"I find it rather remarkable that a number of smart nutrition experts (e.g., Joseph Mercola, The Weston Price Foundation) think that unfermented soy is bad, but fermented soy is good. The idea that fermentation gets rid of the badness—to the point where the good outweighs the bad—is tough to swallow (pun intended), and apparently not well-supported by the evidence." I agree, that is remarkable. Unlike a lot of nutritionists, Mercola and WAPF could say whatever they wanted, no one would complain, no funding would be lost, no reputation would be damaged. And yet they applauded fermented soy in the face of evidence – lots of evidence, if you read the WAPF website – that soy is bad or at least dangerous. I cannot explain it. Maybe they are driven more by general principles ("fermentation is good") than evidence. I really don't know.

JGF (2013-12-10 17:42:18)

Hey Seth, my girlfriend is an avid soy lover, I told her this and she didn't take it too well, I did try to sugar coat it as much as possible.....and I didn't call her stupid at all. Anyway her reply that she is following the "Blood Type Diet" and she is Type A, which this book says her blood type gets the most benefit from a mostly vegetarian diet including soy. She is under the impression that other blood types will get little benefit or even negative effects from soy (and a vegetarian diet). Where types A's process it well and benefit from it. Out of curiosity, what was your blood type in relation to this experiment. Also was the blood types recorded in any of the other experiments you looked into? John Seth: I don't know my blood type, sorry. The epidemiology I described involved people of all blood types.

Audrey (2013-12-10 18:05:16)

Or maybe it's simply that Mercola's in the fermented soy business (selling K2 from natto) but not in the unfermented soy business (tofu.) Occam's Razor.

Frank (2013-12-11 02:11:27)

Hi Seth, thanks for sharing your insights. I'm also interested in your software. Look forward to hearing from you how I can get access when you have a moment. Thanks!

Dimitry Venger (2013-12-11 05:33:51)

I would be delighted to test my diet, which I have recently changed considerably (mostly enriched in iron significantly), simply because my SO is anemic and I take most of my meals along with her. So if I could get access to your software, I'd like to see how I score. BTW - do you have any methodology to test the effects of different foods on other bodily functions? (immune system, general alertness, sleep cycle, tendency towards allergic nasal congestion, metabolism and attention span are the

main factors that affect my life)

Ann (2013-12-11 07:18:13)

FYI I have found that soy is my migraine trigger. After eliminating it from my diet I no longer suffer migraines.

dearieme (2013-12-11 07:20:41)

"Seth: I don't know my blood type, sorry." I'm still reeling from this. Different countries are different, eh?

Joseph (2013-12-11 08:49:47)

"She is Chinese — quite different genetically" Are you serious?!? Seth: I already replied to this. You might want to read that.

Jazi Zilber (2013-12-11 11:04:35)

My experience with soy stuff was always bad. I do not measure reaction times. But my stomach is usually quite clear. and i tried it in many forms before, processed soy was almost always significantly bad. I tried soy protein in its various forms. Tofu was bad enough to make me not try it . But not as bad as the meat-like protein things.

Justin (2013-12-11 12:31:31)

Seth: How do you compensate for the psychological sub-conscience effect of your tests? You ate soy repetitively (as you indicate above) HOPING for a slower reaction to prove your inclination. You can say you were trying as hard as you could for the best time/score, but your sub-conscience knows different; almost like a like-detector. I predict that you could repeat this test 1000 times and still have the same slowing effect. Your initial observation, and then your dissecting of your diet was probably the accurate interpretation, but when you repeat it numerous times LOOKING for a negative correlation, you will find it. [Likewise, recent research uncovered on Global Warming data indicates a similar situation where scientist were looking for Global Warming and some went out of their way to misinterpret data at the fringes to find it. Now that average temperatures decreases from those peaks, they call it "Climate Change".] Anyways, the more scientific and truer test would be to consume the soy, and then something that isn't soy to determine if there is a placebo effect on your results. But it would take a third-party to execute that for you and not telling you what you're consuming. Take a heavily flavored soy-mild versus a flavored rice milk. And repeat it numerous times then look for correlations only after it's revealed what you consumed after the fact. Thanks for the links in your post; I think the outside evidence is there which you seemed to have researched after you experienced the initial delayed reaction ( #4 above). Seth: No I didn't hope for the result I obtained. Actually I always hate it when there is a drop. I wonder if I will recover. But you are certainly right that the question is far from settled. I don't agree that later better evidence will be "more scientific" – science needs all sorts of evidence.

Ed (2013-12-11 12:59:39)

I'd like to try your software please. I eat plenty of soy and feel like this would be important to know for the long term effects. Thanks in advance!

Patricia (2013-12-11 13:21:02)

Hi Seth, This sounds really interesting. I would love to do the experiment. I would really appreciate it if you could send me the software. Thank you! -Patricia

progreterian (2013-12-12 02:37:28)

Your findings are absolutely correct. Within the paleo community it's no secret that soy creates brain-fog. Here's the missing element: Soy is estrogenic. Which means it acts as some weird estrogen surrogate in your body and messes with your hormonal balance. Men can feel impacts quicker than women, because of naturally higher testosterone levels. But the long term effects for women are worse. The little testosterone women have gets basically wiped out. It can't counteract the natural estrogen levels AND soy estrogens on top. That's why soy-rich vegetarianism is the most common road to breast cancer. At least become a pescetarian and avoid soy like the plague. Dave Asprey from [www.bulletproofexec.com](http://www.bulletproofexec.com) has been negatively addressing soy and its effects for years. Check out his research. He's a very innovative thinker similar to you.

Seth Roberts (2013-12-12 03:27:40)

"Here's the missing element: Soy is estrogenic." That's an interesting explanation. I have two questions: 1. Why should estrogens cause brain dysfunction? 2. What other foods are as estrogenic as soy?

progrearian (2013-12-12 15:07:56)

I'm not an expert on the topic, just a well-read and heavily researching self-experimenter. 1. The estrogenic effects of soy kick off a chain reaction slowing down the ways the brain is being "fueled", which results in foginess. Phytoestrogens are quite controversial and as far as I know allowed in the US, but if you want to feed it to your baby in Germany for example, you need a prescription. If you mess negatively with the dominant sex hormone of each sex, you do no good. There's no heavy research on it, but as a self-experimenter you can do the following: do your self-reaction test, but instead of eating soy beforehand like you described above, eat some brazil nuts. Those are the most potent natural source of testosterone equivalents. I did that and it sharpened my thinking tremendously. I guarantee you will find similar results. 2. There are many nuts and oil seeds containing phytoestrogens, but in my own diet I have only found flax seed to be as harmful to my brain as soy.

Nico (2013-12-13 03:01:28)

Thank you for this very interesting finding. I'm a string believer in the effects of food on our (immediate) well-being and a health geek. I'm especially fond of your rigorous self-testing. (I'd love a link to the software you use by the way). But I wondered if you could enhance your self-experiment to prevent a placebo-effect. Since you might have read all those articles about tofu being not good for your health, there is a possibility that your unconsciousness might slow you down during the tests, just to make sure you're right. So you would need not to know in advance, if you're eating tofu or not. In addition you might want to make it double blind. So when you're eating it, the person/the cook doesn't know what you're eating either. I thought about cooking up maybe five different dishes, so heavily spiced for example that you can't taste if it's tofu or something else. Then somebody packs them for you in boxes labeled with numbers. Which is which, you can't know. Then you eat one of those every day, and later check if it really was the tofu all by itself. It is certainly a bit overengineering, but might be worthwhile to make sure, we're not fooling ourselves. Thanks again and all the best Nico  
Seth: I had forgotten about one of the epidemiology articles when I did the test. The other one I never knew about. The food I tested here I ate for years. One day my score was surprisingly low and the only unusual thing about that day is that I had eaten the tofu. That's why I did this test. None of this supports the explanation you propose.

Jerry (2013-12-13 13:09:08)

Here are some observations from a long-term N=1 experiment: I used to eat a strict macrobiotic diet consisting of brown rice, vegetables (mostly brassica), beans, seaweed, and relatively high proportions of soy (tofu, tempeh, miso, soy sauce), nut butters, as well as occasional artificial garbage like "Nayanoise" and "Rice Dream". I did this for years. At first, I experienced weight loss. Eventually (about 3 years later), I noticed that I often had mood swings (no doubt caused by blood sugar changes), cravings, and low energy. I had what today I call "brain fog" most of the time, and difficulty concentrating. Most interestingly, I noticed that I had an increasing tendency to be more sensitive and emotional rather than rational. I attribute this to phytoestrogens in the soy. I believe the effect is quite real and measurable, although the change was gradual. I also had a tendency to feel cold all of the time (probably caused by inhibition of thyroid by brassica and autoimmune thyroid disease caused by gluten). After about 12 years of this, I gradually changed my diet to LC/Paleo, by first getting rid of the soy, then the rice and beans, then the seed oils and incorporating fish, meat, eggs, dairy, coconut oil, etc. My energy level is now far higher, my blood sugar is normal and stable, and the brain fog has cleared up. I have a far easier time concentrating. Finally, I went strictly gluten-free. That made a tremendous difference. I now think that in many ways the macrobiotic diet (as practiced in the early- to mid-90s) is about the worst diet one can possibly consume. It is extremely pro-inflammatory, incorporates all the wrong kinds of fats, high in gluten and free glutamate, and prone to cause blood sugar swings (observe any macrobiot and you will see that many of them can't stop eating carbs). I think that the only conditions in which macrobiotics makes any sense at all is if one is in a state of metabolic semi-starvation. Seth: That's very interesting. Given how bad a macrobiotic diet actually is, why did some diet guru decide that such an unhealthy diet was so great?

Sam (2013-12-13 13:59:45)

Hi Seth, I would like to use your software for testing on myself. Can you also send me the software? Thank you! Sam

Randy (2013-12-13 15:22:30)

I'd like to try the software. Thanks.

Weekend Link Love - Edition 274 | Mark's Daily Apple (2013-12-15 08:44:17)

[...] How eating tofu – even the fermented kind – made Seth Roberts stupid. [...]

Susanne (2013-12-15 11:43:09)

Hi, I found this article fascinating and would love to get a copy of the software. Thanks. Susanne

Reijo (2013-12-16 09:53:21)

I would love to try your software on a long term basis as well if you could send me a link. Thank you.

Papa Hotel (2013-12-18 02:41:44)

So you're not going to reveal the software? We're all waiting. Seth: "Reveal" the software? I'm not sure what you mean. If you have a Windows computer and contact me, I may give you the software to use.

Donald. Gillis (2013-12-21 20:30:05)

Would love to try your testing protocol

Alwyn (2013-12-21 21:07:58)

Hi Seth, Please include me for a copy of your software. I typically perform a variety of nutritional tests, mainly around migraines and your software sounds like it can add an interesting angle.

Jerry (2013-12-22 10:09:16)

"Seth: That's very interesting. Given how bad a macrobiotic diet actually is, why did some diet guru decide that such an unhealthy diet was so great?" It was a series of gurus, starting in the 50s. If you look at the macrobiotic diet as basically a traditional Japanese peasant diet, it makes sense and I believe it to be healthy; i.e. it makes sense if you maintain a state of semi-starvation, constant exercise, and no modern junk foods, none of which are at all common among modern American practitioners of macrobiotics. Many have used a macrobiotic diet to treat serious, advanced disease. There is far too much anecdotal to dismiss macrobiotics. Also, the macrobiotic diet is certainly better than the SAD. Modern macrobiotics has made some unfortunate mistakes, however, like treating all grains as equal, treating soy as a kind of health food, ignoring gluten sensitivity, etc. I remember reading a passage somewhere in "Good Calories, Bad Calories" about blood triglycerides becoming visible in a vial of blood, but not visible if in a state of semi-starvation. That fascinated me, and I immediately thought of my experience with macrobiotics and the constant teaching that semi-starvation was something to aspire to. Seth: Interesting, thanks. I wonder how well people sleep on a macrobiotic diet.

Theodora (2013-12-23 00:40:42)

Great post! "every expert said sugar was fattening, I found it caused me to lose weight" Just wondering if you have a post on your experience on this, I'd be very interested, thank you. Seth: Thanks. See my book, The Shangri-La Diet.

Jerry (2013-12-23 00:41:28)

"Seth: Interesting, thanks. I wonder how well people sleep on a macrobiotic diet." I didn't note any significant effect on sleep while following a macrobiotic diet. However, I did begin to sleep better on an LC/Paleo diet, and on Dr. Kruse's Leptin Reset

diet; the latter emphasizes no food after about 6:00 PM. When combined with exercise in the late afternoon (anaerobic; not cardio), sleep becomes deep and restful. The most profound effect on sleep that I've noticed in my N=1 experimentation was achieved by wearing blue-blockers after sunset, especially if using a computer in the evening. Wearing the blue-blockers also seems to have a pronounced effect on waking blood sugar. Wearing blue blockers also seems to elevate my mood (I am, after all, seeing the world through rose-colored glasses).

[...] How eating tofu – even the fermented kind – made Seth Roberts stupid. [...]

## **Sleep: Summary of What I've Learned (2013-12-11 05:00)**

I want to summarize what I've learned about how to sleep well. I've found about a dozen changes that helped. Taken together they suggest the importance of four dimensions:

1. Healthy brain. My sleep greatly improved [1]when I ate a lot of pork fat. (As far as I can tell, [2]butter produced the same effect.) I wasn't getting enough animal fat. My sleep also improved when I started eating honey at bedtime. I assume honey raised blood sugar to better levels during sleep, improving brain performance. The great importance of this, I believe, is why we evolved preferences that push us to eat strongly sweet foods, such as fruit, separately and later, i.e., dessert. Bedtime honey also caused my muscles to grow more in response to exercise – a sign of better sleep, since muscles grow during sleep. I have never measured the effect of flaxseed/flaxseed oil on my sleep but [3]the brain benefit was so clear in other ways I'd be surprised if it didn't improve sleep.

2. Strong oscillation. Sleep is controlled by three oscillators. The larger the amplitude of their summed output, the deeper sleep.

One oscillator – the well-known one – is sensitive to the light/dark cycle (especially blue light). It makes us active and awake during the day, inactive and asleep at night. Its amplitude depends on the amplitude of the light/dark cycle, which can be increased by sunlight or [4]daylight fluorescent light in the morning, [5]a darker bedroom, and [6]less blue light in the evening. [7]Vitamin D3 in the morning seems to have the same effect as sunlight, and is much more convenient.

A second oscillator is sensitive to when we eat. To ensure we're active when food is available, it wakes us up about three hours earlier. If you usually eat at noon, for example, it will wake you up at 9 am. I realized the practical importance of this oscillator, which is well known to circadian-rhythm researchers, when I found that [8]not eating breakfast reduced how often I woke up too early.

[9]The third oscillator is controlled by the sight of faces – what you see during a conversation. It also controls mood, making us happy, eager, and serene during the day and unhappy, reluctant, and irritable at night. If things are working properly, most of the bad mood will happen while we are asleep. During a critical period in the morning, faces "push" this oscillator much as you push a swing. It evolved to synchronize the sleep and mood of a community so that everyone is awake, happy and eager to work at the same time. Two people cannot work together if one of them is asleep.

3. "Poison" avoidance. Alcohol and caffeine can make my sleep worse, no surprise there.

4. Muscle growth. Exercise that causes muscle growth deepens sleep, whereas aerobic exercise does not. (Aerobic exercise may make you fall asleep faster, which has never been a problem of mine.) [10]Standing more than 8 hours during the day produced better sleep; less standing (such as 6 hours) did not. This was too hard to be practical.

Later I found that [11]standing on one leg to exhaustion had similar effects. That was practical – I still do it.

The biggest advances, compared to what was already known, are morning faces and bedtime honey (brought to my attention by [12]Stuart King), with Vitamin D ([13]discovered by Tara Grant) honorable mention.

A recent editorial in the [14]New York Times described mainstream thinking:

The brief course of sleep therapy teaches patients to establish a regular wake-up time; get out of bed during waking periods; avoid reading, watching TV or other activities in bed; and eliminate daytime napping, among other tactics. It is distinct from standard sleep advice, like avoiding coffee and strenuous exercise too close to bedtime.

I imagine the health experts of 1950 gave similar advice.

[15]Chris Masterjohn's comments about sleep (thanks to Stuart King for the link) illustrate what a very smart very well-informed person figured out. Like me, he stresses animal fat and the light/dark cycle (morning sunlight and dark bedroom). Unlike me, he thinks a cool room helps. I have varied room temperature and didn't notice a difference. He mentions Vitamin B6 but I eat enough meat that I am unlikely to be deficient. He says carbs help but doesn't narrow it down to honey at bedtime. He doesn't mention morning faces or morning Vitamin D. Neither Chris nor I emphasize magnesium, which [16]some people praise highly.

Brian Toomey (2013-12-11 08:39:40)

Great article Seth. Magnesium hasn't helped me noticeably, but a cold room does. I sleep much worse in a hot room. A week of trying bedtime honey seemed to make me sleep slightly deeper, but push my sleep onset forward. Since I have sleep onset insomnia, I don't think I'll keep with it.

Alex Chernavsky (2013-12-11 10:10:46)

Temperature has a significant effect on my sleep. I sleep worse in the summers.

adamlong (2013-12-11 13:04:01)

Seth, I just want to say again how much I appreciate your blog and what you give back to the community. Since reading your blog I have made significant improvements to my sleep and it has really benefited the rest of my life substantially. I can't remember if you've discussed this before but I wonder if you have tried the philips blue light or anything similar. My routine now is that I use orange goggles starting around 8 pm, and then (after taking honey) read in bed with a red light. I find I can't read as long as I used to - I get drowsy very quickly. Then in the morning I use a philips sunrise alarm clock (just started using it recently) to wake up and then a philips golite to expose myself to blue light while drinking my coffee and while shaving. Then I go to the park across the street and do some exercise (indian clubs or sprinting) while facing the sun (one of the benefits of living in Southern California). I have not been rigorous the way you have about teasing out the effects of these different measures, but I can say that overall my sleep is MUCH better than it used to be and I feel that this has improved my mood and my life considerably. Seth: Thanks, that's nice to hear. To answer your question, I put on orange goggles at 8 pm. Haven't tried the blue light.

Li (2013-12-11 15:05:16)

I'm surprised you don't include actual activity - physical or mental - among the oscillators. There's good reason to believe that the former, at least, impacts circadian rhythms.

Jeff Davidson (2013-12-11 15:12:54)

Regarding oscillator number two - Bingo! Some time ago I began experimenting with eating high protein breakfasts within 30 minutes of arising as a way to reduce snacking later in the day. It worked admirably, but since I normally wake at 4AM for work, it didn't take long for me to start having problems with waking at 1:30 - 2AM - quite alert - and not be able to fall back to sleep until, of course, 3:55AM. I was never aware of this affect, but I found the early waking subsided once I started skipping breakfast again. Seth: Definitely supports what I found.

Jeff Davidson (2013-12-11 15:14:38)

@ adamlong, your bedtime routine sounds exactly like mine. It takes me a long time to read books nowadays.

BRW (2013-12-11 15:56:15)

Great summary! I had never heard the 3 hour timing prior to breakfast wake up thing but, it fits with my occasional early rising. Thanks for sharing.

Sentinel (2013-12-11 16:20:03)

@ adamlong - I tried the philips golite too, almost daily for 5 months. i have not noticed any change, but i am thinking that it might pay off over the winter, when the potential for access to sunlight is greatly reduced. the amber glasses seem to have assisted with reducing sleep latency (quickly falling asleep), however.

Jeff (2013-12-11 17:44:35)

Seth - You mentioned in an earlier post that you take your Vitamin D 3 - 4 hours after wakening. Is the reason for this so you can take it with food and still avoid the early awakening effect of eating too close to rising?

Jeff (2013-12-11 17:47:20)

adamlong & Jeff Davidson - Do you recommend any particular red reading light?

Kjartan (2013-12-11 18:04:56)

About the morning faces, for what duration of watching faces have you found to be most effective? In your PDF you mention that you experimented with different amounts of time, but I didn't see any mention or graph showing these results.

Seth Roberts (2013-12-11 20:36:51)

I take my Vitamin D3 at 8:00 am. I don't know if that is best but it seems to work. This has nothing to do with eating it with food - I don't eat it with food. I think Vitamin D3 has the same effect as sunlight - I also try to get plenty of sunlight in the morning. I want those two things - Vitamin D3 and sunlight - to be working together, in synchrony. That will give me the greatest circadian rhythm amplitude and thus the deepest sleep. It's as if two people are pushing a swing; you'd want their efforts to add rather than interfere. There's no substitute for trial and error in finding out what time it is best to take Vitamin D.

Seth Roberts (2013-12-11 20:47:32)

I don't exercise in the evening. I do in the morning, a little bit, you are right I should wonder about it.

Seth Roberts (2013-12-12 03:34:19)

What duration of faces most effective? The longer the better. I usually stop somewhere between 30 and 50 minutes of faces.

AT Natenshon (2013-12-12 12:23:58)

Hi Seth, Any reasons on why no emphasis on Magnesium, I have tried it and found it effective for both muscle cramping and sleep. Seth: In small tests it made no difference. It is hard for magnesium to cross the blood brain barrier, which might have something to do with the negative results. Maybe I should try it again.

Bob Levinson (2013-12-13 17:19:20)

I always thought that coffee in the morning was safe. Calling it "poison" (see number 3 above) led me to [1]this study, which suggests otherwise. Too bad, it will be difficult to quit! Seth: I have two cups of black tea in the morning. No more the rest of the day. Black tea has half the caffeine of coffee. After reading that study I may reduce it to 1 cup of black tea per day.

1. <http://www.ncbi.nlm.nih.gov/pubmed/7796154>

Baeo Maltinsky (2013-12-15 13:29:32)

Eggs seem to cause me horrible insomnia. Back around July 2012, I was trying to improve my diet but I didn't want to give up my vegetarianism, so I started to eat a LOT of eggs. The quantity varied a bit over time but was usually in the range of 10 to 14 per day. Not long after, I started having awful insomnia. I could lie awake all night just unable to fall asleep. There were suddenly just too many thoughts buzzing through my head keeping me up. It was like something was engaging my sympathetic nervous system. I thought it probably had something to do with my dietary changes, but I assumed that it was a result of ketosis disturbing sleep. I tried reintroducing carbs, but when that didn't work I just sort of gave up on dietary modifications (except for when I began supplementing Vitamin D in the morning, but that only helped marginally). I started cycling through OTC sleep aids, but that only sort of worked as I developed tolerance to anticholinergics very quickly and melatonin didn't work at all. By October 2013, I was going crazy. I just couldn't sleep well. It was making me depressed and seriously impairing my academic performance. I was exhausted constantly, but then I noticed something. I slept better when I consumed a lot of caffeine in the morning. I played around with it a bit, and noticed that there was a clear dose dependent relationship between how much caffeine I consumed and how well I slept. Now, there are good reasons not to consume that much caffeine, but it got me looking in the right direction. I had a hunch that the caffeine was depleting my acetylcholine levels, serving a similar function as OTC anticholinergics like diphenhydramine and kava. I wondered what would happen if I sharply reduced my intake of acetylcholine precursors. A lot of people advertise eggs as "choline packed", so I cut back to less than 3 per day. Suddenly, I was sleeping much better. Now, it could be something else in the eggs (I'm not really attached to my choline hypothesis), but either way I feel confident blaming them for my sleep troubles.. My insomnia is just gone now, and it returns whenever I start eating them again. Seth: Great story.

tom (2013-12-15 19:41:58)

I measure my sleep with a fitbit. It just measures motion. Hopefully it corresponds with REM and stage 3 sleep. "What you measure, improves" - Rumsfeld's Rules. But if my sleep is really bad, it logs it under the activity window instead, and I have to edit it to make it a sleep log.

Nathanael (2013-12-16 11:43:53)

For reference, I researched magnesium heavily. Basically, if you have a magnesium deficiency, sleep problems are only one of the many nasty effects – constantly tense muscles are the most common. If you have magnesium deficiency, you need to correct it by taking magnesium. You can't be tested for magnesium deficiency by blood test because it doesn't "hang out" in the blood – you can have a deficiency which can't be found in blood tests very easily. And due to magnesium-depleted soil, it's become much easier to be magnesium-deficient than it was 100 years ago. But if you don't have magnesium deficiency, magnesium will of course do nothing. Seth: I live in Beijing half the year, Berkeley half the year. To my surprise, I seem to be healthier in Beijing, judging by brain test scores. I eat about the same food in both places. The reason may be that in Beijing I drink bottled water with magnesium added, in Berkeley the water I drink does not have magnesium added. I have tried magnesium supplements and they had no effect – but that was in Beijing. Haven't tried them in Berkeley.

daz (2013-12-16 20:06:19)

@Baeo, on the Choline 'thing', i was reading recently that choline (too much?) is not good for people prone to high histamine levels. also choline needs to be in balance with inositol, so may be you are (or your diet is) deficient in inositol. & apparently caffeine can produce an inositol deficiency. just some food for thought...

## **Sleep Apnea, Wheat Allergy, Nasty Cough and Personal Science (2013-12-12 05:00)**

Cliff Styles, a 66-year-old man living in Huntington Beach, commented that his sleep got much better after he stopped eating wheat. I asked him why he gave up wheat. He replied:

I had a morning cough that was very nasty, I didn't smoke, but had read a fair amount about food allergies and that reading suggested an allergic reaction as the cause. I tried several things, over a period of years, including eliminating alcohol for several months of the year (modest help to allergies and depression), reducing sugar consumption (big help to mood swings), with some success. I had been reluctant to eliminate wheat because it seemed benign and I loved all the wheat products, but at one point in reading about food allergies I came across the idea that we develop allergic addictions to foods we eat regularly – and I was probably eating wheat more than three times a day, seven days a week. I made no connection to the sleep apnea and snoring in the allergy research, in fact I took the sleep apnea and snoring for granted, and thought the nightmares were the product of psychological problems.

I decided to experiment with eliminating wheat. Well, it was like I imagine going off of heroin might be like – chills, body aches, flu-like symptoms for four or five days, then all the symptoms cleared up – and the cough went away. My wife was skeptical, so after a few weeks, I went back to eating wheat, the cough promptly came back, she was convinced, I was more certain, went off wheat permanently. I will once in a while indulge, but the quick return of the cough gets me back to the wheat-free diet. The wheat reaction is so pronounced that many friends have noticed my reaction, since I tend to indulge at social occasions.

The sleep benefit happened quite unexpectedly. After quitting wheat, my snoring eased a bit, and the sleep apnea went away, though now I do not remember how quickly, but I think it was pretty fast. Another side benefit is that I lost about 15 pounds of belly fat, and it stayed off for years. My wife notices

that when I indulge in wheat now, my snoring gets worse that night, whereas I won't necessarily notice this myself.

So what was the impetus and chain of causation? A symptom (a nasty cough, you'd think I was a pack a day smoker, especially in the morning), reading about food allergies, self-testing and seeing a result on the cough, and only then getting the benefit to sleep. At no time did I undertake the test of eliminating wheat in order to cure a sleep problem, that was just a very, very fortunate side effect.

How much sleep apnea is due to food allergy? Sleep doctors [1]do not consider this possibility. [2]Here is an example where the food allergy was dairy. [3]Here is another example. [4]Here someone claims "The commonest causes of obstruction sleep apnoea are allergy . . . and being overweight."

1. <http://umm.edu/health/medical/altmed/condition/sleep-apnea>

---

Kyle F (2013-12-12 05:47:49)

My experience with wheat was similar, 4-5 days of flu like symptoms, and then my allergies were gone. Before giving it up I always felt like I had a sinus infection. I did not quantify my sleep but I definitely had a lot easier time studying.

dearieme (2013-12-12 08:16:49)

Do people who give up wheat tend to replace it with other grains: rice, oats, barley, rye ...? Are those grains more benign to the wheat-intolerant? Is it ever enough to reduce wheat intake, or must one expect to need to eliminate it?

GB (2013-12-12 08:33:10)

I also wonder if doctors get the cause and effect order wrong. They always say obesity causes apnea. But many slim people also suffer from apnea. It's possible that having apnea destroys your sleep and thereby encourages muscle loss/weight gain. Or perhaps there's a feedback loop involved. Thanks for your comments Cliff

Charlie Currie (2013-12-12 09:00:28)

All of my allergy symptoms - sinus congestion, cough, watery / itchy eyes, frequent sneezing - all cleared up when I gave up wheat and milk (I still consume butter and heavy cream without any problems - I'm not lactose intolerant, but lactose free whey protein will cause digestive distress - it must be the proteins, not the fat or sugar, in milk that I'm intolerant of). I gave up all grains for a couple of years, now I eat white rice and corn occasionally (tortillas) without any of the allergy symptoms coming back. I eat real ice cream (no additives) occasionally, but I can feel it in my sinuses. If I eat it a couple of days in a row, or drink a couple of glasses of milk, I wake up with sinus congestion. Here's an article in the Daily Beast, which talks about wheat, and wheat germ agglutinin in particular: <http://www.thedailybeast.com/articles/2013/12/10/wheat-threatens-all-humans-new-research-shows.html> Nasty stuff...

Portlander (2013-12-12 09:52:09)

My former manager at work was a textbook wheat allergy case just like this guy, wheat belly, snoring, cough, chronic health niggles, whole nine yards. For \_years\_ that I knew him he had this strange cough that I'd assumed was some sort of tick, like some people crack their fingers. It had gotten so that I'd stoped noticing it even. I would drop hints about low carb and so forth after I'd discovered it, but (hopefully) I was never overbearing or anything. He's a pretty conventional wisdom type of guy

so I wanted to let him know the "new thinking" on Atkins, as I called it. Then, one day he was talking and mentioned that his cough was from acid reflux and he had been on various meds and so forth, but they weren't working so he was going to have to have surgery to fix his esophagus which was being eroded by stomach acid and the irritation from the stomach acid was the source of his cough. When was explaining that a contractor happened to be standing next to me and we were good friends and he had learned the whole low carb & wheat deal from me. The contractor unloaded on the guy. Saying straight-up, and not much nicer than this, that he knows his problems are from diet, and he is absolutely crazy to be choosing surgery instead giving up donuts and beer. He's like a diabetic letting his legs get amputated, or a smoker losing one lung. Besides, it's not like the surgery is going to fix the problem, it's just fixing the most obvious symptom. As an engineer, the manager should understand that. In a sheepish and quite voice the manager said, "yeah, I know but I like that stuff." Well apparently staring down the knife caused him to re-think it all and he gave up wheat completely, cough went away, sleep was better, and he dropped about 20 lbs in 2 months. Again, textbook. I find all of it amazing.

Cliff Styles (2013-12-12 10:26:20)

dearieme: my experience is that all the grains except rice cause the reaction, and the amount can be very small. Sometimes I escape, but I cannot say why. It might be gut bugs that make a difference. portlander: overcoming resistance to a needed test or change often demands hearing it from more than one person, and a crisis. You and your friend were both important. It's just human nature, I think. Perhaps if we all learned to think better, it would not be so true, or if we mastered some of Seth's regular self-testing? Of course, this kind of resistance varies a lot across individuals. I think one of Seth's big points is that experts end up exploiting those weaknesses, and personal science is a way of counteracting that.

dearieme (2013-12-12 14:05:58)

Thanks, Cliff. At the moment I've given up milk, but not yoghurt, cream or cheese. My sinuses are clearer. I'd hate to give up wheat: is there any test that would tell me whether I should be considering it? It would turn our domestic economy upside down!

dearieme (2013-12-12 14:07:37)

It's suddenly fashionable to recommend The Mediterranean Diet. In Italy, at least, that involves plenty of pasta and bread. Is the medical trades' Med Diet an actual Med Diet or a parody of one?

Cliff Styles (2013-12-12 14:36:34)

dearieme: funny you should ask about a test - just last night I was reading the opening chapters of Grain Brain, by David Perlmutter, and he mentions this test: <http://www.drperlmutter.com/learn/resources/563-2/>

dearieme (2013-12-12 14:39:23)

Thank you.

Cliff Styles (2013-12-12 14:54:09)

Seth: the Grain Brain book by neurologist Perlmutter mentions something that might provide a metabolic explanation for your butter and cognition results: 'Most important, cholesterol is looked upon as an essential fuel for the neurons. Neurons themselves are unable to generate significant cholesterol; instead they rely on delivery of cholesterol from the bloodstream via a specific carrier protein. Interestingly, this carrier protein, LDL, has been given the derogatory title "bad cholesterol." In reality, LDL is not a cholesterol molecule at all, good or bad. It's a low-density lipoprotein (hence its acronym), and there is absolutely nothing bad about it. The fundamental role of LDL in the brain, again, is to capture life-giving cholesterol and transport it to the neuron, where it performs critically important functions.' Do you have any knowledge of this? I have never heard of this.

George (2013-12-12 17:17:00)

How is it possible to develop allergies from eating the same foods frequently? Until recently nearly all societies around the world ate the same foods with near complete regularity. There were SOME seasonal changes in fruit and vegetables but for instance bread was eaten year around for one's entire life in Europe and rice was eaten year around in Asia and so was cheese and meat and a host of other foods. Are we expected to believe that people developed allergies to these foods? In some

tropical climates there wasn't even seasonal variations and people at an unvarying diet of sweet potatoes, coconut, fish, and some roots and tubers yet were reported as quite healthy. So what doesn't add up here? Is that just another myth?

Audrey (2013-12-12 17:42:30)

George, the wheat in our diet has changed significantly during our lifetimes. More profitable wheat strains continually push out older versions (with no health testing that I am aware of.) IMHO, this amounts to a massive invisible health experiment.

Portlander (2013-12-12 17:55:12)

I haven't read Perimutter, but FWIW, I'm skeptical of in vitro tests for food allergies. To many positive results, and I don't think they match what really happens the body. No one I know is an IV bread user. Instead, I think if one very thoughtfully pays attention to their mind and body, the food allergies will make themselves known easily enough. Does one have some sort of chronic problem that's been attribute to age or bad luck? Is one's body shape weirdly out of proportion? Are there mornings you just can't get out of bed, or conversely, nights were you just can't sleep? If so, it's likely a food allergy. And if not, don't sweat it. Keep doing whatever you've been doing. :) But if you're suspicious, it should be easy enough to \_completely\_ remove the food from your diet for 7-10 days. Then add it back in with a normal meal of it and see how your system handles it. Classic n=1 testing at its simplest and best. Cheers.

Cliff Styles (2013-12-12 18:10:25)

George: I don't know if 'allergic addiction' is a valid hypothesis or not, but the idea was an essential part of getting myself to test wheat elimination. I, too, was skeptical, and believe me, I did not want to find that wheat was a problem. The change in my life has been dramatic. Armchair science will never be enough for me, ever again. Seth's personal science gets us out of that armchair and into the laboratory we all live in, if we'd just take note.

Kyle F (2013-12-12 20:31:08)

Don't allergenic foods impact serotonin? Could that be a part of it?

George (2013-12-12 20:41:00)

Oh, I certainly think it's possible people are allergic to foods, I just don't understand how it can be the result of eating the same thing over and over again. That's what most people have always done, historically, and continue to do. Things like bread and rice were staples, people had them every day, day in day out, throughout the year. It beggars belief that this could cause allergies. One could be allergic to wheat or develop it at some point but I don't see how regularly eating wheat could be the *cause* of that. I never suffered any particular symptoms and I eliminated wheat and dairy and sugar from my diet several times and never felt any different so I know that for me it makes almost no difference what I eat as long as I eat basically healthy (veggies, fruits, meat, fats, grains) but I don't deny that other people have vastly different experiences. To each his own. These days I eat what tastes good and what I crave, even a little bit of junk food, while trying to keep it balanced and healthy. But that's just me.

dearieme (2013-12-12 21:35:55)

I was in my late fifties when I developed an intolerance for Brazil nuts. I didn't even appreciate the source of my stomach problem until I came across a remark in Jim Watson's book "DNA" about a genetic inability to tolerate a particular protein in the nut. Why my genetics chose to lie doggo for fifty years I've no idea. P.S. The Wikipedia article on Brazil nuts contains no warning of this effect. P.P.S. The index of the Watson book doesn't let you trace his remark. It reminds me of a warning I got as an undergraduate: an American textbook may well have superb diagrams but will always have a lousy index.

Nathanael (2013-12-16 11:52:58)

There are *\*so\** many weird allergies you can get. I have an inhalation allergy to polyester and acrylic dust which has caused no end of trouble, and which took 20 years to figure out. Eliminating those has been extraordinarily difficult and still isn't done. I have a collection of other problems remaining, unfortunately, including one (dry skin) which got significantly worse after I eliminated the allergens.

Nathanael (2013-12-16 11:54:31)

" If so, it's likely a food allergy. " Don't underestimate the possibility of allergy to cosmetics, shampoos, soaps, conditioners, fabrics,... bluntly anything which you come in contact with on a frequent basis could be the allergen.

Nathanael (2013-12-16 11:56:12)

For reference, the pure "eliminate, challenge" scientific test procedure was how I figured out my fiber allergies. Took everything out of the house except cotton, cleaned the house, "detoxed" for a month – providing that it wasn't cotton. Then brought one fiber back in at a time until one of them triggered symptoms.

### **Bedtime Honey: Less Honey May Be Better (2013-12-13 05:00)**

Some people find that bedtime honey does not work, at least initially. [1]One reader wrote:

I tried it out for several days now [1 tablespoon of honey], and it produces in me a similar effect as when I go to sleep when I have drunk several beers before. I wake up several times during the night, vivid dreams, and feel less rested in the morning rather than more.

I suggested a smaller dose – 1 teaspoon, which [2]may be effective. He tried it:

I have taken a teaspoon of honey now for three days and my experience so far is that it is better than a tablespoon of honey. I vaguely remember that I dreamed but do not remember about what. Today I also noticed that reading in the train was easier than before, despite waking up earlier, I felt I understood and retained more of what I was reading. What I find most surprising over these three days is that I don't use my glasses as often as before.

So if a tablespoon causes you to wake up in the middle of the night, try a smaller dose. I haven't yet tried a range of doses.

1. <http://blog.sethroberts.net/2013/11/20/bedtime-honey-improves-sleep-1000-crazy-good-tip/#comment-1156279>

2. <http://blog.sethroberts.net/2013/11/13/more-about-sleep-and-honey-one-teaspoon/>

---

Nile (2013-12-13 07:25:09)

I too have cut back on my honey dose at night from about 2+ tablespoons to about 1 tablespoon. Maybe one has to take a small enough dose to not trigger a big insulin surge but big enough to keep the brain in glucose during the night

Sam (2013-12-13 08:08:40)

Seth, Since you have published this, I have tried various quantities and different kinds of honey, each experiment lasting about 4 consecutive days. Although this is very subjective - what works best (for me) is one level teaspoon of raw fermented honey, taken right before going to bed. I do not know the bio chemistry behind honey digestion nor anything about the changes that fermentation may cause. My source for the honey is [http://www.reallyrawhoney.com/category\\_s/44.htm](http://www.reallyrawhoney.com/category_s/44.htm)

Kelly B (2013-12-13 08:48:10)

I'm still taking a teaspoon per night, just before bedtime, and am still finding benefits. I actually stopped late last week for about 3 days, thinking that it had stopped working, because my hot flashes had increased in intensity and were waking me up again one or more times per night. I was going to sleep without it for a week and then resume to see if there was a real difference. After the third night of really awful sleep, I restarted the honey. Between the hot flashes, which ebb and flow, three dogs that don't always sleep through the night themselves, and a cat that occasionally gets very affectionate after dark, sleep is a challenge at our house. What the honey does for me: 1) gets me to sleep very quickly - in the neighborhood of 15 minutes after lights-out. 2) makes the sleep itself deeper - I also know that I dream, but don't usually remember any of the dreams. 3) helps me get back to sleep quickly and easily after any of the interruptions. Overall, a huge benefit from something so very small.

Elizabeth (2013-12-13 09:47:31)

All of you who have had benefits from this: do you eat any other sweets at all during the day / in the evening?

daz (2013-12-13 15:50:11)

'fermented honey' sounds intriguing, i'll have to see if i can find some where i live (outside US)

Stuart King (2013-12-13 20:33:23)

I measured how much honey is in a teaspoon and a tablespoon with a scale and it's more than I thought. A teaspoon was about 10-15 grams and a tablespoon was about 20 - 25 grams. So a tablespoon could provide up to 20 grams of sugars. I've been measuring my sleep and have found that going over 100-110 grams of sugars per day worsens sleep and makes me feel terrible the next day. I've looked at the point in my day when experimenting with sugary foods (fruits, honey, desert, etc) and I can pinpoint the moment I start feeling bad (elevated heart rate, sore muscles and joints and so forth) and it always seems to occur when I go past 100 - 110 grams of sugar. This may seem like a lot of sugar, and it is, but a can of soft drink can contain 40 grams and many juices have a lot as well, so it may be easy to over do it. So the optimal dose of honey might depend on sugar consumption from fruits, honey or deserts/snacks throughout the day. I didn't count starch sources (or veges), so I guess I'm really looking at fructose consumption... On the days where I consume close to zero sugary foods (fructose), my sleep is bad also. My best sleeps happened somewhere around 70 grams of sugar. This suggests to me that there might be an optimal amount of sugary foods and going above or below that may impact sleep (and health). Seth: I measure 1 tablespoon of honey to be about 20 g. Honey is supposedly 20 % water, so there would be 16 g of sugar in 1 tablespoon.

Gina (2013-12-14 01:41:42)

I drink a lot (a couple bottles of cheap wine, more or less) before bed, and I've found that just a teaspoon of honey is helpful. Sleep is better, and I feel better in the morning. I should add that I take an N-acetylcysteine and a vitamin C pill every other drink or so to prevent hangovers. I also take magnesium and evening primrose oil before bed. It works, but I used to wake up shaky (presumably from hypoglycemia), and the honey has alleviated that entirely. I wake up and have a b-complex and more evening primrose oil and feel great.

dearieme (2013-12-14 04:15:43)

"a can of soft drink can contain 40 grams": but since you are not a child or adolescent, why would that matter?

jeff davidson (2013-12-14 04:51:22)

[1]

1. <http://skipthepie.org/sweets/honey/>

stylite (2013-12-14 13:44:47)

Gina, a couple of bottles of wine just for you, or shared among many people? If the former, you are probably an alcoholic, especially if you have been drinking like that for any extended period of time. Consider enrolling yourself in a 12 Step program like Alcoholics Anonymous. Let me know if I can help.

S.M. (2013-12-14 16:30:49)

Thank you for mentioning this. I tried honey a couple of times but I haven't actually seen any improvements. I was looking for improvements in strength, my sleep is ok. It seemed that I was sleeping longer after it, but I am not sure. But I see that I may have been using too much. I will try smaller doses and try the same type of exercise across a week, to see how it goes.

Gina (2013-12-15 01:38:40)

Thank you, stylite. Yes, the wine is for me, but I've found ways of keeping it from negatively affecting my life and health (see my comment re: supplements). AA may work for some people, but my research has lead me to conclude that it is not an effective treatment for alcoholism. I do appreciate your comment. I am especially touched that a perfect stranger would express such concern and even an offer for assistance. Consider my faith in humanity bolstered.

### **Bedtime Honey: Other Benefits Besides Sleep and Strength? (2013-12-14 05:00)**

After I'd been taking bedtime honey for 3-4 weeks, I began to notice changes in addition to better sleep and [1]more strength. One was a sense of increased well-being throughout the day. Not better mood, not more energy, just somehow better. Another was better motivation. It was easier to do everything – pushups, putting stuff away, and so on. My life was not perfectly constant, however, so I could not be sure these changes were due to the honey.

I asked Jason DeFillippo of [2]Grumpy Old Geeks about this. [3]Bedtime honey really helped him. He replied:

I have noticed that during the day I can concentrate for much longer stretches but I was chalking that up to the sleep. I think the motivation you're talking about is definitely starting to manifest itself quite a bit more as well. I'm putting more effort into my business than I have since I started it 2 years ago and haven't really thought about it being a side effect of the honey but it's possible. Amazing things happen when you haven't slept properly for 20 years and can now sleep through the entire night.

After he mentioned concentration, I realized I had noticed the same thing: I could do work that required concentration for longer periods of time. In contrast to Jason, I had slept well for many years before starting the honey – or so I'd thought.

1. <http://blog.sethroberts.net/2013/12/03/bedtime-honey-increases-strength/>

2. <http://grumpyoldgeeks.com/>

3. <http://blog.sethroberts.net/2013/11/20/bedtime-honey-improves-sleep-1000-crazy-good-tip/>

---

shane (2013-12-14 05:38:29)

Don't you just think that all these other benefits stem from improved sleep quality? Seth: Yes. But they are not obvious benefits of better sleep and they have not accompanied previous sleep improvements of mine.

Chris Highcock (2013-12-15 13:02:25)

Has anyone pointed out that this was all discussed in The Hibernation Diet by Mike McInnes? <http://www.amazon.co.uk/The-Hibernation-Diet-Mike-McInnes/dp/0285637371> Seth: You're the second person to mention this book.

Jeff (2013-12-16 16:55:09)

Seth - I've noticed a similar feeling from taking honey at night. How would you compare the honey induced increased sense of well being to the mood benefits you get from morning faces? Seth: The mood benefits of morning faces are well described as happy eager and serene. Very obvious. The honey effect is a deep feeling of well-being. Less obvious.

Xav (2013-12-19 02:37:27)

Thanks for the tip about the Hibernation Diet. Looking at Amazon, it seems as if the author has a new book out shortly as well, The Honey Diet (2nd Jan 2014 on the Kindle). The blurb mentions "Just a tablespoon of honey every night before you go to bed" along with a list of benefits, including better sleep. Seth: Yeah, independent discovery.

### Assorted Links (2013-12-15 05:00)

- [1]Interview with sufferer from mercury amalgam fillings. Stephen Barrett, founder of Quackwatch, says mercury amalgam fillings are perfectly safe. For many people, this might be true. It is not always true.
- [2]"She was given a three to five year sentence." One of the greatest wrist-slaps of all time. She deserves at least one year in jail per falsification, which would be several thousand years in jail.
- [3]Ron Unz, the minimum wage and social innovation
- [4]Dairy consumption and heart disease risk. "The majority of observational studies have failed to find an association between the intake of dairy products and increased risk of CVD, coronary heart disease, and stroke, regardless of milk fat levels."
- [5]Tourism and mental illness. "A Canadian woman was denied entry to the United States last month because she had been hospitalized for depression in 2012. Ellen Richardson could not visit, she was told, unless she obtained "medical clearance" from one of three Toronto doctors approved by the Department of Homeland Security." Horrifying.
- [6]Snorting baby shampoo to cure sinusitis. A good example of personal science. His understanding of biofilms led him to try baby shampoo. It is also interesting that he doesn't try to strengthen his immune system to solve the problem or maybe he doesn't know how to. A professional sinusitis researcher would never discover what he did, yet another example of how our healthcare system ignores cheap treatments.

Thanks to Allen Jackson and Phil Alexander.

dearieme (2013-12-15 05:51:13)

Yep, a life sentence would be suitable. Pity it can't be "with hard labour" nowadays.

dearieme (2013-12-15 05:52:32)

She may be bonkers by Canadian standards but she could be entirely sane by US standards, surely? :)

dearieme (2013-12-15 06:02:06)

The "dairy fat" abstract is the sort of example I used to use to teach my students how not to write scientific English. Seth: I was amused that the research found no link between dairy fat consumption and INCREASED heart attack risk.

Joseph Moroco (2013-12-15 07:54:56)

Amy's sentence is par for the course here in the Peoples' Republic.

Ross (2013-12-15 08:09:22)

Ugh. That woman definitely deserves to serve all the years that the innocent were sentenced to because of her lies.

Sentinel (2013-12-15 13:11:14)

Seth, it's my understanding from Joseph Mercola, etc., that—for some people—the removal of the amalgam fillings might cause even worse problems than leaving them in, with the severity depending on how effective the patient's body is at eliminating the mercury that is inevitably inhaled or swallowed during amalgam removal. Because my amalgams are breaking down after 25-30 years, I am going to have 10 of them removed in 2014. I was thinking about doing a Quicksilver Scientific "Tri-test" (separate analysis of methyl mercury and inorganic mercury in hair, blood and urine) before and after the first extractions, to see how my body is eliminating the mercury. I recall that you opted for hair and breath tests of your mercury levels. Do you have an opinion as to whether such multi-layered testing as the above-mentioned Quicksilver Scientific's is overkill?

Seth Roberts (2013-12-15 14:00:08)

The breath test was a coincidence...didn't get enough measurements to mean much. Ignore the breath test. I don't learn much from the hair tests, perhaps because they are infrequent. The reaction-time test I do daily showed that there was no bad effects of the removals. I don't know anything about the Quicksilver Scientific test, sorry. If I was really concerned, I would get two (not one) tests before and two (not one) tests after. Otherwise you cannot separate noise from signal.

Alex (2013-12-15 14:16:54)

The link on baby shampoo and sinusitis does not work on mobile devices. You can either click it from a desktop computer or go through the exercise of requesting the full site, then searching for "sinusitis baby shampoo".

Seth Roberts (2013-12-15 16:24:15)

Thanks, Alex, for pointing that out. Too bad because it's a really good story.

Alex (2013-12-15 18:58:49)

The site seemed intent on having mobile users install their site's app to get access. Because it makes so much sense to limit the online reach of their content, and the ad revenue from it, when they can instead lock in users with an unquenchable thirst for news about Omaha, Nebraska.

Resnick (2013-12-16 07:02:27)

The Minimum-Wage is an eternal ideal for the left & Ron Unz - an ideological dogma immune to facts. [http://www.washingtonpost.com/opinions/george-f-will-raise-the-minimum-wage-i-ts-iffy/2013/12/13/f9a8d81a-6363-11e3-a373-0f9f2d1c2b61\\_story.html](http://www.washingtonpost.com/opinions/george-f-will-raise-the-minimum-wage-i-ts-iffy/2013/12/13/f9a8d81a-6363-11e3-a373-0f9f2d1c2b61_story.html) Seth: George Will needs a better grasp of history, such as the Hammurabi Code and the Ten Commandments, both of which promise to protect the weak from the powerful. It is perfectly possible to have a different much lower minimum wage for teenagers. Will apparently doesn't know this, either.

Steve (2013-12-17 09:15:05)

Hi Seth, thanks so much for linking to the baby shampoo story! I had similar issues to the author and was finding nothing working. I tried this method and found it very effective at clearing out a major blockage that I just couldn't shift. It feels so good to be able to breath again! Thanks.

andrew (2013-12-17 16:04:48)

Seth I find the discussion about minimum wage similar to discussions about foreign aid. It is assumed to be obviously positive and the thought that it might have a larger negative affect isn't considered. I would compare it to antibiotic prescriptions for acne from your doctor. It is assumed that it works because that is what we are told but antibiotic use actually made you less well off. Although you could run an experiment on acne and antibiotics it is impossible for us to do that for minimum wage but the following real world example is interesting. The following is from the economist Scott Sumner. Regarding minimum wage,\* here is some data for Western Europe: There are nine countries with a minimum wage (Belgium, Netherlands, Britain, Ireland, France, Spain, Portugal, Greece, Luxembourg). Their unemployment rates range from 5.9 % in Luxembourg to 27.6 % in Greece. The median country is France with 11.1 % unemployment. There are nine countries with no minimum wage (Iceland, Norway, Sweden, Finland, Denmark, Austria, Germany, Italy, Switzerland.) Five of the nine have a lower unemployment rate than Luxembourg, the best of the other group. The median country is Iceland, with a 5.5 % unemployment rate. The biggest country in Europe is Germany. No minimum wage and 5.2 % unemployment. Still want to raise our minimum wage to \$10? Germany used to have really high unemployment. Then they did labor reforms to allow more low wage jobs, combined with subsidies for low wage workers. Now they don't have high unemployment.

Roger Sweeny (2013-12-19 17:00:30)

Will knows that it is theoretically "possible to have a different much lower minimum wage for teenagers." He has observed several attempts to legislate somewhat lower minimum wages for teenagers. Several unsuccessful attempts. Seth: Michigan and Australia are examples of what I am talking about – a lower minimum wage for teenagers than adults. The Australia minimum wage for adults is especially high so I don't understand why Australia is irrelevant. Had Will argued that it doesn't work in Australia, that would have been more persuasive.

Adam's Myth (2013-12-30 07:51:17)

The shampoo treatment was mentioned at the website of a university professor in San Diego, as far back as 2008. I found it then during a desperate search to resolve my own incapacitating sinusitis. In less than a week of shampooing, a six-month headache was gone. It recurred occasionally until I fixed environmental causes. Tried many things, but the two that mattered were to replace the household carpet and to vacuum my mattress every couple of weeks. Couple of years later, my sense of smell returned. When you regain a sense you thought was lost forever, you appreciate even the stinkiest odors! Sinusitis treatment in the U.S. is doubly silly. First, nearly all chronic sinusitis is fungal (says Mayo Clinic in 1999), yet antibiotics are universally prescribed, obviously with no effect on the primary infection. Second, no one ever tackles environmental causes. To Seth's point, though, developing a more discriminating immune system might be an even better solution. But the above worked for me. Final note to Southern California readers: you might notice a link between your sinusitis and seasonal "Santa Ana" winds, which blow dust westward off the deserts every November and December.

## **Soy Can Cause Migraines (2013-12-16 05:00)**

After I posted that [1]tofu made me stupid – made me slower on a reaction-time test – a reader named Ann, who lives in Florida, said she had discovered that her migraine headaches were caused by soy. How she discovered this:

I was 49 years old and in that hot flashes stage of life, had read that soy could help alleviate them and tried a soy capsule not at a meal, immediately noticed sinus pressure and itchiness.

So I started reading all labels and eliminated soy from my diet and my migraines and sinus headaches went away! The hot flashes eventually went away on their own. I was losing whole days every month to the migraines. Every now and then the soy sneaks in at a restaurant but not as bad as before. Whenever anyone says they have migraines I always suggest looking at soy. Regretfully my daughter has the same issue, but she has way fewer headaches after eliminating soy.

I used to blame a lot of my headaches on allergies, never thinking it could be something I was eating. At age 60 now, my cholesterol numbers are excellent and I weigh 122 pounds when so many of my friends are overweight.

I asked how long it had taken to discover this.

I had been having migraines for years, 10-20, but in the mid 90s they got worse (could have coincided with more soy in food). Saw a doctor but he just prescribed imitrex which helped but did not prevent them. He never suggested looking for a food cause. It was dumb luck or divine intervention that I tried that soy capsule in 2001 or 2002. I am often amazed at how much better I feel health wise since then. Since soy is in so much processed food my diet is very basic "real" food. Raw fruits and veggies, plain nuts, fresh meat, real cheese, eggs, yogurt, any desserts I make from scratch with real butter. I'm always excited when I find a cracker that doesn't have soy since that's usually my bread substitute.

Let me repeat part of that: A doctor she saw because of migrains did not suggest trying to find an environmental cause. The same thing happened to [2]a woman I wrote about for Boing Boing. Her doctor just prescribed one drug after another. Her migraines turned out to be caused by cleaning products. Not knowing that migraines often have environmental causes is like not knowing the germ theory of disease.

Few soy eaters realize the dangers of soy, as far as I can tell. I wrote to one of them, [3]Virginia Messina, a nutritionist who has said "there is no reason to believe that eating soyfoods is harmful to brain aging." She has not replied.

A [4]long list of possible migraine triggers (from the UC Berkeley health service) does not list soy, although it does mention soy sauce. It says soy milk should be safe. In a 2006 interview, [5]one headache doctor recommended avoiding all soy. In the comments to [6]this, a woman says:

SOY is the biggest trigger for my migraines. For years I suffered daily from migraines but after watching EVERYTHING I eat and reading all labels and avoiding SOY as best I can I am doing better. The biggest problem is that SOY is in everything!!!! I think one day they will find out how bad it is for us.

Imagine that. Putting something that damages the brain in everything.

Crystal (2013-12-16 06:38:39)

It may be worth noting that soy was one of the first things to be genetically modified, or so I've been told. That might be why it's being put into so much, if they developed cheap and pest resistant varieties with high yields, the usual aim of any GM program. For that reason I like to avoid all but the organic, non GM versions. Another crop I believe is modified is corn, since, having loved it and eaten it frequently growing up, suddenly in the mid 90s I found it was not digesting properly, if at all, and causing issues because of it. Funnily enough, when I find organic heirloom varieties, I have no such problems and it's like when I enjoyed it as a kid again. Seth: very interesting point.

M J B (2013-12-16 08:19:14)

wheat > leaky gut= soy > leaky vessels??? Especially if GMO soy. I try to avoid all GMO grains and I gave up wheat several years ago and my GERD disappeared permanently in just two weeks! I now buy flour from a company that uses only organic ancient Einkorn wheat. I still eat very little of my home made bread.

Jenny (2013-12-16 17:14:22)

A coeliac (therefore not eating gluten anyway), 2 years ago I developed a serious inner ear infection, and was put onto IV augmentin and ppi. Within 48 hours I was reacting to soy in mayonnaise, with immense stomach bloating. I was going from a flat stomach to looking as if I was 6 months pregnant, in 20 - 40 mins, and it was taking at least 30 hours to go down. It took me long time to realise it was the soy - I kept thinking it was the egg to start with. I still react to soy, but now it's as if it were gluten - causing stomach cramps for days and some bloating. The only variant that does not cause a problem is Japanese fermented soy sauce - it can't be some cheap substitute. I don't eat it very often though - I suspect if I had it regularly I would react more.

## **Rules of Innovation: Two Examples about Snowden and Greenwald (2013-12-17 05:00)**

In [1]a recent post called "Government as useful irritant" I said five factors increase innovation: 1. Freedom. 2. Benefit. 3. Resources. 4. Pain. 5. Stability. The effect of government isn't simple. It might freedom - to the extent the coercion outweighs the protection - and of course corrupt governments make it harder to benefit from your innovation. On the other hand, governments often provide resources, pain and stability. Several of the factors are contradictory - pain and stability, for example - which makes it hard to produce optimal conditions, at least without paying attention to what actually happens.

[2]A article I read soon after that ("Snowden and Greenwald: The Men Who Leaked the Secrets") had two relevant examples. One of my points was that increasing inequality reduces innovation bad because it means the people at the top get more and more comfortable, which reduces their desire to innovate. The more inequality, the more of the population falls into two categories: 1. Too poor to innovate (not enough resources). 2. Too comfortable to innovate (not enough pain).

Greenwald saw the value of pain:

After graduation, he accepted a job in the litigation department of Wachtell, Lipton, Rosen & Katz . . . "I could not thrive or even function in a controlling institution like that. There's a huge dichotomy between people who grow up with alienation, which, for me, was invaluable, and people who grow up so completely privileged that it breeds this complacency and lack of desire to question or challenge or do anything significant.

Snowden had all five factors in large amounts. He had freedom because his bosses paid him little attention and, because of his IT talent, it was easy to get a job. He also had a lot of money. Obviously he had great resources, including

IT talent, knowledge and access. He had pain because he was disgusted by NSA overreach and Obama's failure to improve things. He had stability because he had a steady job. The money helped here, too. Because the revelations are so large, he benefits a lot, even if there is also a very big cost.

1. <http://blog.sethroberts.net/2013/12/06/government-as-useful-irritant-and-rules-of-innovation-what-libertarians-and-other-economists-miss/>
2. <http://www.rollingstone.com/politics/news/snowden-and-greenwald-the-men-who-leaked-the-secrets-20131204?print=true>

---

Nancy Lebovitz (2013-12-17 09:24:45)

Unfortunately, a fair chunk of the innovation caused by government restrictions is ways of dealing with the restrictions. Figuring out a clever way for tax accountants to be more efficient would probably be a sensible project in the world as it is, but that cleverness might find better uses in a world with simpler taxes. Idea developed from Howard Ruff, who pointed out the huge cognitive load on a culture from a complex tax code.

Adam (2013-12-17 16:46:23)

I would celebrate a world in which there were no cancer to begin with over a world in which cancer took millions of lives for decades before it was cured, although the 2nd makes a better story.

Portlander (2013-12-17 17:41:12)

Yes. Indeed, this is the problem with the insular and, as often as not, outright nepotistic elite from the Ivy League that's taken over Finance, Govt, and MSM. They are too comfortable with the status quo, and have too much to lose if it is adjusted in the slightest.

chi (2013-12-17 20:16:05)

I dunno, Portlander - it seems like the MSM is going through quite an upheaval right now. Seth: Not because they want to, it has been forced on them.

Brock in HK (2013-12-17 20:42:27)

Struggling to see the way in which Snowden and Greenwald innovated. Can you help? Rebelled against authority, yes, but innovated less so. Seth: Snowden did something highly original and effective. Greenwald at least took a thoughtful position against the status quo.

Nancy Lebovitz (2013-12-17 23:44:58)

Snowden could be said to have innovated getting away (so far) with whistle-blowing, but I'm not sure whether his methods scale. Seth: They scale in the sense that everyone now knows the information he wanted known. There is no need for a million people people (or even one more person) to do what he did.

Brock in HK (2013-12-18 07:26:34)

Pain encouraged the risk taking to do what they did, freedom, cash and stability allowed them the ability to execute. The benefit to Snowden seemed ideological at the time - mainly the personal satisfaction of whistleblowing where he perceived wrongdoing by the government - rather than a thought of the financial gain. However, none of what the pair did is new ground. Confiding in a reporter seems to be a relatively proven way to whistleblow, and reporting the news is not novel for Greenwald. Seeking asylum also already invented - not sure Snowden could patent his method across the whole experience given most of this is in the common domain. I like your framework, but in this case it's more an evaluation of motivation to engage in

potentially risky behavior for those involved rather than innovation. Perhaps we have different understandings of innovation? Seth: Greenwald is nothing like a typical reporter. Except he is paid. Snowden exposed classified documents on a scale that dwarfs anything that came before. But you are right, motivation is a huge part of innovation. So is risk-taking. Of course the term innovation is usually reserved for conventional economic products, such as cars or toothbrushes or services we buy. But the whole point of those products and services is to improve our lives. That is also the point of what Snowden and Greenwald are doing. If you consider the assembly line an innovation – and everyone does – you must realize it merely increased the number of cars. What Snowden and Greenwald are doing/have done is increase the amount of classified info the rest of us know about.

---

Paul (2013-12-18 07:57:00)

I said it over on FTA and I'll say it here too. Given our essentially poor understanding of gut biota, I think it's a mistake to focus on the ratio of firmicutes and bacteroidetes as there are both pathogenic and beneficial organisms in each category. What is clear is that bifidio is the group targeted by human breast milk and is the dominant form in a breast fed infant. There are

probably some lessons to be drawn from that. Seth: I agree. I believe it is a mistake to focus on these sort of measurements. I think it is better to focus on things that clearly matter – pain, absence of pain, good sleep, bad sleep, easy-to-observe stuff like that. Do that before assuming you have a correct theory of how gut biota influence health.

Charlie Currie (2013-12-18 09:13:28)

Here's Mr. Heisenbug's latest post on resistant starch (12/15): <http://mrheisenbug.wordpress.com/> "What Resistant starch lacks in breadth, it makes up in precision. Resistant starch is a laser-guided missile aimed at the two most important strains of mucosal bacteria in one of the most crucial clusters of bacteria in the human gut." "And that, ladies and gentlemen, is the reason Resistant Starch, in the form of raw potato starch, is officially the body hack of \*maybe\* the decade."

Wilson (2013-12-18 16:39:14)

Seth, I wouldn't consider it a great loss, but it seems you're not going to be allowed to post on Reddit anymore: <http://dailycaller.com/2013/12/18/reddit-bans-comments-from-global-warming-skeptics/> Isn't it amazing? As far as I know, flat-earthers, creationists and 9/11 truthers are still allowed, but free speech goes only so far. Wonder what they're afraid of? Seth: I agree, amazing.

Portlander (2013-12-18 22:11:31)

Hello Seth, Concerning RS, might I ask you to add my [1]Indiegogo Project to the assorted links – for those readers that might miss it here in the comments. And of course, I'd love to have you contribute. The personal tour of Oregon Wine Country perk is still available. :) Thank you, -Allan Seth: Thanks for your comment, Allan, and I'm happy to have you mention your project here in the comments. However, I'm afraid I don't think the project is well thought out. I think it is really hard – much harder than you seem to say – to figure out whether this or that gut biota will produce good or bad health. Obviously more variety is better but beyond that what? If it were me, I would try to figure out specific connections between resistant starch and stuff we care about (sleep?). That is relatively simple. And free. Sure, resistant starch will change my gut biota. So what? I want a connection to something I care about first. I do not care about my gut biota independently from other outcomes. Perhaps there is something very important here, but see that "no victory lap" post. You don't see me trying to maximize REM sleep or minutes of deep sleep or my Zeo score. I could measure my sleep in expensive high-tech ways, but I don't. I try to maximize things that are easy to measure and that obviously matter, such as how rested I feel in the morning.

1. <http://www.indiegogo.com/projects/resistant-starch-gut-biome-a-family-science-project/x/5693535>

Nancy Lebovitz (2013-12-18 23:15:52)

The ban seems to be on r/science, not reddit in general.

S.M. (2013-12-19 04:46:32)

Hi Seth, Thank you for the links. Have you seen this? <http://annals.org/article.aspx?articleid=1789253> It's all over the news, of course. It makes for a great sensationalist article (Americans wasting 28 billion a year!) What do you think? It seems a bit over-generalization for me. I have started taking some Magnesium supplements and they seem to help a lot. Maybe it's more a question of targeted vitamins or minerals instead of a multi-pill? Would love to hear your opinion on this. Seth: I agree with the research. If anything, multivitamin pills seem to hurt my health – a conclusion I reached before the research came out. I also agree with you, magnesium supplementation seems to be a good idea. Also Vitamin D in the morning. Putting a bunch of stuff together and failing to control the time of day makes for a mess. Not good research.

Wilson (2013-12-19 05:25:42)

I wonder if the link Seth posted would be allowed on r/science(sic).

Jeff (2013-12-20 04:31:14)

Seth - Can you elaborate on how multivitamins hurt your health and how you arrived at that conclusion? Thanks. Seth: They slowed me down on the brain (reaction-time) test I do. But I need to repeat this result to be sure of it.

Portlander (2013-12-20 09:11:41)

Hello Seth, I appreciate your reply, thank you. I'd like to clarify a little bit if I may. I did see the 'no victory lap' post and

I am aware of the limitations of our knowledge of RS & gut biota. I certainly don't believe RS should be the next panacea. However, I do think gut biota is an interesting avenue for further investigation. A lot of people have reported some incredible outcomes from supplementing with RS, and seemingly the only mechanism RS has for improving health is through gut biota. OK then, which bacteria and how much RS? That is the point of the Indiegogo project, to advance those questions ever so slightly. We're presently a healthy, happy family. What's our biota look like now? After 6 weeks of RS, each person taking a slightly different formulation, what's our biota then? How did we respond as far as sleep, happiness, mental focus, etc. So much of the N=1 science on the internet is from people recovering from pathological conditions, I often wonder for healthy people looking for a modicum of prophylaxis, how much of the N=1 experience (and dosage) is applicable. Best Regards, -Allan Seth: "A lot of people have reported some incredible outcomes from supplementing with RS, and seemingly the only mechanism RS has for improving health is through gut biota." You might be right. But I am less sure that better gut biota is "the only mechanism". Another possibility I find plausible is 1. RS improves sleep (not thru gut biota). 2. Better sleep improves health. Judging by what you say, I would start to measure "sleep, happiness, mental focus, etc." for each member of your family. Day after day – something like that. Then I would test one formulation (not several) of RS. What effect does it have on each of the things you are measuring? That study costs nothing. And would be a lot more interesting, at least to me, than the study you propose. To interpret it does not require a untested theory of how gut biota affects health. I believe you (and your family and everyone else) will benefit more from a better understanding of the effect of RS on sleep, happiness, mental focus, etc., than from a better understanding of the effect of RS on gut biota. And you can make hundreds of measurements of sleep, etc., for the price of one measurement of gut biota. Larry Smarr's failure to reduce his Crohn's disease illustrates how high-tech measurement of something different than what you care about can have disappointing results.

### **Bedtime Honey and Sleep: More Evidence It Works (2013-12-19 05:00)**

In [1]a 2010 forum discussion I found this:

SLEEPY HEAD I read that honey helps you sleep. I've tried it the past few night and have slept very well! I have had trouble falling asleep and staying asleep since I was born. I even take Ambien sometimes and still stay awake alllllll night long. I can't believe how well I slept the past 2 nights. Just take one teaspoon of honey before bedtime and sleep like a puppy!

USER 967048 I took honey again last night and slept awesome. I have found that 2 tablespoons work the best.

USER 968407 I took honey again last night and slept like a baby again! This really works!

USER 602568 I've been sipping a cup of milk with a couple teaspoons of honey on nights I can't sleep. It always works. But I thought it was the warm milk. I didn't realize the honey was the key ingredient.

More evidence that as little as one teaspoon produces a big improvement. One teaspoon of a common food can greatly improve something as important as sleep!

1. <http://www.godlikeproductions.com/forum1/message1061255/pg1>

Beth@WeightMaven (2013-12-19 14:09:41)

I've not tried this (yet), but in searching for something related to apple cider vinegar, I saw a comment that honey wasn't vegan. The poster suggested trying maple syrup as an alternative. It'd be interesting to see if that works the same as honey for those who use it to help their sleep. Seth: I agree, maple syrup is worth trying.

Ben C (2013-12-19 15:38:47)

Hi Seth, I just recently found out about your blog and all the self experimenting you do. I am currently trialling raw cold processed honey and have noticed that my sleep isn't as refreshing as store bought pasturized honey? According to David Asprey Raw Honey is 22 % better at making liver glycogen and should improve sleep more but I'm noticing not as sound sleep! Thoughts? From my own experimenting I've noticed that when I take too much honey (over 1 tsbp + ) my sleep isn't as good as taking 1 or 2 teaspoons. Also +1 for cutting sugar during the day to improve the effects of honey for sleep! Seth: I think Dave overstated things. Too much is unknown about the effect to be sure raw honey is better than pasteurized.

Crystal (2013-12-19 16:35:09)

There's an earlier post on honey that has a drink of cider vinegar and honey as the recipe. As for honey not being vegan, you've hit on one of the controversies of that world. There is NO consensus on this. The issue is the question of whether you are abstaining from using all animal products to avoid causing them suffering or to avoid any form of exploitation. The former will include honey since they're not being forced to produce it and don't have any adverse consequences from us taking it. The latter won't. As for using maple syrup as an alternative, frankly I'm surprised that someone against suffering and/or exploitation would suggest it. Forcing a tree to bleed regularly is better than taking something that's produced painlessly by an insect? Disclosure here, I'm not vegan, and I eat both (as well as bleeding myself regularly for the blood bank). But I'm getting my results from milk and honey. Seth: What about causing animals pleasure? What if doing X causes animals pleasure? Why is that neglected from these calculations of the effect of this or that human action on animals?

Crystal (2013-12-19 16:46:55)

PS after re-reading, I want to clarify, it's not quite such a clear cut divide, and there's a lot of debate over whether taking honey is exploitation. Especially since bee farming recently helped with staying the effects of a disease ravaging the wild bee population. If you search the term "beegan" you'll find more about the controversy over honey and veganism.

Adam (2013-12-19 16:58:40)

I mentioned that honey might aid sleep to my wife & she said "duh, everyone knows that!" Apparently it is well-known in the Chinese-speaking world. Seth: Ask your wife what fraction of her Chinese friends actually do it. It is not "well-known" in the sense of commonly done. However, the Chinese certainly see honey as more of a health food than Americans do.

Dragan (2013-12-20 20:38:53)

Not just a well-known Chinese remedy... I don't have time to check whether someone else mentioned this, but when I lived in Croatia (former Yugoslavia, really) a tablespoon of honey mixed with water and apple cider vinegar served at room temperature and sipped slowly before bedtime was not uncommon. My grandparents, now in their late 80s, still use it when they feel restless before bed. When I tried doing this every day for a summer, I was able to fall asleep within 30 minutes, and it usually takes me closer to an hour. I may have felt more rested, can't remember. Unfortunately I'm just too lazy to do this every night. PS A quick search showed there was an earlier post on honey + apple cider. oh well :) Seth: Forgive me, but I fall asleep within a minute. It's no great secret why, see my post about what I've learned about sleep.

tracy a. (2013-12-21 01:19:27)

So one tsp of honey a night is working for me and it made me think: DayQuil in pill form is great, but I always used to swear that the NyQuil pills weren't as good as the liquid. Maybe the reason it made me sleep better and feel better when I woke up had something to do with essentially taking a shot of sugar liquid right before bed. Seth: I think you're right: [1]<http://forum.lowcarber.org/archive/index.php/t-436795.html>

## Front Lines of Personal Science: Why Did I Sleep So Well? (2013-12-20 05:00)

Last night I slept great. I woke up feeling very rested. I can remember only three situations when I woke up feeling more refreshed. (a) On a certain camping trip. (b) When I was on my feet for ten hours. (c) After eating a lot of pork fat. I cannot simulate camping trips, and standing ten hours/day was very hard. The pork-fat effect was repeatable, in the sense that I slept better after eating pork fat, but I never ate that much pork fat again. It was too much.

Why did I sleep so well? I can think of several possible reasons.

1. Random noise. Let's say there are 20 factors that affect my sleep and they just happened to all line up in a good direction.

Another set of possible reasons derive from what was unusual about yesterday. I can think of five things:

2. I had yogurt and blueberries and honey about 6:30 pm. (In addition to 1 tablespoon honey at bedtime.)

3. I forgot to hang a blackout curtain that darkens my bedroom. Usually I hang two. Last night, by mistake, only one.

4. I started eating dark chocolate daily two days ago. Maybe the good stuff in it (the flavones) accumulates in the brain so that the good effects get larger day by day.

5. I watched faces in the morning a half-hour later than usual. Usually I start watching them at 6:00 am. Yesterday I started at 6:30 am. I had forgotten about this difference until I looked at my records.

6. I switched to a new brand of honey (from a German brand to a Canadian one).

#1 is unlikely. #2 vaguely corresponds to the idea that honey helps us sleep because it supplies energy. Maybe honey at 6:30 fills up the liver (with glycogen) and honey at bedtime goes into the blood. But I've eaten plenty of meals at 6:30 without any obvious effect. Maybe they were too low-carb. I don't know if making my room very very dark (two curtains) is better than making my room dark (one curtain) but there is no obvious reason making my bedroom less dark would improve sleep ( #3). I have never heard anyone say chocolate ( #4) improved their sleep. Morning faces did improve sleep but the mood improvement was much more obvious ( #5). I've tried several brands of honey; there was no obvious difference between them, arguing against #6.

As the day wore on I found myself in a good mood but not a great mood, arguing against #5.

I'd say #2 is the most plausible, the rest less plausible, with #1 the least plausible. But I will test all of them.

More (a day later) I did #3 (only one curtain), #4 (chocolate), #5 (later faces), and #6 (new honey) again. I did not sleep exceptionally well. That makes #1 and #2 more plausible.

GeoffD (2013-12-20 06:23:27)

Seth, I can explain the camping effect. You were grounded to the earth. Look into grounding- its the best sleep hack of all. I started with a grounded bracelet and graduated to a grounding sheet for my bed. It plugs into the ground socket of a properly grounded electrical outlet. It dissipates harmful EMF which normalizes nocturnal hormonal patterns. It really is life changing. Earthing.com sells the one that I have. I do believe there are others vendors. Look into it. Seth: Very interesting. We slept on a tarp (inside sleeping bags, wearing clothes); would we still be grounded then? But your idea seems easy to test.

dearieme (2013-12-20 06:51:52)

"You were grounded to the earth": in Britain we'd say "you were earthed to the ground". Wot larks, eh?

Banh Li (2013-12-20 07:59:20)

Paul Jaminet has a bit exploring a possible link between chocolate consumption and positive circadian rhythm function. Weak, but consistent with hypothesis #4. <http://perfecthealthdiet.com/2012/11/chocolate-what-is-the-optimal-dose/>

Peggy (2013-12-20 08:11:52)

I sleep worse with blackout curtains; I need the gradual decreases and increases in light to calibrate my internal clock. (Which might also explain the camping effect.) I try to avoid using overhead lights after dark or early in the morning, and just use lamps.

Christopher Sturdy (2013-12-20 08:33:13)

I still like the honey idea; it's the quality Canadian honey that did the trick! I suppose I could help test the theory. Mmmm...more honey eating for me.

daz (2013-12-20 14:06:42)

Hi Seth, What colors were the German and Canadian honeys? (i just discovered there is actually a honey color scale/grader called the Pfund Scale) Seth: The Canadian honey is lighter-colored and less viscous than the German honey.

Kirk (2013-12-20 14:11:55)

Another alternate explanation: the honey effect is cumulative. At least it seems that way to me. On those nights that sleep is not as rich and deep, I can associate it with some external cause, such as when the bedroom was much colder than usual, or my wife was sleeping poorly. Seth: I've been taking honey at bedtime for at least a month. No reason the effect should suddenly get larger.

daz (2013-12-20 14:20:16)

i have heard that becoming magnesium replete improves sleep. (magnesium deficiency worsens sleep). & the darker the chocolate the higher the magnesium content (ref usda nutrition database).

Stuart King (2013-12-20 14:39:40)

Seth when you tried to repeat the effect on the second day, did you try another new honey that you hadn't had before? I actually think it's the increase in sugary foods that led to better sleep... But I have noticed improved sleep after trying new honey (but not on the second night) which is interesting Seth: No I used the same new honey as the first night. A "first night" effect is strange. I'll look for it next time I change honeys.

Heisenbug (2013-12-20 14:51:05)

#2 seems to lend even more credence to the prebiotic/probiotic hypothesis. Seth: That honey acts as a prebiotic, increasing butyrate production and a bunch of other things? Yes, I agree, it supports that idea. I found one study where probiotics improved sleep: [http://www.insidershealth.com/article/probiotics\\_not\\_just\\_for\\_your\\_gut/3862](http://www.insidershealth.com/article/probiotics_not_just_for_your_gut/3862)

DA (2013-12-20 22:35:58)

Seth, have you seen much discussion of the role that alcohol plays in poor sleep, particularly alcohol's role inhibiting

gluconeogenesis (glucose secretion) in the liver? It could help explain, by its opposite, the role that sugar plays in honey's sleep-enhancing effect. Seth: That's a good point.

tom (2013-12-21 20:44:23)

I've figured out lately that dehydration causes stress and lessens my sleep quality. Like if I have a lot of protein or dry flour products at my last meal and sleep 2 hours later without drinking enough water.

GeoffD (2013-12-23 06:54:16)

Seth, Unless the tarp was rubber you would still be grounded. Plus, since you were likely in the woods and somewhat remote, you would have been away from any EMF. Seth: I think the tarp was plastic. But I agree with you, I should not jump to conclusions about whether or not I was grounded. It does seem worth looking into. Maybe I slept especially well partly because I was away from light in the evening. The harder-than-usual surface (the ground) may have also helped.

Omnivorous wolves, spiders that play tether ball, worms instead of oranges, and yogurt and honey improve sleep (2013-12-23 23:41:55)

[...] Is it the yogurt or honey? The brain seems to like lactate. The brain can also store glycogen and it probably converts it to lactate (whether or not that is a good thing I don't know, but healthy babies have elevated lactate levels besides the ketones, nonetheless it is still not clear whether lactate is an emergency substrate or preferred) However, the main components in different honey are fairly similar, the glucose and fructose part. If two different brands of honey have different effects, then we can more than likely eliminate the sugar component and look at other properties of various kinds of honey. Different kinds of honey have different antimicrobial properties and contaminants. A little hormesis to improve sleep? How does endotoxin impact sleep? (Personally, honey ruins my sleep even tiny amounts and so does sugar (sugar also negatively impacts my typing tests), I seem to sleep best when I eat about 600g of cottage cheese throughout the day, it's probably less then that since I strain the fat out (I'm after the protein anyway, I eat plenty of butter and full fat yogurt), and beef which I like seems to make me sleepless if I eat it too late in the evening or too much of it during the day) [...]

Tom Passin (2013-12-21 08:40:00)

You're not reading these snippets carefully enough, Seth. The aspirin at night study didn't find that "Patients who took blood pressure medication at night were about a third as likely to have a heart attack or stroke as morning medication takers". That was some other study. This aspirin study found no effect on blood pressure of when the aspirin was taken. It also didn't find that taking aspirin in the evening vs morning reduced stroke or heart attack rates. It only found that evening aspirin reduced platelet activity the next morning, and it didn't measure even half of the participants at that. And the study wasn't blinded to the participants, either. See <http://www.nhs.uk/news/2013/11November/Pages/Bedtime-aspirin-cuts-morning-heart-attack-risk.aspx>. Seth: I knew that blood pressure medication is not the same as aspirin. I agree, my brief description did not make that clear. I hope you can make an equally long list of what was good about the aspirin study.

Nancy Lebovitz (2013-12-21 09:26:45)

Seth, have you looked into traditional Chinese medicine?– it takes season and time of day seriously. Seth: I hear a lot about the seasonal stuff, much less about the time of day.

Richard Sprague (2013-12-22 13:57:40)

Here is a map-based look at health care costs: <http://www.bestmedicareprice.com/>

Jerry (2013-12-24 17:43:47)

If you wake up feeling "jittery" you should check your blood sugar. I've found that if I wake up like this, it's usually somewhat elevated ( 95 to 110). I've also observed that if I lay around in bed reading for a few hours, it will also rise a little. But getting up between 5:30 and 8:00, and getting the day started seems to keep sugar in the normal range.

## **Front Lines of Personal Science: Progress on Why I Slept So Well (2013-12-22 05:00)**

[1]A few days ago I noted that I had slept unusually well. I wondered why. The previous day had been unusual in five ways (yogurt blueberries and honey 2 hours before bedtime, only one blackout curtain, chocolate, unusual timing of morning faces, new brand of honey). Was one of them responsible? Or was it random variation?

The next day I repeated four of the five unusual things: only one blackout curtain, chocolate, unusual timing of morning faces, new brand of honey. Result: I did not sleep unusually well. This pointed to either yogurt blueberries and honey or random variation as the explanation. Those happened to be the explanations I had considered most plausible (yogurt blueberries and honey) and least plausible (random variation).

Yesterday I repeated all five of the unusual things. Yesterday evening it took longer than usual to fall asleep. Usually I fall asleep within a minute, but this time it took about 4 minutes. As I was lying there, I attributed the long latency to lack of exercise that day. In the morning, for the first time in my whole life, I woke up what a friend called "full of jitters". Very rested, yes, but also too much energy. As if I'd had too much caffeine. Usually I have a cup of black tea first thing in the morning. I started to make one and realized it would make things worse, not better. As I said, this has never happened before.

So it was the yogurt blueberries and honey. The first time I had it I had added the honey just for sweetener and hadn't measured it. The second time I did measure the honey – 14 g, about 2 teaspoons. Probably more than I had used the first time, which may explain the different results (1st time: very rested, 2nd time: very rested and jittery). Both times I ate 125 g blueberries, which has 12 g sugar (half glucose, half fructose). I doubt the yogurt (homemade, no sugar added) matters.

Perhaps the best dose (for me) will turn out to be one teaspoon honey 2 hours before bedtime and one tablespoon of

honey at bedtime. I had tried taking more than one tablespoon of honey at bedtime; it seemed to produce the same effect as one tablespoon.

I want to test with and without blueberries, of course, and different amounts of honey 2 hours before bedtime. If honey alone is powerful, then I will test different forms of sugar. I don't want to be at the mercy of differences between brands of honey, although honey is very convenient.

Let's say it turns out to be the sugar in honey that produces these big improvements in sleep. Then it will turn out that the nutritionists of the world have been even more wrong about sugar than they were about saturated fat. All the data is not yet in, let me repeat. But the data so far unquestionably point in a surprising direction. It is entirely possible that sugar – in the right amounts at the right times of day – will turn out to be the greatest health food of all.

Which would explain what has never been well-explained: why we like it so much.

1. <http://blog.sethroberts.net/2013/12/20/dispatches-from-the-front-lines-of-personal-science-why-did-i-sleep-so-well/>

---

Rashad (2013-12-22 12:44:09)

I think your research is pointing in the direction that some ice cream after dinner is ideal. It has lots of cream, so could probably substitute for some of the butter you normally consume, and has a decent amount of sugar, possibly comparable to a tablespoon of honey? Seth: That's an interesting idea. However, the fat in the ice cream might interfere with the digestion of the sugar. Ice cream has a surprisingly low glycemic index. I once had honey and cheese at bedtime, instead of just honey. The results were worse than usual, presumably because the cheese slowed down digestion of the honey. I agree it's worth trying sugar in different contexts.

Gina (2013-12-22 13:14:26)

What Seth is suggesting sounds more like Italian ice or sorbet to me (fruit blended with sugar). I think he found that fat before bed didn't help.

George (2013-12-22 19:22:52)

Hi Seth! I would love to try and replicate your results. I found that what I eat for breakfast and lunch has a strong effect on my sleep with or without honey (if I eat too much carbs before PM I sleep badly, but if too little I get anxious and also sleep badly) Could you please share what you ate for breakfast and lunch on these days? thank you. Seth: No breakfast. Lunch: 60 g butter, 20 g cheese, small amount of pork or duck, 30 g ground flaxseed, 18 g dark chocolate, yogurt, fruit, tea with honey and cream as desired.

John Kojis (2013-12-22 19:46:26)

Do you think it's possible for the quality of sleep to be affected by something even earlier, maybe a few days or more? It might take a longer for some food or environmental factors to work their way through the system. Of course, factors that are closer in time could be assumed to be stronger influences, and would be a logical place to begin, but it seems too simplistic to say it's either what you ate yesterday or random noise. Seth: By "random noise" I meant everything else. As for your hypothesis ("the quality of sleep is affected by something even earlier"), I agree. There is jet lag, which takes several days to recover from. The bad effects of breakfast took me a week or so to recover from.

peter (2013-12-23 10:17:30)

if you eat sweets at the end of the meal it just sits in your stomach on top of the rest of the food and ferments, producing gas. I try to eat food in the order in which it is easily digested. This suggests eating fruit first (which is what they do in Latin America), carbs second, i.e., potatoes etc, vegetables next and then protein last.

### Front Lines of Personal Science: More Progress on Sleep (2013-12-23 05:00)

To recap: [1]Three days ago I slept extremely well, better than usual. I wondered why. What had made the difference? That day (the day before the night I slept so well) had been different from previous days in at least five ways (e.g., chocolate, new brand of honey). I repeated four of them, and did not sleep better than usual. That suggested the remaining difference – I had eaten yogurt, blueberries (125 g) and honey (8 g?) a few hours before bedtime – was responsible. (Every night I had 1 tablespoon – 20 g – honey at bedtime. It wasn't that.) Then I repeated all five elements, including yogurt, blueberries (125 g) and honey (14 g) two hours before bedtime. [2]I woke up wired (jittery). Very rested, but wired, which wasn't pleasant. Too much sugar, perhaps.

The next night I had a banana roughly two hours before bedtime. (In addition, I repeat, to 1 tablespoon honey at bedtime.) [3]A banana has about 6 g glucose, 6 g fructose, and 3 g sucrose, similar to 1 tablespoon honey. I had a strong craving for something sweet at that time, which was new to me – I almost never eat dessert. In the evening I had more brain power than usual. Yet at bedtime I fell asleep quickly, in about a minute.

The next morning I woke up and felt great. Almost perfectly rested, neither tired nor wired. Even though I'd only slept 4.7 hours, a bit low for me. It really was the yogurt, blueberries and honey – almost surely their sugar, which is almost all they have in common with a banana – that had made me sleep so well.

Conclusion: For the best sleep, have sugar after dinner and sugar at bedtime. By sugar I mean a glucose/fructose mixture but for all I know sucrose would work, too.

Mehmet (2013-12-23 06:50:53)

I really wonder how you can sleep so little. Is it a result of your sleep improvements? Did better sleep lead to less sleep? Also, I wonder how you wake up. With an alarm clock or spontaneously? BTW, honey improved my sleep. I have also observed that leg fatigue improves my sleep but I do not practice one leg standings. Thank you for this blog. Your experiments inspired me to do my self-experiments. Although I am in the academia, I have rarely investigated my life with scientific curiosity before discovering your site.

Paulo Paiva (2013-12-23 07:14:29)

[Excuse if I made mistakes, english is not my native language – I'm from Brazil] What a coincidence. Today I told my wife how deep I had slept and connect it to the 1 tbspoon of honey and 1 tbspoon of apple cider vinager mixed with half a cup of water before bed (it tastes really good). Then I saw this post and remembered that yesterday I had banana flour pancakes topped with

honey 3 hours before bedtime! I think you are at the right track. And thanks for your blog. I crave for new posts every morning! For years! :) Seth: So interesting! Thank you for reading my blog all these years.

Remi (2013-12-23 07:53:13)

Sleeping less than 5h could be dangerous to your immunity system.

Ripken Holt (2013-12-23 10:55:52)

Would homemade Ice Cream work? My family makes some really delicious homemade ice cream which I had stopped eating because I had gone mostly low carb except for a serving of potatoes with each meal. How about a slice of pound cake? Those are my two favorite deserts of all time.

dearieme (2013-12-23 11:17:29)

But, but, but... surely many people do this anyway? I mean, a milky drink with sugar before bed - weak tea, cocoa, Horlicks, Ovaltine - is pretty standard in Britain, as is dessert - "pud" or fruit - after dinner. Still, I am currently taking a "probiotic" yoghurt drink because I've just finished a course of antibiotic. It's sweeter than I like at breakfast, this "Actimel", so I'll try it before bed instead.

