk contains lactose which is a disaccharide of glucose and galactose, the latter stimulates glucokinase thereby allowing liver storage of glucose as well. This may lend credence to Seth's question as to why the Dutch's tradition of giving milk and honey before bed contributes to their above average height. There is a crossfit forum where people found eating ice cream before bed resulted in fat loss and better sleep, so there is some anecdotal evidence that sugar and dairy may work. From the theories I have seen, dates should work as would other fruits assuming you are eating the density of calories.

Jenny (2013-11-19 16:22:27)

Since reading about the honey, I've been trying it. The first few nights nothing changed. Then I started sleeping through the night - even on the nights I forgot the honey. I've had years of mid-sleep waking - triggered by a child who woke every 2 hours for 2.5 years. I've tried increasing Vitamin D3 - helped the quality of sleep, meant I went back to sleep (somewhat) quicker. But I would still often wake thoroughly at 3-4 a.m. Now, I often have milk at night, but this didn't do the same thing, and often I woke up thirsty mid sleep. So why didn't that do the same thing as the honey? My feeling is that the honey has somehow 'reset' the sleep pattern. Anyone else noticed this? Also, for about 10 days I became very tired very early, but that seems to have worn off now. Maybe I am catching up a sleep deficit? I'll keep monitoring this.

Seth Roberts (2013-11-19 16:49:26)

"Now, I often have milk at night, but this didn't do the same thing, and often I woke up thirsty mid sleep. So why didn't that do the same thing as the honey?" Milk has the wrong sugar (lactose). A cup of milk has 13 g of lactose, I'm told, which is not so different from the amount of glucose and fructose in the 20 g of honey I've been eating. But lactose is slowly converted into glucose. It would not provide substantial blood glucose for several hours. If milk increased insulin, that would remove glucose from the blood. Anyway, you can ignore comments about mechanism, which are just guesses. What's clear is that (a) the sugar in milk is different from the sugar in honey and (b) milk and honey are very different in several other ways, e.g., milk has lots of fat and some protein. It's also possible that the non-sugar aspects of milk interfere with the benefits of the sugar in milk (if any).

Darrin (2013-11-19 19:08:45)

@Jenny, good feedback/info Jenny, a question...how much honey have you been taking before bed?

Jenny (2013-11-23 15:26:08)

I was taking between a large teaspoon and a desertspoonful. I'm 65Kgs, in case that is relevant. Also, being coeliac, I eat no gluten or sugar, and only a small amount of root vegetables. I am still sleeping all night - and only erratically have the honey! I now take it when it 'feels' right!

## Storing Food Without a Fridge (2013-11-17 05:00)

A Korean artist named [1]Jihyun Ryou has invented [2]modules to keep food fresh without refrigeration. This connects with the themes of this blog in several ways: using science to find cheap safe low-tech solutions, minimal solutions (Ryou's designs use no electricity, I try to find solutions that require no willpower), and increasing (rather than reducing) the microbial content of food. Food stored at room temperature will have more microbes than food stored cold. Ryou says:

I've learned that we hand over the responsibility of taking care of food to the technology, the refrigerator.

We don't observe the food any more and we don't understand how to treat it.

That there could be something wrong with division of labor – handing over tasks to specialists, including specialist machines – is a subtle point. Division of labor works fine for inanimate things, such cloth and furniture and pencils. No economist has realized that animate things (such as our bodies) might be different.

The value of Ryou's designs partly rests on the variability of living things, as does the value of personal science. Well-educated Americans, in my experience, have little idea what they lose when they hand over care of their body to experts, such as doctors and drug companies. As Ryou says, they lose a kind of mental fitness ("we don't observe the food any more," we don't observe ourselves as closely) and are forced to accept solutions in which what the experts want plays a big role. I discovered the power of self-experimentation when I decided to see for myself if the acne medicine my doctor had prescribed was working. I found it wasn't, a possibility the doctor hadn't mentioned.

[3]Early exposure to refrigerated food is associated with Crohn's disease.

Thanks to Steve Hansen.

dearieme (2013-11-18 09:02:55)

Even more important, Alex, can it happen the other way around?

Nancy Lebovitz (2013-11-18 09:55:22)

Not an experiment, but an observational study- during those long boring high school classes, I kept track of whether students had their hands near their heads, and it seemed to correlate with when the teacher was less interesting.

Seth Roberts (2013-11-18 13:53:54)

"during those long boring high school classes, I kept track of whether students had their hands near their heads, and it seemed to correlate with when the teacher was less interesting." that's very interesting. certainly people have a weak desire to touch their face near their mouth. Maybe it's like a weak sound that we don't usually notice.

Nancy Lebovitz (2013-11-18 16:06:38)

The hands near head included touching face, head on hand, fiddling with hair.... Please view the conclusion as provisional. It's not as though I was double-blinding anything.

### **Self-Experimenters Wanted: Idiopathic Thrombocytopenia Purpura (2013-11-18 23:12)**

A woman named Sara Lake has a condition called Idiopathic Thrombocytopenia Purpura (ITP), an autoimmune condition in which your body makes antibodies to your own platelets. She wrote:

I'm having some success keeping my platelet levels on the "high side of very low" using diet and lifestyle, but there is so little research into this rare disorder that I'm just trying anything my education suggests might help. I would love to connect with other self-experimenters with this condition. I believe that most, if not all, autoimmune conditions can be cured if the triggers are identified (for example, as has been done in the case of celiac disease), but it's a long process. If you know of any other people with this disease please pass on my email address, which is sara.lake (at) gmail.com.

---

lipoescultura (2013-11-20 20:07:07)

The ingredients in the said are Citric Acid: 300mg and Magnesium Oxide Complex: 600mg. Medium-density carbohydrates (fruits, starchy vegetables, dairy products): These foods have more carbs per serve than the low-density carbohydrates. Remember that most unhealthy snacks have a healthy alternative.

Angus Stocking (2013-11-21 10:07:26)

I self-experimented successfully with ITP. I had a recurrence, after having a splenectomy that seemed to work for four years or so. When it recurred, I went to a doctor who prescribed prednisone. Instead of immediately starting on the recommended dosage I eased into it—started with much smaller amounts than prescribed, then ramped up slowly until I saw an effect. I was getting daily blood tests at the time, and used the tests to monitor platelet levels. When I got to a normal level, I plateaued the dosage, and then gradually ramped down. I found that the platelet levels stayed normal as I decreased the dose, and when I was off. I have not had a recurrence in about 25 years. I'm sorry, I don't remember amounts, but the ramp up and down periods were about 3 weeks each.

### **Modern Cargo Cult Science: Evidence-Based Medicine, Science Fiction in China (2013-11-19 05:00)**

In [1]a graduation speech, Richard Feynman called certain intellectual endeavors "cargo cult science," meaning they had the trappings of science but not the substance. One thing he criticized was rat psychology. He was wrong about that. Sure, as Feynman complained, lots of rat psychology experiments have led nowhere, just as lots of books aren't good. But you need to publish lots of bad books to support the infrastructure necessary to publish a few good ones. The same is true of rat psychology experiments. A few are very good. The bad make possible the good. Rat psychology experiments, especially those by Israel Ramirez and Anthony Sclafani, led me to a new theory of weight control, which led me to the Shangri-La Diet.

Cargo cult science does exist. The most important modern example is evidence-based medicine. Notice how ritualistic it is and how little progress medicine has made since it became popular. An evidence-based medicine review of tonsillectomies [2]failed to realize they were worse than voodoo. Voodoo, unlike a tonsillectomy, does not damage your immune system. The evidence-based medicine reviewers appeared not to know that tonsils are part of the immune system. Year after year, the Nobel Prize in Medicine or Physiology tells the world, between the lines of the press release, that once again medical researchers have failed to make progress on any major disease, as the prize is always given for work with little or no practical value. In the 1950s, the polio vaccine was progress; so was figuring out that smoking causes lung cancer (which didn't get a Nobel Prize). There have been no comparable advances since then. Researchers at top medical schools remain profoundly unaware of what causes heart disease, most cancers, depression, bipolar disorder, obesity, diabetes and so on.

I came across cargo-cult thinking recently in [3]a talk by Neil Gaiman:

I was in China in 2007, at the first party-approved science fiction and fantasy convention in Chinese history. And at one point I took a top official aside and asked him Why? SF had been disapproved of for a long time. What had changed?

It's simple, he told me. The Chinese were brilliant at making things if other people brought them the plans. But they did not innovate and they did not invent. They did not imagine. So they sent a delegation to the US, to Apple, to Microsoft, to Google, and they asked the people there who were inventing the

future about themselves. And they found that all of them had read science fiction when they were boys or girls.

I know about Chinese engineers at Microsoft and Google in Beijing. They want to leave the country. An American friend, who worked at Microsoft, was surprised by the unanimity of their desire to leave. I wasn't surprised. Why innovate or invent if the government might seize your company? Which is the main point of Why Nations Fail. Allowing science fiction in China doesn't change that.

Thanks to Claire Hsu.

---

Brandon Berg (2013-11-19 05:33:01)

Has the Chinese government seized any companies recently? I didn't realize things were still that bad there.

Warren Roberts (2013-11-19 07:35:11)

Long term follower of your blog. First time commenter. My interpretation of Feynman's criticism rat experiments as cargo cult science is a little different. I remember the story he told about the rat experiments. The one he praised was a scientist who tested every possible variable and documented them all. What he wasn't a fan of was scientists who don't document every possible variable and just publish their positive results. Which means others can't accurately replicate the experiment because they didn't know what wasn't documented. This is just what I got from it.

Seth Roberts (2013-11-19 14:00:59)

Here's what Feynman said about rat experiments in psychology:

When I was at Cornell, I often talked to the people in the psychology department. One of the students told me she wanted to do an experiment that went something like this—it had been found by others that under certain circumstances, X, rats did something, A. She was curious as to whether, if she changed the circumstances to Y, they would still do A. So her proposal was to do the experiment under circumstances Y and see if they still did A. I explained to her that it was necessary first to repeat in her laboratory the experiment of the other person—to do it under condition X to see if she could also get result A, and then change to Y and see if A changed. Then she would know the the real difference was the thing she thought she had under control. She was very delighted with this new idea, and went to her professor. And his reply was, no, you cannot do that, because the experiment has already been done and you would be wasting time. This was in about 1947 or so, and it seems to have been the general policy then to not try to repeat psychological experiments, but only to change the conditions and see what happened.

I take that to be criticism of the whole field of rat experiments in psychology. I have done a lot of rat research and I spent very little time (none) repeating earlier results from other labs. Likewise for the other rat researchers I know about. Of course, some people do that, but very rarely. As Feynman and the Cornell professor said, it is uncommon. I agree with Feynman's general point and would put it like this: go as slowly as possible consistent with progress. Everything is more uncertain than you think. But I have yet to hear another researcher agree with me or say the same thing. So I assume they don't follow this advice.

Nancy Lebovitz (2013-11-19 20:26:35)

[1]South Koreans studying Talmud in the hopes of matching Jewish intellectual achievements

1. <http://issamar.com/strategy/beware-first-china-now-north-korea-the-talmud-is-invading/>

dearieme (2013-11-20 02:54:05)

I believe that some of my colleagues didn't really see the point of my having my students sometimes repeat experiments - both our own and others'. Of course, if their purpose was not to advance science but to get promotion, they were right.

garymar (2013-11-20 17:17:02)

"South Koreans studying Talmud..." Nancy, I follow a few links on this. All South Korean elementary school children are exposed to a book of *stories* taken from the Talmud, it seems. This is hardly an attempt to "match Jewish intellectual achievements." It's no different than reading a book of Bible stories.

Nancy Lebovitz (2013-11-20 22:53:54)

garymar, thanks for checking.

garymar (2013-11-21 03:58:49)

Nancy you're welcome. While googling thru I fell into a world of Hasidic and Torah-Observant websites, and I was quite fearful of causing a shanda!

Brock in HK (2013-11-21 04:37:30)

Similarly, a small "free trade zone" near Shanghai won't change China into a vibrant, freewheeling free market any time soon, if at all. The cargo cult doesn't understand systems thinking. Cargo Cultists implement only one small, visible part of a system hoping the whole end result will spring forth. That never happens.

## **Bedtime Honey Improves Sleep "1000%. Crazy Good Tip" (2013-11-20 13:42)**

On [1]a recent episode of Grumpy Old Geeks, a podcast by [2]Brian Schulmeister and Jason DeFillippo, Jason told what happened when he had [3]honey at bedtime (starts at 1:04:20):

JASON [4]Tim Ferriss posted this . . . I did the experiment. I've been doing it for about six days now. Um, yeah, a thousand percent.

BRIAN Really? It's really helped?

JASON One. Thousand. Percent. I sleep through the night. . . . I can quantifiably tell you that in the morning I am sharper, I get more work done, I am better rested, and I feel a thousand percent better. I'm going with the formula in the article, which is a cup of hot water, mixed with 2 tablespoons of apple cider vinegar and 1 tablespoon of honey. It's tasty, it's really tasty, you wouldn't think vinegar and honey would be great but it almost tastes like an apple cider.

BRIAN That doesn't sound very appetizing to me, but I'll trust you that it wasn't bad.

JASON I found it delicious. And, plus, the hot liquid just before I went to bed, just knocked me out. I fell asleep immediately. . . . I've always had problems waking up five or six times in the middle of the night. I have slept through the night ever since I started this. I wake up in the morning ready to go.

BRIAN Excellent.

JASON This is one of the best sleep tips I've ever found. . . . The last couple nights I didn't really have the time, 'cause I was getting kinda tired and I'm just like, you know what, I popped the lid on the honey and poured it down my throat and that feels like 1 tablespoon or 3, whatever. Same effect. . . . I have a tablespoon of honey right before I go to bed. Man, it has really improved how I sleep. Not even that, it's how I greet the day. I greet the day really just ready to go. I'm a horrible morning person. I hate mornings.

BRIAN [laughs]

JASON If you have problems sleeping, definitely give this a try. Even if you don't have trouble sleeping. I think it will improve how your body solidifies memory and does muscle rebuilding. They [= Seth and Stuart King] talk about strength improvements and it's true. It's ridiculously true. That's when your muscles heal. . . . It's a crazy good tip. So hats off to Tim for passing that one along and I highly recommend it.

BRIAN I don't have sleep issues . . . but I think I'll give this a shot anyways and see if I get any of the other benefits.

JASON Yeah, that's what I'm saying. Even if you don't have sleep problems, it will still help your brain like, hardcode memories. I've found that my memory has really improved. Especially with this project that I'm working on. Before I would wake up and it would take me an hour to get back to where I was . . . [Now] I come back down in the morning and I come back exactly where I was, ready to rock.

BRIAN Awesome. . . . I will definitely try it out.

Lots of research says [5]better sleep = better memory.

August (2013-11-20 14:31:36)

I tried it again and ran into a drawback. It produces dreams. I don't dream well, which tends to mean I wake up because the dream is unpleasant. Anyone know of a way to hack dreams? I've got enough disappointment in my life; I don't need these disappointing dreams. Seth: Maybe if you tell someone your dreams or keep a "dream journal" they might become less powerful. I don't know, I haven't tried this, but see research by James Pennebaker about journaling.

Murray (2013-11-20 14:31:51)

Well, I tried taking a tsp of honey for the first time last night right before going to bed, and ... woke up at 3-something AM, then stayed mostly awake until my normal get-up time of 5:15. So, not exactly a success story! To be fair, over the last few years I've had several stretches where I wake up much earlier than I'd like (around 4 am), so last night was only unusual in that I woke up

even earlier than I'm accustomed to. I rarely have problems falling asleep, but early waking is a problem.

Murray (2013-11-20 14:39:08)

@August That's an interesting coincidence. I was awoken last night at 12:55 by an unpleasant dream (in which I was about to be subjected to a severe group beating) which was so vivid and unsettling that it stuck with me even after I'd gone to the bathroom and back to bed. I rarely experience memorable dreams, and the bathroom usually acts as an effective reset button for sleep-related difficulties. Huh.

Katie (2013-11-20 14:57:35)

Two nights ago, I took a TSP of honey before bed and slept very well. Last night, I skipped, and slept like crap. I'm going to start again tonight and see what happens...this is really interesting and something I NEVER would have expected!

Seth Roberts (2013-11-20 16:15:14)

"this is really interesting and something I NEVER would have expected!" Me too. And I had been trying to improve my sleep for many years.

David199 (2013-11-20 16:41:53)

Does anyone have an idea of what the cider vinegar does and how it affects sleep? Thanks

Joel W (2013-11-20 18:10:40)

It occurred to me that the connection between sleep and immune systems might be evidence that old wives tale cure of honey lemon and tea or whiskey. Perhaps it's the improved sleep from the honey.

Jay (2013-11-20 19:17:40)

This idea has exploded... I tried it out. I've done it for about 5 days. Each night I slept about 8 hours. Usually I sleep about 7-7.5 hours. Just 5+ years ago I used to have vivid dreams. Now I don't for some reason. Almost no dream recall in the past few years. Very frustrating, and I think it has affected me mentally. However, past 5 nights I've had semi-vivid dreams with good recall. Although I feel more well-rested when I wake up, I don't think it's as significant as some are reporting here. I only feel slightly more well-rested than usual. Not 1000 %. I'll keep doing this. I'll try the apple cider vinegar too. Seth: "Exploded"? How can you tell?

daz (2013-11-20 20:14:42)

the acv (apple cider vinegar) comment reminded me i actually have a bottle of acv with honey, which has been sitting in my fridge gathering dust (not literally). it was a good find at the time because i was not keen on the neat or diluted acv taste. so i may give the acv & honey followed by the honey a try. this is the stuff i got, <http://www.wescobee.com/products/apple-cider-vinegar-honey/apple-cider-vinegar-honey-500ml> there is a pdf there which may be of interest, of course it's a bit 'marketing-ey'.

Nile (2013-11-20 20:56:27)

August - Google Lucid Dreaming. It is the state of being conscious / aware that you are dreaming. You can then consciously choose to change the dream - change the monster to a friendly pet for example. You can learn to lucid dream by simply asking yourself several times a day while awake "Am I dreaming?" and seriously trying to answer the question by noting color, details in your surroundings, and so on. After a short time, you will ask yourself that question in a dream and you will come to the conclusion you are dreaming! You can then change the dream. One can also use lucid dreaming for problem solving. Mostly the results are absurd, ridiculous, nonsense but every so often you will get a creative solution. Good Luck - hope it works for you

Tobi (2013-11-21 03:14:35)

I tried it out for several days now, and it produces in me a similar effect as when I go to sleep when I have drunk several beers before. I wake up several times during the night, vivid dreams, and feel less rested in the morning rather than more. I think it is

either due to sugar/carbs or due to that a medicine that cures a condition often also has the side-effect of producing the same condition.

Alex (2013-11-21 04:51:37)

Tried taking 1tsp honey for two days right before going to bed. No improvement whatsoever.

Rocky (2013-11-21 10:23:53)

I have been taking 1 tsp just before going to bed for the last 4 nights. - dreams are more vivid and i recall them now - i still wake up 1-3 times during the night; however, i still feel more rested when i get up in the morning - energy level in the morning has improved  
Seth: You might be able to increase the amplitude of your sleep/wake rhythm – be more awake during the day, more asleep at night (and thus avoid waking up during the night) – if you got some (or more) sunlight in the morning. I try to get at least an hour.

Murray (2013-11-21 10:34:26)

Tried a tsp of honey again last night at around 10 pm. Slept soundly and dreamlessly ... and woke up, reasonably bright and alert, at 3:46 am. I'll keep trying for another couple of nights, but it looks like the honey is not working for me as it is for others. The only difference I can tell is that I MAY be more alert and energetic than I would expect to be for two consecutive nights in which I awoke very early. Seth: What's wrong with waking up at 3:46 am if you feel well-rested?

Kirk (2013-11-21 11:12:44)

Honey before bedtime improves my sleep about 50 % of the nights. Unfortunately, it also makes me gain weight. On the nights it does not work, it either has no impact or there has been some external influence (the house temperature was too cold, the temperature was too hot, there was a loud thump somewhere in the house, people or pet noises . . . ) Also, I find no difference between taking 1 teaspoon or 1 tablespoon.

Brian (2013-11-21 13:17:31)

Put me down in the weight gain crowd. I also notice sinus drainage afterwards. My sleep, however, was noticeably better.

Joe (2013-11-21 13:48:16)

On a whim, I tried taking a tablespoon of honey before bed last night. Results? No difference. Different strokes for different folks? Seth: Two things seem to matter. 1. You must take it on an empty stomach. 2. You must not have sweets during the day. Did you violate either of these?

libfree (2013-11-21 14:17:35)

I've been trying this for two weeks now and have been impressed with the results. Noticeably better sleep with myself feeling more well rested. I didn't notice the effect in the first 2 nights and I also didn't get good results last night. I did have a lot more dairy than usual last night and I went to sleep earlier than usual.

Ashish (2013-11-21 21:04:00)

I'm doing the orange glasses, and it's been great so far. But vinegar and honey are both reputed to be quite bad for the teeth, which are even harder to replace than a bad night's sleep. In other words ... let us know after your next visit to the dentist. I want it to work - fingers crossed. (Why doesn't a jar of honey go bad? Because it isn't full of oral bacteria.) Seth: Vinegar is unnecessary – I don't drink it. I brush my teeth after eating the honey.

Stuart King (2013-11-22 04:28:18)

I have also noticed that my dreams have been more vivid and I have better recall. I've even had a dream within a dream (like the movie inception) and moved between dream levels, with the realities being consistent between dream levels. Its a weird thing to remember details of a dream whilst you are already dreaming, yet not realising that your still dreaming. I also seem to be waking much earlier on many days, but I feel pretty good when I do (it doesn't seem unnatural and it varies from day to

day). Is it possible that you don't need the same amount of sleep every day? I tend to doze lightly for a few more hours - I have a feeling that might not be a good thing though. I think the honey leads to better quality sleep - which may mean that less sleeping hours are needed

Troy (2013-11-22 05:23:54)

My wife and I have both tried this over the last week or so, and it's definitely improved things for us. Huge difference in quality of sleep and energy levels on waking. In the N=1 (or 2!) spirit of your blog, I have a theory on the mechanism - that honey eases the transition both into and out of "real" sleep. I say this because we have a 20-month old child who occasionally wakes up in the night. One the two occasions this has happened since we've started taking honey, I've noticed 2 things: 1) that the awakening on hearing him does not have the normal, slightly traumatic feeling of being "yanked out" of sleep, which I'd feel as chest and head tension in the past. The quality of wakefulness is "full", though, but I just feel calm and alert. 2) Having settled him, it's now possible to return to sleep immediately (which was difficult/impossible to do quickly before) It would follow (if this theory were true) that honey does a couple of things: 1) speeds up time-to-sleep from bedtime 2) militates against the damage to sleep from partial or full arousal during the night (external (or internal stress) stimuli, but also apnea, restless partners, etc.) and might also explain why it doesn't work with everyone (i.e. may not improve problems with "baseline" or "best possible" sleep) Great tip, anyway, from our point of view. Seth: Bedtime honey increased my strength; it increased how much exercise increased muscle. That suggests an all-night effect. So does the fact you felt differently in the middle of the night (when awoken).

Arndt (2013-11-22 09:29:05)

I take honey before going to bed for 2 weeks now and I sleep like a rock and I had always difficulties falling asleep. Actually my sleep problems started at age 5 and I was kind of bedphobic as it took me hours to fall asleep and every bit of noise or light would wake me up. I always knew that honey and dates make me sleepy but I had never the sense to do it before going to bed. I eat mostly fruits and meat during the day and it still works.

Murray (2013-11-22 10:20:42)

Day 3: Bed at 10:40 pm, awake at 3:55 am. The moderate sleep deprivation is beginning to catch up with me, though I still seem alert. It's possible that the honey doesn't work for me because I'm violating the rules Seth mentioned above. I fast (or semi-fast, eating only nuts, seeds, and sugar-free gum) most days, then do much of my eating in the evening, including energy-dense foods like high-fat yogurt and the like. So it's unlikely that I have the requisite empty stomach at bedtime.

Joe (2013-11-22 15:57:00)

"Seth: Two things seem to matter. 1. You must take it on an empty stomach. 2. You must not have sweets during the day. Did you violate either of these?" I violated #2. I'll give it another try... as soon as the paleo brownies are gone. :) Seth: Very interesting...that I was able to sort of predict something.

Nancy Lebovitz (2013-11-24 08:18:10)

I'm getting decent results from honey if I don't eat (much?) sugar during the day. However, I also find that my tongue stings a little the day after, as though I've burnt it by eating excessively hot food. Is this happening to anyone else?

Sentinel (2013-11-24 12:22:59)

Murray—can you describe what you mean when you say that you're now sleep deprived? Is your overall energy level lower? Is your energy level good when you wake at 3 or 4am only to see it collapse later in the day? Or is it just a matter of your expectation about the correct time to wake? I do not mean to criticize, I am just curious! Seth—for the purposes of Pre-sleep Honeying, how would you define "empty stomach" - 3 hours without other calories?

daz (2013-11-24 21:19:51)

...how would you define "empty stomach"... Seth mentioned (under one of the other posts) that eating dessert (after dinner) may have improved his sleep, if that is indeed the case, then may be an empty stomach is not so important?

Seth Roberts (2013-11-25 04:46:43)

"may be an empty stomach is not so important?" Yes, that is a reasonable idea. However, I tried eating the honey with a piece of cheese. It didn't work. Why did it work when I had dessert after a meal – perhaps on a not-entirely-empty stomach? I don't know. There are dozens of differences between 1. honey at bedtime and 2. dessert after a meal. I cannot say that dessert after a meal always made me sleep better. Perhaps with dessert after a meal there is more time for the sugar to be digested – hours, for example – before it is needed. Slowing down that digestion with other food is okay or even beneficial. Maybe the first hour of sleep is especially sensitive to blood glucose.

Nancy Lebovitz (2013-11-25 10:02:25)

Last night, I had my honey– then killed a good bit of leftover cheese/sausage omelet, and still saw improvement in my sleep.

Dan Sullivan (2013-11-27 00:00:24)

Just inspired me to go try. I had apple cider vinegar already that I'd bought for something else, and it tasted nasty but worked (muscle cramps). I had tried to cut the flavor with juice but honey **\*\*worked\*\*** to make it taste better. this is what I have: <http://charliehorselegcramps.com/>.

Chloe Hodder (2013-11-27 00:38:52)

A note for those who are not experiencing positive results - I would make sure that you use raw organic ACV that is, as creepy as it sounds, "with the mother" (this is the cloudy ACV). This is vital if you want to be consuming the nutrients and enzymes. Similarly, raw honey contains all the benefits while the processed counterparts strip all nutritional value and use artificial sweeteners and corn syrup in its place. Raw honey is also cloudy and solid at room temp.

Birgit (2013-11-27 01:08:06)

Will def. try this although a tablespoon of honey contains approx. 17g of carbohydrates and I'm a low-carber. As to the vivid dreams, I found out by chance that Vit. B6 is required to have them. So if you're lacking try to increase food containing it or supplement. It's fun! Seth: The honey effect implies there is something seriously wrong with low-carbing – at least the view that carbs are unhealthy.

Birgit (2013-11-27 01:13:51)

NB: I read the other day that most honey in the US (I'm in Europe) is fake, i.e. no pollen but HFCS. Besides the GMO issue... Yuck! So one should make sure to find the proper stuff.

Jenny (2013-11-27 02:50:23)

I take 500mg of rhodiola in the morning. After 7 days or so the quality of my sleep improved dramatically. Love it. I take 500mg in the morning, look for Siberian rhodiola rosea, plus it MUST be 3 % rosavins 1 % salidroside.

Reinhard (2013-11-27 03:21:58)

Dear Seth, Thank you for your intriguing post. What kind/brand of honey did you use? Do you think the quality of the honey matters, i.e. raw vs. heated, organic vs. conventional? Is Manuka honey a good option?

Sandy (2013-11-27 07:59:46)

I'm not surprised. Sugar (as well as salt) lower adrenaline, which are an issue in people with sleep problems. I've had the same effect having a glass of warm milk with sugar + a pinch of salt, or even some OJ.

George (2013-11-27 13:25:03)

More of a question than a comment. Isn't honey you buy in the store homogenized, heat treated? Maybe try fresh honey for better results. I just read this so I'll give it a try. Seth: Pasteurized (= "heat treated") honey works fine for this. I don't know what you mean by "homogenized".

Seth Roberts (2013-11-27 17:32:40)

"What kind/brand of honey did you use? Do you think the quality of the honey matters, i.e. raw vs. heated, organic vs. conventional? Is Manuka honey a good option?" I have used French, German and Australian honeys. They are heated, probably conventional although I am not sure. I don't know if Manuka honey is worth the extra expense. You certainly don't need it for this.

Joel Alain (2013-11-27 18:34:54)

@August I use to have nightmares from age 10 to age 27 EVERY night. Bad, horrible, make-you-feel-like-crap nightmares... Then i found out why: It only happened when i HATE before bed (2 hours or less). So everytime i went to bed with my digestion going, i was 100 % sure to have nightmares. It took me so long to notice that... but anyway, now i did and im really glad. Digestion is a process that use tremendous resources and energy so it somehow affected my brain. Now that i dont eat before bed, no more nightmares. To solve your problem, i would not eat 3-4 hours prior to bed + drink a SMALL cup of water+honey (100 ml or less). Maybe your cup is too big (americans tend to have a "skewed" vision of what small is ;) Joel

Jason DeFillippo (2013-11-27 18:51:47)

Hey Seth. Thanks for the link! Just some follow-up. I use Aunt Sue's Raw honey. I've tried using the raw organic stuff from Trader Joe's and it tastes like crap and didn't have the same effect at all. Aunt Sue's is about twice as expensive but tastes great and works like a charm. We actually recorded a podcast with Tim Ferriss yesterday and as an experiment I stopped taking it the night before the show so we could talk about it and I slept like CRAP! Went back on it last night and slept like a baby and woke up feeling great. Our new ep with Tim comes out on Friday. We spent a good hour and cover some good stuff including this. Cheers! Seth: Thank you, Jason. If I want people to read just one reaction to my original post, I give them yours.

vincent (2013-11-28 05:56:02)

sugar crash at 3am. it's not for everyone!

Anthony (2013-12-05 07:32:11)

This was in no way tasty!!! I'll keep trying though. Had a late dinner so that may have affected. Went to bed at 1:04 took 17 min to fall asleep woke up once in the middle of the night (morning). Had 3h59min of ligh sleep and 2h46min of deep sleep according to my Withings Health PULSE. Woke around 8am

### **Orange Glasses and Sleep: Correction (2013-11-22 05:00)**

I [1]recently posted that an Oakland woman found that wearing orange glasses (which block blue light) in the evening greatly improved her sleep, which had been bad for decades. My post underestimated the improvement. Before she started wearing the glasses, it took her 2-4 hours to fall asleep. After she started wearing the glasses, it took 15-30 minutes. She wears the glasses from 8 to 10 pm. After that she goes to bed and tries to fall asleep.

I was very impressed by her story and started wearing orange glasses starting at 8 pm, even under incandescent light. Previously I only used them when looking at a computer screen in the evening. I'm not sure if wearing them more improves my sleep, but if I had to guess I'd say it does.

1. <http://blog.sethroberts.net/2013/11/12/orange-glasses-at-night-improve-sleep/>

---

Jeff Davidson (2013-11-22 06:42:33)

I've been wearing orange glasses in the evening for the better part of a year now, putting them on at a time roughly corresponding to Astronomical Twilight\* - which is about 7pm this time of year. The first thing I notice is that I immediately almost immediately start feeling tired and yawning. When I go to bed, around 9pm it will take me only 3-5 minutes to fall asleep. Since I wake for work well before sunrise I also wear them in the morning until the first hints of sunlight. Be careful driving in them though. If you're being pursued by the police their lights are rendered invisible. \* I ignore daylight savings time rules here, meaning that if observing DST Astronomical Twilight occurs at "6pm" but that's an artificial creation.

James D Miller (2013-11-22 13:42:10)

This polyphasic society website says red glasses are better because they block green as well as blue light. <http://www.polyphasicociety.com/polyphasic-sleep/adaptation/night-lighting/>

Jerry (2013-11-24 09:38:39)

I've been using Uvex blue-blockers in the evenings, and put low-blue lights in my house. The blue-blockers really help when looking at a computer monitor. Wearing them definitely helps me fall asleep earlier, and I often find myself crawling into bed around 9:00 pm. Prior to wearing blue-blockers, I could easily stay up till midnight. I am convinced that wearing blue-blockers in the evening lowers my waking blood sugar the next morning, but the relationship is complex and influenced by other factors.

Tobias (2013-11-24 16:00:45)

On the same day as this (Nov 22) the UK Daily Mail had an article about blue light & health. This stuff going mainstream? <http://www.dailymail.co.uk/health/article-2511979/Could-blue-lights-replace-daily-cup-coffee-Scientists-claim-effective-keeping-alert-caffeine.html>

Birgit (2013-11-27 04:07:13)

<http://justgetflux.com/> Love this little app.

Oli M (2013-12-02 07:43:39)

I find orange/amber lenses a lot handier than tools like FLux, which are not available for my non-rooted iPhone & iPad.

Theragingwalrus (2013-12-03 08:37:52)

Could anyone post what orange glasses work for them? I ordered a pair of 3M glasses ('fuel red mirror') but only their reflective coating is orange, looking through them it's more green.

Seth Roberts (2013-12-04 01:21:48)

I use these: [http://www.amazon.com/Uvex-S0360X-Ultra-spec-SCT-Orange-Anti-Fog/dp/B003OBZ64M/ref=pd\\_bxgy\\_hi\\_img\\_y](http://www.amazon.com/Uvex-S0360X-Ultra-spec-SCT-Orange-Anti-Fog/dp/B003OBZ64M/ref=pd_bxgy_hi_img_y)

## Assorted Links (2013-11-23 05:00)

- [1]Against the new statin guidelines. "For people who have less than a 20 percent risk of getting heart disease in the next 10 years, statins not only fail to reduce the risk of death, but also fail even to reduce the risk of serious illness." This is one way of saying that although heart disease has been a top cause of death for more than half a century, doctors still have almost no idea how to prevent it. Vast amounts of money and time have been spent studying heart disease, but, judging by the great emphasis on an almost useless method of prevention (statins), the researchers who spent the money and time didn't do effective research. Cancer could have a hundred different causes. Heart disease, probably not.

- [2]Follow mainstream food advice, increase risk of death. I've covered this [3]earlier but it bears repeating. "There was a 30 % greater risk of cardiovascular death among the people in the study who ate the cholesterol-lowering oil." The cholesterol-lowering oil was safflower oil, high in omega-6. [4]According to the Cleveland Clinic and [5]many others, oils high in omega-6 are "heart-healthy".
- [6]Use of yogurt to prevent infections in hospitals
- [7]Surviving your stupid stupid decision to go to graduate school (a reading list)

Thanks to Phil Alexander and Claire Hsu.

JM (2013-11-23 13:39:42)

As someone who has done extensive reading on causes of heart disease over the past two years - motivated by the heart attack of a loved one who had none of the usual risk criteria - I am appalled at how much time and money has been wasted by scientists pursuing the wrong things. However I am becoming more convinced that there are at least several causes for it and it depends on a combination of lifestyle and genetics with the possibility that infection and other environmental stressors also play a part.

Seth Roberts (2013-11-23 17:52:17)

"[heart disease] depends on a combination of lifestyle and genetics with the possibility that infection and other environmental stressors also play a part." The cholesterol hypothesis of heart disease was very popular, much more popular than it deserved to be based on evidence, I believe, because it allowed health scientists and their supporters to do three things they always want to do: 1. Expensive high-tech research (= high status research). 2. Promote expensive solutions (cholesterol lowering drugs). 3. Promote a pill solution (the whole system is geared for pills). The same thing has happened with depression.

Craig Fratrik (2013-11-23 17:55:31)

As someone considering getting a PHD, I'm not sure exactly what I should take away from #4. 1. Just don't do it. 2. Be more personally hesitant to do it if you have other options. 3. Be more hesitant if you're not going to a highly ranked institution. 4. Be more hesitant if your subject matter is not as employable afterward. Thoughts?