Seth Roberts (2013-12-23 12:39:27)

"But, but, but... surely many people do this anyway? I mean, a milky drink with sugar before bed - weak tea, cocoa, Horlicks, Ovaltine - is pretty standard in Britain, as is dessert - "pud" or fruit - after dinner." Usually I take 20 g of honey (about one tablespoon) before bedtime. I tried 10 g honey - clearly worse results than with 20 g. When I sweeten tea, I use about 4 g honey. "Still, I am currently taking a "probiotic" yoghurt drink because I've just finished a course of antibiotic. It's sweeter than I like at breakfast, this "Actimel", so I'll try it before bed instead." I drink Yakult every day, that's a good idea - have it after dinner rather than in the morning. According to Wikipedia 1 bottle of Actimel has 3.3 g of sugar (sucrose), whereas 1 tablespoon of honey has 16 g of sugar (fructose and glucose).

Seth Roberts (2013-12-23 12:47:38)

"I really wonder how you can sleep so little. Is it a result of your sleep improvements? Did better sleep lead to less sleep? Also, I wonder how you wake up. With an alarm clock or spontaneously?" I usually take a nap in the afternoon, 40-60 minutes. That reduces how much I sleep at night. I wake up spontaneously. I am sure my sleep is unusually deep, partly because I get plenty of sunlight and Vitamin D in the morning, partly because I get plenty of face exposure in the morning. All three of these (sunlight, Vitamin D, faces) I expect to increase the amplitude of a circadian oscillation. Deeper sleep should be more efficient sleep. I hear about other people waking up at night and falling back asleep. That almost never happens to me.

Gina (2013-12-23 13:09:40)

I wonder if the sleep improvements with honey are primarily for people eating a very low carbohydrate diet. My brief low-carb stint was ended because of the complete inability to sleep (elevated cortisol) which was cured with a single carb-heavy meal. Seth: My diet, when I started the bedtime honey, was low-carb - I don't eat rice or pasta or potatoes or bread - but not very low-carb. I ate fruit and honey (to sweeten tea) and sugar (to sweeten yogurt and Yakult) every day. What happened to you supports the general point I am making here: Details of your sugar (and carb) consumption have a big effect on your sleep.

Dan (2013-12-23 13:19:20)

Thank you for sharing your experiment(s) - could you please approximate what was the total amount of sugar you consumed the entire day? Seth: Moderate amount. 10 g in Yakult, 5 cups of tea x 6 g sugar/cup = 30 g, 20 g sweeten yogurt, miscellaneous fruit 10 g = 70 g. Not counting the sugar after dinner (10 g) and at bedtime (16 g).

daz (2013-12-23 14:31:59)

"I hear about other people waking up at night and falling back asleep" ...tho for some of these people, i'm guessing waking up in the night could mean waking up 4 or 5 hours after they went to bed, me included. whereas it sounds like Seth would call this...morning ? :) also, these people may not nap during the day (i don't). Seth: When I wake up after 5 hours feeling rested

and don't fall back asleep later, I don't worry about it. To wake up early and feel tired but be unable to fall back asleep, that was the problem.

Kathy (2013-12-23 17:50:46)

Part of the legendary danger of sugar, to me, is its role in damaging dental health. I can appreciate sugar at the end of the last meal of the day, where the sugar is not unopposed. But it seems honey or dessert closer to bedtime would promote cavities/gum disease. What do you think? I'm very interested in exonerating sugar if it can be done! Seth: I brush my teeth after eating the bedtime honey. The benefits of good sleep are so great that I don't worry about cavities. As for gum disease, that's caused by lack of omega-3. See [1]my post about Tyler Cowen and flaxseed oil, for example.

1. <http://blog.sethroberts.net/2007/07/06/omega-3-and-dental-health-surgery-commuted/>

Ben (2013-12-27 21:47:20)

What time do you usually eat dinner? How long after dinner do you eat the banana? Can't wait to try this out. Thanks Seth!

Seth Roberts (2013-12-28 05:33:41)

I eat dinner around 6 pm. Eat the banana 1-2 hr later.

## **Bedtime Honey Helps an Autistic Boy Sleep (2013-12-24 05:00)**

A reader writes:

My eight-year-old son has autism, on the serious end of the spectrum, with equally serious sleep troubles. A month ago I tried giving honey at bedtime after reading about it on your blog. It has made a tremendous difference.

My son has had trouble sleeping since he was a toddler. Since age four he has seen a pediatric neurologist who is also a sleep disorder specialist. With the doctor's guidance we have tried different over-the-counter and prescription-drug approaches, but none has given him regular sleep, and the side effects from the drugs make increasing dosages risky.

His basic problem is not insomnia (a general inability to sleep) but rather delayed sleep phase disorder. He could sleep fine from the wee hours of the morning to noon. But whenever we managed to advance sleep onset [= get him to fall asleep earlier], he would wake up early. It was hard when we struggled to get him to sleep by midnight and then struggled to wake him at 7:00 a.m. for school. But it was even harder when he would fall asleep at 9:00 p.m., then wake up at 4:30 a.m., often falling back to sleep at 6:30 a.m, just in time for us to wake him at 7:00 a.m.. It's not safe for him to be awake on his own for hours, and he was desperate to go back to sleep until about 9:00 a.m.

Since we started giving him a teaspoon of honey at bedtime he has slept through the night. We still have to give him meds to go to sleep between 9:00 p.m. and 10:00 p.m., but once he's asleep he stays asleep all night until we wake him at 7:00 a.m. The one night, early on, when we forgot to give him honey, he woke up just as he used to.

One factor that may make honey particularly effective for my son is that we've been eating a low-carbohydrate paleo diet for the past two years (because it helps his autism symptoms). Before that he was an extremely picky eater who preferred baked goods, milk, and cheese. With high-glycemic foods all day long a teaspoon of honey at bedtime might not have had much effect.

This is the best my son has slept in his life, and it has been a huge improvement in his and our family's lives. Before the past month, the last time my son had gotten three good nights of sleep in a row was because he'd had a concussion.

---

Charlie Currie (2013-12-24 08:21:24)

Excellent. Hopefully she will keep you, and us, posted on how he does over the coming months. I'm curious to see if the protocol becomes adaptive - does he revert back to his previous sleeping pattern over time, and if so, does upping the dose bring back better sleep. I would suggest, if she hasn't already, looking into the resistant starch protocols that are being discussed on the Free The Animal website...lots of reports of improved sleep there too.

mikimoonmouse (2013-12-25 00:52:19)

I used to wake up with a white coated tongue and bad breath, with bedtime honey my tongue is super clean in the morning even without brushing my teeth at bedtime, just flossing.

A reader (2013-12-25 08:36:21)

Charlie Currie, thank you for the recommendation. I'll check it out.

No One (2013-12-29 03:42:54)

Has anyone here tried trehalose? see e.g. <http://forum.bulletproofexec.com/index.php?/topic/4162-trehalose-an-alternative-to-raw-honey-before-bed/> (And the original thread it links to)

## **Frontlines of Personal Science: Confirmation of After Dinner Sweets Effect (2013-12-25 05:00)**

During the last week I have looked into the possibility that my sleep can be further improved - in addition to [1]the bedtime honey improvement - by eating a similar amount of sugar (fructose and glucose) a few hours before bedtime. After [2]I accidentally slept better than usual (or even better than usual), I tried to determine why. Several things had been unusual the day before. Two tests ([3]here and [4]here) pointed to the sugar (honey or banana) a few hours before bedtime.

Last night (Christmas Eve) I tried again. I ate a banana (132 g, peeled) about 3 hours (7 pm) before I fell asleep (10 pm). I fell asleep within a minute and woke up, after an apparently dreamless night, feeling perfectly rested. On my 0-100 percentage scale (100 % = completely rested, no detectable tiredness), which I have been using for about 8 years, it was the first ever 100 %. I had slept about 6 hours, a good amount of time.

To celebrate, I had a cup of black tea. I didn't need it to wake up but I like the taste. I reflected that countless people had drunk tea or coffee to wake up. I had found a better way.

Discovery that an hours-before-bedtime sweet improves sleep (in addition to bedtime honey - that's what's interesting) is significant not just for the obvious practical reason (better sleep) but also because it is the confirmation of a prediction. After I slept unusually well, I thought of [5]six possible reasons. The notion that sugar improves sleep pointed to one of them. The results of every test I've done (three nights) have agreed with that prediction. I believe [6]the only real test of a theory (such as an explanation) is whether it makes correct predictions - especially, whether

it leads to the discovery of new cause-effect relationships. Many things people say haven't passed that test. An example is weight control. That low-carb diets cause weight loss has been known since the 1800s. Many explanations have been proposed; not one has made correct predictions, as far as I know. In contrast, [7]my theory of weight control led me to [8]three new ways to lose weight (sushi, low-glycemic foods, and fructose water).

I doubt it's a placebo effect because the sleep improvement has happened whether I expect it or not. A commenter named Paolo Paiva, after reading my posts about this, realized [9]something similar had happened to him :

Today I told my wife how deep I had slept and connected it to the 1 tablespoon of honey and 1 tablespoon of apple cider vinegar mixed with half a cup of water before bed (it tastes really good). Then I saw [10]this post and remembered that yesterday I had had banana flour pancakes topped with honey 3 hours before bedtime!

Thanks, Paolo. May you continue to sleep well. May the rest of you sleep equally well.

Merry Christmas!

---

Brian Toomey (2013-12-25 05:53:33)

Merry Christmas to you, too, Seth! I've been sleeping better since adding sweets at night, similar to what you describe. At first I was resistant to the idea of sweets before bed because: 1) I had been not eating after 7 or 8pm as part of an intermittent fasting condensed eating window eating routine 2) I have historically overeaten refined sweets. Recently, though, I've been doing it, having some fruit (or sweets with the Holidays) around bedtime and have been sleeping much better. I would say my rested percent had gone from 90 to 95-98, and I've been getting up about an hour earlier. Definitely much better. When I started reading this before low blue light at night, Vitamin D in the morning, and the above my rested percent was more like 30-40 %. I've also recently (2 months ago) installed blackout curtains and found that my sleep got, to my surprise slightly worse. I have 4 windows in my bedroom, and leaving one of the curtains partially open so some light can get in (there is a lot on my street) seems better than almost no light. Thanks, Seth!

Gina (2013-12-25 10:45:12)

Thanks for your blog, Seth. Merry Christmas! I love the discoveries here, because they are inexpensive and range from easy to pleasurable. Lots of tasty things can be made with just fruit and sugar, why eat plain bananas and straight honey?? Seth: to keep things simple. Simplicity will help me increase my understanding. It is much easier to know what is in a banana or honey than what is in an ordinary dessert.

dearieme (2013-12-25 17:04:45)

From a local orchard we've recently bought candied pears (Comice) and plums (Edwards). They formed two of our thirteen desserts on Christmas Eve, a habit we've adopted from French friends. The table looks magnificent, but iron discipline is required if you are not to make a pig of yourself.

August (2013-12-26 09:13:37)

This reminds me of Kiefer (athlete.io). His focus is mainly for bodybuilders, though I think his first book was for people looking to lose weight. His understanding of hormonal activity throughout the day, and his subsequent recommendations as to when to eat carbs and what type to eat coincides with yours. Now, you are eating a lot fewer carbs and eating them everyday, while Kiefer protocols are to eat a lot after training, and be low carb the rest of the time, but I think you are both tapping into the same daily hormonal cycle.

Xav (2013-12-26 14:58:30)

I was curious to see what research had been done with fruit before bed and sleep, and found this paper : <http://apjcn.nhri.org.tw/server/APJCN/2012/2/169.pdf> ( Effect of kiwifruit consumption on sleep quality in adults with sleep problems ). In the study eating 2 medium kiwi fruits an hour before sleep, helped the subjects sleep better. Seth: Thanks, yes, I knew about that study. You are right I should give it more emphasis. It could have gone the other way (the kiwis made sleep worse) so it supports what I am saying. Two kiwi weigh about 100 g, which would contain about 4 g glucose and 4 g fructose. Not so far from the dosages that I found have worked.

Walter (2013-12-26 21:07:49)

Seth, I always find your blog fascinating and informational. Along those lines I wondered if you have played with resistant starch as a food source for our microbiome? There is a lot of N=1 testing going on the FreeTheAnimal blog and the results are encouraging as a methodology to control blood sugars etc. Walter

Seth Roberts (2013-12-26 22:21:14)

Walter, I will try resistant starch. After I have optimized my sleep without it. I wonder if the benefits claimed for it are due to better sleep. And if it promotes better sleep by being digested slowly during the night.

Xav (2013-12-27 01:59:12)

Seth - you mentioned trying blueberries and now bananas. I wonder if some fruits are more optimal than others ? Here are a couple more studies regarding fruit - juice in this case - and sleep ( in case you haven't come across them already). These are a little different in that in one, time of taking the juice does not seem to be controlled, in the other one serving is taken 1-2 hrs before sleep. 1) Effects of a Tart Cherry Juice Beverage on the Sleep of Older Adults with Insomnia: A Pilot Study <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3133468/> 2) Effect of tart cherry juice (Prunus cerasus) on melatonin levels and enhanced sleep quality. <http://www.ncbi.nlm.nih.gov/pubmed/22038497> Seth: In the second study the two conditions are equated for sugar content.

Gabe (2013-12-27 16:32:59)

You wrote earlier that the total amount of sugar you consume these past few (including post-dinner and pre-bed) is about 95g. Some people write that they experience less of the effect of honey when they eat many non-sugary carbs throughout the day. Do you know what is the total daily number of non- sugary carbs you get these days from food (flax, starchy vegetables, etc)? Seth: Daily "number"? You mean number of servings? I eat 30 g ground flax per day. Maybe 1 serving of non-sweet carbs. Not

much.

daz (2013-12-28 15:17:11)

Hi Seth, in regards to taking honey before bed being effective...in a comment under a prev post you wrote\*... "Two things seem to matter. 1. You must take it on an empty stomach. 2. You must not have sweets during the day" do you still think 'rule' #2 applies? & if so why do you think that may be? \*ref: <http://blog.sethroberts.net/2013/11/20/bedtime-honey-improves-sleep-1000-craz-y-good-tip/> #comment-1156678 Seth: I think #2 applies – you can't eat a lot of sweets, a few sweets make no difference – because it would raise your insulin levels. If your insulin is too high for too long it will remove sugar from your blood at night.

daz (2013-12-29 01:07:40)

ah insulin, thx Seth, i was wondering what the theorised 'mechanism' for #2 might be... the only think i could think of was something to do with liver glycogen, but that made no sense, as i would presume that eating sucrose/glucose/fructose during the day should keep liver glycogen levels high (assuming low/depleted liver glycogen results in poor sleep)

daz (2013-12-29 13:28:10)

...(assuming low/depleted liver glycogen results in poor sleep and 'full'/replete liver glycogen results in 'normal/default' sleep)

nicole (2014-01-02 17:24:47)

i wonder if the reason dessert developed was to give people a bit of sugar before sleep...

## **Lessons of This Blog (1st of 2) (2013-12-26 05:00)**

Kirsten Marcum told me she had "put a number of [my] findings to use in [her] own life." I asked how. She replied:

I've put a few of your specific recommendations to work (SLD, standing on one leg each day, omega-3s, more animal fat/pork fat, butter tea, fermented foods)...but in thinking about this, I realized I've gotten even more use out of general principles I've drawn from your blog over the years:

1. Trust your results. I'm thinking of your own (and other people's) experiments with what caused acne (dairy, etc.) or migraines (soy) and helped restless leg syndrome (b6) or sleep, etc. You and others tried solutions, and the solutions either worked or they didn't, and you/they looked to correct root causes, and those corrections either worked or they didn't. If you still have acne, the acne treatment didn't work—even if it should have, and even if an expert recommended it...and you probably shouldn't just keep doing the treatment just because it's supposed to work. And if you cleared your acne, then the intervention worked—regardless of whether it "should" have. If your brain performance improves in a measurable way after eating butter, trust that result—and be skeptical about the people who tell you butter is damaging your health. If treating a leaky gut improves your thyroid labs, trust that—not the doctor who says your leaky gut diet is too restrictive and is going to damage your health.

2. Many unpleasant circumstances are reversible. It's often possible to find positive interventions that ameliorate, reduce, or remove things that are bothering you—many of which are cheap or free and not hard to implement. It's possible to fix health issues, productivity problems, make learning more fun or effective, etc. It's amazing to me how many people don't think this is true—that you're stuck with extra weight, or acne, or creaky joints, or back pain, or migraines, or the inability to motivate yourself to work—and there's nothing you can do.

3. Most things that are beneficial are also pleasurable, and vice versa. When something is good for us, we usually find it pleasurable (animal fat, salt, sugar at night, umami flavors, learning while moving, faces in the morning). Otherwise, how would we have evolved to do it?

I extend this to say: If something's not pleasurable but supposed to be beneficial, it's either bunk or you're doing it wrong (i.e., in a way that removes the pleasure and possibly the benefit.) So look for the pleasure—because then you're more likely to do it and to see a benefit.

And: If something is pleasurable but not beneficial, your body probably wants something very similar and it's confused—junk food umami vs. fermented foods. In which case, find a pleasurable AND beneficial substitute, and it will be easy to stop doing the thing that is not beneficial.

4. Be skeptical of experts. Most experts have incentives that have nothing to do with the reasons you're consulting them. Understand this, look for their motivations/weaknesses/blind spots, and always check what they're telling you against what your body (or other results) are telling you. Also look for non-experts with interesting ideas.

5. What's good for the brain is good for the body. I would add to this: Many things that we think of as personality or mental/emotional issues actually have a physiological basis—and optimizing your health will likely have a positive effect.

They sound elementary, but they're counter to the way nearly everyone I know thinks.

Over the years, thinking like this has improved my life in multiple ways:

- I 100 % cured my back pain (after 3 rough years) with Esther Gokhale's 8 Steps to a Pain Free back—which cost \$17 and provided more practical and helpful advice than the two doctors, physical therapist, and personal trainer I consulted.
- After a bunch of looking, I found a doctor who, when presented with new ideas, says: "That's interesting. Where did you find out about it, and what have you tried?" More than once, she has looked into the subject, found the new recommendation convincing, and has started to share the information with similar patients—which means I also benefit from what she learns from others.
- I fixed my complexion, have nearly fixed my weight issues, and reversed dozens of nagging health issues (peeling fingernails, bad breath, rosacea flushing, random bad stomachaches, food sensitivities, mood swings, lack of motivation and focus etc.) through a whole-body thyroid/adrenal/gut repair approach that's considered bunk by most mainstream endocrinologists. Parts of this approach happen to incorporate things you've found beneficial—increased amounts of animal fat, fermented foods, focus on optimal sleep, focus on aligning with circadian rhythms. (Interestingly, one of leading proponents of this approach started out focusing on thyroid health and has found even better results by broadening his focus to brain health....very much like your "what's good for the brain is good for the body.")

FWIW, I tend to use topics you've investigated as a check on other people's recommendations—you're not an "expert" in the field of thyroid repair, or gut health, etc., so you have no incentives to adhere or not adhere to a particular line of thinking. So if both you and a thyroid doctor find a particular approach beneficial, that seems very convincing to me.

Those are good lessons. Tomorrow I will explain why I think they all come from one somewhat hidden underlying lesson.

---

q (2013-12-26 07:18:51)

ok, on stomach issues. my stomach is more or less fine, but i have a friend who has a lot of "random" stomach issues. i don't think she's going to do the "experimentation" thing much herself but is there anything i should suggest she read or anyone she should see? ie where should she start? i know what i would do, read a ton of stuff and try some things and keep track, but it's not me. Seth: Read what I've written about fermented foods.

Charlie Currie (2013-12-26 08:23:40)

Excellent...I concur with all 5...

Jackye (2013-12-26 16:06:46)

How did you heal your peeling fingernails? I have also greatly benefited from reading Seth's blog; cured my acid reflux/heartburn by eliminating gluten from my diet.

Portlander (2013-12-26 20:54:59)

The one that most resonated with me is #2. I'm always amazed by the number of people that seem to shrug and assume sub-optimal health is part of life. No, it means you're doing something WRONG THAT NEEDS FIXED! Your job is to pay close attention to try and figure it out. When genetic pre-disposition for one ailment after another was newly the rage (which, I guess it still is), the counter joke was "Hey, our genes didn't evolve to kill us." I think too many people think misery is just bad luck and there's nothing one can do about it. It's Shakespearean. Or Biblical. One is born under a crossed star, or a pox is on one's house, and 'dems da' breaks.

Alex (2013-12-27 08:07:59)

For q: one of the surest ways to make your own life worse is to be more invested in solving your friend's problems than she is.

Alex (2013-12-27 21:44:50)

Great observations and impressive results, Kirsten Marcum. If you ever blog about the process, I'd love to read it. I'm most envious of your having found your doctor. When I told my GP I'd lost 30 pounds by eating paleo, she all but rolled her eyes. I'd love to know how many other patients she has who've dropped over 10 % of body weight in months without any exercise or calorie restriction.

Kirsten (2013-12-30 15:18:45)

Hi Jackye- The fingernails were fixed by stomach acid supplements (HCL with pepsin). My doctor told me that low stomach acid is common with autoimmune thyroid issues. So I did a self-test to figure out the dose size I needed, and about four months after I started supplementing, my fingernails stopped peeling. My theory is that without stomach acid, I wasn't breaking down my food well and so I wasn't using all the nutrients I took in. I have to wonder about the positive effects on the parts of my body I can't see. Incidentally, my nails peeled continuously from age 13 to last January (age 39), with only two breaks: once when I took biotin supplements (when I stopped, it came back) and during the year I drank a ton of raw milk. And Alex: Thanks very much! I've been a blog lurker since 2001, but haven't commented much or blogged myself. Maybe that will change as my health improves....one of my major symptoms is a failure to connect intent to action. So I would read blogs and intend to comment, but never do it, or intend to start a blog, but never post. Now that my health is improving, I find I have a shorter list of things I mean to do and longer list of things I'm actually doing. So you never know.

## Lessons of This Blog (2nd of 2) (2013-12-27 05:00)

Yesterday I posted [1]Kristen Marcum's list of general rules she'd learned from this blog. (For example, "be skeptical of experts.") Behind her list, I think there is one idea, slightly hidden from view:

non-experts can discover important things about health

By non-experts I mean people who are not health professionals. People who do not make a living from health research. By discover I mean learn from data for the first time, actually discover – in contrast to learn from an expert. By important I mean stuff that matters to many people. (It's obvious that studying yourself you can help yourself.) I haven't heard anyone else say this, although it isn't far from the Quantified Self movement.

The first example of this rule was the work of Richard Bernstein, an engineer with diabetes. In the 1960s, he pioneered home blood glucose testing, now enormously important. Another example, I hope, is my work. I used self-tracking and self-experimentation to find [2]important new cause-effect relationships in several areas – new ways to sleep better or lose weight, for example. I believe my conclusions will turn out to be true for many people, not just me, because they fit well with research done with other people and animals. I'm a professional scientist, which obviously helped, but not a health researcher.

Why is this rule true? I found it hard to explain even my discoveries. [3]The first time I tried, I didn't do well. I did better [4]the second time.

I came to see that discoveries require several things – more precisely, rate of discovery is a product of several factors. Everyone sees that experts have several advantages over non-experts:

1. more training (graduate school)
2. more resources (equipment, grants, space, assistants, journals, specialized libraries, and so on)
3. more hours per day (all working day)
4. more experience (their entire working life)

What I've never seen pointed out is that non-experts have several advantages over experts:

1. more time overall (with no pressure to publish, a non-expert can easily spend many years on one question)
2. more freedom (no pressure to follow a party line, obey your boss or be popular)
3. more motivation (non-experts want to improve their own health, or a loved one's health; for health researchers it's a job)
4. ability to self-track and self-experiment (this is too humble for experts)

Because of my job, I was only slightly behind health experts in terms of their four advantages, and I was far ahead of them in terms of the four non-expert advantages. This explains why I discovered many things that experts had not managed to discover.

Once I had a reasonable understanding of what had happened, I saw there was no reason I should be the only one. As a professor, I had excellent library access, much better than most, but now, with the Internet, many people have comparable access to research. Supporting my prediction that I am not the only non-expert who can do this, I have found

other non-experts who have made important discoveries. Tara Grant figured out that [5]the time of day she takes Vitamin D made a big difference. Professional researchers have not yet figured this out. Katie Reid found that [6]her autistic daughter completely recovered – autism symptoms completely gone – when all glutamate was removed from her diet. Professional autism researchers haven't managed to cure even one case of autism, as far as I know. Stuart King figured out that [7]a tablespoon of honey at bedtime greatly improved his sleep. No sleep or nutrition researcher has realized this.

In the 1940s, my mother's mother sent my mother newspaper clippings about computers, of which, at the time, there were only a few. This is going to be important, she said. Let me continue the tradition by telling you this is going to be important.

When even a tiny fraction of non-experts become "health knowledge generators" (for lack of a better term) the world will change. Some of the reasons:

1. The IQ advantage. There are far more non-experts than health researchers. A factor of 100,000? Let's say health researchers have [8]an average IQ of 130. If you take 100,000 non-experts (mean IQ = 100, standard deviation = 15) the top IQ among them will be about 165.

2. Trust and generalizability. When a health expert advises you to do Treatment X (e.g., surgery), what should you think? Can you (a) trust him and (b) is what he says true for you? Any reader of this blog knows that health experts routinely overstate benefits and understate costs of the treatment they are promoting. Even if they are telling the whole truth, their advice is based, at best, on several studies. Is what those studies found – studying animals, or at best, other humans – true for you? When you study yourself – for example, carefully measuring the effect of a drug – error due to distortions and differences from the study population go to zero.

3. Good and bad chemicals. We encounter thousands of chemicals, many of recent origin. How we react to them – do they help or hurt? – is determined by our genome (billions of possibilities) and environmental history (countless possibilities). Any sort of expert testing will be woefully incomplete. The danger in assuming that a chemical safe for most people is safe for you is illustrated by a woman who found her almost constant migraines [9]were caused by household cleaning products and Katie Reid's discovery that her daughter was very sensitive to glutamate (found in a large fraction of supermarket foods). That things claimed to be safe may be dangerous is illustrated by the Berkeley graduate student who became [10]poisoned by mercury when he started grinding his teeth and my discovery that [11]fermented tofu made me stupid for a few days. My experience with tofu and [12]butter shows how a non-expert can do better than simply accept what experts say. My brain tracking, which anyone could do, detected previously-unknown or -unclear costs and benefits.

Our economy runs on specialization. We buy cars from car specialists, for example. Long ago, professionals had a monopoly on knowledge. To learn math, you had to pay a math teacher. Then came cheap printing and mass literacy and mathematics books and libraries. The same knowledge became not just free but widely available. Then came the Internet and Wikipedia and Google – even more available. But all this time, the source of the knowledge, its creation, was restricted to professionals. Only professionals (or rich amateurs, like Darwin) could "make" (or "mine") the knowledge. Now that will change.

---

Nancy Lebovitz (2013-12-27 09:32:26)

Some experts are researching their own diseases or diseases of loved ones– it might be a good idea to take those experts more seriously. Seth: You'd think so, wouldn't you? But in my experience these experts don't do well. I can think of three examples:

1. Stanford molecular biologist who discovered he had diabetes. He cured it via exercise. Nothing special there, in spite of a lot of high-tech measurements. He noticed the diabetes the same way everyone else does, with blood sugar measurements.
2. Geneticist near Stanford whose daughter has a very rare genetic disease. Last time I checked, he had made no progress in reducing her symptoms.
3. Larry Smarr, who has Crohn's. No progress on reducing the symptoms of Crohn's, last time I checked. Do you know of other examples?

dearieme (2013-12-27 10:34:10)

On being sceptical of experts <http://www.forbes.com/sites/larryhusten/2013/07/31/european-heart-guidelines-based-on-disgraced-research-may-have-caused-thousands-of-deaths/> Seth: good example. what's so telling about it is that it wasn't just one expert, one "rotten apple". Many experts (all European doctors?) followed recommendations based on bad data.

Gina (2013-12-27 11:05:42)

Not only do non-experts not have pressure to toe the party line, they are also free to find solutions to problems that are non-patentable. There is a reason that doctors prescribe Boniva instead of prunes and Ambien instead of honey, even though the prunes and the honey are effective, cheaper and have no harmful side-effects. I recently read *Manufacturing Depression* by Gary Greenburg and highly recommend it. Psychiatrists are uninterested in treatment that does not use drugs. Seth: I agree. I would put it a bit differently. Non-experts are free to find solutions that do not provide income to health care professionals. A naturopath, for example, will rarely advise something they don't sell. Lots of what they sell isn't patentable.

Nancy Lebovitz (2013-12-28 06:01:04)

Terry Wahls– <http://www.terrywahls.com/>– a doctor with serious MS who developed a modified paleo diet which controls her symptoms and which has worked for other people with MS. (It doesn't seem to work for some other people with degenerative diseases, which at least suggests that people in general aren't completely ruled by confirmation bias.) The theory behind the diet is that it's good for mitochondria.

Seth Roberts (2013-12-28 13:11:39)

I see, Terry Wahls is an example of a health care professional who has had good results trying to fix their own health problem. I agree.

Heisenbug (2013-12-28 22:38:56)

I believe another advantage that non experts have is that they are allowed to be generalists. They are able to make connections across different areas and disciplines, which is often how innovation and creativity comes about. They aren't fenced in like

experts. Experts, often for professional reasons, are not allowed to draw from disparate fields to make important connections and findings.

Seth Roberts (2013-12-28 23:22:55)

"Experts, often for professional reasons, are not allowed to draw from disparate fields to make important connections and findings." I haven't noticed that. It's true enough that they might not be curious about other fields. At Berkeley, in my experience, few faculty attended talks outside their field, but nothing prevented or discouraged them from doing so. I attended lots of talks in different fields. Nothing bad happened.

Nancy Lebovitz (2013-12-29 08:33:04)

I'm not suggesting that health professionals who work on their own problems will necessarily find solutions. You spent a long time working on your problems before anything useful turned up. However, I would expect that a health professional working on their own or a loved one's problem is much less likely to publicize a solution which doesn't work or has such severe side effects that it's not worth using. There's still the possibility that a solution which works for the health professional doesn't apply to at least some people with similar problems, of course.

### Assorted Links (2013-12-28 05:00)

- [1]Jared Diamond wrong about Easter Island
- [2]Why are the Kuna Indians (in Panama) so healthy? Answer: [3]low-processed cocoa. See [4]this study for details.
- [5]Asthma associated with depression
- [6]Sufficient conversion of ALA to DHA in rats. " This work indicates that DHA [long-chain omega-3] synthesis from ALA [short-chain omega-3] may be sufficient to supply the brain." Many people have complained that I use flaxseed or flaxseed oil to get better brain function. Don't you know conversion from short-chain omega-3 to long-chain omega-3 is poor? I tell them it works – but somehow I must be wrong. This study shows the issue is more complicated than they realize and it is quite possible that ALA is a good source of DHA. Good news for anyone who can't eat seafood.
- [7]National Sleep Foundation gives terrible advice. "Finish eating at least 2-3 hours before bedtime," they say. Whereas I believe the single best thing you can do for your sleep is eat a source of glucose and fructose, such as honey or fruit, at bedtime.
- [8]Sleep apnea associated with cancer. It is unlikely that cancer causes sleep apnea, but quite plausible that bad sleep – including sleep apnea – increases cancer.

Thanks to Eugenia Loli.

Jazi Zilber (2013-12-28 05:14:35)

Heavy meal might disturb sleep. Stomach work etc. Insulin reaction too needs to be factored in. I.e. high glycemic meal might lead to lower sugar due to insulin reaction.

Jazi Zilber (2013-12-28 05:16:31)

My experience is like you. For a long time, I could not fall asleep whatsoever without getting full (usually 100 g rice crackers (puffed) with 400 g yogurt.

Sentinel (2013-12-28 06:58:24)

Re the Kuna Indians' drink: if we wanted to try this, is it basically a hot cocoa drink made from dissolving pulverized organic cacao powder in hot water?

dearieme (2013-12-28 07:45:49)

"anyone who can't eat seafood": that's a new one on me. What's the problem?

Gina (2013-12-28 08:44:23)

Dearieme, I assume he's referring to those with allergies, those that live in areas where seafood is unavailable, vegetarians and people worried about mercury.

Hap (2013-12-28 09:12:00)

The cacao powder I got at Andronico's here in Berkeley is this: <http://www.sunfood.com/food/cacao-chocolate-cocoa/cacao-powder-8oz-organic-ra-w.html> Long list of nutrients, and it mentions "flavonols." The possibility of a connection with lower blood pressure is intriguing. I've started adding this to my milk, heavy cream, espresso drink. An interesting enough taste so I've no desire for sweetener.

JV (2013-12-28 10:07:02)

"Anyone who can't eat seafood". Yes, allergies. We have at least one friend who is allergic to shellfish and I don't think it's that unusual

Seth Roberts (2013-12-28 13:17:53)

Hap, In response to the Kuma Indians info, which suggests great health benefits of nearly raw cacao, I have gotten some CocoaVia products, which are supposed to be high in flavonols. You have to process the cacao "gently" to not destroy them. Maybe I will compare the CocoaVia stuff to the Andronico's powder you mention.

emini\_guy (2013-12-28 15:58:12)

Here is what I have been drinking for some time now - seems less expensive than the alternatives mentioned earlier here - [http://www.amazon.com/Healthworks-Certified-Organic-Cacao-Powder/dp/B00EKLPLU4/ref=sr\\_1\\_1?s=grocery&ie=UTF8&qid=1388271400&sr=1-1](http://www.amazon.com/Healthworks-Certified-Organic-Cacao-Powder/dp/B00EKLPLU4/ref=sr_1_1?s=grocery&ie=UTF8&qid=1388271400&sr=1-1)

dearieme (2013-12-28 18:18:02)

In my family problems with sea-food are highly specific - for example, one can't eat crab but is OK with everything else. Another can't eat lobster, at least of the North Atlantic variety, but can eat crab, Australian species, and so on. I've never met anyone who can't eat white fish, salmon, trout, herring, sardines, mackerel and the other common culinary fish, though I don't doubt

that they might exist. Shellfish: yes, I've heard of that problem. But does allergy to shellfish imply allergy to, say, cod, haddock, sole, plaice ....? I ask from pure ignorance, not as a debating point.

dearieme (2013-12-28 18:20:17)

Whitebait: I do hope that everyone can eat whitebait. It would be a rotten trick by God if some poor soul couldn't enjoy them. (I mean Proper Whitebait, not the dismal stuff so-called in NZ - a lovely country, but unsound on whitebait.)

john (2013-12-28 20:29:18)

Mixing cocoa powder and water would make a drink much less fatty than what the Kuna consume. Try adding back cocoa butter? ...or something with baking/dark chocolate? Seth: Good point. However, I already eat a lot of butter.

john (2013-12-28 20:34:45)

Anyway, cocoa/chocolate is nutritious, but it's not as if the Kuna use it to counter all the HFCS and corn oil they consume. Just like most "traditional" cultures, the foods are good quality, and they don't eat most of the crap Americans do.

Alex Chernavsky (2013-12-28 22:04:11)

@Dearieme, here are some reasons why I don't eat seafood: [1]Fish do feel pain, scientists say [2]Further evidence crabs and other crustaceans feel pain (Both links go to the BBC website)

1. <http://news.bbc.co.uk/2/hi/sci/tech/2983045.stm>

2. <http://www.bbc.co.uk/news/science-environment-21044077>

Elizabeth (2013-12-29 09:23:41)

@dearieme, I have a friend who is so allergic to fish of any sort that she can't even eat something cooked in the same oil fish has been cooked in. She develops life-threatening internal hives (possibility of blocked airway, intestines, etc.).

dearieme (2013-12-29 17:21:54)

Dear heavens, Elizabeth: the poor soul. I watched the family member who can't eat lobster discovering the problem. I thought she was going to die; very frightening indeed.

Jazi Zilber (2013-12-31 03:28:01)

This raw cacao powder we know little about. S few people use it! It sounds better. But I would be careful with large amounts. As it is not so throughoutly used and tested

Alex Schell (2013-12-31 23:05:49)

Re: seafood vs. flaxseed, there is a third option for omega-3. It turns out that hens fed a high-flaxseed diet lay eggs with much higher amounts of EPA and DHA. Given the importance of omega-3 for brain development, it makes sense that the yolk should accumulate a disproportionate amount of the converted long-chain omega-3s. (The brand I'm familiar with, "Christopher Eggs" from Kroger/Private Selection, have 660 mg omega-3 per egg.)

## **Missing Data in Clinical Trials: FDA Officials Refuse to Set Limits (2013-12-29 05:00)**

People who believe in "evidence-based medicine" say that double-blind clinical trials are the best form of evidence. Generally this is said by people who know very little about double-blind clinical trials. One reason they are not always the best form of evidence is that data may be missing. Nowadays [1]more data is missing than in the past:

By [missing data] he [Thomas Marciniak] means participants who withdrew their consent to continue participating in the trial or went "missing" from the dataset and were not followed up to see what happened

to them. Marciniak says that this has been getting worse in his 13 years as an FDA drug reviewer and is something that he has repeatedly clashed with his bosses about.

"They [his bosses] appear to believe that they can ignore missing and bad data, not mention them in the labels, and interpret the results just as if there was no missing or bad data," he says, adding: "I have repeatedly asked them how much missing or bad data would lead them to distrust the results and they have consistently refused to answer that question."

In one FDA presentation, he charted an increase in missing data in trials set up to measure cardiovascular outcomes.

"I actually plotted out what the missing data rates were in the various trials from 2001 on," he adds. "It's virtually an exponential curve."

Another sort of missing data involves what is measured. In one study of whether a certain drug (losartan) increased cancer, [2]lung cancer wasn't counted as cancer. In [3]another case, involving Avandia, a diabetes drug, "serious heart problems . . . were not counted in the study's tally of adverse events."

[4]Here is a presentation by Marciniak. At one point, he asks the audience, Why should you believe me rather than the drug company (GSK)? His answer: "Neither my job nor (for me) \$100,000,000's are riding on the results." It's horrible, but true: Our health care system is almost entirely run by people who make more money (or make the same amount of money for less work) if they exaggerate its value – if they ignore missing data and bad side effects, for example. Why the rest of us put up with this in the face of overwhelming evidence of exaggeration (for example, [5]tonsillectomies) is an interesting question.

Thanks to Alex Chernavsky.

gwern (2013-12-29 14:25:17)

How much missing data is there for home remedies circulated on blogs like this one? If 100 people decide to try out honey before bedtime, what percent will report back and be included in a post? Does the answer look closer to '0 or 1 %' or '99 or 100 %'?

dearieme (2013-12-29 14:31:05)

I became a great cynic about modern medicine when I read about the statin trials when 15 % (if my imperfect memory serves) of the treated group gave up in the first couple of weeks, and were thereafter just quietly expunged from the stats. Presumably - but we'll never know - they gave up because they already were suffering from adverse side-effects. That meant that all predictions of the proportion of the population who would so suffer were effectively lies. It also meant that the most interesting proportion of the subjects of the experiment were deleted. After all, those who gain by statins - insofar as they exist - are just statistical facts, but people who suffer are actual, identifiable humans, to whom one could apply, if I dare use

the word, science.

### Sleep and Bedtime Honey: More About Strength Improvement (2013-12-30 05:00)

In [1]my first post about the use of [2]bedtime honey to improve sleep, I included a graph that showed my legs suddenly got much stronger when I started the honey. I measured how long I could stand on one leg (bent). I had been doing this four times per day (left leg twice, right leg twice) for a long time [3]to sleep better.

A reader of this blog named Nile McAdams found [4]bedtime honey caused him to get stronger, too. He measured arm strength.

Soon after my legs got much stronger I reduced my one-leg standing from four/day to two/day to save time. The improvement stopped, but the gains persisted:

[5]

Note the logarithmic y axis. Each point is a different day, an average of the first left leg stand and the first right leg stand of that day.

The graph shows I am much stronger with half as much effort. As I said, the strength improvement has also been easy to notice in everyday activities, including walking, stair climbing (I live on the top floor of a six-floor walkup) and bike riding.

I have been unable to find research that shows a similar effect. Judging by [6]a 2010 textbook, exercise physiologists don't know about it.

---

Adam Long (2013-12-30 09:03:28)

Seth, this reminds me of a technique called "carbo backloading". The basic idea is that you can gain muscle by (1) exercising later in the day (e.g. after 3 pm) and (2) eating simple carbohydrates (e.g. honey, but I don't remember anyone discussing honey specifically with regard to the procedure) during the 3 hour window after exercising. Not sure if these are related (and I guess there is considerable debate about whether carbo backloading works) but I wonder if there might be a connection to your findings re: honey and strength gains.

Phil (2013-12-30 15:51:07)

Interestingly, I have a weight lifting book from the mid-1980's that claims to be based on Bulgarian olympic lifter training. They recommend consuming a teaspoon of honey about 10 minutes before each exercise session and a protein source between 30-180 minutes afterward.

Jerry (2013-12-30 19:58:55)

This makes sense: the honey is causing either an insulin spike or a rise in basal insulin. In either case, your insulin is rising. Insulin, aside from being a storage hormone (i.e. causes sugar to be stored as fat) also causes muscle growth. The previous two posts make sense in this light. Bodybuilders often take carbs immediately before and/or after a workout for this reason, before or after depending on their philosophy—turns out that an insulin spike will stop HGH secretion after a workout, so this is a potential problem.

Alex (2013-12-31 20:18:34)

Seth, has your weight gone up since you started taking honey at bedtime? Seth: No, it hasn't.

## **The Year in Personal Science: 2013 (2013-12-31 05:00)**

Here are some especially notable results (most notable first).

### **Other People's**

1. [1]Bedtime honey greatly improved sleep. Stuart King found this after many other things had failed to help him. He got the idea from [2]Dave Asprey, who got it from [3]The Honey Revolution (2009) by Ron Kessenden and Mike McInnes, but Stuart made by far the best case that the effect was important and determined some boundary conditions (e.g., don't eat a lot of sugar during the day). The improvement is so big and easy (honey tastes good) that it's quite possible this is why evolution shaped us to enjoy sweets after dinner – to improve sleep. In the future, I believe, it will be understood that sugars (at the right times in the right amounts) are a necessary nutrient – exactly the opposite of what all nutrition experts, [4]including paleo ones and Weston Price, say. When this stunning reversal will happen I don't know – but no one will have foretold it more than Stuart.

2. [5]Avoidance of glutamate cured autism. "Cure" is not too strong. [6]Katherine Reid, who has a Ph.D. in protein chemistry, realized that many many foods, including ultrapasteurized milk, contain glutamate. When all glutamate was removed from her daughter's diet, her daughter, who had been autistic, became completely normal. The generality of this solution is unclear but to cure even one case of autism is more than anyone else has done.

3. [7]Xylitol eliminated lichen planus. Evelyn M. found that if she swished xylitol around in her mouth several times/day, her lichen planus and overall gum health greatly improved. This effect is well-known in Scandinavia but barely known elsewhere. American dentists don't know it, for example. I didn't know it.

4. [8]Caffeine reduced reaction time. Alex Chernavsky wrote his own version of my brain tracking reaction-time test and found, in a well-designed experiment, that caffeine made him faster, at least for a few hours. What's important here is the method, not the result: Alex's success with a test that costs nothing and takes only a few minutes/day. His success brings closer the day that many people can do these tests. When non-experts realize they can study their own health in good experiments, the world will change.

Mine

1. [9]Bedtime honey greatly increased my strength. (More [10]here .) This convinced me that bedtime honey was something special, more than another way to improve sleep. (I also improved my sleep by [11]darkening my bedroom – much less important.) Bedtime honey also seemed to [12]improve mood and motivation. I have been trying to improve my sleep my whole adult life – this, I now see, is the secret. My discovery in the 1990s that [13]lots of standing improves my sleep led to the daily one-legged standing that made the strength increase so clear.

2. [14]A banana a few hours before bedtime (in addition to bedtime honey) improved my sleep even more. The Honey Prescription says it's been known for thousands of years that bedtime honey improves sleep, but no one seems to have noticed this, in spite of the importance of sleep. As Robb Wolf has said, "If someone sleeps well, you can't kill them. If they sleep badly, you can't keep them alive."

3. [15]Tofu made me stupid. One 20 g piece of fermented tofu slowed me down for two days on a reaction-time test. Other evidence has suggested that tofu is bad for the brain, but I find this the most persuasive. In addition to what it says about tofu, it suggests the power of brain tracking to reveal important things few people know. (An earlier example involved [16]butter.) Billions of people eat tofu often.

4. [17]Percentile feedback helped me work. The version of percentile feedback I use now (an R program that tracks my work and compares how well I am doing today to the last 100 days) is an improvement, I like to think, over an earlier version. The biggest difference is the addition of weighting: doing a hard task for one hour counts more than doing an easy task for an hour (e.g., a factor of 1.5, so that 60 minutes counts as 90 minutes). I kept track of how much I worked for a whole year, the first time I've managed to do that. Here's what happened.

[18]

I think the lesson is that with the right push, I can slowly improve.

Xav (2013-12-31 05:53:01)

Another upvote for xylitol from me. It tastes good in green tea (I use 8 - 12g per cup), and, along with your recommendation of having a couple of tablespoons of flaxseed oil daily (although not at the same time as the tea) , makes a huge improvement in how healthy and pain-free my teeth and gums feel.

Alex Chernavsky (2013-12-31 06:20:13)

Consuming even small amounts of xylitol gives me diarrhea. But I add xylitol to my mouthwash. On another subject: Seth, what happened to your productivity around August or September? Seems like there was a sharp drop, and your recovery took four months or so.

Daniel (2013-12-31 07:36:27)

Hello. I am interested in the honey experiment. I Live in south america and here we ate more late at night I think, like at 21 or 22 hs I understand that in the US you eat earlier. At what time is your lat meal? I ask becaius e I think this can affect what taking honey can produce. Is the script from both available? Do you think <http://www.cambridgebrainsciences.com/> can be a good tool to use as a test? Thanks Seth: I eat dinner around 6 pm. Eat banana around 7-8 pm, have honey close to bedtime (around 10 pm). If you are interested in my brain test software, please email me. I think the cambridge brain sciences stuff takes too long and, based on my experience, the tests are poorly chosen. But I haven't tried it.

Jason H (2013-12-31 07:36:42)

I've been self experimenting with a coconut oil mouth wash in the morning. It's typically 10 to 15 minutes and it has resulted in healthier gums, less sensitivity to cold and a small improvement in whiteness. Also this past year I started playing around with raw apple cider vinegar before bed. I usually have major sinus issues in the winter, which leads to having a humidifier constantly running along with nasal rinses and vaporub. So far the ACV has been a huge success. 0 congestion, 0 nasal rinses, 0 vaporub applications but a couple of humidifier sleep sessions. In addition to using honey at bedtime I've also toyed with blocking out blue light by wearing orange glasses and being made fun of by my wife. I'm not sure if this has been a success. I need to separate it out from the honey and see what happens. I am confident that the belittling will continue.

dearieme (2013-12-31 07:54:31)

Months have rolled by, and still nobody has recited I eat my peas with honey I've done it all my life It makes the peas taste funny But it keeps them on my knife. Happy New Year.

Charlie Currie (2013-12-31 09:27:49)

Oh dearieme that is funny... Seth, I think you're a little harsh on the LC / Paleo people about sugar/honey, or at lease a little overly general. I believe the majority today would say the dose makes the poison. Seth: As Gina says, many paleo people use the term "safe starch". Meaning that sugar is not a safe starch. The "safe starch" view opposes the idea that all starches are bad. Not one person has said that sugar is not the problem, which is exactly what I said in The Shangri-La Diet. All this stuff about how honey improves sleep (no doubt because of its sugar content) is more evidence that sugar is not the problem. Maybe they would say "the dose makes the poison" but that would be further misunderstanding. It's the time of day that makes the poison. I haven't heard anyone in the paleo community say that, with the notable exception of Tara Grant, who figured out that the time of day she took her Vitamin D made an enormous difference.

Gina (2013-12-31 10:32:43)

Charlie Currie: The "Safe Starch" debate (moderated by Jimmy Moore!) comes to mind. Starches are controversial and sugar is the devil. But that was 2012. Maybe attitudes have changed since I quit paying attention. It's weird that "Ancestral Health" changes so much.

Sentinel (2013-12-31 11:57:23)

Happy New Year to Seth and all the self-experimenters out there!

Seth Roberts (2013-12-31 13:58:08)

I was travelling August and September. Long trip from Berkeley to Beijing.

Tom (2013-12-31 14:45:48)

By the way, in scandinavia there are several brands of tooth paste and chewing gum with xylitol. I believe I first saw it marketed by a Finnish company. Not sure whether they take international orders or not, but here's a search at the state pharmacist's in Sweden: <http://www.apoteket.se/privatpersoner/commmon/search.aspx?q=xylitol&t=1> Happy new year!

emini\_guy (2013-12-31 16:18:51)

Chewing gum with with xylitol can be purchased in the US too. Just use Amazon.com - [http://www.amazon.com/Epic-Dental-Xylitol-Sweetened-Cinnamon/dp/B005YXU3ZA/ref=pd\\_sim\\_hpc\\_4](http://www.amazon.com/Epic-Dental-Xylitol-Sweetened-Cinnamon/dp/B005YXU3ZA/ref=pd_sim_hpc_4) There may be other places online to get it, I just happen to patronize Amazon.com.

Bill Lagakos (2013-12-31 17:14:21)

I've miraculously avoided cavities for all of my 34 years, but my dentist still complains; tells me to floss more... perhaps I'll try swishing some xylitol for a single-blind study (I won't tell my dentist about it). Seth: Floss more, why? Because of pockets? My pockets greatly improved exactly when I started drinking flaxseed oil. My plaque did not improve. Plaque: xylitol. Pockets: flaxseed oil or other omega-3 source.

Xav (2014-01-01 04:50:56)

On the topic of sugars and sleep, I've recently started an experiment with taking D-Mannose to see if it has any impact on night time urination. I often get up once in the night for this, so I'm in the process of looking for ways to stop it. I wonder if anyone else has had any experiences with using d-mannose ?

Jeff (2014-01-01 09:20:51)

Seth - Just curious if you've tried honey instead of a banana yet for your other source of sugar 2 - 3 hours before bedtime? If so, have you noticed any difference in your sleep rating? OT, what source of faces are you currently using for morning faces? TIA Seth: No, for the sugar 2-3 hrs before bedtime I've just eaten a banana. For faces nowadays I use about 6 bloggingheads shows with relatively large faces. I put them on a large monitor.

Paul (2014-01-01 13:58:24)

Xylitol, is it safe? [http://www.naturalnews.com/022986\\_xylitol\\_health\\_sugar.html](http://www.naturalnews.com/022986_xylitol_health_sugar.html)

daz (2014-01-01 23:10:33)

"Pockets: flaxseed oil or other omega-3 source" it would not surprise me if there is something 'special' about flaxseed itself that improves gum health, & omega-3 may Or may not be a part of that. i cannot recall seeing/reading any studies or anecdotes that reported improvements in gum health from just taking omega-3 ie. fish oils or fish supplements...?

Ozquoll (2014-01-02 01:29:14)

Sadly the honey at bedtime approach did not work for me at all - I gave it up after three nights of very poor sleep, punctuated by vivid nightmares when I actually was asleep. However, I have had greatly improved sleep ( & blood glucose control) from taking resistant starch as discussed at length on Richard Nikoley's blog. There is at least one American dentist who knows about Xylitol - Ellie Phillips. She's got a book, but the following page on he website gives a pretty good rundown of her thoughts on dental care: <http://www.drellie.com/Ellie-Phillips-My-Recommendations.php> Seth: You might want to try a smaller dose of honey and/or banana. Too much will certainly produce bad sleep.

Jeff (2014-01-02 05:31:26)

Seth - If you're still doing alternate day fasting, it seems like your calories on fasting days much be climbing with all the food that you need to eat for your health (e.g., butter, flax, banana, honey, etc.). I believe you'd said in the past you consume 700 - 800 calories on fasting days. Adding a banana and 1 TBS of honey adds around 160 - 180 calories. How is that impacting your

fasting blood sugar readings and other health measures? Thanks for patiently answering all my questions. Your writing has dramatically improved my health in a number of ways. Seth: The banana and 1 T honey seem to have improved my fasting blood sugar readings but it is a complex question because obviously blood sugar will be elevated for hours after eating honey. So I am not sure. I am sure however that the better sleep has improved my health. It is obvious: feel better, stronger, more energy, more motivation.

Stuart King (2014-01-02 15:15:21)

Ozquoll, try taking the honey on its own without adding another food (resistant starch) simultaneously as I've found that certain foods can hinder the effect of honey. Also try switching to a different honey and have a break from eating between your last meal/desert and taking the honey (maybe 2 hours or more).

Sidney Phillips (2014-01-09 00:09:13)

Here is another experimental study of some merit that can easily be replicated. Researchers have found that drinking mineral water rich in silica can remove aluminum from the body and in some cases, actually reverse symptoms of Alzheimer's disease. The waters richest in silica are the Volvic and Fiji brands: <http://www.ncbi.nlm.nih.gov/pubmed/22976072> Seth: Fascinating.

Re: Haller So, we have State employees filing a complaint with State employees regarding the unfair behavior of State employees.

Joseph Moroco (2014-01-01 08:07:29)

It was not a routine tonsilectomy, but a Uvulopalatopharyngoplasty. Is there an ambulance being chased. Seth: This article says it was a tonsillectomy: [http://www.huffingtonpost.com/2013/12/21/jahi-mcmath-life-support\\_n\\_4485119.html](http://www.huffingtonpost.com/2013/12/21/jahi-mcmath-life-support_n_4485119.html) Massive bleeding is a common side effect of tonsillectomy. Are you saying that this particular version of a tonsillectomy is much riskier than other versions? If so where does that information come from? My general point about tonsillectomies is that patients are not told the true risk. You disagree?

dearieme (2014-01-01 08:55:48)

re Peter Higgs: whenever the future of the universities is under discussion and I intone "Dissolution of the Monasteries", I admit that I wonder whether the dissolution is already well advanced.

jon (2014-01-01 11:20:21)

My niece just had her tonsils removed. I sent a link from what you (Seth) posted some time ago. But my sister went ahead with the surgery partly because her daughter kept getting infections and started having trouble breathing. Now my sister is thinking of having all her children's tonsils removed after the "successful" removal of her daughter's tonsils. My sister's family have a very poor diet (although it has gotten a little better) in my opinion. Lot's of processed foods and sugary foods. They have stopped eating quite so much processed foods and have stopped eating cereal but the poor health continues. I guess they still haven't removed enough bad foods. My stepfather recently died after he had another heart attack (4th or 5th?) at the age of 65. He was diagnosed with diabetes sometime ago (15 or 20 years ago). But couldn't muster up the will power to sustain a healthy diet. Apparently a nurse told him 2 weeks before he died that if he didn't change his diet he would be dead within 5 years guaranteed. After having multiple heart/artiary surgeries he started have trouble breathing from the last one. He couldn't even get to the mailbox without breathing heavy. He wanted to live longer but couldn't muster the willpower I guess. It is pretty sad. He basically poisoned himself over his whole life and probably cut 20 years off his life if not more. I think these examples from my family definitely make me want to stick to a healthy and clean lifestyle. I find it interesting when people say, "I want to live a good life, I want my sugar!" It seems like a very selfish thing to say as if other people around them don't care about their life. It is not just their life that they are ruining, it is also affecting those around them. After my stepfather got diabetes he was much more moody and harder to get along with, that's 20 years of being around someone with mood swings that could have been avoided.

jo (2014-01-01 15:20:01)

"tonsil removal is associated with a 50 % higher death rate" What does this mean? Seth: That's what a survey found. The researchers compared people who had had tonsillectomies with similar people who hadn't. I link to the study in my article about tonsillectomies.

Nancy Lebovitz (2014-01-01 21:32:28)

Could you post a link to the previous tonsillectomies post? A fast googling didn't turn it up. I wonder if there's a general problem that the risks of all operations are underestimated.

Joseph Moroco (2014-01-02 06:38:32)

That patients are not told the risks is true. I do not disagree that the simple tonsillectomy is overdone, but one heck of a lot of people survive it, as did my dad who died not of complications from the operation as a kid, but simply from being old at 93. Huffington post is not necessarily wrong, but also does not possess papal level infallability. <http://overlawyered.com/2013/12/jahimcm-aths-routine-tonsillectomy/> Seth: Thanks for the source. Yeah, almost everyone survives it, I suppose no one notices that their immune system is not working so well because the tonsillectomy is given to people whose immune function is already bad (e.g., due to poor sleep). I was really surprised when I started sleeping better and stopped getting sick in the usual ways, nobody had ever said that was possible.

Joseph Moroco (2014-01-02 16:34:25)

I have sleep issues and really started reading you more faithfully when you wrote that line about getting enough sleep and you can't be killed, don't and you can't be kept alive. It's been a help. Thanks.

Seth Roberts (2014-01-03 05:33:33)

Joseph: Robb Wolf said that. I asked him who he was quoting and he said it was his own idea.

Sara (2014-01-05 01:39:36)

## Interview with Mike McInnes, Author of The Honey Diet (2014-01-02 05:00)

Mike McInnes is a retired Scottish pharmacist and the author of [1]The Honey Diet, published today. This book interests me because it advocates [2]eating honey at bedtime.

Could you summarize the book?

It's based on two ideas – that modern obesity is driven by two main factors. First, overconsumption of carbohydrates and sugars. Second, poor quality sleep. The medical profession has been saying that the cause of obesity is fat. We've known since the 19th century that it is carbohydrates, not fat. Poor quality sleep drives up stress hormones and appetite hormones.

In the West we have an early evening meal. We go to bed with a depleted liver. There is not enough fuel in the liver to supply the brain overnight. The way to resolve that is to forward-provision the brain, via the liver. The best food for that is honey. Honey is liver-specific. It is metabolized differently from other sugars. Honey restocks the liver prior to sleep. No other food can do this in the same way that honey can do this. Fruits are unlike honey because honey contains an army of nutrients, bioflavonoids, organic acids and others that ensure honey is not metabolized in the same way as refined sugars, which have none of these nutrients. Indeed it is fair to describe honey as the most potent anti-diabetic food known to man.

What's the background, the history, of these ideas?

I'm a pharmacist. Sold my pharmacy. Went into sport nutrition in the late 1990s. I rapidly discovered that athletes have no concept of brain metabolism or liver store during exercise and recovery. The most critical organ of sport is the liver. I looked for a food that would provide sufficient liver supply during exercise and during recovery. When an athlete collapses, it's not enough fuel left in the liver. Same at night, you go to sleep without sufficient fuel in the liver, after an early evening meal – and then you cannot recover physiologically – the brain is forced to activate stress and this in turn upgrades the orexigenic (appetite) hormones.

I knew from my physiological background that fructose was a key sugar to replenish the liver, fructose is liver specific - it only goes to the liver, where it is converted to glucose and stored as liver glycogen. It also brings glucose into the liver – it liberates the glucose enzyme – glucokinase and optimizes the liver (cerebral) energy reserve. Fructose is critical to replenishing the liver. At the time the usual line was the fructose goes only to muscle, and therefore had no role to play in exercise and fueling in sport.

Birmingham University did studies on fructose with success. Now every sports drink in the world contains fructose. They missed the nocturnal physiology. You have to replenish your liver before sleep. If you have a six or seven o'clock meal, you don't have enough in the liver to see the brain through the nocturnal fast. Having discovered that honey was the key fuel to refuel the liver before sleep, I then developed the theory of replenishing the liver before sleep. Honey is the gold standard food for doing that – no other food that I know of can do this as can honey, and without digestive burden.

Have you tested other foods?

You will find thousands of studies on the Mediterranean Diet. I only know of one scientist who has written about the key question of timing. With this diet you have healthy meal that contains fruits and vegetables at 11 pm. The key principle is the timing. That would allow significant liver replenishment of the liver via the fruits and vegetables. That meant the brain had a good liver supply for sleep. The brain could activate the recovery system via the pituitary gland. That meant you were reducing the risk of all the degenerative diseases – diabetes, dementia, obesity and heart disease.

They've now stopped that. They now do as we do in Europe and America, they have an early evening meal. The fastest growing rate of these diseases is in the southern Mediterranean.

I just looked at the nutrient content of other foods.

I wrote a book in 1995 based on utilizing honey at night. We got feedback from all around the world. What the effect of the honey was on nocturnal physiology. It's not difficult to work out what's going on, it's quite simple. The response from readers was that honey at bedtime, in addition to better sleep, produced changes like "fitter/stronger/healthier/improved mental acuity/less nausea and morning sickness" – all of which can be attributed to reduced adrenaline/cortisol and glucagon, to nocturnal energy homeostasis, and improved anabolic profile.

For decades, people have said sleep is a low energy system. That's wrong. Sleep is a high-energy system. Is the brain optimally fueled from the liver in advance of sleep? That's the critical question. The brain has about 30 seconds worth of glucose. About 5 grams in the blood. The blood glucose would last 5 minutes. The only store that matters to the brain is how much reserve fuel is in the liver. Your liver has about 65-75 g of glucose in capacity. It releases 10 g every hour into the circulation – around 6-6 and a half grams to the brain. Do the math, you see the brain is in trouble at any time in the 24 hour cycle if the liver reserve is low – especially in advance of the night fast. The brain cannot use fats for that purpose. The body cannot convert fat to glucose. Never. What it can do is during starvation it can convert fat to ketones and use the ketones for energy. But you have to be starving for that to happen. The brain must be fully provisioned prior to sleep. The gold standard food for that is honey.

What about eating a banana or apple in place of honey?

A tablespoon of honey is equivalent to a small or medium apple. However the apple doesn't have the huge number of nutrients that affect honey's ability to metabolize optimally in the liver and to stabilize blood glucose concentration. Honey has 200 non-nutrients that make a difference. If you took fruit at night, you would get significant liver replenishment but not as much as honey.

Of course a perfectly good case may be made for fruits and indeed vegetables before sleep since they both have an approx. 1:1 ratio of fructose to glucose, as does honey. However there are many additional nutrients in honey that improve insulin signalling, and partition and disposal of the sugars that are not in these foods – hence honey is a potent anti-diabetic food – it improves the action of two of our most widely used anti-diabetic medications – metformin and glibenclamide – I am not aware of any other sugar or sugar containing food that can do that. In the fullness of time we may find other foods/fuels that are as good as, or better than, honey, but the present knowledge is that honey is the Gold Standard. Nothing wrong with some added fiber – but not required at night, and adds digestive burden.

When is the best time to take the honey?

The honey should be taken as close to bedtime as possible.

Why that timing?

You have to do the mathematics of liver capacity and liver release. We've done several local studies on it. One German scientist is interested in this – Christian Benedict at Lubeck University. I wrote an earlier book on this subject that got a huge amount of responses from around the world. People saying how it transformed their sleep patterns. We found there was a significant improvement. It's not a complicated issue.

Why call it a diet?

The only time you burn body fat exclusively is when you are sleeping. During exercise you burn both glucose and fat. You also burn muscle fat. Let's take a 90-minute moderate intensity work out. A BBC study was done. The subject burned 19 g of fat. Overnight when the physiologist measured it he had burned 49 g of fat. What he did not understand during the exercise that although the total fat was 19 g, half of that was body fat, half was muscle fat. His attempt to explain why he burned more fat overnight was nonsense. The reason is very simple. Recovery physiology is highly expensive and exclusively uses body fat as the fuel from the circulation. If you burn 19 g during the workout then the half which is the body fat portion is 9.5 g. Now you can understand the relationship between exercise physiology and nocturnal physiology with respect to body fat used - it was 5 times as much during the night as during the workout. The key to recovery physiology is how much fuel is in liver. The study that reached that conclusion was done in 1950 and was and is ignored by the scientific establishment. It was a study on mitosis in mice. It traced the mitosis (cell division), an index to recovery. The main point was the recovery depends on the level of glycogen in the liver. This study also noted that recovery utilizes fat - again missed by the scientific establishment to this day.

Most of the stuff that I do is already there in the literature, you just need to know where to look. There's only one scientist that I know of who has developed the same idea about sleep. Christian Benedict at Lubeck in northern Germany. The brain's stress system is activated during the night because of the brain's requirement for fuel. He looked at nocturnal physiology. He looked at the stress system overnight. He didn't measure the effect of honey. It's likely that once the book is published, there's an important group at Lubeck called the Selfish Brain Group who are interested in the relation between cerebral energy deprivation and obesity. They are focusing on the concept that obesity is driven by chronic cerebral glucose deprivation. Basically the same as my theory. Some differences.

The foods we eat overload the circulation with energy. It means that if the glucose in that system went into the brain the brain would fry to death. The cerebral glucose pump, which is called the iPump, is suppressed. This is my theory. Consequently the glucose that you are consuming when you eat a high carb meal does not transfer into the brain. That means the brain is now deprived of energy so you are forced to go back and eat more and you repeat the cycle.

The time we burn body fat is when we are sleeping. For that to happen you have to activate the recovery system. For that to happen the brain has to have reserve fuel in the liver. If the brain does not have enough fuel in the liver it cannot activate recovery, it has to activate stress. The highest consumption of energy during the night is REM sleep and that's when you learn. There's another fundamental question that we need to address. The scientific and health professions will tell you if you are diabetic, you increase your risk of dementia dramatically. They've got that completely the wrong way around because suppressing the cerebral glucose pump is incipient dementia. It means that your brain is already deprived of energy - it's already starving. The first thing that happens is we overload the systemic system with glucose. The second is that we overproduce insulin. Both hyperglycemia and hyperinsulin suppress the cerebellar glucose pump (iPump). That is incipient dementia. Then the excess glucose in the circulation is converted to fat via insulin. Now you're becoming obese. Eventually your ability to keep your glucose stable by storing it as fat breaks down - you become insulin resistant - and then you become diabetic. The first system of energy impairment is in the brain. Then in the body - the sequence is first incipient dementia and chronic cerebral glucose deprivation (hunger) - then the excess circulating energy is converted to fat - then this protective mechanism breaks down - you become insulin resistant - that is diabetic.

I'm a retired pharmacist. I don't have access to university science and study facilities. I just use the existing literature - however this is changing and a number of academics are now interested. There's nothing that I've said that is not based on the literature.

If people take honey at bedtime they will lose weight?

This has been confirmed over and over again. Anecdotally, of course. Talking to athletes. Hundreds of peo-

ple. After the first book, we got feedback from all around the world. Small to massive weight loss. Many people lost several stone. The new book has more science and is based on new science as well that is emerging almost daily. They're realizing that Alzheimer's and diabetes are basically the same disease. They still think that diabetes causes Alzheimer's, whereas it's the other way around. Chronic cerebellar glucose deprivation – that is incipient dementia causes obesity and diabetes. Any high energy system which is overloaded will short circuit. That's what sugars are doing to the brain. The mechanism is very simple, sugars and insulin short-circuit the brain by suppressing the cerebral glucose pump – the iPump. If your blood sugar is too high it reduces the blood sugar/energy in the brain. That means if you have a high carb meal, less glucose enters the brain. Within 15 minutes, you're hungry again. This is why carbohydrates make you hungry sooner. The explanation is stunningly simple.

You see people on TV who are gigantic. That's the reason. These people are suffering from chronic cerebral hunger. The more they eat, the worse it gets.

I lost weight when I drank sugar water. Can you explain that?

I saw that. The fructose would replenish the liver. If the liver is replenished, the brain thinks that's fine. There's research by a guy named Maricio Russeck in Mexico. He discovered glucose receptors in the liver. He advocated the notion, which was correct, that the liver is critical in appetite control. That's now being confirmed by recent science.

How is *The Honey Diet* different from the earlier book?

That book was based on restocking the liver before sleep. There's much more science in this book. The scientific world has moved on in two ways. It's now looking at honey in a serious way. Also, the question of low carbohydrate versus low fat diets is now becoming a major issue.

How would you sum this up?

The critical measure for the brain in all feeding and appetite regulation is based not on what's in the blood but what's in the liver. Russeck was spot on, 5 decades ahead of his time. These are absolutely critical questions. Let's focus on dementia. There's 35 million demented people in the world. That doubles every 20 years. One hundred years from now, one billion people are demented. The human brain is now shrinking, it's not growing. That's because one percent of those demented people is genetically driven. What is causing the other 99 % of dementia, which has happened in the last 40-50 years? The answer is sugar. Refined carbohydrates. Processed foods. Honey is metabolized differently than refined sugars.

If I drink fructose and glucose in water at bedtime, it would have a different effect?

Yes, because they don't contain the nutrients that are in honey that enable it to be metabolized differently. In America, high-fructose corn syrup (HFCS) drives obesity. It overloads the liver with fructose and it's then converted to fat.

HFCS at bedtime would have quite a different effect than honey?

Yes, for sure.

---

Xav (2014-01-02 05:59:28)

Thanks for this interview - very interesting. I recently bought Mikes original book "The Hibernation Diet", mainly for information on his experience with honey, and will be getting his new book as well, as I find it fascinating that such a simple and easy to implement dietary change can have such a positive impact. What is the optimum amount of honey that Mike currently recommends, and at what times of the day ? Secondly, I'm curious as to what the most important nutrients in honey are, which can make its action different from a mixture of fructose/glucose (plus smaller amounts of other sugars).

RAD (2014-01-02 07:55:17)

McInnes said "Your liver has about 65-75 g of glucose in capacity. It releases 10 g every hour into the circulation...". Does anyone have a definitive source for these two values/assumptions? I've seen liver glucose capacity stated as around 100g and also 200g.

Gina (2014-01-02 09:48:38)

Honey has mystery nutrients that make it metabolize differently from fruit or sugar? What are these nutrients and what is this difference? Sugar water replenishes the liver (good) but sugars short-circuit the brain and give you Alzheimer's? What?

Allan Folz (2014-01-02 10:39:17)

Gina wrote about what I was thinking. I realize he's not a researcher, but a little disappointing of an interview. He asserts honey is different from a glucose-fructose water solution, but it doesn't seem like he's even tried. It reads like a snake-oil sales pitch. That said, I have been trying it on my 10 y.o. son. He's always had a hard time with relaxation, falling asleep, and staying asleep. Last night was the third night in a row of about 1 TSP of honey before bed and ss I'm measuring it out he comments, "my ticket to 7:00." So that he doesn't disrupt everyone else in the house we have a rule he's not allowed to get out of bed and start playing until 7:00. Sometimes I'll hear him get up, go check the clock in the kitchen then go back to bed 3-4 times starting as early as 5:30 or 6:00. It's pretty boring for him to lay in bed for an hour not being able to do anything fun, so it didn't take long to figure out that the honey keeps him asleep until closer to 7:00 when he's allowed to get out of bed. :)

Evelyn M. (2014-01-02 11:37:41)

Many thanks for publishing this interesting interview and for all your work on sleep in general.

jeff davidson (2014-01-02 12:19:16)

<http://blog.cholesterol-and-health.com/2010/10/high-fructose-corn-syrup-is-sweet.html>

C.M. Mayo (2014-01-02 12:56:30)

Thanks for this facinating and inspiring post. As a budding apitherapist, may I suggest that raw, that is, unpasteurized honey would be best. Pasteurization destroys many of the enzymes in honey. Best is raw local honey which one can usually find at the local health food store or farmers market. For my money most of what sells in large supermarkets, mixes of whatever cheap honey comes from China (and who knows what pesticides are in there) boiled beyond boiled, is not much better, if at all, from corn syrup. (Google and ye shall find plenty of toe-curling stories about mass merchandized supermarket honey.) There is more information about the nature and benefits of raw vs pasteurized honey on the various apiculture and apitherapy websites around the world. For those who want to learn more I warmly recommend the Charles Mraz apitherapy course offered annually by the American Apitherapy Association. And by the way I got a jar of honey from the co established by Charles Mraz himself in Vermont at Draeger's in Menlo Park just last week. Pretty good stuff!

Stuart King (2014-01-02 15:05:09)

I haven't read Mike's books unfortunately but I have been taking honey before bed on and off for a couple of years and I have done so everyday over the past few months with great success. I have found that heated honey works just as well as raw, if not better. I have confirmed this as I have been measuring my sleep over the past months and have had some of the best sleep in

my life using heated honey. I exclusively used raw for a long time but have been more successful with heated. This suggests to me that it's the fructose/glucose ratio that's more important rather than the other properties of honey. I also think honey is probably easily and rapidly digested - maybe quicker than fruit I don't know. Perhaps heated honey is easier on the digestion but again I don't know. I believe raw honey is a great product and probably superior in many ways for a lot of reasons, but not for sleep. Telling people they need to source raw honey to improve sleep is wrong - heated and even blended honeys work very, very well.

George (2014-01-02 15:06:55)

Anyone who at this late date can still say that carbohydrates is the cause of obesity (yep, it's why the Japanese are obese, and the French, with all their baguettes and croissants) does not deserve to be taken seriously and can comfortably be considered a quack. I like how he doesn't even express his opinion cautiously on this contentious and discredited theory but says strongly that we've "known since the 19th century". Not someone with good intellectual habits. It gets worse - the Japanese are infamous for being one of the most overworked and chronically stressed and under-sleeping - if not *the* most overworked and under-sleeping - nation out there, yet are perhaps the thinnest developed country. Yep obesity is caused by carbs and poor sleep and stress - now I know why the Japanese are obese! At what point do we stop taking seriously anyone who tries to explain obesity by only looking at America? It's don't even like they look at the whole West (France would immediately discredit the carb theory) for chrissake! It's just America. This habit of simply ignoring what's going on in the rest of the world and coming up with these absurd explanations for obesity in America that could have easily been disproven had anyone actually cared to take a single moment to look beyond America is so intellectually disreputable and yet so widespread and endemic to Americans writing on obesity and nutrition that the entire field seems intellectually frivolous and corrupted, at least as it is practiced in the US. It's not just this writer or that - it's intellectual standards across the board. Also the medical profession says the cause of obesity is excess calories not fat. No macronutrient is the cause of obesity and "we've known that" for quite some time now.

Stuart King (2014-01-02 15:38:02)

George, maybe an excess of any nutrient or too many calories is the problem. I think the current war on carbs and sugar/fructose will turn out to be almost as absurd as the war on saturated fat and people like Lustig or Taubes have hugely overestimated how much we need to cut down on sugars. The healthy amount of sugary foods people should eat is probably lower overall, but the ideal range (where there is no toxicity and where the most benefits are found - ie sleep) is certainly higher than what Lustig or Taubes propose. I do believe their research is important but this idea that a whole macronutrient needs to be removed is strange - even in the absence of carbs your body begins to convert protein into glucose, doesn't this tell us something! Seth: The idea that a whole macronutrient that tastes really good - that stands out for tasting really good - should be removed is even stranger.

Ben C (2014-01-02 17:16:14)

I have found similar results to Stuart King regarding Heated Honey v. Raw Honey. For me personally, Raw Honey causes strong brain fog - maybe a reaction to pollen? Heated honey works well for me - much superior to raw honey.

Kirk (2014-01-02 17:23:15)

MrHeisenbug argued that it was the fermentable fibers in honey which leads to better sleep, rather than the sugars. How would experiments be designed to isolate the source of improved sleep? Seth: Eat sugar without the fermentable fibers. Someone has done this and reported excellent sleep. If it is the fermentable fibers, we are left with the mystery of why we like sweets so much and why we eat dessert separately. If it is the sugar, not the fermentable fibers, we have an answer to those mysteries. But I am not certain which explanation (sugar or fermentable fiber) is right and look forward to more evidence.

Kwan (2014-01-02 18:41:31)

According to <http://www.prebiotin.com/fermentable-fiber/> that stuff is also in bananas (hmmmm) yams, onions, garlic, chicory root and Jerusalem artichokes. If you can figure out how much is in honey and then eat a different food with a comparable amount of fermentable fiber at bedtime I think that would be a good experiment. You may have to take into account the bioavailability of it in each food, but that's for someone else to figure out because I'm not that kind of scientist. I've tried honey

on several different occasions now and sometimes on back to back nights but it has ALWAYS kept me awake for 2-3 hours every time I've tried it. It's supposed to be local Great Lakes honey, but maybe I need to try a different type or possibly try it heated. Seth: You should try a smaller amount.

George (2014-01-02 19:03:48)

@Stuart, of course, the best course seems to eat a balanced diet - no excess in any one nutrient, but no deprivation either, like all traditional diets do. Rates of degenerative disease and cancer were extremely low in societies that followed this common sense prescription. I was reading an interesting article on the diet of mid-Victorians that illustrated this well. But the problem with American writing on nutrition is not that their conclusions are wrong but that the intellectual standards are so low. It's astounding that the carb theory of obesity can still be taken serious. Simply astounding. It's as if Japan and France simply did not exist (and a host of other countries). I just don't understand how an entire field can be permeated by such shoddy intellectual standards. The *very first* order of business for anyone trying to understand American obesity is to compare the American diet to those of countries with extremely low rates of overweight. Oh, I don't know, Japan comes to mind. American nutrition writers love nothing more than to compare American eating habits to some imagined Paleolithic diets that we perforce can know little of - but compare it to entire contemporary countries where can get precise, accurate, and comprehensive diet information? Nah, why bother doing that? We might actually get some insight into the problem. Worse, it might disprove our pet theory! It's absurd. It boggles the mind It drives one to despair. I'm not even talking about strict scientific rigor, which can be hard to achieve especially in this field, I'm talking about the most basic rules of good thinking - look for counterfactuals, see if your theory explains all cases, etc, etc. Nutrition writing in America might as well be sold under the novels section in bookstores the entire field functions as some kind of repository for myths, wish fulfillment, and projections for the Western psyche. And that's too bad, because it's so important,

Adam (2014-01-02 20:09:10)

George, it seems like you're doing the same thing you're criticizing. The Japanese have an average daily caloric intake of about 2,800, while people in the US have an average daily intake of about 3,800. Could 1000 calories per day have any bearing on rates of Obesity? Even just looking at Carbohydrates, the Japanese consume about 58 % of calories from Carbs, while people in the US consume about 49 %. It isn't exactly like people in the US are on a low Carb diet! It might also be fruitful to look at where those Carbs are coming from. The Japanese tend to eat more healthful sources of Carbs, like white rice, while people in the US tend to eat French fries, potato chips, cookies, etc.

George (2014-01-02 20:37:17)

Adam. Of course its the calories! That's my point. It's not carbs, its calories. So the Japanese and the Americans both eat high carb (with the Japanese a higher percentage)s. One country is thin and one is fat. Isn't the conclusion that carbs isn't the culprit? Isn't that what logic would dictate? We have one way in which Japan and America are similar and one way in which they are different - and we conclude the way they are similar is responsible for the difference in obesity rates?!?!?! (not you, but the low-carbers) Seth: Yes, that is a good example of mass delusion. It makes no sense, but there it is.

Audrey (2014-01-02 21:07:08)

It's not the calories. Calories are nonsensical in the context of a human diet. J. Stanton is doing a great series explaining why. It's already seven parts long, but here's the first one to start you off: <http://www.gnolls.org/3374/there-is-no-such-thing-as-a-calorie-to-your-body/>

Stuart King (2014-01-02 21:42:15)

I'm not too worried about the weight loss thing anymore - some say its the carbs, others the fats or food toxins, calories, gut bacteria, metabolism/body temperature, thyroid, incorrect eating schedules, omega 6 oils, fructose, wheat, lack of exercise, nutrient deficiencies, etc... What I do know to be true however, at least for me, is that improving my sleep by eating moderate amounts of sugary foods, some starches and honey before bed has made more of a difference to my health and how I feel than any diet plan, theory or strategy yet and this leads me to believe that sleeping well is more important than worrying about specifics regarding macronutrients or calories.

tom (2014-01-02 22:02:27)

Paul Jaminet recommends 15 - 25 g of fructose per day, 3 to 8 g per meal (no more than 10 g per meal). A little bit has some benefit in glycemic control he says. I guess in sugar grams it's double the amount.

Seth Roberts (2014-01-03 05:48:33)

"the best course seems to eat a balanced diet" No, I think the essence of this discussion of the effect of bedtime honey on sleep is that the "balanced diet" concept is misleading and incomplete. I cannot say why bedtime honey improves sleep nor induce the general rule. I am sure, however, that the timing of nutrients makes an enormous difference. For example, sugar at Time A: bad. Sugar at Time B: good, even great. The idea that time of day matters enormously is absent from the concept of "balanced diet", not to mention from every nutritional book and article I have read. I think it is fair to say balanced diet = flat earth.

George (2014-01-03 06:06:36)

Seth, that factors like meal time are also important and it's not just about a balanced diet can certainly be true but I don't think it undermines the basic point about eating all macronutrients and not demonizing any one of them, which I think you agree with. Of course we might be able to discover all sorts of tweaks - like honey at bedtime - but the basic point is that the movement in America to demonize a particular food group is silly.

Eric (2014-01-03 07:31:57)

It strikes me that "time of day" effects are going to be the biggest thing to come out of this blog because the potential implications for so many things are so large. Bedtime honey, morning Vitamin D, really only scratch the surface. Seth: Don't forget morning faces.

Robbo (2014-01-03 09:04:56)

George: What we have "known since the 19th century" is that, amongst people who are well overweight, a low-carb diet is very often a straightforward way to lose weight. Google "William Banting" and check the date. Of course this does not necessarily mean it was the carbs that made them gain the excess in the first place, or even the low-carb that made them lose it, rather than low gluten, or low fructose but in the absence of good scientific data, in Damon Runyon's words, that is the way to bet. @Seth I'm not sure there is a paradox between our being attracted to sweet things like honey and the possibility that eating a chronic excess (seems to) harm us. In a state of nature we never had the opportunity to eat excessive amounts of honey, so one should not expect us to have an evolved defence against the consequences of doing so. Could not sugar be a parallel with alcohol ? a little being good for us, while a lot is harmful, especially as a habit ?

gwern (2014-01-03 09:18:25)

What an interview... I like how he spends hundreds of words in response to the 'have you tested any other foods' question to finally say, 'no'. And some of this crap! > You have to do the mathematics of liver capacity and liver release. We've done several local studies on it. One German scientist is interested in this - Christian Benedict at Lubeck University. I wrote an earlier book on this subject that got a huge amount of responses from around the world. Hail King Publication & Selection bias! Who can see thy ways, who is meet to contend with thee? Of a truth I know that it is so: how can man be just with biases? If he be pleased to contend with them, he cannot answer them one of a thousand. They are mighty in strength: who hath hardened himself against them, and prospered?

Jim (2014-01-03 10:12:32)

George, I saw a paper I think somewhere on [www.high-fat-nutrition.blogspot.com](http://www.high-fat-nutrition.blogspot.com) showing that high levels of omega 6 fats can lead to storage of excess carbs as fat. If this was true, then no carbs, no fat storage OR no omega 6 no fat storage. So now the Japanese and Kitavans can be thin on high carbs, American's eating high levels of omega-6 fats can be fat on high carbs and cutting carbs in America leads to weight loss. My own experience was that cutting carbs was like throwing a switch, I lost 30lbs in 3 months and kept off for 3 years now. I eat a lot, 2500-3000kcal/day when I've tracked it. I don't know if that omega 6 paper is true but I think there is something more complicated going on than too many calories.

Usul (2014-01-03 11:10:05)

Which kind of honey should we eat? anything from the supermarket of specifically raw honey? I heard that processed honey no longer has any nutrients, just sugar and water.

Seth Roberts (2014-01-03 13:19:20)

"I don't think it undermines the basic point about eating all macronutrients and not demonizing any one of them, which I think you agree with. Of course we might be able to discover all sorts of tweaks – like honey at bedtime – but the basic point is that the movement in America to demonize a particular food group is silly." I would say it is wrong but I wouldn't use the word "silly", as if it were obviously wrong. I never agreed with the demonization of sugar, but that was because I didn't think the data supported it. It seemed to be driven as you say by the same forces that drive people to demonize other things and embrace other too-simple solutions. So "demonize" seems fair but "silly" does not. I wouldn't call bedtime honey a "tweak" – it is the whole thing, as far as I can tell. The whole reason we like sugar so much. Not a small change. People who demonized sugar ignored the problems of why we like sweet foods so much and why we separate them and eat them later (dessert). I wouldn't say that is silly, it was rather a case of ignoring inconvenient evidence. Evidence-based medicine (as practiced) does this to extremes – ignores almost all of the evidence. Unwise and reckless, yes, silly no. I think if something is common (as ignoring inconvenient evidence appears to be) I wouldn't call it silly.

Seth Roberts (2014-01-03 13:31:42)

"I'm not sure there is a paradox between our being attracted to sweet things like honey and the possibility that eating a chronic excess (seems to) harm us. In a state of nature we never had the opportunity to eat excessive amounts of honey, so one should not expect us to have an evolved defence against the consequences of doing so." To the extent I understand the anti-sugar position, I agree with what you say: That is exactly what anti-sugar advocates said to themselves. Here is what I say in response: Ignoring a problem – actually two problems – does not make them disappear. Problem 1: Everyone, or almost everyone, likes sweet things. A lot. Massive evidence showing this. Problem 2: Dessert is common, if not universal. I have yet to encounter a culture where sweet foods are eaten at the same time as non-sweet foods. This separation is exceedingly strange; it does not happen for any other way we categorize foods. For example, salty foods are not eaten separately. People who said sugar was bad for us ignored these two problems, in the sense that there was a massive amount of evidence obviously relevant to the effect of sugar (is it good or bad for us) that they could not explain. No amount of common-sense thinking makes the evidence go away.

Audrey (2014-01-03 13:49:54)

The "dessert last" phenomenon is indeed fascinating. I've never seen it discussed before. Presumably, in most of our history we would have turned in for the night shortly after dessert. But today, we have what we call dessert long before we go to sleep...yet the supermarkets are jammed at 11pm with people buying ice cream and cookies for their late-night snacks. As if it were some kind of compulsion.

Jim (2014-01-03 14:10:34)

Seth, In the interview there are two interesting ideas. The first is that low sugar at night releases cortisol, which then drives gluconeogenesis to raise blood sugar. I know that cortisol does this but I'm not sure that low blood sugar necessarily raise cortisol. Wikipedia says that low blood sugar raises glucagon, which in turn drives gluconeogenesis. So if cortisol is always raised as well this is interesting as being stressed while sleeping seems like a bad thing, but I don't know if this is true. Anybody? I have read and have some experience with what's called the reverse cortisol cycle. Ie people with a lot of stress go to bed with high cortisol levels, have a hard time falling asleep, then wake up groggy with low cortisol. The opposite is supposed to be healthy. Go to sleep quickly with low cortisol levels and wake up alert with a slightly elevated cortisol level. When I changed my diet and some other work related issues, I noticed at some point a big change from the reverse cortisol pattern to the "more normal" pattern and slept better. The second idea is that high blood glucose causes processes in the brain to limit or even over limit glucose to the brain which then causes cell death. I've read that high blood glucose causes the mitochondria in the brain to "fail" over time and cause cell death, sort of the opposite idea. The recent book "Grain Brain" makes this point as do others. I don't know if it's true, I'm not a biochemist, but there are many people that think that chronic high blood sugar causes mitochondria damage which in turn starts a cascade of health issues. In any event this second idea seems novel (googling a bit

doesn't turn up anything that I could find, anybody else find something?) and if true remarkable. Any thoughts on this? thanks

daz (2014-01-03 14:42:12)

"So now the Japanese and Kitavans can be thin on high carbs, American's eating high levels of omega-6 fats can be fat on high carbs..." this would seem to gel with the data on omega-6 consumption ( & production) in the US in recent history. lard, tallow, shortening, butter, etc either stable or trending down. & soy, canola, corn, margarine oil, etc trending up do a google image search for something like 'vegetable oil consumption' for some graphics

daz (2014-01-03 14:43:23)

"So now the Japanese and Kitavans can be thin on high carbs, American's eating high levels of omega-6 fats can be fat on high carbs..." this would seem to gel with the data on omega-6 consumption ( & production) in the US in recent history. lard, tallow, shortening, butter, etc either stable or trending down. & soy, canola, corn oil, margarine, etc trending up do a google image search for something like 'vegetable oil consumption' for some graphics

daz (2014-01-03 18:17:37)

"It's not the calories. Calories are nonsensical in the context of a human diet" yes & no. it is about energy. if you absorb more energy into the blood stream then you burn over a period of time, then weight will increase, that can be both fat & lean body mass. the problem with counting calories is that it does not reflect the actual energy that is passed in to the blood stream, which is an individual thing. way too many variables to try & work out how much real energy you will get from a particular 'calorie of any food' at one time...some things that will influence this are, gut flora, thyroid & anabolic hormones/metabolism, food type,...etc, etc Seth: I believe that it is about hunger, not energy or calories. Hunger determines how much you will eat.

daz (2014-01-03 23:56:38)

"I believe that it is about hunger"... I agree. my "it is about" comment was more to do with pointing out that calorie counting is as a very inaccurate science, if you could actually count the calories that are absorbed in to the blood (which would be highly individual), that would mean something (as a metric), but of course that is impossible. on the hunger topic, yes hunger will definitely be a big factor in the qty ( & type?) of food you stuff in your face

daz (2014-01-04 00:23:28)

by way of a bit of an example on the 'calorie counting' subject, here is an interesting study that attempted to compare the predicted calories of Almonds 'on the label (so to speak)' (predicted by the Atwater system [http://en.wikipedia.org/wiki/Atwater\\_system](http://en.wikipedia.org/wiki/Atwater_system)) and the 'actual/real' calories (averaged across 18 subjects). <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3396444/> "Design: Eighteen healthy adults consumed a controlled diet or an almond-containing diet for 18 d. Three treatments were administered to subjects in a crossover design, and diets contained 1 of 3 almond doses: 0, 42, or 84 g/d. During the final 9 d of the treatment period, volunteers collected all urine and feces, and samples of diets, feces, and urine were analyzed for macronutrient and energy contents. The metabolizable energy content of the almonds was determined. Results: The energy content of almonds in the human diet was found to be  $4.6 \pm 0.8$  kcal/g, which is equivalent to 129 kcal/28-g serving. This is significantly less than the energy density of 6.0–6.1 kcal/g as determined by the Atwater factors, which is equivalent to an energy content of 168–170 kcal/serving. The Atwater factors, when applied to almonds, resulted in a 32 % overestimation of their measured energy content." Seth: very interesting, I've always wondered about that – the size of the undercount.