Mark (2013-11-23 19:18:48)

Seth, I'd add a 4th point as to why the cholesterol hypothesis was (and still is!) so popular. Simply, they could measure it. Seth: The neurotransmitter theory of depression has been very popular even though neurotransmitters cannot be measured.

Alex Chernavsky (2013-11-23 21:09:11)

The neurotransmitter theory and the cholesterol theory are both easy to explain to patients: "You're depressed because your serotonin levels are too low". "Your cholesterol numbers are too high, so you are in danger of heart disease".

Nancy Lebovitz (2013-11-24 08:05:25)

I also suspect the cholesterol hypothesis was popular because it gave an opportunity to tell people to not eat food they liked. Telling people they must give up something they like is a basic power grab. Seth: The hairshirt theory of science: the more it makes you suffer, the more true it must be.

dearieme (2013-11-24 15:20:52)

The love of power does much more harm than the love of money.

### **Is Diabetes Due to Bad Sleep? (2013-11-24 05:00)**

When I started eating honey at bedtime to improve my sleep, my fasting blood sugar values suddenly improved. Alternate-day fasting had pushed them into the mid-80s; now they were often in the high 70s, values I had never seen before. Without long walks and alternate-day fasting, [1]my fasting blood sugar values would have been more than 100, which is pre-diabetic.

This made me wonder: Does bad sleep cause diabetes? Plenty of evidence, I found, supports this idea. [2]Here is one example:

Just three consecutive nights of inadequate sleep can elevate a person's risk [of diabetes] to a degree roughly equivalent to gaining 20 to 30 pounds, according to a 2007 study at the University of Chicago. . . . This revelation backs up previous research from Yale and the New England Research Institutes, which showed that people who clock six hours or less of sleep a night are twice as likely to develop diabetes in their lifetime as those who snooze seven hours.

[3]Here is another:

In the study, published in the October issue of the Journal SLEEP, short sleepers reported a higher prevalence of coronary heart disease, stroke and diabetes, in addition to obesity and frequent mental distress, compared with optimal sleepers who reported sleeping seven to nine hours on average in a 24-hour period. The same was true for long sleepers, and the associations with coronary heart disease, stroke and diabetes were even more pronounced with more sleep.

Maybe there is something to it.

---

Veda (2013-11-24 11:59:41)

An interesting finding, but I'd like to see this cross-checked against populations that we know suffer from periods of very little sleep, like countries with mandatory army service. For instance, is the rate of diabetes in Israel abnormally high? Everyone

does army service there which involves many many consecutive days of very little sleep. Did diabetes rates during the great European wars also rise steeply? And then, what about lawyers, finance types, and execs? Obviously there can be confounding factors that are hard to disentangle, but a good starting point would be simply to see if the real world patterns bear out this finding. I would feel much more comfortable if it did. I suspect the real world does not bear this out. One of the problems with much of this health research is not just that it's unreplicable, but that people never seem to check them against real world facts that are easily observable. The low-carb fantasy gained incredible traction simply from the fact that no one one really cared about looking into the eating patterns of Asians and French and other thin countries. That these are carb heavy countries should have put paid to that theory from day one, yet the theory is still popular in serious circles. Taubes is still doing his thing, incredibly, and against all reason. Of course, the facts about Asia were pointed out, but somehow they were brushed aside or ignored - after all, it's so *far* away. There seems to be an interest in only looking at what happens in America. Stephen Guynet has his influential theory of food addiction based on delicious food as a driver of obesity - a simple glance at thin countries (France, Asia) that eat deliciously should be enough to dismiss that, but the theory still thrives because it *seems* to fit the American situation so well - as junk food increased, we got fatter. It's easy to craft a narrative of food addiction around *that*, even if it involves ignoring global realities, so Guyenet just brushes aside and makes absurd dismissals when the facts about France, etc are pointed out to him. Seth: I don't know of any "real world facts" that show that this idea is wrong. (By bad sleep I don't mean a few years, such as what happens to Israeli soldiers - I mean many years.) Here is more supporting evidence: <http://www.ncbi.nlm.nih.gov/pubmed/20425066> The association between sleep apnea and diabetes after being corrected for obesity, mentioned in another comment, is also more supporting evidence.

Dan (2013-11-24 12:57:34)

Do you think it's the honey, specifically, or the sugars? I was thinking of trying a large handful of grapes instead. After dinner I've been eating dessert the last week, ice cream or pie, and have slept better but I don't like the idea of adding sugary desserts to my daily meals. A bit of honey would be fine but it doesn't have much going for it except the sugar. Grapes may add other benefits nutritionally speaking. Seth: I think it's the sugars. I doubt that the other parts of honey matter.

dearieme (2013-11-24 15:19:13)

An extreme case of bad sleep would be people with sleep apnoea. Does sleep apnoea correlate with diabetes? If so, is there a common explanation in being fat, or is that just another correlate? I understand that sufferers from acromegaly tend to both diabetes and sleep apnoea, so those would be cases of a common explanation (tumour on the pituitary) rather than cause-and-effect.

Seth Roberts (2013-11-25 05:07:33)

"Does sleep apnoea correlate with diabetes? If so, is there a common explanation in being fat, or is that just another correlate?" There is a strong association between them. This report [http://www.idf.org/webdata/docs/DRCP %2081\(1\) %20Shaw %20et %20al.pdf](http://www.idf.org/webdata/docs/DRCP%2081(1)%20Shaw%20et%20al.pdf) says

There has long been a recognized association between type 2 diabetes and OSA, and there is emerging evidence that this relationship is likely to be at least partially independent of adiposity [25,1,2].

In other words, the association remains after adjustment for degree of obesity.

## Dark Picture of Doctors (2013-11-25 05:00)

[1]A New York Times article about error in a risk calculator paints an unflattering picture of doctors:

1. The risk calculator supposedly tells you your risk of a heart attack, to help you decide if you should take statins. It overestimates risk by about 100 %. The doctors in charge of it were told about the error a year ago. They failed to fix the problem.

2. The doctors in charge of the risk calculator are having trouble figuring out how to respond. The possibility of a

simple retraction seems to not have occurred to them. As one commenter said, "That the researchers, once confronted with the evidence it was faulty, struggled with how to handle the issue is quite telling."

3. In the comments, a retired doctor thinks the problem of causation of heart disease is very simple:

Statins . . . are only one component in the prevention and treatment of coronary artery disease. Item number one is to have a normal weight. Item two is never smoke. Item three is exercise. Four is to eat an intelligent diet. Five is to remove stress from your life as much as practical. If everybody did these five things (all of which are free), the incidence of coronary artery disease would plummet and many fewer would need statins.

This reminds me of a doctor who told me she knew why people are fat: They eat too much and exercise too little. She was sure.

4. In the comments, a former medical writer writes:

Several years ago, I wrote up, as internal reports, about two dozen transcripts recorded at meetings with local doctors that a major drug company held all around the country. The meetings concerned its statin. Two ideas presented at these meetings by the marketing team, and agreed with by the physician attendees, were: 1) the muscle pain reported by patients was almost never caused by the statin but was the result of excessive gardening, golfing, etc; 2) many children should be prescribed a statin and told that they would have to take the drug for life.

5. Another doctor, in the comments, says something perfectly reasonable, but even her comment makes doctors look bad:

I am a physician and I took statins for 2 years. Within the first 6 months, I developed five new serious medical problems, resulting in thousands of dollars spent on treatments, diagnostic tests, more prescription medications, and lost work. Neither I nor any of my 6 or 7 different specialists thought to suspect the statin as the source of my problems. I finally figured it out on my own. It took 3 more years for me to get back to my baseline state of health. I had been poisoned. I see this all the time now in my practice of dermatology. Elderly patients are on statins and feel lousy, some of whom are also on Alzheimer's drugs, antidepressants, Neurontin for chronic pain, steroids for fibromyalgia. These poor people have their symptoms written off as "getting older" by their primary physicians, most of whom I imagine are harried but well intentioned, trying to follow guidelines such as these, and so focused on treating the numbers that they fail to see the person sitting in front of them. The new guidelines, with their de-emphasis on cholesterol targets, seem to tacitly acknowledge that cholesterol lowering has little to do with the beneficial actions of statins. The cholesterol hypothesis is dying. If statins "work" by exerting anti-inflammatory benefits, then perhaps we should seek safer alternative ways to accomplish this, without subjecting patients to metabolic derangement.

6. A patient:

My previous doctor saw an ultrasound of my Carotid Artery with a very small buildup and told me I needed to take crestor to make it go away. That was four years ago and I still suffer from some memory loss episodes as a result. The experience was terrible and he's toast because he denied it could happen.

## 7. A bystander:

For the past couple of years my job has involved working with academic physicians at a major medical school. After watching them in action – more concerned with personal reputation, funding and internecine politics than with patients – it's a wonder any of us are limping along. And their Mickey Mouse labs and admin organizations can barely organize the annual staff holiday potluck without confusion and strife. So these botched-up results don't surprise me at all.

I am not leaving out stuff that makes doctors look good. Maybe this is a biased picture, maybe not. What I find curious is the wide range of bad behavior. I cannot explain it. [2]Marty Makary argued that doctors behave badly due to lack of accountability but that doesn't easily explain ignoring a big error when pointed out ( #1), an immature response ( #2), a simplistic view of heart disease ( #3), extraordinary callousness ( #4) and so on. In her last book (Dark Age Ahead), Jane Jacobs wrote about failure of learned professions (such as doctors) to police themselves. Again, however, I don't see why better policing would improve the situation.

Thanks to Alex Chernavsky.

---

Alex Chernavsky (2013-11-25 06:09:31)

This post reminds me of an outstanding book I read a couple of years ago. It's called, [1]Mistakes Were Made (But Not by Me): Why We Justify Foolish Beliefs, Bad Decisions, and Hurtful Act, by Caroll Tavris and Elliot Aronson. The book documents the extreme lengths to which people will go in order to avoid admitting that they were wrong. Seth: I agree, several of the examples can be seen as people not wanting to admit they were wrong. For example, a doctor who prescribed statins doesn't want to admit that statins are dangerous. Maybe doctors look especially bad because they make a lot more big mistakes than people in other jobs.

1. <http://www.amazon.com/Mistakes-Were-Made-But-Not-ebook/dp/B003K15I0E/>

jon (2013-11-25 07:52:26)

It would be nice if we had a free market in the medicine market. These results are to be expected. In a free market a possible cure to these mistakes would be: If you go in for surgery you get insurance and get paid an agreed upon amount of money if something bad happens. If a doctor has really poor results the insurance company won't supply or will make the cost of insurance quite high do to the poor results. We will then have price signals that will help us determine which doctors are best and what practices are best. Right now, under government health care (yes, in the USA we have had government health care for a very long time - when the industry is regulated to the point that people cannot choose anymore then it is government healthcare) there are no true or very little price signals. Which is unfortunate. Many people are suffering needlessly and even dying because of it.

Tom Passin (2013-11-25 08:15:56)

I have long suspected that doctors have a strong tendency to have to be right for a combination of two reasons: 1) history - doctors used to be quite dogmatic and arrogant about their practice of medicine, so those attitudes became baked into the system; and 2) High stakes - since peoples' health and lives are at stake, it's hard to be wrong. Very human and understandable, but not adequate as a way to function these days.

MJB (2013-11-25 08:26:32)

John Banja, assistant director of health science ethics at the Center for Ethics and associate professor of rehabilitation medicine: Do perfectionist doctors have trouble managing medical errors? That's part of the idea. A bigger part, however, is that most health professionals (in fact, most professionals of any ilk) work on cultivating a self that exudes authority, control, knowledge, competence and respectability. It's the narcissist in us all—we dread appearing stupid or incompetent. The problem, I think, is that health care is so unpredictable and stressful and contains such high stakes, that many practitioners exaggerate their competence. They come to believe that one ought never appear ignorant, uncertain, hesitant or wrong. So when this professional self-image is challenged, these persons are tempted to withdraw, or become hyper-defensive or just plain arrogant. [http://www.emory.edu/EMORY\\_REPORT/erarchive/2005/February/February7/sandr1.htm](http://www.emory.edu/EMORY_REPORT/erarchive/2005/February/February7/sandr1.htm)

dearieme (2013-11-25 08:31:59)

One thing that's not made clear on any article I've read on this subject is that the whole idea of a "risk calculator" may be bogus anyway. What you'd really like is a list of causes, or of contributors to causes, of heart attacks. What you actually have is a list of positive correlates of heart attacks. That's a plain different animal. For example: is their risk calculator consistent with the unexplained rise in heart attack rates during the five decades before 1960 or so, and the unexplained decline thereafter? Not a chance, I'll bet! In which case, it is not based on causes.

Mark (2013-11-25 08:57:37)

Dearieme, I agree completely with the notion that a "risk calculator" (based on a probability model at the population level) applied to individuals is inherently bogus. Always. Any "risk" calculation (as much as that means anything) must be conditioned on the individual.

Ripken Holt (2013-11-25 09:31:06)

Hey Seth, could you post the code you used to make the programs you use to test your brain function? I'm starting to take flax seeds and want to test my brain to figure out the optimal dose but have no knowledge of writing code. Another thing I would appreciate would be if you could give me a non-computer idea for testing my brain. Thanks so much! Seth: I once posted the code, it was a complete waste of time. I might share the software with you via Dropbox, as I have done for several people, if you could give me a good reason why.

Gina (2013-11-25 09:47:07)

My mother recently had a physical where the doctor scolded her for not taking the Crestor has been prescribing for her every year. She told him that they gave her migraines and that when she researched its efficacy that it didn't seem to provide any benefit whatsoever for women. His response? "Your cholesterol is too high." I asked her what his response was to her complaint of migraines. Nothing. He prescribed it again, and again she is not filling the prescription.

elduderino (2013-11-25 11:19:47)

MD here. I agree with you, roughly. We are, as doctors, neither trained in statistical reasoning nor any kind of critical thinking outside of the diagnose-then-medicate paradigm. With the advent of "guidelines", things got worse instead of better, because the pharmaceutical industry now has only one attack point instead of convincing every single doctor individually, and physicians feel bound by the guidelines because deviating could be interpreted as malpractice. Every morning I go to the hospital, I know that the medical decision making part of my job could be done much "better" (more adherent to guidelines) by a piece of software. This nonsense system is ultimately frustrating. It also defies everyday experience. Whenever someone is about to die, we stop any medication except for fluids and oxygens, and suddenly: blood pressure becomes normal, pulse normal, blood sugar rock stable. What did we do before that, exactly? I wonder. I remember seeing a study where some case was presented and the guidelines said "prescribe this". Something like 95 % said they would prescribe it, less than 70 % were convinced that it is useful and less than 40 % would take it themselves if they had the condition described. That's what I tell my patients: Always ask what your doctor would do if he was in your place, never "what shall I do". You're more likely to get a useful answer. (This idea is a heuristic from Taleb's Anti-fragile). And yes, except for some rather rare cases, to me, statins are the ultimate modern-day quackery. What quackery is is pitifully decided by majority vote, not by independent science, not by statistics, not by experience,

not by observation or even inference. People are so shit-scared by "high cholesterol" that not taking a statin, even only for a couple of weeks, is the same as not taking an antibiotic in a severe infection. "You're gonna die!!!!111!!!11!eleven!11" Erm, what? I furthermore roughly agree with the other commentators above my comment. They all raise good points. Seth: Thanks for your comment. It has seemed to me that doctors are trained in "critical thinking" just enough to criticize alternative medicine but not enough to criticize mainstream medicine.

David (2013-11-25 12:50:46)

How can you have a "risk calculator" when the cause of the disease is officially unknown? It'd be interesting to see an attempt to walk back this "risk calculator"'s basis back through all the dubious correlations to the supposed "data". Seth: You can calculate your risk of dying in a plane crash even though the cause(s) of plane crashes are unknown.

David (2013-11-25 12:53:35)

"The doctors in charge of the risk calculator are having trouble figuring out how to respond." That's because the purpose of the "risk calculator" is to sell more drugs, and to make it more reality-based would sell less. Of course that results in a puzzle. What to do??

dearieme (2013-11-25 15:18:19)

I'll bet the causes of plane crashes are known rather better than the causes of heart attacks. But suppose that there's a positive correlation between plane crashes and the proportion of passengers who are men. In the medical world that would be added to the list of risk factors because it's a positive correlate.

Mark (2013-11-25 16:29:36)

One cannot reasonably calculate their true probability of dying in a plane crash because it depends on nonrandom errors. Again, it's conditional on the precise plane trip, and it's most likely either essentially zero or essentially one.

Alex (2013-11-25 19:47:56)

Elduderino, thank you for an enlightening perspective. I have wondered whether most doctors have ever read anything about cholesterol and stains that wasn't put in their hands by drug companies, through a drug rep or by funding of favorable research.

Audrey (2013-11-25 21:15:10)

Mark said: *One cannot reasonably calculate their true probability of dying in a plane crash because it depends on nonrandom errors. Again, it's conditional on the precise plane trip, and it's most likely either essentially zero or essentially one.* Fly Air India sometime & see if you still think this is true.

Portlander (2013-11-25 22:57:46)

Always remember... (Most) MD's aren't scientists. They aren't even engineers. They are mechanics, and not very good ones.

Audrey (2013-11-25 23:39:52)

Michael Eades has written many times about how most physicians can't comprehend the typical journal article. Case reports yes, journal articles no.

Alex Chernavsky (2013-11-26 05:04:26)

@Audrey: John Ioannidis has [1]written many times about how most journal articles aren't worth comprehending.

Ripken Holt (2013-11-26 11:18:25)

Seth what did you mean by a good reason? I do not think there is any way it could profit you if that is what you meant. I have been reading through your archives after finding your website a week ago (I have read about half of your posts in that time), and want to find the optimal daily dose of flax seeds for me, and since I do not know how to write code I am having trouble

doing it. Any help would be greatly appreciated. Seth: Yes, that's what I mean. I have learned that simply giving strangers code is a waste of time.

How Badly Are Statins Overused? (2013-11-30 18:03:17)

[...] Pointer from Seth Roberts. [...]