George (2014-01-04 07:02:01)

@Daz - one of the things that allowed me to finally lose weight and keep it off for years is disregarding all the experts advice about how many calories I "should" be eating. I realized every time I hewed to the "correct" number of calorie I ended up being ravenous and crashed shortly after - sound familiar? It's pretty much every American's experience with trying to lose weight. Initial success following popular calorie recommendations followed by extreme hunger leading to crashing, leading to bizarre beliefs that it can't be about willpower but *must* be about type of food consumed. Eventually I traveled overseas, forgot about calories, observed what the skinny locals were doing and practiced portion control like them. And I listened to my hunger and never let myself get too hungry, like the locals. And the pounds melted off and stayed off. It seems clear

to me now that paradoxically it's the too restrictive calorie recommendations in America that are actually responsible for the inability of Americans to successfully lose weight. Losing weight isn't a science, it's an art, and the American approach, with its attempt to put everything into a mathematical formula and be precise, which doesn't pay attention to feelings of hunger, and which for some reason gets the calories very wrong, is disastrous and what's fueling our obesity epidemic. It's not that the scientific approach is wrong, it's just that we don't know enough yet about diet and nutrition to craft a reliable scientific approach, so in at this point our best bet is not to do 'pretend' science but to do what skinny countries do; exercise portion control, listen to your hunger but don't pig out, and follow traditional guidelines about how much it's 'normal' to eat.

Jonti (2014-01-04 12:11:33)

Thanks for this. Very useful. I plan to start taking it immediately. Can you please say how much honey? How many table spoons? And is there a difference between cooked and raw honey - which is better? Thanks once again. Seth: try 1 teaspoon to 1 tablespoon of honey. I use cooked honey, haven't tried raw. Some people find differences, sometimes cooked is better, sometimes raw is better. Search the comments for details.

Evelyn M. (2014-01-04 13:00:10)

Thank you, George! The more people concentrate on being "scientific" about their eating habits, the more complicated they make their lives and the less they listen to their own bodies - which, let's face it, are far smarter in knowing what is best for each individual than the medical/scientific research establishment. I would not be surprised if - when all is said and done - we learn that the best diet is the traditional diet from the area of the world from which our ancestors came. In other words, the traditional Chinese diet is best for people of Chinese extraction, the traditional Italian diet is best for people whose families came from that part of the world, etc. Such an approach toward diet takes into account both genetics and the natural environmental experiment in which people have evolved over thousands of years. Seth: I think experts are biased to tell us stuff that is wrong because if they tell us to do what we are already doing, they seem less valuable.

dearieme (2014-01-04 13:24:50)

Eating sweet and sour food together: marmalade at breakfast is a delicious sweet-and-sour food. It's unusual to eat it at any other time of day, though.

Nick (2014-01-04 19:33:50)

This comment section has taken a detour from honey to calories, macronutrients, and bodyweight regulation. Well since that happened I'll chime in and try to unite the two. Honey is fantastic for our gut microbes. Evidence is mounting that the microbiota orchestrates many facets of human health. For example, see this 2012 review of honey and the microbiome: <http://www.mdpi.com/1420-3049/17/1/248> Key quote: "oligosaccharides present in honey might contribute to the antidiabetic and other health-related beneficial effects of honey." It's so silly that people debate macronutrients, totally sidestepping the gut microbiome like we're sterile creatures.

Jay Augustyn (2014-01-05 06:33:40)

I've been paleo/primal(sic) since September 2010. My main reason for trying paleo/primal was constant joint pain mostly in my knees and morning brain fog. These issues cleared up within weeks of starting the new diet. However from April 2011 I started a semi-constant 3am wakeup, with sweating and heart palpitations. This has got steadily worse and recently it's got so much worse that I have been waking up with a severe headache and very bad morning brain fog. Typically I eat my last meal no later than 7pm and then eat again only the following day at around noon. I've never been big on eating in the morning or before 10am. Some days I have only one meal but most days two, rarely three. I've never been overweight, weight now at 49 what I did at 20, and have no other current issues barring the sleep issue. As I am completely averse to ever stepping foot into a doctors office I started to trawl through the internet for answers. It's taken me weeks to get to this blog and the honey solution after wading through site after site talking about diabetes. Given I have no issues during the day and never really feel as though I have to eat even if only doing one feed a day, I ignored much of the discussion on diabetes. In any case I have an almost zero sugar diet with very low carbs - typically no more than 50g a day. Having read through this interview I decided to give the honey solution a try as the nighttime liver glycogen issue resonated with me. So for the last two nights I have taken a

tablespoon of honey just before bedtime and have woken up at 6am with no sleep interruption, no headache and very little brain fog. I'll be convinced this has legs if I can go for a month with no more 3am wakeups and morning foginess. Great blog Seth! Seth: Thanks, that's very meaningful praise – that this blog provides better (not just different) advice than other blogs. I think the failure of paleo gurus to advise a diet that produces great sleep is their single biggest failing. Obviously such a diet is paleo, that is, eaten by our ancestors, because I'm sure our ancestors slept well. Please write again after a month, whatever the results. I hope you will buy McInnes's book, at least to thank him for the improvement.

Brian (2014-01-05 09:36:29)

Does it need to be raw honey or will normal honey work? How about combined with potato starch and kefir?

mikimoonmouse (2014-01-05 10:58:42)

In Germany exists a 'Betthupferl' which means literally 'bedjumper' it's a small sugary food taken just before jumping into the bed and to sleep well. Ray Peat says that bed time sugar reduces adrenaline and this improves sleep. He thinks that darkness is very stressful and antimetabolic and that is why we sleep. He says that total darkness would make good sleep less possible. Red & infrared light could improve sleep. <http://oneradionetwork.com/health/dr-ray-peat-ph-d-answering-a-plethora-of-questions-regarding-health-diet-and-nutrition-january-1-2014/> Seth: I disagree about darkness. I found that when I made my bedroom darker I slept better. Now my bedroom is extremely dark and I sleep great. I haven't tested red or infrared light.

as (2014-01-06 04:21:08)

Seth: *I disagree about darkness. I found that when I made my bedroom darker I slept better. Now my bedroom is extremely dark and I sleep great.* So the break of dawn or the sunrise doesn't wake you up in the morning? Do you wake up in a dark room?

Seth Roberts (2014-01-06 06:41:04)

right, I wake up in a very dark room.

TomGinTX (2014-01-07 19:56:35)

"I lost weight when I drank sugar water. Can you explain that? I saw that. The fructose would replenish the liver. " @Seth, it would have been interesting if you would have followed up with: I (and others) also lost weight by drinking extra light olive oil. How does your theory account for that? Seth: I don't like to ask questions I know the answer to. I know the answer to that one: It doesn't.

William Blair (2014-01-08 12:01:17)

The Honey at nighttime advice worked for me the first night. I have continued it for the last 5 nights. Even when I didn't get optimal amount of sleep - it still worked. When I say it worked, I mean I wake up refreshed, no grogginess, no headaches later after coffee - raring to go. I can't remember the last time I've felt this good waking up and throughout the day. I still feel like napping around 3-4 PM everyday, but I can muscle through no problem now. In short, three words: I feel great!

david s (2014-01-09 11:42:35)

"We go to bed with a depleted liver. There is not enough fuel in the liver to supply the brain overnight. The way to resolve that is to forward-provision the brain, via the liver" "Your liver has about 65-75 g of glucose in capacity. It releases 10 g every hour into the circulation – around 6-6 and a half grams to the brain. Do the math, you see the brain is in trouble at any time is the 24 hour cycle if the liver reserve is low – especially in advance of the night fast." Assuming this is all true, it seems that the liver would be fully depleted upon waking. Would McInnes suggest honey in the morning, as well? If not I would think the brain would be "in trouble". Seth: One possibility is that brain function during the day is less important than brain function at night so that brain function during the day can get by with less blood sugar. Or maybe we should eat honey in the morning. A friend of mine who is a lawyer said that when he did the Atkins Diet he lost cases he would have won. It really did reduce how well his brain worked.

John Smith (2014-01-09 16:32:31)

Stuart King said, (January 2nd, 9:42 pm) it isn't as much to do with the diet as it is to do with the good sleep! Well summarized

Stuart! Diets are varied and contradictory, but sleep is universal! And, Seth, balancing the diet is done simply by using the honey at night instead of in the morning which is our traditional (American?) way. Even those souls who conscientiously use real honey from their own back yards, tend to see it as a breakfast food, especially in wintertime. By switching it to a nighttime food, the balancing act is dramatically induced. We use honey to start us, to stimulate us, to extend our activity levels, but decline to use it to balance us up with the rest and recuperation stage. And to Eric, If you want to improve on your Vitamin D production, put a thin (watery) lotion of honey on your skin 'before' you go out in the sun. It feeds the cells that make the D, and even prevents burning to a great extent. Depending on one's age, learning to use this new-found energy from these insights, is critical. Honey and all nostrums than give increased energy tend to prompt us to get out there and make up for lost time. BIG MISTAKE! Do use some of that energy investing time in restful activity, or down time. Restoring the body is a long time project. Think of the honey as fuel in you motorcar. Just doing double the miles is great, but what about the long term servicing, repairing and repainting? Real honey enjoys about 1 % of the sweeteners market. It won't take much of this kind of talk to double the demand, and still the potential is enormous (98 % untapped). Honey production is a dying industry. Don't get caught shot of real honey. Many thanks to Mike McInnes for his brave venture into these truths. To you also, Seth, for hosting intelligent discussion. As a long term commercial honey producer I figure my industry may just survive. Mankind himself may even survive! Hooray! Seth: I hope honey producers will realize that they themselves can gather data – studying themselves – on the value of honey for sleep. And they can publish it themselves on a website. There are a hundred questions to answer. For example, what is the best dose? What is the best time?

John Smith (2014-01-09 18:18:37)

Would you believe there are more like 7 billion questions to answer? Why? Because to get it 100 % right it must be on an individual basis. We all need to do our own experimenting and believe in the results we find for ourselves. Leaving it to experts will always trend towards mass medication, mass profiteering and computerized averaging which will be good if the masses do it, but will produce poor results for many individuals. Seth: We are on the same page.

William Blair (2014-01-10 12:56:22)

David s Says: January 9th, 2014 at 11:42 am [ Assuming this is all true, it seems that the liver would be fully depleted upon waking. Would McInnes suggest honey in the morning, as well? If not I would think the brain would be "in trouble". ] I thought the same thing and have been taking a shot of honey every 8 hours or so since I started doing this. I missed an 8 hour window just the other day and I didn't notice any difference though. I'm still doing it every 8 hours as a snack, if anything else. Seth: There may be subtle improvement due to eating honey during the day. The improvement in sleep is not subtle.

## Science Critics Are Human: Cautionary Tale (2014-01-03 05:00)

One reason personal science is a good idea is it is simple and immediate (in the sense of near). You study one person, you do experiments (easier to interpret than surveys), you can easily repeat the experiment (so you are not confused by secular trends – big changes over time – and implausible statistical assumptions), you are aware of unusual events during the experiment (so you are less confused by anomalous results and outliers), you are close to the data collection (so you understand the limits and error rates of the measurements). These elements make good interpretation of your data much easier. Professional science generally lacks some of these elements. For example, the person who writes the paper may not have collected the data. This makes it harder to understand what the data mean.

I hear criticism of (professional) science more now than ten years ago. Lack of replicability, for example. What I rarely hear – actually, never – is how often science critics make big blunders. As far as I can tell, as often as those they criticize. This is not to say they are wrong – who knows. Just overstated.

An example is [1]a critique of salt and blood pressure studies I read recently. Many people say salt raises blood pressure. The critique, by Michael Alderman, a professor of epidemiology at Albert Einstein College of Medicine, said, not so fast. The title is: "Salt, blood pressure and health: a cautionary tale." It's a good review, with lots of interesting data, but the reviewer, at the same time he is criticizing others, makes a major blunder.

He describes a study in which people were placed on a low-salt diet. Their blood pressure was measured twice, before the diet (Time 1) and after they had been on the diet for quite a while (Time 2). Comparison of the two readings showed a wide range of changes. Some people's blood pressure went up, some people's blood pressure stayed the same, and some people's blood pressure went down. Alderman called this result "enormous variation between individuals on the effect of salt on pressure". Oh no! He assumes that if your blood pressure is different at Time 2 than Time 1, it was because of the change in dietary salt. There are dozens of possible reasons a person's blood pressure might differ at the two times (leaving aside measurement error, another possibility). Dozens of things that affect blood pressure were not kept constant.

Had there been a second group that did not change their diet and was also measured at Time 1 and Time 2 – and had the subjects given the low-salt diet showed a larger spread of Time 2/Time 1 difference scores than the no-change group, then you could reasonably conclude that there was variation in the response to the low-salt diet. To conclude "enormous variation" you'd want to see an enormous increase in difference-score variability. But there was no second group.

This is not some small detail. Alderman actually believes there is great variation in response to salt reduction. It is the main point of his article. *Spy* magazine had a great column called Review of Reviewers. Such as book and movie reviewers. Unfortunately there is no such thing in science.

---

George (2014-01-03 09:15:57)

Right, so he commits a very basic and fundamental purely logical error that anyone with a good training in philosophy or science or who has taken the trouble to consciously develop good intellectual habits would easily avoid. What strikes me is 1) How relatively basic the error is yet serves as the basis for his entire position. 2) How utterly characteristic this kind of thing is across the nutrition field even with researchers and writers on nutrition. The entire field needs to be massively cleaned up and high intellectual standards imposed. Will this happen? The problem here seems to be that nutrition and diet have some kind of connection with our need for myth and the search for human meaning in a way that a more abstract science like physics simply doesn't have. The result is that nutrition and diet frequently stimulate the emotions and the myth-making faculty in ways that physics does not. This emotion doesn't just distort thinking but seems

B D McCullough (2014-01-03 12:32:42)

Reason #1,113,412 to remember to ask: "Where's the control group?"

Nancy Lebovitz (2014-01-03 13:54:23)

Off-topic: I just ran across this, and it seems like the kind of thing you and/or your readers might want to look into. I drink very little, so I'm won't be helping with the research. "A large social group that I am involved in, which has been known to drink heavily, has started taking N-acetyl-cysteine (500-1000mg) and Source Naturals Hangover Formula (which is primarily a C & B complex), and the effect it has on hangovers is not in any way subtle."

Gina (2014-01-03 15:43:21)

Nancy Lebovitz, I drink a lot, and have used this combination for years. It works! It is a bit of a pain, because you need to pop an NAC, C and B1 with almost every drink, but it's worth it. I bring my pill bottles to the bar and hand them out to friends. Another thing that I think all drinkers should have on hand is Evening Primrose Oil. It prevents liver damage and tolerance.

kxmoore (2014-01-04 19:50:22)

Gina i just started brewing beer. I wonder how adding the anti hangover formula directly to the brew would work. Gonna experiment with my next brew. The question is whether the formula will compromise the flavor of the beer and if the beer affects the formula unfavorably.

John Smith (2014-01-11 13:48:57)

Seth, here is my take on 'science.' It is a new word brought about by the need to quit using the word 'truth.' The priests of our religions just about murdered the word truth, to the point where it was no longer viable. So the 'scientific method' was designed to differentiate between 'truths' as the establishments (religions?) issued them, and workable facts that were in keeping with current understanding. But what we really did at that point was establish a new religion. We created a body of thought more up to date, yes, and far more practical, workable and predictable. It followed that it also made more and better results, which are expressed as money. Yet we only changed what we believed to be true. Never did the scientific method guarantee that the conclusions drawn from the data would be correct or long lasting. New science contradicts old science every day. The science of today will be obsolete tomorrow, so to speak, at least in many instances. Once we as individuals 'believe' something to be true, it becomes truth to us. Unfortunately we are usually loathe to back away from that position, and when the masses believe untruths, the 'church' becomes the haunt of dogma. Individualized science is the only good solution. If I believe it, it is true for me. I can learn better tomorrow, maybe, but for today it is true. Others may find my truth nothing more than lies. Bully for them..... as I see their truth as lies all too often. But it is only truth if the individual believes it really and truly..... like deep down, man. And if I am not prepared to act on that belief, probably I don't really believe it. Unfortunately the 'science' of today has morphed into a religion, duly presided over by High Priests who maintain yesterday's truth for the protection of the power and influence of established methods and organizations. The www is doing to 'science' and the power bases it has spawned what Christianity did to the Roman Empire and the printing press did to the Catholic Church (which the Roman Empire morphed into). Individualism has taken a back seat to collectivism in the last hundred years, but the www has ushered in a whole new epoch. Seth: I agree. The habits of mind, the built-in tendencies, that led to religion didn't change just because science was invented. I think of personal science as similar to literacy, and mass literacy rested on the printing press.

## **ADHD Experts Have a Bad Case of Gatekeeper Syndrome (2014-01-04 05:00)**

[1]Gatekeeper syndrome afflicts many many healthcare professionals. People with gatekeeper syndrome dismiss or ignore any solution that does not involve them (or someone like them) being a gatekeeper and charging "toll", i.e., making money. When I was a teenager, I had acne. None of the dermatologists I saw showed any interest in what caused it or even seemed to understand it was possible to learn the cause. All of them prescribed drugs (antibiotics) so powerful I had to see them again and again to get the prescription refilled. That's garden-variety gatekeeper syndrome.

[2]A recent New York Times article about Attention Deficit Hyperactivity Disorder (ADHD) illustrates gatekeeper syndrome among professionals from whom you might expect better. The article describes ADHD experts at various universities wringing their hands: Did we overemphasize drugs at the expense of "skills training"?

Some authors of the [1999] study — widely considered the most influential study ever on A.D.H.D. — worry that the results oversold the benefits of drugs, discouraging important home- and school-focused therapy and ultimately distorting the debate over the most effective (and cost-effective) treatments.

What about finding the cause(s) of ADHD? And getting rid of it/them? Maybe that would be a good idea? None of the experts quoted in the article even seems aware this is possible.

When an ordinary psychotherapist or doctor has gatekeeper syndrome, I think they're just a foot soldier. The experts in the Times article are not foot soldiers. They're generals. They are professors at world-famous universities, such as UC Berkeley and McGill, with enormous influence. (One is a former colleague of mine, Stephen Hinshaw.) They don't need to see patients and dispense treatments to make a living. They have assured income (tenure) and prestige. They enjoy freedom of thought.

Too bad they don't use their freedom and prestige to better help the children they study and the tens of millions of children who will be diagnosed with ADHD until someone (not them, apparently) figures out what causes it. Instead, they study who should get the revenue stream that each new diagnosis provides.

Thanks to Alex Chernavsky.

## Butter and Heart Attacks in Sweden (2014-01-05 05:00)

Chart 5. Age-standardized incidence rates of acute myocardial infarction, per 100,000 population, 20 years old and older, gender and age, 1988-2012.

This graph from [1]Andreas Eenfeldt (via [2]Mark's Daily Apple) shows heart attacks (left axis) and butter consumption (right axis) in Sweden over the last quarter-century. Heart attacks have been going down, at least in men. What interests me is that when butter consumption suddenly increased, starting in 2006, heart attacks went down more quickly.

If you fit a straight line to the heart attack rates for 1988-2005, you will see that the remaining rates (2006-2012) are below the extrapolation of the line, both for men and women. The Swedes made other dietary changes when they started eating more butter (the butter replaced other foods, for example). Nevertheless, these data make it more plausible that if butter has any effect on heart attacks, it reduces them, the opposite of what we've been told.

I eat a half stick (60 g) of butter daily. [3]It improves my brain speed. After I gave [4]a talk about this, a cardiologist in the audience said I was killing myself. I said I thought my experimental data was more persuasive than epidemiology, with its many questionable assumptions. The new data suggests I was right – butter does not increase heart attacks. It also supports my belief that by learning what makes my brain work best, I will improve my health in other ways (such as reduce heart attack risk).

No doubt a low-carb high-fat diet is better than what many people eat, but I believe the never-eat-sugar part of such a diet is a mistake. [5]There are plenty of reasons to think sugars eaten at the right time of day improve sleep. Whatever you think about nutrition, don't get too comfortable.

gwern (2014-01-05 06:46:57)

> If you fit a straight line to the heart attack rates for 1988-2005, you will see that the remaining rates (2006-2012) are below the extrapolation of the line, both for men and women. Really? It just looks like the usual meandering time-series to me. Data and source code for this claim?

hertm (2014-01-05 07:04:37)

"Really? It just looks like the usual meandering time-series to me. Data and source code for this claim?" Don't you have a worthless anime essay to write?

dearieme (2014-01-05 07:28:53)

I'll say it again: nobody knows why heart attack rates have been trending down in so many countries for so many decades. But it's so marked that it can't be to do with the decline of smoking, with the adoption of low-fat diets, or with medical changes. The infection conjecture sounds plausible, but until the relevant micro-organisms are identified, it remains conjecture. My personal variant is that heart attacks are indeed caused by infections, and that the decline is caused by "over use" of antibiotics by the medical trades. When I'm proved right, I shall happily share my Nobel with those who provided the evidence to back me up. Seth: Epidemics usually decline, in my understanding, because it becomes harder and harder to surprise a host. The virus or whatever spreads faster than the epidemic of acute illness. You may recall my theory that shaking hands is an early warning system. However, this is such a slow epidemic it is hard to know if the usual ideas apply.

Eric (2014-01-05 07:57:26)

The most likely thing butter is replacing is margarine. It seems like the data could be accounted for by a decline in margarine consumption alone.

Jim (2014-01-05 11:00:02)

there are people who have questions about this graph but it is dramatic [http://www.drdaavidgrimes.com/2013/07/an-epidemic-of-coronary-heart-disease.ht ml](http://www.drdaavidgrimes.com/2013/07/an-epidemic-of-coronary-heart-disease.html) Dearmieme, if you haven't read his book, check it out Seth, I'm now with you on the sugar. It can't make sense that something everybody likes is bad for you, but there does seem to be some context that makes it work. Time of day or amount or some co-factor. Ditto on saturated fat, meat has it because that's what mammals are made out of, including us. So maybe there is a situation where it's bad but it can't be universally bad, that wouldn't make any sense

Ripken Holt (2014-01-05 11:18:10)

Seth, I've been following your blog and you have pretty much convinced me that sugar is important to your body's health. However, I am curious as to what DOES cause the astronomical heart disease rates in America if it is not sugar. What do you think the likely cause(s) are? Seth: I don't know what causes heart disease nor can I explain the recent decrease, which as dearieme says is substantial. I explain the fact that heart disease is very low in France and Japan by their high consumption of fermented foods (France and Japan) and omega-3 (Japan). I think Mr. Heisenbug may be on to something when he asks why smoking is a very bad risk factor for heart disease.

Gina (2014-01-05 13:12:03)

I agree with Eric. I'm only convinced that soybean oil, corn oil, cottonseed oil, etc. are bad, not that butter is good. This makes sense with the Esselstyn/Ornish/Barnard stuff (i.e. studies that reverse heart disease and diabetes with ultra-low fat diets). I'm guessing that avoidance of these fats would prevent heart disease no matter what the rest of one's diet. Seth: My Agatston score – a measure of circulatory system calcification and an excellent predictor of heart attacks – went down during a year in which I greatly increased my butter intake compared to all previous years of my life. I did not eat less soybean oil, etc., during that year. I just ate more butter – much more fat overall.

dearieme (2014-01-05 14:52:10)

"astronomical heart disease rates in America": nah, the epidemic is practically over. From Jim's link "At the peak of the epidemic in 1970 there were 520 deaths per 100,000 per year in England and Wales, 700 in the USA, and ... Thereafter there was an abrupt and apparently spontaneous decline, by 83 % during the next 20 years to 1990. This is an important observation as during this time there was no widespread effective medical intervention. The decline continues. At present the death rate is about 20 per 100,000 per year and the decline appears to continue. We appear to have experienced a natural epidemic and it is now almost over. The cause of it has not been obvious, but when we realise that CHD has been an epidemic we can start to think objectively about what might have caused it."

dearieme (2014-01-05 14:57:43)

Which takes us to the Swedish study: if heart attack rates are declining anyway, the correlation with butter consumption is probably meaningless. There could be a similar trend for the consumption of, say, Australian Shiraz or New Zealand Sauvignon Blanc or Single Malt whiskies. Mere observational studies are feeble things, especially when there's no demonstration that it's among the people who eat the butter that the decline is concentrated.

Gina (2014-01-06 08:47:59)

"My Agatston score — a measure of circulatory system calcification and an excellent predictor of heart attacks — went down during a year in which I greatly increased my butter intake compared to all previous years of my life. I did not eat less soybean oil, etc., during that year. I just ate more butter — much more fat overall." I wonder if that can be attributed to the K2? That would explain why some people insist that only grass-fed butter is healthy (higher K2 content). Surely the butter displaced something in your diet? Seth: It immediately displaced pork fat – I stopped trying to eat pork fat every day in order to sleep better, which I'd been doing for about a year. When I started eating more pork fat was when my overall fat consumption went way up. I think at that time everything else went down.

Crystal (2014-01-06 11:01:48)

Why are there 3 extra data points at the left of the graph? Does that data cover a different time period or are the points not

aligned properly? I thought butter was demonized because it was a saturated fat, not that it, alone, was correlated to heart attacks. Publish the same graph against total sat fat consumption and you'll have a stronger case to dissociate the two. Ps there's interesting work that charts the total lack of correlation between sat fat consumption and heart attacks in coconut producing ( & eating) countries, so now there's a bit of work investigating possible heart benefits from specific medium chain saturated fats, like coconut oil, in the diet.

gwern (2014-01-06 13:55:30)

hertm: aww, is someone butthurt over my criticisms here? > Seth: My Agatston score — a measure of circulatory system calcification and an excellent predictor of heart attacks — went down during a year in which I greatly increased my butter intake compared to all previous years of my life. Interesting, but where's the control Seth's scores? This comment seems to assume that if your Agatston score is different at Time 2 than Time 1, it was because of the change in dietary butter. There are dozens of possible reasons a person's Agatston score might differ at the two times (leaving aside measurement error, another possibility). Dozens of things that affect Agatston score were not kept constant. This would seem to be committing a very basic and fundamental purely logical error that anyone with a good training in philosophy or science or who has taken the trouble to consciously develop good intellectual habits would easily avoid.

Joe (2014-01-06 14:25:17)

If you have a Kindle, you can read about the various reasons heart attack rates are plummeting, and for only \$1.46! You Will Not Die From A Heart Attack, by Dr. David S. Grimes: <http://www.amazon.com/WILL-HEART-ATTACK-Medical-Briefs-ebook/dp/B00C4C0XNG>

## **Bedtime Honey and Sleep: Different Kinds and Amounts of Honey (2014-01-06 05:00)**

A reader named Sam, an engineer in Irving, Texas, writes:

I am a long time reader of your blog. Based upon your writings, I have taken Vitamin D in the morning and Magnesium Glycinate powder at night for over a year. Both have helped. So I do not have any sleep issues that needed to be addressed. I took the honey only to see if it would make any further difference. I was a bit wary to begin with as I do not usually consume honey. I have had a mild allergy to eating honey until at least several years ago. Even a teaspoon of honey would within an hour give me abdominal cramps that would last for an hour or more.

I started a Primal/Paleo/PHD way of eating 3 years ago. No processed foods, no wheat, only fermented dairy (kefir/cheese/cultured butter/ghee), occasional alcohol and occasional desserts (generally fresh fruit or some ice cream) and regular use of home fermented food like sauerkraut, beet kvass and lemonade.

So the honey experiment was also to test whether the changed diet had fixed the allergy.

I tried regular store bought honey (Kroger) first. I took a tablespoon approximately 10 minutes before going to bed. It could be a bit more than a tablespoon as I would dip a regular tablespoon in the jar and eat it as soon as the stringing ended. The first day there was anxiety in expectation of an allergic reaction. No cramps but there was some mild abdominal pain, I would just call it discomfort. I thought this could be psychological. So I tried it for 3 more days. Still the same discomfort within the hour. But I would fall asleep at some point and wake up feeling the same as I used to earlier.

I almost quit after this – when my wife reminded me that we had some Manuka honey in the pantry

that we got as a gift and that could be worth trying. So I did. This is a honey produced in New Zealand and has some number on it – that claims to have medicinal properties. This honey was thicker, so easier to measure. About one tablespoon each night, same time as before. Same discomfort – no change in overall sleep quality or post waking up energy. I tried this for 4 days.

It may seem that the obvious course of action would be to quit the experiment at this stage. However, around this time, I read a comment on one of the blogs I follow, describing the process of refining honey for bottling. Apparently it is heated and filtered as a minimum and maybe more processing in most cases. I know a friend who cured his allergy to homogenized milk (skin redness after consumption) by shifting to raw milk which he pasteurizes himself at a low temperature. So I looked for raw unprocessed honey and stumbled upon [1]a source – which curiously had regular raw honey and fermented raw honey. I ordered a jar of each.

Initially I tried the raw honey, in the morning, in white tea just to test for the abdominal discomfort. Surprisingly, there was none. So I decided to take it at night and continue to see if there are any benefits. One tablespoon as before. I usually fall asleep within a few minutes of turning off the lights. This time, I noticed that I would toss around a bit longer before getting to sleep. However, I did notice that I would wake up more energetic. As I said it is subjective – hard to describe. But I would get ready faster and finish up a few chores that I would be lazy about on other days.

After a week I reduced the dosage to one teaspoon. The only observable change was that the tossing in bed now ceased and I would fall asleep quickly. So I stayed with this dose as a smaller dose is difficult to measure accurately.

After a total of 10 days on regular raw honey, I decided to try the fermented raw honey – only because I had ordered it and had it with me. I stayed with the one teaspoon dose just before bed and immediately noticed one remarkable change besides the increased energy in the morning. Normally, I wake up once at night, around 2AM, to go to the bathroom. The very first night, I slept through till the morning. Subsequently, I have noticed that occasionally I wake up at 5AM but most nights I just sleep through.

It has definitely increased my sense of well being and post wake up energy.

His main conclusions are:

1. Raw honey works better than ordinary (cooked) honey. Manuka honey is no better than ordinary honey. Fermented raw honey is even better than ordinary raw honey.
2. One teaspoon is better than 1 tablespoon – fell asleep faster.
3. The benefits include less waking up at night, more energy in the morning, an increased sense of well being, and better motivation (e.g., to do chores).

I fall asleep quickly whether or not I take honey at bedtime. But it is curious that fermented honey works better than non-fermented. Fermented honey has less sugar; maybe that's the reason for the difference.

1. [http://www.reallyrawhoney.com/category\\_s/44.htm](http://www.reallyrawhoney.com/category_s/44.htm)

---

Drini (2014-01-06 06:44:28)

Thank you very much for this blogpost. I think I also noticed that I have more difficulties falling asleep when I eat honey before sleep (1 Tbsp). I noticed for instance that honey raises my body temperature, I think that this is not the effect you want before going to sleep (Isn't sleep associated with lower body temperature?). Maybe having honey 30 minutes or 1 hour before going to sleep might also help getting to sleep faster. This was never a problem prior to using honey. I think I should also try different doses and check their effects. Seth: I agree. You should certainly try smaller amounts of honey. You might also try other sources of sugar, such as a banana.

B.B. (2014-01-06 09:55:51)

This blog used to discuss the benefits of intermittent fasting. Now I am reading about the benefits of eating honey right before going to bed. How do people eat honey before bed and do IF at the same time?

kxmoore (2014-01-06 10:13:29)

what is fermented honey? i googled it and "mead" kept appearing.

dearieme (2014-01-06 13:29:05)

The claim for Manuka honey is some sort of anti-bacterial property. It's delicious stuff, in my view, but if it doesn't work for Sam, then for Sam it doesn't work.

Joe (2014-01-06 14:14:32)

B.B.: If fasting intermittently, I don't think a teaspoon of honey would have much effect, one way or the other. That is, the fasting wouldn't have to be zero calories, only reduced calories.

vs (2014-01-06 18:10:42)

Dr. Michael Eades has recommended honey or sugar at bedtime to help with sleep. He suggests ketosis can hinder sleep. A small amount of honey or sugar (one teaspoon) at bedtime temporarily knocks people out of ketosis. This allows them to fall asleep easier. Dr. Eades wrote this in a 2009 blog post: <http://www.proteinpower.com/drmike/bogus-studies/more-thoughts-on-why-low-carb-the-second-time-around/> He suggests ketosis may hinder sleep: "And once we get going again on a low-carb diet, we usually get into a little ketosis, which makes falling asleep a little more difficult yet." After discussing the benefits of low-dose sublingual melatonin tabs as a sleep aid, he recommends herbal tea with one teaspoon of sugar or honey at bedtime: "The other thing you can do is to have a cup of herbal tea right before bedtime. And sweeten the tea with either sugar or honey. That's right. Real sugar. A teaspoon of sugar is about 5 grams of carb, which won't do a lot to hinder your weight loss, but it will be enough to shut down ketone production long enough to get you to sleep." A search of Dr. Eades' blog reveals that he has mentioned this a few times in response to reader comments about poor sleep on low-carb diets. I do not believe Dr. Eades has written on why ketosis may hinder sleep. A Google site search of his blog did not turn anything up. If anyone has insight on this link between ketosis, sleep, and sugar, please let us know.

daz (2014-01-06 19:09:07)

@Sam, Hi Sam, i been trying to find an image of the label for the 'Really Raw Honey' fermented raw honey showing the nutrition facts, with no luck. could you tell me what the carbs and sugar numbers read on your label pls. i found the non-fermented info, which was Total Carbs: 17g, Sugars: 17g (for a 21g server size).

Sam (2014-01-06 19:42:41)

@kxmoore - here is the source I used for Fermented honey [http://www.reallyrawhoney.com/category\\_/s/44.htm](http://www.reallyrawhoney.com/category_/s/44.htm) @daz - the nutrition facts about FRH are the same as the NFRH - In fact the jars have the same labels - Only "fermented" is written on the lid. It however tastes much different.

daz (2014-01-06 20:10:48)

"In fact the jars have the same labels – Only "fermented" is written on the lid" ...that would explain it...why all the labels looked the same, but the look of the contents varied (using google images) thx for the reply

Paleophil (2014-01-06 20:57:43)

I've been using Really Raw fermented honey for years. It's the only honey or sugar that I notice any benefits from (with the possible exception of the much maligned agave nectar, which I recently started experimenting with, but it's too soon to tell), and I have tried many. The main things I notice from it are reduced skin flaking on scalp, eyebrows and forehead, reduced muscle tension and a mild feeling of well being. I don't get this from their unfermented honey. However, if I consume too much, I get some dental gunk in the morning, though not as much from other honeys. I asked the Really Raw people if they had heard of any unusual benefits like this from their fermented honey and they confirmed that other customers had reported benefits. It's also by far my favorite tasting honey, though not everyone shares that opinion.

Gina (2014-01-06 21:52:40)

vs: Ketogenic diets raise cortisol, which hinders sleep. From what I have read, this is more pronounced in women (and female rats). Side note: I would beware of advice from the Drs. Eades. They are married to low-carb dogma and advise more and more restrictive diets (to the point of an all egg diet) to people for whom low-carb is obviously not working.

daz (2014-01-06 22:13:43)

keep us updated on your Agave nectar experiment Paleophil, pls, are you trying it before bed. i wrote Agave nectar/syrup off without a second look after reading it was very high in fructose...tho i never did investigate any deeper,...brands, production, sugar breakdown,...etc

dearieme (2014-01-07 10:22:54)

Two sorts of honey that might be worth somebody's trying, in hopes of non-sugar benefits: honeydew honey and comb honey.

Joe (2014-01-07 11:16:03)

Gina: "Side note: I would beware of advice from the Drs. Eades. They are married to low-carb dogma and advise more and more restrictive diets (to the point of an all egg diet) to people for whom low-carb is obviously not working." Being wed to the low-carb way of eating is a "good thing," in my opinion, because it works. And he's never, to the best of my knowledge, ever advised anyone to eat an all-egg diet. He has, however, discussed an experiment that Jimmy Moore was contemplating, namely eating nothing but eggs for a week to see how that would affect his cholesterol levels. Dr Eades said it would likely raise his LDL a bit, but his trig and HDL levels would increase substantially (very good things). And that's it. There's nothing really restrictive about the diet Dr Eades recommends either. It's basically nothing more than eating fewer carbs and more healthy fats and proteins, and avoiding sugar and grains, all of which have positive effects on our health. Of course, if you're from the school that thinks it's actually healthy to eat lots of sugar, starch, seed and vegetable oils, trans-fats, refined and processed foods, and "healthy whole grains," I can see why you might think otherwise. Personally, I'm sticking with Dr. Eades, Dr. Jaminet, Mark Sisson, The Weston-Price Foundation, Dr. Sinatra, Dr. Ravnskov, Robb Wolf, Dr. Lundell, Dr. Grimes, Dr. Kendrick, Dr. Bowdon, Dr. Masterjohn, Dr. Westman, Dr. Davis, Dr. Perlmutter, Dr. Hastings, and countless other doctors, researchers, etc., who recommend the low-carb/paleo way of eating. Works for me! Seth: How do you reconcile low-carb advice with data that show honey at bedtime improved sleep? Eating honey is the opposite of avoiding carbs.

Bedtime Honey and Sleep | Mallacoota Honey and Warré Beehives (2014-01-07 11:45:07)

[...] Bedtime Honey and Sleep: Different Kinds and Amounts of Honey ... read Full Article [...]

Joe (2014-01-07 12:27:06)

Seth, eating honey is not the same thing as avoiding carbs altogether. It's called LOW carb eating, not NO carb. I generally eat between 100 and 150 gs of carbs per day. 1 tablespoon of honey contains 17 gs of carbs. No big deal, really. I used to eat a lower number of carbs when I wanted to lose some weight, but now that I've lost what I wanted to lose, the 100-150 gs per

day maintains my desired weight easily. I don't dispute that eating honey at bedtime improves sleep. But it didn't improve mine, after a short n=1 experiment. Which I intend to fiddle around with again soon, incorporating the changes we discussed. Yes, I'm almost out of bananas! Seth: Thanks for explaining that – but it seems to me there really is a contradiction between advocating that people eat less carbs and discovery of an effect that requires eating more carbs. What if the bad effects of carbs were due to 1. eating them in factory food and fast food (food that is especially fattening because it has exactly the same smell every time) 2. eating them at the wrong time of day (the right time of day is after 6 pm)? I am not saying that low-carb diets aren't helpful. Obviously they help many people. I am saying that the theory why they help (used by many of the experts you listed) seems to be quite wrong. And this wrong theory has gotten in the way of improving those diets. You know more about the work of the experts you listed than I do, so maybe I am missing something.

Joe (2014-01-07 13:45:35)

Seth, first, I'm in no position to advocate anything. I can, however, attest to what works for me. And has for a long time. Everything is a trade-off to me. Do I want to eat a few more carbs (than I normally do) if I can sleep a little better at night? Which is going to have the more positive effect on my health? Will I be able to measure it? Feel it? Etc. I can't answer that yet, regarding eating honey right before bedtime. But eating 17 grams of honey probably won't jeopardize the positive effects of my otherwise low-carb/paleo diet, and if it allows me to sleep a bit better, that's a win-win for me, right? And if it doesn't, no harm, no foul. It didn't matter much when I ate carbs, or what they smelled like, etc., but I didn't really do a lot of experimenting with that. I found a way that worked for me, and then I stuck with it. I don't understand why you feel the theory of why low-carb works is wrong. The more carbs one eats, the more carbs one wants to eat. That's the way it works for me, anyway. I can eat a certain number of carbs without getting into trouble. More carbs than that? I blow up like a Macy's parade float. It also provides me with better health profiles and numbers. Yeah, my total cholesterol is a little high, but my triglycerides are negligible, my HDL level is very high, the size of my particles is huge, my BP is better than normal, my inflammation is low, my BS is better than normal, etc. I don't really buy into the diet-cholesterol theory of heart disease anyway. But, like Pascal's wager, it can't hurt to "keep the faith." I'll probably be a better man. And if they are right, I'll still be okay. :) Nota bene: No one who has read: <http://www.amazon.com/The-Great-Cholesterol-Con-Disease/dp/1844546101> ...could possibly believe the cholesterol theory afterwards! Also, I think what you're missing about those experts is that they aren't as rigid as you probably think they are. There's wiggle-room. There's also acknowledgement that what works for me might not work for you, and vice versa.

vs (2014-01-07 16:06:38)

Thanks to Joe for sharing his experience. I agree most low-carb diets are not rigid and there is wiggle-room. If one follows a low-carb diet from start to finish, they are more "controlled carb" rather than "low-carb". Low-carb diets advocate carb-restriction to lose weight and improve health. Then they offer strategies to help a person \*increase\* their carb intake to find the amount they can eat to maintain their weight and health. Take the Eades' book "Protein Power", or Dr. Atkins' book "The New Diet Revolution". Both recommend starting the diet with very low carb intake: Atkins 20 g per day, the Eades 30 or 55g per day. This should promote weight loss and help normalize blood chemistry, blood pressure, etc. But then both books advocate slowly adding carbs back into the diet: 5 or 10 g of additional carbs per day, over weeks or months, following a system set out in the books. The goal of these two plans is not to eat very low carb forever, but instead to find the person's unique carb tolerance- how many carbs they can eat and still maintain their weight and health. Dr. Atkins called this amount the "Critical Carbohydrate Level for Maintenance". This carb level varies, but as Mark Sisson wrote in his book the "Primal Blueprint", it can be as high as 100-150 g per day. This is especially true if the carbs are high quality fruits and vegetables, rather than heavily processed foods. For those following a low-carb diet like the Eades or Atkins plans, a teaspoon or tablespoon of honey at night is a reasonable increase in carb intake.

Seth Roberts (2014-01-07 18:47:19)

Why do I think the theory behind (most) low-carb diets is wrong? Because they say carbs cause obesity. Whereas I lost lots of weight drinking sugar water. They have never explained this, they ignore it.

Joe (2014-01-08 08:49:34)

But Seth, how many grams of CARBS per day were you eating? Yes, including the sugar in the water. Seth: I increased my carb

consumption, which caused me to lose weight. This contradicts the idea that carb reduction causes weight loss (which implies that carb increase should cause weight gain) no matter how many grams of carbs I was eating. When I was losing weight I wasn't eating very many carbs besides the sugar water because I had very little appetite.

Gina (2014-01-08 15:36:25)

I think the theory behind low-carb diets is wrong because of huge populations of lean people who eat starchy diets.

B.B. (2014-01-08 16:03:06)

Maybe bananas work for some people because they are rich in potassium, which can be absent in the modern diet. Also, what about protein and fat at bedtime. I have a favorite snack of ricotta cheese with honey. The honey may help, but the protein from ricotta cheese may stabilize blood sugar and provide nutrients for muscle repair. Does fat like flaxseed oil help in the evening? I am wondering about people's experiences.

Joe (2014-01-08 16:12:08)

Gina, I'd say this: If a high starch diet allows you to remain thin and fit and healthy, by all means, go for it. I'm not really a proselytizer. But too much starch causes me to gain weight. Not a little starch now and then, but a steady diet of it. The vast majority of people I know who eat starchy diets are fat and out of shape, especially as they age. The vast majority of people I know who restrict their carbs are fit and healthy. I'm not a scientist, so I can't explain exactly why that is so. Perhaps the scientists can't either. I just know what my eyes and ears tell me. And eating a low-carb/paleo diet is very EZ for me to do. And I really like the results. I usually don't spend a lot of time "fixin' what ain't broke." I can't explain it any better than that. Seth: I wonder if your low-carb diet hurts your sleep, meaning that a higher-carb diet would give you better sleep. With a good understanding of why low-carb diets produce weight loss, it might be possible to increase how much carbs you eat (to get better sleep) without causing weight gain. Without a theory, it is pure trial and error. A good theory about weight control should be able to greatly reduce the trial and error. When you say "too much starch causes me to gain weight" you may be drawing the wrong conclusion from your experience. Maybe one form of "too much starch" causes weight gain but another form would not.

Joe (2014-01-08 16:30:55)

B.B.: "Maybe bananas work for some people because they are rich in potassium" Define "work."

Jenny (2014-01-08 16:46:24)

I've been trying about 1 tsp of honey at Bedtime since Seth first mentioned it. For the first time in 32 years, I now sleep all night. I never had difficulty falling asleep, just staying asleep past 3 -4 am. I am definitely getting through the chores faster, and more of them (ie more energy). I am also losing the post-Christmas weight at a pretty regular 0.2Kg a night. This rather fits with Seth's sugar water. BTW, I've eaten paleo for the last 8 years since I found I was coeliac, using a relatively low-carb version.

Paleophil (2014-01-08 18:41:42)

@daz, I too had written agave nectar off and had even suggested to my sister to stop using it, thanks in part to negative views on fructose from folks like Dr. Lustig. I have tried taking the agave syrup before bedtime a couple times and didn't notice anything particularly different, though I was already sleeping through the night. I did notice that the first time I tried it in a long time that I was surprised by a nice wave of muscle relaxation after taking it that I sometimes get after consuming RF honey. It's baffling to me, because fructose is supposed to raise lactic acid, not lower it. Does anyone know of a possible cause for this? Perhaps it was coincidence, though I do seem to get a bit of it most times I try it. I doubt I'll add agave nectar to my regular diet, but the early testing has been interesting. In contrast, brown rice glucose syrup, which I also tested a small amount of after glucose syrup was recommended by a fairly well respected Paleo blogger as the safest carb for carb sensitive people like me (even supposedly safer than "safe starches"), had rapid and rather bad negative effects. It also tasted pretty bad to me. vs wrote: "This is especially true if the carbs are high quality fruits and vegetables" Don't forget honey, which is the topic of the article, after all. :)

daz (2014-01-08 20:33:01)

i dropped in to a health shop the other day & looked at the agave offerings, talk about spoilt for choice, a few of the options were agave blue, light, dark, clear, amber, i'm guessing the sugar breakdown & mineral content etc would vary quite a bit between types & brands, & i would assume the 'effects' would/could vary quite a bit as well

Gina (2014-01-08 21:10:32)

"The vast majority of people I know who eat starchy diets are fat and out of shape, especially as they age. The vast majority of people I know who restrict their carbs are fit and healthy." - Joe You must not live in Japan, France, Italy, Greece or Costa Rica. I take it that the people you know who eat starchy diets are also not Seventh-Day Adventists. All these groups eat starchy diets and are healthy and lead long lives. None eat low-carb diets.

Joe (2014-01-09 10:56:17)

Gina, I think if you'll google a bit, you'll find that all of those countries are currently experiencing the same problem we are - an epidemic of obesity and diabetes. But let me add this. I wouldn't care if they weren't. I know what works for me, and what doesn't work for me. And selfishly, that's the only diet I really care about. My own. And starches give me a problem. I don't totally avoid them, but I tread lightly. Nota bene: For someone who warns others of heeding dogmatic advice, you seem pretty dogmatic yourself. Seth: I agree, obesity and diabetes are going up in those countries. That doesn't change the fact that they are a lot slimmer than Americans while eating a high-carb diet. Which they have been doing for a very long time, like a hundred years or more. The high-carb diet is unquestionably not the reason for the increases in diabetes and obesity. It is something about Western foods that is. Or perhaps something else about Westernization (less activity?). All of those countries are eating far more Western foods in recent years. You seem to be ignoring this - it isn't carbs that are bad, it is something else.

Joe (2014-01-09 11:21:23)

Seth: "I wonder if your low-carb diet hurts your sleep, meaning that a higher-carb diet would give you better sleep." Before I started eating low-carb/paleo, I ate like your typical Italian (which I am), and unfortunately resembled Luciano Pavarotti, not Frank Sinatra. And I slept poorly. By poorly, I mean maybe 2-3 hours on a good night. On bad nights, no sleep whatsoever. "With a good understanding of why low-carb diets produce weight loss, it might be possible to increase how much carbs you eat (to get better sleep) without causing weight gain." I sleep pretty well, all things considered, for my age. 7-8 hours on a good night. 5-6 hours on others. Plus a daily nap of 45 minutes. Most mornings I wake up refreshed, others mornings, not so much. I don't even know where perfection lives, so I'm not going to spend a lot of time looking for it. I'm not going to sacrifice my current way of eating, my health profiles, etc., just to sleep another hour per night. I understand the health benefits that come from getting a good amount of sleep, but I also understand what happens to my health when I eat too many carbs, get fat, etc. "A good theory about weight control should be able to greatly reduce the trial and error. When you say "too much starch causes me to gain weight" you may be drawing the wrong conclusion from your experience. Maybe one form of "too much starch" causes weight gain but another form would not." Seth, here's my theory: Find something that works for me, and then stick to it. I like n=1 experiments as much as the next guy, but I also understand the wisdom of not trying to fix things that aren't broken. I got here by experimenting, by the way. And in my experiments, I discovered that eating copious amounts of pasta, Italian bread, pizza, etc. was going to kill me. So I tried all the popular ways of losing weight and getting fit. None worked very long (especially vegetarianism), or very long. Until I tried eating low-carb. Then the weight came tumbling off. Then I learned about the paleo diet, and changed my low-carb base accordingly. Then came even greater weight loss, plus amazing improvements in all my health profiles. What's not to like? Seth: I agree there is a lot to like about that story. As for what's not to like, I suspect your sleep could be better. Maybe your gut biota could be better - check out the correlation of fiber intake and heart disease if you think this is unimportant. I also wonder when you started eating low-carb. Alex Chernavsky lost lots of weight when he started low carb but around two years later he started gaining it back.

vs (2014-01-09 11:28:00)

Thanks to Gina, Joe and Seth for sharing their thoughts and experiences, and for this very interesting discussion. For what it is worth, I believe Gina and Joe are both right. Gina points to countries, and Seventh-Day Adventists, who eat starchy diets and are healthy. One possible reason: they do eat a starchy diet, but don't generally exceed 600 calories a day from starches. Here

is Paul Jaminet and Shou-Ching Jaminet in "Perfect Health Diet": "Although the precise magnitude of the various quantities is uncertain, it appears that the body's natural daily glucose consumption is about 480 calories for brain and nerves, 200 calories for glycoproteins such as hyaluronan and mucin, 100 calories for muscle glycogen and immune, intestinal, and kidney cell use, offset by about 200 calories of glucose produced in the course of fat burning. For sedentary healthy people, then, the natural carb intake is about 600 carb calories per day." These facts inform their diet recommendations. The Jaminets suggest eating: "About 600 carbohydrate calories per day from about 1 pound of "safe starches" such as sweet potatoes, yams, taro, white rice, sago, tapioca, and potatoes and 1 pound of fruits, berries, and sugary vegetables such as beets and carrots." Generally, 600 carb calories works out to 150 g of carbs per day. This is what Joe mentioned above, and what Mark Sisson emphasized in "Primal Blueprint". It appears it is ok to eat certain carbs- and indeed might be beneficial to do so. The key is knowing how much: too many and one is likely to gain weight. Many low carb and diet paleo books are really just about helping people find the right amount of carbs.

Joe (2014-01-09 11:38:14)

Seth: "I increased my carb consumption, which caused me to lose weight. This contradicts the idea that carb reduction causes weight loss (which implies that carb increase should cause weight gain) no matter how many grams of carbs I was eating. When I was losing weight I wasn't eating very many carbs besides the sugar water because I had very little appetite." Life is full of contradictions, my friend. Some people who eat lots of carbs do well, some don't. Some people who eat lots of meat do well, some don't. I can't explain it. I can't explain why you lost weight by consuming sugar water, and you probably can't explain it either. The good folks at NuSi: <http://nusi.org/about-us/board-of-directors/#.Us7qGLQnXng> ...are busy trying to explain it. Using the scientific method, for a change. Maybe they'll be able to explain it, maybe not. But in the meantime, I have results that appear to work well for me, even if I can't explain them in scientific terms.

Joe (2014-01-09 11:47:38)

vs: "For what it is worth, I believe Gina and Joe are both right." Heh. That wouldn't surprise me one little bit!

Joe (2014-01-09 15:40:50)

Seth: "I agree there is a lot to like about that story. As for what's not to like, I suspect your sleep could be better. Maybe your gut biota could be better — check out the correlation of fiber intake and heart disease if you think this is unimportant. I also wonder when you started eating low-carb. Alex Chernavsky lost lots of weight when he started low carb but around two years later he started gaining it back." My gut biota is in very good shape. I drink some kefir almost every day, and I eat a lot of high-fiber veggies and fruits. I also eat a tablespoon of soluble fiber each day (in the form of Konsul). You could set your watch by my "movements." Fiber is important, but not at the expense of everything else. I've eaten this way for roughly 10 years, Seth. I used to weigh 300 pounds. I weigh about 190 today, and it hasn't varied by more than 10 pounds either way, since I first got to 190. 190 puts me at a 24.4 BMI. I've had friends with Alex's experience. Without exception, once they started writing down what they were actually eating, they quickly realized it was no longer low-carb. I usually ask them to consider starting all over again, like in Atkins' Phase 1, and cut carbs way back to 20 grams or less for a few weeks. It has always worked. I'm not saying it always works. For everyone. I'm saying it has always worked for me, and for the people I know. Also, though a lot of experts will tell you not to look at the scale everyday, I do. At the same time every day (first thing in the morning). And what that scale says will dictate how many carbs I eat that day. I nip things in the bud. Again, it works for me. Seth: That's good to know, especially about the fiber sources. I am more interested in measuring my gut biota than you seem to be; I want to find out whether there is room for improvement. When you say "it works for me" you seem to be ignoring my point about your sleep. I am not so sure it works for you, in the sense that there is no room for improvement.

Joe (2014-01-09 16:47:07)

Seth: "I agree, obesity and diabetes are going up in those countries. That doesn't change the fact that they are a lot slimmer than Americans while eating a high-carb diet. Which they have been doing for a very long time, like a hundred years or more. The high-carb diet is unquestionably not the reason for the increases in diabetes and obesity. It is something about Western foods that is. Or perhaps something else about Westernization (less activity?). All of those countries are eating far more Western foods in recent years. You seem to be ignoring this — it isn't carbs that are bad, it is something else." I'm not really

ignoring anything, Seth. There are many contradictions in the literature. Frankly, I haven't seen that many slim Japanese, for example. And when one controls for things like smoking, there probably isn't that much difference overall. For every Kitivan there is a Masai. And no one really knows why there are obesity epidemics in those places (my guess is increased SUGAR consumption), as well as in our own backyard. People are busy looking for solutions, but I seem to have found mine. And it doesn't include sugar. Seth: You're ignoring that there are plenty of examples of people being quite healthy and slim on a high-carb diet. Although the Japanese are not incredibly slim today, they were exceedingly slim as recently as 20 years ago. On a high-carb diet. I have no idea what "contradictions" you are referring to, the slenderness of Japanese was obvious to anyone who visited Japan. As was the fact that they ate lots of rice. Moreover, they stayed thin without weighing themselves daily and adjusting their diet according to what the scale said. Perhaps they were controlling their weight in a better way than you are. I agree, Japan today is different.

Leila (2014-01-09 18:54:04)

FWIW, I went low carb in 2010 & quickly lost about 45 lbs. I stalled at that point, never did lose any more weight although I am well over my target (yes, it's quite reasonable). I stayed on the diet diligently (using my carb counter) for several more months but no luck. I understand this is fairly common in the low carb community. I continue to control carbs & most of the weight has stayed off, which is nice. But shortly after I stalled (spring 2011) I started experiencing some worrying effects that cannot be explained by anything other than diet as that was the only thing that I had changed. I developed what appeared to be keratosis pilaris on my back, arms & legs that is mostly resolved now that I've added back some carbs. My hair also started falling out and it still is. In my experience, a low or controlled carb diet might be one way for some people to lose weight. But it isn't effective for everyone and can have drawbacks. I agree that there is likely some other mechanism at work. Returning to the topic of honey, I've been taking a tsp or so nightly of an unpasteurized locally-produced product. Sometimes it improves my sleep and sometimes not so I'm going to experiment with the dose, maybe added yogurt, maybe try fermented, etc. I do find that the almost daily headaches I usually have upon waking are not entirely gone but are much less painful since I started the honey. I'm not particularly patient & often try several things at once, so that might not be what did it, but I'm thankful. I also enjoyed the 2013 year in review post. I started chewing xylitol gum the other day & find almost no plaque on my teeth any more. Nice! I'm giving it more time to see if it helps my mouth & tongue. The dermatologists all have differing diagnoses, of course. I may try spraying some on my head just in case one of them is right & it really is lichen! I've become a big fan of personal experimentation since I started reading this blog. Thanks Seth!

Joe (2014-01-09 20:25:40)

Seth: "You're ignoring that there are plenty of examples of people being quite healthy and slim on a high-carb diet. Although the Japanese are not incredibly slim today, they were exceedingly slim as recently as 20 years ago. On a high-carb diet. I have no idea what "contradictions" you are referring to, the slenderness of Japanese was obvious to anyone who visited Japan. As was the fact that they ate lots of rice. Moreover, they stayed thin without weighing themselves daily and adjusting their diet according to what the scale said. Perhaps they were controlling their weight in a better way than you are. I agree, Japan today is different." Seth, I really wish you'd stop telling me what I'm ignoring. I have admitted, several times now, that there are people who do fine on a high carb diet. BUT I'M NOT ONE OF THEM. That is, I don't care how the Japanese control their weight. I care about MY WEIGHT, not the Japanese's. I was stationed in Japan in the 60s. I saw many fat Japanese. They ate mostly fish, veggies and fruit (not so different from what I eat. Plus a little rice and tofu. What I noticed most was the very small size of their portions, which appeared to be a cultural thing. Kitivans stay thin and healthy eating a lot of carbs. The Masai stay thin and healthy eating essentially no carbs, just meat and milk. Contradictions, no? You also seem to think that weighing myself daily is some kind of hassle. It's not. I also take my BP almost daily. When I exercise, which I do almost daily, I also time myself, count reps, measure distances, etc. Again, they are not hassles to me. They are just a part of my daily routine. No spreadsheet or statistical program necessary! Why can't my personal success, doing it my way, be just as relevant as any other person's way? It's almost as if you've lost faith in your own axiom, i.e., the importance and significance of PERSONAL EXPERIMENTATION, at least when it comes to me. I just don't get it. Seth: I think it's a good idea to look at what works for other people, in addition to self-experimentation. My self-experimentation would have gotten nowhere if I didn't pay great attention to what worked for other people. Nowhere did I say your personal success is irrelevant. Nor do I think that. I'm not ignoring your success, I'm wondering about how ideal it is. And what caused it. Surely those are topics for discussion? Especially because you are doing

something very popular (low-carb). I keep bringing up what you're ignoring because you keep ignoring it ("I don't care how the Japanese control their weight") at the same time you say you aren't ignoring it ("I'm really not ignoring anything")...forgive me. For all I know you have a good reason for ignoring how the Japanese control their weight but doing so goes against everything I've learned.

Joe (2014-01-10 10:21:41)

Seth, you're still not understanding me. And that's probably my fault. But I'm game-bred, so I'll keep trying. Yes, "I don't care how the Japanese control their weight." But that doesn't mean that I've ignored them. Just like I haven't ignored all the other populations. The Kitivans, Massai, Inuit, etc. Heck, I've been studying them at length for many years, trying to figure it out. The one thing I have actually learned from all this is: there are many ways to skin a cat! And nobody can really explain why any of them work to keep the pounds off, live healthy lives, etc! And that includes you, Seth! What I keep saying here is that I have found a way to lose weight, keep it off, and enjoy a healthy and fit life. It's the only way that worked for me. I tried most of the others and they didn't work for ME. They obviously have worked for others. But I don't really care what works for others, I only care about what has, and is, working for me. Yes, it's a good idea to look at what works for others, if only to figure out why/how something worked. But again, that doesn't appear to be what we are doing here. It seems like you're saying that because the Japanese can eat lots of carbs and stay healthy, I can too. Well, for the gazillionth time, I CAN'T. I've tried doing that. I know what happens to ME. No, I don't know why that happens to me, and neither do you know why it doesn't happen to the Japanese. So you're asking me to explain something that you can't even explain yourself. Is that really fair? Look, my way (low-carb/paleo) has also worked for countless others who have really given it a try. The internet is littered with similar success stories. Sure, there are failures, too. I have no idea why some fail and some don't. I do know why certain people I know have failed, and then got back on track. I've seen many fat Japanese too (and so have you), and can't explain why they didn't get the secret memo that apparently tells the Japanese how to stay fit and healthy. Neither can you. So Seth, I'm not ignoring anything. "My self-experimentation would have gotten nowhere [too] if I didn't pay great attention to what worked for other people." I.e., I found a way that worked for me while watching what worked for others. Just like you, Seth! It just wasn't the same way. And now that I have, why should I look for yet another way? This way has already made me into a fit and healthy human being. I'm willing to work at the edges, say, by trying a teaspoon of honey at bedtime. I've tried that once already, and it didn't work. I'll try it again (while avoiding bananas, as we discussed), and make it a longer trial. Whether it works or not, that little bit of honey at bedtime won't cause me to substantially jeopardize my usual way of eating. But I'm not going to just cannonball into the deep end of the carb pool. That just ain't gonna happen. Nosirree Bob. 🤔🤔🤔🤔🤔 Translation: Experience is the mother of wisdom. :)

## Interview with Mr. Heisenbug (2014-01-07 05:00)

Although the blog [1]Mr. Heisenbug ("Respect the microbiota") is quite new, I have learned a lot from it, especially about the importance of fiber. I interviewed the blogger:

SETH Tell me about yourself, such as your background relevant to your blog.

HEISENBUG My name is Shant Mesrobian. My professional/academic background has no relation to the content of the blog. My background is in tech/politics/publishing. The blog is just a side hobby and is produced from independent research. (I'm a "non-expert" as you might call it.)

SETH When did you start your blog? What led you to start it? Have you blogged before?

HEISENBUG I started the blog about a month ago. I have not blogged before. I started it because the topic interests and excites me a lot. I anticipated a surge in microbiome experimentation and "hacking" and felt I could help direct that conversation in a productive direction. In digging through the research, there seemed to be a lot of dots that needed connecting.

SETH What do you mean, "dots that needed connecting"?

HEISENBUG Certain clusters of bacteria, and certain mechanisms (butyrate production, endotoxemia) kept surfacing in the studies I came across. For instance in the smoking post, it was sort of staring at you in the face that smoking clearly reduces levels of bacterial groups that are implicated in health and disease. Yet the study didn't seem to find that interesting, so there was a gap that needed to be filled. But the pattern could only be detected by someone who reads a bunch of disparate studies. Same with the obesity/transplant study – many people are trying to help themselves because they vaguely know that potato starch can elevate butyrate (perhaps not even that much) – so here is a study showing directly that a different microbiota can achieve that, and it is particularly by elevating levels of bacteria that I had previously implicated as being prime starch degraders + butyrate producers. It's been a series of eerie coincidences that has kept me posting material.

In general, I think there is a bit of an information gap about how to alter gut biota – there isn't a real understanding of what "fiber" is.

SETH What do people fail to understand about fiber?

HEISENBUG First, that fiber is an overly broad and useless term. The only definition you can assign to the term is "a food that, when consumed, is not digested and is transported directly to the large intestine." But what happens to the fiber when it gets there is completely dependent on what type of fiber it is. The type of fiber most people are familiar with is the mechanical kind that is just a bulking agent. Insoluble. No fermentation or microbial impact. Comes out the other end. The fibers we're interested in are the bioactive type that are not only fermentable by gut bacteria, but preferentially fermented by good, commensal bacteria. But this isn't what people think of when they hear "fiber."

The other thing that's not understood is that fiber can make a significant impact on the microbiome. People are just very primed by the germ theory aspect of bacteria – that they're "bugs" you have to "catch." So while people have begun to accept the idea that there are good bacteria that you want, the understanding is still very stuck in the "you have to eat the bacteria to get good bacteria." I'm a big fan of fermented foods (making & eating), but I don't believe it's the primary way to tend to one's microbiome.

SETH How have your ideas/beliefs about fiber changed over the years?

HEISENBUG I currently consume a paleo/ancestral type of diet. Before then, I regarded fiber as most people do: a necessary, functional component of food that you need in order to "stay regular". I sought it out mostly from whole grain foods. I did not realize there were different types of fiber, or that they had anything to do with gut flora.

Then, when I went paleo, I adopted the general paleo attitude toward fiber: fiber comes from grains and grains are bad, that fiber is an unnecessary bandage that covers up for a bad diet, and that good digestive health can be had by simply eating nutritionally dense, non-toxic foods that people are evolved to eat. Fermented/probiotic food being a helpful addition.

Then I came to my current position once I learned more about the microbiome. What I've realized is that while paleo/ancestral eating goes a long way toward correcting the modern standard American diet, it still retains one common feature with it (at least in the way most people seem to practice it), which is that it focuses primarily on feeding the upper GI, while starving the lower GI (ie, your large intestinal microbiota).

And the ironic twist is that by dropping wheat, paleo may in fact have LESS fermentable fiber than the standard American diet. That's because, while it contains mostly insoluble fiber, wheat does contain a small amount of

fermentable fiber, which means that wheat constitutes the primary source of fermentable prebiotic fiber for the average American. So drop wheat, and you probably just lost your predominant source of fermentable fiber for your gut flora.

SETH The most interesting idea I've seen on your blog is that [2]smoking is associated with heart disease (and other diseases) because it reduces microbial diversity. Because of this idea, I've become a lot more interested in fiber. Is this your idea? As you say, because smoking is such a big risk factor, it is a good place to start to understand heart disease (and other diseases). What are other explanations of why smoking is such a big risk factor?

HEISENBUG I've never seen anyone else make the connection between smoking -> microbial diversity -> heart disease. Smoking's high ( #1) correlation has always intrigued me, especially since there have never been solid explanations for it. Separately, I've been reading about endotoxemia-induced inflammation and its effect on chronic metabolic disease. So when I came upon this study, it was sort of a smoking gun.

As I said, the explanations for smoking being a big risk factor, if you really read them, aren't saying anything. They are generalities. "Smoking contributes to heart disease because it contributes to atherosclerosis." Well of course. Atherosclerosis IS heart disease. The question is how? Smoking raises LDL cholesterol. Ok, but how?

The inflammatory cascade that results from loss of microbial diversity, a bloom in "bad" bacteria, and a decrease in "good" bacteria, is an explanation for all of those.

SETH Could the importance of fiber explain [3]that famous failed beta-carotene trial? There had been plenty of correlations between beta-carotene and better health. Yet in an experiment, people taking beta-carotene if anything did worse than the control group. Maybe beta-carotene consumption was a marker for fiber (e.g., people who ate more beta-carotene ate more carrots).

HEISENBUG If the epidemiology that inspired the trial was based on high carrot consumption, then I think that's definitely a possibility – carrots are fairly high in pectin, a type of fiber with decent prebiotic activity. But since the trial subjects did even worse than placebo, I find another explanation convincing – that unusually high doses of beta-carotene, which is a precursor to vitamin A, blocks actual Vitamin A.

SETH Has your better understanding of fiber improved your own health?

HEISENBUG My health is already pretty good, and I think I'm probably too young for metabolic and chronic disease symptoms to make themselves evident, so I "unfortunately" can't report on those types of markers. So for me this is all preventative at the moment. And I have yet to experiment with some more potent, high-dose prebiotic sources. I plan to soon. But I have noticed a significant improvement in sleep and a next-day feeling of well-being, relaxation, and clarity after a day when my fiber intake is higher and I consume yogurt cultured with lactobacillus and bifidobacteria, and I suspect it has something specifically to do with the bifidobacteria. That's just a hypothesis now and something I'm currently exploring on the blog. Figuring out the ideal sourcing, combination, and amount of fiber is really still a work in progress as far as I'm concerned. There's no real handbook, and people are just starting to figure all of this out. Lots of people experimenting with resistant starch (in the form of potato starch) are reporting dramatic stabilization in blood sugar and weight, digestive improvements, and greatly improved sleep. I'm hoping that a lot of personal experimentation and self reporting, combined with gut sequencing services like American Gut and uBiome, will get us closer to figuring it out.

Charlie Currie (2014-01-07 10:03:16)

Thank you. I've been following Mr. Heisenbug's very interesting blog and wonder who this was.

Kelly B (2014-01-07 11:49:27)

Absolutely fascinating - I've added another blog to keep an eye on. Thanks!

JM (2014-01-07 13:05:34)

Great interview Seth. I had found his blog (probably from a link here?) and only begun to read through it but it looks fascinating. Improving gut health is looking more like a new year's resolution for me.

Kirk (2014-01-07 14:46:18)

This is a great interview, Seth, thanks. @MrHeisenbug, thank you. I hope you have time to answer several questions. 1) You say that honey is rich in scFOS. How does one determine which foods contain decent prebiotic capabilities? 2) I find that a rounded teaspoon of honey, taken just before bedtime, significantly improves my sleep. Does that contain enough scFOS to alter the microbiome? 3) What is the transit time, from ingestion to when scFOS starts to be fermented? I know that my sleep is improved by the 3-hour mark, because that's when I historically have woken up from my initial sleep. On the honey protocol I sleep deeply until the 5-hour mark. So whatever it is in honey which makes me sleep better, it is being used by the body/mind within 3 hours. 4) Others suggest it is the sugars in the honey which cause the improved sleep. Or perhaps some of the other 200+ factors in honey. Can you suggest designs for experiments which would tease out the true causes of improved sleep? For example, ingesting a certain type of sugar, or ingesting an isolated fermentable fiber. 5) How long do prebiotics stay in the gut? Are they consumed within a 24-hour cycle or do they stay around longer? So could somebody eat a food with scFOS one day and it would not only improve sleep that night but the next night as well? In conclusion, many thanks for bringing your knowledge and enthusiasm to this fascinating subject.

Grace/Dr.BG (2014-01-07 16:52:50)

Hi Seth and Heisenbug (love your name!) The famed NEJM beta carotene was a failure in not just that trial but ALL synthetic Lurotin beta-carotene trials like HATS, Physicians health, and CARET. It is factory made from benzene petroleum derivatives by the chemical company BASF AG. These are not bio-identical to mammalian receptors. The fact that synthetic non-bioidentical hormones like PROVERA in the Women's Health Initiative where record numbers of women died of strokes, cancer and heart risks are inherently dangerous cannot be overstated, I think. Natural, food-based carotenoids are not only safe but extremely efficacious. <http://www.ncbi.nlm.nih.gov/pubmed/24141200> <http://www.jonbarron.org/article/phs-ii-vitamins-e-c-beta-carotene-and-cancer-0#UySmNIW1r0> Great post and interview! Seth: Thanks. That's a good point. Which I never heard Bruce Ames make.

Stuart King (2014-01-07 18:20:09)

Mr Heisenbug have you considered that the differences in bacterial groups in smokers are due to other causes rather than cigarettes? Smokers may not be as health conscious and may be less likely to eat vegetables for example. Perhaps the positive changes in microbial composition after smoking cessation may be due to other lifestyle changes (improved diet). Quite often smoking cessation is accompanied by an overall effort to improve health in other ways also. I would be interested in seeing the microbial composition of someone who ate more like Michael Pollan but smoked regularly.

Heisenbug (2014-01-08 08:12:51)

Kirk, Foods high in fermentable prebiotic fiber are pretty easy to find provided you know what to look for. Fructooligosaccharides/inulin/resistant starch/mucilage/pectin is a good list and should direct you to plenty of foods. Honey contains many

oligosaccharides that have all been shown to have prebiotic activity. The FOS in honey (kestose, nystose, inulobiose) are among those. The oligosaccharides are formed from honey's simple sugars by the activity of enzymes provided by bees. The amount of fermentable fiber in a teaspoon of honey would be well below 1 gram. If honey has outsized prebiotic activity, it is likely due its unique combination of oligosaccharides. Trying to isolate/duplicate this somehow in an experiment would be quite difficult outside of a lab setting. But I still think it would be worthwhile to test for a prebiotic effect, and a pure formulation of FOS would probably be the closest substrate (something like: <http://www.amazon.com/NOW-Foods-Nutra-Flora-Ounce/dp/B0002JIXLM/>). I guess coincidentally, the 3 hour mark is probably a good general marker for when you'd expect fermentation to begin. That's when the small intestine would be mostly emptied, and this is also confirmed by breath tests which test for malabsorption and small intestine bacterial overgrowth. The cutoff for these tests is 2.5 to 3 hours - anything detected before then is considered premature fermentation. After 3 hours is considered to be normal colonic fermentation. Among fibers, oligosaccharides/FOS are known to ferment very rapidly and preferentially.

Heisenbug (2014-01-08 08:17:26)

Stuart, The smoking study did not just pick random people off the street who had already quit smoking. It was a controlled cessation study. Your second point is a good one. I too wonder if certain dietary or other factors are protective from smoking's microbial impact. After all, tobacco smoking is ancient and has existed for a long time. But the very high levels of the diseases it is strongly associated with are not.

nicole (2014-01-08 18:03:46)

Great post/interview. A few things. I know that people who have heart problems are required to take antibiotics before having dental work...I assume that there are some studies out there showing the connection between these two problems. Might make for some good reading/future posts on Heisenbug. This might also help confirm your theory about heart disease, bacteria, and smoking. Also to Kirk, because I have a toddler at home, I have learned more than I wanted to know about sleep cycles. The three hour mark is the end of a typical sleep cycle. I am wondering if something at 3 hours is waking you up because that is when you are most wake-able...Conversely, I am wondering if the honey somehow extends the sleep cycle to 5 hours making everyone more rested.

Adam (2014-01-08 20:06:23)

Mr. Heisenbug, I searched here & over at your blog & didn't see anything about Lactulose. There's a neat review over on SuppVersity you might find interesting: <http://suppversity.blogspot.com/2014/01/supplement-review-lactulose-isomerized.html>

daz (2014-01-09 03:55:18)

from that suppversity post, "There is "natural" lactulose in milk: Due to the fact that lactulose can be produced by the heat-induced isomerization of lactose (see inset in figure to the left for a reaction curve for milk that's heated at 130°C), all varieties of heat treated milk, even the low-temperature pasteurized variety will contain a certain, albeit low amount of lactulose (see figure to the left)" warm milk before bed anyone...

Heisenbug (2014-01-09 07:34:58)

Adam, Lactulose is definitely shown to be potentially prebiotic/bifidogenic. In fact, it's what they use in those breath tests I mentioned in the comment above. My only issue with it is that it's not really something found in food. It's commercially produced from lactose as a food ingredient and for medical purposes. As the article says, you can find lactulose in milk, but only because of the pasteurization process. As such, I don't see a reason to go out of one's way to obtain lactulose (it isn't very practically obtained) when there are other good options that have more of a basis in human dietary patterns. Daz: I was just thinking that myself.

Kirk (2014-01-09 11:29:31)

I was talking with a friend about using honey. He said that several years ago he asked his Avurpedic physician how to improve his sleep. The physician said to drink warm milk with honey just before bedtime. Seth: very interesting!

Gabriella Kadar (2014-01-09 16:23:14)

Heisenbug, I wondered why UHT milk in Tetrapacks tastes different, sweeter, than regular milk. Also it is a bit of a quandary: some moderately lactose intolerant people report that they can consume SOME UHT milk without catastrophe. I suppose eventually the laxative action of the lactulose will get them if the lactose doesn't again depending on volume ingested.

daz (2014-01-14 21:41:10)

hi Mr. H, i was just looking at an old list i quickly put together quite a while back, in the doc i listed fibres that i did not want to go looking for ie. may be best for me to avoid. & fibres that probably worth getting ie. may be good for me. i should clarify that at the time i probably put things on the 'avoid list' if i read some 'bad press' about it...eg. low fodmap diets? anyway at the time, my list went like this, 'avoid/bad': Insoluble (roughage), FOS, fructan, Inulin, 'good': RS (resistant starch), Pectin, GOS?, the list is likely way over-simplified, if it makes any sense at all...? anyway just wondered if you may have some sort of list of your own, possibly ordering 'good' to 'bad' dietary fibre. &/or comment on my list. i seem to recall at the time that pectin look interesting, & i was already on the RS 'bandwagon'. not sure why i thought GOS may be a good one.

Heisenbug (2014-01-15 10:42:03)

Daz, The only reason to actively avoid any specific type of fiber, as far as I know, is if you have a specific intolerance for it and it gives you gastrointestinal problems. Even insoluble fiber isn't necessarily "bad." But it can come in a package, like wheat, that may give you separate issues. The only reason you'd put FOS or Inulin in the "avoid" bucket is because they are both fructans and belong to the "FODMAP" group – types of carbohydrates that some people do not absorb properly and thus experience gastrointestinal issues. The "FODMAP Diet" is specifically designed for those people. In this case, I think GOS would probably have to be on that list too. The question in my mind about this is that, since that kind of intolerance may be caused by small intestine bacterial overgrowth (ie, fermentation happening where it shouldn't), then presumably any type of fermentable fiber would be an issue, not just FODMAPs. Also, I'm curious as to whether FODMAP intolerant people have a problem with FOS, since it's shorter chain and known to cause less issues than something like inulin. For now, only your personal experimentation can answer these questions.

daz (2014-01-15 21:25:55)

thx for taking the time reply H, i do not have any 'fodmap' issues (afaik), so that makes my life easier...

Charles (2014-01-18 14:17:09)

One of the best, if not THE best source of resistant starch (RS) is potato starch. It's almost pure RS, with no additional carb effects. Bob's Red Mill Potato Starch is the one most people are now using to get more fermentable fiber. Most natural food sections have it, or you can get it on Amazon. Note: it's NOT simply potato flour. It's potato STARCH. Potato flour is just dried and powdered potatoes. It contains almost zero RS. A few hundred people have been experimenting with it, to almost universal positive effect. Check out the Free the Animal blog to get some more info. There are dozens of posts and hundreds of comments. Unnecessary disclaimer: I don't work for Bob's Red Mill :=)

## **Mars Corp. Won't Tell Me the Flavonoid Content of Dove Dark Chocolate (2014-01-08 05:00)**

Via a website, I asked about the flavonoid content of Dove dark chocolate. In China, a package of Dove dark chocolate has a picture of a heart – meaning the food is "heart-healthy". [1]The heart benefits are believed to come from flavonoids. Mars has been exploring this idea in various ways, such as [2]this special process and [3]these special chocolates.

An email from Mars said I should call a hotline. The woman who answered did not know what flavonoids are. "Do you want to know the cocoa content?" she asked more than once. No, the flavonoid content, I said. She looked. "We don't have that information," she said. Haha!

I said the flavonoids in chocolate are believed to be responsible for the health benefits of chocolate. (That's true, but I might have said [4]flavanols – a type of flavonoid – instead of the much broader term flavonoid.) "We don't make health claims for our chocolates," the Mars representative said. (As if a picture of a heart on a package is not a health claim. No doubt there is an important difference between US and Chinese law.) [5]I can see why she would say that. Our brilliant government, protecting us from crazy ideas such as chocolate and yogurt are healthy, but not from the [6]exaggerations of doctors and drug companies. Which is more dangerous, (a) eating chocolate or yogurt or (b) being cut open?

---

Nick (2014-01-08 06:39:09)

Oo. That's even more annoying than when Dove labels it as "dark chocolate" without specifying the percent cocoa.

Matt (2014-01-08 06:52:42)

Hi Seth, Love the blog. Just wanted to let you know that the link at the bottom (<http://blog.sethroberts.net/2013/12/30/man-beats-prostate-cancer/?preview=true>) is broken. Regards, Matt. Seth: I fixed it, thanks.

dearieme (2014-01-08 09:00:42)

Being cut open by someone who's eating chocolate.

Mark (2014-01-08 12:21:25)

"hey, you got chocolate in my gall bladder"... sorry, you have to harken back to the old Reeses' peanut butter cup commercials...

anon (2014-01-08 14:05:28)

Seth, Not relevant to the post, sorry: I'm a teacher, and I'm looking for any websites/books/resources regarding experiments that teachers have done independently in their classrooms to improve test scores, student satisfaction, etc. I'm looking for a sort of "quantified classroom" approach I guess. I like to consider myself science-minded, but when I thought about implementing experiments in my classroom, I wasn't sure where to start. If you have any thoughts or could make any suggestions through a post, comment, or e-mail, I'd appreciate it.

TomGinTX (2014-01-09 21:40:04)

Be worried if someone is eating Junior Mints while observing your surgery.

Christian Kleineidam (2014-01-10 06:24:19)

@Anon Teacher: What do you teach? One of the thing were quantified self works well if it's about something you are interested in. You might just ask your students. One the one hand we could do boring stuff in class. We could also do cool experiments. If any of you has a good proposal for an experiment we will do it. Then have a genuine discussion with your students about their ideas and see whether you can lead them to something that makes a good experiment.

anon (2014-01-11 07:58:26)

I teach English as a Second Language (ESL) to adults. One idea that crossed my mind is having students vote on enjoyment/engagement following an activity using their smartphones--there are sites that allow you to tally/analyze data from such votes. I do interest inventories with my students, as you suggested, and they are great. Good suggestion. We don't run experiments per se, as it's not a science class, but I'm rather free to direct content toward student interest so this idea is still useful. Thanks for your thoughts.

## **Reaction Time as a Measure of Health (2014-01-09 05:00)**

Six years ago I started using a reaction-time (RT) test (a test where you press a key in response to something as fast as possible) to track my brain function. I took the test daily. It must use only a small part of the brain but I assumed that something that made me faster would probably improve overall brain function. Behind this belief, which I call better RT, better brain, were countless studies of brain anatomy and physiology, which had shown that neurons and glial cells all over the brain share many features. Cells in different parts of the brain are much more alike than different. More support for this assumption was that [1]certain doses of flaxseed oil improved both RT and other measures of brain function, such as balance.

I also assumed that changes that improved RT would probably improve overall health – what I call the better RT, better body assumption. It was less plausible than the better RT, better brain assumption because the cells in different organs of the body differ so much. They have many similarities but also many differences. I believed it for two reasons. (a) Flaxseed oil not only improved several measures of brain function, it improved my gums, no doubt because it reduced inflammation. It had been far from obvious that improving gums was so easy or that flaxseed oil (in the right dosage) would do so. The assumption better RT, better body had made a surprising prediction, you could say, that turned out to be true. (b) The brain gets much the same blood as the rest of the body. (Not exactly the same, because of the blood-brain barrier.) In the same way, all plug-in electrical appliances use the same house current. Just as all appliances have been designed to work well with that current, all our organs should have been shaped by evolution to work well with same mix of nutrients. You can't feed your brain differently than your heart.

When I discovered that [2]butter improved RT, the better RT, better body assumption made a second even more surprising prediction: Eating more butter improved my health. This contradicted the claims of all mainstream health experts, who say saturated fats cause heart disease. I stuck with my assumption – I still eat a lot of butter. The data I've seen since then has supported my conclusion. For example, [3]my Agatston score got better, not worse, after a year of eating lots of butter. The Agatston score is currently [4]the best predictor of heart disease.

I recently found more support for the better RT, better body assumption. Several studies have found that RT is a good predictor of health (better RT, better health). Even more impressive, it is a better predictor than many of the predictors we already know of. The RT test used in these studies is close to the test I now use, which I developed independently. The RT test in these studies involves showing a digit (0-4), after which the subject presses one of five keys (labelled 0-4) as fast as possible. My current RT test is very similar but uses 7 digits instead of 5.

[5]A 2005 study looked at the oft-reported correlation between higher IQ and lower mortality. The IQs and RTs of about 900 persons were measured in 1988. Deaths until 2002 were noted. RT was associated with lower mortality, even after taking out associations with smoking, education and social class. RT and IQ are correlated (better RT, higher IQ). When the RT-death association was removed, IQ no longer predicted death. So RT does a good job of capturing whatever it is about IQ that predicts mortality.

[6]A 2009 study compared RT to more conventional health predictors ("risk factors"). About 7,000 subjects were followed from 1984 to 2005. RT in 1984 was a good predictor of all-cause mortality compared to classic risk factors.

Smoking was by far the best predictor, followed by RT. RT was a better predictor than physical activity, blood pressure, a questionnaire measuring "psychological distress", resting heart rate, waist/hip ratio, alcohol intake, and body mass index.

[7]A third study, based on the same subjects as the 2009 study, found that amount of decline (slowing) in RT (from one test to a second test seven years later) predicted death. People with more decline were more likely to die.

All this supports studying how your RT is controlled by your environment, especially what you eat. You have to choose wisely what to study. The point is not to be as fast as possible regardless of everything else. Lots of drugs (stimulants, such as caffeine) decrease RT for short periods of time. I doubt they improve health. (If they harm sleep, they probably worsen health.) What makes sense is to look for two things: 1. Poisons. Things that slow you down. [8]I discovered that tofu did so. I gave several reasons for thinking that tofu affects many people this way, not just me. Billions of people eat tofu, unaware of this possibility. 2. Deficiencies. Study things that are missing from your life now but were likely to be present when we evolved. It is quite plausible that our ancient ancestors ate more omega-3 (in fish, but also in flaxseed) and more animal fat (from big animals, but also in butter) than we do now. My data suggest omega-3 and animal fat are nutrients necessary for health whose importance mainstream nutrition researchers have not fully appreciated.

My RT data have shown me there's a lot I didn't/don't know about how my food affects me. Maybe everyone can say that. Unlike almost anyone else, however, I can reduce my ignorance myself. [9]I don't need to rely on experts.

Dirk (2014-01-09 05:11:24)

Hi Seth, which tool do you use to measure RT?

sam (2014-01-09 05:36:18)

I've been thinking about trying RT tests for a Long time now. As far as I remember you show calculations and have to enter the last digit of the result? Or do you have a plain reaction test now? Seth: The test I use is what psychologists call a "choice reaction time" task. See a digit, type that digit.

Mehmet (2014-01-09 06:41:44)

I did not know there was such a strong correlation between overall health and reaction time. That was very interesting. Measuring brain function is certainly easier than measuring your liver function :) Regarding the RT test, I have a similar question with sam. Have you changed the test from a simple arithmetic test to a digit retyping test? Previously, I coded another version

of your simple arithmetic test. I started experimenting with it but I saw that trying to be fast reduced the accuracy of my results. I accepted a maximum 4 errors in 30 questions for the experiment to be valid. However, there is a significant difference in trying to make zero errors and allowing a margin of four errors. In a digit retyping test, I think it maybe possible to be more accurate and reduce the margin of error. In the end, if you spend enough time, it seems to me that simple arithmetic test boils down to a digit retyping test.

Jeff Winkler (2014-01-09 08:36:22)

That's really interesting. Remember in Eat, Fast where they did the balancing and ruler drop tests? Backs up your thesis (though Mosley did not re-test those measures after the intervention) What I find fascinating about your RT tests is that they're sensitive cheap and quick, with lots of longitudinal data. So you use them like a tremor detector. Signal detection. That turns up things like soybeans. Seth: I remember those two tests only vaguely. I will watch it again. I agree, my RT tests are sensitive cheap and quick. And easy. Room for improvement: Less sensitive during learning period, comparisons across people a bit unclear (timing may depend on your computer), not especially accessible, speed/accuracy tradeoff a possible problem.

Ripken Holt (2014-01-09 09:00:38)

Is there a application online that could be used to test one's reaction time? I would like to test mine but do not have any knowledge of coding? Seth: I am distributing the reaction time test I use. If you are interested in using it, please contact me. It is not online, it runs under R.

as (2014-01-09 09:12:08)

This is off topic, but for flaxseeds, isn't phytic acid an issue? Or do you assume that if you have you have good results with regards to reaction time and dental health, the flaxseeds can't be harming you too much?

Nancy Lebovitz (2014-01-09 10:02:55)

Any thoughts about psychological(?) factors like ADD or hypervigilance?

Alex (2014-01-09 11:09:09)

Mehmet brings up a good question: Seth, in your testing, what do you do with wrong answers? Ignore, track separately, allow some number of them, just never make mistakes?

Alex (2014-01-09 11:18:09)

Nancy Lebovitz, the distractability and hyperfocus of ADHD are two sides of the same coin: impaired ability to \*direct\* attention. ADHD is badly named. It's not really attention deficit; it's attention-control deficit. It would not surprise me if attention control rose and fell with general brain function. I wish I had a dime for every friend who's told me, "My kid doesn't have ADHD; s/he can focus on a video game for hours on end."

Nancy Lebovitz (2014-01-09 13:00:14)

Hypervigilance isn't the same thing as hyperfocus. Hypervigilance is constant awareness of possible threats, and it's associated with PTSD and/or anxiety. <http://en.wikipedia.org/wiki/Hypervigilance>

Seth Roberts (2014-01-09 15:23:02)

to measure RT I use an R program I wrote myself.

Adam (2014-01-09 18:51:30)

Koanic Soul turned me on to this online arithmetic game: <http://arithmetic.zetamac.com/game?key=d10589f4> You can File > Save Page As to save it to your HD if you like

Mike Garcia (2014-01-10 09:31:31)

I would like for you to send me the test if you would? Thanks, Mike

GTR (2014-01-10 11:15:53)

Apparently in 19th century people had lower reaction times than today. More sleep perhaps? <http://phys.org/news/2013-05-victorian-era-people-intelligent-modern-day-counters.html>

Ian (2014-01-11 02:45:21)

An online reaction test can be found here. <http://www.humanbenchmark.com/>

Steve R (2014-01-24 20:01:04)

I'd think testing RT and tracking results would be a great app for a smartphone, but all I see are games, nothing that really keeps track of the times and could be used for research. Have you heard of anything for iPhone or Android?

Steve R (2014-01-24 20:10:34)

Just discovered this after leaving the above comment, there's some interesting stuff here, both some possible apps and some discussion about whether these devices are really usable for testing RT <http://cogsci.stackexchange.com/questions/506/are-there-any-cognitive-test-or-test-suites-available-on-the-ipad>

### **Man Beats Prostate Cancer Without Surgery (2014-01-10 05:00)**

[1]This story by investment blogger Mish Shedlock about a prostate cancer diagnosis illustrates the bias of doctors toward dangerous expensive treatments:

The biopsy showed I had cancer. My "Gleason Score" was 6. The surgeon who performed the biopsy *strongly recommended* surgery. He gave me a cost of \$20,000.

Bad recommendation. Shedlock got rid of his cancer, as measured by PSA (Prostate Specific Antigen) tests, without surgery or any other expensive or dangerous treatment.

The surgeon said something else also highly misleading. He told Shedlock he was "10 % cancerous". When Shedlock repeated this to his oncologist,

The oncologist replied "That's not correct. Of the 12 samples, only one had cancer and one was questionable. The cancerous sample was 10 % cancerous." Now that is a hell of a lot different than being 10 % overall cancerous.

His oncologist seemed unfamiliar with data:

I informed the oncologist that I was going to have a PSA test every month. He commented something along the lines of "Why do you want to do that? Every six months is sufficient. The tests are not that reliable." . . . [I thought:] The more unreliable a test is, the more tests one should take to weed out erroneous outlier results.

This reminds me of the dermatologist I had in graduate school. After I tested the two medicines he had prescribed for my acne, and found that one of them didn't work, and told him this, he said, "Why did you do that?" Haha.

The oncologist predicted that the cocktail that cured Shedlock "would not do [him] any good".

I am sorry Shedlock does not name the doctors involved, as [2]I did in a similar situation. I too avoided recommended surgery and my surgeon made highly misleading statements. Shedlock wrote about bad health care more generally [3]here.

Thanks to Steve Hansen.

Bill (2014-01-10 06:16:57)

Great story. I think he neglected one possibility, though: he had "cancer," as currently defined, but it went away on its own and would have even if he had never known about it in the first place. It seems clear this happens, maybe a lot. Until the biology and natural history of cancer are understood a lot better this raises questions about the wisdom of screening for "cancer." Another possibility is that he still has "cancer," which may or may not ever hurt him, but the latest biopsy samples didn't happen to see it. My sense is that especially as men get older if you only look hard enough (more biopsy samples) almost all of us may have "cancer." Autopsy studies support this idea. If you look less hard, fewer of us do. Same may be true of other cancers, including breast and thyroid. What a mess.

Xav (2014-01-10 07:23:40)

Reminds me of that Upton Sinclair quote : "It is difficult to get a man to understand something, when his salary depends upon his not understanding it!" I was Googling some of the supplements the author mentions in the linked post to see what benefits they have in general, and actually came across another interesting site where people with a different prostate disorder report their personal experimentation with various nutritional approaches. <http://www.prostatitis.org/itworksforme.html>

Jack (2014-01-10 11:25:40)

Most people do not realize what an evil scam is perpetuated by Doctors and how men are actually checked for prostate cancer. Samples of a mans prostate are taken. Then live Cancer cells are put on the man's healthy tissue samples. If the Cancer cells grow in the Petri dish or start to eat the man's healthy sample, the evil Doctors tell the man he has Cancer! Then they proceed to kill the healthy man with deadly radiation, poisonous and/or radioactive drugs or surgery. Since Doctors admit that they do not know how to cure Cancer, why in the world would people trust them at all? There is a Natural cure for everything! You wouldn't go to a person to fix the transmission on your car if the person admitted they couldn't fix it! The lab technicians put Cancer cells on your cells and then say you have prostate Cancer! That's outrageous! If a man's prostate hurts, it's probably from ejaculating too often. Avoid sex and masturbation for a few days. In addition, two saw palmetto capsules taken with two thistle capsules once a day if you are hurting plus sitting down when urinating until you're back to normal will be extremely helpful in most cases.

Jeff Winkler (2014-01-10 11:34:23)

understatement: "misaligned incentives that reimburse more for treating rather than monitoring"

## Joseph Biederman is Still at Harvard (2014-01-11 05:00)

Joseph Biederman is a professor of psychiatry at Harvard Medical School. It makes a certain sense. According to [1]Wikipedia, in 2007 he was

the second highest producer of high-impact papers in psychiatry overall throughout the world with 235 papers cited a total of 7048 times over the past 10 years as determined by the Institute for Scientific Information.

And he has won several awards:

Biederman was the recipient of the 1998 NAMI Exemplary Psychiatrist award. He was also selected by the Massachusetts Psychiatric Society Awards committee as the recipient of the 2007 Outstanding Psychiatrist Award for Research. In 2007, Biederman received the Excellence in Research Award from the New England Council of Child and Adolescent Psychiatry. He was also awarded the Mentorship Award from the Department of Psychiatry at the Massachusetts General Hospital.

But there's also [2]this:

Biederman had pioneered the diagnosis of bipolar disorder in children and adolescents, a disorder previously thought to affect only adults. One of the world's most influential child psychiatrists, Biederman's work led to a 40-fold increase in pediatric bipolar disorder diagnoses and an accompanying expansion in the use of antipsychotic drugs – developed to treat schizophrenia and not originally approved for use in children – to treat the condition. However, Biederman and his colleagues Spencer and Wilens failed to accurately disclose the large consultancy fees they were receiving from pharmaceutical companies that make antipsychotics whilst conducting this research.

For which Biederman received a slap on the wrist from Harvard.

And there's [3]this:

Dr. Biederman pushed [Johnson & Johnson] to finance a research center at Massachusetts General Hospital, in Boston, with a goal to “move forward the commercial goals of J. & J” [said Biederman in an email]

In other words, he felt no shame in admitting that he considered the commercial goals of Johnson & Johnson more important than the health of children with severe problems. One of the few people who can really help these children – by doing good research – he preferred to help Johnson & Johnson.

2. [http://blogs.nature.com/news/2011/07/harvard\\_scientists\\_disciplined.html](http://blogs.nature.com/news/2011/07/harvard_scientists_disciplined.html)

3. <http://www.nytimes.com/2008/11/25/health/25psych.html?ref=josephbiederman&gwh=C3A62AB351690D33D898CAE714EA391E&gwt=pay>

---

Alex Chernavsky (2014-01-11 06:39:49)

Biederman and his cohorts brought great harm on countless children and adolescents. Children who are diagnosed with pediatric bipolar disorder usually receive powerful psychiatric drugs that allegedly treat their "illness". In reality, the drugs cause brain damage that actually worsens the long-term outcome for those children. Robert Whitaker lays out the evidence in his outstanding book, *Anatomy of an Epidemic: Magic Bullets, Psychiatric Drugs, and the Astonishing Rise of Mental Illness in America* (the Amazon link is [1]here.) Anyone who takes psychiatric drugs (antidepressants, antipsychotics, anxiolytics, Ritalin, etc.) – or has a loved one who takes such drugs – should read the book. Seth: I hope someone writes a book about Biederman and his enablers.

1. <http://www.amazon.com/Anatomy-Epidemic-Bullets-Psychiatric-Astonishing-ebook/dp/B0036S4EGE/>

dearieme (2014-01-11 08:50:58)

Alas, being a famous university implies no absence of crooks, conmen, spivs, and chaps who sail close to the wind. Seth: No one word (such as "crook") does justice here. Because of Biederman's great influence, the good he might have done (but doesn't do), the targeting of young children, the bad health of these children to begin with, the involvement of drug ingestion . . . the noxiousness of it is monumental.

Alex (2014-01-11 15:32:10)

Seth, I couldn't agree with you more.

Ruth (2014-01-11 22:22:03)

We open our newspapers and see some monster who murdered a child and have a hard time understanding it. But the Biedermans out there are the real monsters. They have destroyed many hundreds and thousands of lives by setting a chain of events in kids' lives that lead to homelessness, institutionalization, suicide, or just a miserable, unhealthy life. I always wonder how people like this live with themselves.

Adam (2014-01-12 00:31:18)

But is he rich?

Kyle (2014-01-12 09:27:01)

He's relatively rich. According to this article he got paid " \$1.6 million in speaking and consulting fees" from drug companies. Do you guys have any good ideas in terms of leading a campaign against this guy?

Crystal (2014-01-12 19:17:13)

This came out of left field! From the headline, it seems like you expect his sacking, but there's no reference to anything recent that might justify it, or even what prompted you to write it. I went hunting through archives, and it was 2011 when you last had a post in him, so this one, failing to include any reference to the background of your previous posts, and with no actual update material in it, just makes you look as though you have some kind of vendetta going. Consider you previously made mention of comments by his lawyer, did you really expect that an institution like Harvard would risk drawing attention by turfing him out without very good cause? You're treading a very slippery slope here. Imagine the consequences if anyone's job could be put at risk by someone in the public domain calling for their head, and more so, over things that are long since past and which, presumably, they've given no indication is still their mode of practice? I fail to see any actual point for this article, I'm afraid, and it comes across as particularly emotionally driven. Not what I've come to expect of you, Seth. Seth: For money and/or career, Biederman has used – and is still using – his enormously powerful position to cause many thousands of sick helpless children to be given drugs that almost certainly damage them. He deserves this post and much more.

## Eggs and Insomnia (2014-01-12 05:00)

It isn't well known that eggs (large amounts) can cause insomnia nor that caffeine – in special cases – can reduce insomnia. But a reader named Baeo Maltinsky recently made [1]those discoveries:

Back around July 2012, I was trying to improve my diet but I didn't want to give up my vegetarianism, so I started to eat a LOT of eggs, usually in the range of 10 to 14 per day. Not long after, I started having awful insomnia. I could lie awake all night just unable to fall asleep. There were suddenly just too many thoughts buzzing through my head keeping me up. I assumed that it was a result of ketosis disturbing sleep. I tried reintroducing carbs, but when that didn't work I gave up on dietary modifications. I started cycling through OTC sleep aids, but I developed tolerance to anticholinergics very quickly.

By October 2013, I was going crazy. I couldn't sleep well. It was making me depressed and seriously impairing my academic performance. I was exhausted constantly, but then I noticed something. I slept better when I consumed a lot of caffeine in the morning. I noticed there was a clear dose dependent relationship between how much caffeine I consumed and how well I slept. I had a hunch that the caffeine was depleting my acetylcholine levels, serving a similar function as OTC anticholinergics like diphenhydramine and kava.

I wondered what would happen if I sharply reduced my intake of acetylcholine precursors. A lot of people advertise eggs as "choline packed", so I cut back to less than 3 per day. Suddenly, I was sleeping much better. Now, it could be something else in the eggs (I'm not really attached to my choline hypothesis), but either way I feel confident blaming them for my sleep troubles. My insomnia returns whenever I start eating them again.

I asked him why he hadn't realized earlier that eating so many eggs was the problem. He replied:

I just didn't think there was anything special about the eggs. I googled around for it and the only things I could find were about ketosis induced insomnia, so it didn't occur to me that eggs specifically were likely to be problematic. I tried consuming enough carbs to knock myself out of ketosis, but when that didn't improve the situation, I just assumed that something else was going on aside from diet. Eggs seemed like the perfect food. Cheap, nutrient rich, paleo, easy to prepare, and compatible with my (then) vegetarianism. It would have been hard for me to find a suitable replacement, so while the idea of testing it probably occurred to me, performing the test itself wouldn't be trivial and the results wouldn't be actionable.

As it got worse, I tried treating it more aggressively with OTC sleep aids, and that worked well enough that I stopped worrying about it. I wasn't sleeping great, but it was enough to get by. Eventually they stopped working, but not long after that I made the caffeine connection and decided to try removing eggs. It was easier to do at that point because I had given up on paleo and vegetarianism and could just substitute chicken and sprouted lentils, and I had a (probably incorrect) neurochemical explanation to support it. Moreover, it had become VERY difficult to eat the eggs. My body just didn't want to consume them and I had to slowly force them down. Something seemed to know it was bad for me, but I wasn't listening to the signs. My behavior was not at all rational, and believe me after I discovered eggs were the problem I was kicking myself for not trying it sooner.

I asked him what he learned from this, apart from how to sleep better. He replied:

1. Costly experiments sometimes need to be performed.
2. Sometimes your values are bad for your health.
3. Don't give up just because there's no evidence to support a hypothesis.
4. Simple things can easily go unnoticed.

Those are good lessons.

1. <http://blog.sethroberts.net/2013/12/11/sleep-summary-of-what-ive-learned/#comment-1163569>

---

dearieme (2014-01-12 05:54:35)  
He should have been eating quail eggs.

Mehmet (2014-01-12 07:57:59)  
Another lesson maybe: "too much of a good thing is bad" or "dose makes the poison".

Sentinel (2014-01-12 09:08:43)  
Fascinating re caffeine and eggs. Baeo - what time of day were you eating the eggs, and in what form did you consume eggs and caffeine?

Kyle (2014-01-12 09:22:18)  
I agree with Mehmet. I kind of question the idea about ketosis, because eggs have a lot of protein. What do people think about caffeine being beneficial because they help boost certain hormones?

David (2014-01-12 09:24:04)  
I'm a vegetarian and really like eggs, but can't imagine eating a dozen a day even for a single day. I guess my overall caloric intake must just be much less than his. +1 for what Mehmet says. Also "Meden agan" ("Nothing too much"/"Moderation in all things").

Brandon Berg (2014-01-12 11:25:19)  
Eggs only have about 60 calories each. In terms of calorie count, a dozen is a light meal.

Brandon Berg (2014-01-12 11:26:06)  
Got the math wrong. It would be an average-sized meal, not a light one.

Kevin (2014-01-12 11:54:23)  
The caffeine may have worked due to circadian rhythm amplitude, similar to sunlight or vitamin D in the morning.

gwern (2014-01-12 14:49:25)  
> It isn't well known that eggs (large amounts) can cause insomnia nor that caffeine — in special cases — can reduce insomnia. But a reader named Baeo Maltinsky recently made those discoveries: I see we're using an interesting definition of 'known'. I will point out that this would be very easy to do a blind self-experiment on: simply buy a few hundred grams of a choline like choline bitartrate or choline citrate (like \$10), cap it & some flour for placebo (< \$5), and do my usual concealed-containers trick. I can confidently predict that no one will do this, however, not even the OP who claims to be so confident...

Joe (2014-01-12 16:01:22)

I think there must be more to this story. Why would someone try to improve his diet by suddenly consuming 10-14 eggs daily? Where is it written that eating over a dozen eggs a day is a kind of improvement? Improvement in what way? To what end? He tried reintroducing carbs? Why would a vegetarian ever need to RE-introduce carbs? Don't vegetarians, almost by definition, eat a lot of carbs? Caffeine eventually helped him get to sleep? Really? In my opinion, there's too many moving parts, and also some major inconsistencies, here to hazard even a guess as to why he couldn't sleep, then suddenly why he could (what else was going on in his life at these times?), etc.

Jimmy (2014-01-12 16:08:31)

Interesting timing. I've recently come into a weird situation that requires me to eat a dozen egg yolks most days. My sleep has also been really out of whack in about the same time period, but there's enough other possible causes that I'm not sold on the egg thing yet. I actually have choline and gel caps on hand, so I might try that test eventually. However, first I'm going to try the more convenient (but less conclusive) test of piracetam to see if counteracting the extra choline improves my sleep. (I know piracetam helps me burn through choline because I've experienced and corrected for the other end of the spectrum before)

Don (2014-01-12 16:56:08)

I think it is in fact the choline (or phosphatidylcholine) in the eggs. I realized a couple years ago that eating eggs daily for breakfast caused me to experience a marked increase in shoulder and neck tension. I must be fairly sensitive to this effect, since I only ate 2 or occasionally 3 eggs per day. The light went on for me when I remembered that acetylcholinesterase inhibitor drugs can have shoulder tension as a side effect (sleep disruption as well.) These drugs raise acetylcholine levels, as I believe dietary phosphatidylcholine can do as well. Too much lecithin (presumably soy source) has the same effect on me.

Alex (2014-01-13 07:41:03)

This was a helpful clue, perfectly timed. One night last week I woke up at 3:00 and my preteen daughter woke up at 4:00. It's unusual for her to wake up, less so for me. After your post I realized that the previous night I'd made omelets for dinner instead of our usual meat and veggies fare. She asked for seconds, thus eating four eggs at bedtime. She'd had two eggs for breakfast, also. We'll have to try it again.

Baeo Maltinsky (2014-01-14 04:58:02)

Sentinel: The time varied between the late afternoon and late in the evening. Almost always scrambled. Caffeine came in the morning in the form of tea. Gwern: I have serious doubts about the choline hypothesis. For all I know it could have something to do with an amino-acid deficiency caused by having eggs as my primary protein source. Either way I imagine that I probably have some greater sensitivity to whatever-it-is-that-caused it than the general population. Joe: Gary Taubes and Robert Lustig presented very compelling cases I suppose. Given how bad my diet was before, switching to eggs as a dietary staple was actually a massive improvement. You are correct in assuming that low-carb vegetarianism is insane. I agree completely (at least I do now). Caffeine and other stimulants actually do have calming effects in some people (those afflicted with ADHD being the obvious example). Your other criticisms are valid. Humans are complicated and this was by no means a controlled experiment. All I can say is that the eggs definitely caused me sleeping issues, so I tend to avoid them these days. Really, I'm still not sure what's going on. I made some bizarre and probably incorrect connections coming to what may be an incorrect hypothesis. I can say this: eggs cause insomnia for me. I don't know why. Choline toxicity? Amino acid imbalances? Some specific allergy to eggs (which would explain the positive effects of anticholinergics I suppose)? I'll freely admit that I don't know. I haven't performed the tests and frankly at this point I'm not that interested in finding out if it means testing it myself. Also, while it's interesting to see other people reporting similar things, I'm a bit concerned that the choline hypothesis is getting too much attention. A quick reasonability check (looking at the choline content of eggs and comparing it to the TUL) suggests that choline toxicity is unlikely. Insomnia isn't even a common symptom of choline toxicity when it DOES happen. Maybe the form it's in in eggs causes the issue, but that's yet to be established.

Carlos (2014-01-14 05:12:03)

For me the issue are raw eggs. If I made some mayo for dinner I won't sleep well, but I can have 4-6 fried eggs for dinner

without issue. Anyone else has experienced this? P.S: I should point out that I have dinner quite late for US standards, around 22:00 (which is quite common here in Spain)

JRM (2014-01-14 10:01:43)

"Almost always scrambled." Some people, like myself, react to egg whites. I go for hard boiled eggs, eat the yolk and throw away the whites. I had read about egg whites causing a reaction in some people and then noticed the effect in myself. Most of the nutrition is in the yolk, too. Yolk: <http://nutritiondata.self.com/facts/dairy-and-egg-products/113/2> Egg White: <http://nutritiondata.self.com/facts/dairy-and-egg-products/112/2>

Joe (2014-01-14 10:38:33)

Baes: "Gary Taubes and Robert Lustig presented very compelling cases I suppose. Given how bad my diet was before, switching to eggs as a dietary staple was actually a massive improvement. You are correct in assuming that low-carb vegetarianism is insane. I agree completely (at least I do now). Caffeine and other stimulants actually do have calming effects in some people (those afflicted with ADHD being the obvious example). Your other criticisms are valid. Humans are complicated and this was by no means a controlled experiment. All I can say is that the eggs definitely caused me sleeping issues, so I tend to avoid them these days." Thanks for the feedback, Baes. Yes, Taubes and Lustig present very compelling cases (in my opinion), but what about those cases caused you to suddenly start eating 14 eggs per day? I didn't find anything like that in any of the Taubes books or Lustig videos. I agree with you that choline toxicity is unlikely. But too much protein might be the culprit, especially if you were consuming other forms of protein (meat, milk, cheese, etc.) at the same time. A lot of my gym-rat friends used to talk about how consuming too much protein caused many of them to sleep poorly. I think you will agree that we all have different sensitivities to caffeine, and while I think ADHD is grossly over-diagnosed, I don't think caffeine is actually helping you sleep. How about another experiment: Try having a couple of cups of coffee in the evening, before you go to bed, and see how that works out for you. If it's the caffeine that is actually helping you sleep, you should sleep at least as well, right? My prediction: You won't. Again, thanks for the feedback. Carlos: Try commercial mayo - it's pasteurized. That is, the eggs are essentially cooked. See if it makes any difference. Personally, I don't think there's enough egg in mayo (typically 6-8 % by weight) to have the effect you're describing.

Baeo Maltinsky (2014-01-14 12:29:27)

Vegetarian protein sources that aren't heavy in carbohydrates are few and far between. Eggs seemed like the best option at the time. My protein intake wasn't exceptionally high. It was normally between 80 and 120 grams per day, which is about average for someone my size (I'm about 6'1"). I never claimed that caffeine in the evening helped me sleep. Caffeine in the morning though seemed to. I'm not going to say that it definitely did something, but it seemed to. Maybe if I kept closer records I'd see that it was nothing after all. Hard to say.

Joe (2014-01-14 14:51:31)

Baeo: "Eggs seemed like the best option at the time" Why? Don't you like meat, poultry, or fish? Why just eggs? Protein requirements are all over the board, depending on whom you ask, your age, your activity level, etc. But unless you're trying to build (or prevent the loss of) muscle mass due to age, inactivity, injury, that seems a bit much to me. In fact, the CDC says that the adult male needs 56 grams of protein per day. The AMA says .36 grams per pound of BW (thus, a 190 pound person would need only 68.4 grams of protein per day). And Mark Sisson has this to say: . How do those recommendations apply to your personal situation? "I never claimed that caffeine in the evening helped me sleep." Didn't say that you did. I asked you to try drinking your coffee in the evening, instead of in the morning, to see what happens. If it helps you to sleep then, too, you just may be one of those rare individuals who get better sleep with caffeine. But if it doesn't help you, and actually makes your sleep worse, then it's highly unlikely, I think, that caffeine in the morning makes you sleep better either. You might want to find this out about yourself for future reference.

Joe (2014-01-14 14:53:18)

Oops! Forget the link to Sisson. Here it is: <http://www.marksdailyapple.com/how-much-protein-should-you-be-eating/#axzz2qPRzVqIJ>

Baeo Maltinsky (2014-01-14 17:09:32)

Joe: I was, at the time, a vegetarian. I've since given that up. With regards to protein intake, while the requirement for someone my size may have been only 70 grams, in practice most people consume well more than their requirement without ill effects. 100 grams of protein just doesn't seem like enough to cause issues, especially given that consuming the same amount from different sources doesn't cause me problems. I'm considering trying evening caffeine in the near future. However, if this blog has taught us anything it's that time-of-day is such an important indicator. Morning caffeine could improve sleep while hurting it at night, like with Vitamin D.

Joe (2014-01-14 17:36:15)

Baeo: One thing too much protein can do for you is to make you fat. Excess protein is stored as fat. I call that an ill effect. Yes, time-of-day can be important. But there are confounding factors. For example, some research shows that taking vitamin D first thing in the morning, on an empty stomach, is a waste of money. It'll go right down the urinal. The Cleveland Clinic says to take vitamin D in the evening, with what is usually the biggest meal of the day (increases vitamin D absorption). That's why it's important to EXPERIMENT on yourself. Anyway, I hope you figure it out one day. Good luck!

daz (2014-01-14 20:57:00)

histamine is another potential explanation... excessive egg consumption may raise histamine levels (in some people) over time. (looking around the web) foods raising histamine seems to be a bit like filling a bucket with water. histamine levels may be rising without any symptoms...until one day they overflow 'the bucket'. then you need to try & empty 'the bucket' by avoiding high histamine foods & foods that raise histamine. purportedly eggs (or specifically egg whites) "are potent histamine liberators", Source wiki, [http://en.wikipedia.org/wiki/Egg\\_allergy#Egg\\_white\\_intolerance](http://en.wikipedia.org/wiki/Egg_allergy#Egg_white_intolerance)

daz (2014-01-14 21:10:22)

cont. i forgot to finish my thought process... purportedly, one symptom of high histamine is insomnia. which may be why antihistamines are sometimes used as a treatment for insomnia (usually the first generation H1 antihistamines (the 'sedating antihistamines'))

Jazi Zilber (2014-01-16 06:16:56)

I fell asleep multiple times fast after drinking coffee. I felt it has a connection.

Cathy (2014-01-13 08:58:07)

Wow, just wow at the Katherine Reid video. I got chills and tears in my eyes watching the last video of Brooke talking about kindergarten. This subject is worth a deeper look.

John Eels (2014-01-13 11:08:38)

All great ideas evoke the question: "Why hasn't anyone thought about this before?" The Floy Leg is compelling. I like it very much.

Joe (2014-01-14 12:32:16)

Re: Katherine Reid's video, I like it! We are not only what we eat, but are also what we eat eats. WHOLE FOOD = REAL FOOD.

### **Does Smoking Increase Heart Disease? If So, Why? (2014-01-14 05:00)**

[1]Mr. Heisenbug says that smoking is the best predictor of heart disease. (Not quite. A high Agatston score is a better predictor. [2]For example.) It is the best lifestyle predictor. People who smoke, according to [3]this, have a six-fold increased risk of heart disease compared to non-smokers.

Why would this be? Heisenbug points to a study that found that when smokers quit, the microbial diversity of their gut increased. He speculates that (a) smoking decreases microbial diversity, which is quite plausible and (b) decreased microbial diversity increases heart disease – which has some plausibility.

I commented:

It would be interesting to find other factors that have a big effect on microbial diversity and whether they are also associated with heart disease. The idea that smoking causes heart disease via its microbial effects predicts, or at least suggests, that a change that reduces microbial diversity a lot will increase heart disease.

Heisenbug replied:

The only lifestyle factor that we can safely say leads to a lack of microbial diversity is a diet that is low in fermentable fiber. And fiber intake is consistently linked (negatively) with heart disease. I've never seen data linking lower overall diversity to a decrease in risk for any disease. And lots showing the opposite.

I replied:

The stuff about diversity (fiber intake increases diversity and is associated with less heart disease, many associations of more diversity with less risk of Disease X, no associations in the opposite direction) is substantial support for your idea, in my opinion.

His theory, in other words, made a prediction that turned out to be correct. A large fraction of what we're told about health hasn't led to any correct predictions. Here is an idea about how to prevent heart disease, a major killer, that there is actually reason to believe. And Heisenbug can say whatever he wants, in contrast to a heart disease expert quoted, say, in the *New York Times*, who is under pressure to say certain things. So we can take what he says at face value.

Heisenbug replied:

I agree. Especially because there's never been a good explanation WHY fiber has that effect on [he means "association with" – Seth] heart disease.

Suddenly I am a lot more interested in microbial diversity and the association of fiber and heart disease. Smoking has countless health effects – it increases many cancers, for example. Obviously it increases lung and throat cancer. This means there are many ways it could cause heart disease. Fiber is quite different than smoking and as far as I know has no effect on lung and throat cancer. If it could be established that fiber causes a reduction in heart disease (not just is associated with a reduction), that would be considerable evidence (but far from proof, of course) that microbial diversity influences heart disease.

---

Andy (2014-01-14 06:03:10)

I think this is nonsense. Quitting smoking is associated with an increase in phylum firmicutes bacteria (often associated with, obesity heart disease and T2D). Smoking is associated with an increase in bacteroides recently famous because they promote leanness. Trying to dig up a study where smoking was associated with increased bacterial diversity in UC patients especially in butyrate producing groups and nicotine patches reduced occurrence of flare ups. I'd say it's a fair bet the increased heart rate and blood pressure inflict most of the damage.

Nancy Lebovitz (2014-01-14 09:11:28)

I'm not going to say it's the strongest factor, but sunlight seems to do a lot to prevent heart attacks by a path which doesn't involve vitamin D. Exposure to sunlight causes human skin to release a precursor for nitric oxide.

dearieme (2014-01-14 09:29:16)

"Coronary Calcium Independently Predicts Incident Premature Coronary Heart Disease Over Measured Cardiovascular Risk Factors": now there's a fine sample of lousy English.

Charlie Currie (2014-01-14 09:36:07)

Andy says: "Smoking is associated with an increase in bacteroides recently famous because they promote leanness. " So what's going on with all the obese smokers? Also: "I'd say it's a fair bet the increased heart rate and blood pressure inflict most of the damage." From this - "<http://www.ncbi.nlm.nih.gov/pubmed/9162447>" you get this - "It is a paradox that while smoking acutely increases blood pressure, a slightly lower blood pressure level has been found among smokers than nonsmokers in larger epidemiological studies." Exercise also acutely increases heart rate and blood pressure and regular exercisers are known to have lower heart rates and blood pressure than non-exercisers, yet exercise is recommended as a defense against heart disease. Go figure.

Nancy Lebovitz (2014-01-14 11:28:36)

Just for another angle- Wim Hof (who does a lot with enduring cold) believes that intermittent exposure to cold (like cold showers) increases the flexibility of blood vessels. It could make sense that exercise + rest is good for the circulatory system because it increases its range in a way that constant high blood pressure doesn't.

Heisenbug (2014-01-14 12:25:56)

Thanks, Seth, for leading me to that initial insight. I put it in my back pocket, and forgot it was there. I do think there must be protective factors when it comes to smoking. And not just for heart disease. But there just isn't much fiber/cancer research out there, probably because it isn't intuitive the way it is with heart disease. Colorectal cancer being the only exception, for obvious reasons. No one cares about the microbial link, so the disease has to have a clear & intuitive dietary connection to merit fiber research. But there is some data to at least raise suspicion: <http://www.ncbi.nlm.nih.gov/pubmed/1851150> "Of the seven case-control studies, which evaluated the relationship between the fiber-rich diet and breast cancer, six demonstrated an inverse association. For cancers of the esophagus, mouth, pharynx, stomach, rectum, endometrium, and ovary, there are only a limited number of studies, most showing a protective effect from eating a diet high in fiber-containing foods." But we can always start from the other end - the microbiome/cancer link. A decent amount there: <http://www.nature.com/nrc/journal/v13/n1-1/abs/nrc3610.html> And since we know fermentable fiber is a (if not THE) major modulator of the microbiome, I think there's enough for a similar inquiry.

Heisenbug (2014-01-14 12:31:45)

Andy, The research you are referring to is outdated. In fact, if you read the blog posts where I talk about this, you will see that the research indicates the opposite of what you say, and figures prominently in the case that's being made. I'd be interested to see whatever UC study you are referring to. IBD and microbiota is pretty complicated, but most of what I've seen involves a reduction in the butyrate-producing Clostridia (ie, Firmicutes), which is a big part of the microbial pattern I've documented.

Antonio (2014-01-14 13:03:03)

Interesting but it seems to be one of those guesses that makes very sense outside the country. In Europe it seems that a lot of people smoke but the incidence of heart disease is lower than USA. This seems to be specially true in France.

Heisenbug (2014-01-14 13:16:20)

Andy, I forgot to address the last part of your comment. "I'd say it's a fair bet the increased heart rate and blood pressure inflict most of the damage." You don't mention how, or what mechanism, but I'll assume you are referring to nicotine inducing those affects. Pipe-smoking exposes smokers to far less nicotine, yet has not been found to be any safer: <http://www.ncbi.nlm.nih.gov/pubmed/20952559> Nicotine patches do not contribute to arrhythmia or ischemia: <http://www.ncbi.nlm.nih.gov/pubmed/9784902>

JM (2014-01-14 13:33:49)

So if smoking is the best lifestyle predictor, what could we learn if we looked at the people who smoke for years and never get heart disease - what is it about them that protects the heart? The first example that I can think of is a family friend who recently died, in his 90s and active but also still smoking. And he is not the only one I have known. A more thorough analysis of these smokers, including things like their gut health, might actually yield some good answers. But since all most experts want to focus on is cholesterol!

William Blair (2014-01-15 13:02:07)

Forgive my ignorance - is it the smoking that causes this particular problem mentioned (not including the obvious hazards - you're inhaling smoke!) or is it the nicotine that causes the microbial diversity?

William Blair (2014-01-15 13:02:51)

that causes the reduction in microbial diversity\*

Heisenbug (2014-01-15 14:09:25)

William, It's a good question. Unfortunately, the study did not look into that, so we do not know. But as I mention in the original post, tobacco smoke has been shown to directly introduce pathogenic bacteria & their endotoxins into smokers. So that would suggest it is not, in fact, the nicotine.

William Blair (2014-01-16 12:07:43)

If I could, I would have a study conducted with smokers of all "flavors" - cloves, pot, tobacco (those seem to be the most popular / quasi-legal ones) and see what happens. My guess is that smoke is the culprit. I think having all varieties of "common" smoke in the study would lead to a more definitive conclusion. Thanks, Heisenbug.

## **"Bedtime Honey is a Godsend" (2014-01-14 20:19)**

A reader writes:

The [1]bedtime honey treatment has been a godsend for me. I had been sleepless for several months when you first wrote about the honey, waking up many times every night and staying awake for long periods. I immediately began trying the honey, and the first night, though I still woke up a few times, I had dreams for the first time in ages. After a couple more nights I was sleeping all night. I usually wake up once a night for one reason or another, but wonderfully, get back to sleep which was impossible for so long before the honey. Sleep deprivation is so miserable, I cannot thank you enough!

In case you haven't tried it. What did I blog about before? I can't remember.

1. <http://blog.sethroberts.net/category/sleep/honey-sleep/>

---

Rif (2014-01-15 03:51:46)

So am I the only one honey \*doesn't\* work for? I've been trying it for about a month now [I think since one of the very early mentions]. I \*want\* it to work, because I sure do need to sleep better and honey is delicious, but so far I seem to be sleeping

neither better or longer. Right now it's the third night in a row when I've tried honey before bed but I've woken up after about 3 hours of sleep, still tired but having a hard time getting back to sleep. I've experimented with quantities between 1 Tbs and 1 Tsp. Seth: You might want to try taking it earlier in the evening, such as 2 hrs before bedtime.

Sentinel (2014-01-15 05:53:05)

Rif, don't worry, honey does not make much difference for me either! It seems that people suffer insomnia for a variety of reasons: toxin exposure, anxiety, depression, poor sleep hygiene, a room that is too warm/cold/bright/noisy, etc. It would be surprising (to me, anyway) if a given supplement or food could improve sleep for ALL of these types of insomnia. Seth does not even currently suffer from insomnia (jealous!), but instead (sorry if I am misstating this, Seth!) has sleep that tends to vary only between 99 % restorative and 100 % restorative; so we are all dealing with different sleep issues, different starting points. What I learned from Seth is not "honey will fix your sleep," but "theorize and experiment until you find what fixes your sleep." Seth: After 20 years of trial and error, I managed to sleep well...but honey easily improved on that. That is the lesson I draw. I feel better the whole day because I have slept better. I have the wrong scale to show how much better I feel the whole day.

Three Pipe Problem (2014-01-15 06:48:46)

My presumption has been that honey works better for those who are more carb/fructose depleted

Bob (2014-01-15 07:35:51)

Hasn't worked for me or my wife, either. Not that we were sleeping poorly before trying it, but all the reports here made it worth checking out. No effect for me, worse for my wife (hours of wakefulness in the middle of the night after a few hours of sleep, what someone jokingly said Seth would call "morning" since he sleeps far less than most of us).

Bruce McCullough (2014-01-15 07:42:06)

Tablespoon of honey before bed works wonders for me; did nothing for my wife. But she sleeps like a log anyway - probably there is no improvement to be had in her case. Rif, try taking vitamin D in the morning as an aid to sleep. Search this blog for posts on the phenomenon. I doubt that honey would have worked for me if I hadn't already been taking D.

Joe (2014-01-15 11:11:20)

Hasn't worked for me either. At least not yet. I wonder of the placebo effect might be in play here? Perhaps some of us are just more suggestible than others?

peter (2014-01-15 12:22:49)

it helped my sleep some; but the clear difference for me was more stamina and more energy. I seem to get more out of my workouts. My experience seems consistent with the view that honey restores a depleted liver.

William Blair (2014-01-15 12:51:41)

I must say it's been phenomenal for me for a couple weeks now. I am happily amazed at the difference it made for me, daily. Even with inadequate amounts of sleep I can wake up on a dime without any grogginess - such an event happened just last night. The wife turned the nightstand light on at 3AM. I woke up immediately, alert and ready to go. I wish it worked for everyone like this and I'm sad to see that it isn't (judging by some of the comments). I've even been eating badly the last couple of days (in moderation) - still no problems! I'm rambling now, but I honestly can't remember ever feeling this good. Years and years, literally. All I can say is: I'm glad I found this blog and that article!!

William Blair (2014-01-15 12:58:47)

[Joe Says: January 15th, 2014 at 11:11 am Hasn't worked for me either. At least not yet. I wonder of the placebo effect might be in play here? Perhaps some of us are just more suggestible than others? ] From what little I know, the placebo effect is certainly a squirrely thing, so it would impossible to effectively refute your suggestion. I can only speak for myself and say I had no expectations either way. However! I can say this as a personal observation (in the same vein as personal science, I suppose). I have eaten honey with breakfast periodically and let me tell you - I sure didn't feel any better afterwards or the next day.

Joe (2014-01-15 13:50:33)

William: "From what little I know, the placebo effect is certainly a squirrely thing, so it would impossible to effectively refute your suggestion. I can only speak for myself and say I had no expectations either way." William, if you had no expectations, why did you try it? I didn't try it because I didn't think it would work. I tried it because I thought it just might work. It had worked for others, maybe it would work for me. I agree that there are things about the whole placebo/nocebo theory that are not easily explained. The way I look at it is this: I don't care if it can or can't be explained scientifically. But if someone can take a pill that is supposed to make, say, his headache go away, and it's only a placebo, but his headache goes away, I don't think it would matter much to the person taking the pill. I have no doubt the honey is working for you. I also have no doubt that it's not working for me. The mystery continues...

John Smith (2014-01-16 00:38:40)

There are so many variables in our lives, it is presumptuous to expect honey to be a cure all for everyone in the matter of one week, or even one month. Perhaps many of you readers and commenters know more of each other's details, but I can only guess at: How old is this person? How Sick? With what other symptoms? What is the lifestyle, including the diet, mindset and disposition? What was the origin of the honey? (And pertinent to my case:) How close to your bedhead is there excessive electromagnetic fields? What priority does this person give to getting good sleep? Good health follows on from good lifestyle, which includes myriad factors to be considered. And each of us has the challenge of working on our own leading edge causes of illnesses of all types. Not being able to sleep well is certainly in the loop, both as a cause of disease and as a result of disease. But at the end of the day, by eliminating each 'cause' as it comes to our notice, we can energize our body and be delightfully healthy. Disease cannot exist in a fully energized body. Failing energy will promote diseases of every persuasion. Modern sweeteners are an abomination. They are a factor in most everyone's energy problems. Getting off them is a big challenge, as is finding foodstuffs that are high quality. Modern medicines are also a major factor, as we easily get hooked on them and lose our awareness of just what real health feels like. Trying to wean ourselves off 'treatments' of all types is a big challenge. But for those of us with reasonable lifestyles and average health, a well fed belly and a well stocked liver is the key to good sleep. Honey is the gold standard food to achieve this liver 'charging' with glycogen. Honey that has been diluted with any other commercial and cheap sweeteners probably will not work, but the percentages of real honey to the substitute is to be considered. Determining the difference is not easy, this is why the remark, "Buy your honey from someone you trust" becomes so pertinent. Unfortunately not everyone has immediate access to someone they trust to get their honey from, but giving this detail some priority will pay big dividends. In my case, I was pre-diabetic, but probably with Type III as I have been a health fanatic for most of my life, thanks to my father before me. But as age took its toll I had spells of not sleeping at all on occasion, and once for three nights in succession. Not good. I thought I was dying. Without consulting any professionals, I read McInnes's book, seriously policed my 'other' sweeteners intakes, shunned alcohol and caffeine, and commenced to reduce my work hours. My health completely turned around, although I did go through several months of 'withdrawal' which was not encouraging. Even now, I have occasion not to sleep at all for one night, and nerves are usually indicated, but overall I sleep quite well, and have energy above and beyond many other men my age. I need to work on my brevity now, don't you think? Cheers

daz (2014-01-16 14:38:15)

just talking on the sleep benefits of honey here, not any other benefits... one possible explanation why honey does not improve sleep (or certain sleep issues) for some people, could be because they need more than the liver glycogen 'hack' mentioned previously (here & under other posts)... take an example of two people, both of whom wake up in the middle of the night, lets say at 3am ( & they would prefer not to), Lets say that Person A already has full liver glycogen before taking the honey dose before bed. & Lets say that Person B has low liver glycogen before taking the honey dose before bed. & lets assume that the honey dose replenishes the liver glycogen of person B to that required for a good nights sleep (as far as liver glycogen requirements are concerned). So from a liver glycogen perspective for a good nights sleep both persons are covered. But both persons still wake at 3am...so the presumptions would be that the wakings are not related to liver glycogen in these cases. & the reasons/causes for the wakings lies elsewhere. I am not saying that the appropriate liver glycogen levels are not required, but in these cases something else is also 'broken' (or multiple 'things are broken') that need to be resolved as well (on top of any potential liver glycogen shortfalls).

Nathen (2014-01-16 19:25:29)

I've been taking varying amounts of honey just before bed for several weeks now and after what seemed like great results the first night, have noticed no effect since on number of instances of sleep onset, maintenance, or morning insomnia, nor on energy level upon waking or during the day. This does not seem to depend on how much carbohydrate or sugar I've had during the day. I'd like to have a more precise dependent variable than my subjective experience—something like reaction time measurements, but I use a Mac so can't use yours. (Anyone have a Mac solution?) I suspect that even with a better measurement I'd be ferreting out a small effect, if any. Disappointing because I love honey and really need better sleep. Maybe a post updating your theory to explain negative results? Seth: Maybe you don't get enough circadian-rhythm-establishing events, such as morning sunshine and morning Vitamin D3. No doubt they matter too.

Drini (2014-01-25 07:38:10)

After several trials, I can say as well that honey did not improve my sleep. On the contrary, it actually worsened it, because it made me self-conscious about my sleep, which used to be ok. I wanted honey to work especially for improving my energy levels during the day. Alas, it did not work on that either. Other forms of sweets before sleep don't work either, I've tried bananas several times before sleep without any noticeable improvement. I have still to try having honey 2-3h before sleep. Or trying to up my dose (2T). 1t up to now has been better than 1T. 1T impairs sleep onset. Seth: What works best for me is having something sweet at three different times: 1.3-4 hr before bedtime. 2. 1-2 hr before bedtime. 3. At bedtime. Each time, roughly 40-60 kcal.

Pine Cone (2014-02-13 09:30:07)

I tried 2 tsp of honey before bed two nights in a row. The first night I definitely 'felt' like I had deeper sleep, but it almost seemed like I was 'dreaming' that I was sleeping deeper. I've read many comments about increased dream activity, so maybe that make sense. I generally wake several times per night, this did not change with the honey either of the two nights. However, I've suspected for some time that I need a new mattress :) I use Sleep Cycle to track my sleep and per the app, my sleep DID improve... by 12 %. That's enough for me to keep at it. THE REASON FOR MY COMMENT TODAY, is that I've encountered another possible side effect, and I'm curious if it's been noted yet? The first morning after the honey, my resting heart rate was 49 bpm (usually in the 60 bpm range, sometimes higher), AND my blood pressure was WAY down (110/75). I've been wrestling with high blood pressure for months, in fact the previous day it was 160/89... typical. The second morning, my heart rate was in the 'normal' range for me (60 bpm) but my blood pressure was close to the same, 110/77. Possible caveat that I will test against, is that I also added red light exposure before bed in hopes of winding down... BUT I did expose myself to red light the night before... and the morning of the 160/89 reading. Any similar experiences with blood pressure??

## **Who Tests the Genetic Testers? And the Experts? (2014-01-15 05:00)**

In the New York Times, a writer named Kira Piekoff, a graduate student in Bioethics, tells how [1]she sent her blood to three different companies, including 23andMe, for genetic analysis and got back results that differed greatly. As usual, none of the companies told her anything about the error of measurement in their reports, judging from what she wrote. So she's naive and they're naive (or dishonest). Fine.

I'm unsurprised that a graduate student in bioethics has no understanding of measurement error. What's fascinating is that the experts she consulted didn't either, judging by what they said.

A medical ethicist named Arthur L. Caplan weighed in. He said:

The 'risk is in the eye of the beholder' standard is not going to work. We need to get some kind of agreement on what is high risk, medium risk and low risk. [Irrelevant – Seth] If you want to spend money wisely

to protect your health and you have a few hundred dollars, buy a scale, stand on it, and act accordingly.

As if blood sugar and blood pressure measurements aren't useful. [2]A good scale costs \$15.

A director of clinical genetics named Wendy Chung said:

Even if they are accurately looking at 5 percent of the attributable risk, they've ignored the vast majority of the other risk factors — the dark matter for genetics — because we as a scientific community haven't yet identified those risk factors.

She changed the subject.

J. Craig Venter, the famous gene sequencer, does not understand the issue:

Your results are not the least bit surprising. Anything short of sequencing is going to be short on accuracy — and even then, there's almost no comprehensive data sets to compare to.

The notion that "anything short of [complete] sequencing" cannot be helpful is absurd, if I understand what "short on accuracy" means. He reminds me of doctors who don't understand that a t test corrects for sample size. They believe any study with less than 100 subjects cannot be trusted.

I told a friend recently that I have become very afraid of doctors. For exactly the reason illustrated in these quotes, from well-known experts who are presumably much more competent than any doctor I am likely to see. The experts were unable to comment usefully on something as basic as measurement error. Failing to understand basics makes them easy marks – for drug companies, for example – just as the writer of the article was an easy mark for the experts, who managed to be quoted in the *Times*, making them appear competent. Surely almost any doctor will be worse.

1. <http://www.nytimes.com/2013/12/31/science/i-had-my-dna-picture-taken-with-varying-results.html>

---

dearieme (2014-01-15 07:29:12)

Dear God, I hate it when people chunter on about "risk factors" as if they were causes. Or even just features that make you more vulnerable to other causes.

Nancy Lebovitz (2014-01-15 09:40:12)

It seems to me that measurement error is only the start of the limits of DNA testing. There's no simple way to measure the limits of knowledge about the prevalence of diseases or the limits of current theories.

C.M. Mayo (2014-01-15 10:36:16)

Comments sections are just so perfect for tossing out frisbees of vocabulary. If one uses a highfalutin word, one surely must know what one is talking about. The Emperor has no clothes in all too many professions, not just medicine. But especially

medicine. (But don't get me started about investment banking.) Who tests the testers is a vital question. Re the tragedy of what happened in the state of Massachusetts with deliberately fudged lab tests that sent untold numbers of people to jail. Anyone who doesn't know about that, google and ye shall find. Seth: Yes, I linked to a story about the Massachusetts forensics tester who made up lab results. I wonder if better technical competence by the people who read her reports would have caught her fabrications much earlier.

libfree (2014-01-15 11:00:19)

23andme did give you those numbers but they also gave you the links to the research it was generated from and which gene it related to.

Nancy Lebovitz (2014-01-15 12:04:40)

Off-topic: I'd like it very much if you'd offer a longer list of recent comments- it's a way of letting discussions continue longer.

dearieme (2014-01-15 15:03:39)

Experts: 800,000 corpses is a lot. <http://www.forbes.com/sites/larryhusten/2014/01/15/medicine-or-mass-murder-guideline-based-on-discredited-research-may-have-caused-800000-deaths-in-europe-over-the-last-5-years/>

Sentinel (2014-01-15 16:34:34)

Ms. Peikoff (who I believe is the daughter of Leonard Peikoff, who was Ayn Rand's choice for heir to her estate -- interesting if not relevant) ran into the same problem I did with the Quicksilver Scientific Co. "mercury speciation" test -- New York does not allow these test kits to be mailed from New York to labs that are not certified according to some specific NYS standard. I am surprised she admitted that "my in-laws mailed it from their home in New Jersey." It seems New York is hostile to the concept of "health-test buyer beware," though in this context there may be something to that....

gwern (2014-01-16 13:11:01)

> They believe any study with less than 100 subjects cannot be trusted. I'd agree with them. See: publication bias, underpowering, winner's curse, base-rates, self-selection, internal vs external validity, assumption of normality and the central limit theorem. To name just a few reasons why small n studies, even if they have nice <0.05 p-values, are predictably untrustworthy.

Christian Kleineidam (2014-01-17 05:43:57)

A study can only be trusted if the participants are independent from each other. If you test Alice with SNP-detection chip X 100 times those 100 times aren't independent measurements. SNP-detection chip X might have a systematic bias. As far of the subject of what makes a good scale, I think these days a good scale should measure body fat. If you do spend money on an expensive scale like the Withings scale you also get pulse measurements in addition to weight and body fat data. Having the air CO2 and temperature data can also be useful. \_\_\_\_ Claiming that Wendy Chung changed the subject shows misunderstanding of how to read a newsarticle. Chung probably spend >10 minutes at the telephone or in person with the journalist of the article and during that time she said that sentence or something that the journalist considers to be equivalent to that sentence. Given that the sentence is true, it doesn't suggest that Wendy Chung said anything wrong. I also don't see any indication that the journalist who wrote the article is naive. She did what a good journalist is supposed to do. She investigated whether the 3 companies are going to report similar results. She might have already expected the result of the measurements but I commend a journalist who actually goes out and tests and then tells the readers about the experiment. She doesn't just tell readers about what the FDA has to say but she actually goes out and experiments and reports the results to the readers. Seth: She is naive because she failed to address the question of measurement error. The subject of the article. It isn't clear she even understands what it is. I agree that it is a good article, just for the reason you said. Sometimes naive people do good work.

## Donald Knuth and Dessert: A Heretic (2014-01-16 05:00)

I claim we eat dessert after dinner – separating high-sugar foods from other foods – so that we are more likely to get sugar near bedtime. We need sugar near bedtime to sleep well, I suspect. Donald Knuth, the computer scientist, [1]seems to disagree:

Donald Knuth came on time [to dinner at a Stanford dorm] and started his dinner with dessert. Only after he finished the cake he proceeded to the salad. He explained that order of courses by not being consistent.

Perhaps he's been reading Taleb, who stresses the value of randomness. I would have been more impressed had he eaten the cake at the same time as the rest of the meal.

1. <http://www.quora.com/Stanford-University/What-is-it-like-to-have-dinner-with-Donald-Knuth>

---

Nancy Lebovitz (2014-01-16 05:03:49)

Non-obvious problems with randomized control trials <http://www.edge.org/response-detail/25497>

Mark (2014-01-16 06:56:26)

Ornish apparently doesn't know how to interpret an RCT (either that, or he's intentionally trying to mislead, which isn't out of the question since the WHI results didn't confirm his pet hypothesis). Seth: I think Ornish missed the real problem with RCTs. If you have to run a giant study to find an effect, it must be a weak effect. If you understand how something works, you will be able to find large effects. RCTs, as presently done, try to use large numbers to substitute for understanding – to cover up lack of understanding. It doesn't work.

Robbo (2014-01-16 09:26:21)

My understanding is that the old-fashioned way of serving a formal meal was service a la francaise, which was everything was served at once, starters, main courses and desserts. Diners ate their food in whatever order they liked. In the 1800's fashion changed to service a la russe, which is the service by courses we have now, which imposes a starter, main course, desert pattern

dearieme (2014-01-16 09:34:27)

There is still contention as to whether one should have cheese before or after dessert.

peter (2014-01-16 10:15:02)

i try to eat food in the order that it first digested. first fruit, second vegetables, third starches and last protein. if you eat fruit/dessert at the end of the meal it just sits on top of meat etc.. and ferments, causing gas and perhaps discomfort.

Mark (2014-01-16 14:35:24)

Actually, besides seeming to believe that a "significant" result indicates a "real finding" and that a "non-significant" result indicates no difference, I think Ornish's biggest misunderstanding is that RCTs are able to identify the biological efficacy of a treatment (i.e., how a treatment would work if used 100 % correctly). Most RCTs, including virtually every drug trial in which the patient has the option to adhere or not, cannot get directly at efficacy (no matter what their authors contend), they can only assess effectiveness... and, actually, they can only assess effectiveness of being randomized to receive one treatment

or the other. Thus, the WHI didn't provide any evidence that dietary changes didn't protect against heart disease or cancer, only that being randomized to a group that was instructed to make those changes didn't result in any appreciable differences. HUGE difference! Seth: Ornish is right that a system – ours – with heavy reliance on RCTs isn't working very well. But his ideas about what would work better are pure speculation. He is unaware of a better-working system.

Michael (2014-01-16 15:04:26)

I had a friend who'd always order and eat dessert before the rest of the meal. Sadly he died. He was the most fun person to eat out with as it often caused much confusion. Seth: This reminds me of my advice about how to give a talk: Make a blunder. Something that makes people laugh. Long ago you could put a slide in backwards. Now it is less clear how to do this.

Christian Kleineidam (2014-01-16 17:49:04)

I don't think that Taleb argues for randomness in a case like this. Taleb said much about the value of following traditions.

### **More on Government as Useful Irritant: Why Are Economists Stupid About Innovation? (2014-01-17 05:00)**

Martin Feldman, a Harvard professor of economics and former advisor to President Reagan, is [1]against a hike in the minimum wage. One of his arguments:

When low-skill labor becomes more expensive, employers have a greater incentive to mechanize or out-source their work.

He – like most economists – ignores the point that an increase in the minimum wage, by forcing employers to reexamine familiar practices, will increase innovation. (I have seen non-economists make this point.)

How you can hope to understand economics without understanding innovation is beyond me. I realize that economics is a job – that academic economists try to write papers that make incremental improvements in understanding and innovation is not always important. Yet the whole profession seems stuck in a world where it is okay to ignore innovation and okay to try to increase productivity yet not acknowledge that [2]productivity and innovation are often at odds. (For example, almost all foreign aid programs ignore innovation.) I have never heard or read an economist make this simple and obvious point. The situation reminds me of a friend of mine. When she was in first grade, she had a lot of pennies. Now and then she would spend some. She knew how to add but not subtract, so after she spent some she had to count them all again. At least she got the right answer eventually. Economists, not understanding the effect of Policy X on innovation, really cannot predict the effects of any policy that affects innovation.

It isn't just economists. Epidemiologists seem stuck in a world where it is okay to ignore the immune system. They act as if the immune system does not exist, except perhaps when someone asks them why smoking is so bad and they reply "maybe it reduces immune function". Statistics professors seem stuck in a world where it is okay to ignore the question of how to generate an idea worth testing, except to grant that making graphs is helpful.

Psychology professors, at least the ones who do experiments, are also stuck that world. With few exceptions, they have no idea how to generate ideas plausible enough to be worth testing. You can read a thousand psychology textbooks and ten thousand psychology papers and end up knowing no more about how to do that than when you started. It is a methodological question, yes, but maybe you have to be a psychology professor to grasp how disabling it is to not have a good way to generate ideas (ideas plausible enough to be worth the cost of testing). It is like having a car – psychology professors know a lot about how to do experiments to test ideas – but no fuel.

Something is making a lot of very smart very capable people ignore the obvious. I have a theory of why these vast

areas of ignorance – easily noticed, yet rarely acknowledged – exist. It is because science is slow and difficult and [3]in several ways incompatible with careerism. Science is innovation, careerism is productivity. You, a professional scientist, are trying to climb up a wall of rock (= discover stuff) but you have to lift your career at the same time. Really really hard. If you can pretend to climb, that's much easier. (My solution was to ignore my career, which [4]suffered great damage.) Distant observers, including granting agencies, university administrators, [5]journalists and the general public, have a hard time telling the difference between real climbing and pretend climbing.

---

Brandon Berg (2014-01-17 05:21:23)

The problem is that innovation to solve an artificial problem (such as unskilled labor being too expensive because of government fiat) is often wasteful. If the government passed a regulation requiring all manufacturing workers to work with their dominant arms tied behind their backs, you'd see a lot of innovation in the field of one-armed manufacturing processes, and this would substantially mitigate the harm caused by the new regulation. But the new equilibrium would almost certainly have lower total productivity. You can make an argument from complacency, i.e. that employers don't bother innovating when the status quo is good enough, and the supply shock caused by a higher minimum wage would wake them from their complacency and spur them to innovate in ways that would result in a more productive equilibrium. Maybe that's true, and maybe it's not, but it's not at all obvious, especially since many low-wage industries are highly competitive and unlikely to encourage complacency. And this argument for a higher minimum wage becomes an argument for any kind of negative supply shock. Seth: Of course innovation is "wasteful". We need such waste. It is inevitable. It is the price you pay for innovation. Thorstein Veblen made exactly the same mistake over and over and over. Complaining about wasteful decorations, for example. He failed to see the value of "useless" decoration and could do nothing but make fun of it. It was a serious limitation of his understanding. I agree that innovation is never obvious – it is never obvious that Change X will produce innovation.

August (2014-01-17 07:46:37)

There are economists talking about innovation, but they are talking about intellectual property and how your useful irritant is strangling innovation. When economists talk about minimum wage laws they usually talk about the poor people who are being screwed in the name of helping poor people. The irritant frames the debate, so to speak.

jon (2014-01-17 08:41:00)

The previous comments say it well. Like all government programs, the stated goal is one thing but the outcome is another thing which creates more "need" for more regulation rather than just remove the old regulation that caused the problem in the first place. It is more about controlling other people than anything else, power hunger.

Portlander (2014-01-17 10:11:04)

I'm completely convinced economists, in particular, are so stupid because they are so obviously lying. It is a one party system (Keynesian) used to give a cover story so that bankers and govt can rip-off the productivity of the middle class. To sell a pack of lies takes some effort and is inevitably going to have some contradictions to deal with. Trying to paper over those contradictions with yet more lies is going to make one sound stupid. If your job was to defend pre-Copernican astronomy, you'd sound

stupid too. Also, it's interesting you mention innovation because the 20th century had massive innovation which should have made the middle class incredibly, almost unimaginably wealthier. There's no denying in a lot of ways it has, however, in quite a few others and relative to those in the banking and govt classes, it's been a disaster. The reason is, the system has been set up to skim a large part of the wealth generated by innovation to the banking and govt classes. They control the money supply and get first dibs on it. This is all well-known, but there's a series of institutional lies used to justify it. Nowadays almost anyone that questions it is lampooned and dismissed, without even honest debate of the merits. It's treated like questioning the lipid theory of heart disease some 20 years ago. Anyone attempting that case would be labelled a kook and completely ignored by those that owned the megaphone and set the agenda. The internet has broken their monopoly on the megaphone, but they are still maintaining their grip on the real financial power. They've set up the system to have too much divide and conquer for dissenting voices.

jon (2014-01-17 10:31:31)

Coyote blog does a good job explaining why looking at the bare numbers of unemployment after a minimum wage hike doesn't make sense. Basically, he talks about how businesses plan ahead and cut jobs/hours months before the actual implementation of the minimum wage (since they are announced well in advance). Also, that only 3 % of workers work at minimum wage, so, if the minimum wage lowers employment by 10 % of those 3 % of workers, that is not that much. [http://www.coyoteblog.com/coyote\\_blog/2014/01/this-just-in-demand-curves-slope-down.html](http://www.coyoteblog.com/coyote_blog/2014/01/this-just-in-demand-curves-slope-down.html)

Daniel (2014-01-17 10:34:51)

I would like to see more differentiation between useful and useless or wasteful irritants. Let's frame this problem as an optimization problem, i.e. always looking for the highest mountain in a given map. It's very easy to find a local optimum: just always move upwards. But you get stuck at local optima very easily. Now you can throw an "irritant" at the system, i.e. move randomly downwards sometimes. This might lead you to discover a higher optimal point at another place on the map. In optimization theory people spend a lot of time tweeking these sorts of problems: how often should I move downhill, what should my step size be, and so on. (They will use different methods from this simple search, also, of course.) If you move downwards to little, it does nothing to find a new optimum. If you move downwards to fast or to often, you might not even find an optimum. It all depends on the structure landscape. If we assume for there to be just one optimum, all we need is productivity methods, i.e. moving upwards the hill. So, the relevant questions are: - Do we assume that there are not enough irritants already? - If it is, is the probability to small or is the step size to little? The minimum wage or any other of your given strategies might well be the wrong perscription. You might increase the frequency of irritants, when you "should" be adding magnitude, or you might add irritants to an overirritated system. These conditions should be elaborated quite a bit. Sounds interesting, though. Seth: I agree. It would be helpful to look at examples of each (government stifling innovation, government causing innovation) to see if there was a way of distinguishing the two. However one way that governments create innovation is that they disgust/mistreat people so much that they leave - move to America, for example. No one will ever argue that governments should mistreat people, yet in the past that really has increased innovation.

dearieme (2014-01-18 04:45:20)

A profession that busies itself in writing footnotes to Smith, Ricardo and Keynes may simply not understand what innovation is.

Paul (2014-01-18 09:33:31)

Yeah, remember how, when we had a high minimum wage like in the 60s, it created mass unemployment? Me neither. Just like with capital gains tax, there's a record of policy implementation here that the libertarian types in this comment section steadfastly ignore. Seth: I am puzzled that Australia, with a high minimum wage and exceptions for teenagers, is ignored.

MJB (2014-01-18 11:36:37)

Do successful anti-smoking campaigns reduce the population's level of intelligence? Other researchers point out the positive impact of smoking on the major advances and artistic creativity that have taken place in Europe and the U.S. over the last few centuries. A large number of writers and artists have been known as a passionate smokers, and geniuses like Niels Bohr and Albert Einstein have praised tobacco positive effect on their thinking. The English psychology professor Bruce Charlton asks

on his blog ; "Are we sacrificing genius and great inventions with anti-smoking campaigns in favor of longevity?" His answer: Maybe ... <http://www.sott.net/article/269265-Brain-Researchers-Smoking-increases-intelligence>

jon (2014-01-22 10:47:33)

I think saying government interventions are good because it causes innovations is a similar argument to the proverbial "broken window" fallacy. Yes, breaking the window will make the shop owner buy a new one (and maybe one that is shatter proof) but it will also cause the shop owner from putting the money towards something that could be even more innovative and useful that more people would rather enjoy. If it wasn't for all the government "irritants" maybe we would be putting that money to more interesting projects and maybe we would be flying places instead of driving or maybe we would be living on Mars by now. Seth: I'm not saying ALL government intervention is good. I'm saying the effect of government intervention is more complicated than what libertarians have said and more complicated than what other economists have said – because all of them (libertarian and non-libertarian) ignore the effects on innovation. In general, economists ignore innovation. They advocate this or that policy without grasping even a little what the effects on innovation will be.

jtw (2014-01-18 08:47:38)

Seth, I am unfamiliar with David Suzuki or with the details of climate science. So I watched the clip naively. I thought he didn't have any trouble answering the question: there is warming. He referenced the IPCC report. One of the first figures in the 2007 report is this one: <http://www.ipcc.ch/graphics/syr/fig1-1.jpg>. This shows a warming trend. How else should he have answered?

as (2014-01-18 08:58:39)

Top Ten Retractions: I found it hard to understand exactly what was retracted. An Indian guy faked data for his PhD. Indian people cheat a lot.

Joe (2014-01-18 10:10:10)

David Suzuki...the greatest living Canadian? Harump. EVERYONE knows that's Gordie Howe! To jtw: Check out this web site: <http://www.climatedepot.com/> No warming for almost 17 years. Which is why the warmists are busy looking for explanations.

JV (2014-01-18 10:11:59)

Scary facts about Splenda but can't say I'm all that surprised. And interesting the effects on gut flora is so bad. Have avoided all of these artificial sweeteners as much as possible, kind of assuming we weren't getting the whole story from manufacturers. But it's scary how many people consume them believing they are safe.

shtove (2014-01-18 13:02:50)

Hoax article in the retraction list: <http://retractionwatch.com/2013/09/23/a-serbian-sokal-authors-spoof-pub-with-ron-jeremy-and-michael-jackson-references/>

jtw (2014-01-18 18:01:00)

Joe: the graph at the link you supply that purports to show no warming comes from the not-very-credible-seeming Lord Monckton Foundation with no attribution or explanation.

dearieme (2014-01-18 18:14:44)

Suzuki's answer was woefully ignorant. If he really doesn't know the names of the main sources of the temperature records he should be thoroughly ashamed of himself. It was also disingenuous; it of course does not refute the proposition that a warming trend has been replaced by a flat trend to say that the last few years include the ten warmest, since that's what you would expect from a flat trend, or even from the start of a cyclical decline. It's hard to believe that anyone with a background in science could make that mistake honestly.

MJB (2014-01-18 20:07:37)

Here is Jo Nova's take on Suzuki (with 568 comments!): David Suzuki's performance on Q & A last night was extraordinary. I was knock-me-over amazed that he has not heard of UAH, GISS, HADcrut and RSS, and knew nothing of the pause in global surface temperatures that even the UK Met Office and IPCC lead author climate scientists like Hans von Storch are discussing. How afraid is Suzuki about man-made global warming? So afraid, it doesn't occur to him to check the data, incredibly he doesn't even know what the data is. Tony Jones had to rephrase the questions to explain them to Suzuki, who doesn't even understand them. How much is his reputation as a scientist worth when he doesn't even bother to check the evidence for a cause he stakes his reputation on? Three times in Q & A he admitted he didn't know — he didn't know there was a pause in warming for the last 15 years, he didn't know how global temperatures are measured, and he didn't know that cyclones were not increasing over the Great Barrier Reef. He wants politicians jailed for "denying the science". "You bet!" he exclaims, but then admits he hasn't thought that through either. <http://joannenova.com.au/2013/09/david-suzuki-bombs-on-qa-knows-nothing-about-the-climate/>

dearieme (2014-01-19 04:54:47)

Here's another interesting one, Seth <http://www.theguardian.com/books/2014/jan/19/lewis-wolpert-sorry-using-others-work> What do you make of his excuse "When downloading material from the internet as part of my research, and coming back to

it after a gap of maybe weeks or sometimes months, I simply did not recall that I had not written these passages myself.”? It strikes me that his own writing must lack character if he can confuse it with bits and bobs cribbed from the literature. I used to think that the old-fart scientists who were automatically suspicious of fellow scientists who sought popularity and large circulations were being dog-in-the-manger. Now I'm less sure. Seth: I ignore Wolpert's excuse. Maybe he paid someone to write it. Who knows. My experience is that when scientists write for a large audience they are as good or as bad as when they write for fellow scientists. For large audiences, Hans Eysenck and Richard Herrnstein wrote badly. For fellow scientists, they also wrote badly. On the other side, Leon Kamin and Ben Williams wrote well for both audiences. So I see nothing wrong with writing for a large audience. Good scientists do it well, bad scientists don't. There may be something to the idea that a certain deep dishonesty is behind some popular science writing by scientists – a willingness to say things are simpler than you know they are.

dearieme (2014-01-19 07:37:26)

Ahoy, Seth. Your sort of thing? [http://www.theguardian.com/science/2014/jan/19/mathematics-of-happiness-debunked-nick-brown?CMP=tw\\_t\\_gu](http://www.theguardian.com/science/2014/jan/19/mathematics-of-happiness-debunked-nick-brown?CMP=tw_t_gu) (H/T Bishop Hill) Seth: I am sort of on Fredrickson's side. She didn't understand the math. In psychology theories rarely matter. The math was theory. It is not wildly different from pointing out a spelling or grammar mistake if you realize how little theories matter.

Joe (2014-01-19 10:03:25)

jtwt: "the graph at the link you supply that purports to show no warming comes from the not-very-credible-seeming Lord Monckton Foundation with no attribution or explanation." Why does the Lord Monckton Foundation seem "not-very-credible"? As someone who claims to be unfamiliar with climate details, are you really in the best position to make that judgement? Additionally, Monckton is using data from RSS, the same data that's often used by the IPCC. That is, it's not his data. It's available to just about anyone who's interested. Moreover, the IPCC itself ACKNOWLEDGES there has been no warming for 17 years: "IPCC Head Rajendra Pachauri Acknowledges 17 Year Stall In Global Warming" <http://canadianawareness.org/2013/02/ipcc-head-rajendra-pachauri-acknowledges-17-year-stall-in-global-warming/> Suzuki should have known about this, no? If you spend some time on that web site, you'll learn far more about climate science than you will ever learn by reading, say, the NYT. And if you want to ask specific questions, feel free to join in the conversations on this web site: Watt's Up With That <http://wattsupwiththat.com/>

donny (2014-01-19 10:50:53)

Will splenda affect the palatability of the food that rodents eat? Studies where sweetener is added to the diet are problematic. If it affects either the quantity of food eaten, or the meal pattern (continuous nibbling vs. discreet meals, light cycle eating vs night cycle eating) then gut bacteria could be affected through the sweetness—and you'd expect to be able to find all sorts of poor results with sweetened foods—no matter what the sweetener. This would apply to cancer as well, when given with food—increased chow intake or a disordered meal pattern can worsen cancer. There are all kinds of bitter substances that seem to have beneficial effects, as well... Stephan Guyenet once suggested to me in his comment section that the bitterness might be affecting consumption, and as often be what leads to a good result, rather than some more complicated explanation.

Jonathan Graehl (2014-01-22 16:24:55)

<http://thephysicspolice.blogspot.com/2013/12/baking-with-splenda.html> "The results clearly show that overall, the same (or fewer!) dl-PCBs were produced with the addition of sucralose, whereas a different organochlorine molecule (1,3-DCP) did cause higher dl-PCBs. This demonstrates that knowing a molecule is an organochlorine does not imply it will necessarily result in elevated dl-PCBs as a byproduct of cooking."

## **Journal of Personal Science: Baby Shampoo Cured My Sinusitis (2014-01-19 05:00)**

by Bill Mitchell

Chronic right-side sinusitis came as a shock in November 2008, at age 42. For weeks both sides (left and right) were blocked. I lost my sense of smell even after my left sinus cleared. An incapacitating headache lasted months. My right sinus was often totally blocked. I had previously been in very good health. I had never been to a hospital, never taken medication, no drugs, slender, athletic, normal blood sugar and pressure, no dental fillings, etc. Some hay fever, but no other allergies.

The breakthrough was finding out about baby shampoo. In less than a week of shampooing my nose, a six-month headache was gone. It recurred occasionally until I fixed environmental causes. I tried many things, but the two that mattered were replacing the household carpet and vacuuming my mattress every couple of weeks. A couple of years later, my sense of smell returned. When you regain a sense you thought was lost forever, you appreciate even the stinkiest odors!

I found out about the use of baby shampoo to treat sinusitis from the website of a UCSD professor of medicine named Terence Davidson, who died recently. [Use of baby shampoo to treat sinusitis seems to have been recently [1]rediscovered by an Omaha journalist named Michah Mertes.] The website no longer exists, but is [2]archived in the Wayback Machine. The Wayback Machine shows that Dr. Davidson added mention of shampoo in summer of 2008, but by the summer of 2009 had removed it. Why remove mention of the only treatment that seemed to matter?

Sinusitis treatment in the U.S. is doubly silly. First, nearly all chronic sinusitis is fungal (said the Mayo Clinic in 1999), yet antibiotics are universally prescribed, with no effect on the primary infection. Second, no one ever looks for environmental causes.

#### **Things that didn't help:**

- Consulted five doctors: family GP, two urgent care, one internist, one ENT [ear nose throat]. None explored environmental causes.
- X-ray ordered by internist. Found a blob in the right sinus; ordered antibiotics, which had no effect.
- Scoped by ENT doctor. He viewed only the left sinus, because the right (the one with the problem) was too narrow to get the instrument in. Pronouncing the left side normal, he prescribed steroids, which had no effect.
- Medications prescribed in various combinations by all five docs, to no avail: antibiotics, Claritin, Sudafed, steroid inhalers, Nasonex, pain relievers.
- In my home, I sprayed bleach solution onto a small patch of mold found under my bedroom carpet.
- Replaced a leaky shower stall and mushy floorboards that had caused the mold.
- Hired an environmental consultant to look for mold in HVAC system. Found none.
- Had all acoustic ceilings removed, as they had been raining fine dust.

#### **Things that helped slightly:**

- Sinus rinse with saline alone. Has worked well for daily "maintenance," but when trying fix the headache and closed sinus, was like chipping at an iceberg with an icepick.
- Sinus rinse laced with topical antibiotic (obtained under prescription, at my request, from a doctor friend who saw no harm in it – purchased pre-mixed in saline solution, from a compounding pharmacy). Not obviously better than rinse alone.

- Sinus rinse laced with topical antibiotics, administered with my head upside-down, and left to steep in the sinuses for 20 minutes. My idea here was to use the antibiotics in part to prevent the side effect of an ear infection, since some water might go into the ears when re-inverting. No ear infection, but not much sinus relief either.

### Things that obviously worked:

- Reading about and treating biofilms with surfactants. This was a breakthrough.
  - Shampoo-laced sinus rinse was the first real success.
  - Repeated shampoo rinse, at intervals of 30 to 60 minutes. My idea was to let the surfactant break things up, then wash again while everything was wet and loose. This was much more effective than just once a day.
  - Simplest setup: I use a Neilmed squeeze bottle and salt packets (avail in supermarkets), mixed with tap water. I use tap because I trust that our city water is clean and chlorinated. I do not use warm tap water, because water heaters are supposedly bacteria farms. I use almost a teaspoon of Johnson's baby shampoo in 16 oz. of water. Using this much is painful – stings the nasal passage. Recently I learned that someone else gets the same relief, and no pain, using only a few drops of shampoo.
- Became more aware of a "sinus closing down" feeling. After a few months of relief, I could more keenly sense when my sinus would begin closing/inflaming/whatever, usually in response to dust exposure at home. This feeling could be used as a signal to decide what to fix next. Examples:
  - When sinuses closed, e.g. while kicking up dust cleaning the garage, I tried putting on a HEPA-filtered painter's mask (bought at Ace Hardware), to verify that sinuses promptly opened back up again. They did.
  - Purchased a highly-rated (per Consumer Reports) bagged vacuum cleaner. I suspect that cheap bagless vacuums (anything you buy at Target) silt up immediately, then simply blow dust around the house. So my sinus tells me.
  - Replaced the carpet, and vacuumed up the thick layer of dust beneath the carpet. Have not had a serious sinusitis recurrence since doing this.
  - Began vacuuming my mattress every two weeks. Probably should replace it: even now, I can feel my right sinus start to close after a few weeks if I don't vacuum it.
  - My sofa is a dust trap. I can feel it. Vacuuming doesn't help – it's on the replace-soon list, but I can afford to wait because things are under control now.

### Possibly interesting endnotes:

- At age 45, I got my first cavity. Dentist said this was unheard of: you either get cavities before age 25, or never. Cavity immunity is hereditary; neither my father nor his father ever had any; my siblings have none, except for a few my brother got after radiation treatment for cancer. My own unusual cavity occurred in the right maxillary first molar – a tooth whose root reaches up into my troubled right sinus. I mentioned to the dentist that it seemed interesting that this cavity, which he considered so unusual, should occur in the same location, at almost the same time, as the only other medical problem I've ever had. He said there was no connection, and, sounding a little bored, changed the subject.
- My right nasolacrimal duct is now wider than before – air escapes from beneath my right eyelid when I sneeze. Seems benign. Amuse your friends, loads of laughs.

- Warning on ear aches: nasal irrigation with too much pressure, or laying down on your side too soon after nasal irrigation, can let water drain into the middle ear, causing ear aches. I read the warnings and was careful, but still had this problem a few times. It was a small price to pay.
- I tell other sinus sufferers how well this worked for me, but it's hard to get anyone to try. Either they are grossed out by the process (understandable), or they have read the scare stories about fatal amoebic infections after sinus rinsing with bad tap water. These cases are extremely rare, and I believe all occurred when using untreated water in hot, humid climates. But the phrase "brain-eating amoeba" sure resonates – no one wants to try it.

### Possible origins of my sinusitis:

- 3-week visit to the Philippines a year earlier (no obvious infection).
- 1-week camping trip in the Sierras 6 months earlier (no obvious infection).
- Exposure to smoke from the [3]Freeway Complex Fire, the 4th largest fire in Orange County history, which partially burned a landfill, i.e. potential random toxicity. The sinusitis and headaches began within days after the fire; however, I was 10 miles downwind – pretty far.
- 1-month stay in someone else's house in December 2008, where the central heater was later found to be leaking a trace amount of carbon monoxide. This was concurrent with the worst of the sinusitis, but it did not get better when I went back to my own home. My family stayed in the same house, with no ill effect.
- In recent years, eating crappy batter-fried restaurant food increasingly causes strange nose/throat effects, such as wheezing and temporary sinus blockage. Fried chicken at Knott's Berry Farm is the worst – instant shortness of breath. I can think of no reason this should happen, but there it is.

### More

Remember how baby shampoo disappeared from the UCSD prof's website? Something similar happened at NeilMed's website, and the reason may be a nasty side effect. [4]This post says some people lost their sense of smell after using Neilmed's surfactant additive. Neilmed makes my favorite sinus rinse product, which uses a squeeze bottle instead of gravity feed. A few years ago they briefly began selling a surfactant additive, but then pulled it off the market, and now have only [5]an undated post saying the re-release is 2 to 3 years away. Maybe risk of side effects is why the UCSD guy removed it.

---

Cathy (2014-01-19 06:50:57)

Very interesting! First off, using baby shampoo sounds plausible, but once a hairdresser told me that any shampoo that has anti-tear properties is very harsh. Could other "basic" shampoos be as effective? I admit that it is extremely difficult to find a 'normal' plain shampoo. I have recently taken up drinking plain, warm water. It makes sense that water heaters are "bacteria

farms” as they tend to stay warm for a good part of the time. I enjoy warm water because I think it tastes differently from just tap cold or refrigerated water. I can change that I'm not picky. Interesting observations about battered fast food. Whenever my husband eats fast food battered or otherwise, he gets a fair amount of mucousy congestion (coughing, throat clearing) almost immediately! He knows there is a correlation, too. He has also suffered from mild asthma his whole life. I wonder if the asthma symptoms have other causes than what he thinks like cats etc? Since he likes the crispy chicken sandwiches but doesn't always eat them, I peg the oil used to prepare French fries and other deep fried stuff even if it isn't breaded. I don't trust these places not to use the same oil for cooking multiple items.

Alex J (2014-01-19 07:13:06)

Fascinating, thanks for sharing. Now we just need someone to pioneer the first snout transplant.

peter (2014-01-19 11:32:43)

you can buy Hypoallergenic Mattress Protector , and do the same for your pillows, so you don't have to vacuum the mattress.

Evelyn M. (2014-01-19 14:19:31)

Some years back I suffered from eczema on my eyelids that persisted and persisted. I knew if I saw a dermatologist I would be given a steroid and did not want something that serious near my eyes - so stayed far away from the medical profession, except the medical literature. One source - a Mayo Clinic document - suggested using baby shampoo full strength on the eyelids twice a day. It worked amazingly well - after about 18 months of disfiguring and painful eyelids the baby shampoo cleared it up in less than a week. Hasn't returned since (knocking on wood).

Laurel (2014-01-19 15:07:15)

Interesting article. I think the literature does use J & J Baby Shampoo. Recently, the company is replacing the old formula with one that doesn't have formaldehyde (supposed to hit the stores in the near future). Any recommendations for other baby shampoos for the sinus rinse that are equally effective without formaldehyde? Also, given that biofilms are the problem in sinusitis, and the surfactants in the detergents are the solution to breaking down the solution, what are the active ingredients that we should be looking for when selecting a proper baby shampoo for this rinse?

Kathy (2014-01-19 15:22:24)

It's no surprise that your dentist would not confirm your correlation - I would not be surprised if they are taught in dental school to deny, deny, deny! The differing metals in the typical amalgam filling constitute a battery, with saliva as electrolyte. So you might be able to get a lasting solution with the right dental work - I recommend Dr. Hal Huggins'-trained dentists (he has a website and contact number). My dental revision is making a huge difference for me!

Portlander (2014-01-19 18:41:23)

Which came first, cavity or sinusitis?

Bill (2014-01-19 20:33:48)

Sinusitis, by about 3 years, unless a cavity had gone undetected in prior dental visits.

Jason H (2014-01-20 09:37:45)

My wife and I usually have major sinus issues from Nov to March each year. This involves sinus rinses multiple times per week, Vaporub at night + a humidifier and taking the occasional decongestant. This fall I ran into a blog (can't remember where) that recommended drinking a Tbsp of unpasteurized apple cider vinegar before bed. We only do this every other day or so and we dilute it with half a glass of water (I can't image drinking it straight). The results have been shockingly awesome. I haven't done a single rinse, the humidifier is still stashed away in a corner somewhere and I haven't purchased any decons. We've experimented with skipping a 3-4 days and we both start to get a little clogged up. Seth: That's interesting, especially since Japanese and Koreans drink vinegar drinks - for example, pomegranate vinegar. I like them and drink them too. There is about 1 tablespoon of vinegar in each drink.

Bill Counselman (2014-01-20 12:01:00)

I have suffered sinus congestion for 30 years, trying everything from inhalers- effective for 12 hours-then no nose breathing whatsoever- and addictive; Pseudoephedrine- ineffective- and raised BP; steroids- ineffective; nasal antihistamine spray and pills- ineffective; months long series of allergy injections- so far no result; double dose of amoxicelien for the tooth-no change. A recent continuing sinus infection was surely caused by a right maxillary first molar infection which had an, apparently unsuccessful, root canal in 2011. I had it removed a week ago (leaving a hole the "size of a nickel" into my sinus cavity which had to be stitched up) but my right nostril is still partially blocked. I have been using a neti pot which helps for a while. I am considering breathing steaming water with a few drops of tea tree oil because of its antibiotic, and hopefully anti-fungal properties after seeing a 'Dr. Oz' program touting oregano oil for the same reasons. I would hesitate to sinus rinse with any commercial shampoo because of the many GRAS chemicals which I DO NOT RECOGNIZE AS SAFE and do not use. Remember that chemicals are easily absorbed through the skin and mucus membranes. My weak Delta Dental plan does not cover tooth implants, very little toward the cost of the Periodontists' tooth extraction fee, and of course nothing toward 'silver amalgam' (Wikipedia: "It commonly consists of mercury (50 %), silver ( 22-32 % ), tin ( 14 %)" tooth filling removal. Seth: I have Delta Dental and it covered about half the cost of my "silver amalgam" removal. Contact Sandor Hites, my dentist in Berkeley, to find out how this is done. About your sinus congestion: Have you considered the possibility that it is due to an allergy?

Portlander (2014-01-20 12:13:43)

Thanks Bill, that's what I thought but Kathy's comment seemed to imply (at least to me) she thought it went the other way. Re-reading your story I didn't see it clearly mentioned so I thought I would ask. MD's & antibiotics are like the old saying about hammers – when one's only tool is a hammer, every problem looks like a nail. Great story, and thanks for sharing. I've filed this away in my long-term memory. :)

Seth Roberts (2014-01-20 15:41:45)

"MD's & antibiotics are like the old saying about hammers — when one's only tool is a hammer, every problem looks like a nail." How true.

Bill (2014-01-20 22:26:55)

"Remember that chemicals are easily absorbed through the skin and mucus membranes." This is a good point. I use J & J baby shampoo, because it was (briefly) recommended by the UCSD researcher. Obviously it was designed to be non-irritating – "no more tears" – but as another commenter mentioned, until recently it contained quaternium-15, which breaks down over time into formaldehyde. J & J claimed in a Time interview that one apple contains more formaldehyde than 14 bottles of shampoo... <http://ideas.time.com/2012/08/22/the-real-lesson-of-formaldehyde-in-baby-shampoo/> ...yet they changed the formula this month to eliminate quaternium. <http://www.theverge.com/2014/1/18/5322990/johnson-johnson-drops-formaldehyde-from-baby-shampoo> To reduce the unknowns, if anyone can suggest a simpler product, the simplest possible surfactant that does not irritate mucous membranes, that would be helpful.

Can self treatment be useful? | Fratrik's Blog (2014-01-21 14:36:53)

[...] it is clear that conventional medicine did nothing for Bill Mitchell and his solution [...]

tom (2014-01-21 17:34:56)

You should check out <http://drellie.com> . She says cavities are caused by the wrong bacteria in your mouth making acid or acidic foods, and suggests using 3 different common mouthwashes, the original crest, and xylitol to reduce it, and it seems to work for me. I even have a xylitol nasal spray, but I haven't tried it. I had gotten a lot of cavities lately and I'm in my upper 40s. I also have this weird inflamed feeling in the base of my nostrils when I'm hungry. And I have some stomach gastritis, but my dr said 'everybody has that'. But I think my better mouth state helps everything else.

Sean Murphy (2014-01-22 13:36:44)

When I was younger and even into my 30;s I had sinus trouble and ear infections frequently. In the last decade or so I take

N-Acetyl-Cysteine (NAC) 500mg morning and noon and xylitol (4 grams or so morning and evening). You can buy xylitol in bulk (e.g. 1-2kg bag) and get enough for 4-6 months. Theories, NAC thins mucous keeps flowing, xylitol breaks down bio-film and has a specific anti-bacterial effect (confused with sugar but not digestible by them). Two more things to consider stirring into the mix.

Sam (2014-02-07 16:30:24)

I haven't heard of the Baby shampoo treatment. I had really bad sinus trouble and heard from Jerry Pournelle that a SinuPulse would help. I bought one and used it with salt water for a couple of years almost every day. It helped but what worked best and finally stopped my sinus was using sea salt, a pinch of baking soda, a couple drops of Lugal's solution and a 1/2 teaspoon of H<sub>2</sub>O<sub>2</sub> in the sinupulse for wash. Now I still use it but infrequently as my sinus problems are not near as bad. The sinupulse is expensive but worth it if you have sinus as bad as I had. There's two different kinds. One has a round tank. My round one stopped working in about a year. The other has a square tank and I still have it. It's lasted longer. Of course the square tank cost more. I think the square one is called a SinuPulse Elite. I have no financial interest in SinuPulse. Just have used their products. I also would not use the dial valve that lowers the flow. I believe that it puts more pressure on the pump. If the flow is too much don't press so hard against the nostril and let a little of the flow escape.

Sam (2014-02-07 16:30:56)

Forgot I added xylitol to the wash also.

Sam (2014-02-07 16:48:04)

One last thing. Twenty Mule Team Borax I bet would work better than baby shampoo. Borax is anti-fungal. Borax is also used to treat logs in log cabins but as borate but I believe it's the element boron that causes the effect.

Alain (2014-02-08 08:14:14)

Humming cures chronic sinusitis by increasing nasal gaseous Nitric Oxide (NO) -a natural antifungal- and it is actually free. Relevant studies: Strong humming for one hour daily to terminate chronic rhinosinusitis in four days: a case report and hypothesis for action by stimulation of endogenous nasal nitric oxide production. <http://www.ncbi.nlm.nih.gov/pubmed/16406689> Humming-induced release of nasal nitric oxide for assessment of sinus obstruction in allergic rhinitis: pilot study. <http://www.ncbi.nlm.nih.gov/pubmed/15305890> Humming greatly increases nasal nitric oxide. <http://www.ncbi.nlm.nih.gov/pubmed/12119224>

Carol (2014-02-08 15:35:52)

I had terrible sinus problems in high school - sinusitis, polyps. Eventually, my sense of smell was gone. Multiple visits to my ENT got me nowhere. Finally, in my late 20s, I started rinsing with a very strong saline solution (using an enema bag). Worked like a charm! My sense of smell, which had been mostly non-existent for 10 years, returned and has been with me now for over 20 years. No maintenance rinsing has been needed. The nice things about using the enema bag were that 1) the force was very easily controlled by my grip on the tube, and 2) those bags hold much more water than any neti pot or squeeze bottle.

daz (2014-02-09 18:31:22)

using an "enema bag"...now there's a good idea i'll have to go in search of a cheap 'bag' device myself now. i have used a netti type bottle and a smallish squeezable bottle in the past, & was looking for a better option without forking out loads of \$ \$ on some fancy powered machine

## **Who Will Make the Future Better than the Past? Professors or the Rest of Us? (2014-01-20 05:00)**

Stephen Hsu, who has [1]an excellent blog, recently became Vice President for Research and Graduate Studies at Michigan State University. Before that, he was a professor of physics. At a dinner for faculty promoted to full professor, [2]he said:

When an attorney prepares a case it is for her client. When a Google engineer develops a new algorithm, it is for Google – for money. Fewer than one in a thousand individuals in our society has the privilege, the freedom, to pursue *their own* ideas and creations. The vast majority of such people are at research universities. A smaller number are at think tanks or national labs, but most are professors like yourselves. It is you who will make the future better than the past; who will bring new wonders into existence.