Barry Brolley (2013-12-09 10:42:18)

Hi Seth, Dr. Michael Eades (Protein Power) blogged yesterday a moving piece about the frustration he dealt with from the medical system concerning his father: <http://www.proteinpower.com/drmike/statins/statin-madness/#more-5428> scroll down to the comments and look at the one from Gregory Porkrywyka "Statins work and are safe. Period. This has been shown again and again, in men and women"

### Assorted Links (2013-11-26 05:00)

- [1]No correlation between omega-3 levels and cognitive function. I found strong effects of flaxseed oil (high in omega-3) in experiments, so this finding doesn't worry me. Maybe the measures of cognitive function in this study depended on too many things they didn't measure or control.
- [2]Does methanol cause multiple sclerosis? Woodrow Monte makes a good case. "In the 1940s, . . . the National Multiple Sclerosis Society found the incidence of the disease to be virtually equally distributed between the sexes. . . . The real sea change in the incidence of MS in women did not come until after the introduction of a brand new methanol source . . . a can of diet soda sweetened with aspartame has up to four times the amount of methanol as a can of green beans. . . . At the 59th annual meeting of the American Academy of Neurology in Boston on April 26, 2007
- [3]Honey in human evolution. "Upper Paleolithic (8,000 – 40,000 years ago) rock art from all around the world depicts early humans collecting honey. . . .The Hadza hunter-gatherers of Tanzania list honey as their number one preferred food item."
- [4]What one climate scientist really thinks about Michael Mann. "MBH98 [Mann et al.] was not an example of someone using a technique with flaws and then as he [Mann] learned better techniques he moved on... He fought like a dog to discredit and argue with those on the other side that his method was not flawed. And in the end he never admitted that the entire method was a mistake. Saying "I was wrong but when done right it gives close to the same answer" is no excuse. He never even said that . . . They used a brand new statistical technique that they made up and that there was no rationalization in the literature for using it. They got results which were against the traditional scientific communities view on the matters and instead of re-evaluating and checking whether the traditional statistics were [still] valid [in this unusual case] (which they weren't), they went on and produced another one a year later. They then let this HS [hockey stick] be used in every way possible . . . despite knowing the stats behind it weren't rock solid." Smart people still fail to grasp the weakness of the evidence. Elon Musk, the engineer, [5]recently blogged, responding to Tesla fires, that Tesla development must happen as fast as possible because if delayed "it will . . . increase the risk of global climate change."

Thanks to Dave Lull, Stuart King and Joe Nemetz.

Scott Pierce (2013-11-26 08:29:32)

I wonder about the estrogens in flaxseed and what their impact on your cognitive measurements might be vs. the omega-3s. Seth: I agree, I should try another source of omega-3, such as fish oil.

Zach H (2013-11-26 09:29:07)

Is Michael Mann the only one whose model says this? One common problem with critical examples like this is that people latch onto them and insist that to discredit the key example somehow refutes all future work based on the same ideas, even as the results are applied to good effect. I'm not familiar with this situation, but the constant discussion about the hockey stick seems counterproductive when newer, presumably stronger work exists. Seth: I'm not sure what you mean by "this" ("whose model says this"). If you mean "there has been a very sharp warming during the 20th century, much faster than previous warming" the answer is yes, only Mann's model showed this. To call this "one example" is not quite fair. Mann's work was given enormous publicity. At the time of the enormous publicity, many climate scientists must have had considerable doubts about it but said – at least to the public – nothing.

dearieme (2013-11-26 16:54:53)

Mann's model also suppressed the Medieval Warm Period (the period of, for example, the Viking settlement of Greenland) which the global warmongers were ecstatic about - otherwise they would have to explain how you can get rapid warming before industrialisation. It was a wonderfully convenient untruth.

dearieme (2013-11-27 06:07:26)

Zach, here's the account you need of the great Hockey Stick fraud/swindle/accidental error, it could 'ave 'append to anyone and that's God's truth.

### **Darker Bedroom Better Sleep (2013-11-27 05:00)**

When I moved back to Berkeley from Beijing last spring, I noticed that my sleep was worse in Berkeley, months after arrival. I woke up less rested than in Beijing. There was no obvious explanation. My life was similar in the two places, especially on dimensions that influence sleep. I had expected my health to be better in Berkeley than Beijing because of Beijing pollution.

Wondering why my sleep was different, I realized my Beijing bedroom was probably darker than my Berkeley bedroom. In Beijing I live in an apartment complex and cover most of my bedroom windows to block outside light and for privacy. In Berkeley, I live in a house. My bedroom window looks out over an enclosed backyard. That my Berkeley bedroom might not be dark enough had never occurred to me. It was fairly dark – no street light, no alley light, no light from neighbors.

Did the (likely) difference in darkness contribute to the difference in sleep? I tested this possibility by making my Berkeley bedroom much darker. Later I made it lighter, then darker again (an ABAB design). I measured sleep quality by rating how rested I felt when I woke up on a 0-100 percentage scale where I estimated how rested I felt compared to completely rested (= 100 %). I have used this scale for many years. Here are the results:

[1]

To my surprise, when I made my bedroom darker my sleep improved. It got worse when I returned my bedroom to its original darkness. It improved again when I again made it darker. Until I graphed the data, I hadn't realized that my baseline ratings probably shifted shortly before I made my bedroom darker. (I kept a paper record of my sleep, which made it hard to graph the data. Failure to notice this baseline shift was the last straw....I have gone paperless.) In spite of the baseline problem, the data are convincing that even at low intensities, light intensity mattered.

Depth of sleep (controlled by the amplitude of a circadian rhythm) is surely controlled by the amplitude of the light/dark rhythm. Below a certain threshold of light intensity, however, reducing light at night won't make a difference. These observations implied that the threshold was lower than I'd thought. Support for the idea that the threshold is low – lower than other people realize, too – comes from [2] a study published last summer after my experiment. Researchers reanalyzed old data to see if there was a correlation between lunar phase and sleep quality. Their subjects had slept in a windowless laboratory room. Nevertheless, sleep was worse during a full moon. [3] One researcher was baffled. "What I can't get my head around is, what would that cue be?" he said. In other words, how could the phase of the moon influence sleep? I'm not puzzled. The subjects spent only a few nights in the sleep lab. I believe there was carryover from when subjects slept at home, in rooms open to moonlight. Light from a full moon reduced the amplitude of sleep. This affected sleep later in the lab for the same reason jet lag lasts several days.

Is your bedroom dark enough? The light at night in Person X's bedroom will differ in many ways from the light at night in someone else's bedroom so a one-size-fits-all rule (your bedroom should be darker than . . . ) makes little sense. What does make sense is personal science: measure your sleep and test different levels of darkness.

dearieme (2013-11-27 05:15:03)  
I just wear an eye mask.

August (2013-11-27 07:22:04)

Yes. This one is much more obvious to me than the blue blockers. When I blacked out my windows, and reduced the overall amount of light I was exposed to, I saw a great improvement in sleep. The blue blockers however, didn't seem to do anything. Some of the Amazon reviews suggest some blue blockers are better than others, so maybe I need a different pair. Without the blue blockers I would get sleepy and go to sleep. With the blue blockers on, it seemed I was not getting sleepy. My sleep quality seemed the same, but I think I might stay up longer if I wear the blue blockers and don't pay attention to the time.

Rxshauna (2013-11-27 08:54:40)

This makes sense. I am so sensitive to any amount of light when I sleep that I have to put sticky notes over lights on the TV, DVR, clocks, etc when I am in hotels. I find them incredibly bright and annoying. I have a niece and nephew who keep a TV on while they sleep and I worry about how this negatively affects their health.

Charlie Currie (2013-11-27 08:56:48)

Seth's sleep improvement guide: 1. Vitamin D early in the morning 2. Blue light blockers at night 3. Honey before bed time 4. Dark bedroom I'm surprised he ever wakes up...ha What I'd like to see/know, is how much improvement each one provides independently of the others; does anyone of them overcome a deficiency of the others; i.e., will darkening your bedroom provide the same quality of sleep as doing all four? This seems, to me, that it would be a very long experiment, involving many confounders - time of year being the largest (does our sleep improve, naturally, as daylight lessens, or the opposite, or not at all?). All good stuff for those who have trouble sleeping - inexpensive and easy to do. But, I think the darkened bedroom is probably the winner over all the others. Of course, our early ancestors, before they moved into caves, slept under very bright night skies, especially when the moon was full.

peter (2013-11-27 15:57:33)

wouldn't a sleep mask be easier than darkening a room? (that's what i've using for years) Seth: I have been told a sleep mask is worse. Someday I will try one.

gwern (2013-11-28 08:19:02)

> Support for the idea that the threshold is low — lower than other people realize, too — comes from a study published last summer after my experiment. Researchers reanalyzed old data to see if there was a correlation between lunar phase and sleep quality. Their subjects had slept in a windowless laboratory room. Nevertheless, sleep was worse during a full moon. One researcher was baffled. I have completely failed to replicate their claim using 1600+ nights of Zeo data from myself & 2 other people: [http://www.gwern.net/Lunar %20sleep](http://www.gwern.net/Lunar%20sleep) There's nothing there. It was a years post hoc analysis on their part, and probably just data dredging.

dearieme (2013-11-28 09:09:35)

The Berkeley story is good fun. Whether our own (Cambridge's) department of "Arch and Anth" has such antics I don't know. (An Oxford-educated friend once complained to me that "the trouble with Cambridge is that people don't gossip enough. A college or department could be in civil war and the rest of us wouldn't know about it. In Oxford everyone would know in no time.") The last time I was involved with a change in Head of Department, the body with the power of choice (called, can you believe it, a Syndicate) not only canvassed the views of the academic staff but also of the assistant staff, and then the Chairman of the Syndicate held a meeting with the academics to discuss what was to be made of those responses. It proved a good way to proceed, with a widely respected chap appointed Head and only one nose put badly out of joint. It turned out that the views of the academics and of the assistants (secretaries, workshop staff, IT and electronics staff, and so on) were pretty congruent. I must say that the consulting of the assistant staff reminded me of a comment from a German research student whom I supervised decades ago: "You are so democratic here". I corrected him: "We are so democratic here". He had the good grace to chuckle. Naturally the power of the central administration grows by the year: whether the university still feels "democratic" to the old hands, I don't know.

George. (2013-11-28 12:41:39)

Why do you need keyboard covers? Seth: They make cleaning possible. Or at least much easier.

S.M. (2013-11-28 12:45:44)

The laptop keyboard cover is a good one :) After I had my inspiron repaired, I got a cover because no matter how hard I tried I could never keep it cleaned. Now I need a new laptop and I am looking at an asus. What I really like about it is the chiclet keyboard. Much easier to clean around keys. You can probably find good ones for a desktop as well. [http://en.wikipedia.org/wiki/Chiclet\\_keyboard](http://en.wikipedia.org/wiki/Chiclet_keyboard) Would something like this work better? [http://www.ebay.com/itm/10pcs-Apple-Chiclet-Style-Ultra-Slim-wired-USB-Keyboa rd-Black-FCC-CE-Approved-/141085947031?pt=PCA \\_Mice \\_Trackballs &hash=item20d960b497](http://www.ebay.com/itm/10pcs-Apple-Chiclet-Style-Ultra-Slim-wired-USB-Keyboa rd-Black-FCC-CE-Approved-/141085947031?pt=PCA _Mice _Trackballs &hash=item20d960b497) The keyboard cover is great at keeping my keyboard clean, but I still want to get rid of it. Maybe I'm being picky :) Thank you for the links!

Nancy Lebovitz (2013-11-28 12:54:39)

The month of birth effect is larger in Austria than Denmark, so it's not just latitude. Maybe Austria is cloudier?

Seth Roberts (2013-11-28 13:52:04)

I too prefer a chiclet keyboard. I just got a laptop with a chiclet keyboard but I still was a little reluctant to use it until I got a keyboard cover for it. Maybe I have mild OCD.

Crystal (2013-11-29 16:42:25)

Interesting link about the gut bacteria. I saw a show a few months back where they had an 'expert' who specialised in the internal bacterial environment for humans - makes sense, we are an ecosystem. Personally, I wonder whether this might be more likely the reason for the success of the raw food movement, ie that it promotes a better internal bacterial balance, rather than the touted enzyme activity, especially since Tim Ferriss has found fermented foods to be a critical part of diet for weight loss purposes. I'd be fascinated to know the differences in bacterial types and populations between modern man and his predecessors.

## **Why Does Bedtime Honey Improve Sleep? Helpful Data (2013-11-29 05:00)**

I speculated that [1]bedtime honey improves sleep because it consists of an equal mix of glucose and fructose. Glucose is used by the brain during the first half of the night. By the second half, the fructose has been converted to glucose. However, honey has other ingredients, so it is not obvious that fructose and glucose are responsible. I focused on them partly because a need for glucose and fructose during sleep would explain (in evolutionary terms) why we eat dessert after meals, a puzzling separation.

Other carbohydrates also increase blood glucose. Do other carbs also improve sleep? Stuart King (who told me how much bedtime honey improved his sleep) pointed me to a 2010 discussion on a body-building forum. One person wrote:

I save a good portion of my carb intake for my last meal as I've found I sleep better afterwards. The worst nights of sleep I'd have during my prep were during my low carb days. Brutal.

Which supports the idea that blood glucose is running down, with bad consequences, during sleep. Even more telling was what someone else said:

Why does this happen to me? Before I was eating 2 cups of milk and a banana right before bed and would sleep fine. In the past few days I've tried to switch to 1 cup cottage cheese and 2 tbsp natty peanut butter. I've figured out this is why these past few nights I've had much more trouble sleeping and have had to resort to taking more OTC sleep aids. Then I'll still wake up in middle of the night and can't fall back asleep so I end up having a peanut butter and jelly sandwich and a cup of milk and 20 min later fall back asleep and sleep fine through the rest of the night.

Bedtime Snack A (2 cups of milk, banana): Good sleep. Bedtime Snack B (1 cup cottage cheese, 2 T peanut butter): bad sleep. There are hundreds of differences between the two snacks but one is that A, [2]because of the banana, has about 6 g glucose and 6 g fructose (plus 3 g sucrose) and B has [3]neither glucose nor fructose (nor sucrose). Stuart and I and several others have found that one tablespoon of honey (20 g) at bedtime greatly improves sleep. That much honey has about 8 g glucose and 8 g fructose. This is excellent evidence that it is the glucose and fructose in bedtime honey that improve sleep. Further evidence is that a snack with lots of sucrose (jelly) also produces good sleep.

[4]More about bedtime honey and sleep.

Jogo Tyree (2013-11-29 07:03:08)

I am an American living in Thailand. There is a brand of Thai honey that comes with a booklet that lists uses of honey. One item in the list says that honey promotes good sleep. I'd never seen that anywhere else until your series of posts. I saw no noticeable effect when I tried it just before bed, but I had no sleep issues to overcome to begin with. For someone with issues, though, using honey as an aid seems to be backed up by Thai folk wisdom....for whatever that's worth.

Alex (2013-11-29 07:55:37)

I tried the bedtime honey, because I had already noticed that evening carbs would make me sleep better: so far, it totally backfired 3 times out of 3. I suspect it is due to the fact that I am generally trying to avoid sugars, and a lot of carbs: what happens with a spoonful of honey is that my brain goes in hyper-mode like it did not happen to me in ages. I used to suffer from insomnia, it is better now... and honey seem to make it worse. Vitamin D in the morning: good. Blue blocking glasses/f.lux: good. Meditation: good. Honey: 2-3h wide awake, no worries, just my mind speeding all over the place. I will experiment more when I will go back to freelancing, when sleeping 3h later can be compensated waking up later... Seth: Have you tried a smaller amount of honey? You might also want to try getting more sunshine in the early morning and adjusting the time of the Vitamin D - it's hard to know the best time to take it without trial and error. That may help "turn off" your brain at night.

dearieme (2013-11-29 13:45:28)

Not entirely facetiously: have you thought of trying the effect of a lullaby? Seth: On a visit to Stockholm when I was a teenager, I noticed that the Swedish narration in a museum put me to sleep. Later, when I was a graduate student, I tried listening to a foreign language at bedtime. I can't remember the effect. Nowadays I fall asleep very fast.

Tom (2013-11-29 20:54:51)

After having some sleep problems, basically sleeping "normally" yet never feeling rested, and feeling a bit curious, I tried some of the ideas here. f.lux: Using it, not sure of effect. A number of other sources of light, so the orange glasses could be more decisive. Vitamin D: One capsule 5000 IE within 5 minutes of waking up; effect unclear, possibly some improved wakefulness. Honey: One teaspoon before going to bed; when tried, vivid dreams and wake up after about 3 hours fairly rested, though I then normally wait and go back to sleep again for a normal total of 7-8 hours. Interesting. Standing until exhaustion: One-legged knee bends until exhaustion before going to bed, quickly done and seems to help well with falling asleep. Seth: I take my morning Vitamin D at 8 am, which is 3-4 hours after I get up. You might also want to try getting more sunlight in the morning.

shtove (2013-11-30 16:44:50)

Seth's Shangri La oil method had obvious benefits for appetite, so much so that I didn't need to continue past a month. So I'm happy to hear his recommendations for sleep improvement. Sadly the vit D hasn't done it for me. Tried variations over the past year, but nothing that helps with sleep. Happily I've gone a long way in the past couple of months to solving my chronic insomnia. The main thing is magnesium supplementation, especially epsom salt spray - good link here: <http://culinarytidbits.com/how-to-make-magnesium-oil-spray-painless/> Not perfect, but it's a big improvement. This week I took the honey (1 tsp) along with the magnesium supplement - on one night it gave me the best night of non-pharma sleep I've had for thirty years: almost 10 hours, and I awoke rested with an arms-out-wide stretch. Will apply this combination more carefully for the next fortnight and report back. The best explanation of the honey effect I've read is at this commercial link: <http://www.cornectfamilyfarm.com/index.php/articles-tips-links/21-honey-more-than-a-sweetener-naturally>

dearieme (2013-12-01 07:24:41)

My wife and I have both just had an exceptionally good night's sleep. Perhaps the secret was eating dessert (tiramisu) about

an hour before bed. Unfortunately, much though I love it, I couldn't face eating tiramisu every evening.