In this blog, in thousands of posts, I have argued a much different view: everyone can make the future better than the past in the way Stephen is talking about, by adding to our understanding. In particular, anyone – not just professional researchers, such as professors at research universities – can increase our understanding of how to be healthy. This has already started to happen. Some examples:

1. Stuart King (a musician) commented [3]how much bedtime honey helped him sleep better. Learning about [4]this effect is a big step forward in knowing how to be healthy – good sleep is at the center of good health. No professional researcher has come close to Stuart's insight.
2. Katherine Reid (trained as a protein chemist but not a professor) discovered that if she removed all glutamate from her daughter's diet, [5]her daughter's autism disappeared. This is more progress than any professional researcher has made. None of them has made even one case of autism disappear.
3. Many people told me about how various treatments they learned about from this blog have helped them – for example Vitamin D3 in the morning and bedtime honey. I recently posted [6]a comment about bedtime honey, for instance. These treatments are so new and surprising that these experiences are meaningful. They help others decide if these treatments should be taken seriously. (For anyone who dismisses these reports as "anecdotes", I have one question: What have you discovered?)
4. I have used a brain tracking test to find out new things about how my environment affects my brain, including the [7]benefits of butter and the [8]bad effect of tofu. At least a billion people – everyone in China, for starters – eat tofu regularly. You might think that such a popular food would have been extensively tested for safety but, shockingly, other research supports my conclusion that tofu is bad. Anyone can do the sort of tests I did. Let me repeat my offer to give my brain tracking R software (which only works under Windows) to others who want to use it. There is an associated [9]Google Community to join.
5. Although I am a professor, [10]my self-experimental discoveries about sleep, mood and weight were outside the area of my graduate school training (animal learning). For example, I am not a sleep expert. I made my discoveries without expensive equipment or university resources beyond the library – that is, I made them with resources to which almost anyone has access.

I am sure these examples are the beginning of something important. They are easy to explain. Who is better equipped to discover important stuff about health, professional researchers (e.g, professors) or non-professionals (the rest of us)? Although professional researchers have big advantages over the rest of us – this is the usual view – non-professionals have big advantages over professionals that few people seem aware of. Sometimes the non-professional advantages outweigh the professional advantages and the non-professionals get there first. For example, a professional autism researcher could have done what Reid did (measure the effect of removing all glutamate on autism), but Reid did it first.

The advantages of non-professionals over professionals, a topic I have discussed [11]many times, include:

1. Ability to self-track and self-experiment. This is too humble for many professionals. In *The Theory of the Leisure Class*, Thorstein Veblen emphasized that professors like to show off via their work. This is a disaster for science, where small (low status) and fast is much more effective than big (high status) and slow – a lesson that few

health scientists have learned.

2. Freedom. Non-professionals can study anything, consider any crazy idea, test any treatment. Professionals must be respectable. Institutional rules and committees also constrain them.

3. Time. Non-professionals can study any problem for as long as they want. Professionals must publish regularly.

4. Motivation. Because they study their own problems, non-professionals are highly motivated to find the truth. For example, no one cares more about the safety of your food than you do. Professionals usually study problems whose solution gives them no practical benefit. While non-professionals care only about their own health, professionals care a great deal about their career, which makes it [12]quite a bit harder to do the best thing for other people's health.

5. IQ (which Stephen often blogs about). If you randomly select one professor who studies health, and compare him/her to a thousand randomly-selected non-professionals, the top IQs among the non-professionals will be much higher than the professor's IQ.

I [13]keep writing about this – hardly saying anything new – because it is so important, so non-intuitive (in almost every other area of knowledge, such as physics, only professionals make lasting contributions) and no one else says it.

gwern (2014-01-20 08:40:32)

> (For anyone who dismisses these reports as “anecdotes”, I have one question: What have you discovered?) So, you can only criticize some music if you're a musician? You can only criticize research if you've published research? You can only criticize a movie if you've directed a movie? A classic excuse, but it doesn't wash: you don't need to be a farmer to know what bull shit smells like.

Sidney Phillips (2014-01-20 09:00:20)

Seth: I'd just like to point out what you had mentioned earlier on the dangers of mercury fillings. I'm studying for my USMLE Step 1 medical board exam and I noticed my memory wasn't nearly as sharp as it used to be. At the same time my doctor diagnosed me with hypothyroidism; he said it was Hashimoto's without even running labs. I paid for my own labs and my tests came back negative for anti-thyroglobulin antibodies, which should be present with Hashimoto's. Around this time, I read your earlier post how your memory improved after removing your mercury fillings. Also in that same post one of your readers had cited some pubmed studies linking mercury fillings to thyroid problems. I decided to have my fillings removed by a dentist knowledgeable in doing so since you have to remove them carefully. It's been only 5 days since I had them removed but I already feel sharper, as if the brain fog has lifted. I'm detoxing now with chlorella, cumin, and water high in silicon (Fiji). So, I was able to better my health thanks to one of your blog posts. My own doctor didn't have the time or inclination to think deeply about my problems, and had the arrogance to diagnose Hashimoto's without even running labs. I will certainly not go back to him. The problem is finding a doctor who is open to alternative remedies and is current with the latest research. As I told my parents, I can't imagine most doctors after a long day's work wanting to come home and sit in front of pubmed for 2-3 hours. Seth: A doctor would not need to sit in front of pubmed for 2-3 hours to realize it might be a good idea to order labs. And doctors are supposed to continue their education, which should definitely include looking at recent research.

MJB (2014-01-20 12:15:33)

Mathematics of happiness debunked by Nick Brown The astonishing story of Nick Brown, the British man who began a part-time psychology course in his 50s – and ended up taking on America's academic establishment Who was he to doubt the work of a leading professional which had been accepted by the psychological elite? "The answer," says Brown when I meet him in a north London cafe, "is because that's how it always happens. Look at whistleblower culture. If you want to be a whistleblower you have to be prepared to lose your job. I'm able to do what I'm doing here because I'm nobody. I don't have to keep any academics happy. I don't have to think about the possible consequences of my actions for people I might admire personally who may have based their work on this and they end up looking silly. There are 160,000 psychologists in America and they've got mortgages. I've got the necessary degree of total independence." "Not many psychologists are very good at math," says Brown. "Not many psychologists are even good at the math and statistics you have to do as a psychologist. Typically you'll have a couple of people in the department who understand it. Most psychologists are not capable of organizing a quantitative study." <http://www.theguardian.com/science/2014/jan/19/mathematics-of-happiness-debunked-nick-brown>

Cliff Styles (2014-01-20 12:32:59)

It seems to me that apart from the value of self-testing to discover new health things, you are actually promoting a kind of heuristic for living that can apply to any arena, a heuristic that is as valuable as learning valid rules of inference. Part of what self-testing does is help us question our own convictions in a way that can produce evidence of an apt answer one way or another. Simply committing to self-testing, to mastering it, and then learning from doing it alters the way we think, not just our behavior in a particular domain. 'Learning from really doing it' is as much an education and testing of our own feelings as it is some objective test of the non-subjective world.

emini\_guy (2014-01-20 14:59:16)

I agree with gwern that experts and non-experts should be treated in the same way and subjected to the same level of scrutiny. I have benefited quite a bit from gwern's research into melatonin and I have found melatonin helpful for improving my sleep. I have yet to find Seth's ideas equally useful, but I do appreciate them as stimulating and I did give them a fair try and continue experimenting with them. It is not particularly hard, though, to find people who make their careers or build online reputations by attacking the ideas of others without giving them due consideration. The Internet made it quite easy for such people to flourish. Some of them may have hidden agendas, which you will not find out unless you do some extra digging.

gwern (2014-01-20 15:09:51)

Sidney Phillips: > It's been only 5 days since I had them removed but I already feel sharper, as if the brain fog has lifted. Mercury poisoning onset can take a long time (Minamata disease took 5 years from initial release to first diagnosis), the symptoms can persist for decades, and many are irreversible. Nootropics users taking worthless substances often report 'feeling sharper' and

a lifting of 'brain fog' in the first week of consumption... MJB: you should really read Gelman's comments on that research: <http://andrewgelman.com/2014/01/19/british-amateur-debunked-mathematics-happiness/> Many stories are oversold, and that's no exception.

CC (2014-01-20 15:21:01)

Seth, I get your larger point, but I think the stuff you wrote about weight loss and AS has to be the most revolutionary. The rest of the medical establishment has made basically zero progress on obesity, and you discovered something significant and actually cured a bunch of people. Not surprisingly, academics refuse to take it seriously. So here you have a major health crisis, ONE person put a dent in the problem, and none of the authorities want to acknowledge it. [Btw, any hints for what what to do if the AS effect from ELOO fades over time?] Seth: I wish I could say I "put a dent in the problem" but I am afraid hundreds of thousands of people doing the Shangri-La Diet is not many compared to hundreds of millions of obese people. Maybe someday. I think the obesity epidemic is partly driven by a depression epidemic – that is the more serious problem. If you are depressed you eat certain foods to feel better and they are more fattening than other foods. I do have a new idea about what causes depression (lack of morning faces) but I have yet to write a book about it. If the AS effect from ELOO fades – and even if it doesn't – I suggest you switch to nose-clipping other sources of fat, such as flaxseed oil and butter.

Seth Roberts (2014-01-20 15:39:53)

"It seems to me that apart from the value of self-testing to discover new health things, you are actually promoting a kind of heuristic for living that can apply to any arena, a heuristic that is as valuable as learning valid rules of inference." I have tried to do experiments in other areas but only in the area of health have I found my experiments paid off. For example, I used to measure the mileage of my scooter. These measurements were never very helpful, although I did them for years. On the other hand my self-testing has helped me in other ways, as you say. 1. It has made me very skeptical of experts (because what they said was contradicted by what I directly observed) and I agree that such skepticism is at least a good starting point for understanding many things. For example, journalists gain nothing by being so credulous about what scientists claim. I recently gave the example of James Fallows and Eric Lander. 2. I believe that if professional scientists did the self-testing I advocate they would learn better how to do their jobs, and that would help the rest of us. 3. Another general lesson from self-tracking and self-experimentation is not to be dismissive. To realize you can learn from small things and imperfect things. This isn't taught – if anything, the opposite is taught. Lots of smart people are dismissive.

Cliff Styles (2014-01-20 18:49:20)

I got enormous and unexpected benefits from trying the experiment of eliminating wheat from my diet, and apart from the health benefits, it made me aware of some of my own biases, and that they are correctible, at least somewhat, if I am willing to self-test. I emphatically did not WANT wheat to be a problem, and it was only a nasty symptom that motivated me to try the experiment of eliminating it. I was somewhat dismayed by my discovery, though relieved, too. If I had been more attuned to self-testing earlier, for instance if I had learned self-testing as I learned about logical fallacy or other useful thinking methods, I might have approached many things in life with a view to self-experimentation and testing. That might have included testing things where I felt something that made the prospect of testing unpleasant. Your point about people being dismissive is something that I did to myself in many arenas. I think - suspect, really - that an attitude that included testing might have led me down some interesting paths. The question is how to test that, I suppose? Seth: No, I don't think there is any need to test whether self-testing (doing it, learning about it) is beneficial. It obviously is. I think of literacy. It is obviously beneficial, we don't need to wonder whether it is. Literacy and self-testing both give a wider relatively-unfiltered view of the world. Literacy shows the outside world, self-testing the inside world.

Sara (2014-01-21 01:36:09)

Great post. I do think that credulity serves journalists in that questioning scientists would force them to do much more work, and expose them to having their own authoritativeness questioned.

DA (2014-01-21 01:54:56)

@Sidney Phillips Sidney- I urge great caution with your detoxification procedure. Mercury is a neurotoxin and must

not be moved around without appropriate understanding and care. Your use of chlorella, in particular, can make things much worse. Please visit these two email lists: <http://groups.yahoo.com/neo/groups/adult-metal-chelation/info> <http://groups.yahoo.com/neo/groups/frequent-dose-chelation/info> and look at this book: <http://noamalgam.com/> Good luck.

Brock in HK (2014-01-21 05:31:57)

Hsu's comments should be accepted as the same platitudes that are offered to every graduating high school or college class regardless of its quality. "You are the future!!!!" The obvious clue is he told them they would advance science out of pure motives rather than for profit or gain. While a good launching point for this blog, it's mostly innocent as a speech of its type. It certainly would be less inspiring to tell them they are insignificant cogs in a wheel and will probably not perform their chosen profession correctly, which is your assertion will happen. That said, you are probably correct about most of the promotees addressed.

Nancy Lebovitz (2014-01-21 11:51:40)

Maybe it's time for a list of self-experimentation friendly doctors. There's already a list of fat-friendly health professionals: <http://fatfriendlydocs.com/> - it exists because many health professionals tell fat people to lose weight instead of paying attention to actual symptoms. Actually, what I'd like is a list of health professionals who listen and think, but that's a little harder to define and publicize. Seth: That's a good idea. If someone sends me as little as one name I will post it. I would like to find a doctor near Berkeley who will approve lab tests that I will pay for.

Nancy Lebovitz (2014-01-21 18:47:12)

Posting a doctor's name is good, but having a page that's easy to search for is better.

Nancy Lebovitz (2014-01-21 18:47:40)

Correction: having a page that's easy to search for and add to is better. Seth: Yes, I agree.

John Smith (2014-01-21 22:07:17)

Seth, you ask the eternal question: which one..... egg or chicken? Which is the most important, the flintlock or the flint? In truth, it is neither, but both. Which gender is the most important, the male or the female? The answer is the same: it takes the pair of them to make it tick. Individuals can come up with innovative ideas, revolutionary ideas even and great solutions to problems, and they are the active entity. The establishments act as the stone, the flint, and the unmovable. It is the spark that they two emit that fires the cannon. Individuals whether professional or one of the people can come up with this new perception, but until enough of 'we the people' embrace it, it will not influence the establishments. The establishments are self-preserving and unmovable, whereas individuals are self-sacrificing and irresistible. Establishments will not embrace any innovation that threatens their status or the equilibrium of the 'economy' or the interest of the masses collectively. They are far more likely to sacrifice individuals as collateral damage just to maintain the status quo. The evolution of the round earth concept is my favorite example of how new perceptions take forever to be incorporated into the establishments. The unfortunate part of it all is when professionals come up with good ideas that work for individuals but would topple the society were those ideas to be implemented, they are faced with choosing between their own wellbeing and the advancement of the new idea. A cancer cure (for example) would be a disaster right now for our economy. The older an establishment is, the bigger it is and the more powerful, the more is at stake should it be made redundant by newer and more workable ideas. These new ideas can come from both professionals and common people. Ironically, the professional has more to lose should he postulate something that is against the interest of his power base, so the wise ones often look to see which side of their bread the butter is on. We the people have nothing to lose, so we speak our own truth regardless of how it may suit the establishments. As an example, I may postulate that the earth is still growing, as it reduces the light from the sun to matter in the form of minerals, which would be quite in keeping with Einstein's theory. A professional is far less likely to postulate such a foreign idea, yet Jules Verne, (a playwright) could suggest space travel, regardless of how long it took Tsiolkovsky and his like to bring it into the realm of serious human endeavor. Jesus taught the people in parables. Lewis Carol hid his 12 place decimal system in a children's book. Any new idea that is perceived to be a threat to the establishments will only fly when enough laymen endorse it. It could be suggested that until establishments yield we the people cannot progress (as a class). As individuals, however,

we may progress and influence other individuals. Individuals are at liberty to change. Sufficient numbers of 'us' can change establishments. Establishments are loathe to change except in favor of themselves and their influence and control over the masses. By what measuring unit, standard or specification will we be able to know if the world improves? Isn't this present moment the most perfect one?

## **Carbohydrate Near Bedtime Improves Sleep, Say Two Books (2014-01-21 05:00)**

Janet Rosenbaum, a professor of epidemiology at SUNY Downstate Medical Center, Brooklyn, writes:

Has anyone mentioned the connection between the honey/banana before bedtime and the advice to have an ounce of simple carbohydrate without protein before bedtime? There have been at least two books on this idea: Potatoes, not Prozac by Kathleen DesMaisons and The Serotonin Power Diet by Judith Wurtman. The first book suggests a small baked potato and bans alcohol and sugar during the day. The second book allows an ounce of any carbs such as pretzels. The proposed mechanism is that eating protein during the day, and carbs before bed without protein increases serotonin production over night, and my own experience is that it improves sleep and creates more vivid dreams.

I cannot easily get the Serotonin book here in Beijing but I found [1]this related to the Potatoes book:

Now that you are having three meals a day at regular intervals, let's add Mr. Spud to your routine. Have a potato (with its skin) every night three hours after dinner. It will help your body raise your serotonin level and make you feel more confident, competent, creative and optimistic. You can eat your potato baked, mashed, roasted, cut into oven fries or grated into hash browns. Just be sure you eat the skin. And you can top it with anything you like except foods that contain a protein. (Protein eaten along with the potato at bedtime will interfere with your serotonin-making process.) Good toppings are butter, salsa, mustard, spices, or olive oil. Toppings you should NOT use are cheese, sour cream, bacon bits, or cream of chicken soup.

I found when I ate honey with cheese the sleep-improvement effect of the honey was much reduced, in agreement with what is said here about avoiding cheese.

[2]Here's what happened when one person tried this. I am quoting only the parts about sleep:

[Day 1] I had the infamous potato at the recommended time. That potato really kept me up. I barely slept. What was this about her saying that a potato helps you get a good night's sleep? But I'm willing to give it some time. I never get a good night's sleep so it will be nice to see what that's like again.

[Day 2] This night, I could not sleep at ALL. I was up till around 4 am. How can a little potato keep a person up so much?

[Day 3] I finally had that promised sleep that the author was talking about. WOW. I haven't ever felt quite like this before.

[Day 4] A blissful night's sleep.

[Day 9] Those potatoes really work on making one's sleep much better.

[Day 23] I am not eating potatoes at night most of the time, which is part of the **PNP** [Potatoes Not Prozac] diet, but not something that you start from the beginning. [Nothing about sleep.]

Maybe she stopped the bedtime potato because she wanted to lose weight faster.

A potato near bedtime will surely increase blood glucose during sleep, supporting the idea that a better supply of blood glucose is what improves sleep. Presumably it's important to do this without (a) triggering too much insulin production or (b) increasing brain activity so much you wake up. Whether glycogen, in the liver or elsewhere, has anything to do with this I have no idea. Glycogen is one source of new glucose as the brain burns thru blood glucose but another is not yet digested carbohydrate in what you've recently eaten (e.g., potato).

1. <http://www.radiantrecovery.com/4r.htm>

2. <http://www.fatassdiet.com/potatoesnotprozac.html>

---

Charlie Currie (2014-01-21 08:05:48)

A spoonful of honey seems, to me anyway, a much easier solution than eating a potato (with the skin) every night. Seth: True. But both fruit and potatoes have fiber, honey doesn't. Mr. Heisenbug has convinced me that fiber is very important.

Scott Pierce (2014-01-21 08:20:28)

I have suffered from cluster headaches, which wake me up regularly around 4 AM near every morning. Since starting a tablespoon of honey, I have only woken up once with a headache and was easily able to go back to sleep. I have slept all the way through to my alarm and actually don't want to get up. I haven't done that in maybe a decade. This last Saturday, I actually slept until 8:30. This is all definitely new territory for me. I have tried so many things from melatonin to holy basil extract and nothing has come close to the honey. It took several days before I noticed a difference and I almost gave up. Thankfully, I didn't. One protocol I followed for a short period was taking glycine, which is recommended by some for sleep problems. I wonder if it might be a similar mechanism in place for both?

gwern (2014-01-21 09:07:13)

So, it's great that two books speculate about this, but did either include any actual experimental evidence? As in, systematically recorded interventions and data collection with objective metrics collected by eg an actigraph?

dearieme (2014-01-21 09:13:26)

Avoiding cheese must be much easier in the USA.

Nancy Lebovitz (2014-01-21 10:49:18)

Any theories about why a potato before bedtime could make sleep a lot worse and then a lot better?

Charlie Currie (2014-01-21 14:32:08)

And, why not a sweet potato...there's over 5 times the amount of sugar...so you should be able to eat 1/5 of a sweet potato and get the same effect.

tom (2014-01-21 17:22:28)

Video on Dan's Plan about sleep. He stresses 1/2 hr of sunlight in the day. <http://www.dansplan.com/blog/2553-how-light-exposure-affects-health-an-interview-of-dan-by-dr-joseph-mercola>

daz (2014-01-21 18:57:34)

anyone read the 'Potatoes, not Prozac' book... looking at the excerpts above, it seems that eating the potato skin (as well as 'flesh') is important (critical?) for it to 'work', does it mention why in the book?

daz (2014-01-21 19:15:04)

i found some related text which hooks in to this topic on a site here, <http://goaskalice.columbia.edu/serotonin-and-foods> (caveat, i know nothing of the credentials of this site or author). some of the text, "Carbohydrate-rich meals often increase serotonin levels. However, manipulating serotonin levels through food may be very difficult to achieve because serotonin's properties may have varying effects in different people. Some people may experience a temporary lift in mood after a carbohydrate-rich meal, while others may become relaxed or sleepy. Certain foods that increase serotonin levels aren't the healthiest choices either. Believe it or not, candy and sweets, which are simple carbohydrates, have the greatest impact, but the effect will only last 1 to 2 hours. Complex carbohydrates (rice, potato, pasta) may increase serotonin levels, but not to the same extent because the protein content of these foods might actually inhibit serotonin production. Here's a brief explanation of the mechanism behind the effect of food on serotonin levels: after consumption of a carbohydrate-rich meal, the hormone insulin is secreted. Insulin lowers the blood levels of most amino acids (the building blocks of protein), except for tryptophan (a precursor to serotonin). Amino acids compete for transportation across the blood-brain barrier, and when there is a larger proportion of tryptophan, it enters the brain at a higher rate, thus boosting serotonin production. To make matters more interesting, tryptophan is present in many protein-rich foods, which have been found to prevent serotonin production. So, you can see how intricate and complex this system is. In terms of the effects of actual foods on serotonin, here are some suggestions from nutritionists: If you're having trouble falling asleep, try a small snack of carbohydrate-rich food. Warm milk may work for the psychological comfort, but also because milk contains a moderate amount of carbohydrate in the form of lactose (milk sugar)" "The carbohydrate/tryptophan/serotonin pathway is simply a hypothesis at this point. Since each of us is unique, in order to get a "desired effect" from food, you would need to experiment eating different foods and observing how your body reacts to each of them. You'll also need to take into consideration your other lifestyle choices — how much sleep you get, whether or not you exercise regularly, the medications you take, your stress levels, etc. — when figuring out what affects your moods in what manners"

John Smith (2014-01-21 20:28:09)

Certainly the protein foods are big consumers of energy in the digestion process, so a handful of nuts or soybeans prior to sleep seems risky to me. Carbs like potato, rice, oats etc., that digest quickly and easily, yield a higher percentage of net energy. The fiber provides the slow release effect, making the energy from the gut longer running. The honey, of course, requires almost no converting, i.e. energy input prior to utilization by the cells. All foodstuffs need a 'net energy' score, as some take almost as much energy to utilize as they yield, and this is strongly influenced by how efficient the metabolism of the individual is. So a young person will get a better 'yield' owing to a strong digestive system, whereas an old person can at time get a negative result, i.e. it took more energy to process than what it delivered.

Justin Irving (2014-01-22 11:34:37)

This makes me wonder about the mechanism behind "carb backloading", the protocol of the physics guy/bodybuilder Kiefer. If Seth or others are familiar with this protocol (go nuts on carbs a few nights a week), maybe all the hand waving about mTOR is a side show, and what is really happening is that a late carb meal is causing better sleep, and better sleep the muscle gains ? Anyway, my point is that other healthy-oriented bloggers have found a connection between carb timing and health. Background: <http://robbwolf.com/2012/11/27/kiefer-carb-backloading-episode-160/> Seth: Good point.

daz (2014-01-22 15:30:33)

"[Day 3] I finally had that promised sleep..." i wonder why in this anecdote, it took till the 3rd night for this person to see

an improvement in sleep (a vast improvement by the sounds of it). in fact on nights 1 & 2 the person reported worse sleep. ...anyone have any ideas/theories (why it took till 3rd night to work)...? ... & any possible explanations/reasons why nights 1 & 2 would be worse...? thx Seth: I agree, that's a good question. One possibility is that there is large random variation in his sleep and on the first two nights it would have been unusually bad had he not taken the honey.

Adam (2014-01-24 11:10:28)

The Serotonin aspect reminds me of SSRIs like Sertraline (Zoloft). They have listed as common side effects BOTH somnolence (excessive sleepiness) AND insomnia. People starting SSRIs commonly feel stimulated or even anxious, presumably due to the greater Serotonin activity going on. If it is too bad, sometimes the doctor will have them reduce the dose. Often it just improves after a while on its own. Perhaps the lady had deficient Serotonin activity for a long time & the sudden increase due to the potato led to her reaction. Makes me wonder if reducing the dose to half a potato during the acclimation period would have helped.

### Assorted Links (2014-01-22 05:00)

- A very common knee surgery ( \$14 billion per year spent on it in America) [1]turns out to be no better than sham surgery in many cases. Plainly this supports critics of medicine who say there is overtreatment. To be fair there is good news: 1. At least this particular operation wasn't [2]contraindicated by high school biology. 2. The study was done and published. 3. And publicized widely enough to influence practice.
- [3]Heart guidelines based on fake research probably killed tens of thousands of people. Making useless knee surgery look good.
- [4]"The time you're taking to help this girl, you could be ..." A great talk by Jessica Alexander about ten years working for NGOs. Her book is Chasing Chaos: My Decade In and Out of Humanitarian Aid.
- [5]On EconTalk, Judith Curry, the climatologist, makes the excellent point that it is weird to call someone who believes climate questions are more complex than portrayed a "denier". In every other use of the term, a denier is someone who avoids recognizing complexity, i.e., the opposite. On the other side of the ledger, Curry makes an elementary physics mistake when she says that as an ice cube floating in your drink melts, the water level of your drink rises. (It stays the same.)

dearieme (2014-01-22 05:54:00)

What can you make of a world where a leading climatologist isn't familiar with Archimedes' Principle? She should have mastered that at thirteen or fourteen. Seth: I think it means you don't even have to understand Archimedes' Principle to realize the vacuity of the arguments for anthropogenic global warming.

GB (2014-01-22 06:17:58)

I haven't listened to Curry's talk, but surely there's a difference between melting sea ice (which is analogous to the melting ice cube in a glass) and melt from continents (Antarctica, Greenland) and glaciers, which would add to sea level. Seth: Curry said that when the ice in your drink melts, the level of the water rises. Sure, when a glacier sitting on land melts, the water level rises.

Tom Passin (2014-01-22 07:55:33)

Well actually, the water level in the glass will fall, because ice has a lower density than water. When the ice melts, its density will increase and its volume will get smaller. Judith Curry seems to have other reasoning problems when taking about climate change: <http://tamino.wordpress.com/2014/01/21/one-of-the-problems-with-judith-curry/>

Roger Sweeny (2014-01-22 08:45:34)

Tom, no, the water level will not fall. Yes, as the ice melts, its density will increase and its volume will be smaller, but some of the ice was NOT IN THE WATER. It was floating above the water. That part of the ice now goes into the water and exactly counteracts the effect of increasing density. That's because how high something floats depend on its density. The less dense it is, compared to water, the higher it floats. (The buoyant force on something is equal to the weight of the fluid it displaces. So a bit of pure ice in pure water has to weigh exactly the same as the fluid it displaces. Then, when it melts, it will take up exactly the same amount of space as the water it previously displaced, and there will be no change in water level. Glaciers in the sea are more complicated. Salt water is more dense than pure water but glaciers also contain rocks and dust.)

Greg (2014-01-22 09:02:19)

Her quote from the EconTalk transcript. "Again, the bigger wildcard is how much the glaciers are going to melt. So, once you melt the great glaciers, it's like adding more ice cubes into your glass of water, once they melt it causes the level of water in your glass to rise." This is different than just melting ice in a glass causing the water to rise. Seth: It is? She said "once they melt..." meaning "when they melt, but not before that . . .".

Stephen (2014-01-22 14:14:32)

I've had that knee surgery, and it was very successful! Which makes me wonder what actually is happening there. For example, was my return to normal function actually the result of my post-operative care and exercise regime? Or perhaps the surgery isn't very accurate and helps some to roughly the same extent it harms others? Apropos the glaciers: my country (New Zealand) has several glaciers on land, which is also the case for a large chunk of Antarctica. Sea level will rise when they melt – that ice wasn't floating on the sea before and the meltwater will add to the sea's volume. They are consistently melting now too. Curry may be wrong about the mechanism but she is right that melting glaciers will cause or are causing sea level rise.

Tom Passin (2014-01-22 19:50:45)

I stand corrected, Roger Sweeny is right. The decreased volume of the melted ice exactly offsets the volume of ice that had been above water before melting. I worked it out for a simple example to cross-check the thinking. And, as he says, the case of real glaciers consisting of frozen non-salty water and having embedded materials makes the details more complex (not to mention density changes with temperature changes), but clearly won't change the result in any important way. At any rate, the glacier melt from non-floating ice is what would affect the sea level, not the floating ice.

Alex Chernavsky (2014-01-22 21:37:33)

With regard to NGOs and helping poor people in third-world countries: <http://www.npr.org/blogs/money/2013/08/2-3/214210692/the-charity-that-just-gives-money-to-poor-people> A charity called "Give Directly" has had remarkable success with just giving money away, no strings attached. It's a wonderful concept.

Shep (2014-01-22 22:03:15)

Again, the bigger wildcard is how much the glaciers are going to melt. So, once you melt the great glaciers, it's like adding more ice cubes into your glass of water. Once they [the great glaciers on land] melt it causes the level of water in your glass to rise." Change the comma in the transcript to a full stop and the meaning changes.

Matt (2014-01-23 02:04:35)

I think her point is that glaciers, on land, melt \*into\* the water, so more water is there overall. Seth: That's so obvious no sane person would say it. I don't think that's what she meant, especially since she mentioned ice cubes in a glass.

MJB (2014-01-24 04:57:07)

Judith Curry doesn't think that "as an ice cube floating in your drink melts, the water level of your drink rises" just like President Obama doesn't think there are 57 states even though he said so. Here is her recent testimony before the Senate: [http://www.epw.senate.gov/public/index.cfm?FuseAction=Hearings.Testimony &Hearing \\_ID=e07101a7-0715-7690-b6e9-c39e56a3b468 &Witness \\_ID=b46b2226-01bf-4156-a675-ae9093e5e140](http://www.epw.senate.gov/public/index.cfm?FuseAction=Hearings.Testimony&Hearing_ID=e07101a7-0715-7690-b6e9-c39e56a3b468&Witness_ID=b46b2226-01bf-4156-a675-ae9093e5e140)

### **Berkeley Undergraduates and Professors: Then and Now (2014-01-23 05:00)**

Stephen Hsu mentioned the documentary At Berkeley. In response, someone who had graduated from Berkeley long ago and recently returned [1]commented:

One thing hasn't changed much though, most professors still hate, and with studied contempt, having anything to do with undergraduates.

My mom was an undergraduate at Berkeley. I asked her what she thought of this comment. She didn't agree, but she didn't exactly disagree:

I got absolutely no sense of "studied contempt" or dislike from profs. Some were dull, one went on my forever hate list because he humiliated a student in public, some were difficult, one was very conservative but provoked me into doing good work. More or less enjoyed my economics courses, including one on "labor" taught by Clark Kerr. Maybe the sociology professors were like that. I'd declared it as my major, but didn't like a single sociology prof I had, and barely escaped thru to graduation with them.

[2]As I've said, [3]Ken Jowitt, a political science professor at Berkeley, humiliated students who came in late. At one point he was Dean of Undergraduate Studies.

When I got a job at Berkeley, I remembered my mom's comment that she'd had only three good professors (Kerr, Robert Nisbet, and David Mandelbaum, an anthropology professor). I wondered if I would be her idea of a good professor. It turned out that quite a few professors treated undergraduates badly, as Hsu's commenter says. One professor told me that when a student came to him with a grading complaint, he made the student put the complaint in writing – just like [4]in post-Soviet Russia, where paperwork obstacles were placed in front of those who wanted to start a political party. Another professor, I was told, did not look at students who came to see him during office hours. He sat with his back towards them. A third professor, when I asked when the assigned reading would be available (I was auditing his class), wouldn't say. "Sometime," he said.

With few exceptions, the profs I knew avoided students, as Hsu's commenter says. One of them, when a student asked to see him, told the student, "I'll be around." It was easy to see why they avoided students (students bored them, wanted stuff, were full of complaints, "wasted" their time, and had nothing to do with what they really cared about, their research) but it said a lot about the situation, such as how much the professors learned from the students – not much, apparently.

Yet I learned an enormous amount from my undergraduate students, especially two of them. One student, in response to an open-ended term project assignment, chose to give a talk to a high school class about depression. Yet she had stage fright! It was extremely difficult for her to give that talk. But she did. Based on more conventional assignments, she had seemed a mediocre student. After I read her paper about what she'd done, I saw how much I had underestimated her. And it wasn't just her. I suddenly saw how much the whole system – which judges undergraduates by how much they resemble professors – grossly underestimates almost all of them. What a tragedy. This is the fundamental thing to realize about undergraduate education, that students are judged by how closely they resemble professors. Excellence in other ways is ignored. It is an incredibly wasteful system. It is like "evidence-based medicine" reviews that ignore 1000 papers on a topic to focus on 4 papers that meet their restrictive criteria. And then claim to have summarized the subject.

She wasn't even the most extreme case. I taught introductory psychology for a few years. One of my lectures was on weight control. I showed a graph of how I had lost weight when I had started eating less processed food – oranges instead of orange juice, for example. At the same time as the weight loss, I had started to sleep less (40 minutes less per day). One of my students came to my office hour. He said he knew another way to lose weight and need less sleep: eat food high in water content. He showed me a thick book that promoted this. The book looked bad – no data, just words. But he said it had helped him.

So I tried it. At first I ate four pieces of fruit per day. Nothing happened.

I ran into the student. Hey, I'm eating four piece of fruit every day, nothing's happened, I said. He said, "I eat six pieces of fruit a day."

So I went from four to six. I was already eating so much fruit that to eat two more pieces meant I had to change my breakfast. I changed it from oatmeal to two pieces of fruit. Exactly then my sleep started getting worse. I had been waking up early about half the time; I started waking up early all the time. Eventually I discovered that any breakfast caused early awakening. Oatmeal was simply better than fruit.

This experience was the turning point in my whole scientific life. It made me begin to realize that personal science – or self-experimentation, as I called it then – was a powerful tool.

My views about both teaching and research, in other words, were greatly shaped by contact with undergraduate students. The influence wasn't passive – I did a lot more than simply listen to them – or simple. I did my part: gave unusual assignments, gave students much more freedom, tried student suggestions. In both cases, I ended up with a point of view very different than my colleagues and very different from the point of view I started with. I think professors can learn a lot from undergraduates because some of them are so different than professors. They are challenging and inspiring in ways graduate students are not.

dearieme (2014-01-23 15:46:20)

I much enjoyed supervising final year undergraduates on research projects - principally experimental, sometimes computational. They are cleverer and more interesting than you would think if all you did was lecture them. Especially if you lectured past them rather than at them. On the other hand I remember with horror the twerps who taught me freshman physics. Could I face spending another three years in their company? I could not. Seth: I liked my undergraduate professors, at Caltech, College of Marin, and Reed, except for the College of Marin French teacher who wouldn't let us, his students, speak French because we mispronounced it.

bjk (2014-01-23 21:07:06)

One professor said that professors avoided undergrads to avoid the adulation of students. This was at U of Chicago, that may be something unique to Chicago. It made a certain sense to me, though; that is a responsibility most professors don't want (and some do, of course).

Portlander (2014-01-23 23:44:56)

Seth, you're a Reddie? Nice. I'm not one myself, but there's a few of them that end up never leaving town. Generally, I've found them to be sharp, interesting people and a lot of fun to be around. I'm guess I'm not overly surprised you'd have gone there, nor overly surprised you didn't finish there - or did you? Seth: I finished there. When I was there, Reed had its own version of mistreating undergrads - assigning grades but not telling students what they are. School policy.

dearieme (2014-01-24 03:58:57)

"assigning grades but not telling students what they are": rather different from my experience. Not only were my, and everyone else's, grades published on notice boards, our Finals results appeared in the better sort of newspapers.

Portlander (2014-01-24 09:02:16)

"assigning grades but not telling students" Haha. Funny that's what you bring up. A friend liked to joke... sleeping with students was frowned upon and would result in a letter of reprimand; telling students their grades meant immediate termination.

Alex (2014-01-27 19:39:07)

"French teacher who wouldn't let us, his students, speak French because we mispronounced it"? Wow, that is a special kind of crazy. How does no one put a stop to it?

Dragan (2014-01-30 16:28:15)

Having studied at Berkeley and now working there as an instructor, the quality of teaching and uh "civility" of the professor seems quite variable. However, I will say that in 7 years I've been involved with the university, I never had the impression it's as bad as some of those stories make it seem. Nor have I noticed a significant difference in this matter between Berkeley and the few elite, research-heavy, private universities I'm familiar with (both east and west coast). Perhaps it has something to do with a particular department(s)? Seth: My direct experience is in the psychology department. However, antipathy toward teaching undergraduates seemed to me to be universal. In 25 years as a Berkeley professor, I don't think I ever heard another professor - including me - say something positive about teaching undergraduates. I heard lots of negative comments. In contrast, people often liked teaching graduate courses.

## Beijing versus Berkeley: Which is Healthier? (2014-01-24 05:00)

This graph shows my brain test reaction times over roughly one year. Each point is a different test; I usually do two tests per day back to back. I assume faster = better. In February 2013 I returned to Berkeley from Beijing. In August 2013 I went back to Beijing. When I returned to Berkeley, my scores got worse (slower). I was shocked. Surely Berkeley is healthier than Beijing. At first I thought it was jet lag, but the scores stayed worse long after that made sense. Then I thought it might be some difference in diet, even though I eat similar food in the two places. I tried to make my Berkeley diet closer to my Beijing diet. This might have helped. I noticed accidentally that chocolate improved my score and started eating chocolate frequently. This artificially reduced the difference since in Beijing I had not been eating chocolate. In Berkeley I started doing two things I hadn't done in Beijing: alternate-day fasting and whole-body vibration. I don't know if they made a difference. When I returned to Beijing in September, my scores got better, even though I was not eating chocolate. Eventually I improved my sleep in Beijing but that seemed to make little difference. The comparison is far from perfect – many things varied – but by and large my scores got worse when I went from Beijing to Berkeley and improved when I went from Berkeley to Beijing.

What might have caused this? There are a hundred possibilities but one stands out. In both places, I brew and drink several cups of tea every day. In Beijing, everyone, including me, drinks water from big plastic bottles that are delivered to your house. You can choose pure water or "mineral" water, which has added magnesium and potassium. In Berkeley I use tap water (Brita filtered). I don't think potassium affects brain function – for example, eating bananas makes no difference – but there is [2] plenty of evidence that magnesium improves brain function. In Beijing I had tested a magnesium supplement and found no effect, consistent with the idea that I was already getting enough. Magnesium is also believed to improve sleep. In Beijing I seemed to sleep better than in Berkeley. Again, this is consistent with a difference in magnesium levels (more in Beijing). If ordinary magnesium-enriched water improves brain function, it would be significant because it is so easy, in contrast to [3] other ways of increasing magnesium levels.

2. <http://www.nature.com/news/testing-magnesium-s-brain-boosting-effects-1.11665>
3. [http://www.lef.org/magazine/mag2012/feb2012\\_Novel-Magnesium-Compound-Reverses-Neurodegeneration\\_01.htm](http://www.lef.org/magazine/mag2012/feb2012_Novel-Magnesium-Compound-Reverses-Neurodegeneration_01.htm)

Xav (2014-01-24 05:50:09)

What's whole-body vibration ? I don't think I've seen you mention it before.

Brock in HK (2014-01-24 06:50:55)

Maybe because Beijing is otherwise so unhealthy you take extra precautions there whereas in Berkeley, where you would perceive your day-to-day environment as relatively benign, you aren't as careful about other potentially negative environmental exposures to toxins? Your water choice could be one of those 0.5 % things that add up over a number of different items to become statistically significant. I know when I go back to the US, I relax on the bad stuff that I would otherwise not eat in Hong Kong, where I pay more attention. Part of it is some home cooked meals from my childhood contain ingredients I don't eat now, for example. Part of it is that in the US, Taco Bell is right there and calls my name, but in all of Asia there is no such temptation.

August (2014-01-24 07:08:18)

Does Berkeley have flouride in their water? The Brita filters don't get rid of flouride.

Tom Passin (2014-01-24 07:56:39)

To me the data look like one smooth curve that has not got much to do with location. The reaction times rose during the first Beijing trip, picked up in Berkeley at about the same level, then began a long steady decline that continued through your entire Berkeley residence and through the next Beijing one. I don't see a discontinuity when you went back to Beijing. With that much scatter in the data, you shouldn't pay much attention to details like wiggles and shelves in the smoothed data, even if you use LOWESS smoothing. Or use a much wider smoothing window. To me, the simplest explanation would be that when you got back to Berkeley, you started doing something that has a small but long term beneficial effect. The improvements are still playing out. Judging by the data, the rate of improvement appears to be declining - perhaps the effect has nearly run its course. Now what is causing the change, if anything? Seth: The Berkeley Beijing discontinuity is somewhat hidden by the fitted lines which average over large periods of time. Look at the points closely and you will see it.

Charlie Currie (2014-01-24 08:01:29)

Maybe it's stress. Whether you think about it or not, maybe Beijing is less stressful than Berkeley. I find that sitting on the beach is very relaxing, much more so than any other "natural" environment (i.e. parks, mountains, desert), and usually take a little nap. The ocean has high levels of magnesium and as waves break on the shore their magnesium filled mist is carried on shore by the sea breeze where it is easily inhaled. Maybe the magnesium in the water reduces your stress level, improving your scores.

Mark (2014-01-24 08:15:18)

I agree with Tom Passin, your results (with the exception of the weirdness present in the Beijing "run-in" period) would seem to be consistent with a continuous improvement from Berkeley period through second Beijing period. Also, wondering if you use the same computer in both locations? Seth: I use the same computer in both locations. Had I used a different loess parameter, the sharp change from Berkeley to Beijing would have been clearer.

Scott Pierce (2014-01-24 08:32:05)

My first thought was perhaps the impact of being in new surroundings (e.g. Beijing) would cause an excitability that would positively impact reaction times whereas Berkeley, even after a stint away, is old-hat. Returning to Beijing a second time would be less impactful as the "newness" would not be present the second time around. Seth: I'd spent a lot of time in Beijing before this data.

Joe (2014-01-24 14:07:02)

"Maybe the magnesium in the water reduces your stress level, improving your scores." Which should be easy enough to test.

Richard Sprague (2014-01-24 15:31:10)

Looks like classic training effect to me: your reaction times are getting faster because you take the test so often. What, exactly, is the test? Did you make some kind of adjustment back in late 2012? I don't have self data like yours about reaction times, but

my Zeo data (several years, across both countries) shows no difference at all. Eg. if REM is a proxy for stimulation or something, I see no patterns. FWIW, anecdotally I feel more "alive" when I'm in Beijing: Lots of new, interesting stimuli everywhere, regular interaction with unusual people from different backgrounds. In the US I'm just another guy. It'd be interesting if that anecdotal sense was quantifiable. Seth: The practice effect stopped long before this data was collected. The test is a choice reaction time test. It was constant over the period shown.

anon (2014-01-24 22:05:04)

seth, i've played dozens of video games in my life, many of them nothing but elaborate "choice reaction time tests", and skill plateaus followed by gradual improvement are common all along the skill spectrum. you cannot say with any confidence that practice effects have stopped. Seth: Going from Beijing to Berkeley I slowed down. That cannot be due to a practice effect.

John Smith (2014-01-25 16:06:55)

Seth, I have yet to discover just where you stand on the subject of astrology, or better yet, the cycles of life (which are never out of sync with the solar system!). But you must be aware that cycles accompany most parts of our lives. I have no doubt that a competent 'astrologer' would reveal that some important cycles were involved in your personal ups and downs. If you dig deeper into your own awareness of self, you may discover that many things in your life were in a state of flux, change, reorganization, etc. about the time your dots were dancing. Sleepless nights in my life can be triggered by many events, of course, but no one causative suspect can ever be relied on to promote such. It takes several of them to produce the effect, and that generally occurs when there are negative aspects in the solar clock to the position of Uranus in my birth chart. Your reaction time will be affected seriously at times when Mercury is in a challenging position to your birth positions. In my experience, the 'mood' of the solar system is the only causative factor that reliably is indicated in any situation. Do the planets compel us? Not necessarily, but we certainly respond to their transits and we cannot escape their influence, only adapt to it. Try getting your daylight off sync to the real one. Try getting summer in California to be winter, just for your own purposes. It will not work. Even being on the moon is no escape, it is only a variation.

anon (2014-01-25 18:08:03)

my comment was not about the increase in RT from beijing to berkeley. i said, specifically, that practice effects cannot be excluded as a partial explanation for the observed improvements because it is not easy to tell when practice effects have stopped. even simple skills develop in fits and starts.

Steve (2014-01-26 14:38:41)

Seth - what was responsible for the very abrupt slowdown in Beijing before you left for Berkley? It looks quite unnatural compared to the other changes and discontinuities? Seth: Good question. I don't know.

BRW (2014-01-31 12:31:54)

So, are you planning on taking a magnesium supplement for a period in Berkley and testing after that? Seth: Yes, I will test the magnesium explanation.

BRW (2014-02-01 16:43:32)

Terrific, can't wait to hear the results!

Ben (2014-02-02 19:58:55)

Does this test rely on the site of your computer network? In the vane of a practice effect: some suggest lots of plateaus in skill before improvement as new neural networks are built. Not likely the reason though IMO.

"Unfortunately you [US residents] still need a doctor to order them"?

Mike (2014-01-25 13:24:38)

Hi Seth! Love your stuff. I follow this basketball coach/trainer's blog, and thought of you: "Why did I prevent the player from using ice? Everyone knows that RICE (rest, ice, compression, elevation) is the accepted treatment for an injury like an ankle sprain. Whereas it is accepted, is it the best treatment? When a player twisted his ankle earlier in the season, and went to the doctor, the doctor told him to rest 3-5 days and ice the ankle. Who am I to suggest that a medical doctor was incorrect? Of course, he missed almost two weeks of practice time and games doing his own form of rehab (he went home, so I never saw him), whereas this player could have returned to the same game and played the next day without any rest or ice (just compression and elevation)." <http://developyourballiq.com/return-to-play-after-an-ankle-sprain/>

John Smith (2014-01-25 16:16:36)

A sportsperson brave enough to rub a little Manuka Honey on the throbbing spot as immediately as possible after the incident will be amazed at how the honey talks to the cells in such sweet tones that the trauma is extinguished as though water had been put on a fire. The ice trick was mainly to prevent bruising, as that was a visible sign. However, for healing to commence (and infection and bruising to be prevented) blood flow needs to be adequate with plenty of nutrient in it as well. The Honey ensures both. The extent of the injury is crucial, of course, but the effect of the honey is welcomed by the tissue regardless.

anon (2014-01-25 18:10:37)

what does everyone think of metamucil as a source of fibre?

dearieme (2014-01-28 02:04:56)

A case for a balanced diet from the Old England Journal of Medicine. [http://www.dailymail.co.uk/health/article-2546975/One-twin-gave-sugar-gave-fa t-Their-experiment-change-YOUR-life.html](http://www.dailymail.co.uk/health/article-2546975/One-twin-gave-sugar-gave-fa-t-Their-experiment-change-YOUR-life.html)

## **Journal of Personal Science: Nasal Congestion Due to Fabric Allergies (2014-01-27 05:00)**

by Nathanael Nerode

I have an inhalation allergy to polyester and acrylic dust that caused no end of trouble, especially nasal congestion. It took 20 years to figure out.

I live in Ithaca, NY. My nasal congestion started after a multi-month trip to China in 6th grade, in 1988. The air in Beijing was truly awful, and literally everyone had nasal congestion while there. But my congestion didn't go away when I came back.

To figure out why it hadn't gone away, a doctor (allergist) back in roughly 8th grade did prick tests. The "dust" test was said to use actual dust collected from houses. In retrospect, it presumably included polyester dust. It was the only prick test, other than the control histamine injection, to show an allergic response. The idiot doctor proceeded to claim that I had a dust mite allergy even though the "dust mite" prick test was negative. I told him no, I didn't, and he should learn to read his test results. I asked what was in household dust other than skin, hair and mites. He somehow did not manage to come up with "fabric". If I'd been bright enough to think of that then, I might have been able to figure this out much sooner.

In some ways my nasal congestion was quite bad. I got secondary sinus infections repeatedly, due to the airways never, ever clearing out. I carried Kleenex with me everywhere, and bought it by the case. I had to mop my nose a few times every hour. When I caught a cold, the frequency would increase to every couple of minutes.

The congestion lasted continuously through multiple living quarters at college and back in Ithaca – of course, at all those locations I had brought a full set of clothes, and had a typical polyester bed, and most had carpeting. It mysteriously cleared up once – during a trip to North Carolina. Only in retrospect did I realize that on the trip I was sleeping on a futon in a house with no carpeting, with nothing but cotton clothes.

The allergies were definitely triggered more indoors than outdoors and were worse in fall than spring. I quickly eliminated the possibility of detergents by repeated changes of detergent with no result. I was then stuck with no further ideas for 20 years.

After 20 years, I moved into a new house while bringing very little with me (only a couple of sets of clothes). Suddenly my allergies went away. I realized the cause was something in the old house but not the new house.

I could keep stuff at the old house, and I moved in really slowly, so I was able to do challenge-response experiments, with a multi-week test time for each.

I had had work done on the new house. I first eliminated wood dust, tile dust, drywall dust, and grout dust as possibilities, because they were all over the place while I was there. Then I moved in huge piles of books. Still no allergies.

Then I moved in my clothes. (Still no bed, latex futon.) My allergies came back instantly. I moved the clothes back out, sorted them by fabric, and waited four weeks for my symptoms to clear.

Then I moved the clothes back in one fabric at a time, with a two-week testing period to see whether symptoms developed for each. Luckily I was not allergic to the first thing I tried, which was cotton.

After finding the polyester allergy and moving the polyester out, I waited four weeks for symptoms to clear up before moving the next set in. Eventually I found the acrylic allergy too.

I also had to stop testing for a month or so at least three times when I caught colds, as determined by additional symptoms or by family and friends developing the same symptoms.

This took a long time – about a year – and is not a straightforward option for most people. I haven't tested every fabric yet. I stopped after I got through all the common ones.

After I was "detoxed", I started having a noticeable mild contact allergy to polyester and acrylic, which confirmed the conclusions. I think this wasn't noticeable before due to constant exposure creating suppression of the response.

So I solved the problem from a combination of luck (moving into the new house showed that it wasn't generic "dust") and pure grinding testing, much like most science.

I'm not sure many people would have the opportunity to test the way I did. I modeled what I did on the hardcore "challenge" protocol used for food allergies where you start with a very limited diet and "challenge" it with one thing at a time. How many people can do that with fabrics? You need a place to store the rest of your clothes. You may need to buy all-cotton socks or underwear or shirts or pants if you didn't own any (luckily I did) – and you need to have no carpet and remove your BED from the house (which I had done anyway coincidentally).

---

Josh Manley (2014-01-27 08:45:41)

Thanks for the great article Nathanael. The key insight was that you took the absence of symptoms seriously and decided to investigate it further. Too often we fail to recognize that a sudden change in symptoms is both relevant and an interesting question to explore further.

Jack (2014-01-27 10:41:18)

Fascinating.

JRM (2014-01-28 13:15:51)

Wow. Just wow. I have read anecdotes about people who follow a paleo diet see their allergy response decreased. Presumably, removing inflammatory foods from the diet causes the body's inflammation response to go down and the body reacts less to the allergen. I wonder if the author of this tried removing certain foods from his diet (dairy, grains, etc.) after figuring out the polyester and acrylic allergy to see if the body reacted less severely.

Bill (2014-02-02 16:02:12)

This is impressive, thanks for posting.

## Which Ideas of this Blog are the Most Useful? (2014-01-28 05:00)

"Your writing has dramatically improved my health in a number of ways," a reader said. I asked for details. He replied:

I've tried most of your health interventions. The first was SLD. Overall, I lost about 90 lbs. Roughly half of this was from a more traditional diet of eating whole foods esp. vegetables and exercise. I had plateaued until I discovered SLD and lost the rest. I added flax oil, butter and homemade kefir to my taste free meal over time. The butter helped me lose more weight. At the same calories, the saturated fat was somehow more filling. Initially the butter made me happier but that wore off after a few months. My HDLs and triglyceride levels are better than when I was training for a marathon and not eating this stuff. The flax oil has improved my gum health. I can't really see a direct result from the kefir. I'm more eating it on faith. I skinned my knees quite badly a while ago. My wife commented on how quickly I healed. So maybe the kefir and other items are helping me heal faster.

I tried morning faces twice over about a week without success. My job exposes me to a lot of evening fluorescent lights. I picked periods when I wouldn't be exposed, but even if it worked, I couldn't have maintained it over a long period.

Insomnia has been a long-time problem for me. One legged standing didn't have a noticeable impact. Shifting my vitamin D3 to the morning seemed to help a bit. Bedtime honey has led to a big improvement. It's uneven, but more often than not I'm sleeping much better. Even when I don't sleep as well, I don't feel as tired as I did without using honey. My mood has also improved. I'm calmer and happier. The honey seems to reinforce my circadian rhythm. I have more energy in the morning and am tired in the evening. I'm currently tracking what else I'm consuming and when to see if I can figure out how to get the benefits on the honey more consistently. My wife and friend have tried honey at bedtime and both report improvements.

My view is that of the cause-effect relations I have emphasized, the most useful will be (a) the [1]effect of morning faces on mood (hard to use at first), (b) the [2]effects of sweets on sleep (easy), and (c) the [3]effects of foods on brain functionb. Bedtime honey is just the first of the sweets effects and [4]flaxseed oil and butter are just the first of the brain effects. Full understanding and use of the morning faces discovery lies many years in the future. Of the various methods I've developed, I think the most useful will be the [5]use of reaction time measurements to improve brain function (and, probably, overall health). At the level of what might be called "meta-methods" (the usual name is big ideas), I think the most useful will be that [6]people who aren't health experts can discover important things about health.

AI (2014-01-28 08:37:14)

What is the long term effect on the pancreas of eating that teaspoon of honey each night? Seth: I don't know. But better sleep -> better immune function -> less of many diseases, including cancer.

Sara (2014-01-28 10:29:46)

Al, you know that tens of millions of Americans eat cookies or ice cream before bed each night, right? Visit your local market around 10 pm any night and see what's being scanned at the registers. Seth: No, I did not know that. That's a very interesting idea, that there is a shift in what is bought toward sweet stuff in the evening. Where I live in Beijing there is a massive shift in what is sold in the evening: fruit is much more available after 6 pm than before because a bunch of fruit vendors open for business.

Kelly B (2014-01-28 11:06:25)

I'd vote for honey (still going strong!) and just the general promotion of self-experimentation science; that we can and should set up n=1 controlled trials of our ideas and look hard at the results, rather than waiting for the rest of the world to come up with the "Way to be Healthy (TM)".

Xav (2014-01-28 14:07:22)

Two results I have had from two ideas on this blog : 1) Flaxseed oil, which has mostly fixed my problems with bleeding and painful gums. 2) Probiotics. Unexpectedly, a long standing, nagging pain in my right hip has almost gone since I started taking a daily probiotic supplement to improve my gut microflora. Taking the probiotic, and adding more prebiotics like leeks to my diet, are the only major changes I can think of that happened at the same time. It may just be coincidence - however a Google search for people with conditions like Crohns and IBS and with hip pain brings up quite a few results, so who knows there may be a connection.

Jake (2014-01-28 14:55:35)

The greatest benefit I have received from this blog is the idea of being a personal scientist. Try new things and evaluate the results. I try to inspire my friends to do the same thing. Seth: Thanks!

nansen (2014-01-28 20:12:33)

Item [b] (bedtime honey) helped me with item [a] (morning faces). Since I have been on hemo-dialysis, it's been very difficult to get out of bed around 5:30 am PST in order to get a strong effect from the faces. With the honey, I have plenty oomph even on only 5-6 hours sleep. (After the treatment, I can take a nap to catch up.) Thank you!

John Smith (2014-01-28 23:33:01)

I really like the idea of do it ourselves science, especially if you can pull a bunch of like minded people together, Seth. Not that there is a great dearth of good science, but mostly the good stuff is too controversial so it gets swept under the carpet if favor of something more 'politically correct.' Even on a full tummy, sugars can find space, hence we can always roll up for pudding regardless of having gagged previously on turkey. Just as water will find room in a jar full of marbles, sugars can squeeze into a glass full of water without changing the volume. Seth, what do the Chinese think of honey? Is real honey vs analog honey an issue there? I hear they are keen importers of Australian honey yet are regarded statistically as the world's greatest exporter of 'honey.' Seth: The Chinese think honey is a health food. Many vendors sell only honey. However, I don't hear about it being associated only with bedtime. I can buy Australian honey at stores that sell foreign products but not most stores. Most Chinese food stores sell only honey from China.

Jack (2014-01-29 09:22:52)

I have tried taking honey before bedtime(I tried 1,2,3 and 6 teaspoons on different occassions) and in every case I could not get to sleep for hours! It kept me awake for hours and acted like a strong stimulant! I felt terrible and mean in the morning every time; not well rested. So like most things, Honey before bedtime may help some people sleep better but may not work for everyone. In Chinese Medicine, honey (and/or sugar, liquorice or anything that tastes sweet) is used to cure ailments of the

stomach and small intestine. It is a YIN energy tonic, taken for energy. It is also good for the lungs and large intestine but bad for the kidneys, bones, teeth, sex organs and hair on the head. Sweets are also used to water down the effects of stronger herbs and medications. Two tablespoons of sugar in 12 ounces of water will usually cure nausea or stomach aches quickly. Also Seth, I've been wanting to tell you how foolish it is that modern medicine uses sugar pills as placebos for medical studies, because sugar itself is a medicine and cures many ailments it cannot be considered a placebo. And as you have proven, it can also be used as an appetite suppression. And Seth, it's amazing but oil and butter fall into the same Chinese medicinal category as honey and sugar... so strengthening the stomach and small intestine may be yet another benefit of the Shangri-La diet! And as to Honey, the great mathematician Pythagoras is known to have eaten only bread and honey all of his life, and he lived to be well over 100 years old.

JM (2014-01-30 10:42:16)

Sorry Jack, but if you check wikipedia you will find that very little is known of Pythagoras actual life (we are talking Greece circa 500 BC) and even how and when he died is in question so I wouldn't put much stock in that bread and honey story.

funder (2014-01-30 13:06:05)

Nobody's mentioned Vitamin D in the mornings yet? Totally changed my life.

Anne (2014-01-30 13:21:06)

I am so very grateful for this blog. I have learned D vitamin in the morning, for me it is a life saver. I live in the nordic countries and have problem in the winter. I also find it helps me sleep better. Sunglasses in the evening when looking on TV or computer, makes it much easier to go to sleep. Earlier I had to stop at 8pm to be able to sleep in normal time. Omega tree helps my gums and I do not need to go to the dentist so often. I used to have severe gum problems with a lot of inflammation and bleeding, as I lost my own teeth in a car-crash back in the 70. As I think gluten is not that good for me anymore, so I make crackers out of flaxseed to have for breakfast instead. I also use a lot of butter today and I feel it is good. I am raised in the fat phobic generation, I did not eat any butter or fat for more than 30 years. When I work a lot from home I do faces in the morning, but when I work I meet a lot of people early in the morning I of course tried the bedtime honey since a couple of weeks, I cannot for sure say if it is very good or only good. Some nights I wake up at 02.00 am on honey, I mix with a green banana before bedtime. On the banana I do not wake up at 2 am. But I am more alert the day after on honey before bedtime. Perhaps those that get insomnia on honey react different. Like some people like my self cannot drink coffee later than 3 pm and other can drink coffee just before bedtime.

Draga (2014-01-30 16:17:41)

For me, I'd say the "most useful" was just seeing another academic say some of the things I've been thinking about (but seemed crazy). For example, "appreciative" vs "critical" thinking. Stuff like that. On self-experimentation front, eating food with no taste (noseclip) is so effective it's like cheating.

Bill (2014-02-09 08:50:36)

Sleep and allergies have been your most useful subjects for me. A subject you haven't covered, but which might be popular, is female hair loss. It seems possibly more treatable than male pattern baldness - there are hints of nutritional or hormonal causes (lysine, iron, thyroid, estrogen, etc.) - but it does not seem to have the full attention of the normal medical community. I wonder if you have any self-experimenting readers out there who have succeeded with this.

## **The Turning Point in My Self-Experimentation (2014-01-29 05:00)**

Several people have said that bedtime honey made them wake up too early. [1]For example:

No effect for me, worse for my wife (hours of wakefulness in the middle of the night after a few hours of sleep)

The commenter said this meant it wasn't working.

My view is different. To me, this experience suggests that there is something safe, cheap and practical (honey) that has a powerful and non-intuitive effect on sleep. Finding something like that is extremely hard. (Drug companies have spent billions of dollars trying to do this, with far worse results.) It isn't easy or obvious or trivial to learn how to use that powerful force to produce improvement rather than harm ("hours of wakefulness in the middle of the night"), but I am sure it is possible.

My first important use of self-experimentation was in graduate school. I discovered that one of the medicines my dermatologist had prescribed for my acne wasn't working. The notion that a prescribed medicine didn't work is useful, but not shocking. This success was enough to launch me into self-experimentation to improve my sleep – specifically, to reduce early awakening. This turned out to be very hard.

After ten years of trial and error (all error), [2]I discovered something that made my early awakening reliably worse. I was thrilled. After ten years, something finally made a difference, albeit in the wrong direction. It was a turning point. I did many experiments and finally figured out that any breakfast made my sleep worse. This was far more progress than finding out that a prescribed medicine didn't work. It was progress because (a) nutrition experts usually said that breakfast was "the most important meal of the day". My discovery flatly contradicted that. I became a lot more skeptical of experts, a view that has served me well. (b) Eliminating breakfast greatly reduced early awakening, and (c) the discovery showed that self-experimentation could do better than expert advice in surprising ways. My interesting self-experimentation began with the discovery of something that made my sleep worse.

I too have found that although I am sleeping much better, bedtime honey and other evening sugars have also made me wake up too early more often. I too need to learn how to better use this new knowledge.

Jon (2014-01-29 11:10:34)

Hi Seth, Today I came across a recommendation for honey before bed from another source, Dave Asprey (bulletproofexec..best known for recommending coffee+butter+mct(coconut) oil in the morning) He wrote: I also recommend that, on zero starch days, you consume up to 1 tablespoon of raw honey before bed along with MCT oil. Raw honey forms liver glycogen preferentially compared to other forms of sugar, and liver glycogen fuels the brain better than muscle glycogen. Some people don't need to do this, but if your sleep quality improves, it's an easy biohack that doesn't take you out of ketosis thanks to the wonderful powers of MCT oil. No comment on whether or not it works..just thought you may be interested in another person linking honey and sleep. Seth: Thanks. I got the idea from Stuart King, who got the idea from Dave Asprey. Who got the idea from a book by Mike McInnes.

Michael (2014-01-29 13:21:06)

This is interesting for me because I have the opposite problem. I'm a very deep sleeper and it take a lot to wake me up. If I didn't set an alarm I'd oversleep every morning, and even after I wake up I'm still groggy for some time. I used to never eat breakfast, but I started after reading that it caused you to wake up too early. I found that it does help me wake up earlier, but I would still naturally oversleep without an alarm. And actually, writing this now, it occurs to me there's probably room for improvement. I always get up, shower, get dressed, and then eat breakfast, when I should probably eat breakfast immediately after getting up. This would move my breakfast a half hour or so earlier each morning, and hopefully

I'd see a corresponding shift in when I'd naturally wake up. I'm not sure why this never occurred to me before, but I'll give it a try. Back on point though, for someone like me, something that causes you to wake up earlier may be a feature and not a bug.

John Smith (2014-01-29 16:53:38)

Few who comment on honey/sleep divulge their age, health status, etc. I am a committed user of honey, but I also know that the older one is, the longer they have been pre-diabetic (or worse) the longer it will take for them to realize the full benefit of these principles. It has to do with the health of the endocrine glands. When they are old, sick and worn out (at any age) one needs to allow for their inability to perform as perfectly as the text book says they should. Also, I always take notice of the age of the author of any book or advice page. Young people assume youth is forever. If only it were so! And we have been conditioned (by the drug pushers) to expect immediate results. Like right now, Man. Overnight! Hey if it didn't work the first time it is no good! Yet we all know we have tried myriad other 'approved' methods that didn't work either. Seth is right on top of the ball having had the light come on in his head, that the experts are looking after their own garden. We as individuals will either tend our own or suffer the consequences.

JP (2014-01-29 17:49:14)

Seth - In the comment section of an earlier post you mentioned you are now eating sugar three times before bed. What are you eating each of these times?

Seth Roberts (2014-01-29 18:18:30)

yes, I eat sugar 3 times after dinner and before bed: Time 1 (soon after dinner): longan (approx 140 g) plus Yakult (1 bottle, 60 kcal) Time 2 (a few hours before bedtime): banana (approx 120 g) Time 3 (near bedtime): honey (20 g)

Ben C (2014-01-29 21:05:13)

How long after waking is your first meal on average?

Sidney Phillips (2014-01-29 22:04:07)

What do you think of Trehalose? It's a disaccharide composed of 2 glucose molecules. The enzyme required to digest it apparently resides in the small intestine, so theoretically it should last longer while providing a steady stream of energy through the night, unlike honey which gets digested quickly. Honey helps me get to sleep quickly, but it has not solved my early waking problem. I am going to try Trehalose on my next order from Swanson's. It's not cheap, but not prohibitively expensive either:<https://www.swansonvitamins.com/swanson-ultra-pure-trehalose-1-lb-454-grams-pwdr> Seth: I haven't heard of Trehalose. Very interesting.

Seth Roberts (2014-01-30 01:39:27)

I wait at least 3 hours after waking up to eat anything solid, such as butter.

C (2014-01-30 19:27:43)

I always sleep better with bedtime ice cream. The more the better. I wonder what mothers milk would do

Charles (2014-01-30 20:28:32)

To be honest, waking up after a couple of hours would be what I expect would happen. The sugar would cause low blood glucose, and eventually your body would kick out some adrenaline to get your blood sugar back up. And then you would be wired and not able to get back to sleep. That won't happen with everyone, some people have more stable blood sugar, but I would imagine that's exactly what happened with that guy's wife.

Charles (2014-02-01 14:13:55)

@Sidney Phillips: That waking up problem is specifically what a number of people have reported as being helped or eliminated by potato starch (as a concentrated form of resistant starch) supplementation. I've had that problem for decades and it was almost completely eliminated a couple of weeks after starting potato starch, and has stayed that way for months. The same

for my girlfriend and other friends. Seth and I have disagreements about the mechanism, but it's been reported by too many people to be an illusion or confirmation bias.

daz (2014-02-01 17:18:04)

Hi @Sidney Phillips, keep us posted on your Trehalose experiment. i too still have trouble with nighttime/early awakenings. & have been experiment with various sugar/carb strategies myself, with various timings & doses. @Charles, potato starch is definitely 'good stuff' imo. tho for me personally it had no effect on my sleep (good or bad). i started 'supping' with it back in April (2013). i am still taking it tho & will continue to do so. i currently take 1.5 to 2 tablespoons per day. ( i did go as high as 4 tbls p/d for a while in the beginning).

Charles (2014-02-02 11:53:09)

@daz, Sorry to hear it hasn't helped. For those people who have had little sleep benefit, the protocol that will sometimes help is to take a couple of tablespoons in water an hour after dinner, then no more food after that. If you've been doing that, and it hasn't helped, then I guess your unique biome and/or other affected systems aren't where the issue is. That's a bummer. It's really helped me and a lot of others I know. But everyone is different.

daz (2014-02-02 15:37:01)

Thanks Charles, "...the protocol that will sometimes help is to take a couple of tablespoons in water an hour after dinner, then no more food after that" This is actually new info to me, would you have a link that would take me to more on this pls Charles. (is it from comments on the f-t-a web site, i have not checked that site in months & i am sure there are hundreds of comments now, under multiple posts...). it's been a while since i did the PS post dinner & then my max would have likely been 1.5 tbls, but more likely 1 tbls. (i currently take my PS during the day)

Amelia (2014-02-04 15:56:55)

I just wanted to chime in that when I was pregnant (my son is now 11 months old and nursing) I started waking up in the wee hours of the morning every a few nights, quite alert, and felt unable to sleep unless I had a snack. This also happened another time a few weeks ago. Trying a spoonful of honey before bedtime sounds like a sensible thing to try; I didn't have this problem pre-motherhood, but perhaps I need to compensate for the higher 24/7 glucose demands of pregnancy and nursing, which should be especially interesting to try in future pregnancies.

Science is a method, not an institution (2014-02-05 20:25:09)

[...] corruption and inaccuracy of studies produced by modern academia. Mr. Roberts frequently advocates self-experimentation and using the scientific method to get reproducible results and to understand them [...]

The misbehaviour of a Search Committee is God's way of shouting "Don't be an academic". Unusually sound advice from the old boy, I'd say.

JM (2014-01-30 09:06:22)

I'd find the scoliosis treatment article more credible if they showed before and after x-rays. Less pain and easier breathing are great but what is the actual long-term prognosis, especially if the curvature is severe. My daughter had the rods put in her back about 10 years ago and has done extremely well since - very active and no pain. She only has some limits in flexibility such as yoga or dance moves. If there had been another option at the time I would have pursued it but we were told her curvature was one that would continue to increase as she aged (most scoliosis doesn't progress after the child hits puberty, she was one of the unlucky ones that did).

Allan Folz (2014-01-30 12:02:41)

That reminds me... Seth, did you see the club foot piece on Morning Edition this week? It's the classic story-line of motivated parents empowered by information sharing made possible by the internet up-ending the highly-invasive (and highly lucrative) surgical status quo, er, standard of care with a 50 year-old non-invasive technique developed by a country doc in fly-over country. [1]How Parents and the Internet Transformed Clubfoot Treatment Seth: Thanks. Yes, I did see it and put it in an upcoming Assorted Links.

1. <http://www.npr.org/blogs/health/2014/01/27/265254533/how-parents-and-the-internet-transformed-clubfoot-treatment>

shtove (2014-01-31 13:32:35)

Anyone seen this - music & Alzheimer's (6:30) - 7m hits? [#t=43](http://www.youtube.com/watch?v=NKDXuCE7LeQ) Seth-style casual miracle.

## **Depression, Pain and Addiction: The Connection (2014-01-31 05:00)**

Because of cold weather in America, [1]Longform (the website) linked to [2]a 1995 article about the death by freezing of Teresa McGovern, daughter of George McGovern. She was drunk and fell down. Her alcoholism was intractable. She went for treatment dozens of times. I have a theory about what causes alcoholism and other addictions and why they resist treatment.

Let me start with the fairly obvious part. People go to their addiction (alcohol, gambling, smoking, whatever) to escape pain. The addictive activity provides a hit of pleasure that eliminates the pain for a while. It is difficult to endure pain and after a while, if you can escape, it is impossible - your "willpower" runs out. An addict keeps feeling pain, keeps doing the addictive activity to get rid of the pain. Pain triggers the addiction. Addictive activities, such as drinking, often produce cravings, which are an additional source of pain. This makes the problem worse - makes the total pain even harder to endure - but it is not the whole problem. The addiction started when there were no cravings. This is why abstinence alone - which does get rid of the cravings - is not a good solution. It does not get rid

of the sources of pain that were/are the ultimate cause of the problem.

The McGovern article illustrates the pain-reduction aspect of addiction:

I can numb the pain, says a voice. "It doesn't sound like an evil voice. It sounds like a friend, telling you the truth." Teresa's younger brother, Steven McGovern, is describing the voice of alcohol, as it whispers to you when you are feeling tense or dissatisfied or empty: Here's your old pal, I can get you through this. "I have experience with this," he explains. Like Teresa, Steven has struggled for years with addiction.

At the end of [3]Double Down, a great memoir by Frederick and Steven Barthelme, about loss of a large inheritance due to gambling addiction, the authors say something similar, that their addiction derived from depression. I haven't talked with addiction specialists but I doubt any of these ideas would surprise them.

The less obvious part of this comes from my discovery that [4]seeing faces in the morning caused a large oscillation in mood: happy during the day, unhappy at night (while asleep). The effect of being happy during the day was that small amounts of badness (e.g., bad news) made me less happy but did not push me all the way to feeling bad (= painful). I had a buffer. If I feel very happy and then something bad makes me feel less happy – only slightly happy – this has no effect on my behavior. I don't go out of my way to increase my happiness. Only when the border between happy and unhappy is crossed, and I start to feel bad (pain), not merely less happy, do I feel any desire to reduce the pain.

Life is full of pain-causing stuff. Everyone should have a buffer of happiness provided by morning faces but almost no one does. For almost everyone, as far as I can tell, most of the time they are in a neutral state, neither happy nor unhappy. When something bad happens, lowering their mood, they don't go from very happy to slightly happy, they go from neutral to unhappy (= painful). And when in pain they seek ways to escape it. This makes all sorts of pleasure-causing activities, including drinking alcohol and eating "comfort food" (= food with a strong flavor-calorie association – the stronger the flavor-calorie association, the more pleasant a food tastes), more attractive.

Long ago, people had this buffer of happiness during the day which made it possible for them to forage together in spite of problems, such as hunger and thirst and yesterday's disappointments. In the evening, the buffer disappeared as your mood went down. The problems indicated by pain became more urgent and were dealt with. If you were thirsty, for example, you would drink something. Modern life has reduced or eliminated many sources of pain but it has also (a) eliminated the buffer, our natural protection, and (b) provided many short-term sources of pleasure (such as drinking) harmful in large doses. Because we live in a world that is inevitably painful now and then – no treatment can change that – the combination of (a) and (b) causes addiction. Treatments for addiction, at best, push people away from one short-term source of pleasure. They never restore the buffer, the natural protection.

When The Shangri-La Diet was published, many SLD dieters said it had become easier for them to stop smoking. My explanation is that because their hunger (one source of pain/discomfort) went down, they had more willpower left over to deal with another source of pain/discomfort, craving a cigarette. As my sleep has improved in recent months, due to bedtime honey and related changes, [5]I have found it easier to do everything. My explanation is essentially the same. No longer having to use willpower to overcome tiredness – I am less tired – leaves more of it to do everything else.

dearieme (2014-01-31 09:26:37)

The Theory of Conservation of Willpower. And why not? But I used to propound a Theory of Conservation of Fretting: if you solved some social problem that people were whining about, the same people would just start whining about another. In other words, the problem isn't the problem, the problem is the people.

Gina (2014-01-31 09:41:29)

Addiction treatment is another area where the experts haven't made any progress whatsoever, yet they don't seem interested in innovation.

Therapsid (2014-01-31 09:50:27)

This is interesting. Since reading on this blog about the morning faces phenomenon, I've been turning to it as alternative to heavy drinking. However, if morning faces exacerbates night unhappiness, and if heavy drinkers drink disproportionately at night, it might only help reduce drinking insofar as people go to sleep very early.

Alain (2014-01-31 10:09:29)

It can all be related to a better equipped, less disturbed/stressed out, better functioning decision power "muscle", if I may. I've seen this before. Trivial and abnormally frequent decision making does typically wear out any kind of willpower we have left to make more important decisions throughout the day. Should we have to exert that willpower on overcoming other people's frowns, sad faces and bad temper, we will (I assume) end up with impaired decision making capabilities at the end of the day. A quote from an NPR article on how Obama deals with decision making processes: "He had very self-consciously sought to eliminate all trivial decision-making from his life, such as what he wears to work," Lewis tells NPR's Renee Montagne about his interviews with the president for his piece in the October issue of Vanity Fair. "So, he says, 'I got rid of all the clothes I have except for gray suits and blue suits, so I don't even have to think about what I put on.'" Why? The president "started talking about research that showed the mere act of making a decision, however trivial it was, degraded your ability to make a subsequent decision," Lewis says. "A lot of ... the trivial decisions in life — what he wears, what he eats — [are] essentially made for him." <http://www.npr.org/2012/09/11/160898373/inside-obamas-decisions-from-libya-to-lunch>

Alex Chernavsky (2014-01-31 10:23:56)

Addiction-treatment is probably the most backward, pseudo-scientific sub-specialty within psychiatry. As writer Maia Szalavitz once put it, "In any other area of medicine, if a physician told you the only cure for your condition was to join a support group that involves 'turning your will and your life' over to God (AA's third step), you'd seek a second opinion."

George (2014-01-31 10:43:06)

I don't think its pain so much as it is boredom. Most people don't really experience pain but boredom is the great scourge of life for many people especially in modern times. People turn to the bottle out of boredom.

Jack (2014-01-31 12:04:59)

In China, the age old cure for alcoholism is putting one to three teaspoons of dried tiger feces in an alcoholics favorite drink. This makes the patient's favorite drink taste absolutely terrible... so terrible that the brief negative flavor association of the feces with that of their favorite drink is never forgotten. Usually the alcoholic only needs to take this "medicine" only once or twice, and they will never, ever touch the stuff (any alcoholic drink) ever again. No expensive "therapy" sessions are ever needed. (Of course, the alcoholic patient is not usually told what the medicine actually is.) Tiger feces is very expensive in China for this reason. Probably regular dried house cat feces powder would work as well, but without the

mystique of being from a Tiger. The Chinese have been involved in self experimentation and natural cure research for thousands of years. The West would do well to learn from the Chinese. I would trust natural Chinese cures and/or treatments that have been proven to work for thousands of years over modern poisonous medicines and treatments developed only in the past few to hundred years anytime. I think any sane person would. I believe most of modern medicine is harmful and should only be tried as a last resort; when natural cures and those discovered from self experimentation have not born fruit.

Nancy Lebovitz (2014-01-31 13:33:58)

I like the idea of a happiness buffer, though I believe faces in the morning aren't the only way to fill it. See [1]Heal Thyself, also published as *The End of My Addiction*, by a surgeon who found that Baclofen (a prescription muscle relaxant) stopped his cravings for alcohol and incidentally cured his addiction to spending money. A number of commenters at amaxon have found that Baclofen stops their addiction. A detailed description of raising a happiness set point: [http://lesswrong.com/lw/20l/ureshiku\\_narital/](http://lesswrong.com/lw/20l/ureshiku_narital/)

1. [http://www.amazon.com/Heal-Thyself-Destroyed-Alcohol-Personal/product-reviews/0374532206/ref=cm\\_cr\\_pr\\_btm\\_link\\_2?ie=UTF8&pageNumber=2&showViewpoints=0&sortBy=byRankDescending](http://www.amazon.com/Heal-Thyself-Destroyed-Alcohol-Personal/product-reviews/0374532206/ref=cm_cr_pr_btm_link_2?ie=UTF8&pageNumber=2&showViewpoints=0&sortBy=byRankDescending)

Joe (2014-01-31 14:03:59)

Alex: Addiction-treatment is probably the most backward, pseudo-scientific sub-specialty within psychiatry. As writer Maia Szalavitz once put it, "In any other area of medicine, if a physician told you the only cure for your condition was to join a support group that involves 'turning your will and your life' over to God (AA's third step), you'd seek a second opinion." Joe: If I ever experienced the horrible PAIN that Seth attributes addiction to, I'd try just about anything to rid myself of it. That is, if I heard of a program that had the best success at dealing with addiction (i.e., AA, <http://www.burningtree.com/effectiveness-12-step-programs/>), and all the PAIN associated with it, I'd try praying to Bugs Bunny if that was part of the program. Hell, I'd turn my life over to Kanye West, if doing so would just rid me of that awful PAIN. When a person has hit rock bottom (Step 1), I don't think that would be that hard to do. By then, the person would probably have already sought second, third, fourth, fifth, etc. opinions anyway. Ditto for other disorders that produced great PAIN. Successfully turning off the horrible PAIN by turning your life over to God (pick the diety or program of your choice) would be an example of negative reinforcement, wouldn't it? Maybe some kind of "spiritual change" is exactly what's needed by some folks? What's the downside? Probably leading a better life?

Alex Chernavsky (2014-01-31 15:08:25)

Joe: AA has a host of problems associated with it. See: <http://www.orange-papers.org/>

Seth Roberts (2014-01-31 15:15:21)

"if morning faces exacerbates night unhappiness, and if heavy drinkers drink disproportionately at night, it might only help reduce drinking insofar as people go to sleep very early." Morning faces make me tired much earlier, like 2 hours earlier. It is a huge effect.

Seth Roberts (2014-01-31 15:19:25)

Re AA. My research suggests that AA meetings (a) should be held only in the morning (b) quite early, like 7 am. Maybe the seating arrangements should be changed, too, so that people are closer together. Or the meeting should be preceded by 30 minutes of simple socializing.

Gina (2014-01-31 15:27:54)

"If I ever experienced the horrible PAIN that Seth attributes addiction to, I'd try just about anything to rid myself of it." Saying that 12 step treatment is the best we can do is a pretty grim view. You see how well it worked for Teresa McGovern. When someone has been to rehab 10 times, right now all the experts can recommend is an 11th trip to rehab. The rehab industry has absolutely no motivation to find better treatments. They would lose all the repeat business.

Joe (2014-01-31 15:43:16)

Alex: For every orange paper there is a green one. :) <http://www.green-papers.org/> This is just a guess, but I wouldn't be

surprised if AA's success rate was as good as psychotherapy's alone. Done together, they appear to be the best thing we currently have to offer. Gina: "Saying that 12 step treatment is the best we can do is a pretty grim view." I didn't say that, of course. I'll refer back to my posts on various diets and say again that there are many ways to skin a cat. And lots of cats have lost their skins to AA. We should be thankful for that, while we look for even better ways to help people in distress and pain. Seth: That sounds like an idea worth testing! The trick, as I see it, would be to get them up that early. :)

Sara Lake (2014-01-31 15:47:53)

Seth, have you heard of the 'rat park' experiments? I think you must have. Addicted rats were put into a happy rat environment (about 200x the size of a regular rat cage with both space and privacy tunnels), and allowed to do things rats like to do (have sex, socialise, eat, sleep, play with toys). Most detoxed themselves, even when their substance of abuse was freely available. Seth: No, I haven't heard of them. Thanks.

Gina (2014-01-31 15:53:04)

"Re AA. My research suggests that AA meetings (a) should be held only in the morning (b) quite early, like 7 am. Maybe the seating arrangements should be changed, too, so that people are closer together. Or the meeting should be preceded by 30 minutes of simple socializing." My grandfather spontaneously quit drinking after years of having to be frequently hospitalized to "dry out" and severe liver cirrhosis. He had a job where the older guys would show up an hour or so early to work and sit at benches outside, drink coffee, chew tobacco and socialize. Now I'm wondering if his habit of going to work early came first. It's interesting.

Karen (2014-01-31 16:13:47)

Sara Lake or anyone: Do you have a link or citation for the paper describing the "rat park" experiment?

Alex Chernavsky (2014-01-31 16:31:55)

Journalist Anne Fletcher wrote an excellent book about addiction. It's called, [1]*Sober for Good: New Solutions for Drinking Problems – Advice from Those Who Have Succeeded*. She interviewed hundreds of people who had been sober for at least five years. Turns out (not surprisingly) that people quit using a variety of different approaches. And some people had not actually quit but rather moderated their drinking (which is a big "no no" in 12-step circles).

1. <http://www.amazon.com/Sober-Good-Solutions-Drinking-Succeeded/dp/0618219072/>

Joe (2014-01-31 17:22:27)

A story about addiction: I quit smoking 41 years ago. I was a 4-pack (Lucky Strikes) a day smoker. Before I turned off the alarm clock in the morning, I would light a cigarette. I HAD to have a cigarette. Yeah, it was that bad. I only needed a few matches to get through an entire day - and 4 packs of Lucky Strikes. I tried to quit dozens of times. I would try cutting back, try filters, even menthols (yuck!). I might make it two weeks, then back to puffing like a locomotive. Nothing worked. I LIKED smoking. I NEEDED to smoke. Then a lucky thing happened to me while confined to a hospital bed with double pneumonia. My second bout of pneumonia in just 6 months. I almost died. Some do-gooder doctor wheeled in a movie projector and showed me a film about what smoking can do to you (okay, I already knew it could kill me, but that apparently wasn't enough). The film was of an autopsy of a person who died from lung cancer. And the mere sight of the cancerous lung, and the horrible damage the smoking had done (imagine the sight of someone peeling hot asphalt off a roadway), and I was done with smoking. Forever. Haven't had a cigarette since. Not one. Do I still get urges to smoke? Yes. Especially when having a drink. But I will never smoke another cigarette. Period. Haven't had pneumonia since, and rarely even get a cold. The dumbest thing I've done in my life was to start smoking. The smartest thing I've ever done was to stop. Thank God for do-gooder doctors!

as (2014-01-31 18:30:37)

Teresa never married. She had two children with a man she lived with for four years. The article said that she was sober during those years and that she broke up with her boyfriend when she started drinking again. Maybe lack of a good stable family life leads to addiction? Sara Lake's "rat park" comment was interesting.

Alex Blackwood (2014-01-31 19:56:21)

I believe the Rat Park experiment Sara Lake is talking about is discussed here: [http://sub.garrytan.com/its-not-the-morphine-its-the-size-of-the-cage-rat-par k-experiment-upturns-conventional-wisdom-about-addiction](http://sub.garrytan.com/its-not-the-morphine-its-the-size-of-the-cage-rat-par-k-experiment-upturns-conventional-wisdom-about-addiction)

anon (2014-01-31 20:17:35)

Have you heard the Radio Lab (the NPR radio program) that discusses a woman taking a medication (for parkinson's tremors, if i recall) that makes her a gambling addict, and then her symptoms go away when she stops the medication? Seth: No I haven't heard it.

Sara (2014-01-31 21:53:51)

Apparently hypnosis works quite well for smoking.

John Smith (2014-01-31 23:23:32)

According to the gospel of John (me!) addiction has two components, one physical the other spiritual, mental or psychological (you choose one from those three or add the correct one). No one can administer any help, pill, advice, or whatever, that will work for any individual until that individual is ready to accept the challenge and make changes. Depending on the addiction, it will take more than just a little effort. AA did well as long as it was alcohol and cigarettes it targeted. When Overeaters Anonymous came along (same problem, addiction to food) the 'cold turkey' the 'never another mouthful of food' type of logic, simply wasn't enough. The overeaters had to learn a better way, as quitting eating proved to be fatal. They found that following the 12 steps was all it took, just that they had to dig deeper into the psyche to work out why they were so unhappy, fix that, then curing the addiction was easy going. In the 12 steps programs, reference to god is somewhat ambiguous as it speaks to "god as you understand him or perceive him (something to that effect)." Which is erroneous, of course, as it assumes god is a male, humanoid, personalized etc., but worst of all 'perceivable.' It denies the fact that we are god unto ourselves. Replace god with yielding to the other side of your head as in 'right brain' would work for me. The opposite is true also, yielding to the 'left brain.' Addiction cannot be cured without the assistance of both hemispheres. Males in particular are loathe to go into right brain stuff, females equally, do not care to live by logic (as a generalization). But it is all in our head, both the problem and the solution. If you read the Book, Feed Your Brain First, by Dr. Fessenden (Co-Author with McInnes in The Honey Revolution) you will discover the energy used by the brain is not always full speed ahead. As the health deteriorates or the day wears on, energy level get low, the voltage to the brain falls and the survival lobes get the first pick with the cerebrum (higher brain) taking what is left over. Chronic Depression always includes the condition of chronic partial brain starvation. So to cure any addiction especially those leading to depression, get the body energized (using natural foods and herbal medicines) so the brain is fully powered. Then one can think straight about using the decision making process intelligently. However, until that individual is ready to make the big change, nothing will work on a permanent basis. Making the big change will always work, even if the body lags behind. Fixing the body only will only partially work..... With the problem reoccurring further down the track. Another good book (which I haven't read) is called "The Pleasure Trap." I think there are several of a similar title, so can't speak for them all.

Alex Blackwood (2014-02-01 06:57:14)

Accounts of people wrecking their lives with gambling and compulsive sexual behavior while taking dopamine agonists go back years. Here's one: <http://www.houstonpress.com/2005-09-15/news/overstimulated/>.

James M. (2014-02-01 08:01:24)

Socializing more, talking fully about issues to someone, exercising at least three times a week, regular long sleep, going Primal/Paleo, has helped with my depression.

Tam (2014-02-01 13:28:25)

Matt Stone talks about similar ideas in a few differnt articles. One, about Rat Park, and another about 1811 Eastlake, in Seattle. 1811 is a very successful so -called "wet house" for the homeless that allows its residents to have alcohol. The success is measured in taxpayer money saved and also by how much drinking has declined. It seems to point to the idea that seeing a

human, or even a rat, as who they are, and allowing them to be seen and take care of their most basic needs which includes socialization and acceptance, can make all the difference in addiction healing.

Charles (2014-02-01 14:24:33)

RE: Morning faces...one of my favorite jobs over the years was being a breakfast cook. I got to see a lot of morning faces. And looking back, it seems to me that the regulars, who would come in every morning (a common breakfast joint phenomena) were basically pretty happy. Hardly any regular "grumps." And I still love going out for breakfast, it's my favorite meal to go out for. And I don't think it's just the coffee that makes people feel good, based on Seth's hypothesis. As to addiction, there is a major neurochemical component to it, and it can be turned on and off with various amino acids (for a lot of people, not everyone). That can be related to the happiness buffer, too, of course. If your neurochemistry is screwed up, by environment or genetics, and you're always fighting that, it doesn't take much to push you over the edge. Fix that, and it's a lot easier to deal with other habitual behavior. And yes, I worked with a chemical dependency program to do just that, and it helped a lot of folks.