Jay (2013-12-01 21:55:50)

I have to admit that I am quite often awoken by the urge to urinate. One of my speculative hypotheses as to why honey and other more simple carbohydrates might improve sleep is that carbohydrates make your body hang onto water (carbo...hydrate). The inverse is also true – most bodybuilders who are preparing for contests and those preparing for sports with a 'weigh in' eliminate carbohydrates entirely a few days before the event to empty their body of as much stored water as possible to increase definition. People who go on low carb diets hit a point where they are also urinating frequently as their bodies utilize their glycogen stores before going into ketosis. This initial weight loss is a cause of confusion and frustration for people who think that they are making very quick progress on whatever diet they have chosen, as even diets that are not "low carb" still cause one to consume less of them due to the calorie deficit – people lose water weight as a result. I think I may have even learned that from your Taubes interview! Anyway, not sure of any of this. Just an idea. Some people report getting up several times during the night to urinate when starting out their low carb diets. Maybe you have stumbled upon the reverse? Seth: When I started using the honey, I found myself getting up to pee more often than usual (usual = zero times). The opposite of what your theory predicts. After a few nights it stopped (maybe because I reduced my fluid intake).

dearieme (2013-12-02 03:10:42)

The Old England Journal of Medicine chips in. <http://www.dailymail.co.uk/femail/article-2516510/The-honey-diet-Drop-dress-size-party-season-having-spoonful-honey-bed-following-delicious-recipes.htm> I

tom (2013-12-02 14:55:34)

This lady dr says when she got her patients' vitamin D to 60-80 ng/ml, they had more stage III sleep and started healing problems. She thinks it's something about vitamin D receptors in an area of the brain that help paralyze the body during certain stages of sleep. <http://www.youtube.com/watch?v=xF24xmJQK1k> Seth: Thanks. Her name is Dr. Stasha Gominak. Maybe it was only patients who took the Vitamin D in the morning who improved. Others have reported that taking Vitamin D in the evening made their sleep worse. In other words, her study confounded two things (= changed two things at the same time). 1. Taking more Vitamin D. 2. Doing something that improves sleep. It may have been the second factor, not the Vitamin D, that was crucial. Maybe if her patients had all taken the Vitamin D in the evening, the results would have been much different.

Xav (2013-12-02 16:15:22)

Perhaps another bit of anecdotal evidence for late night carbs in general helping with sleep - I was just reading a blog post about resistant starch with comments from people taking potato starch, especially in the evenings. There were a couple of comments like this one : "On week three of 3 TBS of Potato Starch per evening. Any explanation on the exceptional, uninterrupted deep sleep? No complaints mind you. Have never slept so well. Never." TR <http://freetheanimal.com/2013/06/resistant-starch-now-were-getting-somewhere-and-talking-shit-too.html> #comment-529975 Seth: Thanks, that's very helpful.

## **Mo Ibrahim: My First Semester (2013-11-30 05:00)**

[1]Mo Ibrahim, a friend of mine, teaches high school in New York with hard-to-teach students. He and I want to find out if my ideas about teaching can help him. His blog posts here are the story of that.

I moved to New York in the summer of 2004 to start the Teaching Fellows summer training program at City College of New York. My wife and kids stayed in Chicago until I could find an apartment.

I found an apartment through a Teaching Fellows message board. It was in a nice section of The Bronx, but I only had three months before I had to find another apartment. I spent the first two months taking Master's degree classes at City College and studying for two teacher certification exams – a general exam that all aspiring teachers took and a specialized one for students who majored in special education. There was a lot of pressure to pass the exams, because if you failed you would be expelled from the program.

By the end of the summer, I had passed both exams, gotten a provisional certification to teach, and gotten a job teaching at a high school near Columbus Circle that served underprivileged students. Most of the students were poor and performed far below grade level in reading and math. But I didn't have a place to live anymore, because my lease was up and the landlord refused to renew it. I applied for a number of apartments all over New York City, but all of my applications were denied. Once I called to make an appointment to visit an apartment and the owner asked me to come over immediately, but when he saw me he said the apartment was no longer available. On another occasion, I was told that the apartment was no longer available after I faxed over a copy of my driver's license. I assumed all this was because I was black but an elderly Jewish lady said it was due to my Islamic name. So I moved into a hostel in the East Village. By September, I was teaching full time during the day and taking classes at City College at night. Due to the hostel's two-week limit, I moved to a different hostel in Manhattan every two weeks.

A couple of things struck me when I starting teaching. One was the New York slang. I found myself frequently asking students to translate words and phrases they used. For example, "Yo, it's mad brick in this class!" meant "It's very cold in this class!" I was also struck by their apathy. Most of the students appeared to care little about completing class assignments, turning in homework, and studying for quizzes and exams. I would say, "Why didn't you do your homework?" They would respond, "What's the big deal? It's just homework." Their measure of success was "Did I pass?" Not all of them were like this, but most of them were.

The first subject I was assigned to teach was 11th and 12th grade math – the two grades were mixed in one class. I had diligently reviewed my high school and college math over the summer, so I was confident I knew the subject. I was assigned to co-teach this class with a veteran teacher. By then he'd been teaching at least fourteen years.

I had gone to a professional development workshop for co-teachers. It had taught seven different co-teaching methods. For example, one was "you teach one day, I teach the next day" or "you teach the first half, I teach the second half". Different ways of sharing the teaching. In fact, not only did I not teach a single lesson, but I was relegated to the back of the classroom. My co-teacher was really nice otherwise, but he would not let me teach the class. I don't really know why. When the students were allotted time to work on math problems I would rush to the special education students (students with a learning disability or who were emotionally disturbed, e.g., anger management problems) to give them one-on-one help, but they were usually resistant. They stared at me blankly, or asked off-topic questions like, "Did you see the Yankees game last night?"

Occasionally, students, including non-special education students, would ask me for help. But often in the middle of my explanation the whole-class discussion would resume, and I would have to stop teaching, because my co-teacher asked me not to talk to students while he was teaching. That was my role during my first semester of teaching. I wasn't despondent, though, because I considered it a blessing in disguise. Since my co-teacher kept me from teaching, I didn't have to prepare any lessons. He didn't even allow me to grade any papers, which was a good thing since I was in night school and still living in hostels.

Things changed drastically after the first semester. A veteran English teacher took an emergency leave of absence and I was given her English classes. My math co-teacher asked that all the poor performing special education students be given their own class to be taught by me. A young and friendly English teacher lent me her English curriculum and I developed a modified math curriculum based on the class where I sat in the back. And I was finally able to leave the hostels. I moved into a shared apartment in Brownsville, Brooklyn, the neighborhood where Mike Tyson grew up. It took an hour and twenty minutes on the subway to get to work. During my first commute to work, I overheard someone say: "Did you know Brownsville's the worst neighborhood in New York?" I hadn't known that.

---

Roger Sweeny (2013-11-30 14:52:36)

They don't tell you in ed school—in fact, they kind of try to get you to believe otherwise—but some truths about high school teaching are: Your students will not care about your subject as much as you do. Many will not care about it at all. Some will, however, be interested in passing. You will try to get them interested in something more than passing. You will largely fail. Most of what you test on, and that students seem to have learned, will be forgotten before they start the next school year. You can pretend this isn't true, which is dishonest but may spare your sanity. You can just not think about it, which is the default of most teachers. Or you can revel in the small, real triumphs. " \_ \_ \_ \_ \_ wrote three complete sentences which followed each other logically." " \_ \_ \_ \_ \_ now cares enough to get a diploma."

Adam (2013-11-30 16:33:30)

As a public school teacher you are essentially a jailer in a prison for children, so it shouldn't be too surprising that there is some tension between you & the inmate-students.

jason y (2013-12-01 03:02:52)

it sounds like the problem isn't how to devise better teaching methods but how to persuade students to care enough to be taught. you can't teach a kid algebra if he doesn't see how algebra helps him get something he already wants, or if learning algebra prevents him from getting something he wants even more. algebra has to be important enough to capture his attentional resources long-enough to learn it. the entire system of values matters. there's a lot of cynicism surrounding this topic, and i think a good chunk of it springs from the assumption "better at school = intrinsically better" (a shared assumption that probably makes it easier for members of some communities to invest in education!). if academic achievement has more to do with modifiable values than the presence of a super-enzyme in the brain a lot of people's self-worth will be jeopardized (unnecessarily, i might add).

## Bedtime Honey Doubles a Measure of Strength (2013-12-03 05:00)

A reader of this blog named Nile McAdams, who lives in Minnesota, wrote:

When I read [1]your first blog post about honey I was gobsmacked. Not so much by the improved sleep – the idea of a bedtime snack improving sleep has been around a long time – but by the fact that a tablespoon of honey could double the time you were able to stand on one leg. [One bent leg. After being roughly constant for a year, the time doubled in two weeks. – Seth] Impossible!! Not that I thought you were lying – I didn't – it is just that a lot can go wrong between collecting the data and interpreting the data. So I had to try it for myself.

A little back story. In June I began lifting some 40-pound dumbbells I had laying around. I would hold one in each hand and then, alternating arms, lift them over my head for a total of 10 lifts – 5 for each arm (right arm, left arm, right arm, and so on). For me, the dumbbells were very heavy. I had trouble keeping them stable especially with my left, weaker, arm. Every time I lifted I had a little anxiety that I would lose control and the dumbbell would come crashing down and break stuff. The last straw was that I wasn't really getting better or not getting better fast enough. I lifted almost every day for a month or so but then gradually drifted away. Here is the point of the back story: I had very minor improvement, if any, over the course of that month. I felt a little stronger and I may have been able to do 12 lifts but I was too unsure of how steady I would be on lifts 11 and 12 so I never tried it.

When I decided to try the experiment with honey I thought that these dumbbells would be a good test of strength. I am 70 years old and quite obese – 6' and 300 lbs. I take 2 or 2 ½ tablespoons of honey right before I go to bed – my thinking is that my body mass could be almost double yours or other people taking honey so I should adjust the dose a little bit.

I started lifting on the same day I took the honey or perhaps the day after I took the honey. Here are my dumbbell lifts by day.

10,10,10,10,10,10,12,10,[three day gap]

I went to Chicago for a long weekend so I did not lift that Friday, Saturday or Sunday. I also did not take any honey. I didn't think much of the day I had lifted 12 times, even though it is a 20 % improvement. I felt it was similar to when I was lifting back in June – random variation. Here are my lifts since I came back from Chicago after missing 3 days.

16,14,16,20,14,20,18, 22,16,[1 day gap],22,24

These lifts are outside the bounds of any random variation as far as I'm concerned. In 15 days I doubled my lift with weights I had prior experience with!! This is incredible! The effect is real, at least for me.

A prediction of something that sounds impossible (bedtime honey quickly doubles a measure of strength) is confirmed – how often does that happen? I agree with the underlying idea. Lots of things improve sleep. It isn't astonishing that X or Y improves sleep. The strength improvement, however, astonished me.

When I was standing on one bent leg to improve my sleep, I knew that if I did the exercise every other day instead of every day, my legs would get stronger – much stronger. I didn't want that. I wanted to sleep well every night (that was the reason for the exercise) and I didn't want the exercise to take too long. (To improve sleep, I am pretty sure the exercise must be done to exhaustion.) When he started lifting in June, apparently Nile did not realize that he would get better results – become stronger faster – if he lifted weights every other day instead of every day. The strength increase, it appears, happens whether you want it (Nile) or not (me).

Niles added later:

I am now certain that it is easier for me to go up and down stairs. When I first started lifting these weights, both in June and when I started again in November, I had a lot of "popping" and "cracking" in my shoulder and elbow joints. That has all but disappeared. I have definitely added muscle. My lifts show it and I have gained 3 or 4 pounds.

It took me awhile to feel the effects of the honey both in lifts and in sleep. I didn't notice any differences in lifts until about 11 days and I didn't notice any difference in sleep until 2 weeks or more. About half the nights my sleep is heavier or deeper [than before honey]. I'm not sure of the correct adjective but when it happens it seems clear. On those nights I have deep sleep I don't take a nap the next day. I don't wake up feeling "refreshed" as others have reported but I am not a morning person and it takes me awhile to wake up and get going. I am more productive the day after one of these deep sleeps.

I am on an Ancestral Health Society (AHS) steering committee. After the first symposium, some members of the committee wanted to make recommendations about how to eat. I argued against this, saying it was too early to be sure. No paleo theorist, as far as I know, has said that sweets have value, but at the same time, the honey effect supports the practical value of evolutionary thinking, the rationale for AHS. A big reason I believed the effect of honey on sleep was very important is that it provided an evolutionary explanation of dessert. Another big reason was my sudden strength improvement. Repetition of the sudden improvement suggests that evolutionary thinking pushed me in the right direction.

So bedtime honey doesn't just improve sleep, it also increases muscle growth – a lot. I wonder how to test its effect on memory. [2]Jason DeFillippio of Grumpy Old Geeks said, "My memory has really improved". A reader named Crystal made [3]the astute comment that the impact of a sugar-containing food (honey) on growth would explain why children like sweets so much, something that has never been well explained.

Nile's experience impresses me not just because of the strength increase but also because the effect of the honey increased over a few weeks ("It took me awhile to feel the effects of the honey both in lifts and in sleep"). Maybe the honey caused healing. Some healing processes take years. Maybe bedtime honey speeds them up. The long-term benefits may be more than sleep and strength.

dearieme (2013-12-03 07:22:46)

I've been thinking about what sort of cheerer-uppers might encourage sleep if taken by the glass, so that both sugars and alcohol would help send you to the land of nod. Various digestifs are obvious possibilities; so is Pedro Ximénez sherry, or Bual or Malmsey Madeiras; I wonder how well this lesser-known drink would do. [http://en.wikipedia.org/wiki/Pineau\\_des\\_Charentes](http://en.wikipedia.org/wiki/Pineau_des_Charentes) My motive is that I'd want some variety from honey, and tiramisu is not enough by itself. Madeira keeps very well after the bottle is opened, so that might be the place to start. Mind you, gently chewing a liquorice twist might be quite enough, and a good deal cheaper, and perhaps wiser if you've already had a drink or two during the day. Seth: A few weeks ago I went to an all you can eat Japanese restaurant – and it included all the sake I could drink. I just had one serving but that was enough to clearly disturb my sleep that night. There wasn't anything else unusual about the meal. I like to drink (in small amounts) but since then I have cut way down on drinking in the evening.

dearieme (2013-12-03 07:29:01)

Hold on; I've just googled "liquorice twist". Here's the ingredients list from Tesco (a British supermarket chain). Treacle, Wheat Flour, Sugar, Glucose Syrup, Desiccated Coconut, Vegetable Oil, Glazing Agent (Beeswax), Liquorice Extract, Beef Gelatine, Flavourings, Humectant (Glycerol), Colours (Plain Caramel, Beetroot Red, Curcumin, Capsanthin), Fat Reduced Cocoa Powder. With its treacle, sugar, glucose and beeswax it sounds a bit like synthetic honey. A bit short of fructose, maybe.

B.B. (2013-12-03 10:05:34)

A traditional remedy for insomnia is a teaspoon of honey in a glass of warm milk. The honey part you have already gotten. Maybe milk helps also. Lactose is a type of sugar and may work with honey. Perhaps the calcium in milk calms the nerves and also makes healing / growing at sleep easier. Finally, amino acids in milk may have a calming effect. Anyone test himself using milk as well as honey?

Nancy Lebovitz (2013-12-03 11:21:47)

It wouldn't surprise me if improved sleep improves memory.

Cliff Styles (2013-12-03 12:26:49)

My wife and I have been testing honey at bedtime for a couple of weeks, and we have both had a noticeable improvement in sleep, mostly in the 3am restless wakeup period disappearing. She has more trouble with this than I have, so she found the improvement easy to notice. We take it with a nighttime concoction the includes a nitric oxide releaser and some kefir. That said, the thing that improved my sleep most dramatically was eliminating wheat from my diet several years ago. Before that I had a ferocious sleep apnea and snoring problem (which my wife would attest to). The sleep apnea went completely away and has not returned, and the snoring is down about 90 %. One side effect of the sleep apnea, also gone, was probably long nightmares where I was frequently killed by monsters in my dreams - those, too, are long gone.

dearieme (2013-12-03 14:17:06)

In view of Cliff's comment, may I ask whether we are the first generation of Westerners to have trouble from wheat? If so, why? Seth: Not enough fermented food? Too much refrigerated food? Not enough microbe-rich leftovers?

GB (2013-12-04 05:23:12)

dearieme, perhaps the introduction of dwarf wheat varieties is part of the reason

Cliff Styles (2013-12-04 08:42:19)

Seth: your comment about fermented food may be apt. Here's one small test I have done over the last couple of years, because of an accidental discovery. On vacation, I tend to indulge eating bread or pizza, and that night my snoring will increase and the cough will come back the next morning. Well, a couple of years ago while on vacation we happened to stop at a small farmstead which advertised cheese. The cheese was excellent, and they also made yogurt, an intense and funky yogurt that I loved. I ate quite a bit of it that day, after eating quite a bit of bread at lunch and dinner, and the next morning - no cough,

and my wife said I had been very quiet that night. So, I have tried this experiment perhaps half a dozen times since then, and a little more than half the time taking yogurt at bedtime on a day I have indulged in some wheat product will eliminate the reaction. The older, funkier the yogurt, the better, store-fresh yogurt either works poorly or not at all. Perhaps not conclusive, but suggestive? Seth: Maybe the microbes in the yogurt and cheese made it harder for the wheat molecules to be absorbed into the blood. The microbes and microbe fragments clogged a lot of holes that would not otherwise be clogged. It's a very interesting argument for the importance of fermented foods.

dearieme (2013-12-04 18:11:52)

What is "funky" yoghurt? Seth: short answer, yogurt that smells like socks.

Cliff Styles (2013-12-05 09:09:50)

'Funky' - I was going to say smells like 'cheese cellar by the barn' but 'socks' is better...The taste is different from regular yogurt as the taste of aged cheddar is different from mild cheddar.

dearieme (2013-12-05 12:39:16)

I knew only that the title of the old jazz tune "Funky Butt" means "Farty Arse". Now I know more.

Cap (2013-12-08 12:06:05)

In the weightlifting / bodybuilding community it's heavily emphasized that one of the most important things you can do for full recovery and progress is get enough quality sleep. So perhaps the sleep improvements from the honey were enough to improve the body's response to a training program.

Paul N (2013-12-09 01:35:59)

On the topic of wheat, Joel Salatin had an interesting take on it. His theory is that in pre-mechanized times, when wheat was harvested and tied into sheafs and allowed to stand in the field for several weeks, that the dew each night caused a mild fermentation. Weston Price and observed that the health benefits of whole grain wheat were only gained when the wheat was freshly ground and eaten within days. Modern wheat not only is harvested straight into the combine, but the flours can be years old by the time they are consumed, plenty of time for the omega oils in them to oxidize. I have seen comments by some (American) people that have wheat sensitivities, but to do not have them when travelling in Europe, and they attribute that to different types of wheat being grown there. Finally, on the topic of kefir settling the stomach, I can personally attest to that, it does wonders!

Cathy (2013-12-10 18:39:23)

I have gluten allergy and dairy sensitivity (not lactose intolerant) and when traveling to Italy this past fall I ate all the bread, pasta and cheese I wanted with no ill effects. I do believe there is a difference in the foods in Europe. Could it be the bromated flour here, which is not used in Europe? I am going to try the honey tonight. I stumbled across this blog from Tim Ferris on FB. Glad I did!

Cliff Styles (2013-12-11 13:32:25)

I've travelled in France and Italy a fair amount, and when I do I eat wheat in many forms, since I won't even try to resist all the creativity with wheat in those cuisines. I invariably get my wheat cough back, and the bad sleep, too.

## **Magic Dots: User Satisfaction (2013-12-05 05:00)**

A reader named Niles McAdams, who told me about [1]his strength increase from bedtime honey, also wrote about his experience with [2]magic dots (a way to mark progress):

I have become a HUGE fan of your Magic Dots idea for many reasons. I started using them to increase the time I spent at my standing desk but since then I've used them to keep my writing and programming projects on track.

Here are some of the advantages of Magic Dots:

They can be customized to the individual. Instead of using 10 points and lines to make a box with an X in it, I use six points and lines (10 min. increments) to make a triangle. I would imagine for almost any time increment that a person wished to use, a shape could be found. I used 10 minute increments but one wouldn't have to - imagine, for example, a grade school child studying a spelling test. The parent could ask the child to study for one triangle or ½ hour where each dot or line represents a 5 minute increment. There are many many shape and increment possibilities - enough for any person or task.

They are mostly an intellectual tool not a physical tool. One doesn't need a laptop, tablet, smart phone, Fitbit or any other modern technology to use Magic Dots. One could scratch them out in the dirt with a stick if need be (and in fact, I may do just that when it comes time to weed my garden next spring). Of course you need some way of telling time so a watch is handy but if the sun is shining you don't even need that - a vertical stick in the ground and a few scratches in the ground could record the passage of time well enough. It goes without saying they don't need electricity - pencil, paper and watch or clock and you are in business.

They can be used to show work history. For a while, I would mark my Magic Dots horizontally, side by side, on a piece of paper. Each new day I would start a new line. This allowed me to see at a glance how much standing I had done during the week.

They can be used to show work by category. A few times I have drawn vertical lines on the paper to represent different work categories, e.g., writing versus programming. I combined this with the line per day technique above. At a glance I could see "on Tuesday I had 3 triangles standing, 2 triangles writing, and 1 triangle programming.

1. <http://blog.sethroberts.net/2013/12/03/bedtime-honey-increases-strength/?preview=true>
2. [http://blog.sethroberts.net/wp-admin/edit.php?category\\_name=magic-dots](http://blog.sethroberts.net/wp-admin/edit.php?category_name=magic-dots)

---

Kristian Dupont (2013-12-05 07:15:13)

I've added a "magic dot timer" to my pomodoro app. I thought the 25-minute timebox was the highest resolution time management that I could apply, but being allowed to make a little bit of tangible progress every five minutes \*does\* make a difference. It's rather surprising that the constant distraction isn't actually counterproductive. One problem that I find though, as with all gamification, is that I tend to think that if I won't have enough time to finish a complete pattern, I might as well not start at all. This applies to pomodoros in general as well - if I don't have a full 25 minutes before that meeting, I often catch myself wasting the 15 minutes that I do have.

Jim (2013-12-05 08:08:43)

My thoughts are similar to those of Niles. First, I've also gone to a triangle, but with 5-minute increments, so that each triangle is a half hour. (The half hour blocks minimize the starting friction problem mentioned by @Kristian). Second, I've also started keeping a record for tracking purposes. I think the initial benefits mentioned in earlier posts were mostly directed to getting started and keeping momentum. Magic dots are also a great tool for tracking work over time.

Cliff Styles (2013-12-05 09:05:54)

I've been trying this since Seth mentioned it, and it's not helping much. I am very interested in measuring attention, apt and inapt, and so far I find this particular method difficult to sustain. Trying different variations now.

Jim (2013-12-06 16:46:23)

Seth, Do you still have a percentile feedback tracking app on the back burner? Seth: Still working on it. I use an R version every day.

## **Government as Useful Irritant and Rules of Innovation: What Libertarians and Other Economists Miss (2013-12-06 05:00)**

Hayek, Keynes, Milton Friedman and Paul Samuelson disagreed about many things but shared one important belief: Their ignorance about innovation didn't matter. Countless economics textbooks, which say nothing of interest about innovation, agree with them: ignorance about innovation doesn't matter. This belief freed Hayek et al. and textbook writers to make sweeping policy statements. Had they realized that innovation matters, not just productivity – and, especially, that innovation and productivity are sometimes at odds – it would have been far less clear what policies are best.

If you ask how will this affect innovation? about any economic proposal everything changes, especially your certainty that it is right or wrong. I will give just one example. Libertarians – I hope I am describing Tyler Cowen's "smart" libertarians – believe that government interference by and large makes things worse. People function best when given freedom, and so on. A smart libertarian recognizes the value of speed limits, and so on. An example of smart libertarianism, I assume, is [1]Tyler's recent view that a local increase of the minimum wage is "expressive voting at the expense of good economic policy."

Libertarians and other economists neglect the possibility that government serves as a useful irritant. Government regulations are truly an impediment. No doubt about it. No doubt they make life harder for people with some power. The usual argument is they protect the weak from the powerful. Without them, the powerful would exploit the weak. Sure. They would. But that's not all. What goes unsaid and apparently unnoticed is irritating the powerful makes them think. Pain produces thought – about how to avoid the pain. And thought increases innovation.

As a professor at Berkeley, I hated the government-mandated institutional review boards – the human subjects approval committee and the animal research approval committee. They didn't just make research far more difficult due to paperwork requirements, they did horrible things to people based on misunderstandings and mistakes. And there was no appeal. How awful, right? Well, it was certainly painful. That pain is one thing that pushed me toward personal science, where I could be free of them. Pain pushed me to try new things – such as long-term non-trivial self-experimentation. The less I could do professional research (my Ph.D. is in animal learning), the more time I had for personal science. And I brought to my personal science the skill set of a professional scientist (an understanding of experimental design and data analysis, subject-matter knowledge, and so on). Innovation always comes from exploration. The more exploration, the more innovation. Pushing powerful people (such as a Berkeley professor) to explore is a seriously good thing.

Planet Money recently did a series on T-shirts. Planet Money reporters travelled the world – the Planet Money men's T-shirt is made in Bangladesh – and encountered several things not in economics textbooks. One was [2]the story of how clothing factories came to Bangladesh. That you could put a clothing factory in such places and make a profit was a discovery with great consequences, especially for Bangladesh. In the 1970s, American clothing companies felt endangered by imported clothes – from South Korea, for example. They pressed government for trade protection. This led to the passage of the [3]Multi Fibre Arrangement (MFA) which regulated clothing imports. The agreement,

however, said nothing about Bangladesh, which at the time did not make clothes. When South Korea reached its limit under the MFA, a Bangladeshi businessman approached Daewoo, a giant South Korean clothing maker, suggesting that they duplicate their factory in Bangladesh. The head of Daewoo – a powerful man pained by government regulations – was open to their suggestion. Daewoo helped open the first clothing factory in Bangladesh. There are now more than 4000.

When it comes to productivity, there is one set of rules, which economists have worked on since Adam Smith. Innovation has a different set of rules. Most economists seem barely aware that the two sets of rules often clash – what is good for productivity is bad for innovation. Let me sketch a few of the innovation rules. Innovation needs freedom, of course, and the ability to profit from your invention, which I'll call benefit. It is also called self-interest. The importance of benefit/self-interest for innovation is the main point of [4]Why Nations Fail by Acemoglu and Robinson. Innovation is also increased by resources, such as skills, knowledge, space, and equipment. After discussing this with Bryan Caplan, I believe many economists are well aware these three factors (freedom, benefit, resources) affect innovation. All three also increase productivity – for example, more resources, more productivity. Far fewer economists realize that two other things, which act against productivity, are also very helpful for innovation:

1. Pain. Not a lot – not debilitating or all-consuming pain – but enough to make you think hard. Necessity is the mother of invention is the aphorism, which isn't quite right. Pain, not necessity. Government is useful here, as I said. So is war. Many innovations came from wars. A famous example is [5]the greenback, which came from the Civil War.

2. Stability. To innovate, you need free time, which is different from freedom (ask any prisoner). Free time allows painless failure, very helpful for innovation. To have free time, you need a secure job. Government is useful here, too. So is tenure. Pain plus stability = peacetime military spending. The internet came from peacetime military spending. Professors were the first users. Stability also promotes innovation because it makes it easier to detect small improvements. The quieter it is, the better you can detect soft sounds.

[6]My personal science had a good amount of all five factors. 1. Freedom. Studying myself, I could do whatever I wanted. 2. Benefit. At first, I benefited because my discoveries were very practical. If I discovered how to sleep better, I would sleep better. If I discovered how to lose weight, I would lose weight. Later I also benefited because others were interested (I like attention) and my discoveries helped others. 3. Resources. I knew a great deal about the relevant subjects (e.g., circadian rhythms, weight regulation) and how to do research. I could get whatever articles I wanted from the UC Berkeley libraries. And so on. 4. Pain. In addition to the pain caused by Berkeley IRBs, I wanted to sleep better and lose weight. My sleep was not awful nor was I especially fat – it was not intense pain. But it pushed me. I tried to improve my sleep for ten years before I started making progress. 5. Stability. My life was very stable. I rarely took long trips, for example. Failure in my personal science – a treatment that I hoped would improve my sleep didn't work, for example – cost very little. Failure to publish cost nothing.

In contrast, professional scientists, who have plenty of resources, are generally low or at least lower on the other four factors (freedom, benefit, pain, stability). They lack freedom. They are constrained in many ways, which they don't like to talk about. They lack benefit. A few papers that hardly anyone reads – the result of most research – provides little benefit. Almost all research has no practical use. Few scientists study problems that they themselves suffer from. A cancer researcher does not himself have cancer, for example. They lack pain. I cannot think of a single instance where professional research was motivated by the researcher's pain or discomfort. If they don't need a grant for their research and have tenure, they have stability; but if they do need a grant or don't have tenure, they have less stability than I did. Most research grants are only three years long and renewal is rarely easy or assured.

I wrote about the same question – why was my personal science "unreasonably effective"? – [7]here.

What does this say about economics and how to increase innovation? The importance of benefit and resources is already clear. But the remaining three factors – freedom, pain, and stability – are complicated. By and large they are corners of a triangle. The more freedom, the less pain and stability. The more pain, the less freedom and stability. The more stability, the less pain and freedom. You need all three – a point in the middle of the triangle – and where that point should be and how to put it there are exceedingly non-obvious. Once you realize this, your certainty about how to organize society, how run a government, and the best size of government should decrease. A problem with increasing inequality, which I have never seen pointed out (e.g., in a speech about why inequality is bad, [8]Obama didn't mention it), is that it makes the powerful (those at the top) more comfortable. When you make the powerful more comfortable, you reduce innovation.

jon (2013-12-06 07:54:51)

In a free market I wonder if people would have been doing the personal science anyways since market forces would push towards that which is normally most efficient and cost effective. So, if you didn't have the government bureaucrats in your way to begin with maybe you would have been doing personal science for a much longer time. It's hard to tell, the broken window fallacy, the seen and the unseen. The detrimental effects of government seem to outweigh any benefits. Just because we would live in a free society doesn't mean that there wouldn't be speed limits still, or something even better that works to keep people safe while driving (who knows, without the government we might be flying instead of driving).

August (2013-12-06 07:56:47)

Are you afraid to say you are just different from other people? The assets wasted by government far outweigh any value the pain it brings might have in forcing people to be innovative. The global resources dumped on the climatology researchers, for instance. Then there is the flip side of the waste. How much science is actually happening any more? When I first read Celia Green I thought she might be a bit crazy, but there's enough crap research coming out for me to realize I could do a better job- and if it weren't largely a political rent-seeking operation now, I would be. Even my fellow students could tell I was different- they mainly wanted to know how I could remember all the stuff, and I finally realized it was mainly because I was more interested in it than they were. But pain comes from poor sleep, acne, etc... Pain would also come from half a dozen other things, and there is no way to qualify how much pain is actually necessary. Suppose I actually got stability, and more resources than I knew what to do with. I'd experiment more, and my experiments would just get bigger. They wouldn't necessarily be based on pain. Indeed, your own ideas about hobbies and gifts would suggest pain isn't crucial to the innovative process, especially not the pain of government.

dearieme (2013-12-06 08:07:39)

To encourage innovation by academics, I recommend that a large proportion of research funds be distributed by drawing lots.

(i) Then instead of devoting time to preparing untruthful grant applications they can devote time to their work, or to productive leisure. (ii) With smaller grants, they will be obliged to be more ingenious in their work. Seth: Yes, I agree. The Canadian system is similar, lots of small grants.

Charlie Currie (2013-12-06 09:18:02)

There was no government pain in 1947 when hydraulic fracturing (fracking) was invented. I would say just the opposite. Now that it is economically beneficial to employ it, and it is wildly successful, there is going to be a whole lot of government pain brought to bare in the form of regulations and restrictions on its use. So the question is, will this new government pain bring about innovation (which will then be regulated and restricted) or less energy.

Charlie Currie (2013-12-06 09:32:30)

I'm not too concerned that increased inequality will lead to the elite and powerful being less innovative. How much innovation actually comes from the elite and powerful anyway? Elite and powerful tech companies seem to release new innovations on a daily basis, however, when you look closely most of these innovations were purchased or licensed from non-elite and far less powerful individuals or companies.

Taconic (2013-12-06 09:40:33)

Nature puts more than enough pain and irritants in human life paths; no need for artificial (government) obstacles to increase that vast natural burden. The natural state of human beings on this planet is abject poverty, suffering and death. The only economic system ever known to raise large masses of population from poverty – is free market capitalism; collectivism in all its various forms (e.g., coercive economic regulation & central planning) has consistently failed to do so in all of history. The post was obviously intended as a mild slam against libertarians and free markets. Note that "innovation" is a central principle of free market economics – it's an absurd assertion to proclaim otherwise.

Seth Roberts (2013-12-06 14:38:39)

"Collectivism in all its various forms (e.g., coercive economic regulation & central planning) has consistently failed to do so in all of history." You don't realize that all governments have collectivist (= coercive) elements? You think that the Internet and greenbacks – not to mention Darwin's theory of evolution – arose because of "free markets"?

Seth Roberts (2013-12-06 14:44:10)

"How much innovation actually comes from the elite and powerful anyway?" Okay, tell me one major innovation that didn't come from the elite and powerful? Darwin: inherited wealth, didn't have to work. Mendel: rich religious order. Pasteur: powerful chemist. Bell Labs: rich, AT & T very powerful.

Seth Roberts (2013-12-06 14:51:43)

"In a free market I wonder if people would have been doing the personal science anyways since market forces would push towards that which is normally most efficient and cost effective." Whereas I think the fact that people can find health specialists (doctors) pushes them away from studying their own health. They would rather leave it to the specialist – do what the specialist says. They fail to understand that the fact that the specialist needs to make money has a big effect on what he advises. They fail to understand how much they are losing. When I started to study my own sleep (to improve it), I had no idea how much better solutions I could find compared to what a doctor would tell me to do (take sleeping pills).

Adam (2013-12-06 18:43:32)

I see a central planning fallacy here. Who knows what the right amount of innovation is? It also boils down to a moral question. People should be free to do what they want so long as it does not harm others or interfere in the others' freedom to do what they want – this is liberty. Government's pain violates liberty. Is violating liberty justified because it might increase innovation? Seth: Long ago, at the very dawn of governments, everyone had a choice: live under a government (coercive but also protective) or not (no coercion, no protection). Apparently the government system was the more popular choice, since that's what we have now. Now there is no longer much of a choice. Governments provide both loss of freedom (coercion) and protection. It

seems to me not to be a "moral" question but an economic one: is the cost (coercion) worth the benefit (protection)? The innovation is a kind of unanticipated bonus, that the original choosers (between government and no government) didn't think about. Curiously governments, by producing pain, caused better governments to be invented. That's where democracy came from – government-induced pain.

MJB (2013-12-07 03:20:24)

Shumpeter and Kondratieff were the economists of innovation. The pain of the economic collapses of the 1870's and 1930's fostered innovation, hence the term 'creative destruction.' The whold focus of modern democratic government is to prevent the pain of another economic depression. Some argue that the black plague of the 1340's and the little ice age fostered the innovations that produced our world.

MJB (2013-12-07 03:50:58)

"Bad Medicine: Doctors Doing Harm Since Hippocrates" by David Wootton discusses historical impediments to innovation in medicine.

TomGinTX (2013-12-07 08:27:04)

[...] Innovation changes everything, by Seth [...]

TGGP (2013-12-07 16:32:03)

I don't understand the point of your Bangladesh example. It just sounds like government causing a pecuniary shift from South Korea to Bangladesh rather than any innovation. Seth: It was more than a location shift. It was the discovery that you could get good output using a lower-quality location. In Bangladesh the workers were less well-educated than in Korea and there were many other differences. It was somewhat like discovering a new source of energy.