Alex (2014-02-01 16:15:43)

Dearieme, the "The Theory of Conservation of Willpower" is in fact laid out, with neurochemical basis, in Willpower: Re-discovering the Greatest Human Strength, by Roy F. Baumeister and John Tierney. Baumeister makes the case that what we call willpower is glucose availability in the brain. Tierney also wrote a piece about Baumeister's work in the NY Times: <http://www.nytimes.com/2011/08/21/magazine/do-you-suffer-from-decision-fatigue.html?pagewanted=all>. I don't have a country to run, but I have found it useful, as Obama mentioned doing in the Michael Lewis piece, to reduce the number of trivial decisions I make throughout the day.

Sara Lake (2014-02-01 20:48:58)

The original rat park paper is this one: <http://www.ncbi.nlm.nih.gov/pubmed/98787?dopt=Abstract> and here is an interesting article by the lead researcher <http://www.parl.gc.ca/Content/SEN/Committee/371/ille/presentation/alexander-e.htm> Here is a list of some of his other publications. It's not hidden research, just didn't get a lot of attention. I think it's easier for governments to focus on 'the drug' rather than 'the addictive society'. [http://www.ncbi.nlm.nih.gov/pubmed?term=Alexander%20BK%5BAuthor%5D&cauthor=true&cauthor\\_uid=98787](http://www.ncbi.nlm.nih.gov/pubmed?term=Alexander%20BK%5BAuthor%5D&cauthor=true&cauthor_uid=98787)

Sara Lake (2014-02-01 20:52:54)

Also, if you look at the 'related citations' in pubmed, you'll see that it's not exactly an untested hypothesis (that the drug is not the root cause of the addiction).

Seth Roberts (2014-02-02 02:41:28)

"I think it's easier for governments to focus on 'the drug' rather than 'the addictive society'." I agree. Easier for governments and professors who need to publish regularly. Just as it is easier to focus on "which is the best treatment for Disease X?" rather than "What causes Disease X?"

Alex Chernavsky (2014-02-11 20:28:50)

Just saw this interesting article about Alcoholics Anonymous: "[1]After 75 Years of Alcoholics Anonymous, It's Time to Admit We Have a Problem", by Maia Szalavitz

1. <http://www.psmag.com/navigation/books-and-culture/75-years-alcoholics-anonymous-time-admit-problem-74268/>

## 9.2 February

### Announcing PaleoCon (2014-02-01 02:18)

I am one of the presenters – that is, interviewees – at [1]PaleoCon, which began a few days ago. The presenters were interviewed by John Durant. Among the presenters are Paul Jaminet and Chris Kresser.

1. <https://gv166.infusionsoft.com/go/pcreg/twoutopias/>

---

Kristi Vice (2014-02-07 10:53:02)

I really liked your presentation and listened to it twice. I just wrote down six of your "weird" tricks for better mood, sleep and brain, but I seem to be short one trick. Thanks for your unusual thinking and sharing.

### Charles Dickens, Demons, and Personal Science (2014-02-01 05:00)

In [1]a review of biographies of Charles Dickens I found this:

In 1849 he showed a short account of his early years to his close friend John Forster, revealing a story he never told his own family: the shame-inducing months he spent, while his father was in a debtor's prison, as a 12-year-old "laboring hind" in a factory that bottled shoe-blackening.

Suddenly I understood why he wrote *Oliver Twist* and why it is so good. Budding writers are told write what you know. They should be told write what you feel bad about.

The work of [2]James Pennebaker has shown the benefits of even small amounts of self-disclosure. No doubt this is why all sorts of psychotherapy, supposedly based on enormously different theories, help roughly the same amount: All involve self-disclosure. I see this effect as something built into us by evolution to increase self-disclosure. Talking about bad experiences helps your listeners avoid what happened to you. To motivate such disclosures, evolution has built into us something that causes us to feel better after we talk this way.

Scientists are not told study what you know and they are especially not told study what you feel bad about. Scientists are mostly men, of course, and that sort of thing makes men uncomfortable. [3]My personal science, however, suggests the correctness of this idea.

1. [http://www.nytimes.com/2011/11/06/books/review/charles-dickens-biographies-review.html?\\_r=1&nl=books&emc=booksupdateema4&pagewanted=all](http://www.nytimes.com/2011/11/06/books/review/charles-dickens-biographies-review.html?_r=1&nl=books&emc=booksupdateema4&pagewanted=all)

2. [http://en.wikipedia.org/wiki/James\\_W.\\_Pennebaker](http://en.wikipedia.org/wiki/James_W._Pennebaker)

3. <http://escholarship.org/uc/item/2xc2h866/>

gwern (2014-02-01 09:09:50)

> Budding writers are told write what you know. They should be told write what you feel bad about. Charles Dickens was made famous and financially successful by his humorous light fiction \_Sketches by Boz\_ and \_The Pickwick Papers\_.

Peggy (2014-02-01 10:59:49)

Self-disclosure works better when there is someone on the other end listening. i think this effect partly explains some of the successes seen by alternative medicine practitioners: they take much more time to listen than is the norm in conventional medicine these days. Also, those who listen may learn surprising and unexpected things that may prove useful in treating others. I gather that your doctor didn't learn anything about treating acne from you, but he could have and should have.

John Smith (2014-02-01 12:31:17)

The Amway mantra is: Just tell your own story! I am often criticized (not prosecuted) for practicing medicine without a license, as I occasionally 'give out advice.' This is illegal in most Western Cultures, but isn't usually prosecuted unless money changes hands. But to avoid the criticism, my intention is to simply tell my own story, and or give my personal opinions. Telling my own story is possibly more healing for me than it is for my listeners. However, even the listeners may remember that story in years to come and benefit from some little part of it. AND its all so legal to tell your own story and no one knows it better than the individual who lived it! Nonetheless, when I meet someone whose only conversation is crying about their misfortunes I consider them addicted and tend to avoid that person. Good post, Seth. If we want to get some good science, we have to become scientist ourselves, aye? (and you don't need a piece of parchment to be a good scientist!)

LemmusLemmus (2014-02-02 05:04:47)

Why would a trait be selected for on the basis of its helping others? Kin selection? Group selection? Tit for tat?

Seth Roberts (2014-02-02 14:02:07)

"Why would a trait be selected for on the basis of its helping others?" When you help others in many cases you help yourself. For example, when you live with 10 other people you have 10 other brains working to solve your common problems, of which there are no doubt many. By helping those 10 other people, you are helping solve your problems.

## **Adult Acne, Water and Milk Thistle (2014-02-02 05:00)**

A reader writes:

I suffered from moderate acne as a teen, which continued well into my adult years. In my early forties, I sought help from a dermatologist, hoping that progress had been made since my teenage experience which included tetracycline and sunlamp therapy to induce drying and peeling. I was disappointed to have this doctor recommend basically the same treatment twenty five years later. I declined.

Fortunately, a friend recommended drinking lots of water, and I began doing so, attempting to drink eight glasses a day. This was in December. The acne actually got worse . . . but I received a Brita water filter pitcher for Christmas and began drinking filtered water. Within a week my skin was totally clear, and remained so with minimal exception thereafter, even when my water consumption waned over the years. I was delighted and grateful to have found such a simple and healthy solution, and annoyed that no doctor had even suggested it.

But about 15 years later – about a year ago – I began to experience significant breakouts again, this time confined largely to my nose. I assumed that I needed to simply up my water intake again. This time

it didn't help. Maybe the filter was overdue for a change, I thought (we'd long since upgraded to a reverse osmosis filter), so I had it changed but still no improvement in my skin.

I began cutting out various foods, eggs, coconut oil, whey protein, things I was eating lots of, thinking maybe I'd developed a sensitivity. Nothing worked, although I did see immediate improvement when visiting family in the states, which made me wonder if it was the change in the water. So back home I tried to drink bottled water or club soda exclusively and it seemed to help maybe slightly.

I continued to search for a more complete solution. While perusing several online blogs devoted to acne treatment, I read a comment from a self-described longtime sufferer who claimed to have recently discovered a cure for his acne – milk thistle and NAC [n-acetyl-cysteine]. I got some milk thistle, took a few capsules a day for maybe three days, and voila, clear skin again. I never had reason to add NAC since the milk thistle worked so well.

I have reduced water consumption to normal levels (meaning I try to drink several glasses daily but don't bother to track), take a few milk thistle capsules a week (don't track that either), and only start to get breakouts if I happen to miss taking any for about a month, which I did just recently over the holidays. I still don't know what causes the acne, and I don't know why the milk thistle "cures" it, but it works wonderfully for me.

[1]Here is more evidence for the effectiveness of milk thistle for acne.

1. <http://www.acneeinsteinstein.com/studies-reveal-almost-irrefutable-evidence-for-the-root-cause-of-acne/>

---

Kevin (2014-02-02 10:05:02)

The milk thistle helps the liver, which removes toxins from the body. When the liver is overloaded, toxins will also be removed via the skin.

John Smith (2014-02-02 11:44:27)

and..... our cells, bodies and brains have memory. Once an avenue is established for the excretion of waste products the liver and kidneys cannot process, it continues to use that outlet. Should one outlet be eliminated, as in the removal of the tonsils, then a new outlet would be established. I Found in my own life, that water fasting made a life changing difference. Many toxins in the body are the residues of past pains whether real or imagined, especially the hurts we collect as children. The water fasting cleared much of this for me and released the liver and kidneys to do their normal functioning once again.

Bill (2014-02-02 15:47:23)

I had awful adult acne, hideous cystic lumps that left scars. My college pictures are hard to look at. This continued into late twenties. It was a food allergy, but took forever to figure out: black tea. Especially Oolong. My face would begin to itch within minutes of drinking, and the breakout came the following day. But it took years to notice the connection, I'm embarrassed to say. The allergy – if that's what it is – is highly specific. Green tea is no problem. Coffee is no problem. The only offender is black tea, especially Oolong. Even now, in my late forties, I break out if I drink two cups of black tea. The effect can be mitigated by drinking a ton of water.

daz (2014-02-02 15:52:28)

"But about 15 years later — about a year ago — I began to experience significant breakouts again, this time confined largely to my nose" makes me wonder if your water supplier made a change...something that your water filter could not block/clean. Adding Chloramine comes to mind (<http://en.wikipedia.org/wiki/Chloramine>). I read somewhere this has become more common in recent years...'chlorine on steroids' perhaps. As far as i know only Vitamin C type filters remove/negate this stuff (or adding Vit C to drinking water & bath water). You should be able to find out what's in your water by checking info on the suppliers web site. It still doesn't change anything i guess...but would be interesting to know. (pls post up if you find they do use chloramine)

Florinescu Eduard (2014-02-03 03:49:08)

Milk Thistle is good for psoriasis too so it must hit a common cause. By the way I discovered that soluble barley drink (tries to imitate Coffee) in the evening improves sleep, especially when you had a active day.

CC (2014-02-03 17:34:11)

Good to know about milk thistle. In case anyone cares, I've had great success with taking 100 mg zinc picolinate daily. I recently started applying apple cider vinegar (1 part ACV to 2 parts water) to my face 1-2 times daily. It seems to have worked really well, though this could be a coincidence. I'll keep observing for a few more weeks before concluding anything. I think I got both these suggestions from the SLD forums.

Sam (2014-02-04 04:46:45)

The Vitamin C trick to remove chlorine works. It only takes a pinch per five gallon bucket. I used to do this for my plants. If you have a white bucket try it. Add a pinch then stir. Look in the bottom and you will see a small grain in the middle. That's the chlorine. The info comes, if I remember correctly, from the San Fransisco water department.

Trev (2014-02-07 00:32:16)

I recently started taking D3 4000iu a day, just because there's no sunshine here in England. A pleasant side effect was that 4 persistent spots on my forehead have disappeared. Medication wouldn't shift them but now they've gone. A quick search pulled up the same experience for other people.

### **More Muscle Strength, Less Cancer (2014-02-03 05:00)**

[1]A 2009 study followed about 9000 men for 10-20 years. It found that strength (how much you can bench and leg press) measured at the start of the study was associated with likelihood of dying of cancer during the study. Men in the upper two-thirds of the study population in strength had 40 % less cancer mortality. This might be the most surprising result:

Further adjustment for BMI, percent body fat, waist circumference, or cardiorespiratory fitness had little effect on the association. The associations of BMI, percent body fat, or waist circumference with cancer mortality did not persist after further adjusting for muscular strength.

In other words, muscle strength was a better predictor than several similar measures (BMI, etc.) and these other measures stopped predicting when corrected for muscle strength. Muscle strength is closely connected to something important.

Men who are stronger by and large exercise more, no doubt. Yet muscle strength is determined by resistance training, not aerobic exercise – and it is aerobic exercise (and to some extent walking) that have been promoted by countless

experts since the 1960s and the invention of the concept aerobic. Jogging reduces how much time you have for resistance training.

These findings interest me because I do a lot of resistance training – stand on one leg to exhaustion several times per day – purely to sleep better. By improving something easy to measure (sleep), these data suggest I have also been improving something hard to measure (chance of dying from cancer). Not surprising, but reassuring.

My data also suggest two different possible reasons for the strength-cancer association. One is that men who exercise more sleep better as a result; better sleep, better immune function, less cancer. Another possibility is that strength is a marker for good sleep. Among men who do equal amounts of exercise, [2]those who sleep better will be stronger.

From [3]The Breviary.

---

Charlie Currie (2014-02-03 09:09:00)

My father-in-law would be the exception...he had very strong legs and arms. He was an athlete in his younger days and worked labor intensive jobs prior to becoming a realtor. In his thirties he grew a large belly...solid, not flabby. Aerobic exercise was not on his to-do list. In his fifties he had high blood pressure, by sixty he had heart disease, T2 diabetes, required knee replacement (both) and was diagnosed with bi-polar syndrome. In his sixties he had quadruple by-pass surgery, in his seventies he developed throat cancer. He died at age 86 from complications from aspirating a piece of chicken. If not for excellent medical, and home care, he would have died much younger, either from his heart disease or cancer. I think the fact that he was never feeble was also a benefit and contributed to his multiple recoveries. Maintaining leg and arm/shoulder strength is excellent advise, but it may not prevent you from contracting life threatening diseases.

Max (2014-02-03 09:12:41)

Another likely contributing explanation for the strength-cancer association: resistance training improves (reduces) HbA1c. Elevated HbA1c has been shown to be an independent predictor for cancer. Dr Richard Bernstein connected all these dots years ago, which is why his program includes serious strength training for T1 and T2 diabetics. (love the blog, thank you)

Jake (2014-02-03 09:21:25)

Two reasons why muscles help prevent cancer: Active muscles produce myokines. Myokines reduces inflammation which reduces your chance of getting cancer. Muscles act as a glucose sink to reduce glucose and insulin peaks. These peaks are a major driver of cancer.

Adam (2014-02-03 12:19:21)

"It found that strength (how much you can bench and leg press) measured at the start of the study was associated with likelihood of dying of cancer during the study." This should read "was \_inversely \_ associated". When I first read it, I thought you were saying the stronger you are the more likely you are to get cancer.

aretae (2014-02-03 13:57:13)

I think there's a reasonable chance that Muscle Mass is a generic health marker. Mark Rippetoe, who is the most interesting person in health that I haven't yet started reading (linked often from Instapundit), has been saying things like this for a while: Muscle Mass is your basic measure of health. Beats almost anything else, at least for some groups (men?). You're now the second person who's said: No, really, muscle mass matters a lot. Beats the pants off fat. More muscle & more fat: Healthier. Less fat + less muscle = less health.. Fascinating.

Bo (2014-02-03 14:09:01)

"These findings interest me because I do a lot of resistance training — stand on one leg to exhaustion several times per day — purely to sleep better." I'm sorry, but standing on one leg isn't really resistance training (at least not even for the average not-so-healthy individual). If you can stand on one leg for more than a few seconds (and after a few goes once you master balancing) it's not really strength training. It's strength-endurance at best, though I wouldn't count on even that.

John Smith (2014-02-03 14:37:32)

I would think that the strength of the will and the psyche, the level of determination, these are what form the basis of good muscle and good health. Many folk give up far too early.....'I can't' they wail. Just watch them on the fat shows. Admittedly that strength of will needs to be developed just as one develops muscle and not just on the day of the TV shoot, so heavy people should not be expected to perform like a flyweight overnight. Those who believe they can, are usually right. Those who believe they can't are always right.

Justin Irving (2014-02-03 15:50:18)

A few years ago Art De Vany linked to a study (on his old subscription blog) showing that lean mass was the best/a top predictor of cancer survival. I guess that's not shocking. Thanks for this post though, motivation for dead lifts!

Charles (2014-02-03 15:57:38)

Well, strength requires muscle. Muscle building requires growth hormone, and I believe GH is released in sleep. So there could be a connection.

aretae (2014-02-03 23:38:11)

Other point re: muscle mass/Strength. It seems to be substantially to hugely genetic. As with most things, putting 50 % of variance as a lower bound for the genetic share seems reasonable. This makes me less convinced by your sleep hypothesis. Example, my teenager has much larger/more muscular legs than I do, despite my having been semi-seriously lifting for 1/3 of the last 15 years, and his being mostly a couch-potato.

Paul N (2014-02-04 11:46:13)

Having more lean muscle mass also helps you live longer. This excerpt and graph from the book "[1]bending the aging curve gives a good illustration. Further within that book (which I have not read, only seen excerpts), it talks about the decline of fast twitch muscle mass with age, while the amount of slow twitch remains roughly constant until the last decades. All this might have something to do with the fact that to retain your fast twitch fibres, you need to be doing lifts, sprints and power exercises. At the other end of the scale, marathon runners die younger, so I know which group I'd rather be in

1. <http://www.humankinetics.com/excerpts/excerpts/what-do-we-mean-by-bending-the-aging-curve-from-bending-the-aging-curve-by-joseph-signorile>

## **Philip Seymour Hoffman's and Cory Montieth's Death From Heroin: Why? (2014-02-04 05:00)**

Philip Seymour Hoffman, the great actor, was found dead a few days ago with a needle in his arm. Last year, Cory Montieth, the actor, died in similar circumstances. Why did they die? It was hardly the first time they'd taken heroin.

Starting in the 1970s, [1]Shepard Siegel, a psychology professor at McMaster University, did [2]a series of rat experiments that showed that drug tolerance and craving involved a large amount of Pavlovian conditioning. Repeated exposure (e.g., injection) of Drug X in Situation Y (e.g., your bedroom at 11 p.m.) will cause learning of an association between X and Y. This association has two effects. First, when exposed to Y, you will crave X. Second, when you take Drug X in Situation Y, the effect of the drug is diminished. You become "tolerant" to it.

You have probably experienced both effects – they occur with caffeine, chocolate and alcohol, for example – but are unaware of Siegel's explanation: Situation-drug associations. After you learn the association, Siegel said, the situation generates a response in your body that opposes (reduces) the drug effect. If the drug makes you less sensitive to pain, the conditioned response is more pain sensitivity. If the drug makes you awake, the conditioned response makes you sleepy. It's easy to realize that drug craving involves associative learning: You notice that you crave coffee or whatever in familiar situations but not unfamiliar ones. You crave Drug X at college but not at home. It's much harder to grasp that the tolerance involves associative learning.

Drug users, such as Hoffman and Montieth, as they become "tolerant", take larger and larger doses, not realizing that their "tolerance" depends on a learned association. The situation becomes more and more dangerous because if you take the drug without eliciting the conditioned compensatory response, you may die. Without the conditioned response, a drug amount you survived yesterday may kill you today.

Siegel explored the possibility that this actually happened – that drug addicts died of "drug overdose" because they took the drug under unusual circumstances that didn't evoke the compensatory response. He found plenty of support for this idea. One sort of support was [3]interviews with "overdose" survivors. They often described unfamiliar circumstances at the time of the injection – e.g., there's usually music, but this time there wasn't. Another sort of support was [4]a rat experiment with heroin. After developing tolerance to heroin, rats injected with a really large dose in a strange situation were much more likely to die than rats injected with the same dose in the same situation where they became tolerant.

I am pretty sure Hoffman and Montieth didn't know about this research. There is a connection with the Shangri-La Diet. In both cases, Pavlovian learning has a big effect on something we care a lot about (life/death in the drug case, body weight in the diet case) and this connection is highly non-obvious.

---

Xav (2014-02-04 05:35:34)

I was thinking about your ideas from the Shangri La Diet earlier today. I was wondering if the fact that so many hygiene related products have food related scents added in affects appetite in the general population as we are constantly exposed to smells associated with food. Just this morning I counted orange (in shower gel), various fruit smells (in handwash), lemon (in washing up liquid), and cocoa and vanilla (in perfumes of people I passed in the street).

CC (2014-02-04 06:26:14)

This might be a dumb question, but does this mean we should mix up the "situations" in which we take ELOO? Don't do it in the same room at the same time each day? Seth: No, because learned CS-US associations when the US is a food (rather than a drug, such as caffeine) seem to involve purely CS's that are smells. There is association with the smell of the food but not the place where you ate it. It is when the US is a drug that you get associative learning where the CS is a situation, such as a place and/or time of day.

Alex Blackwood (2014-02-04 11:54:12)

Another factor: when you are taking a street drug the purity and strength are not predictable. There is speculation about whether PSH's overdose was linked to heroin mixed with fentanyl--no worthwhile sources to cite, since it's all speculation at this point. But the variability in how much drug you are actually getting and what adulterants are enhancing the effect may be adding a variable schedule of rewards, a powerful reinforcer, to the addiction situation.

Gina (2014-02-04 13:26:08)

They both recently went to rehab. Overdoses following rehab (e.g. Amy Winehouse) are common. Rehabs are not interested in teaching people how to be safe when they relapse, even though they know how likely people are to relapse, so there's no way they would be told about Siegel's research or any other information that could be useful in saving their lives.

Joe (2014-02-04 14:54:27)

I'm with Alex. I think it was a "hot shot." Something added to the heroin, or maybe a far more pure (stronger) heroin. He had (apparently) injected the heroin in a familiar setting, so any conditioned response should have been present. Sad story. He was a hell of an actor. Seth: If he was exposed to the familiar situation many times without exposure to the drug, the familiar situation-drug association may have gone away -- been "extinguished" to use the technical term.

Al (2014-02-04 20:03:08)

You wrote: "After developing tolerance to heroin, rats injected with a really large dose in a strange situation were much more likely to die than rats injected with the same dose in the same situation where they became tolerant." But, what about comparing rats injected with the same dose in a strange situation to rats injected with the same dose in the same situation? How does that comparison work out? Seth: by "injected with the same dose" I meant injected with the same really large dose.

Adam (2014-02-04 22:21:53)

Al, I think "same dose" in that paragraph is referring to the same \_large \_ dose, not the dose they were previously treated with.

eric (2014-02-05 02:05:32)

Real cause of death is the fact that they were obliged to purchase their drug of choice on the black market, which practically by definition includes unknown dosage and ingredients. If addicts were (not criminalized and) permitted to purchase heroin by prescription at pharmacies, there would be close to zero deaths from overdose. Almost all heroin deaths in the USA are directly attributable to the US government, which makes its sale and possession a crime. Ergo like anything illegal that is in demand, a black market springs up with questionable quality in its goods.

Seth Roberts (2014-02-05 04:59:29)

"If addicts were (not criminalized and) permitted to purchase heroin by prescription at pharmacies, there would be close to zero deaths from overdose." What about the work I describe, which suggests this is wrong?

kayvee (2014-02-05 08:16:09)

Hi Seth I found your blog through your presentation at PaleoCon Your ideas were fascinating and I find your writing the same I have an odd question: What do you think of Ayahuasca tea and Iboga. They are used as a means to heal past traumas that is believed to be the cause of addictions?

kayvee (2014-02-05 08:17:06)

To add: <http://www.ibogaine-therapy.net/index0a14.html?PAGE=40>

AI (2014-02-05 08:57:40)

I read it wrong. Thank you for the clarification.

Joe (2014-02-05 10:01:46)

Seth: "If he was exposed to the familiar situation many times without exposure to the drug, the familiar situation-drug association may have gone away — been "extinguished" to use the technical term." Seth, from all reports, he's been exposed to the situation AND to the drugs, for quite some time. I don't think anything was ever truly extinguished. Nor do I think he was ever "dry" for 22 years. Until more information develops that could change my mind, I'm sticking with Occam's Razor: He died of a "hot shot." Nota bene: I raised and trained field-trial retrievers for many years. I used the principles of classical AND operant conditioning in training. But certain dogs just didn't respond in the anticipated way. E.g., the same principle that would work so well on dog A wouldn't work at all on dog B. Behaviorism is a great guideline for training dogs (or as learning theory per se), but it's riddled with exceptions. Hoffman could be an example of such.

Joe (2014-02-05 10:30:55)

New developments regarding Hoffman: "I was Philip Seymour Hoffman's gay lover and saw him freebasing cocaine the night before he died", says writer who found his body" <http://www.dailymail.co.uk/news/article-2552207/I-Philip-Seymour-Hoffmans-gay-lover-I-saw-freebasing-cocaine-night-died-says-Manhattan-writer-star-body.html> I don't think anyone is ever going to untangle this man's psychological turmoil.

Nancy Lebovitz (2014-02-05 13:36:48)

How stressful do rats find strange situations? They're just put into a strange situation, and this might be different from a human who's gone somewhere they want to go.

Seth Roberts (2014-02-05 14:44:15)

"How stressful do rats find strange situations? They're just put into a strange situation, and this might be different from a human who's gone somewhere they want to go." The rat experiments equated novelty of the injection situation between the two groups. Both groups were injected with a very large dose in a situation with which they were equally familiar. In other words, the injection situation was equally "strange" for the two groups.

Alex Chernavsky (2014-02-05 17:30:18)

Psychologist Stanton Peele [1] argues that heroin overdoses, as such, are rare. He claims that overdoses are usually caused by mixing heroin with other drugs. It's an interesting article.

1. <http://lifeprocessprogram.com/lp-blog/library/the-persistent-dangerous-myth-of-heroin-overdose/>

Alex Blackwood (2014-02-05 21:24:16)

Seth, what changes to the treatment of drug addiction do you think would be warranted by these findings?

eric (2014-02-06 01:35:07)

Seth Roberts Says: "If addicts were (not criminalized and) permitted to purchase heroin by prescription at pharmacies, there would be close to zero deaths from overdose." What about the work I describe, which suggests this is wrong? Notice I said "close to zero".

Suzanne (2014-02-06 15:25:08)

I understood he nearly died before and the shock of THAT experience pushed him into rehab.

Seth Roberts (2014-02-06 16:55:38)

Seth, what changes to the treatment of drug addiction do you think would be warranted by these findings? 1. Further study of the issue, so it can be better said what circumstances are likely to trigger "failure of tolerance". 2. Publicize the findings.

Alex Blackwood (2014-02-07 21:00:35)

My conjecture was that the variable schedule of rewards from street drugs of unpredictable purity and strength could be a significant factor in addiction. Well, these figures on the rising death toll from overdose of prescription opioids don't exactly support that. [http://www.washingtonpost.com/national/health-science/philip-seymour-hoffman-heroin-death-points-to-broader-opioid-drug-epidemic/2014/02/07/42dbbc5a-8e61-11e3-b46a-5a3d0d2130da\\_story.html](http://www.washingtonpost.com/national/health-science/philip-seymour-hoffman-heroin-death-points-to-broader-opioid-drug-epidemic/2014/02/07/42dbbc5a-8e61-11e3-b46a-5a3d0d2130da_story.html)

D. M. Mitchell (2014-02-09 09:59:23)

That was quite interesting and seems to be a valid explanation for some heroin "overdose" deaths. However, years ago I read about a re-study of heroin overdose deaths in Baltimore. The researchers found that in two-thirds of those deaths both heroin and alcohol was involved. Two downers at the same time can quickly lead to death.

### **Better Sleep, Less Cancer (2014-02-05 05:00)**

A few years ago, [1]two studies found that people with sleep apnea have a much higher rate of cancer than people without it, even controlling for several cancer-related variables. In one study, the increase in risk was five-fold. These studies raised several questions: 1. Were the associations due to chance? 2. If real, did the associations reflect cause and effect? Surely people with sleep apnea are different in several ways from people without it. 3. If the associations did reflect cause and effect, which of the many effects of sleep apnea was/were responsible?

[2]A new study found that rats woken up frequently got more cancer. This is a correct prediction from the idea that bad sleep increases cancer, increasing the plausibility of that idea.

[The study] used mice, housed in small groups. During the day—when mice normally sleep—a quiet, motorized brush moved through half of the cages every two minutes, forcing those mice to wake up and then go back to sleep. The rest of the mice were not disturbed. After seven days in this setting, both groups of mice were injected with cells from one of two tumor types (TC-1 or 3LLC). All mice developed palpable tumors within 9 to 12 days. Four weeks after inoculation the researchers evaluated the tumors. Tumors from mice with fragmented sleep were twice as large, for both tumor types, as those from mice that had slept normally. A follow-up experiment found that when tumor cells were implanted in the thigh muscle, which should help contain growth, the tumors were much more aggressive and invaded surrounding tissues in mice with disrupted sleep.

[3]Great Sleep! Reduced Cancer! is a whole book (98 pp) about the connection between sleep and cancer.

Epidemiologists haven't yet figured out that they should always measure sleep quality, just as they always measure cigarette smoking and body weight, but at least [4]interest is growing. Both short and long sleep [5]are associated with a higher risk of heart disease.

Ahoy, Seth. [http://pipeline.corante.com/archives/2014/02/05/the\\_evidence\\_piles\\_up\\_antioxidant\\_supplements\\_are\\_bad\\_for\\_you.php](http://pipeline.corante.com/archives/2014/02/05/the_evidence_piles_up_antioxidant_supplements_are_bad_for_you.php)

tom (2014-02-05 20:21:16)

Exercise helps fat metabolism (and sleep?). Summation at the bottom. <http://www.gnolls.org/3637/what-is-metabolic-flexibility-and-why-is-it-important-j-stantons-ahs-2013-presentation-including-slides/>

Ozquoll (2014-02-06 01:25:19)

Mothers looking after babies are definitely short on sleep! I seem to recall reading that the most long-lived groups of women are celibate nuns...

John Smith (2014-02-10 21:19:02)

Ozquoll, at least mothers are young enough to pull out of it, all other things being equal. When bad sleep befalls the aging and the elderly, it is quite a different matter. Shift workers should take advantage of their youth to make a fortune, yes, but they should progress onwards towards more sapient friendly employment. I wish our researchers would always fully describe the ages of those who participate in their experiments. What may kill an old person may go unnoticed by a young college student.

### **Evidence that Antioxidants Increase Cancer (2014-02-06 05:00)**

Many researchers were shocked when a large 1984 experiment found that a beta-carotene supplement increased lung cancer. Because beta-carotene is a potent antioxidant, and epidemiology had linked eating vegetables with less cancer, it was supposed to decrease lung cancer. My Berkeley neighbor Bruce Ames was the foremost proponent of the idea that antioxidants will decrease cancer.

Now [1]more evidence supports the idea that antioxidants may increase cancer.

A request for comment elicited this:

"It's disappointing but not surprising that people's beliefs are not modified by scientific evidence," said Dr Paul Marantz, an epidemiologist at Albert Einstein College of Medicine in New York. "People so want to believe there is a magic bullet out there."

One commenter on the article rightly says:

"It's disappointing but not surprising that people's beliefs are not modified by scientific evidence," . . . Rather a snide comment considering the fact that it was science that spent years telling everyone that antioxidants and supplements were beneficial.

1. <http://news.yahoo.com/antioxidants-including-vitamin-e-promote-lung-cancer-study-190119863--finance.html>

---

Edward (2014-02-06 09:11:38)

Snide, maybe, but it does not get around the larger effect: that people want to rely and believe what "experts" say. It is easy to blame an "expert" or use them as scapegoats when things turn out to be wrong than it is to take responsibility for it. That is exactly what personal science/self-experimentation avoids. It puts the responsibility back with the individual. Hindsight is always 20/20.

Dirk (2014-02-06 10:19:20)

Does this mean we have to stop eating carrots?

Sara (2014-02-06 10:55:31)

It wasn't "science" that was running the huge marketing campaigns for these particular additives.

AI (2014-02-06 11:03:18)

The study seems to have found that the antioxidants are too much of a good thing. From the article: "What seems to happen is that antioxidants indeed decrease DNA damage, as expected. But the damage becomes so insignificant as to be undetectable by the cell. The cell therefore does not deploy its cancer-defense system ..."

August (2014-02-06 13:06:24)

I think the best argument for being careful with antioxidant intake came from sports medicine. I want to work out and get the benefits of working out and I could see how antioxidants might impede the process. But the first thing I thought of when I clicked on this link was, were they using real vitamin E or that fake stuff? And soy free vitamin E products are hard to find, so there's another confounding factor. So, this sort of study makes me think nobody can patent antioxidants and cancer seems to be quite lucrative for the medical industry, regardless of whether or not the patient eventually dies, so I need to be careful believing these results.

William Mullan (2014-02-06 13:55:06)

It's important to note that this does not apply to food: "The scientists stressed that the results do not pertain to foods such as fruits and vegetables that are naturally high in antioxidants." One could hardly eat enough of some of these high antioxidant foods (although I can demolish the cacao and Okinowan Purple Yams) for them to be harmful. As with much consumption, there seems to be a U-shaped curve. Further, there are plenty of other benefits attributed to antioxidants that go beyond whatever previous cancer prevention benefits were assigned to them.

Nancy Lebovitz (2014-02-06 15:17:11)

This is hindsight, but I wonder if there were ways to tell that antioxidants didn't have a good enough theory behind them. There was no detail or quantification. How much of which antioxidants? Perhaps more importantly, there was no feedback—no hint of how you could tell whether you were taking too much of something.

Allan Folz (2014-02-06 16:46:58)

If you've been keeping up with Mr. Heisenbug and the other gut biota bloggers, this would not be surprising. The cancer-fighting effect from vegetables is likely not from feeding anti-oxidants to ourselves; rather, it's from feeding soluble fiber to our gut bacteria. They found a correlation and jumped to a causation. Well, in their defense, I'm sure it sounded good at the time. Seth: good point. yes, there is a long history of jumping to conclusions in nutrition.

daz (2014-02-06 19:50:28)

Agree with William, "It's important to note that this does not apply to food" "As with much consumption, there seems to be a U-shaped curve" When looking at/thinking about taking a new supplement, I always think, how much food would I need to eat to get that particular dose of vitamin/mineral etc... & is that feasible or would that have been feasible in the past... Take astaxanthin as an example, plenty of hype around this one in recent years, especially over at mercola.com (who sells it), with info like "550 times stronger than vitamin E, and 6,000 times stronger than vitamin C" as per the ORAC values

(purportedly). the mercola product contains 4mg of astaxanthin per capsule, dose one per day. & on his web site he talks about doses up to 12mg per day for certain ailments. even 4mg is a lot of Haematococcus pluvialis (MicroAlgae) even if you happen to have access to some...and even more shrimp & krill. [http://en.wikipedia.org/wiki/Astaxanthin#Natural\\_sources](http://en.wikipedia.org/wiki/Astaxanthin#Natural_sources)

daz (2014-02-06 23:44:33)

... & you need to eat the complete shrimp/krill, shells & heads to get the astaxanthin (but that would have been how our ancestors would have eaten them i assume, no wimpy peeled & beheaded shrimp)

John Smith (2014-02-10 21:28:16)

Superfood supplementation, right on up to vitamins, minerals and hi-tech isolates are not exempt from the rule of 'iatrogenics' in that they all help us compensate for the imbalances caused by lifestyle without forcing us to correct the lifestyle. After all today's medicines are the result of centuries of herbal medicine. Today's pill poppers are little different from the pill poppers of yesteryear and of the next century. I continue to use my favourites, just the same. Will fix up the lifestyle just before the cancer gets me!

Charles Williams (2014-02-13 08:22:21)

It is unfortunate that the term "antioxidant" is not routinely preceded by the qualifiers "endogenous" or "exogenous". While exogenous antioxidants are frequently sources of oxidative stress themselves (and the attendant increased rate of mutation), endogenous antioxidant enzymes are responsible for the evolution of aerobic life itself, and without them, no aerobic life-form can exist. It is becoming progressively more apparent to members of the medical community, as it has been to members of the biochemistry community for years, that activation of the Nrf2 master transcription protein, which controls the activity of the activity of the genes for endogenous antioxidant enzymes, may well be a giant step toward the prevention, and perhaps the treatment, of degenerative diseases. See Biogen's recently FDA-approved Nrf2 activator, Tecfidera, for the treatment of multiple sclerosis. Ironically, the most potent Nrf2 activator yet tested is a combination of extracts from phytonutrients, which the FDA classifies as a "supplement", putting it in the same category as the "worthless" compounds in recent government and medical publications.

Alex (2014-02-07 08:59:50)

The marketing success of diamond engagement rings is an ever-present reminder that you can fool too many of the people too much of the time. I wonder if the custom will diminish as gay marriages increase, since those couples don't fit the ready script that the man must spend two months' salary on a ring for the woman as the first step to marriage.

Gina (2014-02-07 10:45:57)

I think the Twinkie diet proved that it really is how much one eats that matters when it comes to weight.

peter (2014-02-08 17:19:19)

Gary Taubes, author of "Why we get fat" would disagree; his research establishes that carbs are the culprit. Seth: I agree with Taubes that food matters. The point of the link was that Marian Nestle was about 60 years behind the times.

Daniel (2014-02-11 07:03:34)

Have you seen this? <https://experiment.com/projects/will-vitamin-d-improve-the-health-of-patients-with-heart-failure> One of my favorite sites/services. Seth: Very interesting site, didn't know about it. Unfortunately these researchers fail to understand the importance of the time of day that the Vitamin D is taken.

### **"Night and Day": Steve Hansen on Teaching (2014-02-08 05:00)**

At a recent dinner, Steve Hansen, a friend of mine, said the difference between his current teaching and earlier teaching is "night and day," partly due to this blog. I asked him to elaborate.

ROBERTS What is your teaching situation?

HANSEN I've been teaching at Peking University [in Beijing] in the Guanghua MBA program for the last two years. I teach courses in innovation (big company Clayton Christensen sort of stuff), entrepreneurship, and social responsibility/social enterprise. The classes usually consist of 30-50 students from all over the world.

My teaching at Peking U. is a part-time job. Full-time I run a social enterprise here in Beijing ([1]Phonemica). Before this I was a professional market researcher working at a large company and I worked as a consultant for years. Although I had a little teaching experience early in my career (e.g. taught undergraduates when I was a grad student), I certainly did not have any special teacher training or background. I was hired at Peking U. on the basis of my professional experience. Thus when I started teaching I was to a large extent repeating to my students the experience I had had as an MBA student myself, years ago.

ROBERTS How did you teach this course at first?

HANSEN My teaching changed quite a bit in the first year. The first semester I did lecture and discussion. I didn't like it. I felt it was a lot of work to prepare, and while it helped me personally a lot, by getting me to summarize my learnings from years of reading and work experience, I didn't feel it gave the students a lot. Even though the course got mildly positive reviews, I felt the students weren't engaged in a way that made me excited about going to teach.

The second semester I started making changes. First, I took to heart some advice I got to follow more of a

case study approach. The experience I gave the students in the beginning of that semester was fairly standard "case study" method made famous by Harvard. [2]Here's a mini-documentary of how Harvard expects case study method to work. The professor asks pointed questions from the case and expects the students to have answers and defend them.

ROBERTS What caused you to change how you teach it?

HANSEN I like the case study method in theory. I like it a lot. I think by mimicking real life situations and summarizing the many facts that synthesize a business manager's knowledge and must be put to use in making business decisions, the case study method has the potential to help students learn in a way that is useful: giving them the skills to make real-world decisions, and doing it faster than they could get the same experience by going out and working. As far as activities that can be done in an academic environment go, the case study is pretty darned close to "learning by doing".

However, I found my classroom reality was different from the ideal portrayed in [3]that Harvard Youtube video, in which a professor says, "I have been amazed... at the consistent level of high preparation".

In my reality, students often didn't come prepared. Sometimes they would say, "Sorry, I didn't have time to read the case" – despite significant portions of the grade being dependent on in-class participation. And even if they were prepared, to some extent, often it wouldn't be to the extent that I had hoped, where they were able to argue the intricacies of a position and defend it. Instead they might give a cursory answer, with a weak defense, and much of the class would be spent with me pushing them to elaborate their answers through Socratic questioning, lecturing, and so on.

So I was still doing a lot of the talking, and really leading the class. It was better than my first semester, but it wasn't meeting my standards of what a real learning environment should be: student-led because they're motivated to learn.

It was about at that time that I must have read some of the articles and ideas you published about "learn by doing". Those rang true to me. Learning by doing is something I've always believed in and tried to practice, and I realized that my students still weren't doing it.

So later during that semester I started experimenting. My first experiment, I'm sorry to say, was a complete failure. My approach for a few classes was to have students simply teach the class. I would assign the next class's case study to a group. They would read the case and come up with main points. I would meet with them and review what they were going to do. Then they went in and tried to teach their fellow students.

In retrospect it seems obvious that this was wrong. As business school students the "doing" that I wanted them to do shouldn't have been to "do teaching" but to "do business" as simulated in the case. When the students were teaching the case they were (again naturally, in retrospect) worse than I was. They would lecture rather than ask. They would miss key issues. And of course they had the same problem I'd noticed myself: other students weren't prepared enough, even though the lecturing group was extremely prepared.

After enough experimentation to realize this wasn't working, I cut it off and went back to my semi-successful case study method.

But the failure had given me an idea. I saw that students who were forced to present were MUCH more engaged than those who sat and listened. Why not, I thought, just make everyone present? It would kill several birds with one stone. First, I'd noticed that students' presentation skills needed a lot of work. They had trouble being concise and answering the critical questions. Having to present would give them practice on this critical skill. Second,

they'd be engaged and motivated – at least for the part where they were presenting. Third, by divide-and-conquer of the case itself, we'd get far deeper into the details and (sometimes) quantitative analysis of the cases.

And so that's what I started doing this year. It has worked even better than I imagined. Not only are students engaged for their part of the lecture and discussion; the preparation seems to spill over into the whole case, so most students really know what's going on. The presentations get better and better as the semester progresses. In contrast to the past, now I'm having to shut down vigorous discussions in the interest of time, rather than ask pointed questions to stimulate interest. And best of all, this environment satisfies my own desire of creating a place where students want to learn. I work less, and the students learn more. That's the part that seems "night and day" to me.

For anyone who's curious, there are some details I've worked on to make the approach better, at least for my particular situation. Here's the nitty gritty:

I divide the class into random groups of 4-5 students. That group is together for the semester, and for each class they're tasked with presenting on one part of the case. I assign that presentation the week before, and it's often a question that forces them to take a position. Often, too, I assign the same question to two different groups. This has the effect of creating a sort of debate between the groups, because they almost never come up with the same answer to a question.

I require VERY short presentations. Usually 2 minutes. Sometimes 3 or 4 if the topic is very complex. I allow any member of the group to present. Although I encourage them all to take the opportunity to practice presenting, I don't force the issue.

All the students in the group get the same grade, but with the following "peer evaluation" element that I adapted from someone else (i read about it online but have now lost track of where). Peer evaluation means that your fellow students give you a grade at the end of the semester. If your fellow students all give you 100 %, then you get 100 % of the group grade. That's the usual case. On the other hand, if all your fellow students give you 50 %, that probably means you didn't do much and you get only 50 % of the group grade – a guaranteed failure for that portion of the class. In even more detail, what I do is take the average of the peer scores, but not including the lowest score. This virtually eliminates the possibility that one enemy classmate can sabotage a groupmate's grade.

Overall I've found that the peer evaluation mostly eliminates the freeloader problem that general plagues groupwork. In cases where someone tries to freeload, they simply get a bad grade, so the other groupmates aren't really bothered about it.

At least as importantly, this entire system, once explained, makes my grading job much easier.

I also like the "group is responsible for the presentation" approach because it allows some flexibility. There's always going to be a week during a semester that a student simply gets swamped with other things and doesn't have time to prepare. Under the group presentation regime, the busy students can beg groupmates to cover for them, and then return the favor another week. Would it be better if everyone were always prepared for every class? Well, maybe, but that doesn't really seem realistic.

ROBERTS What did you read that influenced you? HANSEN I read [4]all your posts about education and teaching. It's hard to say any one post made me change the way I teach. It's more that your posts about teaching, like your posts about diet etc., often help me consider what my goals are and how I can do low-risk experiments to find better ways to reach those goals. As for specifics... I remember reading [5]this, for example, that helped me remember to think about my students' goals rather than my own for them (not that I think I should have no influence on their goals – more that I should keep in mind they are autonomous agents about whom I know little and should learn more). I still grade, but I've experimented with "grading less" I guess you could call it, partly inspired by [6]discussion like

this. I was probably most influenced/inspired by [7]the Halmos paper (also [8]here) you [9]mentioned. I was a math major as an undergraduate, so I liked the subject matter. I was always interested in the kind of simple statement of problems and choices that he describes in that paper, not just in math, but in business and elsewhere. I really enjoy simple problem statements that force one to go through complicated analyses and yet still reduce everything back to a simple statement of resolution. Business at its most interesting can be quite like that. You have to make decisions: fund this project or don't. Build this product or build that one. What do you do? Even more than enjoying the problems, though, I completely agree that the hard part is making students ask questions. It's not actually solving the problems that's hard; it's figuring out what the problems are in the first place. After reading his paper, I started doing some searching and found others who were experimenting with teaching techniques. It would take me a while to re-find those people, but I definitely gleaned ideas from others. These helped shape my own experimentation.

"the hair-brained idea": somebody isn't eating enough butter.

jacobber (2014-02-09 09:04:42)

carbs and sugars at night definitely keep me calm at night and it's easy to fall back asleep when i wake up. However: I'm still trying to figure out a way to stop having to wake up and pee at night. That's the next step.

Nancy Lebovitz (2014-02-09 09:27:02)

That's the same Epstein interview you linked to on the 7th. Still, fascinating stuff, and now I'm wondering how the diamond cartel has managed to maintain focus instead of just trying to slide along on past dominance.

peter (2014-02-09 10:14:04)

Lactobacillus brevis also is found in pickled turnips. I've used it for weeks and noticed a difference. It seems to clear my lungs (i probably have a low level infection that once cleared by i took intravenous antibiotics). I buy the Japanese style fermented turnips. I'll try the Japanese pickles, since they probably taste better.

Joe (2014-02-09 13:41:49)

In the sugar for insomnia article: "I've even skipped the spoon and just stuck a wet finger into my little sleepy dust container and licked it off, and that works, too. Puts you back to sleep in no time!" That just makes me think there's something else going on here. Not exactly placebo, but having to do with degree of suggestibility. A few granules of sugar and salt puts him back to sleep in no time? I ain't buying it. :)

dearieme (2014-02-10 14:42:11)

Ahoy, Seth. <http://www.forbes.com/sites/larryhusten/2014/02/10/leading-european-cardiologist-accused-of-plagiarism/>  
Seth: Thanks, good article.

Josh (2014-02-11 11:23:01)

The "Sugar for insomnia" article was interesting. But I thought I'd forget about it before I ever got to use it because I rarely have the type of insomnia this trick addresses (e.g. can't fall back asleep in middle of night, after waking). Lo and behold, last night I had this type of insomnia (due to over-training, something I consciously avoid, but couldn't avoid yesterday). I awoke at 330am and couldn't fall back asleep. At 530am I decided to give the salt + sugar trick a try, and I was back out like a light. Too bad I had to get up an hour later:(

## **Adult Acne Due to Allergy (2014-02-10 05:00)**

Someone [1]commented:

I had awful adult acne, hideous cystic lumps that left scars. My college pictures are hard to look at. This continued into late twenties. It was [due to] a food allergy [that] took forever to figure out: black tea.

Especially Oolong. [Oolong and black tea are usually distinguished. Black tea is "fully-fermented", oolong "semi-fermented". – Seth] My face would begin to itch within minutes of drinking, and the breakout came the following day. But it took years to notice the connection. . . . Green tea is no problem. Coffee is no problem.

In response to my questions, he verified the connection:

On Tuesday night, I drank two cups of strong black tea. Itching began within a hour, and mouth sores hit 18 hours later. Now at 48 hours, very slight acne breakout, but not bad at all.

Part of figuring out the problem was realizing that face itching was a bad sign. The black tea -> itching connection was relatively easy to notice. Another difficulty was the wrong ideas he'd been taught:

To figure out the tea, I first had to unlearn things that turned out to be wrong. Unlearning seems to be much slower than learning.

First, when I was in high school, acne was widely considered to be partly a hygiene problem. So I spent vast useless effort washing several times a day, while possibly missing signals that the cause was something else. Later, in college, I tried washing my face only with water, and then not at all. This turned out to have no effect on acne. That was the first clue of wrong learning.

Second, in high school I drank a lot of grapefruit juice. The citric acid was extremely painful on the mouth sores. I somehow concluded, maybe just emotionally biased by the sharp pain, that grapefruit juice was causing the sores. In college I didn't drink grapefruit juice, but there was no effect on mouth sores.

Third, a received wisdom was that acne is hormonal, and there was not much you could do but try to manage it. So I didn't even try to look for an environmental cause, until I was still suffering from acne well into my twenties.

These three wrong conclusions probably cost me years.

Not to mention the astonishing claim of dermatologists that [2]acne is not caused by diet. This [3]list of what to do about acne from the American Academy of Dermatology says nothing about food. It is plausible that in this situation – in 2014, after hundreds of years of experience treating the problem and thousands of medical journal articles about it – the overall effect of doctors is to make things worse.

Alex Blackwood (2014-02-10 08:28:49)

It's infuriating that for a variety of conditions doctors say, "diet does not affect xxx." They can correctly say, "We do not have evidence that diet makes a difference in xxx," but instead go for the broader, false, "We have evidence that diet does not make a difference in xxx." Personal science has been a lifesaver for me in navigating the gap between those two statements. Seth: There is plenty of evidence that diet causes acne. E.g., dairy. Dermatologists ignore it. Then they claim the opposite. That they are not ridiculed for doing this is interesting.

Frankr (2014-02-10 09:39:07)

Dermatology should be viewed as an industry, like any other. They don't want to loose customers. It's kind of like how the tobacco industry for a long, long time, refused to admit the connection between smoking and cancer.

MikeW (2014-02-10 10:10:58)

A while back I read a paper where they analyzed the sebaceous gland output of 10 adults, and found that each individual's sebum had a distinct, markedly different, fatty acid/wax ester profile. Maybe that's one reason bloodhounds can tell us apart, but it also explains why acne sufferers blame a wide variety of trigger foods for their blocked pores (for me, it's definitely cheese and trans fat, but I don't have any problem with chocolate or tea). I feel some sympathy for dermatologists, who can hardly be expected to determine an individual's unique food sensitivities in a 15-minute office visit. But they could do a better job of pushing patients to pay attention to their diets and do their own experimentation.

Ward (2014-02-10 18:22:47)

Sounds like a possible histamine reaction to me. Teas cause exactly this reaction in folks who are are histamine intolerant.

John Smith (2014-02-10 21:49:05)

The Antropops taught me that acne is the body disposing of bad blood associated with unsuitable or unwanted DNA in the maturing person. Hence, if it persists into full adulthood, it would indicate a person not fully coming to grips with the traumas of youth. And lets face it, all of us thought we were badly done by, aye?

Sara Lake (2014-02-13 18:11:57)

I had terrible adult acne and spent years looking either spotty or patchy because my skin turned a nastly mottled colour. Even when not really 'breaking out' my skin was bumpy all over my face. I found the cure accidentally when I started taking niacin (B3) for my cholesterol. The acne went away in less than two weeks. I've heard of the same thing happening to someone else but with B5. I now only need to take niacin about once a month (100mg) to keep the acne gone. It takes about 6 months for it to recur if I stop completely.

## **Journal of Personal Science: L. Planturum-Rich Fermented Foods and Supplement Prevented/Cured My Eczema (2014-02-12 05:00)**

by [1]Shant Mesrobian

At some point during the last decade, while living in Washington D. C., I began to suffer from hand eczema. Painful red itchy inflamed dry skin covered most of my hands. It was usually triggered by cold dry weather in the fall and winter. It also flared up after a lot of cleaning — when my hands were exposed to a lot of water and soap, which dried them out. I was in my twenties when it began.

Eczema, also called *atopic dermatitis*, is believed to be a too-extreme allergic reaction. It is common. About 10 % of American adults suffer from it, according to two recent surveys ([2]here and [3]here). In my case, a certain level of dryness is required. I believe the dryness, which may reduce a protective coating, allows something in the environment, like dust or pollen, to trigger an allergic inflammatory response.

The first thing I did to solve the problem was see a dermatologist, who prescribed a steroid-based cream. The cream did reduce the inflammation. It was just something to apply when the inflammation appeared. It didn't stop it from happening. As I learned more about eczema, I decided this was an absurd solution. Steroids have nothing to do with the cause of eczema. At best they treated the symptoms, and had bad side effects (is anything creepier than "skin thinning"?).

Then a funny thing happened. A few years ago, my eczema disappeared. I didn't notice it had stopped until this fall (2013), when it came back. I had forgotten about it. As soon as the weather turned cold and dry, it hit hard.

Why had it disappeared and returned? My environment had not changed in any big way. Nor, when I first thought about it, could I think of any dietary changes in the past year or two. Then I realized I had made a dietary change – and recently. In September (2013), I had stopped eating a few fermented foods that I had steadily eaten for the past few years — sauerkraut, kimchi, and kombucha. I had drank kombucha only a few times a month but had eaten sauerkraut or kimchi almost daily (3-4 forkfuls/day, \$0.50/day). I had started eating them in 2011, hoping they would improve my health. The last time I had had eczema was the winter before I began regularly eating them.

Had the fermented food prevented eczema? This was not far-fetched. The ideas that (a) bacteria in food can influence your immune system and that (b) bacterial exposure can "calm down" an over-reactive immune system are both well-accepted. Review articles are [4]here, [5]here and [6]here. There is lots of supporting evidence. An early example is the evidence behind the hygiene hypothesis – children in "dirty" places had fewer allergies than children in cleaner places. [7]This article says "approximately 70 % of the entire immune system" is in the gastrointestinal system.

Fermented vegetables like sauerkraut and kimchi are dominated by the bacterial species *Lactobacillus plantarum*. If sauerkraut and kimchi had prevented eczema, it was probably due to *L. plantarum*.

After multiple flares over a few months, I tested this idea. I found a probiotic supplement (Jarrow Formulas Ideal Bowel Support) solely composed of *L. plantarum*. Then I waited for my eczema to flare up again. When it did (early January 2014), I began taking the supplement (one pill daily, \$0.50/day). Within three days, the eczema had completely disappeared. In the past, three days after it started the eczema got worse. It usually lasted about two weeks from start to disappearance. I had never seen it disappear like this. Usually at this point (3 days after it started) hand washing would be painful and make it worse. Now I could hand wash with abandon. Even more amazing: I could walk around outside during a cold spell without gloves, and did not have any exacerbation or return of symptoms. Being able to do these things three days into a flare up had never happened before.

I kept taking the supplement (one pill/day). In the past, before the fermented foods, I had at least some inflammation on my hands through the entire fall and winter, with extreme periods and less extreme periods. Now (February 2014) I have zero inflammation. In the past, dryness on my hands immediately led to inflammation. In normal people, dry hands are dry hands. I never have just dry hands. Dryness is a trigger. I'm not used to seeing a dry hand without inflammation on it. For the past few weeks, I've had mildly dry hands without inflammation. I've become a normal person with dry hands.

Several studies – which I didn't know about when I saw that the probiotic supplement helped – support the idea that *L. plantarum* can reduce eczema. Two studies ([8]here and [9]here) found that *L. plantarum* inhibited house-dust-mite-induced eczema in mice. [10]Another study found that *L. plantarum* inhibited allergic reaction and histamine-induced scratching (itching is a hallmark symptom of eczema) in mice. It concluded that *L. plantarum* "may improve allergic diseases, such as . . . atopic dermatitis". In [11]another mouse study, *L. plantarum* was successfully used to reduce dust mite allergy. The most impressive evidence was from [12]a 2012 study done with children in South Korea. All of them had eczema. Those given *L. plantarum* improved much more over 14 weeks than those given a placebo.

In contrast to my success, many studies have found no effect of probiotic supplements on eczema. [13]One review concluded “Initial meta-analyses suggest no benefit of probiotics [supplements] in the treatment of eczema or asthma.” Maybe they tested the wrong bacteria or used a too-small dose. I haven’t noticed any effect of yogurt (which contains different bacteria) on my eczema.

After [14]I posted about this in my blog, several people tried something similar and reported what happened. Overall [15]I would summarize their results as modest improvement. The most positive result was this: “After 5 days of radish kimchi the eczema in that person [a family member] is very clearly receding and, in a few spots, is completely gone. From prior experience, it would not have done this on its own.” The least positive result was no change, which a few people noticed.

My interpretation is that kimchi and sauerkraut – that’s what everyone tried – have far less *L. plantarum* than the probiotic supplement I took. [16]This article considered sauerkraut “probiotic” when the concentration of *L. plantarum* was “higher than  $10^6$  colony-forming units (CFU) per gram of product”. [17]This sauerkraut maker says their sauerkraut has  $8 \times 10^6$  CFU per gram. A serving of sauerkraut might be 60 g, so the total number of *L. plantarum* in one serving will be roughly  $5 \times 10^8$ . In contrast, the probiotic supplement I took supposedly contained  $10^{10}$  CFU – a factor of one hundred more. A daily dose of  $5 \times 10^8$  CFU might eliminate eczema if you eat it for months, as I did, but might produce much more modest results after just a week.

Meegs (2014-02-12 11:21:24)

I suffered from hand eczema for years during cold weather, and it has gotten a lot better since I started a whole foods diet that includes a lot of fermented foods. I’m not sure what specifically helped, but I drink a lot of kombucha and kefir.

Todd Fletcher (2014-02-12 15:53:20)

My eczema and other skin problems of 15 years disappeared completely from regular kefir and yoghurt, which I did because of this blog. Seth: Great to hear!

Evelyn M. (2014-02-13 10:21:51)

Many thanks for this post. I am ordering the product specified and will let you know if it has any effect on the psoriasis and/or lichen planus (different practitioners give different diagnoses) that has been plaguing the skin on my legs for years.

rudy (2014-02-16 06:08:57)

i had the same problem, at least the same symptoms in winter, also increased by handwashing. in my case the solution, suggested by my doctor, was much simpler: just to wash my hands with cold water instead of hot water. i haven't had a recurrence this winter. i assume hot water washes off more skin oils.

Leila (2014-02-16 20:04:25)

I've now seen two dermatologists for scalp issues & resultant bald patches, and have received two diagnoses, lichen planopilaris & pseudopelade. Both diagnoses were made by looking at my head, rather than performing a biopsy. When I questioned the 2nd one about it, he said a biopsy wouldn't show anything, that it's an "old-fashioned" investigative method. They both gave me steroid prescriptions and freely admitted that it won't likely help. The 2nd one referred me to a 3rd who specializes in hair transplants. I find the whole thing vastly irritating. Doctors who write a quick prescription and send me on my way, doctors who treat symptoms instead of looking for underlying causes, doctors who do less research than I do. One of these docs is the assistant head of dermatology at the local university, so I had high hopes. When I got to his office I thought I had the wrong address, as the signs & brochures on offer were all about lipo, dermabrasion, skin tightening procedures and looking youthful. It's no wonder there's so much interest in personal experimentation - the medical profession is failing it's responsibility. Oh well, they don't call it a practice for nothing! I've also ordered the Jarrow I. Plantarum product. I doubt this is an allergy but I don't see how it can hurt to try it.

## **The Idealist: Jeffrey Sachs and the Quest to End Poverty by Nina Munk (2014-02-14 05:00)**

After I finished *The Idealist: Jeffrey Sachs and the Quest to End Poverty* by Nina Munk, I thought of something a graduate student in English had told me: A little Derrida goes a long way and a lot of Derrida goes a little way. It was literally true. A few sentences by Derrida, you could think about for days, maybe productively. A whole book by him was baffling and irritating. A lot of Jeffrey Sachs goes a little way, I thought.

When it came out (2005), I thought *The End of Poverty* by Sachs was the ravings of a lunatic. Munk's book shows I was right but I had to admit that George Soros giving Sachs \$100 million or whatever to put his ideas into practice (to "test" them) was considerably more interesting than the activities of the other billionaires Munk had written about before Sachs. Soros had an advisory board whose reaction to Sachs's ideas was the same as mine but Soros overruled them. Soros was right. A tiny bit was learned from spending all that money, which is better than learning nothing. Certainly I learned more than if the money had been used to buy a private jet.

As an assistant professor doing animal learning experiments, I saw over and over that it was incredibly hard to learn anything. Anything. No doubt all science professors who are honest learn this. But then I saw something that is less easy to see: If doing the "right" thing pays off worse than we expect - Sachs's flamboyant failure in Africa is an example - then doing the "wrong" thing should pay off better. If spending an enormous amount of money we learn less than expected, then when we spend very little money we should learn more than expected. This is the upside of ignorance. The less you know, the easier it is to learn more. And we know much less than famous professors, such as Sachs, say we know.

My personal science is the polar opposite of what Sachs did. He tried to help others (poor Africans), I try to help myself. He tries to help people he knows almost nothing about, I try to help myself – and I know a lot about myself. He tried to do something big (end poverty). I try to do something small (e.g., sleep better). What he did cost millions of dollars. What I do costs nothing. I can test a new idea about how to sleep better in days. Sachs took years to test his ideas. For me, failure costs almost nothing. Sachs's failure cost him years of his life. You have to be an extraordinary person with great talent to do what Sachs did. Whereas anyone can do personal science.

---

Alex Chernavsky (2014-02-14 07:19:58)

I think I've previously posted a comment on this subject, but I'm excited about a new charity called "Give Directly". This organization has the radical idea that you can alleviate poverty by giving away money, with no strings attached. Here's a recent [1]article from *Forbes* magazine:

**Give Directly's Breakthrough 'Free Money' Model Grows As Evidence Mounts** Give Directly has an extremely simple model – find poor people and give them money. That's it. It's a radical idea which sometimes rubs people up the wrong way – a popular refrain is, won't people just drink the money? But the program, which gives extremely poor people in Kenya and Uganda \$1000 split over two payments and transferred by mobile phone, is gaining ground thanks to the data it's gathered backing up its claims. [...] The system works by removing the usual arbiter, an NGO, and putting money straight into the hand of poor people to spend on whatever they want. Faye hopes the approach will make donors think about more about giving to non-profits – will they do more good with the money then the poor could do themselves?

1. <http://www.forbes.com/sites/hollieslade/2014/02/10/give-directlys-breakthrough-free-money-model-grows-as-evidence-mounts/>

MJB (2014-02-14 12:40:19)

"I saw over and over that it was incredibly hard to learn anything. Anything. No doubt all science professors who are honest learn this." I remember a Richard Feynman video where he said the same thing.

Seth Roberts (2014-02-14 20:51:07)

"I remember a Richard Feynman video where he said the same thing." That's interesting! I do not remember Feynman ever talking about this. Can you remember the video?

aretae (2014-02-15 08:03:05)

"I saw over and over that it was incredibly hard to learn anything. Anything. No doubt all science professors who are honest learn this." This also was the line I was going to comment on...but I see it's also been noted by MJB. "We're wrong a lot" is at this point the center of my epistemology. You say it very well here.

Valerie (2014-02-15 14:04:14)

I think I saw the same video with Feynman. He was commenting on nutrition science, how the so-called knowledge on nutrition was not solid, the scientists behind it had not done the hard work that is needed to truly figure things out. In a related vein, I sometimes see professors who publish several articles per year, or a few hundreds over their careers. I have a very hard time imagining that they have a significant contribution to make to science (the criteria to have an article published, I was told in graduate school) several times per year, or a few hundred times during their careers. As a professor yourself, what do you think happens? Do you believe those publications are honestly meaningful? Did all the authors really contribute?

Cliff Styles (2014-02-15 15:20:46)

That last paragraph is the pithiest summary of your thinking, and nails why I keep coming back to your blog. It may be the most important paragraph I will read this year, I am passing it around to everyone I can think of with my evaluation attached. It's a Seth Roberts coda, at the end but not an ending. Seth: Thanks, Cliff, that's nice to hear. Yes, this blog is a long exploration of that point of view. If I had to do it all over again, I would have named it Personal Science.

Seth Roberts (2014-02-15 17:32:35)

"As a professor yourself, what do you think happens? Do you believe those publications are honestly meaningful? Did all the authors really contribute?" I believe that the distribution of progress per article follows a power law: A very large fraction of articles contribute very little (make little or no progress), a very tiny fraction of articles make great progress. I also believe the same distribution holds for individuals: If someone has written a hundred papers, and you measure how much progress each paper made, the distribution of those measurements will follow a power law. The problem is with the SLOPE of that power law distribution (relatively flat slope = high average progress per paper, steep slope = low average progress per paper). I think there are aspects of the system, especially the pressure to publish, that make the slope steeper (= reduce average progress per paper).

John Smith (2014-02-18 15:42:26)

My Take: We learn almost automatically that which is stored in our DNA. In other words, what our parents knew, we can pick up on without effort. So we unfold as we grow into adults just as a blow-up Santa Clause does on Christmas Morning. But beyond that, we have to work at it, as in learning what other DNA strings know, and there is far too much of that for us to ever take it all in. So we specialize and avoid all information not relevant to our specialty. Once all that has been rummaged through, we are in very creative territory, and only when we are aware of the question will we pick up on the answer. This may take much pain and suffering to attain. This is why two people hearing the same lecture pick up on different points. Unless we are ready to take on new ideas, they will just float on over our heads. Usually the answers to the 'exotic' questions will be obvious in ancient texts but having been committed to maxims and clichés are usually ignored. There is nothing new under the sun, only new ways to express the same form. In effect we can learn as much as we are willing to.

Adam Long (2014-02-15 09:13:46)

Seth, first link was very interesting. Ok, I admit that the pics of cute girl didn't hurt, but also discussion of benefits of honey (e.g. for wound dressing) are very interesting to me. I had a question about the exact definition of "raw honey" Since reading about it here, I have been taking a tsp of honey about 5 to 6 nights per week and have noticed significant reduction in sleep latency – as in, I used to be able to read in bed, now when I try to read, I get through a few sentences and then conk out. I have purchased a few bottles/jars of "raw honey" from Sprouts, a local grocery store here in LA. In some cases, this "raw honey" comes in a jar and is solid at room temperature. Other containers, also labeled "raw" contain honey that is liquid at room temperature and also a little bit darker than the honey that comes in a jar. As far as anybody knows, is there any significant difference between the "solid at room temperature" and "liquid at room temperature" honey. For what it's worth I haven't noticed a difference myself but would be curious to hear from others on this.

Gina (2014-02-15 09:14:03)

Seth, Anytime I read about sleep, there's always the lark/owl distinction. Your sleep discoveries seem to suggest that with all the oscillators working correctly and in sync that there is no real distinction (i.e. all humans in a given area would have the same circadian rhythm). I just started morning faces and it has been terrible to drag myself up early. If being a "night owl" truly is inherent then it would be better to do it later. I'd love to know your thoughts. Seth: I completely agree with your interpretation of my research – that "with all the oscillators working correctly" there would be no night owls. Lack of the right (best) environment increases variability, including person to person variation. You could say the wrong environment reveals underlying genetic variability. It is hard to know the best time to watch morning faces, you should just try different times. And the more sunlight (and Vitamin D) you get in the morning, the earlier you will wake up.

Sidney Phillips (2014-02-15 18:15:12)

Reading about Tyrone Hayes' battle with Syngenta just confirmed what I already knew: companies like Syngenta and Monsanto are pure evil. Seth: They never considered the possibility their activities might be exposed.

Bill (2014-02-19 09:41:51)

The acne photo series shows her becoming noticeably leaner as her skin became clearer. Is it possible she simultaneously stopped consuming something else, such as dairy or other carbohydrate?

## **Elegant Variation, Fashion and Employee Free Time: What Do They Have in Common? (2014-02-16 05:00)**

I am learning Chinese by studying a Chinese version of The Three Little Pigs. The story contains a phrase that irritated me: "Three's home" (in Chinese). Although I did know the Chinese for "home", the rest of the story used the term "Three's brick house" (in Chinese). Why couldn't they stick with one name for it? I thought.

I knew the answer: In language, we like to use different words for the same thing. [1]A famous archeological decipherment puzzle was solved when someone realized the stone cutter had used different words for the same thing. A little repetition is okay but extreme repetition is not. Thus the term elegant variation. Using different words for the same thing is not just confusing, it makes the language harder to learn (because it is larger), with no obvious improvement in breadth or speed of communication.

Why do we do this? Why do we dislike certain sorts of repetition, even though language is built on repetition? I

think the answer is that this is built into us to help the language to expand and grow. The variation seems useless but it isn't because (a) there is a new word and (b) the new word can shift in meaning. The old word can continue to mean what it meant.

Fashion has a similar function. Our shifting preferences in art and decoration force artists to keep inventing. They cannot merely do the same thing over and over and over. Fashion obviously increases innovation.

In her brilliant book [2]*The Good Jobs Strategy*, Zeynep Ton, an MIT business professor, says that retailers should "operate with slack" – meaning hire more employees than necessary. The effect is to give employees some free time. Why should this be? Because when you give employees free time you give them to think. Giving them time to think gives them time to think of improvements.

Language (elegant variation) and material science (fashion) might be more central to human life than well-run stores (slack) but in each case there are real problems to solve – and they are solved, in part, by adding seemingly-useless elements to the system. The new elements help the system improve.

Three Pipe Problem (2014-02-16 06:42:22)

When I was in college, the professor who helped to improve my writing the most would make us read our papers out loud to him. I was reading a paper about Plato to him, and he stopped me because he could not follow my train of thought. It turned out that my unconscious training to avoid using the same phrase repeatedly had made the paper incomprehensible. I remember telling him I had wanted to avoid using the same terms, and he said, "It helps."

George (2014-02-16 06:44:58)

Its interesting you should be writing this in China. Some cultures don't seem to prize elegant variation but prefer to fix their fashion in architecture and literature to a single mold, which they repeat for centuries.

Audrey (2014-02-16 08:39:03)

Since language variation demonstrates mental agility and creativity, we might be unconsciously motivated to do it to show off, to help attract the opposite sex. Why do we have so many songs, or even one song? Maybe for the same reason we have oral sex: it's appreciated. Seth: When I hear that this or that feature of human behavior evolved for the sake of showing off to the opposite sex – and I hear it often – I think, sarcastically, thank goodness things are so simple. There is certainly a lot of sexual signalling and as far as I know it is always very asymmetric: one sex does it much more than the other (e.g., dance). I am unaware of any sexual asymmetry in language variation. Both men and women do it, roughly the same amount.

Nancy Lebovitz (2014-02-16 11:06:30)

[1]Slack: Getting Beyond Burnout, Busywork, and the Myth of Total Efficiency gets into various aspects of why you need slack in organizations- time to think, learn, recover from delays, etc.

1. <http://www.amazon.com/Slack-Getting-Burnout-Busywork-Efficiency/dp/0767907698>

Chris West (2014-02-17 01:30:25)

I read The Odyssey for my A Levels in school and I remember the formulaic descriptions of things like the sunrise. I found this increasingly frustrating and it detracted from my enjoyment of the book. Why was it so annoying? I guess it felt lazy and it was just really boring to re read the same phrases and descriptions over and over. I couldn't mentally 'buy in' to the description of a beautiful sunrise after I'd read the same description 10 times. Outside of my day job I run a small record label. Writing is not one of my strong points and creating press releases is a hard task. I have to come up with many different way of referring to the same thing - "the album, released today", "the band's full length debut was recorded at...", "the band had this to say about their self-titled release..." etc. I figure the people I'm sending these to must read many of them every day so I need to keep it as interesting as possible. As always, context is important. I would assume in a research paper its acceptable to use the same, and probably very particular, terms for things. Is this the case?

garymar (2014-02-20 03:08:17)

The Odyssey and Iliad come out of *oral* traditions of storytelling. When you've got 11,000 lines to recite, repetition gives your hearers a chance to assimilate and gives you a break at the same time. This highly non-repetitive [1]Onion piece cracked me up, because the writers used as many different synonyms as they could think of for "a # #hole".

## Cheating at Caltech (2014-02-17 05:00)

Caltech has a serious problem with undergraduates cheating on academic work, which Caltech administrators appear to be ignoring. A few years ago, one alumnus considered the problem so bad that he urged other alumni to stop donating. I attended Tech (that's what we called it) for a year and a half in the 1970s. I didn't think cheating was a problem then. Now it is.

[1]A recent article in the Times Higher Education Supplement by Phil Baty praised Caltech's "honor system", which includes trusting students not to cheat on exams. A Caltech professor of biology named Markus Meister told Baty that "cheats simply cannot prosper in an environment that includes such small-group teaching and close collaboration with colleagues because they would rapidly be exposed." That strikes me as naive. How convenient for Meister that there is no need to test his theory - it must be true ("cheats simply cannot prosper").

A few years ago, a Caltech alumnus named Peter Seidel, after receiving a donation request, told his fellow alumni not to donate until the system was cleaned up. Here's some of what he said:

I found out today that Dean of Students Jean-Paul Revel said the following to my dad on the phone while I was at Caltech (Not realizing that my dad is a former Caltech student and BOC [Board of Control] rep) "Peter has a real problem with cheating. The fact is that people cheat. Peter needs to get over it."

I think it's safe to say that the Caltech 'Honor Code' is obsolete. [= is no longer working - Seth]

There is a small and growing population of students at Caltech [who] are systematically cheating,

and the Caltech administration is aware of it but refuses to do anything about it. I suspect the problem began when Caltech started advertising its 'Honor Code' to prospective high school students in the 90's, which lead to self-selection of students who were willing to bend the rules.

In my personal experience, I caught students cheating red-handed while I was a student, and though I took my findings to the BOC, nothing ever came of it.

I also went to one of my professors (along with several of my classmates) and we explained that we were very concerned that there was a significant amount of cheating going on in his class. While he was very empathetic and gave us a significant amount of his time, ultimately he essentially said that his hands were tied because the school does not allow him to give proctored exams.

The Caltech exam system is set up in such a way that it is extremely easy to take extra time on an exam, open a book on a closed book exam, or search for the answers on the internet. Most exams are taken by students alone in their dorm room, with no one watching, at the time of their choosing, with the student timing themselves and with both the coursebook and an internet connection in the room, with only the student's integrity preventing them from using resources they are not allowed to use. For that matter, many quizzes and exams are turned in to unlocked boxes in empty hallways where it would be simple to take another student's answered exam to copy or check answers against, and then return it when turning in one's own exam. <

In my job in the financial industry I interview a number of Caltech seniors every year for potential jobs. And unfortunately, I have to try to answer the question 'Is this person a cheater?' as part of my interview process. I have seen examples of resumes where students flat out lied about their GPA.

But probably the most blatant example . . . is a student [he means graduate – Seth] that I recently interviewed [who] claimed, as his two 'hobbies', to be a member of the Caltech fencing team his freshman and sophomore years, and a member of the Caltech chess club all four years at Caltech. As it happened, when I was handed his resume, the coworker sitting to the left of me was a former Caltech grad student that coached the fencing team during those years, and the coworker sitting to the right of me was a former Caltech undergrad who was an avid member of the chess club as both an undergrad and an alum. Both of them also happened to be part of the group scheduled to interview this student, and received copies of his resume. I asked them what their opinion was of the candidate.

Neither of them had ever heard of him.

We decided to go ahead and give the candidate an interview, and give him a chance to explain, in case we were somehow misunderstanding the resume. The first person to interview him was the former fencing coach. The interview began normally, and then after a while they had the following exchange (I'm paraphrasing somewhat):

Former fencing coach: I see you have two years on the Caltech fencing team.

Candidate: That's right.

Former fencing coach: Well, I was the coach at that time... and I don't remember you.

Candidate: Well, it wasn't actually my freshman and sophomore years; it was just my freshman year.

Former fencing coach: I was the coach both years.

Candidate: Well, I wasn't really on the official team, I just took the PE class that taught fencing.

Former fencing coach: I taught that class.

Candidate: Well, I didn't really take the whole class. I signed up for it, but I only went to the first week, and then I dropped it.

After the first interview, we decided we wouldn't be making him an offer, but I decided to go in and talk to the candidate anyway. [In] the meantime, the coworker who was a Caltech chess club member asked another chess club friend of his if he knew the guy, and he didn't. I told the candidate that we wouldn't be offering him a job, but I wanted to talk to him about his resume. I told him I had heard about the previous interview, and that there were also a couple members of the Caltech chess club who did not know who he was. He responded 'Well, it wasn't a formal team, and not everyone went every time.' I asked him what night of the week the club met, and he told me (confidently) 'Saturday nights.' (I knew that it was actually Friday nights.)

When people cheat and get away with it, they are more likely to cheat in the future, Seidel believes – a very plausible idea. Given the disinterest of professors and administrators in the problem, the Caltech mascot should be a monkey with its hands over its eyes.

1. <http://www.timeshighereducation.co.uk/features/caltech-secrets-of-the-worlds-number-one-university/2011008.fullarticle>

---

dearieme (2014-02-17 07:00:20)

Everything should be examined the old-fashioned way unless there is something intrinsic to the material that requires, say, "continuous assessment" examining. So the candidates enter a room just before nine a.m., or 1 p.m., and have three hours to answer a paper that they've never seen before. They are equipped only with calculators of a specified type - no phones, laptops, books or whatever. Repeat five, six, seven or more times across the course of a week or two. The papers should be set and marked by academics who are not the people who taught the course. The Caltech system described here is absurd. Why on earth would anyone think it a good idea? Seth: It makes life easier for professors. Much easier.

Sara (2014-02-17 08:41:33)

It minimizes staff workload while maximizing the number of summa cum laude graduates?

mit (2014-02-17 10:14:17)

interesting...I also don't believe the honor code system works. But even without honor code systems, there is cheating occurring! For example, most Greek houses keep records of previous exams and finals and then new pledges use them. I went to a college where my affiliated housing unit also had this. I have heard stories of people back in the 70's using their frat's finals and I have heard stories of people in the 2000's using their frat's finals. Apparently the professors didn't think it necessary to change the exams over the past ten years, or they cycle them in a very predictable fashion. Which just made me think of mark twain about never letting school interfere with my education. I think the greater lesson is that for many people, going to university is almost like a finishing program and cheaters do prosper (Steven A. Cohen for example). From what I saw, many

go to college in order to fit into an upper class... and professions that used to not require a degree now do for reasons I don't understand. David Brooks has spoken about this, nothing new. For what it's worth, and though I saw both women and men cheat, women were more likely to get caught, confess, and take the penalty for cheating than men were. Caltech is a much higher proportion of men, which makes me wonder if its environ is anything like the Tour de France? Everyone's doing it and you're not competitive if you don't cheat.

Steve Johnson (2014-02-17 15:09:39)

Seems likely that there is an element that's not being mentioned in this story: <http://educationrealist.wordpress.com/2013/10/08/asian-immigrants-and-what-no-one-mentions-aloud/> "The stereotype, delicately put: first and second generation Chinese, Korean, and Indian Americans, as well as nationals from these countries, often fail to embody the sterling academic credentials they include with their applications, and do not live up to the expectations these universities have for top tier students. Less delicately put: They cheat. And when they don't cheat, they game tests in a way utterly incomprehensible to the Western mind, leading to test scores with absolutely zero link to underlying ability. Or both. Or maybe it's all cheating, and we just don't know it. Either way, the resumes are functional fraud. "

as (2014-02-17 15:13:20)

What was the ethnicity of the students? Were they Indian or Chinese?

as (2014-02-17 19:33:55)

Steve Johnson beat me to it.

Boisfeuras (2014-02-17 22:38:27)

Steve Johnson and "as" beat me to quoting Education Realist. A quick look at Caltech's student demographics shows it as 39+ % "asian/pacific islander/native Hawaiian". So there's a 4-in-10 chance that the cheaters are Asian.

GB (2014-02-18 03:13:12)

To paraphrase Charlie Munger, if you're a shopkeeper it's immoral if you don't make it difficult for your employees to steal from you. We know people are more likely to cheat when they feel the chances of getting caught are lower. The university is encouraging bad (but rational?) decision making by students. Better off not testing them than playing this game.

Joe (2014-02-18 14:20:34)

The question that should be asked here is, What would Sheldon Cooper do?

John Smith (2014-02-18 16:29:19)

How can they learn how to teach until they learn how to learn? (Steiner?)

Bill Mitchell (2014-02-19 13:09:25)

For some reason this didn't post before, so here it is again... I graduated from Caltech in the 1980s. Cheating was rare then, as far as I know. At risk of sounding quaint, most students attended for knowledge, not prestige or financial gain. Cheating just wouldn't be interesting to people I knew there. I was aware of one small cheating network: students who knew each other from a particular private high school openly shared answers on homework and take-home tests. That private high school is in a developing country notorious for corruption. It is not any of the countries mentioned in previous comments above, and I won't say which, lest it spawn unproductive nationalist finger-pointing. Not to say the other commenters' are wrong. It's just that generalizations about cheaters' ethnic origin are not actionable. Maybe a more useful observation is that the cheaters I saw at Caltech had, compared to the rest of us, bigger incentives to cheat (financial and prestige compared to home-country alternatives), and lower barriers (knew each other well, and trusted in each another's cultural assumption that anything goes). In the ensuing 30 years, the U.S. in general has become more like those students. Incentives are greater, because college is more expensive, income disparities are greater, and so your lifetime return on investment from attending a top-tier school is now much higher than that from a second-tier school. Barriers are lower, because the Internet eases cheating, and because

for a decade, high-profile corruption and fraud in the US has often gone unpunished or lightly punished (finance, banking, corporate governance), reinforcing a message that anything goes. Until those things are corrected, clearly a school must police itself to preserve its reputation. Sad but obvious. It would sure help if employers would hire more intelligently. When we fetishize a Caltech diploma, and rank it over skills, initiative and enthusiasm, we sustain the huge incentive for students to get that degree by hook or crook.

Seth Roberts (2014-02-19 14:35:29)

Your comment didn't post earlier because the first time you make a comment it is moderated – held for approval – and I hadn't yet approved it. I suppose the more people who know that Caltech still has an honor system – that is, makes cheating considerably easier than other schools – the better.

Bill Mitchell (2014-02-19 15:29:49)

The honor system appeared to work when I was there. Decades later, Caltech remains one of the hardest things I've ever done. As the school's president put it to incoming students at our orientation, "we will challenge not just your mental limits, but your physical limits," meaning sleep deprivation. The intensity was incredible. Exhausting, but rewired me to think better. But it does depend upon the student culture. If cheating takes root, an honor system can't work. I would hate to see them lose a well-earned reputation by not putting a lid on cheating, if it is a growing problem.

Bill Mitchell (2014-02-19 15:53:12)

Actually I just realized the honor system was likely working in the 1980s, deducible from two facts: most courses there were still being graded on a C curve, and individual student scores in applied math and electrical engineering tests often averaged below 70 %, with wide variance. If cheating were rampant at that time, this seemingly could not have occurred. The bell-curve grading would have driven competition among cheaters, which would either have driven scores up, or driven variance down, or both. That doesn't seem to have happened. I have no idea if any of that is still true today.

Seth Roberts (2014-02-19 22:57:11)

The president said there would be sleep deprivation? Counter-productive. Sleep is when long-term memories are formed. Many studies have shown that sleep deprivation reduces long-term learning. I imagine that anyone at Caltech paying attention, including faculty, realizes there is now lots of cheating. If they (the faculty) keep the honor system in the face of that, they deserve to lose their reputation. It is honest students who suffer. They get lower grades and are tainted by the cheaters. It's interesting that honest students don't band together and demand proctored tests.

as (2014-02-20 13:23:30)

I also wonder if the liar at the interview was a woman?

Bill Mitchell (2014-02-20 18:17:43)

Agreed, the celebration of sleep deprivation seems obviously counterproductive. I'm curious now to inquire with someone currently involved at the university about prevalence of cheating. Will let you know if I learn anything.

Bill Mitchell (2014-02-21 11:38:44)

Some confirmation of a very recent rise in cheating, but also assertions that core courses are already responding with in-class exams: <http://www.quora.com/California-Institute-of-Technology/Why-are-some-core-clas-ses-at-Caltech-administering-in-class-exams> One of the commenters there recalled something I'd forgotten: traditionally, Caltech's honor code exams are unlimited-time and open-book. This allows exams to ask harder and more interesting questions, which in turn helps solve a challenge in teaching there: huge variance in student aptitude. Most Techers scored between 790 and 800 and the SAT math section, but the narrow spread of scores does not imply a narrow spread of aptitude. Instead, it means the SAT was simply too easy for the top tier of students there. The right tail on that aptitude distribution is very long. Traditional in-class, closed-book tests might result in a similar spread to the SAT: half the class scores 100 %, and is bored out of their minds, while the other half has a more normal spread. Harder questions, open books and no time limits permit a wider variance of outcomes, and

more closely resemble real-world problem solving, in which there is typically no time limit. As long as students are honest. A second challenge to testing in class is that students can no longer spend 15 hours on a test. Potential problem, because not every student at this level can think both deeply and fast. In-class exams would dramatically reduce grade outcomes for honest students that think deeply but deliberately – a profile that may exactly describe students destined to make great contributions later. So I don't have a solution, but begin to appreciate the scope of the challenge.

Dragan (2014-02-21 15:15:36)

Cheating is a great indicator that something is wrong with the educational system in question. But, hey, it could be worse. Some teachers I work with suggest they'd be happy if their students attempted to cheat. At least that would show they cared, and they might even learn a thing or two.

Seth Roberts (2014-02-21 15:23:57)

Those are good points. I agree, a good reason for take-home exams is to pose interesting thought-provoking questions. Here's another point: Should grades be based (partly) on how smart students are? Or would an ideal grading system be solely a measure of whether they have mastered the material put in front of them by the teacher? If the latter, it is not so obvious that you want to pose problems that separate geniuses from everyone else. If you want to measure learning, not intelligence, you are pushed toward simpler questions. In my own teaching I avoid tests (and grading) altogether. My goal is learning. I find that other sources of motivation can replace grading. I have no interest in ranking my students according to their intelligence. I wonder why other teachers want to do this – or are they mindlessly copying how they were taught?

Cliff Styles (2014-02-21 19:33:56)

'I find that other sources of motivation can replace grading. I have no interest in ranking my students according to their intelligence' That's the honorable way, it seems to me. Installing a grading and status widget into a student's head is crippling for life, and once it's in there, it's very hard to remedy. I speak from personal experience.

Bill Mitchell (2014-02-23 11:05:29)

Any links to non-grade motivational methods you use in class? That sounds interesting.

Seth Roberts (2014-02-24 02:45:24)

non-grade motivational methods: <http://blog.sethroberts.net/2013/01/26/my-ideas-about-teaching-put-into-practice/>

## **Interview with Zeynep Ton, Author of The Good Jobs Strategy (2014-02-18 05:00)**

[1]The Good Jobs Strategy by Zeynep Ton, published in January, argues that retailers should change low-level jobs in four ways:

1. Offer fewer choices – fewer versions of each product.
2. Standardize common tasks and empower employees to handle unusual situations.
3. Cross-train employees so that each employee can do several jobs.
4. Operate with slack, that is, hire more employees than seemingly necessary.

The brilliance of this book is that it addresses a major problem (bad jobs), includes substantial evidence and persuasive argument, is practical, and is exceedingly non-obvious (judging by how many retailers already follow her recommendations). Ton is an MIT business school professor whose area of expertise is operations.

I interviewed her by email.

ROBERTS How did you get into studying this? My impression is that the details of how employees are treated is not what operations professors usually study.

TON Early in my career I studied pervasive operational problems at retail stores that hurt supply chain and financial performance. My doctoral thesis was on misplaced products and the resulting phantom stockouts. I found that even retailers that were great at managing the backend of their supply chain, by getting the right products to the right stores at the right time, were pretty bad at managing the last ten yards of their supply chain. Once the products made it to the store, they would stay in the backroom or in the wrong place and often not meet the customer that wanted to buy them.

Problems like misplaced products were common, frequent, and had a huge impact on customer service, sales, and profits. When I studied what drove these problems I found that stores that had more workload for employees, lower training, and more employee turnover had worse performance.

Things really clicked for me several years ago when I was presenting my research to a group of retail managers and executives. I showed them my findings from analyzing a lot of data from Borders that showed that if stores increased the amount of people they would make more money. This finding just didn't make sense—why would managers staff their stores with too few people even though having more would increase profits? When I asked people in the audience to raise their hands if I would find a similar result if I analyzed data from their chain, almost all raised their hands.

What I saw was that a lot of retailers were operating in what I call a vicious cycle. Low investment in employees caused operational problems, which reduced customer service, sales, and profits. When stores had low sales and profits, they had low labor budgets, which further reduced their investment in employees.

Everybody suffers from this vicious cycle. Employees have bad jobs, customer get bad service, and investors are worse off because there is a lot of money left at the table. I thought there have to be some companies that operate much better. That's how I started looking at firms that follow the good jobs strategy.

ROBERTS How have your ideas on this subject changed over the years?

TON There was a period when I wasn't sure if excellence was possible in low-cost retail. All the examples around me were of retailers that offered bad jobs and had poor operational performance. When I went to Spain to study Mercadona I realized that I finally had found the "Toyota Production System" of retailing. What really excited me was studying QuikTrip after Mercadona. Here were two completely different companies—the largest supermarket chain in Spain and a convenience store chain with gas stations based in Tulsa, Oklahoma. Yet they were both beating their competitors by offering much better jobs than their competitors. At the same time they were both offering low prices and great service to their customers.