Ray Lopez (2013-12-07 22:01:44)

Professor, please let the scales drop from your eyes! CNTRL + F "patents" yields NO hits on this blog post. NONE! Please quit being blinded by ideology and mention how a reformed patent system can increase innovation. How government-say by offering a prize as GMU's Alex Taberrok has suggested, with the invention then becoming public domain-can increase innovation. Inventions \*can\* be 'engineered'. It is a humanities major's myth that inventions happen in a 'flash of genius' akin to a lightbulb going off. Please turn the corner and take your arguments to the next level-mention PATENTS. It's amazing how economists think that because good Samaritan nerds who invent for free (yes, they not only exist, pretty much all Nobel Prize winners are in this category, and are responsible for much of human progress) are the only people out there. If inventions were better compensated by government, you would have more of them. It's akin to a "public good". Thank you! Seth: Blinded by what ideology? Care to offer some evidence that a reformed patent system will significantly increase innovation? Reforming the patent system might one of my five factors – how much an inventor benefits. Please notice there are four other factors. It is far from clear that lack of benefit is the big problem now.

Ray Lopez (2013-12-08 07:01:31)

Seth says: "Blinded by what ideology? Care to offer some evidence that a reformed patent system will significantly increase innovation?" Yes, here is some historical evidence: <http://www.ladas.com/Patents/USPatentHistory.html> The 1474 Venice patent act predates that city-state getting into manufacturing-coincidence? Not. The 1624 English reform of patent monopolies predated England becoming a manufacturing powerhouse-coincidence? Not. The US Founding Fathers thought patents so important they put it into the US Constitution, and the rest is history-coincidence? Not. US Patent were reformed so as to abolish the need for a working model in 1880, and US industrialization took off after that change-coincidence? Not. U.S. Patent Act of 1952 clarified and simplified existing U.S. patent law and the US economy enjoyed a Golden Age thereafter-coincidence?

Not. US Patent law was restricted by caselaw in the 1960s and 70s to make it harder to get a patent—and US productivity slowed down around the early 1970s—coincidence? Not. US patent law was again relaxed by R. Reagan's administration with the creation of a special court to hear patent cases, and make patents stronger, in 1982; the US economy and stock market boomed—coincidence? Not. You may ignore the evidence, or you may say it is a coincidence, or you may say that the patent laws were concomitant or coincident with the events that followed—that's your choice depending on your ideology. "Reforming the patent system might be one of my five factors — how much an inventor benefits. Please notice there are four other factors. It is far from clear that lack of benefit is the big problem now." - if it's "far from clear", then I may possibly have a point, yes? I'm glad you have an open mind on this issue professor. Thanks for the soapbox. Seth: I don't think the evidence you provide supports your position. It takes decades for a new invention to have a significant effect on the economy – to grow big enough. Yet you describe cases where the economic change followed the patent law change much soon than that. For example, your 1982 example. On the other hand, yes, you may have a point. I mentioned Why Nations Fail which makes roughly the same point as you are making.

Do sharks smile? | 43coms (2013-12-08 17:50:33)

[...] Seth Roberts likes that government could be seen as the irritant necessary for change, lest we get too comfortable with a status quo. [...]

RAD (2013-12-09 07:13:44)

Seth, if you were appointed "Czar of Useful Irritants" do you believe you could increase the rate/degree of innovation in the United States? Seth: No I don't think this theory of mine is ready to be used as the basis for public policy. Better to be used to guide research. For example, compare theory to practice, where innovations come from. To increase innovation in the United States, I would make life easier for small businesses. Some regulations are useful irritants, plenty of others serve to crush small businesses. I agree with that aspect of libertarianism.

Charlie Currie (2013-12-09 08:11:08)

Seth says: "Okay, tell me one major innovation that didn't come from the elite and powerful?" Skateboards three-axis aircraft controller Seth: Skateboards are a major innovation? I disagree. Who invented the three-axis aircraft controller? Speaking of skateboards, I do know that the mountain bike came from the elite and powerful. It was invented by the brother of one of my classmates.

m (2013-12-11 07:22:22)

FYI, the Bangladeshi example has been discussed a fair amount by economists <http://www.amazon.com/The-Elusive-Quest-Growth-Misadventures/dp/0262550423> [http://www3.grips.ac.jp/globalcoe/e/publications/working\\_papers/empirical/GCOE\\_EWP21.pdf](http://www3.grips.ac.jp/globalcoe/e/publications/working_papers/empirical/GCOE_EWP21.pdf)

## Why Does Bedtime Honey Improve Sleep? More Helpful Data (2013-12-07 05:00)

At [1]Free The Animal, Richard Nikoley blogged about the value of potato starch and other examples of [2]resistant starch (RS) which is slowly-digested starch. As a reader of this blog named Xav [3]points out, three commenters say it has improved their sleep:

1. On week three of 3 TBS of Potato Starch per evening. Any explanation on the exceptional, uninterrupted deep sleep? No complaints mind you. Have never slept so well. Never. [Richard did explain the deep sleep – Seth]

2. After a few days of a few Tbsp RS in the evening, here are my observations . . .

- sleep has been better the last 2 nights without any particular change of lifestyle.
- dreams are vivid, I remember them much more

3. I took 4 tbsp of PS last night. . . I had an incredible sleep (but no vivid dreaming, however). I mean, I did not wake up even once. I was sound asleep from the beginning to the end and it was such the most sweet and tranquil sleep I ever had in a long time!

Emphasis added. Someone else said, "Have been doing this for about a week now. 2T in am and 2 T after dinner. Sleep may be better." No one reported better sleep after resistant starch at other times. Richard said nothing about the time of day to eat it. Several people say it raised their blood sugar.

Readers of this blog know [4]there is abundant evidence that bedtime honey improves sleep. Honey is not a resistant starch, although fructose (honey is half glucose, half fructose) is digested relatively slowly. Potato starch and honey differ in many ways. That both, eaten near bedtime, produce better sleep, suggests that the better sleep is due to something they share. One thing they share is both increase blood glucose throughout the night. Honey does so because it contains a quickly-digested sugar (glucose) and a slowly-digesting one (fructose). Potato starch does so because its carbohydrate is slowly converted to blood glucose.

The potato starch stories support what I've said ([5]here and [6]here) about why bedtime honey improves sleep, namely: You need a certain amount of blood sugar to sleep well. Many people have too little (e.g., due to a low-carb diet). Honey, [7]a banana, or resistant starch near bedtime are three ways to ensure enough. When this becomes well-known, the improvement in well-being will be great.

---

david s (2013-12-07 07:52:28)

In a previous honey-sleep entry, you quoted someone noting that raw honey had less effect than cooked honey. If cooked honey, PS/RS, or a banana each work to improve sleep, would it make sense why raw honey does not? Does cooking change the relative levels of fructose and glucose, or is it more likely that raw honey does actually work and the observation was skewed by something else?

Douglas Clegg (2013-12-07 08:44:26)

I can attest to resistant starch improving sleep and even a sense of morning calm (as opposed to a kind of morning argument in my mind, which I'd frequently had – and which might've been a result of poor sleep.) I take the starch with kefir, and have become hooked on kefir as a daily staple. I don't know how much the kefir plays into this. I go for unsweetened but sometimes they're out, so I get the sweetened. There are other benefits of the resistant starch (or great sleep) for me, as well, mainly

overall improved mood and outlook whether I take it at night or in the morning. But to be clear: for sleep, I take 1-2 tbsp at night. For morning, 1-2 tbsp mixed with kefir is often breakfast-appetite suppressant. (Not hungry again until the afternoon.) My husband often feels unrested from sleep. He went for a sleep study and they found no sleep apnea. When he took 2 tbsp of the unmodified potato starch with about a cup of kefir before bed he experienced great sleep. Also we both get intense, memorable dreams that seem less "flat" in memory later and retain their vivid quality. All of this may be an effect of deep sleep. To see how long the effects lasted, I stopped the resistant starch three weeks ago. It took 2 weeks for my poor sleep to return. However when I used honey instead – just to see if there was a difference and after reading your blog – I had a few of the worst nights of sleep in awhile. Not sure why, but part of it may be that I'm one of those people who gravitate toward non-sweets over sweets. I like sweet things, and I like honey – but I've always known via taste that there's something about direct sugar and honey and any sweetener separated out from other food (as opposed to mixed or baked within something or occurring naturally within it like milk) that doesn't taste that good to me. However my husband puts honey or sugar in coffee every day and loves hard candy (I've haven't liked it for years). When he got the teaspoon of honey at night, he again had great sleep. Also started on the blue blocker glasses, which have helped me get to sleep. All of this has made me understand that sleep may have been my main stumbling point in life – for decades. Good sleep with remembered, intense dreams has always equalled good mood, productive day and a willingness to participate more and tackle problems. Long note, but wanted to put it all down. And thank you for your insights. I typed this via smartphone so please pardon typos.

Hap (2013-12-07 08:55:52)

A few years ago, Kathleen Des Maisons wrote a book called "Potatoes, Not Prozac." As an aid for recovering addicts — most of whom, she says, are sugar-sensitive — she recommended a baked potato before bed. The release of serotonin was what she focused on. Seth: Interesting, I'll check that out. Eating a baked potato before bed has many effects. I wonder why she chose one of them to emphasize (release of serotonin). Perhaps she believes what professors of psychiatry say about causes of depression, but she shouldn't.

dearieme (2013-12-07 09:01:17)

Presumably not a baked potato with coleslaw? Perhaps just with plenty of butter?

Brock in HK (2013-12-07 09:14:49)

Honey is also more easily incorporated in the diet, as it doesn't require a restructuring of the gut biome to make it effective. Even Richard and others have commented they needed some time for their digestive system to get used to the resistant starch, which they attribute primarily to needing the RS adapted gut flora to flourish and crowd out some of the other flora that were not RS adapted and caused flatulence.

dearieme (2013-12-07 10:21:18)

"RS"? Seth: RS = resistant starch

Charlie Currie (2013-12-07 10:46:22)

I found that consuming 2TBLS of potato starch in the morning improved my sleep (1 wake up - to pee - instead of 2 or 3. I've always been an 8-9 hour sleeper but I found as I got older - I'm 67 - waking up to pee and waking up, but falling right back to sleep increased in frequency)...I really don't think it matters when you consume it. I'm also giving the honey at bedtime a new look...I'm doing it to test the muscle strength component...so far no difference in sleep. I have to be certain not to eat anything for at least two hours before consuming the honey and going to bed. If I don't - as happened last night - the honey causes acid reflux - not a fun thing to wake up to. Knowing that you are also very focused on gut health (consuming fermented foods) you should find this post on FTA regarding resistant starch and improved gut health very interesting: <http://freetheanimal.com/2013/11/resistant-american-comparison.html>

Tatertot (2013-12-07 14:02:35)

Hey, Seth! Richard's buddy here from FTA... I love everything you say except that RS is slowly converted to glucose. It's actually slowly converted to fat-SCFA to be exact. Hardly and, if any at all, gets converted to BG-simple to test with BG monitor! I

don't think anybody ever said that potato starch raised the BG—not in the thousands of comments anyway. There was some concern with tapioca starch, which we initially thought was good RS source, but it definitely caused raised BG...maybe that's what you saw? I like you are looking into timing, it's something we haven't toyed with much. We just consider better sleep a nice side-effect. Keep and eye on FTA for some cool crowd-sourcing projects we have up our sleeve. Cheers!

Xav (2013-12-07 14:56:40)

My main self experiment at the moment is using the VSL3 probiotic for a period of 8 weeks, as animal experiments with this specific probiotic have shown appetite / weight reduction amongst other things. I'm currently contemplating starting using the potato starch at night, instead of honey, as the effects of the starch on both the gut bacteria AND sleep may give a 2 for 1 benefit . If I do, I'll report back with any results.

Jeff Davidson (2013-12-07 15:55:27)

I tried honey a few times (1 tbsp) but I felt I slept more fitfully. I couldn't rightly isolate honey as the cause though so I may try again in the future. Regarding potato starch - it's about 85 % Resistant Starch, meaning this: enzymes in the small intestine can't break down the starch molecules into glucose, so it travels into the large intestine for fermentation via bacterial action. In doing so, the gut bacteria produce short-chain fatty acids (butyrate) as waste product that the cells of the colon use as fuel. In other words, RS is a source of dietary fat. A lot of knowledge about RS is just coming to light, but Tim Steele (aka tatertot) did an excellent series of posts on Animal Pharm about his experiences with RS as a means to cure gut dysbiosis. A few people have noticed improved sleep on such a regimen. I've been taking 4 tbsp/day of potato starch for about 3 weeks now (2 tbsp AM / 2 tbsp PM). Sleep quality has been good, but I still occasionally but less frequently experience early AM waking (1:30-2:30 AM). I find I fall back to sleep easier in general though. There was an adjustment period for me as well - tremendous amounts of gas for five or six days (not smelly though, just windy). It has subsided now. Waiting to see if I notice other effects.

Jeff Davidson (2013-12-07 15:59:21)

Regarding muscle strength improvement I have two thoughts: 1. Increase might come from improved sleep. 2. Increase might come from sufficient rests between workouts. I find I gain strength more consistently though working out 1-2 x per week versus 3-7 x per week. Muscles take a lot of time to repair it seems. Seth: when my sleep improved due to honey, the timing of my workouts (daily) did not change.

BRW (2013-12-07 17:07:04)

@Jeff " Yes, the rest between workouts was my initial impression of what happened to an older fellow in a previous post with bell presses. It is well documented that allowing for more rest makes greater strength gains. I would imagine better sleep would promote strength gains. Working out more infrequently resulted in similar gains for me.

Mark L. (2013-12-07 21:00:29)

I have never had any problems sleeping. I have been taking potato starch after my evening meal since July and have been taking a tablespoon of honey since Seth mentioned it in his blog. I noticed more vivid dreaming from the potato starch and hope that it helps my colon since colon cancer and other colon problems have occurred in my family. I look forward to taking the honey before I go to bed and I love its taste; I haven't noticed anything from taking the honey.

Seth Roberts (2013-12-07 23:11:30)

"In a previous honey-sleep entry, you quoted someone noting that raw honey had less effect than cooked honey" I think someone theorized that. I don't think there was any evidence it was true. I suppose the theory was wrong. Someone who actually compared the two found no difference between raw and cooked honey.

daz (2013-12-08 02:17:19)

"In a previous honey-sleep entry, you quoted someone noting that raw honey had less effect than cooked honey" one possible reason, some people may be 'sensitive' to raw honey, ie. raw honey usually contains small amounts of propolis and pollen, it could be possible that this is problematic for a few people... & therefore cancel out the sleep benefits & possibly even worsen

sleep. this may or may not be an allergy, idk, but i did see mention of a 'honey allergy' which listed some possible symptoms to look for, - Itchy throat, - Tongue swelling up, - Watery eyes, - Hives or constant sneezing.

daz (2013-12-08 02:26:17)

(should have read) ...but i guess if the reaction/"allergy" was only very minor, you would Not notice any of these symptoms...but may be it would disturb sleep (and non-raw honey would not)

pond (2013-12-08 08:19:42)

About that glucose/fructose thing, I have a way to test the hypothesis: table sugar and high-fructose corn syrup are both about 50-50 glucose/fructose. So if honey aids sleep by providing the sugar mix, then so would a tablespoon of table sugar in water, or a few ounces of non-caffeinated soda. I wonder if anyone in the dieting group taking the sugar water before bed has had improved sleep? Seth: I'm not sure the timing of blood glucose would be the same comparing table sugar and honey. Table sugar is not 50/50 glucose/fructose, it is 100 % sucrose. Yes, the sucrose is split into glucose and fructose, but that takes a while. But HFCS should work.

tom (2013-12-08 13:45:58)

I wonder if sleep is dependent on how 'fat adapted' you are, or how long you can comfortably go without a meal (I'm not good at fasting).

Stuart King (2013-12-08 16:16:24)

Tom I think you may be on to something there - I don't know much about 'fat adaption' but I noticed my sleep was excellent recently for over a week (I have been measuring my sleep quality) and interestingly enough, that week I lost weight. I got on the scale every morning, and everyday there was a small reduction in weight which ended up being about 1kg (about 2 pounds). As part of my experimentation (trying different dietary approaches), my weight went back up (everyday) to where it originally was after another week or so and my sleep declined dramatically. I think there is a correlation between the two things which probably suggests I was doing something which was good for me. I did originally discover the honey when I was very low carb and it worked well then. I quit very low carb because of health problems it created. I think I might try alternate day fasting for a couple of weeks to see if that improved the honey effect.

Heisenbug (2013-12-09 18:26:59)

Seth, I'm surprised no one's made the probiotic/prebiotic connection between honey and RS. That might explain it. Honey contains oligosaccharides, which feed bacteria and cause blood glucose to stabilize. Just like RS. <http://www.mdpi.com/1420-3049/17/1/248> <http://www.ncbi.nlm.nih.gov/pubmed/15826039>

Seth Roberts (2013-12-09 19:04:17)

"I'm surprised no one's made the probiotic/prebiotic connection between honey and RS." the effect of bedtime honey is instant - same night. surely improving gut biota will take days weeks or months.

Heisenbug (2013-12-09 19:20:52)

Not necessarily. While increasing bacterial count takes longer supplementation, short-chain fatty acid production by one's existing bacteria (which is what creates the hypoglycemic effect) should happen right upon dosage, whether it's the first time or the hundredth. And from anecdotal accounts, many experience the sleep affects of RS almost immediately. Seth: The brain - which controls sleep - runs on glucose. It does not run on SCFAs. To say that small changes in SCFA concentration affect the brain you have to get really speculative (speculative = beyond what is known). What about the possibility that RS improves sleep because it increases blood glucose during the night? Based on my theory that it is the glucose produced by honey that matters, I predict that if I take the honey 10 hours before bedtime it won't improve my sleep. Does the SCFA theory predict what will happen if I do that?

Heisenbug (2013-12-09 19:53:10)

But it doesn't increase blood glucose. It's an indigestible fiber. It passes through undigested and is fermented in the colon. People on ketogenic diets who supplement with RS stay in ketosis. No rise. Seth: I was under the impression that RS is slowly digested starch, not undigested starch. I agree that some of it is not turned into glucose, but I am not so sure that none of it is. However, I agree with you that it is not settled. It's just that when a starch (resistant or not) greatly improves sleep, and sugars greatly improve sleep, and this would explain why we eat dessert, it is tempting to think that the starch improves sleep because of the sugars it generates. Rather than assume two different mechanisms.

Heisenbug (2013-12-09 20:07:27)

And in fact, people's fasting blood glucose in the morning is lower when supplementing with RS, as a result of the SCFAs. Whether or not the lower FBG is what's resulting in better sleep is not clear. To see if the same thing is happening with honey, I think the test is simple enough. Measure your morning FBG after a day without any honey. Take honey that evening, and measure your FBG the next morning. If it's lower, then you've replicated the RS mechanism. Seth: I don't think it's that simple. You write: "People's fasting blood glucose in the morning is lower when supplementing with RS, as a result of the SCFAs." Why is SCFAs the only possible (or even the best) explanation of why their FBG is lower? What about the possibility that RS increases BG at night and this lowers FBG? People who like RS make a big deal of how it differs from other starch, but if a banana (with no RS) at bedtime also improves sleep and lowers FBG – just like RS – I begin to doubt they understand the effects of RS as well as they think they do.

Heisenbug (2013-12-09 21:29:37)

It is the best explanation because: a) It is undigested, and its only effect is fermentation of bacteria and production of SCFA. b) Butyrate's (the primary SCFA stimulated by RS) effect on blood glucose is well-established. c) Again, blood glucose does not rise with intake of RS. Day or night. Try it yourself. Seth: How do you know that blood glucose during the night does not rise with intake of RS? I cannot measure my blood glucose while asleep or I would try it. Also, to get the sleep improvement provided by RS, at what time of day can the RS be eaten? In the examples I've read, it was eaten in the evening. What about eating it in the morning?

Gina (2013-12-10 00:33:41)

Kiwifruit before bed increased sleep onset, duration and efficiency in this study: <http://www.ncbi.nlm.nih.gov/pubmed/21669584>. Better than honey? Seems like a good self experiment. Seth: It's not so easy to get kiwis. Much easier to get honey and to vary the dose. But yeah, worth trying.

Heisenbug (2013-12-10 08:55:02)

Given that RS's physical properties don't allow it to be digested and affect blood glucose, it stands to reason that time of day doesn't have any effect. I don't know for sure whether the time of dosage influences the sleep effect. Most people seem to be breaking up their intake into two doses, daytime and evening. Though my guess is that there is a correlation, as a nighttime dose would feed your gut/boost SCFAs closer to bed. I don't know if anyone's tested this. Also, figuring out if honey lowers morning FBG would be a relevant finding, as it would bring it that much closer to mirroring the RS mechanism.

The Honey and Resistant Starch experiments: Is There a Link? | Mr. Heisenbug (2013-12-10 11:50:35)

[...] an exchange with Seth Roberts in the comments section of this post, I postulate a possible link between the honey experiment that Seth has been blogging about, and the Resistant [...]

Mark L. (2013-12-10 19:47:20)

I take the potato starch after my evening meal in order to experience vivid dreams (which I assume is a healthy symptom), and to encourage a complete bowel emptying upon rising in the morning, and to minimize flatulence during daytime hours at work. The meaning of a vivid dream for me is: when I briefly awake from a dream, I realize that my dream was of long duration with many "scenes" and that those "scenes" were vivid; however, generally I can't remember the dreams in the morning when I get up.

Nathanael (2013-12-16 12:02:13)

Warning about resistant starch. It's great for a lot of people, but for some people, like me, it's absolutely horrible and leads consistently to digestive upset. I had to learn to avoid it as much as possible. I think it depends on the nature of your personal digestive system. My hormone/neurotransmitter balance runs towards a very, very slow-digesting digestive system to start with. Slowing it down further causes gas, bloating, and cramps. It's important that I eat stuff which digests \*quickly\*, because for me, quickly is a matter of hours. I figured this out in a fairly unpleasant way due to neurotransmitter-balance-altering medications and really bad digestive reactions.

### **Warning, Soybean Eaters: Tofu Made Me Stupid (2013-12-09 05:00)**

I've been testing my brain function daily for the last six years. I use a reaction-time test (see digit, type digit as fast as possible) that takes about five minutes. I have gradually improved the test over the years – this is about version 8. One reason for this testing is that I might observe a sudden change. That could suggest a new factor that affects brain function – whatever was unusual before the change (e.g., a new food). This is how I discovered [1]the effect of butter. My score suddenly improved, I investigated. Another sudden change (improvement) happened soon after I switched from Chinese flaxseed oil to American flaxseed oil. I hadn't realized that something was wrong with the Chinese flaxseed oil. I started brain tracking after I noticed a sudden improvement in balance the morning after I swallowed about five flaxseed oil capsules. Millions of people had taken flaxseed oil capsules, but no one, it seemed, had noticed the balance improvement. Maybe other big changes in brain function go unnoticed, I thought.

A month ago, my score suddenly got worse (= I became slower). There was one unusual thing that day, before the test: I had eaten a piece of bai fu ru, a kind of fermented tofu popular in China. [2]To make it, "cubes of tofu are first fermented, then soaked in brines that contain a number of ingredients: rice wine, vinegar, chili peppers, cinnamon, star anise, and red yeast rice, the last which imparts the deep red hue that you'll see in certain varieties." [3]Here is a discussion of fermented tofu in Los Angeles. It's popular in China. Most people use it as a condiment, but I ate small amounts (one cube) alone.

To find out if the bai fu ru caused the worsening, I did a test. I deliberately ate one 20 g cube at 11 am. I do the brain tests in the afternoon, usually 4-5 pm. What happen to my brain score that day? Here are the results.

[4]

Each point is a different test. I conclude that the tofu slowed me down by about 20 ms and the effect lasted two days. I didn't notice the change in other ways – I didn't feel tired or slow, for example. Presumably that is why this has gone unnoticed.

I think these results reflect cause and effect for several reasons:

1. Clarity. A  $t$  value would be very large.
2. Surprising prediction. A surprising prediction turned out to be true. Sharp drops like this are rare. Perhaps they happen once every 3-6 months.
3. Repetition. A research assistant found similar results, although not as clear. She is Chinese – quite different genetically.
4. Other evidence that tofu is bad for the brain. After I found these results, I remembered [5] an old study. It found an association between midlife tofu consumption and late life cognitive decline among Japanese-American men in Hawaii (more tofu, more decline). [6] A related study of the same men found a correlation between cognitive decline and miso consumption. [7] A later study of Indonesian men and women also found a correlation between tofu consumption and cognitive decline (more tofu, more decline). The same study also found a beneficial weak correlation between tempeh consumption and cognitive decline (more tempeh, less decline). A weak epidemiological association found only once means little – epidemiologists, in my experience, do not adjust for the number of tests done and usually ignore the problem. More recently, [8] an experiment using a mouse model of Alzheimer's disease found that a high-soy diet made brain function worse.

Because of the other evidence, I conclude that all tofu (and other soybean foods, such as soy milk) probably impair brain function, not just this version, which contains slightly more than tofu. The other evidence involves lots of non-fermented tofu. Because of the other evidence and my assistant's results, I believe these results will be true for other people.

I can't explain the effect. Tofu is high in omega-6, but the amount of omega-6 in 20 g of tofu is small. Others think that tofu impair brain function due to its isoflavones.

Most nutrition experts say tofu is good for you. Catherine Newman, in O Magazine, [9]raves about it. "In addition to being wonderfully inexpensive, tofu is high in protein, low in fat, and very low in saturated fat. . . . One daily four-ounce [= 120 g] serving is an excellent addition to a healthy diet." [10]The Mind Health Report (October 2012) says tofu is good for the brain. "For vegetarians, good choices are tofu, beans and eggs."

Better informed experts criticize soy but say fermented soy is good. [11]Joseph Mercola wrote, "For centuries, Asian people have been consuming fermented soy products such as natto, tempeh, and soy sauce, and enjoying the health benefits." The [12]Weston Price Foundation website says a lot about the badness of soy but claims fermented soy is healthy. In an article about why unfermented soy is bad, [13]the Healthy Home Economist says, "Please note that fermented soy in small, condimental amounts as practiced in traditional Asian cultures is fine for those who have healthy thyroid function [as I do – Seth]." My 20 g dose was a small, condimental amount. John Robbins, author of The Food Revolution (2001), dismissed the association of tofu and dementia. [14]He argued:

That's not all we know. We know, for example, that dementia rates are lower in Asian countries (where soy intake is high) than in western countries. We know that the Japanese lifestyle (with its high soy intake) has long been associated with longer life span and better cognition in old age. And we know that Seventh Day Adventists, many of whom consume soyfoods their whole lives, have less dementia in old age than the general population. . . . A number of clinical studies have shown that soy and isoflavones from soy are actually beneficial for cognition. . . . Having studied the literature, soy researchers Mark and Virginia Messina conclude that "there is no reason to believe that eating soyfoods is harmful to brain aging." [Robbins failed to mention that [15]Mark and Virginia Messina own a "nutrition consulting company specializing in soyfoods nutrition" – Seth]

I don't know when the Messinas said this. Maybe there was once "no reason" to think soyfoods bad for the brain, but there is now. The new evidence, epidemiology, and mouse evidence make a good case.

Here are two interesting things. 1. A very popular food is dangerous, maybe harmful. 2. Nutrition experts had claimed the opposite: the food is good for you. Even the better ones (Mercola, Weston Price Foundation) got it wrong, ignoring evidence (the epidemiology). It is a good example of experts overstating their understanding. The Shangri-La Diet is another example (every expert said sugar was fattening, I found it caused me to lose weight).

Even more interesting is the methodological implication. Anyone can do what I did, with any food. It's easy, safe, cheap, and takes little time. The bad effects were large enough, and the method sensitive enough, that the bad effects were well above noise. And this is a non-trivial case. Tofu is popular.

We eat thousands of foods. We have millions of genotypes. We eat our food in millions of environments. Your genotype and environment affect how a food will affect you. So a good understanding of how foods affect us would seem to require thousands times millions times millions of tests. It is absurd to assume that anyone else (government, academia, industry) will do the necessary tests. They can't begin to do the tests. In contrast to people doing a job (for example, people in government responsible for food safety) you have a much simpler problem: Is my food safe for me? You only care about one genotype (yours) and one context (yours) and you eat far fewer than thousands of foods. You can do good tests. You can test exactly what you eat in exactly the context you eat it. Compared to the present, where we extrapolate from epidemiology, animal tests, and the rare human experiment, the reduction in uncertainty and increase in generalizability is immense.

If you want to do experiments like this – test foods one by one – with my software (which requires Windows), please contact me. The tests require a training period of 1-2 months so that the scores during an experiment are roughly constant.

---

dearieme (2013-12-09 05:28:29)

Breakfast experiments: I have found that soy milk disagrees with me; Greek yoghurt doesn't.

MaxPower (2013-12-09 09:25:11)

Hello Seth, As an avid reader of your blog, I'm interested in your cognition tracking software. Please do send me a link. Thank you.

tacker (2013-12-09 13:52:46)

I am interested in the software you use to do this experiment. Let me know the details, and I will try it out. Thanks

John Kojis (2013-12-09 14:34:50)

Hi Seth, Not for the comment section. I'm interested in your software, please let me know how to obtain it. John

Martha Rotter (2013-12-09 14:45:50)

Hi Seth, very interesting! I sent this to my sister, who has been a vegetarian for several years. Her comments: "I would maybe give more credit had there been any reference to GMOs. Because of how heavily this crop is subsidized, I will only purchase items with Organic Tofu/Soy. There are correlations that clearly show how GMO products affect performance, underlining how dangerous they are - including soy/tofu, but addressing many other items as well. Corn, anyone?" So just wondering if you noticed whether the tofu you had was organic or possibly GM? I noticed some of the studies you cite are older so perhaps those were done before there was much modification of soy products? Seth: The label is in Chinese but I doubt that it was organic. Whether it is GM, I have no idea. As you say the studies I cite involve people eating tofu 40 years ago, long before GM became widespread.

James (2013-12-09 15:16:08)

Could it have something to do with the red yeast rice? RYR has statin-like properties; my GP is trying to get me to go on it to lower my LDL. Statins have a long history of negative cognitive effects - perhaps it's not the tofu here? Could you try again using tofu w/o RYR? Seth: I used white fu ru. No red yeast rice. That's red fu ru.

Adam (2013-12-09 16:42:35)

Weston A Price foundation summary of harms of soy: <http://www.westonaprice.org/soy-alert> Chris Kresser discussing soy (repeats a lot of the points from WAP; +F for "Soy."; toward the bottom): <http://chriskresser.com/9-steps-to-perfect-health-1-dont-eat-toxins> Pages of studies showing harm from soy: <http://www.westonaprice.org/soy-alert/studies-showing-adverse-effects-of-soy> Seth: Yeah, I said WAPF says soy is bad ("The Weston Price Foundation website says a lot about the badness of soy"). They also say that fermented soy is good – and I tested fermented soy. WAPF ignored the epidemiology in the sense that the epidemiology didn't show that fermented soy was safe.

epictetus (2013-12-10 00:18:57)

I would like to have a go at these experiments. Can I get a copy of the software?

dearieme (2013-12-10 05:40:45)

Ahoy, Seth: an interesting story. <http://www.theguardian.com/science/2013/dec/09/nobel-winner-boycott-science-journals>  
Seth: Thanks, my mom sent me the link with the comment "this is sort of interesting..."

Adrienne GiryGirl Harvey (2013-12-10 09:39:40)

Interesting, I noticed that when I came back to complex fiction books after NOT eating loads of soy I was able to read them faster, gain more info from them, and not struggle. As a soy-product eating vegan I had a VERY hard time with some cognitive tasks, now omnivorous and avoiding soy, I find these same tasks to be VERY easy. It'd be great to try your software and get some numbers to support this... :)

Austin Lutz (2013-12-10 09:43:15)

Seth, Very interested in the possibilities of your software if you have a link and are willing to share I would like to test and give my feedback/story. I have been very closely watching my health and can feel the difference many times when I eat bread or pasta it slows me down but to what quantitative degree I don't know? Yet. Austin Lutz

Sean (2013-12-10 09:44:53)

More than interested in the software. Please contact me

Darren (2013-12-10 09:45:22)

Definitely interested in trying this. Would the software, as-is, work with supplement experiments as well? Either way, this is awesome. I'd love to give it a try if possible. I could see a community get behind this to create dozens of different heuristics that can test the effect of a single dietary choice on an array of different performance tests. There would be so much to discover, especially once you have a pile of data.

Laura (2013-12-10 09:51:59)

I would love access to the test as well. Thank you!

richard murphy (2013-12-10 09:56:52)

I stopped at 'A research assistant found similar results, although not as clear. She is Chinese — quite different genetically' ridiculous statement Seth: Like "loud" and "soft" and "heavy" and "light" "different genetically" is a relative term. There is always an implied comparison. I meant compared to a random person.

steve (2013-12-10 10:02:18)

I'd like a copy of the software. Thanks!

Diego (2013-12-10 10:04:57)

Hi, I would really like to test this on my self. Please let me know how can I get a hold of the software you mention.

Cy Hossain (2013-12-10 10:09:39)

Hey would love to try out this software of yours thanks!!

Michael (2013-12-10 10:42:54)

Very interesting, but you really cannot draw conclusions based on an individual datapoint. You say the t-value would be very large, but if you mean the results of a statistical t-test, this is wrong, you have no degrees of freedom. Why not repeat the experiment a couple more times? Granted you'd be sacrificing a bit of reaction speed for a few days, and the test would still be imperfect because you have expectations about the results and couldn't be blinded to the treatment, but I would find this much more credible if you repeated it even once more and saw the same spike in reaction speed. Seth: This was a repetition. I had seen the same drop earlier when I had eaten the same tofu in the same amount. A t test would compare the tofu day results with the baseline days before and after. I have no idea why you think there are no degrees of freedom. There are plenty... multiple tests per day and multiple days.

Damian (2013-12-10 10:47:06)

I find it rather remarkable that a number of smart nutrition experts (e.g., Joseph Mercola, The Weston Price Foundation) think that unfermented soy is bad, but fermented soy is good. The idea that fermentation gets rid of the badness—to the point where the good outweighs the bad—is tough to swallow (pun intended), and apparently not well-supported by the evidence. I haven't done the sort of testing Seth did, but I have had blood and intestinal tests confirm that I am soy intolerant—and I feel much better, now that I've given soy, of all varieties, up. I don't remember all of the biochemistry behind this, but the lectins apparently cause problems in the intestines and bloodstream (and brain?), while the indigestible, bacteria-feeding starches, cause digestive problems as well.

Jeff (2013-12-10 12:32:59)

Hi Seth, Great post. I'm also interested in testing and your software. Thanks!

kieran (2013-12-10 13:26:01)

Seth, would love a copy of the software! Very interesting post.

Elizabeth (2013-12-10 13:48:23)

Thinking this is a one person, 'western' adaptation situation .. tell all to the people on Okinawa, one of the Blue Zones and healthiest places on the planet!

Sherif F (2013-12-10 13:54:11)

Question: a good way to double-check the results would be to do this on another day after a couple of weeks of avoiding soy, then, maybe to wait a couple more weeks and then do it again. This would show reproducibility. Would also help show whether the first result was a fluke/coincidence. Seth: A research assistant got a similar result. It is no fluke.

nospoonz (2013-12-10 13:58:50)

I like experimenting with different diets. Would be great to see their cognitive effects. I'd like to try your software if I can. Thanks.

mystic\_eye\_cda (2013-12-10 14:17:50)

Unless you're a truly avid label watcher it's very likely you eat soy every day, it's in bread, condiments, and many meat products. Also studies need to control for how the soy is processed, particularly the use of hexane.

allen (2013-12-10 14:37:51)

Hi Seth, thanks a lot for this article, especially for the way you pay attention to the effect of your environment and intake. Devising, testing, and following through with such a testing method, requires a lot of consequence. I admire that. As I experiment on optimal nutrition myself, and also optimal exercise/training regimes, your software approach to measure influence of substances to the body could help me a lot. Is this the way to contact you? Or did you have something else in

mind? thx and bye allen

cody (2013-12-10 15:41:55)

I'm also interested in the self testing software.

Mark (2013-12-10 15:54:29)

I would like a copy of the software as well.

Dave (2013-12-10 17:22:54)

I'd love to use the software to test myself. What do you need from me?

Seth Roberts (2013-12-10 17:31:17)

I disagree that there is something "Western" about this. Epidemiology involving people in Indonesia found tofu consumption correlated with dementia (more tofu, more dementia). And my research assistant got similar results. She's Chinese.

Scott (2013-12-10 17:36:35)

I'm interested in your software, please let me know how to obtain it. Thanks - Scott

Seth Roberts (2013-12-10 17:37:23)