When I looked into what allowed them to deliver value to their employees, customers, and investors at the same time, I saw that they were both excellent operators. They were both making a set of operational choices that reduced costs, increased employee productivity, and allowed employees to have a big role in driving profits. When I looked at Costco and Trader Joe's, I saw they were making the same choices. In my book I highlight the four choices I observed [shared by these four companies].

ROBERTS When you present these ideas to retailers, what is their reaction? Of course there is a range of reactions, but which reactions surprised you the most? Which reactions did you learn the most from?

TON The reaction that I learned most from is the following. When Marshall Fisher, a Wharton professor and a thought leader in operations management, presented his finding that retailers could make more money by increasing staffing levels, a CEO said, "I spend my days saying no to a long line of people suggesting ways to spend money, including adding more staff. I don't need a couple of Ivy League professors with their fancy statistical analysis giving them more ammunition!"

This really shows how retailers view their labor — as a cost to be minimized.

ROBERTS What do you think about how Amazon treats employees? Do you have any suggestions for them? [The book is published by Amazon.]

TON I have not studied Amazon.

ROBERTS Your book lacked a chapter called "What Happens When..." about what happens when companies try to implement the changes you suggest – I mean, make changes based on your research. Can you say anything about that?

TON Of the four model retailers that follow the good jobs strategy, only one went through a dramatic change. Mercadona started as a company that operated just like most companies operate right now, but had to change in order to compete against much larger companies. I hope that my book will encourage more companies to adopt a good jobs strategy. If I can observe some of these changes, I will be in a better position to offer suggestions for implementation.

ROBERTS It seems to me the underlying theme of your book is "Look, your employees have brains. The more you take advantage of those brains, the better off everyone – you, them, owners, customers – will be." Is that a fair summary?

TON One could say that the book is about designing the work that employees do to leverage committed, motivated, and capable employees. It's also about making smart operational choices that benefit employees, customers, and investors at the same time.

ROBERTS Do you have a theory – is there a theory – that ties your four suggestions ("operational choices") together? Is there an underlying principle from which all four of them can be deduced?"

TON The four choices I observed are choices that operationally excellent companies have been making for decades and they could be traced to lean manufacturing. Overall, the good jobs strategy—the combination of the four choices and investment in people—is a blueprint for operational excellence.

ROBERTS Why has it been hard to learn to make the choices you describe?

TON Unfortunately, the dominant view in business is that paying employees as little as possible and treating them as a cost to be minimized is the best and perhaps only way to run a profitable business, especially in industries with low profit margins.

As I show in my book, that's not the only way and that's not even the best way.

But companies can make bad choices just like people can make bad choices. We know exercising is great for our health but regular exercise requires commitment, discipline, hard work and a long-term view. The good jobs strategy is good for companies' health but that too requires commitment, discipline, hard work, and long-term view.

Excellence is always harder to achieve than mediocrity. And right now we have too many companies stuck in mediocrity.

ROBERTS You say "the dominant view in business is that paying employees as little as possible and treating them as a cost to be minimized is the best and perhaps only way to run a profitable business, especially in industries with low profit margins." That is a common-sense view that Adam Smith might have expounded. Why has such a wrong view persisted so long? On the face of it, I would think that how to treat employees would be one of the central questions that business professors (and CEOs) try to answer and nobody would be satisfied with repeating ideas of several hundred years ago. It's one thing for a third grade teacher to tell students "the earth is flat" – yes, it looks vaguely flat. But for sophisticated university professors and captains of industry to say "the earth is flat" for hundreds of years when there is a vast amount of money to be made from realizing it isn't flat, that is puzzling.

TON But it's not just ignorance. Perhaps I should have worded it differently. Following the good jobs strategy is not easy. You have to get many things right. It requires excellence.

POSTSCRIPT This is what Ton said in the book – that the good jobs strategy is difficult. I wasn't persuaded. CEOs of major retailers have done many things that are not easy. Why has this difficult thing been out of reach?

I suspect an examination of why the 4 retailers Ton study broke from the pack and treated their employees differently would not find that the people in charge were more capable of excellence than the leaders of other companies. Maybe their personalities were different, maybe their cultures (internal company culture or external society culture) were different, I have no idea.

I am unsurprised that business profs had failed to figure out what Ton figured out (although her conclusions are supported by the work of other professors). Other disciplines have enormous blind spots – epidemiologists never study the immune system, for example. The more things you can take for granted, such as the idea that labor is a cost to be minimized, the easier it is to publish papers. In academia what is rewarded and selected for is not solving real problems, it is publishing papers in prestigious journals, which is quite different.

1. <http://zeynepton.com/>

---

Alex Chernavsky (2014-02-18 05:58:58)

And speaking of things that are not easy and that companies routinely do not do: Why do so few companies try to make their products easy to use? And I'm not talking just about high-tech devices. Last night, I assembled a [1]cat tree that I had ordered through Groupon. The instructions were not very clear. They looked like they were composed *by* an engineer *for* other engineers (and, the print and drawings were quite small, making it difficult to read, even with my reading glasses on). With only a minimal amount of effort, the instructions could have been made much more user-friendly. I imagine that the manufacturer does all sorts of difficult things, from implementing employee health plans to buying & maintaining industrial-grade woodworking equipment. Why can't they expend more effort to make their product easier to assemble?

1. <http://www.groupon.com/deals/gg-1-deluxe-cat-trees>

Kirk (2014-02-18 11:33:45)

@Alex, I remember reading, many years ago, an answer to your question. Don't remember the source. As I recall, at the last minute somebody remembers that the product needs an instruction page. This task is assigned to the least-competent, most unproductive worker in the area (engineering or from the production floor) because everybody else is busy doing real work.

Which explains the brilliance of Apple, Amazon, and insert-your-favorite-example. Somebody at the top cares about everything.

Nancy Lebovitz (2014-02-18 12:15:40)

Employees don't just have brains– a high proportion of people want to do good work.

Jim Keller (2014-02-18 12:56:22)

If you take these two ideas together, people care more about status than success and people care more about the short term than the long term you get lot's of seemingly counterproductive strategies. One interesting thing happened at Apple retail. The new person in charge cut labor costs at retail stores. Revenue per employee went down. So they realized quickly that low cost didn't mean more profit. <http://online.wsj.com/news/articles/SB100008723963904443751045775932715051216> 02 So this might be a small experiment based on the the ideas in the book.

Bob Ramsey (2014-02-18 17:45:27)

This is great, but there's nothing in this about honey and sleep and recovery. Isn't that what this blog is about?

Seth Roberts (2014-02-18 18:31:25)

"This is great, but there's nothing in this about honey and sleep and recovery. Isn't that what this blog is about?" The connection between Ton's work and this blog is that both Ton and I believe that people who are usually ignored or treated as passive recipients have a lot to contribute. Ton believes low-level retail employees are a powerful force that can be used for the good of everyone (customers, bosses, etc.) In health care, I believe that the rest of us – people outside the health care system, non-experts, people usually considered by those inside the system to be passive recipients – are a powerful force for better health. For example, the idea that bedtime honey can improve sleep came to me from someone outside the health care system. I am outside the health care system. In my teaching, same thing: I believe that students have untapped capabilities that will help them learn and help you teach them and make teaching much easier.

James M. (2014-02-18 18:53:58)

To add two cents, I thought this blog was about more than honey and sleep, and looking at self-testing and experimentation. That being said, in an effort to address some sleeping issues, I tried the honey approach for a couple of nights using raw honey. That woke me up in the early morning hours with heart burn/indigestion. To resolve that, I took a table spoon of 10 % Greek yogurt and went back to bed. Thought this may be worth adding to your database. Keep up the blog variety. Seth: Thanks. If bedtime honey causes you to wake up too early, I suggest you reduce the dose. Try cutting it in half.

Duncan (2014-02-22 14:27:08)

For what it's worth, I think Kirk is remembering something from Zen and the Art of Motorcycle Maintenance: "I'm from the factory too," I say, "and I know how instructions like this are put together. You go out on the assembly line with a tape recorder and the foreman sends you to talk to the guy he needs the least, the biggest goof-off he's got, and whatever he tells you—that's the instructions." Something I'd forgotten from the book was Pirsig's decision to stop grading his English students. It turned into career suicide for him, though, as I recall. You weren't thinking of ZMM when you tried different approaches to teaching, Seth? Seth: I've never read that book. It sounds interesting.

## **DIY Medical Devices: No Science, Please (2014-02-19 05:00)**

[1]An article about DIY medical devices – devices created outside of big companies – does illustrate the predatory nature of our health care system:

It can still be difficult for inventors to break into the medical-device market. Amy Baxter, a pediatrician

specializing in pain management, found this out firsthand. When her four-year-old son developed a fear of needles, Baxter set up shop in her basement and created [2]Buzzy, a vibrating ice pack shaped like a bee that numbs the sting of injections. . . She says, “I decided to use my solution as a mother to be a better — more globally impactful — doctor.” Baxter held randomized controlled trials comparing the device to ethyl chloride spray and published the results. But when she launched the product in 2009, she found it nearly impossible to get her product into hospitals.

“It’s the nature of the system marketing to hospitals to pad prices and make items disposable to ensure repeat sales,” she says. Medical sales reps paid on commission will only take the time to push a new product if it is very expensive, with a high profit margin, or if it’s a cheap item that has to be reordered often, she says. “A reusable, low-cost product doesn’t work.”

On the other end, she says, hospitals’ complex budgetary processes often disconnect the physicians who order products — and pass the price on to patients and insurance companies — from their true cost. “Decisions to buy aren’t as straightforward as looking at a catalog,” she says. “There is no easy way to comparison shop, and less incentive in the medical environment.”

The result of all this inefficiency [which curiously works only in one direction – to make things worse for consumers and better for health care professionals], Baxter says, is not only [3]notoriously inflated hospital prices — like \$36.78 for a \$0.50 Tylenol with codeine pill and \$154 for a \$19.99 neck brace — but also a high barrier to entry for devices like Buzzy, which is currently available only online, with no marketing beyond word of mouth.

A predatory relationship is one where one side is much more powerful than the other side and uses that power to take from the other side.

The article says nothing about science – better understanding of the connection between environment and health. Science is so poorly understood by so many people that even a doctor, such as Baxter, fails to understand that it exists:

The more people become involved in medical making, says Baxter, the less the human body will seem like a mysterious black box whose problems and solutions are only within the realm of experts. [Not true. Making is not science. There is still a great need for science – Seth] “The truth is,” she says, “the place where the body interfaces with the rest of the world is just engineering.”

No, it isn’t just engineering. There is a vast amount we don’t know about the world’s effect on the body. Even a small improvement in understanding how environment (including food) controls health (e.g., how to sleep better) can easily be worth billions of dollars per year, more than all DIY medical devices put together. And knowledge (and the associated benefits) spreads at no cost at all, in contrast to medical devices.

Engineers assume people will get sick. Scientists do not.

Thanks to Alex Chernavsky.

dearieme (2014-02-19 05:14:45)

"I decided to use my solution as a mother to be a better — more globally impactful — doctor." More globally bloody impactful? Jail her for assault and battery on the English language.

garymar (2014-02-19 06:06:28)

"This is where DIY is exquisitely powerful: you make it for yourself, your friends and loved ones. You have a vested interest in making it work."

This sounds very similar to the philosophy of this blog.

Trev (2014-02-19 07:42:44)

The UK is heading the same way. And even worse than that is the fact that the grown ups letting it happen. Looks like Huxley was more right than Orwell.

Sidney Phillips (2014-02-19 10:21:32)

I am in medical school right now. My training in nutrition at my school consisted of one powerpoint lecture on vitamins. That's how it is in most schools. Doctors do not understand proper nutrition, beyond telling patients to "eat a balanced diet". I have gained so much benefit from going gluten free, removing mercury fillings, and getting 23andme genetic analysis done (learned I have methylation cycle defects). It is amazing how in the last 2 months I have done more to help my health on my own than doctors have ever done for me. I hope to be a different kind of doctor, one who actually spends more than 10 minutes with a patient and can explain proper nutrition and lifestyle choices. Sadly, with the way healthcare is heading I don't see myself being part of healthcare teams with nurses running the show (insert sarcastic "thanks Obama!"). I think I will probably have my own concierge practice in a wealthy area like Beverly Hills or Manhattan.

## **Good Sleep Prevents Cancer (2014-02-20 05:00)**

I have long said that good health begins with good sleep. I came to this conclusion when I improved my sleep a great deal and [1]at exactly the same time stopped getting obvious colds. I concluded that better sleep made my immune system work better. At the 2012 Ancestral Health Symposium, in Los Angeles, Rob Wolf said something similar about the centrality of sleep: "If a person sleeps well, you can't kill them. If they sleep badly, you can't keep them alive."

Mainstream health researchers, on the other hand, haven't figured this out. James Watson, the co-discoverer of the structure of DNA, in [2]a recent paper about how to fight cancer, wrote this:

Long known has been PERIOD 2 (PER2) involvement as a clock protein at the heart of the circadian rhythms of higher animal cells. Later, quite unexpectedly [emphasis added], PER2 was found to function as a tumour suppressor, with the absence of both its copies causing the rate of radiation-induced cancers to rise.

When PER2 is absent, circadian rhythms disappear and sleep becomes very fragmented, spread out over the whole day. When you sleep better (which usually means more deeply), your immune system works better and does a better job of suppressing tumors. There is plenty of other supporting evidence. For example, in 2012 [3]two studies found sleep apnea associated with higher cancer rates. The PER2 evidence is especially good at establishing cause

and effect.

CC (2014-02-20 07:52:53)

Great! But improving sleep isn't easy. So what do you suggest for someone who needs 10-11 hours of sleep each day? I know I've asked this before, but I'm curious if anyone has new ideas.

Joe (2014-02-20 10:55:08)

CC: Why do you think you need 10-11 hours of sleep per day?

Sidney Phillips (2014-02-20 11:52:02)

I was having a lot of problem staying asleep. Never had sleep problems before, but I am studying for my USMLE Step 1 exam (medical boards) and this has caused a lot of stress leading to my present sleep problems. I've tried honey before sleep, morning faces, not eating breakfast, red glasses at night, standing on one leg to exhaustion. Nothing worked. I always waked up 4 hours after I went to sleep. The post about "sleepy dust" glucose+salt to get back to sleep got me thinking. What if I took glucose + salt before I went to sleep would that make a difference? However, instead of using pure glucose I decided to use ribose (more heart healthy) and trehalose (2 glucose molecules held together which digest slowly) instead. I tried the following mixture, and lo and behold I slept 8 hours without waking up early! My SleepCycle (what an awesome app) scores went up from 55 % to 75 % with night movements reduced from 1000+ to around a 100. I tried substituting pure glucose for the ribose and rrehalose a few nights later and did not get the same results. The cheapest source for ribose I found is Swanson's and for trehalose it is brooklynpremium.com's NeuroCoat brand. 5 g Ribose 10 g Trehalose 1 teaspoon Himalayan salt 1 teaspoon lemon juice (for vitamin c)

dearieme (2014-02-20 13:01:27)

Has it got to be Himalayan salt?

Look (2014-02-20 14:20:00)

If you need 10-11 hours of sleep does that mean you are not sleeping well?

Sidney Phillips (2014-02-20 14:30:36)

No, I'd imagine any salt would do the trick. I just like Himalayan salt's taste and it doesn't have the additives that normal table salt has.

Seth Roberts (2014-02-20 15:55:15)

very interesting. What happens without the salt and lemon juice?

daz (2014-02-20 16:02:57)

...time for me to google Ribose and Trehalose

Sidney Phillips (2014-02-20 16:10:11)

Didn't work without the salt. Lemon juice probably doesn't make much of a difference; haven't tried it without it. I'll try without it and see what happens.

Alex Chernavsky (2014-02-20 17:14:12)

Sidney, what dose do you take of the dry mixture? And do you take the lemon juice separately, or do you mix it in?

Sidney Phillips (2014-02-20 18:36:38)

I take one dose of the above mixture right before sleeping. I mix the lemon juice with it, using 8 oz of water.

libfree (2014-02-20 19:03:39)

While I have little doubt that sleeping well is a good indicator for immune health, I still have questions about how much it affects it or why it affects it. I've struggled with sleep apnea since I was very young. About 12 years ago, I decided to begin working out vigorously on a regular schedule. Before that, I would say that I got an average number of colds and flu's a year. Since that time, I only miss a day of work every 3 or 4 years even though I had untreated sleep apnea still. Even more recently, I've managed to beat my apnea after starting the paleo diet so now I'm probably invincible.

daz (2014-02-20 19:40:00)

the Trehalose is pretty cheap to get, the Ribose is a bit more pricey. might get some Trehalose & give that a try either in its own or with sugar/glucose/fructose

bjk (2014-02-21 05:07:31)

Is 4 hours of sleep, some of it very deep, better than 8 hours of shallow sleep? I can wake up and not feel rested at all even after getting a long night's sleep. Jared Diamond said in his most recent book that the New Guineans he was familiar with would get up and talk throughout the night, so getting 8-9 hours of straight sleep might not be entirely natural. Seth: I agree, depth of sleep is really important. I haven't seen Diamond's latest book but now I am curious what conclusion he drew from his sleep observations.

Adam (2014-02-21 11:43:02)

From what I recall, a biphasic sleep schedule is the most natural. One blogger, JD Moyer did a self-experiment where he went without electricity at night & he ended up sleeping about 4 hours, then waking up in the middle of the night for a couple of hours before falling back asleep. Afternoon siestas are pretty common in a natural sleep cycle too.

Seth Roberts (2014-02-21 15:15:11)

to determine what sleep is "natural" you have to set every variable that affects sleep to its natural level. Surely Moyer does not know every variable that affects sleep. For example, I suspect he doesn't know about the effects of evening sweets. Which is a really big effect.

Look (2014-02-21 16:07:41)

See this excellent stifle for the history of sleep. Indeed it appears as if we slept twice a first sleep of 4 hours followed by a 1 hour rest and then a 2nd sleep. Sleep We Have Lost: Pre-industrial Slumber in the British Isles The American Historical Review (2001) 106 (2): 343-386

Adam (2014-02-22 09:28:23)

I found this as well, interesting read: <http://slumberwise.com/science/your-ancestors-didnt-sleep-like-you/>

Charles (2014-02-22 12:19:46)

<http://www.ncbi.nlm.nih.gov/pubmed/23399661> Time-restricted feeding of rapidly digested starches causes stronger entrainment of the liver clock in PER2::LUCIFERASE knock-in mice.

Lazer (2014-02-24 18:37:58)

Try a thin comforter on the floor. You have to be extremely concious of where your hips sit when you sleep this way, so your posture stays correct. I used to have wicked insomnia before starting this. Now time to sleep is less than five minutes and can

rise immediately upon waking, no matter what I have eaten, or if there's caffeine in my system.

Seth Roberts (2014-02-24 19:15:03)

"Try a thin comforter on the floor. You have to be extremely conscious of where your hips sit when you sleep this way, so your posture stays correct. I used to have wicked insomnia before starting this." What sort of insomnia did you have? trouble falling asleep, trouble staying asleep, waking up too early (not feeling rested when you wake up)?

daz (2014-02-26 18:01:08)

"Try a thin comforter on the floor. You have to be extremely conscious of where your hips sit when you sleep this way, so your posture stays correct" The posture 'thing' is interesting, I take it the comforter on the floor 'forces' you to sleep on your back?... ..the 'best' sleep position suggestions/recommendations seem to vary, different people suggest different positions and for various different reasons/theories. Some of the reasons are based on ailments, ie. GERD, heart, lungs,

John Smith (2014-02-26 20:43:42)

Seeing as recovery hormones are released when our muscles work, I figure the tossing and turning is an emergency measure to quieten down the endocrine glands. For just a few seconds after rolling over (in a sleepless fit) one really feels some good endorphins flowing. With this in mind, I sometimes do some exercises in the wee hours if I can't sleep. The success rate varies depending on many other factors.

Adam (2014-02-26 21:58:54)

Re: Posture You have to read this: <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC1119282/>

## Fermented Foods/Probiotics Clear Lungs? (2014-02-21 05:00)

On this blog, [1]Peter commented:

Lactobacillus brevis also is found in pickled turnips. I've used it for weeks and noticed a difference. It seems to clear my lungs [emphasis added] (I probably have a low level infection that once cleared by taking intravenous antibiotics). I buy the Japanese style fermented turnips.

At Mr. Heisenbug, [2]libfree commented:

I've taking the probiotic for just this week (twice a day plus some kimchi when I can + I started eating Kimchi at the beginning of last week) and I've seen some dramatic improvements. My feet have always had dry, itchy skin which has just disappeared. I have a chronic bunionette, a bunion on the outside edge of the foot, that has softened dramatically. My Rosacea hasn't changed at all. Sinuses seem better but I'm still holding off on whether this intervention is helping. **The most dramatic change has been in my lower respiratory area. My lungs are nearly free of mucus. I don't remember a time that they were this clear.** [emphasis added]

Lungs: canary in the coal mine of modern life?

Sam (2014-02-22 20:54:19)

Water kefir has many of the bacteria known to help immune function. I hate kraut. I hate sour foods. This might be an easier way to get what you need. "...L. brevis is one of the major Lactobacillus species found in tibicos grains (aka water kefir grains)..." [http://en.wikipedia.org/wiki/Lactobacillus\\_brevis](http://en.wikipedia.org/wiki/Lactobacillus_brevis)

Sam (2014-02-22 21:04:51)

Forgot to add. I wonder if resistant starch in combination would help also. Particularly potato starch. Might help feed healthier microbes. <http://www.edsgym.com/resistant-starch.html> Here's a couple of links to the guy who experimented with resistant starches. <http://freetheanimal.com/2013/05/resistant-starch-4-letter-word-nope-goal-create-mashed-potatoes-a-diabetic-can-eat-every-day.html> <http://freetheanimal.com/2013/04/resistant-assimilation-resistance.html>

libfree (2014-02-23 16:15:24)

Sam, I don't particularly like kimchi or kraut and I find Kombucha too expensive to drink on a regular basis. I take the Jarrow v299 supplement twice a day. I did it originally hoping it would do something about my Rosacea. Then I noticed the dry skin on my feet cleared up, I stopped coughing up phlegm all the time and my gums stopped bleeding. I tried the flax seed oil and fish oil for the gums for a few months and it seemed to help a little but they stubbornly remained sore and bleeding. I've had this problem since I was a child and the dentist told me it was because I wasn't brushing enough. They were still telling me that last year. I have a follow up, because it didn't do anything to clear the chronic congestion in my nasal passages. I read about someone that swabbed their nose with kimchi juice and cleared up chronic sinusitis. I got to thinking that if I was ingesting Kimchi rather than swallowing a supplement, that the bacteria would be working into my sinuses and into my lungs as I breathed. As an experiment, I started swabbing my nose with the Jarrow v299 once a day. The change has been dramatic. I'm 4 days in and have had 4 mornings where I could breathe through my nose when I woke up. At most, I have one morning here or there where that happens. I've also seen steady improvements in congestion in my nose. Still too short to know for sure but I'm thinking I'm on to something.

Sam (2014-02-23 21:10:00)

"...swabbing my nose with the Jarrow v299 once a day..." That's extremely interesting. I used to have chronic sinus. Jerry Pournelle advised using a sinupulse to wash out the sinuses. I bought one and used it for a year frequently and after a while I rarely needed it. I still use it every now and then but it's made a tremendous difference. A netti pot would also work but I believe the pulsing helps. Over time I've changed my washing liquid. Now I use a prepackaged salt baking soda mixture, then I add one teaspoon xylitol, 1/2 teaspoon of H<sub>2</sub>O<sub>2</sub>, and three drops of 2 % Lugol's solution. One thing about the Water kefir is it's cheap. A little sugar, water and maybe molasses. Lot cheaper than any supplement.

John Smith (2014-02-23 23:04:28)

A drizzle of that Manuka honey into the nose with the head laid back over the edge of the bed is all I use to heal the sinuses. To avoid the risk of complication, I only do one nostril at a time. Some burning and 'fright' accompanied my first attempt, but was apparently mostly mental, but with asthmatics, it might be dangerous. They stay clean for many months thereafter, although I do seem to have some weakness there (my father had many complications of the sinuses, so guess I inherited some of that memory).'

## **The Great Prostate Hoax by Richard Ablin (2014-02-22 05:00)**

[1]A recent study in the BMJ concluded that the massive breast cancer "prevention" program – having women get annual mammograms – had done more harm than good. Women were randomly assigned to get mammograms plus

self-exam or self-exam alone. The death rate from breast cancer was the same in the two groups. However, women in the mammogram group were told they had cancer and received very painful and expensive treatment far more often than women in the other group. This being modern medicine, the true situation is even *worse* than what you read in any article about the (very negative) study. One critic has said that the randomization was not done properly. If true, this means that medical researchers, even when told exactly what to do, don't do it, in ways that make a multi-million dollar study useless. In spite of billions of dollars and billions of hours spent on mammograms and billions of pink ribbons, we still know practically nothing about the environmental causes of breast cancer. (I suspect bad sleep is a major cause. [2]Shift work is associated with breast cancer.)

A new book (to be published in March), titled *The Great Prostate Hoax: How the PSA Test was Hijacked by Big Medicine and Caused a Public Health Disaster* says that prostate cancer screening is no better. The book is by Richard Ablin, who discovered the prostate-specific protein used in the screening test. The trouble with the PSA test is simple. First, the reading is often high for reasons that have nothing to do with cancer. Second, prostate cancer is common (cancer increases as the fourth power of age) and usually benign.

In [3]an interview, Ablin made some good points:

The US Food and Drug Administration failed in its duty to the public: its advisers warned that routine PSA screening would cause a public health disaster, but it was approved under pressure from advocacy groups and drug companies. . . . The unfortunate reality is that no current data show that men who undergo PSA screening live longer than men who decide against it.

A few years ago Ablin wrote [4]an op-ed about this.

1. <http://www.bmj.com/content/348/bmj.g1403>
2. <http://www.medicalnewstoday.com/articles/262864.php>
3. <http://www.newscientist.com/article/mg22129564.400-prostate-cancer-test-has-been-misused-for-money.html>
4. <http://www.nytimes.com/2010/03/10/opinion/10Ablin.html>

---

dearieme (2014-02-22 14:20:40)

In the late 70s-early 80s my wife worked on a breast-screening research project. About the time she left, her boss, the P.I., was coming to the conclusion that annual population mammography was a bad idea. Years later, in Gerd Gigerenzer's excellent book on Risk, I was impressed by his remark that in Germany asymptomatic mammography was not used by doctors for themselves or their wives, but it was used for their patients.

Bruce McCullough (2014-02-22 15:25:49)

Wouldn't be the first time a multi-million dollar study was ruined by lack of statistical knowledge. The Women's Health Initiative writing group (which had a lengthy roster of people with initials following their names) responded to criticism with this sentence (among others): "The CIs, interpretable individually at a single point in time as having a 95 % probability of including the true hazard ratio..." JAMA, December 11, 2002—Vol 288, No. 22 p2823 where CI is, of course, "confidence interval". As anyone who has taken a first course in statistics knows, the interval includes the population parameter or it doesn't. The "probability of including the true" parameter is either 0 or 1. That someone wrote this mistake into a draft is understandable; we all make mistakes. That no one in the entire writing group picked up this freshman mistake is horrific. The above article contains a link for the members of the writing group, but this link went inactive a long time ago (I wonder why!). Seth: I've

taken a first course in statistics. I find no fault with their description. I don't see why you say the probability of including the true parameter is either 0 or 1. You don't know what they meant? Or how a 95 % confidence interval differs from a 50 % confidence interval? I seem to be missing something.

Allan Folz (2014-02-22 22:28:41)

Mish, a financial blogger, has a very interesting (incredible, IMO, due to the borderline malpractice) [1]first-hand account of his experience with prostate cancer. Of course, an elevated PSA test is what precipitated the whole chain of events. Here's my favorite quote concerning the PSA tests because it shows how unscientific MD's really are in their thinking and understanding: *I informed the oncologist that I was going to have a PSA test every month. He commented something along the lines of "Why do you want to do that? Every six months is sufficient. The tests are not that reliable." That is not an exact quote, but is best as I can remember. My thought - which I did not express - was "What kind of mathematical silliness is that? The more unreliable a test is, the more tests one should take to weed out erroneous outlier results."* It's a long piece but stays interesting and informative all the way to the end. Seth: I agree, I blogged about it.

1. <http://globaleconomicanalysis.blogspot.com/2013/12/cancer-free-i-beat-prostate-cancer-mish.html>

Allan Folz (2014-02-23 13:56:37)

Oops. My bad, sorry I missed it.

Denise Burchard (2014-03-08 12:02:56)

Actually, it's Richard ABLIN, not Albin. Seth: thanks, I fixed it.

## The Conditioned-Tolerance Explanation of "Overdose" Death (2014-02-23 05:00)

[1]I recently blogged about [2]Shepard Siegel's idea that heroin "overdose" deaths – such as Philip Seymour Hoffman's – are often due to a failure of conditioned tolerance. In the 1970s and 80s, Siegel proposed that taking a drug in Situation X causes learning of a situation-drug association. Due to this association, Situation X alone (no drug) will cause an internal response opposite to the drug effect. For example, coffee wakes us up. If you repeatedly drink coffee in Situation X, exposure to Situation X without coffee will make you sleepy. As the learned response opposing the drug effect grows, larger amounts of the drug can be tolerated and the user needs larger amounts of the drug to get the same overall (apparent) effect – the same high, for example. Trying to get the same high, users take larger and larger amounts. But if you take a really large amount of the drug and don't simultaneously evoke the opposing response, you may die. What is called "overdose" death may be due to a failure to evoke the conditioned response in the opposite direction.

[3]Siegel's Science paper about this – a demonstration with rats – appeared in 1982. Since then, plenty of evidence suggests the idea is important.

First, "overdose" death has become more common. [4]A Washington Post article prompted by Hoffman's death says that death due to "overdosing" on drugs – usually opiate drugs – has [5]doubled in the last ten years and is now "the leading cause of accidental death in the United States, accounting for more deaths than traffic fatalities or gun homicides and suicides."

Second, new data has supported Siegel's explanation. Alex Schull linked to [6]a 2005 case report that says: "K.J. did not return home with the heroin purchased as he did on other occasions but went to the public toilet in the pedestrian underpass at the Népilget Metro station where he injected the same quantity (0.5 gram) that he had taken the previous day in the accustomed place, at home with his wife." The report cites other supporting evidence.

Third, new data has contradicted other explanations. The Post article includes an interview with an addiction expert named Keith Humphreys, a Stanford professor of psychiatry. Humphreys said, "Toxicology results after a fatal over-

dose usually indicate that the victim has consumed either their normal dosage level or a dose slightly lower than their normal level.” He also said, “Toxicology studies of overdosed people very rarely find that impurities played an important role.”

Yet Humphreys appears unaware of Siegel’s idea, even as he provides supporting evidence:

Typically overdose occurs because they’ve had a loss of tolerance. This loss of tolerance often arises because they haven’t used for a while. Maybe they had a voluntary period of abstinence. Maybe they were in jail, and their body can no longer handle the same dose.

The other leading cause of loss of tolerance is consumption of other substances. This is particularly true of alcohol, which seems to lower the body’s ability to tolerate opiates (so do benzodiazepines). Most of what we call “opiate overdoses” are really polydrug overdoses: alcohol and heroin, alcohol and oxycontin, benzodiazepine, alcohol and Vicodin, combinations like that. [This is consistent with Siegel’s explanation. The second drug makes the situation less familiar, reducing the conditioned opposing process. – Seth]

Siegel’s idea was [7]recently mentioned in the *New York Times*:

A change in where a person uses his or her drug of choice can increase the likelihood of an overdose, studies suggest. “If you habitually use in your car, for example, the body prepares itself to receive the drug when it’s in that environment,” Dr. Rieckmann said. “It’s called conditioned tolerance. When people using are in an unfamiliar places, the body is less physically prepared.”

This was the first mainstream mention I’d ever seen. I told Siegel about it and he said it was the first mainstream mention he’d seen, too. He added, however, that he had come across the idea in a crime novel:

A Scottish constable, Hamish Macbeth, appears in a series of books by M. C. Beaton. In one 1999 book in the series, “Death of an Addict,” Macbeth has a conversation with a Dr. Sinclair, a pathologist on the scene of an apparent heroin overdose: “Dr. Sinclair leaned his cadaverous body against his car and settled down to give a lecture. ‘The reason for tolerance to heroin is partially conditioned by the environment where the drug was normally administered. If the drug is administered in a new setting, much of the conditioned tolerance will disappear and the addict will be more likely to overdose’” (Beaton, M. C. *Death of an addict*. New York: Warner Books, 1999, p. 23). M. C. Beaton is the pen name of Marion Chesney, and I wrote to her asking how she knew this. She couldn’t recall, but thought that it likely was due to a conversation she had with a Scottish police officer.

There are several similarities between Siegel’s idea and the Shangri-La Diet, which I will point out later.

---

Rashad (2014-02-23 07:33:58)

Just FYI, I'd definitely heard this idea and assumed it was more widely known before you mentioned it. Probably from my mother who is a retired public health doctor who has done a lot of work on addiction.

Nancy Lebovitz (2014-02-23 09:29:36)

Does this imply that people who want to get the most for their money from drugs should keep taking them in different circumstances? Seth: Yes. I think if you really want to keep the cost down you should wear headphones and listen to different music each time. Maybe clip your nose shut to reduce smells to focus more attention on sound.

LemmusLemmus (2014-02-23 10:03:57)

I, too, had read about the idea, I believe in a 2004 ARP paper on smoking. But I had never considered it in connection to a data point that one often sees cited in connection with addiction. The data point is that, apparently, there were many U.S. soldiers who got addicted to Heroin in Vietnam, but many of whom quit when they came home. This is quite often cited in support of the idea that addiction/drug consumption is a choice (rather than something that is beyond the addict's control). I think I may also have seen it linked to the sociological idea of framing (different situations trigger different behaviours). Be that as it may, it suggests that the best moment to quit is when you know you'll be in unfamiliar situations a lot. It may also help explain why I drink so much more coffee in the office than at home. Seth: Siegel has emphasized that Vietnam heroin data. I'd say the best moment to quit is when you change where you live - when starting grad school, for example. Or moving to a new apartment. Or even to a new office in the same building. You make a good point, I have never heard "move to a new apartment, change your workplace" as part of how to get rid of an addiction.

Christopher Sturdy (2014-02-23 11:15:22)

I mentioned your earlier post and talked about this in my learning class, although I used a different study of Siegel's (morphine tolerance) to make the point.

Sara (2014-02-23 11:26:29)

Someone should develop a blood pressure cuff that automatically injects naltrexone when it can no longer detect a heartbeat. Of course, there's then the issue of moral risk. But if Hoffman had had one he'd still be here.

Sara (2014-02-23 12:08:46)

Hmm... That wouldn't work, because if there's no pulse, the naltrexone isn't getting to the brain. Maybe it could detect shallow breathing, then sound an alarm, then if no response, an injection?

seth (2014-02-23 21:33:46)

Just an FYI: Keith regularly blogs at <http://www.samefacts.com>

JP (2014-02-24 16:41:09)

Seth - I wonder if your 2007 blog post on visual and auditory cues possibly raising the body's set point could function in a similar manner. "I'm not surprised that auditory and visual signals for food cause hunger. There are lots of conditioned cravings like that. Tim goes on to wonder if these learned signals for food raise the body-fat setpoint, as the theory behind the Shangri-La Diet says that food-associated flavors do. If you walk by your favorite bakery every day, will you weigh more than if you don't?" <http://blog.sethroberts.net/2007/08/21/do-all-signals-for-food-raise-the-set-point/>

Seth Roberts (2014-02-24 17:48:43)

I really don't know if sounds and sights associated with food raise the setpoint. However, I am sure they cause hunger and I am sure hunger increases the probability of eating. For that reason, it is better to avoid them, if possible, if you want to lose

weight.

'A change in where a person uses his or her drug of choice can increase the likelihood of an overdose...' (2014-02-27 03:55:47) [...] This was the first mainstream mention I'd ever seen. I told Siegel about it and he said it was the first mainstream mention he'd seen, too. He added, however, that he had come across the idea in a crime novel: [...]

bebo (2014-02-28 07:08:16)

This phenomenon was discussed in lectures in every psychology course I took in college in the 90's. Friends I had at low-end state schools at the time also learned the same thing in their intro-level psych courses. Very old news, and widely known. They always discussed the case of the girl found ODeD in Grand Central Station who took half of her regular dose that she usually injected at home. Sounds suspiciously like the "case study" cited from 2006.

### **Fermented Food Can Cure Eczema: More Evidence (2014-02-24 05:00)**

After reading Shant Mesrobian's story of [1]how he eliminated his eczema with fermented foods and a probiotic supplement, Todd Fletcher left [2]a comment:

My eczema and other skin problems of 15 years disappeared completely from regular kefir and yogurt, which I did because of this blog.

I asked for details.

*Who are you?*

I live in Mesa Arizona, 49 years old, software developer.

*When did it start?*

I had lots of allergy problems as a child; had to have soy milk as a baby, had allergy shots for 5 years until I was 22 or so, I was allergic to trees and grass. The allergies pretty much went away after I came to Arizona and now have had no problems at all with it for many years.

I am pretty sure my eczema started in Maryland before I moved to AZ, that would put it before 1992. It started on the outside of my right shin. I can't recall and never had any notion of any change that brought it on. It continued up until I started the kefir, though it would go dormant from time to time, often after which it would reappear elsewhere. It progressed from my shin to the back of my right knee, my right inner thigh, then my back, then my hands. It was always most prominent on my right side; I am right-handed.

*Before fermented foods, what did you do to get rid of it?*

I tried vitamin E both orally and topically very early. It did seem to soothe it but I hated the smell and mess. Otherwise I used cortisone when it was really bad, but tried to minimize that. Mostly I just put up with it.

*What were the fermented foods?*

I liked Nancy's Peach best for kefir; it was the most sour, and the other flavors of that brand had berry seeds that I didn't like. Otherwise I got Lifeway Pomegranate [kefir], second most sour. Yogurt was mostly Strauss Farms or

Brown Cow, though occasionally I'll get Fage if the others aren't there. I would have probably 3 containers of kefir and one or two of yogurt a week. For the yogurt I would get unflavored and add some bananas or maybe a little honey.

*After you started eating kefir and yogurt, how long until you noticed improvement?*

Less than a week. I went on and off many times, both intentionally and inadvertently, and the pattern was repeated every time. Now I can go off of either one without it returning; I don't think I have seen any eczema in more than a year even though I might go a week or two without it. I have slowed down in the kefir because most of them have sugars and stuff, I mostly go for the plain yogurt these days.

*Did you expect the improvement?*

Not at all. I was trying to recover from a bad stomach bug that left me with digestive distress. I only tried the kefir because I read it had more cultures than yogurt. It solved the digestive problems but I only noticed the effect on eczema when I stopped it and the eczema returned. I hadn't noticed it had stopped since it sometimes went dormant for a few weeks at a time.

*What were the other skin problems?*

I had splitting of my fingertips, really painful and right on the tip making it hard to use. I assumed this was just the eczema presenting itself here, but it might have been something else. I also had generally dry itchy skin no matter how much lotion I used, which is not a problem now.

---

Adam (2014-02-24 11:38:53)

I had 2 small patches of eczema on my left & right wrists while I was living in China. When I got back to the US I started eating Greek yogurt mixed into 2 tablespoons of Potato starch four times a day. The eczema has gone away completely. Seth: Good to know. I hope this blog will be an eczema-free zone.

Joe (2014-02-24 13:43:51)

Adam: How did you arrive at 4 times per day? Did, say, 2-3 tablespoons once per day not work?

Adam (2014-02-24 17:15:06)

I started with 1 tablespoon four times a day. For the first week or so I was getting a lot of gas. Not painful or smelly, just a lot of it. After the first week it subsided, along with the vivid dreams I was getting at night. I doubled up to see if the dreams, the gas, or both would come back. I honestly have no idea what the "correct" dose of potato starch is... I am just playing with it & experimenting at this point. It isn't as if I titrated the dose to the eczema - I actually didn't even notice the eczema disappearing, as it wasn't that bad to begin with. One day I just examined my wrists & found it was completely gone.

cathy (2014-02-25 07:33:22)

@Adam, was your greek yogurt plain or flavored? I like Greek Gods or Brown cow as well as Fage, the last being the one I can eat plain easiest. I like the Greek gods w/honey the best.

Adam (2014-02-25 10:22:12)

I like it plain. Usually I got ZOI brand, but I have Greek Gods in the fridge right now. I have had it with honey & Macadamia nuts mixed in, which was delicious, but I usually only eat honey before bed.

Justin (2014-02-27 00:17:13)

I had eczema as a teen and into my early adult years. It came on with a vengeance around age 28. By age 33, it was so bad that I often wished for death. We are talking bloody sheets from my skin splitting open in up to 20 locations during the night; eyes swelling shut from eczema on the lids. It looked as though someone had stabbed me all over. Just terrible and without relief, minute after minute after minute. Then I read on Mangans that fish oil cured a lot of simple health problems and that some Dutch researcher had done a lot of work on fish oil and inflammation. I had already been taking 2g/day of fish oil. I immediately went to 14g per day buying from bulk natural oils (about 2,000 capsules). Within two weeks my eczema was reduced by >90 %. As soon as I lowered the dose to 6g, the eczema would return. I now use about 10g per day to keep it in check. The Dr's say I should be wary of heavy metals, but I see no other choice (though I am going to try adding yogurt as per the original post). I should mention that during my horrific period of outbreak, I was prescribed and religiously used Elidel for my eyelids and very strong steroids for my hands, arms, back, legs, etc. The efficacy of the steroids compared to fish oil at 14g/day was poor. The side effects of the steroids are very real as well. The skin on my hands is now very thin and I blister easily; this is not a major life problem, but it is worth noting. As for experts, when I told the Dr. that I was taking 14g of fish oil per day, he replied, "you mean 14mg..." I admire much of the medical community, but so much of it is just out of whack. I am sure Dr.s are over regulated and face a litany of challenges, but the end result is substandard care. I should mention that I consulted more than eight dermatologists over a period of six years. Not one mentioned fish oil as a potential solution. They are all one thing: diagnose then drugs. Now I only get flare ups from vasodilators likes niacin and yohimbine (great stuff when matched to dmaa and caffeine; otherwise perfectly terrible).

## **Fermented Foods, Eczema, and the Room for Improvement in Medicine (2014-02-25 05:00)**

When I was a graduate student, I had acne. Via self-experiment, I discovered that the antibiotic my dermatologist had prescribed didn't work. He appeared unaware of this possibility, although antibiotics were (and are) very commonly prescribed for acne. "Why did you do that?" he said when I told him my results. As I've said before, I was stunned that in a few months I could figure out something important that he, the expert, didn't know. He had years of training, practice, and so on. I had no experience at all. Eventually I gathered [1]additional and more impressive examples – cases where I, an outsider with no medical training, managed to make a big contribution with tiny resources. The underlying message seemed to be that professional medicine rested on weak foundations, in the sense that big conclusions could be overturned with little effort.

Two recent posts ([2]here and [3]here) on this blog argue that eczema, which afflicts about 10 % of Americans, can be cured and prevented with fermented foods. This observation makes perfect sense because of two pre-existing ideas: 1. Eczema is due to an overactive immune system. 2. Fermented foods "cool down" that system (a variant of the hygiene hypothesis). Professors of dermatology failed to put them together, but people outside medicine were able to.

After I learned that eczema could be cured easily and safely, statements by medical professionals about eczema became horrifying. A dermatologist [4]recently wrote about eczema on Reddit:

Eczema is a chronic condition, which includes hand eczema. It's a condition of dry and sensitive skin. Topical steroids are a useful adjunct in getting your skin clear, and - in certain cases - keeping your skin clear. I tell my patients that the most important thing in management of eczema is the skin care regimen. This means avoidance of irritating factors and restoration of the skin barrier.

The [5]National Eczema Association:

The exact causes of eczema are unknown. You might have inherited a tendency for eczema.. . . Many doctors think eczema causes are linked to allergic disease, such as hay fever or asthma. Doctors call this the atopic triad. Many children with eczema (up to 80 %) will develop hay fever and/or asthma.

The [6]Mayo Clinic website: "The cause of atopic dermatitis is unknown, but it may result from a combination of inherited tendencies for sensitive skin and malfunction in the body's immune system." The various remedies listed have nothing to do with the immune system.

What else don't they know? Doctors have great power over our well-being. Imagine learning that the driver of the car you are in is nearly blind.

BoSelecta (2014-02-25 10:44:02)

<http://suppversity.blogspot.com/2014/02/fish-oil-or-gla-to-treat-acne-vulgaris.html> (Fish Oil or GLA to Treat Acne Vulgaris? Controlled Human Trial Confirms) Seth: very interesting, thanks

Valerie (2014-02-25 14:50:01)

If I had to guess, I would say that your dermatologist didn't change his practice after you told him what happened to you. Based on my experience, I think he just dismissed it. For a long time, I had problems finding just a non-stupid doctor. Now that I have a competent doctor, I find that I would need a competent AND interested doctor. Many times, I bring observations to my doctor, observations that seem important or at least relevant to me, and he just doesn't care. For example, I have idiopathic polydipsia (excessive thirst of unknown origin [no, I don't have diabetes]). At some point, I noticed that if I fast for a few days, I completely stop being thirsty. The change in thirst is very obvious. This is great, right? It should bring insight into the problem, right? Doctor doesn't care. As another example, I observed that my hypertension is much worse in winter than in summer. Maybe that could help us find the cause of the hypertension, or a treatment, right? Doctor doesn't care. That instance baffles me even more since the doctor is a hypertension specialist. I have learned to keep my expectations very low with doctors.

An Appreciative Reader (2014-02-25 15:43:33)

Dear Seth Roberts: I appreciate your blog so much. After many years of dealing with doctors of all kinds I have concluded (don't laugh, readers) that my best strategy is, TAKE RESPONSIBILITY FOR YOURSELF AND TRUST YOUR INTUITION. I stay

far away from them, for I do indeed feel good, I am healthy and every single time I have gone near one, they want to give me flu shots and run me through a zillion checkups. It has not escaped my notice they inevitably write down everything with a pen that is emblazoned with the name of a pharmaceutical company. I recently found out my sometime doctor's hospital insists that its clinic's doctors fulfill quotas, eg so many chest x-rays per month. It is obvious to me now that the whole industry that almost all doctors are part and parcel of is set up to make money, not necessarily heal anybody. (Just look at the food the hospitals serve their patients...) Apart from good habits and a healthy diet, scrappy attitude, etc., I believe a good strategy is to learn to listen to one's body, to know- to really know, a gut sense- when one has to go to the doctor. Obviously, sometimes one does need a doctor. But otherwise, steer far clear. Re Healthy diet, after a surgery and round of treatments that left me more than a decade of complaining to my various doctors on every visit, not a one recommended yoghurt. This is a total head-slapper. I am sure the Greeks and Romans knew about this! Long story short, with a daily dose of yoghurt and Keffir I am just fine for the past 10 years and the last five years, with the addition of raw honey and vinegar, even better. And the floaters in my eyes cleared up, too. But one doesn't need a prescription for that.

James M. (2014-02-25 17:59:06)

By following a paleo/primal diet (reduction/removal of refined carbohydrates and sugar), + reducing/addressing stress, I reduced and cleared up chronic skin problems, lost about 30 lbs, corrected some age related issues, that my family doctor could not resolve. He usually comes across as an astute doctor, but for one of my issues that cleared up, his solution was "luckily I have a medication for that", and prescribed me a medication that required regular blood monitoring and follow-up visits to have the prescription renewed (don't like needles and don't like wasting time). No longer take the medication by accidentally not taking it for a while and realizing I did not need it, and the health issue has been resolved. When I went back to him and asked why he had not suggested a diet and exercise based approach to correct the problem, he said patients generally don't listen, and just want a pill, over changing their life-style/diet. I would have appreciated the opportunity to have heard that advice and made the choice. I saw a natural path and she provided more health support than the doctor. Not wanting to knock doctors, because they do have lot of knowledge and training to help those in need, but there does seem to be something lacking in the medical system, if amateurs can find solutions that the experts with all their training and experience cannot find.

Seth Roberts (2014-02-25 18:07:26)

Not wanting to knock doctors, because they do have lot of knowledge and training to help those in need, but there does seem to be something lacking in the medical system, if amateurs can find solutions that the experts with all their training and experience cannot find.

yes, exactly

joseph (2014-02-25 21:39:38)

To An Appreciative Reader Says: you wrote at the end of your comment "floaters in my eyes cleared up" im curious about that can you tell more? which of the things you did helped at least in your estimation? thanks

Bill (2014-02-25 22:46:52)

To solve chronic problems, run your own experiments. A close relative has fought autoimmunity his whole life. Eczema as a toddler, allergies in childhood, supposedly idiopathic brain tumor as a teenager (excised), visual migraines since his 20s (unrelated to tumor), rosacea and rheumatism since his 30s, and, for the past 4 years, a yet-unnamed energy-sapping ailment that forces him to lay down and rest every hour or two throughout the day. He's essentially housebound in his mid-40s, lucid, intellectually normal, not depressed, not lazy, not anxious, just physically unable to get through a day. For 4 years, he has seen dozens of doctors, specialists in every field you can imagine, taken every test, been prescribed a witch's brew of medications. None of it has ever made any difference. Yet no doctor, over a period of years, has ever suggested, even as a last resort, that he examine environment or diet. His energy collapse began concurrently with a 2-year spate of mysterious, nearly constant belching, even on an empty stomach. Yet no one has ever examined his GI tract, nor treated for GI problems, nor suggested dietary changes, let alone something as novel as fermented foods. Unfortunately, my close relative considers doctors to be

absolutely authoritative, so he runs no experiments of his own. He just keeps going back to a dry well, visiting more doctors, who run more random blood tests, find nothing, and prescribe the standard we-dunno-what's-wrong-with-you drugs, such as steroids. To solve chronic problems, run your own experiments.

AI (2014-02-25 23:50:10)

Good article, but why should it come as any surprise that dermatologists etc. would make such statements? They have to maintain an air of mystery around health because permanently healing people would put them out of business. Seth: But if they appear too ignorant people will stop asking them for advice.

An Appreciative Reader (2014-02-26 01:37:29)

Joseph wrote: "To An Appreciative Reader Says: you wrote at the end of your comment "floaters in my eyes cleared up" im curious about that can you tell more? which of the things you did helped at least in your estimation? thanks" Hi Joseph and all, I am not sure what exactly I did or did not do that made the floaters diminish. They started getting bad about 2 years before I began to study apitherapy and from that time, for the past few years, I have been taking a teaspoon raw honey once or more per day, and a homemade salad dressing for a dose of vinegar also daily, and slowly, the floaters improved. Other things that might (or might not) have helped diminish the floaters: on one occasion I tried meliponna eyedrops. These are made from honey of the stingless bee (indigenous to the Americas and Australia). Ha, the drops did sting!! But they are reputed to help eye trouble, in particular cataracts (which I do not have) so I thought I'd try it for the floaters. I did only that one application and it was (now that I look back on it) about the time I began to notice a marked improvement with the floaters. So maybe that one dose did it, or at least helped. Maybe. One other thing I tried was reading books by Meir Schneider, an Israeli healer who runs the School for Self-Healing in San Francisco, and trying some of the exercises he suggests, in particular "palming" and focusing on the floaters- yes, just looking at the floaters, directly. Maybe that was what did it. I don't think it would have been taking yoghurt and/or other probiotics because I had been taking yoghurt daily for some years before the floaters began to appear. But possibly the yoghurt combined with the honey and/or vinegar and/or meliponna drops or something else had some effect. Originally, I suspected that the floaters might have started in response to my staring at a laptop screen for so many hours a day. But my habits have not changed in that regard. So in sum, I tried a bunch of things and whether it was one or two or all or none- and my own sense is that it was probably the raw honey in my diet plus the Meir Schneider exercises- floaters are no longer the annoyance they once were. Hope this helps. PS I had been informed by two doctors that I would have to just live with the floaters. Yet another reason why my confidence in doctors has so badly eroded in recent years. I am not anti-doctor, by the way- I do appreciate their lengthy education and experience and on more than one occasion a doctor has saved my life. But in general (there are exceptions, of course), my experience has been that doctors presume to know far more than they actually do and their attitudes toward me as patient, and eagerness to prescribe tests and prescription medicines- which may be in part cultural and in part in response to increasingly perverse incentives- I find downright consternating. Mr Roberts, I find your blog both fascinating and empowering and I thank you again.

Adam (2014-02-26 11:30:57)

"When I went back to him and asked why he had not suggested a diet and exercise based approach to correct the problem, he said patients generally don't listen, and just want a pill, over changing their life-style/diet." This is one of my biggest gripes with "in addition to a healthy diet and exercise" or "when diet and exercise fail"... many doctors do not check the first box - they don't make sure that the 1st, most effective treatment has been tried; in some cases they don't even suggest it! If patients do try it, they are basically guaranteed success - diet and exercise DON'T fail for most common conditions.

Bill (2014-02-26 17:37:02)

» Unfortunately, my close relative considers doctors to be absolutely authoritative, so he runs no experiments of his own. « Correction. He has recently experimented with kombucha, probiotic yogurt, and saliva transplants from healthy people. I feel silly for leaving this out, because he just told me about it a month ago.

John Smith (2014-02-26 20:30:28)

Water Fasting was the first protocol that gave me a real boost in good eyesight. The water in our iris relies on osmotic transfer

to be refreshed, cleared and regulated as there is no duct circulation apparently. So the water in our eyes can be no cleaner than the water in our body generally. Hence, if our kidneys are compromised (almost all adults with Western Lifestyle!) our eyes cannot improve. Anything that improves the kidney function helps the whole body, eyes and all. I like protocols that alter lifestyle over potions and palliative procedures, but the older I get, the more I tend to reach for soft medicines, foods, vitamins, minerals etc. I do find that taking myself away from TV, Fluorescent lights and computer monitors early rather than later makes a big difference to my eyesight. Of late, I have been putting tiny drops of Manuka honey in my eyes. This feels like it is burning, but in fact no evidence of damage is found. Instead, one wakes up the next morning with clear eyes and good vision range. The honey is a great osmotic water mover. I see a doctor every time I am required to by some law, some contract or some urgent social need. I try to make friends with them in case I need them one day for some real emergency. It is hard to make friends with someone you see only ever 15 years! I gather from doctors I do know well, that after a few years of dealing with the general public a contempt for them arises as they are for the most part hopeless and useless at looking after even the simplest of problems. I blame health insurance for part of this, as having now paid for these services, one tends to want to collect something in return. Free medicine for the elderly is a cause too, as they are often lonesome and go to their doctor for social purposes more than good medical help. Doctors are often really excited when they are able to actually help someone in true need. The rest of the time, well I think it must be like farming pigs.

Justin (2014-02-27 00:24:23)

Please feel free to consult my message in the previous post about eczema. I used fish oil to largely rid myself of a very severe case. Anyone with severe eczema should consult the post. When eczema is bad, it is a serious condition that also exposes you to a huge number of pathogens through the open sores.

Lynne Logan (2014-02-27 16:12:52)

A friend of mine referred me to your blog because I suffer from psoriasis, which is, of course, very similar to eczema. I've written several posts on my blog about my trials/tribulations with this obnoxious skin disorder and the issues I've had with my dermatologist, i.e. - <http://tenaciousbitch.com/2013/12/13/post-123-make-no-mistake-i-am-also-a-head-bitch-and-im-not-going-to-apologize-for-it/> - which most people found rather amusing. Anyway, I want to thank you for posting this information about fermented foods because I got tired of asking my doctor if there were any foods or homeopathic remedies that would make my psoriasis better only to be told there weren't. Knowing that I was able to cure my own hypoglycemia by altering my diet, I, like you started experimenting with various Vitamins and supplements as well. Unfortunately, fish oil didn't really help me much. Why? Because psoriasis is a bastard, and that would just be way too easy...!). However, last fall I began taking borage oil pills as part of the Fat Flush Diet, and I noticed a major reduction in the severity of my breakouts. Now, I take 500 mg twice/day in the gel cap form, which cost me \$3.94 for 50 pills from Walmart.com - much better than the \$598 I was spending per month on Taclonex, the topical steroid ointment, which is the subject of the post I mentioned above. Borage oil is made from a wild flower found all over the world, and its healing property have been utilized as far back as the time of the Roman Empire. Maybe, you've already written about the benefits of the oh, so, awesome borage oil. I don't know. I've haven't had time to peruse any of your other posts as yet. From what I understand borage oil helps the body to suppress inflammation in one's skin and such, which I read about on this site: <http://www.shikai.com/publications/borageSkin.htm> That said, since it doesn't completely rid my skin of the dreaded psoriasis, I'll definitely give fermented foods a try! Again, thanks for sharing. Have a great day! LL/otherwise known as TENACIOUS BITCH

anon (2014-02-27 16:59:29)

Seth & readers, You talk a lot about acne, any experience with enlarged, clogged pores on the nose? I don't get many pimples, but I have the pores as described. I looked online and people repeatedly said (paraphrasing): "pores size can't be changed, use chemical treatments or pore strips that tear the material out of pores." Has anyone done any diet change that had an effect?

Bill (2014-02-27 18:27:28)

Here's an experiment you could try for pores. Consider what chemists say: "like dissolves like." Oil dissolves oil-based things. The gunk in our pores is oil-based. So wash your face with a harmless, non-irritating oil. This will mix with, and soften, the oil-soluble gunk in your pores. Then clear the excess oil away by washing your face with a non-irritating facial cleanser. Over time, this should leave you with spotlessly clean pores. Using this reasoning, for years, I have shaved every morning using olive

oil as pre-shave balm, with regular shaving cream on top. The olive oil dissolves any oil-soluble gunk on my face, and then the shaving cream clears it all away. Pores have never been clearer, and it has not given me acne, despite many years of adult acne in the past.

Jan (2014-03-01 11:38:55)

Seth, just to let you know that MDs in Slovakia, Europe are very similar to those in the US. I too have something reddish on my skin, and all they were able to do after several trials (and errors) was to prescribe the usual suspects. I declined that cosmetic solution. My "eczema" gets worse with the approaching winter. I wonder if I eat less fermented food as winter gets closer ... will have to test it. Jan Seth: "cosmetic solution" is a good description.

Mark (2014-03-02 22:54:55)

At least part of the problem is, most of them don't seem inclined (or...incentivized?) to LOOK for any solutions other than what is presented in pill form. Seth Roberts Says: February 25th, 2014 at 6:07 pm Not wanting to knock doctors, because they do have lot of knowledge and training to help those in need, but there does seem to be something lacking in the medical system, if amateurs can find solutions that the experts with all their training and experience cannot find. yes, exactly

Mark (2014-03-02 23:00:20)

Also, interesting timing (not sure if this has been referenced yet on this blog or not): <http://mrheisenbug.wordpress.com/2014/01/27/l-plantarum-cured-my-eczema/> Seth: That is one of the two cases that prompted this post.

Alex Chernavsky (2014-02-26 08:33:11)

The fake-Nobel website reminded me of this simple but amusing Google search: "[1]MBA from Princeton" Princeton University doesn't have a business school and has never awarded an MBA degree.

1. <http://www.google.com/webhp?nord=1#nord=1&q=%22mba+from+princeton%22>

Adam Long (2014-02-26 09:04:21)

the BBC story on guts biome and brain function is interesting but is also somewhat – to me anyway – exasperating in that way that mainstream media reports frequently are: "here's this exciting possibility that researchers are working on, but you are just going to have to wait for big pharma to turn this into a product" that you can buy. In the meantime, the article cautions us to be VERY skeptical of these "probiotic supplements" – "take it with a pinch of salt" that these actually work. Because heaven forbid that they list the bacteria that seem to work so that people could, gasp, actually spend \$23 on a bottle of supplements and, I don't know, TRY it for themselves. Seth, I don't mean to be snarky – thanks for posting the link, it's just frustrating that, for a variety of reasons, I see lots of these articles in the main stream press that are interesting but only cover 90 % of the practical information and then stop short.

dearieme (2014-02-26 12:00:14)

"fake Nobel Laureates": everyone who claims to have a Nobel Prize in Economics. Seth: Sometimes appreciation of economics reminds me of appreciation of art.

CC (2014-02-26 20:06:38)

Adam: I thought the same thing. Some of that article sounded like it was boiler-plate "leave it to the scientists" stuff that I'm so used to reading.

AI (2014-02-27 10:25:28)

Some articles on the topic of gut bacteria populations (e.g. the "gut bugs and brain function" article on bbc.com, linked to above) say that a diverse diet fosters a diverse gut bacteria population. Other articles (e.g. Art Ayers's CooingInflammation blog) say that a simple, non-diverse diet fosters a diverse gut bacteria population. I wonder who is right.

MJB (2014-02-28 11:05:46)

Another cancer diagnosis not to worry about We have repeatedly discussed the problem of over-diagnosis and the consequences: treatment of cancers that would not harm the person in which they are found — some breast and prostate cancers definitely fall into this category. A new study just published in JAMA Otolaryngology now extends this finding to thyroid cancer. They examined the data on thyroid cancer incidence, type, tumor size and mortality, and found that the incidence (new cases) of thyroid cancer nearly tripled (from 4.9 to 14.3 cases per 100,000 persons) between those dates. While that certainly sounds like a frightening statistic, the authors also found that most of this increase was due to an increase in papillary thyroid cancer — a type that is not deadly. Further, many of the tumors were too small to ever become life-threatening. In addition, they found that the mortality rate from thyroid cancer had not increased between 1975 and 2009, which also suggests that the increased incidence was not due to deadly forms of disease. In their discussion, the authors note that the apparent epidemic of thyroid cancer in the United States does not "seem to be an epidemic of disease." Instead, their data indicate that the problem is over-diagnosis. <http://acsh.org/2014/02/another-cancer-diagnosis-worry/>

Suzanne (2014-03-01 13:18:57)

Seth Thanks for the mammogram article. I've always refused the test, despite attempted coercion from many quarters. This strengthens my resolve. I've also come across people who get benign cysts and go through cycles of alarm and distress each time they are tested and she gets the all clear.

## Brain Test Phenomenology: Bad Beijing Restaurant? (2014-02-28 05:00)

[1] 

This graph shows recent results from the test I used to track my brain function. The test is a choice reaction task done on my laptop: see a digit (e.g., "2"), press the corresponding key as fast as possible. The x axis shows the time

of the test. The ticks ("Sat", etc.) mark the beginning of the associated days. The y axis shows the average percentile of the reaction times. Higher percentile = faster. (Let me explain what "percentile" means: Each reaction time is compared to earlier reaction times with the same stimulus, and its percentile is computed. For example, a percentile of 60 means that 60 % of previous responses were slower.) An average of 60 is quite good and 40 is quite bad. I usually do two tests per day, one right after the other, in the late afternoon (e.g., 4:30 pm).

On Friday and Saturday, my scores were close to normal. On Sunday afternoon, however, my scores were much worse than usual; the average score was about 15. A score that low might happen once per year. The next day (Monday) I tested more often than usual – both morning and afternoon – and my scores gradually returned to normal. On Tuesday I also tested both morning and afternoon. My scores were ordinary the whole time. This showed that the improvement Monday morning was not normal.

What happened Sunday? I am pretty sure the problem is my lunch at a middle-cost noodle restaurant whose English name is [2]Flying Noodle. It is close to the Tsinghua campus but I'd only been there once before (and eaten almost nothing that time). On Sunday I had a small pickled vegetable dish and an ordinary-sized plate of fried eggs and tomatoes. I suspect the problem is the oil used to cook the egg and tomato. It might have been soybean, corn, sunflower or peanut oil, all high in omega-6. (There are also complaints about reuse of cooking oil.) As I entered the restaurant, I worried about the oil, but also thought *who really knows?* By the time of my brain test, I had forgotten my concern.

A friend was with me. She ate different dishes. She found that her scores on a iPhone game she often plays, which requires fast reactions, were suddenly and mysteriously worse after the lunch. Then, in about a day, they recovered.

This interests me in several ways:

1. New phenomenology. In this example and [3]my earlier tofu results (a piece of fermented tofu reduced my brain score for two days), I noticed something never noticed before: Sharp changes (bad) in brain function. Fortunately I quickly recovered. Nobody knew this happened. It's like looking through a microscope or telescope for the first time, but with much more relevance to everyday concerns.

2. Comparison with [4]*Super Size Me*, a 2004 documentary by Morgan Spurlock, which argued that McDonald's food was unhealthy. Spurlock ate only McDonald's food for 30 days. Realism: Spurlock ate far more McDonald's food than anyone would normally eat; I ate one meal. Information value: Spurlock's test was so unrealistic and his diet so plainly unhealthy that I doubt the results – Spurlock's health got worse, he gained weight – have any implications for the rest of us. In contrast, I find my results horrifying. Bias: Spurlock was obviously biased against McDonald's before he started. I thought favorably of the Flying Noodle – that's why I went there. Cost: My data cost essentially nothing, Spurlock's movie [5]cost \$65,000, not to mention the damage to Spurlock's health. Recovery time: Spurlock took 14 months to lose the weight he gained. I recovered in a day. Repeatability: My test is easy to repeat, Spurlock's very difficult.

3. Public health disaster? China has a very high rate of diabetes, for unknown reasons. Chinese teenagers and college students have much worse (inflamed) skin than I see in other countries. Old people in China look much worse than old people in Japan. Could heavy use of high-omega-6 cooking oil be a big reason?

4. Where were authorities? We expect our government – in combination with academia – to protect us against dangerous chemicals in our environment. If I'm right about the cause of my low score, that didn't happen here. Cooking oil is the opposite of a rare food. If ordinary amounts of a common cooking oil did cause these results, it suggests something is seriously wrong with the regulatory system. A big argument for personal science – and brain tracking in particular – is that you monitor exactly the environment to which you are exposed in exactly the genetic context you care about (yours).

dearieme (2014-02-28 07:50:38)

Ahoy, Seth - more from The Old England Journal of Medicine. <http://www.dailymail.co.uk/health/article-2570081/Why-fatter-These-graphs-exp-lain-sugar-fruit-juice-XXX-blame.html>

Sidney Phillips (2014-02-28 09:35:13)

Interesting. That's why these days I really dislike eating out. No matter the cost of the restaurant you know the restaurant will be using the cheapest ingredients possible, especially when it comes to oils. It is just not economically feasible for restaurants to not re-use oils. Maybe the good ones re-use the oil just a few times, who knows though. Re-using oil after frying is not healthy at all. I had similar results as yours recently. I've been on a strict gluten and dairy free diet with great results. Recently my parents visited me and brought some take out from an Indian restaurant. Even though I avoided eating anything with gluten and dairy, the next day I felt off. I use the Quantified Mind website to track my reaction times and they were noticeably slower. I attributed the bad results to the cheap oil (soybean, corn, canola?) the restaurant must have used. Never again.

Paul N (2014-02-28 09:41:45)

I wonder if there might also be something at play with MSG? I know several people who feel sick after eating foods -often asian restaurant foods - containing MSG. Maybe that restaurant uses it? In any case, would probably be a simple one to test, by spiking a home prepared meal with some MSG and see what your scores do. Makes me wonder about doing the same with aspartame (NutraSweet), which is neuroactive in some way (stimulant, I think). Great data, and as you say in comparison to super size me, far easier to test and under more real world conditions, which makes the result more relevant. All that SSM showed was that an obviously unhealthy diet makes you unhealthy - we already have plenty of public health/obesity statistics to show that! Seth: Good idea about testing MSG and aspartame.

Allan Folz (2014-02-28 10:38:01)

5. Pay **very** close attention to your diet for 2-3 days prior to taking any high-stakes tests. Eg. AP's, SAT, GRE, etc. Seth: Yes, I agree. It's not just high-stakes tests. It's anything requiring a quick response. Since I have managed to become much faster at my brain test I am also much better at catching things when they fall. Surely much better at bike riding (reacting quickly) and sports that involve quick reaction, such as baseball.

Nancy Lebovitz (2014-02-28 11:24:35)

Seth, do your brain test scores correlate with anything you can feel or notice directly? Seth: If I am tired I'll be slower. that is uninteresting so if I am tired I won't do the test. Cases like this - low scores - are not noticeable, at least by me, without the test.

dearieme (2014-02-28 11:39:57)

"5. Pay very close attention to your diet for 2-3 days prior to taking any high-stakes tests. Eg. AP's, SAT, GRE, etc." Follow Bertie Wooster's advice: eat fish.

dearieme (2014-02-28 13:30:52)

Seth, have you ever tried using your tests to compare yourself pre- and post- dental treatment? <http://www.forbes.com/sites/larryhusten/2014/02/27/tooth-extraction-prior-to-cardiac-surgery-may-not-be-a-good-idea/> I have long argued that a likely reason for American lifespans being a little shorter than those in many other developed countries is excessive dental treatment, but that link is probably the first I've seen to carry a hint of the effect.

john Smith (2014-02-28 14:11:00)

Being considered pre-diabetic, and well aware of how well I sleep at night, I have come to avoid the 'Asian' style of cuisine available in my city here in Australia. The last four or five times I had meals of that type left me quite sleepless that same night. I suspected the MSG, but did not test at home. MSG covers a host of names and similar products added to food according to the Wikipedia, but avoiding them all is a task if one eats either processed food or restaurant food. At home I avoid all bottled oils. According to one report olive oil is the most written up complaint about substitution and dilution, and if it is that bad with olive oil, why trust all the rest? And speaking of dilution and substitution, that same report listed (along with the oil) milk, fruit juice and honey as the top four!

Bill (2014-02-28 15:23:43)

I wonder whether stale oil triggers systemic inflammation. I get wheezy (sort of like asthma) after eating deep-fried food at certain restaurants.

dearieme (2014-02-28 16:21:27)

John Smith: we've lately taken to buying Portuguese olive oil, now available in the many Portuguese shops in East Anglia. It is our hope that it might be less prone to adulteration than Spanish or Italian, if only because the shopkeepers may have more idea of which suppliers to trust than a supermarket buyer has. And even if we're wrong, there is the compensation that, so far, it has tasted better.

dearieme (2014-02-28 16:22:57)

Oh yeah, and the only fruit juice I drink nowadays is from the cherries we grow ourselves. Morello cherries, of course, so that the juice isn't packed with sugar.

dearieme (2014-02-28 16:27:42)

If you scroll down here you'll see the comparison of the nutritional content of sweet cherries and morellos (sour cherries). [http://en.wikipedia.org/wiki/Cherry#Nutritional\\_value](http://en.wikipedia.org/wiki/Cherry#Nutritional_value)

Justin Irving (2014-02-28 20:10:53)

I remember being struck by how much healthier Mongolians (in independent 'outer' Mongolia) looked next to Northern Chinese when I visited Mongolia in 2007. I wonder if you'd be willing to share the R script you're using these days for the reaction time test? I'd like to start doing this and would like to work off your script if possible.

Seth Roberts (2014-03-01 03:11:59)

To use the R programs join the Brain Tracking group and follow the directions.

Alex Chernavsky (2014-03-01 06:46:56)

The Brain Tracking group is here: [1]<https://plus.google.com/communities/114619130176100669530>

1. <https://plus.google.com/communities/114619130176100669530>

as (2014-03-01 19:27:15)

Seth Roberts: China has a very high rate of diabetes, for unknown reasons. Chinese teenagers and college students have much worse (inflamed) skin than I see in other countries. Indians are even worse. Sidney Phillips: Recently my parents visited me and

*brought some take out from an Indian restaurant. Even though I avoided eating anything with gluten and dairy, the next day I felt off.* Indian restaurants are terrible about reused oil. It's not just soybean oil, it's soybean oil which has been reused several times. Sometimes, the restaurant will reek of that reused oil stench. Seth: I guess the good news is that the effect went away in a day. The notion that Chinese restaurants (in China) regularly use bad cooking oil is very old news but no one has had any idea how long the effects last. Maybe you get bad skin if your exposure is too frequent.

Seth Roberts (2014-03-01 23:14:07)

"Seth, have you ever tried using your tests to compare yourself pre- and post- dental treatment?" yes, I found that after removal of mercury amalgam fillings my brain test scores substantially improved. I was puzzled by improvement for a long time – none of my various explanations predicted correctly – until I noticed that the improvement started exactly at the time of the removal. Those particular fillings were broken. After removal of other fillings, my score did not change.

dearieme (2014-03-02 03:37:25)

Thank you for that answer. It makes me suspect that we've had this conversation before and I've forgotten it. Any remedies for bad memory? (Mine has always been patchy at best.) Seth: Yes, I wrote a post about it several years ago. The post said little more than what I said in my reply so it seemed pointless to link to it.

Daniel (2014-03-07 14:45:40)

Are you still working on an iPhone app for these tests? Seth: yes

## 9.3 March

### How to Brew Black Tea (2014-03-02 05:00)

After I discovered the Shangri-La Diet (2000), I started drinking lots of tea. Tea has smell without calories, which complemented the calories without smell of the diet. Mostly I drink black tea – more complexity than green or oolong tea. Until recently, I made it the usual (Western) way. 1. Add hot water to tea. 2. Wait 3-4 minutes. 3. Add cream and sweetener. 4. Drink. 5. Throw away tea.

Now I do this: 1. Rinse tea with hot water, discard rinse water. 2. Add hot water. 3. Wait short time (e.g., 30 seconds). 4. Taste the results in a certain way. 5. Drink. 6. Reinfuse tea for longer time (e.g., 45 seconds). And so on. From 2.5 g of tea leaves I make 3 cups of tea (200 ml each), with infusion times of 35, 55 and 90 seconds. I drink the first two cups straight (no additions), then add sweetener (xylitol), salt and cream to the third cup. It's like three different sorts of tea. The first cup is a little sweet, the second cup is slightly bitter with more complexity, the third cup has bitterness, complexity, fat (cream) and sweetness. I use [1]a Polder timer that, at the end of the interval, resets to the length of the interval. For example, if you time 30 seconds, it ends up reset to 30 seconds. This makes it easy to remember the length of the last infusion.

What interests me is Step #4: "Taste the results in a certain way." After brewing the tea, I pour a little of it into a small glass. I have four of them. I pour the tea from #1 to #2 to #3 to #4. This greatly cools it, making it much easier to assess the taste. If you drink the tea before cooling, the heat is distracting. As soon as I started doing this, it was easy to see that short infusion times (e.g., 30 seconds) gave better results than long infusion times (e.g., 3 minutes) and that the tea could be used several times. I could easily distinguish between a brewing time of 30 seconds and 40 seconds.

Without Step #4, you (or at least me) are in very bad shape. Soon after brewing, the tea is too hot to taste clearly. The heat is distracting. Within a few sips, however, taste adaptation is so strong you cannot taste it clearly either. This is

why I drank tea for 13 years without understanding what is going on.

With the particular black tea I am drinking now, the first 30 seconds or so of infusion releases a slightly-sweet tasting chemical. If I cold-brew tea, this is what it will taste like. After that comes more complexity but also more bitterness. All in all, I like more bitterness (not too much) and complexity, so I reduced the amount of tea from 2.5 g to 2.0 g and increased the first infusion time to 60 seconds. That produced better results.

For many years, in other words, (a) I brewed it wrong then added cream and sweetener to fix my mistake and (b) due to poor feedback I had no idea what I was doing. Does that remind you of anything?

1. <http://www.polder.com/shop/measuring-temperature/timers/3-in-1-timer-clock-amp-stopwatch-1>

---

peter spero (@guaif1) (2014-03-02 08:22:33)

years ago i read that it is unhealthy to steep tea for longer than 4 minutes because of the increase in oxalates, which can produce kidney stones. i couldn't find anything directly on point, but there a ncbi article, here <http://www.ncbi.nlm.nih.gov/pubmed/23532418>, Effect of different brewing times on soluble oxalate content of loose-packed black teas and tea bags. in addition, one article claims that "the majority of flavonoids (the health benefits of tea) are infused from the tealeaves to the brewed tea after about 4 minutes of brewing." it also mentions the potential of kidney stone from oxalates. <http://toxicfoodie.org/tag/black-tea/> i suppose if i looked longer i'd find more, but i can't spare the time right now. i rinse my green tea once to reduce the acidity (rinsing it reduces the number of P-H drops i add to the tea) , but try to brew it for no more than 4 minutes.

AI (2014-03-02 08:33:28)

yeah. my career.

TVG (2014-03-02 08:53:22)

I'd be careful drinking a lot of tea. Tea contains heavy metals that can accumulate to high amounts given how easy it is to drink large quantities of tea. See here and keep in mind the clearance time of heavy metals can be a month+: <http://www.hindawi.com/journals/jt/2013/370460/>

Sidney Phillips (2014-03-02 13:44:17)

I'd be careful drinking any variety of tea. Tea has been proven to be anti-androgenic. I looked into this after realizing I wasn't losing any weight despite drinking 3-4 cups of Japanese matcha. See <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3739374/> Also, any tea from China, organic or not, has been proven to have high levels of aluminum. Don't have the time for the cite, but it's out there. If you are going to drink green tea, make sure its from Japan. Adding some tamarind to the tea will reduce the fluoride. However, with the radiation accident ove there I'm not sure I'd even drink Japanese green tea now. I switched over from drinking green tea to yerba mate. As far as I can tell, mate doesn't have the high levels of aluminum, fluoride, and lead that green tea has. Perhaps its because mate is cultivated in south america. Here is a good white paper on yerba mate: <http://amambay.de/wp-content/uploads/2011/11/Heck-Mejia-Yerba-Mate-Tea.pdf>

Ripken Holt (2014-03-02 15:34:54)

Do you drink coffee as well Seth? What are your thoughts on the bulletproof coffee recipe Dave Asprey has? Seth: No, I don't drink coffee. I support adding butter to coffee, of course.

Adam (2014-03-02 21:12:21)

Everyone always goes on about heavy metals in tea. I drank all kinds of tea for three and a half years, all day long almost every day. I was tested because one of my coworkers kept warning me and I started to get paranoid. Everything came back clean. Seth: thanks!

Allan Folz (2014-03-02 22:25:03)

A friend got kidney stones from drinking too much green tea. Though, he drank quite a lot. I think a pint or a quart a day, and no other water. Not sure how long they took to develop. He was a young guy, in his early-40's at the time, to have kidney stones.

john (2014-03-03 16:17:52)

If I was a Chinese anthropologist at a Chinese university, I would find American food habits worthy of several PhD candidatures, including new export products potential . 1. A want to take a beverage and if it did not hit a conditioned bliss point, add sugar until bliss point hit. If slightly astringent, add a mammalian calf food until it tastes like mammalian calf food. 2. If taking tea , don't examine the thousand years of knowledge and the billion plus people that it has succoured, find what can generate a concern and cause FDA approval and quality control import permits to be established and then create a patentable genetically modified plant so that leaves have not one atom of heavy metals .

gwern (2014-03-03 18:16:04)

> Until recently, I made it the usual (Western) way. 1. Add hot water to tea. 2. Wait 3-4 minutes. 3. Add cream and sweetener. 4. Drink. 5. Throw away tea. What tea expert did you learn this from? Was this endorsed by any tea textbook you read? > Now I do this: 1. Rinse tea with hot water, discard rinse water. 2. Add hot water. 3. Wait short time (e.g., 30 seconds). 4. Taste the results in a certain way. 5. Drink. 6. Reinfuse tea for longer time (e.g., 45 seconds). And so on. This sounds similar to the Chinese gongfu style beloved of tea connoisseurs & experts ([https://en.wikipedia.org/wiki/Gongfu\\_tea\\_ceremony](https://en.wikipedia.org/wiki/Gongfu_tea_ceremony) #Brewing), dating back who knows how many centuries (but not as far back as the \_Classic of Tea \_, according to this paraphrase <http://www.teanamu.com/2010/10/lu-yu-classic-of-tea-chapter-5/> ). > For many years, in other words, (a) I brewed it wrong then added cream and sweetener to fix my mistake and (b) due to poor feedback I had no idea what I was doing. Does that remind you of anything? I dunno, this seems like a pretty clear cut case of laymen Doing It Wrong compared to the experts (when all your blog posts are trying to argue the opposite). Seth: I am unaware of any expert advocating Step #4. That is the important step.

Adam (2014-03-03 22:23:08)

FWIW the black tea I drank earlier today said "Steep for at least 4 minutes" in the instructions. I promptly ignored the instructions.

Bill (2014-03-06 09:01:59)

Wonder if the acne I get from black tea is just from bad brewing. I would leave the bag in for a long time, like an hour. These comments suggest that would result in high oxalate, which the interwebs suggests can cause acne and mouth sores.

Jason (2014-03-03 06:07:30)

I'm puzzled by the anti-vaccine links here. In the first, your link text is "Is it possible that vaccines are not perfect?" which is not the topic of the article. Rather, the article criticizes the press for being too hard on anti-vaccine views. This is itself a pretty laughable assertion, but there's a more important deception embedded in both the link text and the article. No one actually claims that vaccines are perfect. Not immunologists, not doctors, not vaccine makers, not the CDC, not anyone. The second article, blandly linked with the benign sounding "More about vaccines," is deeply dishonest, engaging in a classic bit of misdirection by talking about death rates outside the context of the greater morbidity of vaccine-preventable diseases. It has lots of pretty graphs, but the argument doesn't pass the smell test, particularly if you're familiar with the authors and the axes they're grinding. I get the sense that you're sympathetic to the anti-vaccination argument. A comment box isn't an adequate forum to discuss the many problems with those arguments. But as a regular reader I ask this of you: Apply the same standard of skepticism to articles like these as you do to everything else. Learn something about the history of the argument before posting such obviously biased material. Thanks for listening. Seth: By and large anti-vaccine arguments are poor and I am unsympathetic. What is true, however, in spades, is that experts with power over our health – in charge of vaccination programs, for example – are much less competent than they say they are or we are told by journalists. If you've read much of this blog – and there is no reason you should have – you will know that I think the basic idea behind vaccines is correct. In practice, however, there are many difficulties that the public is never told. You may be unaware of them. For example, do you know why the Secretary of Health resigned in 1955?

babar (2014-03-03 07:22:45)

nothing going on at caltech that oral exams couldn't fix.

Alex (2014-03-03 08:07:46)

I am with Jason on this one. I was disappointed to see in this blog links that amount to nothing more than the usual dead horses getting another beating.

Jason (2014-03-03 11:07:36)

I assumed it was swine flu and GBS, but I was off by about 20 years. (Embarrassing for an MPH holder.) Still, I'd offer two counterpoints. The first is that the Cutter Incident isn't an example of the failure of vaccine theory or the safety and efficacy of vaccines categorically. It's an example of industrial failure. The second is that to say that "the public was never told" is a little silly. It was a major scandal that led to many law suits and contributed to the resignation of a cabinet secretary. I think perhaps you paint "experts" with too broad a brush. In public health prevention at least, experts typically go to great lengths to clarify the limits of the evidence base and the climate of uncertainty under which many of their decisions have to be made. In many ways, this is exactly why anti-vaccine proponents have so little trouble getting coverage in the media and capturing the public's attention. Unlike the cautious experts, they present their views with an almost fundamentalist zeal. Seth: That an MPH holder

didn't know about this case illustrates my broad point that what we are told is biased in a pro-vaccine direction. Surely you knew the pro-vaccine side of the history. Yes, "never" is a little too strong.

Joe (2014-03-03 14:32:02)

Until more scientists rediscover and start practicing the scientific method, and other time proven scientific techniques (e.g. Koch's Postulates), and understand the difference between the presence of antibodies to a virus and the presence of the virus itself, new vaccines and vaccinations will remain suspect (as they should). The HPV "vaccine" is but one example. First, HPV doesn't cause cervical cancer, so there is no possible way a "vaccination" (Gardasil) against cervical cancer can work. Having HPV antibodies is not the same thing as having an active HPV infection. (They tried to pin this on herpes simplex virus first!) Cervical cancer occurs in older women, and is rarely fatal. HPV warts (papillomas = warts) usually clear within days of infection, thanks to our immune systems. 50 % of the American adult population has been infected with HPV. Yet less than 1 % ever develop cancer in their lifetime. Over 1/3 of women with cervical cancer have never been infected with HPV. Plus, the cancer is never subject to antiviral immunity, because no viral proteins are ever expressed in cervical cancer. Vaccinations can save lives. They can also take them, along with causing unbelievable suffering and harm. In my opinion, letting your teenaged daughter, for example, be "vaccinated" for a virus that doesn't cause anything but genital warts, and certainly not cervical cancer, is borderline criminal. Yep, that's my opinion, and I'm sticking to it. Seth: This reminds me of a UC Berkeley faculty member, in the biology department, who was one of the founders of molecular biology. He knew more about viruses than almost anyone. He did not allow his children to be vaccinated.

Seth Roberts (2014-03-03 14:56:28)

"I think perhaps you paint "experts" with too broad a brush. In public health prevention at least, experts typically go to great lengths to clarify the limits of the evidence base and the climate of uncertainty under which many of their decisions have to be made. In many ways, this is exactly why anti-vaccine proponents have so little trouble getting coverage in the media and capturing the public's attention. Unlike the cautious experts, they present their views with an almost fundamentalist zeal." I'm not sure who these "cautious experts" are, could you give examples? What you say does not describe the public health experts I hear. For example, I have never heard Robert Lustig "go to great lengths to clarify the limits of [his] evidence base." Quite the opposite: He presents his views with "almost fundamentalist zeal". Nor have I heard caution from the public health experts who claim that obesity is due to not enough exercise. If you mean epidemiologists like Walter Willett, I have never heard him point out how consistently wrong his predictions have been (eight out of eight?) when tested in clinical trials.

Joe (2014-03-03 16:58:26)

Seth: "This reminds me of a UC Berkeley faculty member" That would probably be Peter Duesberg, and I agree with you, he knows more about viruses (and probably cancer, too) than almost anyone. Unfortunately, he's in the minority. The establishment has been successful in shutting his ideas down, to the detriment of millions of lives. I wouldn't be surprised to see him win the Nobel Prize one day, but it'll probably have to be posthumously. Seth: No, it wasn't Duesberg. The person I'm thinking of is a little older than Duesberg. I forget his name.

Joe (2014-03-04 00:17:47)

Harry Rubin? Seth: yeah, probably.

Mark (2014-03-04 04:58:07)

Seth, I completely agree regarding "public health experts" (as someone with a PhD in a public health field, myself). In particular, Walter Willett is a complete hack, his nutritional epi group at Harvard spews out bs result after bs result, each of which manages to garner huge media attention. Utter garbage.

Jason (2014-03-04 12:29:22)

Sorry, I can't let Joe's comment go unaddressed. The evidence is extremely strong: virtually all cervical cancer (90 % +) results from certain strains of HPV. HPV is also linked to several oral, anal, and penile cancers. Again, this kind of propaganda relies on misdirection. Case in point: Joe's note that cervical cancer occurs mainly in older women, and that this is a reason not to vaccinate young women against high-risk strains of HPV. The progression from HPV to cervical cancer is a long one, typically

occurring over 10-20 years, and sometimes longer. Of all HPV infections, only a tiny number can result in cancer. Of the women infected with those strains, only a tiny number will develop pre-cancerous cells. Of those women, only a tiny number will go on to develop cervical cancer. The older women who have cervical cancer today overwhelmingly have it because they were infected with certain strains of HPV when they were young women. Joe's free to believe what he wants. But it doesn't make it true.

Jason (2014-03-04 12:55:53)

To get to your broader point, it seems like a stretch to suggest that the lack of broad public awareness of a vaccine-related industrial failure from nearly 60 years ago is strong evidence of pro-vaccine bias. But you're right that the information most people receive is pro-vaccination. But isn't it possible that this is because from a scientific and medical perspective, the anti-vaccine perspective is inherently weak? How else to explain that most anti-vaccine arguments rely on a combination of misdirection and outright falsehoods? Anti-vaccination views are as old as vaccination, and the political and economic arguments are very big. The scientific arguments are very small, because in most instances, the benefits greatly outweigh the risks. Seth: I didn't say it was "strong evidence". Just evidence. What I am doing, in a broad way, is saying: "Here is information that opened my mind. I didn't know about it. Maybe you would like to know about it also." In other words, I like to learn about complexities, facts that show things are not so simple. I assume readers of this blog are the same as me. You are simply saying, without any new facts, that things are so simple ("in most cases, the benefits [of vaccines] greatly outweigh the risks"). I fail to see the contribution. What about my question: Who are some of these "cautious experts" you seem to believe are common? Here I am asking for new facts – facts that might show my simple view of public health experts (they usually overstate their case) is wrong.

Joe (2014-03-04 18:03:23)

Jason, thanks for your reply, but I don't appreciate the "propaganda" nor the "misdirection" comments. Your "facts" are wrong. Viruses don't cause cancer. Period. And there's ZERO scientific evidence that they do. <http://vactruth.com/2011/10/26/hpv-vaccine-cancer-repackaged-as-an-std/> <http://www.rense.com/general78/hpv.htm> Now, if you still think that you're preventing your teenaged daughter from getting cervical cancer, by "vaccinating" her against a virus that couldn't possibly cause any kind of cancer, go right ahead. But no teenager of mine will ever be sacrificed on the altar of pseudoscience. Seth: "Viruses don't cause cancer"? Check out Peyton Rous.

Joe (2014-03-04 20:42:49)

Sorry, Seth, for not being more precise. Rous is a retrovirus (RNA), and a freak laboratory mutation. And speaking of Duesberg, Rubin, and Temin...here's what they have to say about Rous: [http://books.google.com/books?id=pRWVZJKOONsC&pg=PA117&lpg=PA117&dq=duesberg+peyton+rous+virus&source=bl&ots=OntyVgM3LP&sig=c5mmUOaME7mhA10\\_E-WSZnCFbM8&hl=en&sa=X&ei=JJoWU6PcEYSqkAeW6oHACw&ved=0CD4Q6AEwAg#v=onepage&q=duesberg%20peyton%20rous%20virus&f=false](http://books.google.com/books?id=pRWVZJKOONsC&pg=PA117&lpg=PA117&dq=duesberg+peyton+rous+virus&source=bl&ots=OntyVgM3LP&sig=c5mmUOaME7mhA10_E-WSZnCFbM8&hl=en&sa=X&ei=JJoWU6PcEYSqkAeW6oHACw&ved=0CD4Q6AEwAg#v=onepage&q=duesberg%20peyton%20rous%20virus&f=false) For anyone who wishes to know more about viruses, retroviruses, cancer, and especially all the politics in science, I couldn't recommend this book more highly. Seth: I think you're too sure that viruses don't cause cancer. There is a very strong association between HPV and cervical cancer. The conventional explanation (it reflects causality) might be right. I don't think anyone has proven it is wrong.

Adam (2014-03-04 22:46:53)

There was a lot of press recently about the HPV vaccine guarding against cancer. For example: <http://www.webmd.com/cancer/cervical-cancer/news/20140304/study-adds-to-evidence-that-hpv-vaccine-helps-guard-against-cervical-cancer> Except they did not show less cancer in women, they showed a reduction in "abnormalities". They then go on to say "the vaccine has a significant impact on the health of women", but has it? Depending on the abnormalities prevented, there might have been no symptoms, no negative impact to health, and no treatment needed. I'm also curious if anyone knows if these abnormalities sometimes spontaneously resolve. What percentage of them will progress to cervical cancer? These are important things to know in order to judge the real impact on the health of women. Seth: I agree. There is a big difference between what is claimed (less cancer) and what was measured (less abnormalities).

Seth Roberts (2014-03-05 03:06:42)

"The evidence is extremely strong: virtually all cervical cancer (90 % +) results from certain strains of HPV." I'd say the association is extremely strong. Evidence of causation: not so strong. Until this particular theory ("virtually all cervical cancer (90 % +) results from certain strains of HPV") is used to reduce cervical cancer – and such evidence is a long way off – I would not say the evidence is strong.

Joe (2014-03-05 09:51:34)

Seth: "I'd say the association is extremely strong. Evidence of causation: not so strong. Until this particular theory ("virtually all cervical cancer (90 % +) results from certain strains of HPV") is used to reduce cervical cancer — and such evidence is a long way off — I would not say the evidence is strong." The reason the association is so strong is because of the now explosion in testing for ANTIBODIES to HPV. HPV is essentially a ubiquitous virus, i.e., most of us have antibodies to it. Just like EBV, HSV, etc. So the "association" is going to be strong. But as we should all know, antibodies don't cause diseases. They are merely a sign that our immune system is doing, or has done, it's job. Koch's Postulates were designed to test for causality, not association. Which is why the "virus hunters" (by ignoring Koch's Postulates) get away today with blaming so many diseases on relatively harmless viruses. All the better to sell more vaccines and drugs! Seth: "I think you're too sure that viruses don't cause cancer." I try never to be too sure of anything, Seth. I try my best to go where the facts, the science, and common sense, take me. And that's where it's taken me. Seth: "Until this particular theory ("virtually all cervical cancer (90 % +) results from certain strains of HPV") is used to reduce cervical cancer — and such evidence is a long way off — I would not say the evidence is strong." That's precisely my point. I would never endanger the health of a teenager (all vaccinations have consequences), for example, until it's proven that there is a reduction of cervical cancer in those who are "vaccinated" for HPV. (And even then, I'd want to know by how much). Of course, that's why the "virus hunters" love "slow" viruses so much (tip: there are no slow viruses). [http://www.whale.to/vaccine/slow\\_viruses.html](http://www.whale.to/vaccine/slow_viruses.html) They'll probably be long gone by the time the evidence is in. How convenient. Note: Statin drugs, for example, reduce cholesterol. But do they actually prolong life? Most studies say no. Statins come with serious, even fatal, side effects. Whatever happened to: "First, do no harm"? Seth: You seem to misunderstand what an association is. It is a correlation. Start with two groups of women: one has cervical cancer, the other doesn't. HPV 70 times more common in the first group than the second. Curiously Peter Duesberg had difficulty understanding this, too.

Joe (2014-03-05 15:45:06)

Seth: Could you please point out the precise comment I made that caused you to believe that I don't understand that association means correlation? And also, please, point out what Duesberg has ever said that caused you to believe that he doesn't understand it either. And in what group is HPV 70 times more common than in another group? What are you trying to say here? Note: Firemen are almost 100 % correlated/associated with building fires. Did the firemen cause the fires? Of course not. Which is why correlation alone doesn't PROVE anything. In fact, it can be downright misleading. And why Koch's Postulates is the gold standard for causation.

Seth Roberts (2014-03-05 15:54:33)

Here is the comment that suggested you don't understand what association means:

The reason the association is so strong is because of the now explosion in testing for ANTIBODIES to HPV. HPV is essentially a ubiquitous virus, i.e., most of us have antibodies to it. Just like EBV, HSV, etc. So the "association" is going to be strong.

I forget Duesberg's exact comment. It was something like "Everyone who eats tomato soup is going to die. Does that mean eating tomato soup causes death?" He seemed to think that "everyone who eats tomato soup is going to die" = association between tomato soup and death. There is no association between eating tomato soup and death. People who eat tomato soup are no more or less likely to die than people who don't eat tomato soup. HPV infection was 70 times more common in the cervical cancer group than in the other group. I'm illustrating what an association is.

Joe (2014-03-05 17:27:59)

Seth, HOW does that graf suggest that I don't get it? And if Duesberg ever said that, I'm sure he intended it to be an illustration that associations/correlations mean very little when it comes to PROVING the CAUSE of any disease, just as my firemen/fires example was trying to do. At best, a strong association/correlation is an invitation to perform more experiments, research, testing, etc. By the age of 50, 80 % of women have been infected with HPV. So who comprised the "other group"? Moreover, for the sake of discussion, let's say that HPV infection was 70 times more common in the cervical cancer group than in "the other" group. What were all the other things in common (association/correlation) that the first group shared, compared to the second group? Things such as recreational drug use, promiscuity, alcoholism, smoking, impaired immune systems, obesity, family history, diet, other prescription drugs, age, etc. Why jump to the conclusion that it must be the HPV? Seth: You seem to believe that more sensitive testing for HPV – revealing that HPV is more common than previous tests showed – will increase the association between HPV and other things, such as cervical cancer. It won't.

Joe (2014-03-06 09:53:17)

1. HPV (an STD) infection rates have probably always remained pretty steady, even when we weren't routinely testing for it. 2. There was no HPV association with cervical cancer, because we weren't then looking for one. 3. Now we know that by the age of 50, 80 %(!) of women will have been infected with HPV, and that all but a very tiny fraction of them will ever get cervical cancer, the SAME tiny fraction of women who have historically gotten cervical cancer (older women). 4. To then jump to the conclusion that it must be those all-powerful HPV antibodies that are causing a tiny fraction of those women to get cervical cancer, and to begin "vaccinating" everything that moves, is the very definition of ANTI-science. 5. Your belief in the mythical powers of viruses borders on the religious. Seth: Where do you get 80 %? The studies I've seen say 20 %-50 %. For example, <http://www.ncbi.nlm.nih.gov/pubmed/18809145>.

Joe (2014-03-06 10:36:59)

Oops! Make that: ...and that BUT a very tiny fraction of them will ever get cervical cancer

Joe (2014-03-06 12:40:41)

Seth, the CDC, WebMD, etc. "The Centers for Disease Control has postulated that at least 80 % of sexually active women will have evidence of an HPV infection by age 50 (CDC, 2004)." <http://blogs.webmd.com/womens-health/2011/03/hpv-a-perpetual-problem-or-brief-infection.html> <http://www.cdc.gov/vaccines/pubs/pinkbook/hpv.html> And YOUR argument would be stronger if the vast majority of women ( 80 %) were NOT infected by HPV by the age of 50. And I would bet that the number is even higher. Maybe as high as 95 %. So think about that. Only 5 % (or 20 %, pick your poison) of women with HPV infection ever get cervical cancer, and only a tiny fraction of them die from it. And we want to "vaccinate" everything that walks? Please. Actually, the extremely high rate of HPV infection (almost universal), along with the tiny fraction of women ever getting cervical cancer, should tell you that HPV couldn't possibly be the cause of cervical cancer. And why it doesn't is a mystery to me. Seth: Thanks. I think I see the reason for the discrepancy. You have confused sexually active women with all women.

Joe (2014-03-06 13:32:55)

Seth, what percentage of women (say, over the age of 14) do you think have never been sexually active? Seth: You should ask those who used the term "sexually active" that question. I don't know what they meant by it. And you might want to read the links you cite in support of your claim of 80 % HPV infection rate. This link – which you sent me – shows a HPV infection rate of about 25 %. <http://blogs.webmd.com/womens-health/2011/03/hpv-a-perpetual-problem-or-brief-infection.html>

Joe (2014-03-06 14:51:30)

Seth, what part of 'The Centers for Disease Control has postulated that at least 80 % of sexually active women will have evidence of an HPV infection by age 50 (CDC, 2004).' are you failing to understand? It's right after "How many of us have HPV?" You can also google it yourself. Also, I don't need to ask anyone about "sexually active." Common sense and seven decades of actual experience with women leads me to believe that they're essentially all sexually active at some point, if not their entire lives. I've yet to meet one who wasn't. Note: I think you're just trying to pull my chain again, so absent a sensible comment on your part, I'm done with this topic. Seth: I fail to understand what they mean by "sexually active". You equate "sex-

ually active women" with all women. I don't. I'm sure if they meant all women, they wouldn't have qualified the word "women".

Joe (2014-03-06 18:08:21)

Presumably, it's because HPV is sexually transmitted. "HPV is the most common sexually transmitted infection (STI)... HPV is so common that nearly all sexually active men and women get it at some point in their lives." <http://www.cdc.gov/STD/HPV/STDFact-HPV.htm> PS: We must know different women. :)

### **Who is the Smartest Person Who Believes Climate Change Fear-Mongering? (2014-03-04 05:00)**

A few days ago I read about [1]Apple CEO Tim Cook's response to a shareholder complaint about sustainability programs:

At a shareholders meeting on Friday, CEO Tim Cook angrily defended Apple's environmentally-friendly practices against a request from the conservative National Center for Public Policy Research (NCPPr) to drop those practices if they ever became unprofitable.

I support the practices Cook defended. But the incident was summarized by a headline writer like this: "Tim Cook tells off climate change deniers." I am a climate change denier in the sense that I don't believe that there is persuasive evidence that humans are dangerously warming the planet.

The headline – not what actually happened – reminded me of something surprising and puzzling I noticed soon after I became an assistant professor at Berkeley. I attended several colloquium talks – hour-long talks about research, usually by a visitor, a professor from somewhere else – every week. Now and then the speaker would omit essential information. Such as what the y axis was. Or what the points were. The missing information made it impossible to understand what the speaker was saying.

I didn't expect graduate students to interrupt to ask for the missing info but surely, I thought, one of the five or eight professors in the room would. *We all need to know this*, I thought. Yet none of them spoke up. I cannot think of a single example of a professor speaking up when this happened (except me). Even now I am unsure why this happened (and no doubt still happens). Maybe it reflects insecurity.

I mention climate change on this blog because it is interesting that so many intelligent supposedly independent-thinking people actually believe, or claim to believe, that humans are dangerously warming the planet. The evidence for the supposedly undeniable claim ("97 % of scientists agree!") is indistinguishable from zero. Of course journalists, such as Elizabeth Kolbert of The New Yorker and Bill McKibben (a former journalist), are often English majors and intimidated by scientists. I don't expect them to question what scientists say, although questioning authority is half their job. Of course actual climate scientists do not dissent, for fear of career damage. It is when smart people who are not journalists or climate scientists take this stuff seriously that I am impressed. Just as I was impressed by Berkeley professors who did nothing when they didn't understand what they were being told.

It seems to me that the smarter you are the more easily you can see that climate change fear-mongering is nonsense. There must be some other important human quality (conformity? religiosity? diffidence? status-seeking? fear of failure?) that interferes with intelligence in non-trivial ways. To try to figure out what the quality is, I ask: *who is the smartest person you know who believes global warming fear-mongering?* Does that person do other extreme or unusual things? These might shed light on what the intelligence-opposing personality trait is.

People talk about intelligence quite often ("you're so smart!" "she's very bright"). Many people, including me, think

it matters. There are tests for it. But this other trait, which can negate intelligence and therefore is just as important...not so much. In my experience, not at all. My fellow Berkeley professors were very smart. But they were also something else, much less apparent.

1. <http://arstechnica.com/apple/2014/03/at-apple-shareholders-meeting-tim-cook-tells-off-climate-change-deniers/>

---

Christine (2014-03-04 05:26:52)

As a reasonably intelligent but not very well educated person, here's what I figure. Earth's climate changes, it has to, because change = stability over the long term. The "climates" of all the planets in our solar system are changing. Our sun's activity is changing - or at least not doing what our scientists expect it to do as this recent solar max has been very meek indeed. But most humans don't think in the long term or see the big picture. Maybe it is just plain too scary for most to believe that our climate is something that is out of our control. Maybe people are somehow comforted in believing that humans are causing climate change, because that implies we can fix it too? It might also be a game of bait and switch. Focus our attention on the evils of carbon and it takes our attention away from all the other nasty crap poisoning our air and water.

MJB (2014-03-04 06:17:11)

People of very high intelligence are especially susceptible to large abstract theories about society. Those of a literary inclination fall for romantic and imaginative theories like those identified by Stephen Pinker: illusions about the Noble Savage, the Blank Slate, and the Ghost in the Machine. Mathematical and scientific types are prone to see politics in terms of engineering; to see human populations as quantities of concrete to be shoveled around. As P.J. O'Rourke said after visiting Poland in the 1970s: "Commies love concrete." In my 2000 article I proposed the following counterfactual thought experiment: Suppose that in, say, 1920 the U.S. franchise had been limited to citizens holding a Ph.D. What would the consequences have been? Is there any doubt that we should have had a Soviet America in very short order, and that we should right now be digging ourselves out of the same pit the poor Russians find themselves in? Political stupidity is in fact a special kind of stupidity, not well correlated with other kinds. Think of the barmy political programs that issued forth, with such confidence, from Jean-Paul Sartre, Bertrand Russell, Norman Mailer and other members of the mid-20th-century preposterentsia, as exposed in withering detail in Paul Johnson's book *Intellectuals*. At the very highest levels of intelligence, the correlation between IQ and sensible political opinions may actually be inverse: the more brilliant you are, the dumber your politics. Albert Einstein thought well of Stalin; Hitlerism got its first mass following in the highly-selective German universities. <http://www.vdare.com/articles/john-derbyshire-s-modest-proposal-on-politics-and-intelligence>

hofrum (2014-03-04 06:20:48)

"But they were also something else, much less apparent." I think that some of the many cognitive biases (listed at [https://en.wikipedia.org/wiki/List\\_of\\_cognitive\\_biases](https://en.wikipedia.org/wiki/List_of_cognitive_biases)) are in action here, as for example the bandwagon-effect or the in-group favoritism.

Robbo (2014-03-04 07:25:25)

"It is when smart people who are not journalists or climate scientists take this stuff seriously that I am impressed. Just as I was impressed by Berkeley professors who did nothing when they didn't understand what they were being told." Is there a "not" missing somewhere in there? I think there may be different types of 'smart', one practical, another theoretical. People who don't much come into contact with harsh reality can spin whatever theory their fancy takes, and probably believe it too. The more practical tend to ration out their credulity by the spoonful rather than the bucket.

Tim (2014-03-04 07:36:13)

You need a home button. Seth: what's a home button?

Al (2014-03-04 08:30:39)

Something similar happens in company meetings. People working for, say, a software startup, tend to be quite competent, energetic and smart. But when the CEO tells them during a group meeting that a sock puppet selling pet food is gonna be bigger than IBM and Microsoft combined, no one stands up and calls BS. I'm sure 97 % of startups fail eventually. And everyone knows it. Don't be a hater, bro'. Just smile and high-five the CEO. Seth: During the company meetings, when the CEO says something delusional, I think there are three differences from what I observed at research talks: 1. At the research talks to speak up is just to tell the speaker that they left out something essential, presumably by mistake. The speaker is very likely to be grateful. They want to be understood. No one wants to be told they are delusional. 2. At the research talks, the professors in the audience who say nothing are at least equal status with the speaker. 3. At the research talks, everyone in the audience wants to understand. If Professor X asks a clarifying question, everyone in the audience will be grateful. At a company meeting, I suspect reactions to a delusion-challenging question would be more complicated.

Sidney Phillips (2014-03-04 11:06:08)

I believe the more intelligent you are, the greater you are susceptible to the pressures of group think. Just from my own experience I'm a graduate of a selective liberal arts college (Williams) and I can guarantee if you went against the grain and questioned global warming you'd have been classified as a kook by professors and classmates. There is intense pressure to accept the commonly held "smart" beliefs. I've also believe based on what's happened to me personally, it certainly does not pay to rock the boat. To be classified as an eccentric in fields such as law, medicine, banking, academia is a sure fire career killer. Thus, the pressure to go along with the group think. Whereas a lesser educated person can afford to be a maverick and go against the grain since they usually have much less to lose.

Kelly B (2014-03-04 11:26:02)

Maybe restating something above, but academics, in particular (and probably Tim Cook too), are former nerds. I think they've been battered throughout life by the desire to be part of the cool kids, and once they find a group to hang with, are less likely to do anything to prompt shunning. As a former nerd myself, I can say that I'm a "climate change denier", but the group I hang with doesn't seem to pay much attention to that particular issue, so I guess I can afford to be.

jon (2014-03-04 11:55:23)

A great TedX talk on the subject, "Willful Blindness." <http://www.youtube.com/watch?v=Kn5JRgz3W0o>

Kirk (2014-03-04 11:57:37)

Challenging a speaker in a room full of educated people feels like a confrontation. Most people can tolerate only a limited number of concurrent fights. Most people probably already feel like they're fighting on two fronts, work and politics, and some people have relationship/family fights also. Also, people don't like to feel stupid. Sometimes questions ARE stupid, although sometimes questions are smart. Often the person who wants to ask a question has no idea if the question is stupid or smart.

RAD (2014-03-04 12:02:16)

I think that Catastrophic Climate Change Belief/Skepticism has more to do with political world views than it does with intelligence. If you want to delve into the intelligence/motivations of smart Catastrophic Climate Change Believers then Paul Krugman is probably a fine example: <http://www.nybooks.com/articles/archives/2013/nov/07/climate-change-gambling-civilization/> Am I the only one that finds it surreal that a Berkeley Psychology Professor is challenging the intelligence of people who believe in climate change? Seth, your curiosity about the missing y-axis units is not the only way you stand out :-)

Joe (2014-03-04 12:07:32)

Seth: "But this other trait, which can negate intelligence and therefore is just as important...not so much. In my experience, not at all. My fellow Berkeley professors were very smart. But they were also something else, much less apparent." "I know

that most men, including those at ease with problems of the greatest complexity, can seldom accept even the simplest and most obvious truth if it be such as would oblige them to admit the falsity of conclusions which they delighted in explaining to colleagues, which they have proudly taught to others, and which they have woven, thread by thread, into the fabric of their lives." Tolstoy Moreover, it's just about impossible to even discuss the climate these days. The vernacular has now been so corrupted by the alarmists (and not by accident) that we might as well be speaking in tongues. And while I'm no climate scientist, I refuse to believe that we even have the ability to measure GLOBAL temperature changes, to within a few tenths of a degree(!), in the first place (computer models, or no computer models). I've seen no evidence of it. No, not even with satellites, much less with ground-based temperature stations. Tree rings? You gotta be kidding me. My hunch is that this is all about politics and nothing about science. And always has been. It's just another government grab for even more power over our lives, to be able to "redistribute the wealth," to enact "social justice," to extract more taxes from us, etc. The best thing we can do to these people is to mock them. To ridicule them. To make fun of them. To puncture their balloons. And, of course, to laugh heartily at them. They deserve it! PS: I hope everyone is following the legal goings-on between Michael Mann (the actual driver of the clown car that is global warming hysteria) and Mark Styne. Mann is now suing Styne because Styne made fun of him! Everyone SHOULD make fun of him...because he's a freakin' buffoon! [http://www.realclearpolitics.com/articles/2014/02/12/mann\\_vs\\_steyn\\_the\\_trial\\_of\\_the\\_century\\_\\_121528.html](http://www.realclearpolitics.com/articles/2014/02/12/mann_vs_steyn_the_trial_of_the_century__121528.html)

Elizabeth (2014-03-04 12:47:30)

Maybe the Berkeley professors already had or wanted a relationship with the guest speaker that caused them not to want the distinction of being remembered by that guest speaker for having publicly embarrassed him.

Seth Roberts (2014-03-04 13:14:33)

Albert Einstein thought well of Stalin? Whew. I knew he thought well of Freud and Veblen. (Freud a fabulist and Veblen a great economist.) Maybe the liking of Stalin is a comment on the information available at the time.

Brandon (2014-03-04 14:49:48)

I see this a lot in what I call "Intellectual Atheism". Smart people talking about the non existence of God or a higher being. I believe there is a God but if I didn't, I would spend exactly zero time discussing it. I certainly would not attend a meeting or put up a billboard explaining why I do not think God exists (any more than I would spend any time talking about American Idol or some other show that I have no interest in watching).

aretae (2014-03-04 14:50:15)

Tribe – My very short, nearly self-contradictory theory of human nature is that individuals almost never have opinions. Groups have opinions. People belong to groups. And people assert opinions in order to indicate belonging into the groups. Disputing an opinion held by a group is read by almost everyone (both in and out of the group) as being substantially to primarily about attacking the group. Only very strange people who are permanent outsiders actually address opinions as being about a topic, and then only because they're somewhat socially inept, and never figured out how to belong to a group anyhow. Belongingness appears nearly orthogonal to intelligence. I can think of very smart insiders, and very dumb outsiders .

dearieme (2014-03-04 14:54:57)

The category "intelligent but obtuse" is worth investigation no doubt, but isn't much of what we see just people preferring to stay with the flock? Seth: Yeah, I would agree that science is both supported and pushed against by human nature. It's human nature to be curious, which improves science. And it's human nature to "stay with the flock" which works against science. That's an argument for personal science, which is done in isolation. So no effect of what other people think.

Cahokia (2014-03-04 15:19:50)

I'm not convinced that such an overwhelming majority intelligent people, at least in the U.S., fully buy into anthropogenic global warming. 40 % of Americans in 2013 agreed that climate change was a major threat according to Pew Research. Undoubtedly the 60 % who disagreed or had no strong opinion included many intelligent people.

john (2014-03-04 15:36:47)

what are the consolidated x axis criteria being used to define intelligent people?

Todd Fletcher (2014-03-04 16:24:57)

As a proponent of bitcoin and one who talks a lot about it I have observed often that most people will never hold an opinion not shared by most, doesn't matter what you tell them, they won't do it. Conversely, they will readily claim a falsehood to be true if it's held by the group. Nobody ever wants to be the odd man out except those who can't be anything else

bjk (2014-03-04 17:24:01)

How many things do we seem to understand without genuine understanding? It's got to be immense. Here's an example of economists not understanding basic econ concepts. [http://marginalrevolution.com/marginalrevolution/2005/09/opportunity\\_cos.html](http://marginalrevolution.com/marginalrevolution/2005/09/opportunity_cos.html)

Mark Snders (2014-03-04 17:37:58)

I see quite a bit of smugness in these comments, and while everyone is curious about group think, I notice everyone here seems to come from the same flock. There are two issues here. One is, does global warming (or climate change) exist? The other is, if this does exist, is man causing or exacerbating the situation? I'm not a scientist, but I think it's pretty obvious things are changing. And while I have a hard time not falling asleep examining the arguments one way or the other, I want to note that man can cause climate change at least on a minor local way. One example is that tearing out trees and plants and replacing them with concrete and pavement will make an area hotter in the summer - Atlanta comes to mind. And if man can do it in a metropolitan area, I don't see it as a stretch that he can affect larger areas too.

Glen Raphael (2014-03-04 19:03:15)

I think the quality you're looking for is just religiosity. Environmentalism is a secular religion complete with the notion of a mythical past utopia (when man didn't yet exist or "walked lightly upon the earth"), a fall from grace, and a predicted apocalyptic future caused by our collective sins against Nature. Some people just find that stuff intuitively appealing. Knowing that "the end of the world is nigh" due to scary "truths" you are privy to that others aren't. The exact same characteristic that motivates street-corner preachers (and their followers) motivates climate catastrophists.

TomGinTX (2014-03-04 19:10:54)

Tim, click on "Seth's Blog" at the top of the page. It is like a Home button.

TomGinTX (2014-03-04 19:17:36)

Glen says: "The exact same characteristic that motivates street-corner preachers (and their followers) motivates climate catastrophists." I dunno, Glen. AFAIK nobody ever got a government grant to do street-corner preaching.

Glen Raphael (2014-03-04 19:41:29)

Various people start out motivated by apocalyptic environmentalism - the idea that whatever people do is somehow "damaging the planet". They get this meme from their parents, friends, teachers or the media they consume, just as they would get any other religion. Some of those people go into science and then DO their science in a way that helps further their preexisting religious beliefs about imminent environmental catastrophe. The belief comes first, THEN the grants. I don't think it goes the other way around. It's true that you can make a lot of money promoting alarmism - a lot MORE than you can make fighting it - but I think most people promoting alarmism do so because they honestly believe we are DOOOOOMED if we don't change our sinful ways and start "listening to the planet". Which affects what they choose to study and what results they tend to find credible. The money is just an extra bonus on top of the core opportunity to help promote views they find compelling and important.

John Smith (2014-03-04 20:13:07)

The Herd instinct, yes. But every herd has some form of common belief (system) which is the religion of that herd. Todd Said: "Nobody ever wants to be the odd man out except those who can't be anything else." That's me, perhaps. I share little with

most groups, but something with most groups. I grew up in a unique family group and was left free to decide for myself on most things. So by my analysis I am the only person I consider smart enough to decide anything critical to my belief system, but also fully aware that many are smarter than me especially with regards to their own affairs. I contend that mankind is responding to global warming, just as the dinosaurs did, not causing it. Does the algal bloom cause the summer heat? Do the krill warm the oceans? This is why the smartest man I know says he learns more from the kids in his 'handicapped' home than from the university trained. Those kids have a quality one might call, Total Honesty, or at least they are not handicapped by societal moors. Joe said: "My hunch is that this is all about politics and nothing about science. And always has been. It's just another government grab for even more power over our lives, to be able to "redistribute the wealth," to enact "social justice," to extract more taxes from us, etc." Every regime needs an enemy, every household needs a boogey man. The church has the devil, medicine has the germs, and now governments have climate change. Like god herself, it is great to be an expert on something that can never be finalized. Seth, you must be the smartest person any of us know who is a doubter, as I didn't notice anyone nominating any other! Cheers

GB (2014-03-05 00:55:34)

I don't know if he quite fits the definition of your question, but Nassim Taleb is probably the smartest person I know of that supports minimising carbon emissions. I don't think it's because he thinks there's compelling proof of man-made warming, it's just that he approaches the unknown differently to you. If I could be so bold as to try and read both your minds, you seem to be seeking proof of man-made warming as a prerequisite to large scale action (apologies if I've misunderstood your thoughts). He supports action in the absence of compelling proof that man isn't causing warming. It's his consistent approach to preference natural over non-natural, with the onus of proof required by the non-natural - same with GMOs etc. In this case, the natural is not releasing masses of carbon dioxide into the environment as a grand experiment. His arguments have logic, but also cost (action on emissions). But he's not a high IQ conformist, if that's what you were specifically after. Seth: I like Nassim but his logic doesn't make sense. Pollution is a proven serious problem - living in Beijing, I know - why not work on that? There are plenty of known problems. Work on them. That's hard enough.

dearieme (2014-03-05 04:21:57)

Bruce Charlton, whose blog I used to frequent, has a category he calls clever-sillies.

jason y (2014-03-05 05:07:56)

aretae nails it. i don't have an opinion on anthropogenic climate change. i have opinions on the credibility of climatologists and the judgment of believers and skeptics. holding an opinion on the science would be foolish because i am unqualified to scrutinize the evidence. it is self-defeating and pointless to deny in the presence of believers and believe in the presence of skeptics when all anyone really cares about is whether you're an ally or an enemy. unless you can contradict and challenge others with style, aplomb, and grace, you're better off just agreeing.

David Watson (2014-03-05 06:23:28)

I would agree with Jason y and add that if you simply change the title in the link below, the article aptly describes why college professors and doctors don't argue nearly as much as they should. The whole system is setup to reject these people outright regardless of what Thomas Szasz thought. <http://www.madinamerica.com/2012/02/why-anti-authoritarians-are-diagnosed-as-mentally-ill/>

JM (2014-03-05 06:38:57)

Doesn't starting with the title "Who is the Smartest Person Who Believes Climate Change Fear-Mongering" get this off to a start begging the question? And is the "I've met smart people who went along with bad science" part supposed to be an evidence-based criticism of man-made climate change? I'm confused about the lack of science in this blog post. Seth: I wasn't trying to convince anyone that the "humans are dangerously warming the planet" idea is wrong. I take that for granted. The post is about human nature, not climate change.

Eric (2014-03-05 07:08:03)

It is very dangerous to paint large groups of people with a single brush because it is easy to find bad apples in any large group and then to use those bad apples as the basis of your comparison. E.g. there are lots of examples of psychologists behaving badly, falsifying research, etc. but it would be foolish to conclude that the whole field is a hoax or should be ignored. I happen to know a bunch of people that work on climate science, and in general they do it because they passionately believe in what they are doing. Several of them also happen to be brilliant. I also know some people working in climate science that don't have a clue how to construct and test a proper model. Same goes for other fields that I have worked in - Psychology, Computer Science, Neuroscience. Sturgeon's Law says that 90 % of everything is crap. The trick is to find the 10 % that isn't. Ultimately it comes down to this: the field has been making general predictions for several decades now. Are those predictions coming to pass or not? The evidence is that the world is a fair bit warmer and that there is more volatility in the weather. So those predictions seems fairly solid at this point. That has to be tempered against the fact that this could be mere coincidence. It also needs to be tempered against the fact that predicting complex systems is incredibly difficult at best. However, if it was coincidence then it just as easily could have gone the other way. The question is when there is enough evidence to be sure. Personally I think Global Warming is the wrong fight. There are loads of reasons to pursue renewable energy that are hard to argue about. Not relying on foreign governments for our energy for starters. The plummeting costs involved (e.g. solar) as it scales up. As Seth points out there is pollution. Fighting pollution covers lots of the same ground as fighting global warming, but there are not too many people who are "pro pollution." Ironically I think the argument that has always been used against the pro global warming side - economics - will ultimately be the one that wins for them, just not for the reasons that they think. Seth: The current long-lasting "pause" in global warming was not predicted by any model. How do the people you know in climate science deal with this fact?

Bob (2014-03-05 07:40:21)

Seth asked: "who is the smartest person you know who believes global warming fear-mongering? Does that person do other extreme or unusual things?" OK. Rather than people I "know of" like Tim Cook of Apple, I will answer this with someone I know personally, whose intelligence I have been able to gauge over many years. My "smartest person...who believes in global warming fear-mongering" is an Ivy League educated engineer. "Does that person do other extreme or unusual things?" He is extremely religious and active in his church and in church politics at a national level. I would describe him as a leftwing extremist in politics generally. He is a guy who, when he has a strong opinion about something, is unpleasant toward those who disagree with him. He is intolerant toward opposing viewpoints on topics he's passionate about. In his field of work, with which I have been involved at times, he is extremely good. Seth: That's really interesting. I don't know anyone who is extremely religious. At the heart of cooperation is shared beliefs - a shared belief that what you are doing together is a good idea. If your shared beliefs (your religion) are too strong, too all encompassing, you'll believe too many things that are wrong and will fail to be persuaded by evidence. But if your shared beliefs are too weak or too few you will be impossible to work with.

Casey (2014-03-05 13:20:24)

There isn't "Global Warming" because the glaciers are melting to keep the temperature stable. When all the glaciers melt, then there will be "Global Warming". Also, the amount of CO<sub>2</sub> is at a all time high - due to many things - one of them being the big rain forests are not-so-big anymore... I would recommend watching "Chasing Ice" with the realization that all the energy it takes to melt ice keeps the temperature constant. For example: if you have a cup of ice water - the water is 32F until all the ice melts - once all the ice melts then the water will heat up to room temperature. Note that the water is 'cold' until all the ice is gone...

Roger Sweeny (2014-03-05 16:20:53)

Joe, To determine if average temperature is increasing, decreasing, or staying pretty much the same, you don't have to have perfect measurements. You just have to have measurements that are taken the same way, and combined the same way, over time. You can be pretty precise, even if you're not accurate. E.g., if your thermometer reads two degrees too high, you can still use it to determine if the temperature is going up, down, or staying the same.

Roger Sweeny (2014-03-05 16:37:39)

Seth, The most recent explanation I have seen for the "pause" in global warming is that there is indeed more thermal energy but it is going into the oceans. So it doesn't show up as a rise in air temperature. However, at some point it will and air temperatures may rise quickly. You're right that none of the models predicted the "pause." Various people are now trying to change various models to incorporate it.

Roger Sweeny (2014-03-05 16:58:25)

Watts Up With That reprinted part of the Nature article that says essentially, "the ocean ate the heat."  
<http://wattsupwiththat.com/2014/01/16/the-journal-nature-embraces-the-pause-and-ocean-cycles-as-the-cause-trenberth-still-betting-his-heat-will-show-up/>  
<http://wattsupwiththat.com/2014/02/28/the-top-ten-reasons-global-temperature-hasnt-warmed-for-the-last-15-years/>

Eric (2014-03-06 12:12:31)

Re the pause: <http://www.economist.com/news/science-and-technology/21598610-slowdown-rising-temperatures-over-past-15-years-goes-being> The explanation is a combination of a) the ocean, b) changes in the solar cycle, c) aerosols. As for a smart guy that believes in global warming, Neil deGrasse Tyson is a pretty good candidate. Not that it seems to matter. As others on this thread have indicated, both sides are so dug in that very few opinions are going to change anytime soon. What would it take to change your mind Seth? I'm genuinely curious as I really admire many of the things that you have done on your blog. Are there any possible set of experiments, measurements, models, etc. that would change your mind?

JM (2014-03-07 08:04:51)

"Seth: I wasn't trying to convince anyone that the "humans are dangerously warming the planet" idea is wrong. I take that for granted. The post is about human nature, not climate change." Sure, but how can you even start to evaluate your human nature hypothesis when you "take for granted" the metric by which you evaluate the hypothesis? Is there any good way to move past a couple of anecdotes and some supposition here and actually improve the way that we learn, model, communicate, and do science? Or are we doomed to have everything be dominated by badly handled data teased to tell the wrong stories? Seth: In my experience, the evaluation of any idea involves taking stuff for granted. And I've learned to start as small as possible, e.g., with "a couple of anecdotes".

Joe (2014-03-09 13:43:17)

"One example is that tearing out trees and plants and replacing them with concrete and pavement will make an area hotter in the summer - Atlanta comes to mind. And if man can do it in a metropolitan area, I don't see it as a stretch that he can affect larger areas too." Exactly. But that doesn't affect our climate. It affects the temperature in a very, very small area. "E.g., if your thermometer reads two degrees too high, you can still use it to determine if the temperature is going up, down, or staying the same." But how do they know if the thermometer reads "too high"? Or "too low," for that matter? Compared to what? There is no gold standard, so all temperature station results are highly suspect. But, again, this has very little, to nothing, to do with climate. It has to do with the temperature of a very, very small patch of ground. Ground that is affected in many ways by changing nearby development, weather (weather is not the same as climate), etc.

Nathen (2014-03-09 14:32:37)

Sounds a bit like Cialdini's bystander effect, but it also reminds me of ideological immunity, intelligence correlated with closed-mindedness to new information. I have no idea if it's a real thing, but it seems plausible. All of the smartest people I know believe in climate change. They tend to be well educated, skeptics, liberal, feminist, and artists. And probably eccentric to those outside our cultural bubble, which is difficult for me to analyze objectively. A couple of them write publicly-maybe you can discern some commonality like what you have in mind: <http://thequodlibetarian.blogspot.com> <http://basecase.org/env/>

Joe (2014-03-09 14:49:55)

Is the U.S. Surface Temperature Record Reliable? [http://wattsupwiththat.files.wordpress.com/2009/05/surfacestationsreport\\_spring09.pdf](http://wattsupwiththat.files.wordpress.com/2009/05/surfacestationsreport_spring09.pdf) In other words, no. Imagine what it must be like in other countries.

Dragan (2014-03-10 12:51:27)

Among the smarter people I know, all but one believe in climate change. He tells me that most people he knows do not believe in climate change. Might be something there.

Joe (2014-03-10 15:44:20)

Dragen, it all depends on how the question is asked. Virtually no one disputes that the climate is changing. It has always changed; it will always change. But most of us believe that man can't, and hasn't, had much (if any) effect on it. And that there's nothing that can be done about it anyway, except to ADAPT to the changes as they happen. This has essentially been the case since the beginning of time. The CAGW (catastrophic man-caused global warming) crowd (Al Gore, James Hanson, Michael Mann, and all the other Chicken Littles), enjoy running around and screaming that "The sky is falling!" and hope that they can use this scare tactic to raise our taxes, make money off of carbon futures, or fund phony "green" energy projects for their cronies, etc. It's an ANTI-science scam. Please don't buy into it.

Kjartan (2014-03-15 13:10:21)

What? How can you people be serious? You honestly do not believe that humans influence climate? Such amazing arrogance

Seth Roberts (2014-03-15 15:33:20)

Arrogant? It is arrogant to be unsure? I am unsure if the influence of humans on climate is dangerous. I do not know what size it is – although you are right in the sense that I suspect it is small compared to other influences.

M. Goff (2014-03-21 22:56:34)

You might find the take Cliff Mass has on climate change fear mongering interesting. [1]<http://cliffmass.blogspot.com/2014/03/moses-versus-joseph-biblical-lesson-in.html> He's at the University of Washington and works on weather, not climate. He has stated in the past that he believes global warming is happening (but the obvious effects won't happen for quite some time, as they are currently swamped by short term variability). That said, he on several occasions posted criticism of the the way climate change issues are presented by both scientists and the media. In particular he has argued against the extreme and/or overly precise claims of possible futures (especially in light of poor predictions so far), the hype of current weather as climate change driven, and general fear mongering (not all of which are addressed in this most recent post on the subject).

1. <http://cliffmass.blogspot.com/2014/03/moses-versus-joseph-biblical-lesson-in.html>

Hamsta (2014-03-31 17:47:55)

I do notice that the folks buying into climate change tend to be on the higher side of the mean IQ. I myself don't buy the androgenic thing, although pollution is real and controllable with will and money. There is another take I have. I have been reading Joseph Tainter on "The Collapse of Complex Societies". It was written in 1988 but is selling better now than when released. Anyway, Tainter was looking for a more cohesive framework for understanding why complex cultures and societies have collapsed through the ages ( and there have been a lot of them). The big idea is that societies and civilizations start out simply. The entire purpose of a civilization is to Hoover out materials and energy from the environment and distribute the goodies to members of the society. As challenges present themselves (weather changes, running out of game or resources, threat from other societies, disease) the society must rise to a new level of complexity to deal with the threat and survive. As years pass and challenges are met, complexity increases to an unsustainable point. The society becomes less able to deal with threats or change because of vastly diminished returns on increased use of energy, materials and information flow (administration and vested interests). So, after all that, I believe many of the intellegensia in western culture intuit (but don't articulate) that our own civilization may be way down the path where sustainability of resource and energy use is questionable. This, in spite of stunning technological progress (high complexity). So.....maybe the collective consciousness is saying "let's slow down a bit". How to do this? Well use less energy and resources for one thing. Yeah, maybe WE have enough for now and don't need so much growth for now. And - the emerging nations should stop demanding their share of the pie too. So let's keep them where they are by halting use of the good stuff like oil. Let them have, maybe, solar or wind. So, I believe, we may be seeing the climate change movement as class warfare fought on a different front. The "science" is almost irrelevant. The beliefs will follow the unconscious imperative that western culture needs to buy time while figuring out a way to "complexify" even further. The third world is going to get screwed.

Seth Roberts (2014-04-01 00:08:41)

I would put it like this: Lots of societies get stuck doing the same thing over and over. They fail to innovate. They overuse this or that resource and, when it runs out, they die. For all I know, a misguided belief in AGW may cause valuable innovation. Perhaps that's why we humans are so credulous – so we will innovate and explore more. Fake crises help us survive real crises.

### **The Polio Vaccine Disaster: Precursor of the Obamacare Website Fiasco (2014-03-05 05:00)**

When friends complain about evil government (e.g., NSA surveillance), I tell them "never underestimate the stupidity of government employees" – by which I mean their stupidity outweighs their self-interest. The Obamacare website fiasco is a good illustration. Everyone has heard "power corrupts" but closer to the truth is power makes you stupid.

The Obama website fiasco had many precursors. One was in the 1950s – in the details of [1]the introduction of the polio vaccine.

Rather than staging a long series of careful field trials with appropriate scientific evaluation, Salk darted ahead on his own in the remainder of 1953 and 1954. The trials were successful. The foundation released the results to the press, and such were the nation's expectations that from that point there was no turning back. In August 1954 the foundation ordered five drug companies to begin producing mass lots of vaccine, on the basis of a formula for inactivating the virus with formaldehyde, according to a procedure Salk himself had devised. . . . James Shannon remembered very well what happened next. At this point he had become the associate director of the NIH. "I was working over the weekend and I got a telephone call from Los Angeles, and this is eight or nine o'clock on Friday night. It was the Health officer of the City of Los Angeles and he said they just had two reports of polio in some children who had been vaccinated nine days earlier. He wanted to know what should be done about it?"

One of the companies that contracted to make the vaccine, the Cutter Laboratories in Berkeley, California, had released several lots of vaccine that had been improperly inactivated. Live polio virus was being injected into children. The gratitude of the public turned to horror, as the cutter vaccine gave polio to almost 80 recipients; these children in turn went on to spread the disease to another 120 playmates and relatives; three quarters of the victims were paralysed and 11 died. . . . NIH's Laboratory of Biologics Control, which had certified the Salk vaccine, had received advance warning of problems. . . .

In 1954 the rush was on. [Eddy's] lab had gotten samples of the inactivated polio vaccine to certify on a "due-yesterday" basis. "This was a product that had never been made before and they were going to use it right away," she recalled. She and her staff worked around the clock. "We had eighteen monkeys. We inoculated these eighteen monkeys with each vaccine that came in. And we started getting paralyzed monkeys." She reported to her superiors that the lots were Cutter's, and sent pictures of the paralyzed monkeys along as well. "They were going to be injecting this thing into children. . . .They went ahead and released the vaccine anyway, a lot of it. The monkeys they just disregarded."

Shannon called the Surgeon General Saturday morning. Additional cases of paralysis continued to occur. "It seemed obvious that we had a crisis on our hands, the magnitude of which was unknown." Late Saturday afternoon a working group of senior virus specialists, whose advice the polio foundation had started to ignore a year earlier, began meeting in Shannon's office. Note that Shannon had completely taken charge of the crisis. "Sebrell was not the man to manage this," DeWitt Stetten recalled. 'James Shannon was a man of quite different character."

Shannon had brought in the Surgeon General, who called polio chief Basil O'Connor in New York. On Monday evening O'Connor and his advisers came down to Bethesda. Shannon wanted to withdraw the vaccine, "It was a very stormy meeting," he said. "O'Connor and the polio group in general disallowed any possibility of induced infections [as a result of the vaccine]. ... So Basil O'Connor stormed out with dire warning of what he was going to do to the NIH and the Public Health Service. Further vaccination was stopped. I had many sleepless nights."

The basic problem had really not been the carelessness of the Cutter company, which rightly or wrongly was exonerated in a later report. It was the difficulty in jumping from Salk's lab experiments with killing (formalinizing) the virus to large-scale industrial production.

. . . Ruth Kirschstein, the director today of an important NIH institute, added, "The Cutter incident resulted in everybody up the line who had anything to do with it—very few people know this story—being dismissed because of it." All went out: the director of the microbiology institute lost his post, as did the equivalent of the assistant secretary for health. Oveta Culp Hobby, the secretary of Health, Education and Welfare (or Oveta "Culpable" Hobby, as she was known), stepped down. Dr. Sebrell, the director of the NIH, resigned.

Whereas I think the "basic problem" was overestimating the competence of powerful people, especially powerful experts.

1. <http://www.whale.to/v/eddy.html>

---

dearieme (2014-03-05 07:42:07)

An era when people who perpetrated cock-ups got the sack? "In olden times".

MikeW (2014-03-05 08:10:43)

The Obamacare website / polio analogy is interesting, but you seem to be perpetuating the myth that the website's problem was scalability. Unlike Salk's efforts, the website was sloppy work from the start, riddled with broken links, misspellings, and a confusing user interface. In this case, incompetence pervaded the whole project, from the bureaucracy all the way down to individual programmers.

gwern (2014-03-05 08:42:05)

> In 1954 the rush was on. [Eddy's] lab had gotten samples of the inactivated polio vaccine to certify on a "due-yesterday" basis. "This was a product that had never been made before and they were going to use it right away," she recalled...The gratitude of the public turned to horror, as the cutter vaccine gave polio to almost 80 recipients; these children in turn went on to spread the disease to another 120 playmates and relatives; three quarters of the victims were paralysed and 11 died. To put this 'due-yesterday' haste in perspective: at the time, polio was killing 9 children & paralyzing 58 children a day in the USA, and killing or paralyzing 1300 children a day worldwide.

OzMan (2014-03-06 13:49:25)

Thanks for sharing this little-known but important piece of vaccine history. It is also important to note that since the Cutter event, there have not been any vaccine reactions due to manufacturing issues - to my knowledge, please correct me if wrong. (I do not refer to known reactions such as the 1 in million risk of getting paralysis from oral polio vaccine, or the 2 in 100,000 who will get a bowel blockage after rotavirus, and the few other rare known serious vaccine reactions. But any time there are

some serious events that happen AFTER a vaccine is given, the natural tendency for governments is to suspend vaccine use. Eventually, the investigation finds the deaths or other events unconnected to vaccine - and meanwhile children are needlessly put at risk of infectious disease. (Or a vaccine scare like pertussis in the UK in the 1970s or MMR-autism impact lead to massive disease outbreaks). How do we address these cognitive biases - and focus on fixing system failures instead of blaming individuals? \*\*\* Like others, not sure I agree this is same issue as the ObamaCare fiasco; perhaps of more substance is the what is human and financial cost of not having universal health care - even after Obamacare; and what was cost of delays in getting cover? And what is the accountability of our political representatives, who now seem to just represent moneyed interests...

Charles (2014-03-21 12:28:50)

The ones designing and implementing the web site were not federal workers. It was a consulting company who had previously demonstrated incompetence at this kind of project, and should probably have never been given the project. Problems were compounded by unrealistic deadlines for all the features requested, and last-minute changes, never tested. My understanding is that federal procurement rules made it difficult or impossible to choose another contractor. That's not the fault of federal employees other than whoever drafted the laws specifying those rules.

Seth Roberts (2014-03-21 13:22:58)

yeah, those are fair points.

### **"We Need Only One Santa": My Answer to Grand Health Promises (2014-03-06 05:00)**

"We need only one Santa" is a line from [1]a video by Icelandic's Best Party, which won enough support that its leader, Jon Gnarr, became mayor.

"We need only one Santa" would have been a good response to any big health promise in the last 20 years. Not one has come true, just as there is no Santa Claus. "Beating cancer now is a realistic ambition because, at long last, we largely know its true genetic and chemical characteristics," [2]wrote James D. Watson, co-discoverer of the structure of DNA, in 2009. We need only one Santa, Dr. Watson.

At the NIH, "one of our biggest projects is the BRAIN initiative . . . We are bringing together the best and the brightest people from a variety of disciplines to figure out, over the next 10 years, exactly how the brain works," [3]said Francis Collins, head of the NIH, a few days ago. We need only one Santa, Dr. Collins.

1. <http://www.youtube.com/watch?v=xxBW4mPzv6E>

2. <http://www.nytimes.com/2009/08/06/opinion/06watson.html?pagewanted=all>

---

dearieme (2014-03-06 09:54:41)

You'll be accused of the War on Santa, Seth.

Maarten (2014-03-06 12:42:50)

Don't you think the above efforts should be made, or are you just opposed to the hyperbole? I'd rather have scientist run ahead of themselves out of ambition, then pessimistic scientists who don't even try.

Seth Roberts (2014-03-06 13:10:57)

I am opposed to the hyperbole. If liars get all the available grant money...

dearieme (2014-03-06 16:51:06)

"I'd rather have scientist run ahead of themselves out of ambition, then pessimistic scientists who don't even try." What a wonderful example of the false dichotomy.

Cahokia (2014-03-07 11:42:37)

"I'd rather have scientist run ahead of themselves out of ambition, then pessimistic scientists who don't even try." I agree. I know Seth Roberts isn't opposed to cutting edge medical research per se, just to inflated claims and academic group-think. However, posts like this easily read as arguments against biotech, genetics research, stem cell research, etc. There's only so much fermented foods and honey before bedtime can do to extend healthy human lifespan.

Cuhtzaka Indlis (2014-03-07 19:17:52)

Gnarr squeaked into office on a 34 % combined protest vote /comedy /off-the-wall campaign and has made some progress on his promises, but Reykjavik's major -and very real- problems are still there. Overstatements are expected in campaigns. Watson helped discover DNA structure while pursuing anti-cancer strategies. Your quote is from his campaign (note the word 'campaign') to free up more cancer research money and again change the FDA's perpetually outdated drug-testing policies. Overstatement is expected in campaigns. Collins shepherded the Human Genome Project, the DNA mapping project that allowed Watson to dream so large. Now he is describing a vastly larger, longer, and more complex project; but he's describing a reasonable expectation for a decade-long project. Seth: You are unaware of the overpromising of oncogene researchers? Collins is "describing a reasonable expectation"? You know this how?

Cuhtzaka Indlis (2014-03-07 21:00:18)

Seth: ". . . overpromising of oncogene researchers . . . You know this how?" Proof of performance. Collins never promised to cure cancer, he promised -and delivered- on mapping the human genome. This latest is not much different than a contractor's promise to build a high-rise bigger than one successfully built before. In this case, a high-rise that makes extensive use of building techniques pioneered in the previous project. You put Collins' description in with two examples of issue advocacy; issues where real performance has always lagged far behind the verbiage. Both Gnarr's and Watson's hopes/promises have followed the traditional success (and failure) rates for political change and cancer therapy. Neither has 'bumped' or radically altered the trajectory of their subjects. Gnarr and Watson promise changes of \*things\*: governance and cures. Collins' promise is discovery. Can I or anyone guarantee the project's on-time on-cost performance 10 years out? No, but nobody can absolutely predict anything -perhaps not even the sunrise- ten years out. But 'reasonable expectation' is a reasonable description of the brain mapping project. Seth: You believe Collins's promise ("to figure out [in 10 years] exactly how the brain works") is not much different than "a contractor's promise to build a high-rise bigger than one successfully built before"? Surely not. If Collins truly thinks that mapping a network = finding out exactly how something works, he has lost his marbles and should be removed from his job. If Collins knows better but thinks his listeners will believe anything, that is unfortunate and really is a lot like a parent telling a three-year-old about Santa Claus.

Joe (2014-03-08 12:52:32)

Chromosomal Chaos and Cancer [http://mcb.berkeley.edu/labs/duesberg/pdfs/2007,\\_Duesberg0507,\\_SciAm.pdf](http://mcb.berkeley.edu/labs/duesberg/pdfs/2007,_Duesberg0507,_SciAm.pdf) Here's my hunch (if we're lucky). The 21st century will find us making more progress against disease, especially one like cancer (including ways to totally prevent them), even cures, by exploring clean new paths, instead of mindlessly following the same old, pothole-riddled ones.

## Sleep and Depression: More Links (2014-03-07 05:00)

In 1995, hoping to improve my sleep, I decided to watch TV early in the morning, [1]for reasons explained here. One Monday morning I watched tapes of Jay Leno and David Letterman that I'd made. Nothing happened. On Tuesday, however, I woke up and felt great: cheerful, eager and yet somehow calm. I had never felt so good so early in the morning. Monday had been a normal day, I had slept a normal length of time. The good feeling was puzzling. Then I remembered the TV I had watched. It had seemed so innocuous. The notion that 20 minutes of ordinary TV Monday morning could make me feel better Tuesday but not Monday seemed preposterous. Absurd. Couldn't possibly be true.

Except for one thing. I had done something to improve my sleep. Plenty of research connected sleep and depression. That research made it more plausible that something done to improve sleep would improve mood. [2]I went on to confirm the morning faces/mood linkage in many ways. The research connecting sleep and depression had been the first signs of a hidden mechanism (we need to see morning faces for our mood regulatory system to work properly) I consider very important.

[3]Two new studies further connect sleep and depression. One of them found that people who sleep normal amounts of time are less influenced by genes associated with depression than those who sleep longer or shorter lengths of time. The other found that teenagers who sleep less than usual are at greater risk of depression.

The theories that psychiatrists have used to justify anti-depressants (e.g., "chemical imbalance") do not explain the many connections between sleep and depression. Depression is associated with lots of bad things, unsurprisingly, but the association with bad sleep is especially strong. It is not easily explained away. You might think that if you are depressed you are more tired than usual and therefore sleep more/better than usual. The opposite is true. All this might have generated, among psychiatric researchers, a search for a better theory – an explanation of depression that can explain the sleep/depression connections – but it hasn't.

1. <http://escholarship.org/uc/item/2xc2h866/>

2. <http://escholarship.org/uc/item/2xc2h866/>

---

George (2014-03-07 05:32:05)

Why does it matter that we have a theory to explain depression? We need a cure for depression. If sleep works, great (although I doubt its important). I've actually heard that sleep deprivation is helpful for depression, but whatever. I am resistant to any theory that posits the human organism to be incredibly delicate and only capable of thriving in a narrow set of conditions. I think that's clearly wrong. If you tell me we're obese or unhealthy because oops, vegetable oils! I'm gonna laugh. We're not that delicate. If depression is caused by imbalances in sleep, when we evolved in an environment rife with nighttime hunters and menaces and raids, I'm gonna say, no, its unlikely we're such delicate creatures that not getting our 8 hours is gonna hurt us so much. Seth: My theory says we have a circadian oscillator that controls both mood and sleep. That oscillator needs certain input to function correctly. Just like we need Vitamin C for other things to work correctly. My theory suggests new treatments for depression.

Gina (2014-03-07 07:17:00)

Seth: In your quest for the perfect night's sleep, have you tried nonalcoholic beer? It raises GABA. I've been drinking one an hour before bed and it seems to help. I recently quit drinking (again), and morning faces, avoidance of blue light at night and fruit and NA beer before bed have resolved the sleep issues that have been my undoing in this endeavor before much more quickly. Link to study: [http://www.plosone.org/article/info %3Adoi %2F10.1371 %2Fjournal.pone.0037290](http://www.plosone.org/article/info%3Adoi%2F10.1371%2Fjournal.pone.0037290) George: It's hard to know where to look for a cure for an ailment if one does not know the cause of it. I've also read that one night of sleep deprivation can help depression, but that is very different from chronic sleep deprivation.

Audrey (2014-03-07 09:07:15)

Seth, are you still getting good results with the orange glasses before bed? Mine arrived yesterday, and I think they helped me fall asleep faster, but it'll be a while longer before I've had time to do a/b testing & be more confident about that.

Adam (2014-03-07 10:39:21)

Here's an article suggesting that the sleep deprivation effect may be due to enhancement of Serotonin and/or Norepinephrine (Noradrenaline): <http://www.ncbi.nlm.nih.gov/pubmed/15694238>

Seth Roberts (2014-03-07 11:43:22)

I haven't measured the effect of orange glasses but I wear them anyway.

George (2014-03-07 16:44:28)

Gina, not true at all. Many of the most important breakthroughs in medicine occurred not through directed research but completely by chance or as a byproduct of searching for something else entirely. Antibiotics, probably the biggest saver of lives ever, was a complete chance discovery. In fact, since the switch to large scale directed research, breakthroughs have become far fewer. Theories in fact come after you observe something works. In this case, oh I noticed sleep cures depression now let me invent a theory for that. The theory never would have existed without the prior observation, and plays no important role. There is a whole tradition of empirical medicine that doesn't rely on theory but relies on tinkering and serendipity. Directed research has some successes but overall a worse track record. This is surprising but true. We overvalue theory. Seth - maybe your theory is right, but it seems unlikely that we didn't evolve to handle regular disruptions in sleep and to go without sleep periodically. In any event if sleep does in fact cure depression then your theory may or may not be right who knows.

Seth Roberts (2014-03-07 20:19:27)

"In this case, oh I noticed sleep cures depression now let me invent a theory for that." That doesn't describe what happened to me. I noticed that morning faces improved my mood. I wasn't depressed. In fact, morning faces did NOT especially improve my sleep.

nansen (2014-03-07 20:22:22)

Even the mainstream media has gotten the word about the fallacy of "chemical imbalances". Here is David Brooks in 2011 in the Times: "Many of us have been taught that depression arises, in part, from chemical imbalances in the brain. Apparently, there is no evidence to support that. " Seth: good to know.

Sara (2014-03-07 22:49:19)

The convenient thing to drug companies about the "chemical imbalance" meme is that it suggests that one will need to purchase chemicals to restore balance.

Seth Roberts (2014-03-08 06:29:17)

"Antibiotics, probably the biggest saver of lives ever, was a complete chance discovery." Not true. The discovery that antibiotics were useful against disease owed a great deal to the germ theory of disease. This supports what Gina said.

George (2014-03-08 13:49:26)

Seth, noticing that some substances make you better or worse does not require any germ theory. Man has been doing that since the dawn of time. Had Fleming had all sorts of theories about what a bacteria is and how one might go about killing it he would not have had as much success in a hundred years as one chance event. "...Antibiotics transformed medicine. The discovery of antibiotics began by accident. On the morning of September 3rd, 1928, Professor Alexander Fleming was having a clear up of his cluttered laboratory. Fleming was sorting through a number of glass plates which had previously been coated with staphylococcus bacteria as part of research Fleming was doing. One of the plates had mould on it. The mould was in the shape of a ring and the area around the ring seemed to be free of the bacteria staphylococcus. The mould was penicillium notatum. Fleming had a life long interest in ways of killing off bacteria and he concluded that the bacteria on the plate around the ring had been killed off by some substance that had come from the mould." <http://www.historylearningsite.co.uk/antibiotics.htm>

Zach H (2014-03-08 14:25:02)

George - You need the germ theory of disease in order to recognize that staphylococcus has anything to do with getting sick. Otherwise no one would have been interested in learning how to kill bacteria. There's a big difference between directed research in general and the sort of studies in particular that you are complaining about. Tinkering doesn't exist without some over-arching principle leading up to it (correct or not).

Seth Roberts (2014-03-08 18:09:57)

George, there's a lot of truth to the saying "chance favors the prepared mind". Chance favors the prepared mind (often full of theories) in two ways: 1. the "prepared" person is more likely to do the thing that leads to the chance observation. As Zach says, the germ theory of disease is the reason Fleming was studying bacteria in vitro. 2. the "prepared" person is more likely to see how the chance observation can be used. In Paris, I suddenly lost my appetite. A chance observation. This had nothing to do with any preparation or theory. But what happened after that did: based on my theory of weight control, I came up with an explanation of my loss of appetite. Then I tested my explanation. The results led to the Shangri-La Diet. Surely lots of people have had a sudden loss of appetite for reasons similar to mine. But, because of my "preparation" (my theory of weight control), I seem to be the only person to have learned from it.

Nathen (2014-03-09 14:03:05)

I had a biopsychology textbook in the mid-2000s that stated that intermittent total sleep deprivation—I think the best "dose" was staying awake all night once every three or four days—completely alleviated symptoms of depression. I never read the source articles but I wondered since then if we would find out that depression, or some subset of depressed states, was a sleep disorder.

### **Defenders of the Indefensible: Jim Dean, University of North Carolina (2014-03-08 05:00)**

Starting in 2011, [1]Carolyn Willingham, a tutor at the University of North Carolina, complained to the press about fake classes for athletes. In place of an education, she said, athletes, some of whom could barely read, were encouraged to take fake classes, such as classes that never met.

Jim Dean, executive vice chancellor and provost, responded to her charges like this:

Dean asked Willingham to provide raw test data supporting her analysis. She declined, explaining that she'd obtained the confidential information by promising the university's Institutional Review Board not to share it with anyone. She told Dean he could obtain the data directly from the athletic department, which gathered it in the first place. He declined to do as she suggested. "If she had the proof," Dean says, "why wouldn't she share the proof?"

Later Dean handled Willingham's charges like this:

Dean said of Willingham: "She's said our students can't read, our athletes can't read, and that's a lie."

In fact, Willingham had said

18 out of the 183 special admit athletes whose records she assessed read at roughly a third-grade level. An additional 110 of the athletes, she said, read at between fourth- and eighth-grade levels. She never said that most, let alone all, of the 800 athletes at UNC are illiterate, and she said nothing at all about the other 18,000 undergraduates.

When challenged, Dean conceded he'd misspoken.

Even the reporter, apparently, finds Dean's defense repugnant. An important detail is that Willingham, who is wealthy, did not need the job. She was free to say whatever she wanted.

1. <http://www.businessweek.com/articles/2014-02-27/in-fake-classes-scandal-unc-fails-its-athletes-whistle-blower#p1>

---

dearieme (2014-03-08 08:27:44)

It's always lovely to see someone with financial independence actually use it to do something for the rest of society, rather than just bleating about fashionable causes. Seth: I agree. How much charity money is wasted because the people giving the money know essentially nothing about the people they are supposedly helping?

Audrey (2014-03-08 08:32:49)

"An important detail is that Willingham, who is wealthy, did not need the job. She was free to say whatever she wanted." This is a key point, yet it is rarely made. I'm not sure why. For the last several years, the myth that poor people have the same freedoms as the rich has been pushed hard, despite its obvious falsity. Kerry Kennedy could afford to hire attorneys to fight DUI charges, so she did and she won. Yet almost no members of the public can finance a legal defense. Their actual innocence is irrelevant. So prosecutors can file unwinnable cases left and right, knowing that only the 1 % can afford to contest them. In Kennedy's case, the prosecutor was handed a well-publicized loss. <http://www.nydailynews.com/new-york/kerry-kennedy-buying-good-lawyers-helped-beat-drugged-driving-rap-article-1.1708774>

Audrey (2014-03-08 08:40:04)

What's further interesting about the above article is that in its original form, it was built around misquoting Kennedy, and is essentially prima facie evidence of libel. So, possibly after being contacted by Kennedy's lawyers, they inserted the italicized sections, which correctly describe what Kennedy said, putting the lie to the rest of the article. That makes one wonder about every "shocking" article in the paper that ISN'T about someone wealthy enough to put muscle behind a libel complaint.

Sidney Phillips (2014-03-08 10:05:33)

True, wealth does buy you "justice" in this country. Like when Alice Walton killed an innocent bystander most likely while DUI, and wasn't even charged by the local police. <http://bud-meyers.blogspot.com/2012/04/alice-walton-in-wonderland.html>

jason y (2014-03-10 06:35:34)

Sidney, the blog post you linked to doesn't claim Alice Walton was DUI when she drove over a bystander. As for the main post, it is common knowledge that a large fraction of athletes can't read and do not belong in the classrooms of colleges

and universities. It's an open secret. It's only inappropriate to notice if you suggest it's a bad thing. It's also an open secret that athletes are offered "made up classes" like underwater basketweaving, and it's been one since the 60s at least. [http://www.urbandictionary.com/define.php?term=underwater %20basket %20weaving](http://www.urbandictionary.com/define.php?term=underwater%20basket%20weaving)

## The Coming Reunification of Korea (2014-03-09 05:00)

A few years ago, a Korean friend of mine spent a college year abroad in Tanzania. In South Korea, access to information about North Korea on the Internet was blocked. In Tanzania, it wasn't. Impressed by what she learned, she cut-and-pasted some of it into an email to her sister.

After she sent the email, she remembered that in South Korea it was illegal to cut-and-paste from a website. She called her mom to tell her sister not to read the email. The message was successfully conveyed and her sister deleted the email without reading it.

In the last year, however, the South Korean government has changed its policy and is now trying to educate citizens about life in North Korea. Information is no longer blocked. Now and then people escape. They are put on show and tell about North Korean life many times. The intention is to prepare for [1]the coming reunification. [2]Special committees have been formed to discuss how to solve the anticipated problems.

We are used to hearing about the advantages of dividing one country into two, but my friend had no trouble explaining why the South Korean government wanted reunification. One reason was that the war with North Korea was very expensive. Another was that families had been divided. A third was that since North Korea has nuclear weapons, reunification will mean that South Korea has them. (My friend had not read [3]a certain newspaper article the day she said that.) [4]This article suggests that the real reason cannot be said out loud. It is that reunification will allow South Korea to take advantage of the land and people freed by the collapse of North Korea.

"What have you learned from the reunification of Germany?" I asked.

"There will be chaos for a long time," she said.

---

Brandon Berg (2014-03-09 05:54:44)

*After she sent the email, she remembered that in South Korea it was illegal to cut-and-paste from a website. Are you sure about that? I'm having trouble confirming this.* Seth: Yes, I'm sure that's what she said.

Brandon Berg (2014-03-09 06:25:56)

For that matter, why would the South Korean government want to censor information about North Korea? It could only make the South Korean government look good by comparison.

gwern (2014-03-09 08:58:21)

Brandon: the SK censorship is aimed at NK propaganda. This is not as stupid as it sounds for two reasons: 1. NK was actually wealthier and better off than SK early on, immediately after the Korean War, where they were being subsidized by China/Russia and were busy industrializing (NK has all the mineral resources and great stuff you want for industrialization which would make unification so valuable ([http://www.nkeconwatch.com/nk-uploads/global\\_economics\\_paper\\_no\\_188\\_final.pdf](http://www.nkeconwatch.com/nk-uploads/global_economics_paper_no_188_final.pdf)), while SK has the agriculture; as well, Communist regimes have always been pretty OK at industrialization; see "The Myth of Asia's Miracle" <http://web.archive.org/web/20090302203414/http://web.mit.edu/krugman/www/myth.html>). Unsurprisingly, the military dictatorship did not necessarily want NK materials around. 2. Some South Koreans are crazily, bizarrely, delusional about NK. You have no idea how many sympathizers there already are, and how many spies NK has had working for it willingly over the years. To us, NK seems about as appealing as working for Sauron, but to many South Koreans, it's apparently a fine idea. To give you an idea of what I mean, one of their congressmen was convicted a month ago or so after the intelligence agencies recorded him discussing how to best overthrow the SK government and welcome in NK, where to store their gun caches which bases and power stations were best to sabotage, etc. Can you imagine an American representative being put on trial for planning landing locations for Spetsnaz? It wouldn't've been plausible in the heart of the Cold War, much less now.

BRW (2014-03-09 10:26:44)

Gwern, You mean like Alger Hiss? [http://en.wikipedia.org/wiki/Alger\\_Hiss](http://en.wikipedia.org/wiki/Alger_Hiss)

AI (2014-03-09 10:42:29)

Are we talking about NK taking over SK – because I'm finding it hard to imagine NK leadership rolling over and letting SK leadership have any new influence or power. At all. Why would the NK leadership allow any change that would lessen their own power? Also, there's the American troops in the DMZ – Washington would certainly have something to say about such a reunification. And what about Beijing? It's all so complicated. How will all of these participants come to terms?

dearieme (2014-03-09 14:38:35)

If SK has a declining birth rate, then an obvious way to add people is to take over NK. That is one view of what West Germany did.

## **Human Papilloma Virus and Cervical Cancer (2014-03-10 05:00)**

After I say that Nobel Prize in Medicine is usually given for research of little or no proven value, one counterexample I've heard is the 2008 prize for the discovery that cervical cancer is caused by the human papilloma virus (HPV). This should allow us to reduce cervical cancer via vaccination.

There are several things wrong with this example:

1. The predicted improvement has not been observed. The average age at which a woman is diagnosed with cervical cancer is 48 years old. To assess the effect of HPV vaccination – usually given to young girls – on cervical cancer [1]you need to wait thirty years. Thirty years haven't passed. The history of medicine is full of examples where treatments that supposedly worked – such as tonsillectomies, given to millions – when tested turned out to not work. The history of medicine is also full of examples where supposedly wonderful treatments (e.g., frontal lobotomies) turned out to have side effects so bad the treatment was stopped.

2. Cervical cancer is not a big source of death. In the United States, it kills perhaps five thousand women per year. Heart disease kills hundreds of thousands of people per year; so do all forms of cancer taken together. And pap

smears, which cost little, actually work. "Cervical cancer is 100 % curable if detected early," [2] says one website.

3. Because pap smears work well, it isn't clear there is room for improvement. To find out you'd want to compare two groups: (a) pap smears plus HPV vaccination and (b) pap smears alone.

4. It isn't clear the vaccine will work, even if HPV infection does cause cancer. There are at least 100 varieties of HPV; the vaccine protects against two. Does vaccination against two varieties increase infection by other varieties (because different viruses compete for the same niche)? Hard to rule this out. Again, there are many examples in medicine where actually helping people turned out to be far harder than experts had predicted, even when the initial idea wasn't nonsense. An example is the oncogene theory of cancer, which also has a Nobel Prize associated with it.

In summary, not a counterexample.

2. <http://www.uihealthcare.org/health-topics-pap-tests-and-cervical-cancer/>

---

RAD (2014-03-10 06:10:23)

Seth, some counter points: - You seem to be conflating the discovery that HPV causes cervical cancer with the efficacy of the HPV vaccine. I'm assuming these are separate things. - Cervical cancer may not be a big source of death but, like breast cancer, it seems to kill relatively young people. If you were to define some notion of "Cost to Society" then 5000 mid-age women might be significant. - Pap smears may be low price but that may not be the same as low cost. Pap smears are costly in terms of patient time and discomfort (both physical and psychological). If HPV vaccinations eventually reduce the frequency of required pap smears then this can benefit women without bending the price/cost curve. Seth, I'm not disagreeing with your assessment, I don't know enough about the topic, but I'd re-focus the target of your skepticism before accepting it as fact.

Jason (2014-03-10 06:41:03)

What a narrow and — dare I say it — misleading critique. Let's take a look: 0. I'm not sure you're the ultimate arbiter of what has or will have "proven value," but the 2008 prize, shared between the HPV-related discovery and the discovery of HIV seems by several measures to be yielding practical benefit, of which vaccination is only one. Also, the prize identifies what the committees views as important discoveries within the basic science of physiology and medicine. As with much basic science, the value often doesn't emerge for a long time, or emerges from discoveries stemming from the original one. 1. This is true, although not exactly relevant to evaluating the Nobel prize. This is one application, and it will take time to discover if the vaccine affects cancer rates (among other things) over time. However, the data is already showing strong affects in a) infection with cancer causing strains of HPV, and b) cervical abnormalities. Perhaps you're right that some other cause will emerge to mean that cancer rates down the road persist despite these signposts that they won't, but if you have a compelling theory as to why, you haven't presented it here. 2. As is the case with most disease, mortality is not the only important measure. The vaccine and other advances stemming from this discovery has the potential to reduce a lot of morbidity, both physical, and psychological (see below). But I'd also add that in the third world, cervical cancer is a leading cause of death among low-income women. The wealthy U.S. is not a typical example. 3. Pap smears work pretty well in part because they have a medium-high false-positive rate, and false negatives matter relatively little because of the slow moving nature of the disease. Assuming of course that women get regular, expensive testing. For women who don't, the usefulness of a single pap goes way down. But there's good news on this front thanks to — yes, that's right — the discovery that certain strains of HPV cause cervical cancer. New testing that detects the actual strains of infection increases the accuracy of detection, and should decrease the needed frequency of screening. So in addition to reduced morbidity from actual cancer, women should experience less physical discomfort from screening and from unnecessary interventions. It will also reduce psychological morbidity by reducing the

number of false positives. These advances should also reduce the cost of screening while increasing the convenience, which means more women in poor countries should be able to get screened, saving more lives and preventing more suffering. 4. The vaccine doesn't protect against non-cancer causing strains. It protects against the most common cancer-causing strains. You're right that there isn't long-term data yet, but I'm not sure I understand your point. We shouldn't promote vaccination because it's not 100 % effective? No vaccine is 100 % effective. We shouldn't promote a vaccine shown to reduce infection rates of cancer-causing strains and reduce cervical abnormalities because... why exactly? So in summary, the discovery that HPV strains lead to cervical cancer has no predictable practical benefit except for: leading to improvements in screening that will reduce mortality, reduce morbidity, and save money; leading to a vaccine that reduces infection rates, reduces morbidity, and will likely — in 30 years or so — show reductions in cervical cancer mortality; and also vastly increasing scientific understanding of the mechanisms of a type of mutagenesis. I don't know if you're a Monty Python fan, but the example of the Romans and the aqueduct springs to mind.

Jason (2014-03-10 06:44:24)

Oh, who could resist: <https://www.youtube.com/watch?v=ExWfh6sGyso>

as (2014-03-10 12:23:18)

It's important to know whether venereal warts causes cervical cancer whether the vaccine works or not because it illustrates the danger of promiscuity. Getting a Pap smear done is a terrible thing. You have to go to a doctor's office, get naked, put on a paper gown, lie down on a bench and put your feet up in stirrups. Then the nurse sticks a long metal thing in your vagina in order to scrape your cervix. It would be a good idea to tell girls that cervical cancer is caused by a venereal disease and that they don't have to get a pap smear done every year if they're sure they haven't been infected with the HPV virus. The recommended Pap smear intervals have changed. They used to say get it done every year, but then it was changed to every three years if your previous ones hadn't shown any irregularities. It was probably performed too frequently for many women. If a doctor or nurse finds out that you don't get regular check-ups at the gyno, they jump on you (out of concern I understand) to get a Pap smear done. They never tell you about the connection to venereal disease. I used to go to a dermatologist regularly and they would always ask me about my last Pap smears. I also know women (like my mother and her friends) who NEVER go to the gynecologist and same thing, they get yelled at on the rare occasion they do go to a regular doctor for something.

as (2014-03-10 12:43:13)

HPV also causes oral cancer and anal cancer. People don't usually get Pap smears in their throat or buttohole. Seth: Let me ask you the same question. How do you know that HPV causes oral and anal cancer? All that's been observed is a correlation, as far as I can tell. What about the possibility that early stages of the cancer make HPV infection more likely?

as (2014-03-10 12:58:56)

Chastity is the issue at hand here, correct? If a woman gets cervical cancer, it means that (1) she was bad (2) the man was bad or (3) they were both bad. What if they lied about their chastity or faithfulness? [1]"Roving Mates Called Factor In Cancer"

1. <http://www.nytimes.com/1996/08/07/us/roving-mates-called-factor-in-cancer.html>

Seth Roberts (2014-03-10 13:04:58)

Jason, do I say "we shouldn't promote a vaccine because it's not 100 % effective?" No, I say that treatments should be tested before they are applied to large numbers of people. Since when is that controversial? Such tests will make clearer the relative size of costs and benefits. Surely you know that the assumption you make here – you assume that costs are small relative to benefits, since all you talk about are benefits – has been wrong dozens of times in medical history. Dozens of popular treatments (at least) were stopped or drastically scaled back after it became clear their costs outweighed their benefits. Mammograms are the latest example where it has become clear that the cost/benefit ratio is substantially worse than expected. Also, why are you sure that HPV infection (infection with certain strains) causes cervical cancer? What about the possibility that early stages in cancer progression make HPV infection with those strains more likely? Lack of certainty that HPV infection causes cervical cancer is another good reason to test the effect of vaccination.

Joe (2014-03-10 13:22:56)

as Says: "HPV also causes oral cancer and anal cancer" That is one powerful little virus! It shouldn't be long now before "global warming" will be blamed on HPV, too, merging two of the biggest scientific hoaxes of all time. Jason: "the 2008 prize, shared between the HPV-related discovery and the discovery of HIV seems by several measures to be yielding practical benefit, of which vaccination is only one." What that particular prize actually identifies is the moment in time when many previous laws of science were turned on their heads. When correlation would now essentially mean the same thing as causation. When the scientific method would mostly be discarded. When historically proven and effective scientific techniques would now simply be ignored, like Koch's Postulates. When viruses and retroviruses would now be deemed capable of doing things they absolutely are not capable of doing. When the "virus hunters" and BigPharma won the battle for control of the scientific paradigm. A sad day indeed.

as (2014-03-10 13:58:29)

Seth: *Let me ask you the same question. How do you know that HPV causes oral and anal cancer? All that's been observed is a correlation, as far as I can tell. What about the possibility that early stages of the cancer make HPV infection more likely?* "The first was posited by a doctor in Florence in 1842. He noticed that prostitutes and married women died of cervical cancer, but nuns almost never did. Though he might have discerned that it was sexually transmitted, he was thrown off by another fact: Nuns often died of breast cancer. His conclusion was that nuns' corsets were dangerously tight." [1]Link Oral and anal cancer: you get the cancer where you perform the sex act, right? Seth: More associations. I don't see how that answers my question.

1. <http://www.nytimes.com/2006/08/30/health/30iht-snvaccine.2638963.html?pagewanted=all>

as (2014-03-10 15:03:54)

Cervical cancer is also on the list of AIDS defining illnesses.

Joe (2014-03-10 15:18:19)

as Says: "Cervical cancer is also on the list of AIDS defining illnesses." But only with a positive test for HIV antibodies. Cervical cancer with no HIV = cervical cancer. Cervical cancer with HIV = AIDS. Does that make any sense to you?

as (2014-03-10 15:36:24)

Joe Says: *March 10th, 2014 at 3:18 pm Cervical cancer with no HIV = cervical cancer. Cervical cancer with HIV = AIDS. Does that make any sense to you?* If you have HIV but not HPV, would you get cervical cancer? (I realize such a person is unlikely to exist). If you don't have HPV, would you ever get cervical cancer? If a person with HIV develops Kaposi's sarcoma or cervical cancer, what does that mean? Could they have developed Kaposi's sarcoma without being infected with herpesvirus 8?

Joe (2014-03-10 16:02:10)

as Says: "If you have HIV but not HPV, would you get cervical cancer? (I realize such a person is unlikely to exist)." No, because neither virus can cause cancer. "If you don't have HPV, would you ever get cervical cancer?" You could, yes, but it would have nothing to do with HPV. "If a person with HIV develops Kaposi's sarcoma or cervical cancer, what does that mean? Could they have developed Kaposi's sarcoma without being infected with herpesvirus 8?" A person with KA almost certainly got it because of long-term "popper" abuse (amyl nitrate), plus a weakened immune system (probably caused by additional recreational drug abuse). <http://www.duesberg.com/media/jlpoppers-3.html> And no one really knows how women get cervical cancer, no matter what he or she might tell you. It's a disease of older women, yet only a very tiny fraction of them actually die from it. If a woman has routine Pap smears, it's almost impossible to die from it.

as (2014-03-10 21:10:57)

Seth: *More associations. I don't see how that answers my question.* Nuns don't get cervical cancer, but they do get another female cancer and that is breast cancer. It's not that they live some super healthful lifestyle where they don't get cancer at all like hunter gatherers. Prostitutes get cervical cancer. The more a man cheats, the more likely it is that his wife will get cervical cancer. The cervix is in the female genital area. This makes it seem like cervical cancer is caused by a venereal disease. When people have sex in the mouth or in the butt, they get the cancer in that area instead. I don't understand why you don't find the HPV - cervical cancer link plausible. Seth: I do find it plausible. But I also find another explanation worth considering.

Jason (2014-03-10 22:12:07)

Contra Seth's argument, there's very little controversy about the HPV-cancer link. (Nice summary here: <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC1769629/>) I'm not enough of an expert to find holes in the molecular genetics research (and neither is Seth), but my rudimentary understanding is that the evidence goes well beyond mere association. Not to mention the emerging medical literature that demonstrates reduced cervical abnormalities in the vaccinated population, which pokes a pretty big hole in Seth's alternative theory about cancer leading to infections rather than the other way round. Speaking of that alternative theory, let's look at it in the context of the evidence. Seth is suggesting that cervical cancer develops in some undetectable form of the disease (which I'm not sure is even possible in how we define cancer), remains latent for years and years showing no physical symptoms except HPV infections, until finally it becomes detectable — and just by coincidence — tends to do so in women with higher viral load from HPV infection. Is that possible? I suppose. Is it plausible? Not very. Is it more plausible than the current prevailing theory? Certainly not. Seth: In general, cancer develops very slowly. One theory is that four different mutations are required for a cell to become cancerous. The first three mutations have no obvious effect. This is not terribly controversial, since most cancer increases as the fourth power of age. I haven't been able to find how cervical cancer changes with age.

Robin (2014-03-11 02:32:31)

Nobody seems to have mentioned that the HPV vaccination has led to a small number of otherwise healthy young women/girls having severe reactions and either dying or ending up in a pretty bad state. As a father of two young girls, I'm super-focused on knowing a hell of a lot more about so-called vaccinations before they go anywhere near my kids. Scaremongering? Well, it seems that measles is pretty low in the mortality stakes amongst those who get it and are not either immune-compromised and/or malnourished. Why then are most national "health services" so relentless in their characterisation of measles as a terrible disease, seemingly up there with tetanus and cholera, that needs endless resources and attention to stamp it out?

Jason (2014-03-11 07:33:54)

Robin: Nobody has mentioned it because the publicized cases don't hold up to scrutiny. That doesn't mean the vaccine is 100 % of course. Nothing is. As for your point about measles, you're falling victim to a classic misdirection technique: focusing on mortality to the exclusion of all other harm from disease.

Joe (2014-03-11 08:55:17)

as Says "Nuns don't get cervical cancer, but they do get another female cancer and that is breast cancer. It's not that they live some super healthful lifestyle where they don't get cancer at all like hunter gatherers." Nuns lead healthy lives. They don't smoke. They don't abuse drugs. They generally eat healthy foods, and not too much of it. They get lots of sleep. They don't have promiscuous sex. And they're generally happy, stable people (except for Sister Mary Catherine, my 2nd grade teacher, who whacked me with a ruler almost every single day). That's why nuns practically never get cervical cancer. Unfortunately, they also have a much higher incidence of breast cancer than married women, because early pregnancy is protective against cancer. And hunter-gatherers did get cancer, although it was very rare. "Prostitutes get cervical cancer." Because they are promiscuous, abuse recreational drugs, eat poorly, get little sleep, take antibiotics prophylactically, have severely compromised immune systems, etc. "When people have sex in the mouth or in the butt, they get the cancer in that area instead." The vast majority of people (perhaps as high as 99.99 %) who have sex in the mouth or the butt never get cancer in those areas. "I don't understand why you don't find the HPV - cervical cancer link plausible." Unless you believe that correlation is the same thing as causation, there's no reason to believe it. There is no scientific proof that HPV causes cervical cancer. There is only correlation.

Joe (2014-03-11 09:09:21)

Jason: "Contra Seth's argument, there's very little controversy about the HPV-cancer link" That's a little like claiming there's a "97 % consensus" on global warming. :) <http://wattsupwiththat.com/2013/11/20/the-97-consensus-myth-busted-by-a-real-survey/> There is all kinds of controversy about the cause of cervical cancer, HPV, etc., but you have to be willing to look for them. Note: It's just a hunch, but I think you'd probably say the same thing about, say, statin drugs, too, right? :(

Joe (2014-03-11 09:15:22)

Robin: "Nobody seems to have mentioned that the HPV vaccination has led to a small number of otherwise healthy young women/girls having severe reactions and either dying or ending up in a pretty bad state. As a father of two young girls, I'm super-focused on knowing a hell of a lot more about so-called vaccinations before they go anywhere near my kids." Good for you! Educate your girls, do your best to raise them to avoid recreational drugs, unhealthy lifestyles, etc., urge them to get regular Pap smears, and they'll have a greater chance of being struck down by lightening than by cervical cancer.

as (2014-03-11 11:24:18)

Joe Says: *urge them to get regular Pap smears* I would never urge any girl to do that. A hand in the vagina is a terrible thing.

Robin (2014-03-11 11:40:14)

Jason wrote: "Robin: Nobody has mentioned it because the publicized cases don't hold up to scrutiny. That doesn't mean the vaccine is 100 % of course. Nothing is. As for your point about measles, you're falling victim to a classic misdirection technique: focusing on mortality to the exclusion of all other harm from disease." The publicised cases DO hold up to scrutiny. Not all of us here are in the US and outside the US, for example in Denmark and New Zealand, there are cases of healthy young women reacting severely to Gardasil. To be clear: it is uncommon, but measles mortality is minuscule also. Now, measles and other harm. What, exactly, are you talking about? Gambling, alcohol and tobacco are fully legal, contribute to GDP, raise significant amounts of tax, and result in massive, widespread harm to society that studies show is acute and enduring (alcoholics are a disaster for their immediate and extended families, and the relationships of the same people with others). A life in perspective is about appropriate responses to risks. What risk are you referring to that measles causes that is so devastating, that is worth the concern, cost, adverse reactions, and risk of vaccine use where there is no long-term knowledge about it? As for "misdirection technique"s, I think you are referring to the Straw Man fallacy, and if so I utterly reject this. The measles issues is directly relevant to this discussion. However, YOU are referring generally to general health benefits of measles vaccinations. What are you talking about?

Robin (2014-03-11 11:42:26)

as wrote" "Joe Says: *urge them to get regular Pap smears* I would never urge any girl to do that. A hand in the vagina is a terrible thing." I can't honestly work out whether you are serious (scary; what is a pap smear compared with terminal cancer? I have a prostate DRE every year. Not my idea of fun, but better than being unlucky and ignorant) or just joking!

Robin (2014-03-11 11:43:11)

minuscule → miniscule

Joe (2014-03-11 11:47:16)

as Says: "I would never urge any girl to do that." That's supposed to be a joke, right? Or do you just prefer that they die?

as (2014-03-11 12:35:40)

I'm serious. It's important to tell girls that cervical cancer, oral cancer, and anal cancer are the outcome of venereal diseases. Ectopic pregnancies too. I would never recommend a hand in the vagina every year or every three years or whatever the new standard will be.

Joe (2014-03-11 13:06:38)

as Says: "I'm serious. It's important to tell girls that cervical cancer, oral cancer, and anal cancer are the outcome of venereal diseases." Even when there is no scientific proof that they are? And not even bother to tell them what can happen to them if they end up destroying their immune systems, by abusing recreational drugs, alcohol, smoking, taking antibiotics prophylactically, not getting enough sleep, good nutrition, etc? Just tell them to "get this little vaccination, honey, and you can have all the sex you want, with as many men as you want, in as many ways as you want"? You do realize that even the HPV = cervical cancer supporters recommend that women get routine Pap smears, right? That's right. Gardasil or no Gardasil, they recommend routine Pap smears. Why do you suppose that is? "I would never recommend a hand in the vagina every year"

But getting a useless vaccination every few years, for perhaps the rest of their lives, a vaccination that may have already killed over 100 girls and harmed 20,000 others, that's okay, eh? Wellalrightyhen!

Seth Roberts (2014-03-11 13:07:05)

"The publicized cases don't hold up to scrutiny." You mean, unless you can prove that New Product X has caused harm, the public should not learn about cases where it may have caused harm? Yet the benefits of New Product X should be widely publicized, even though the benefits too are not proven? And they call this "evidence-based medicine". A better name would be "good-news medicine".

Jason (2014-03-11 21:38:22)

Robin: What I mean by misdirection in this case is this: focusing on measles mortality as the sole measure by which we evaluate whether or not the measles vaccine is 'worth it' is a strategy to draw people's attention away from the entirety of the measles disease burden on the infected, their families, and society. Robin and Seth: When I say the cases don't hold up to scrutiny, I mean the evidence linking these reports doesn't rise above the level of coincidence. Not even to the level of association that Seth insists is inadequate to connect a pathogen to disease. (Talk about a double standard...) As to Seth's other point, no, of course I wouldn't agree with such a broad statement about proof, and I don't think many people would. Anecdotes in and of themselves represent a pretty low level of evidence, but they are evidence. But an anecdotal case of a young woman who died within 72 hours of receiving a vaccine is not in and of itself evidence of harm from the vaccine and more than an anecdotal case of a young woman dying within 72 hours of having a bagel is proof of harm from the bagel. Back to Joe... it really depends on how you define controversy, doesn't it? Do I consider a few people whose arguments rely on willfully ignoring or misrepresenting evidence to be adequate to call something controversial? No, I guess I don't. At least as you've represented them, your arguments refuting the HPV-cancer link a) ignore much of the evidence base, perhaps intentionally; b) rely on theories that were flawed even when produced 100 years ago, long before the science behind much of the current evidence was even developed; and c) don't actually offer much of an argument beyond that you just don't believe the existing evidence. To me, that's not a controversy. Or at least, it's not a scientific controversy. But people try to call the science in the question to back up political arguments that they know aren't defensible purely on political grounds. On the statins question, you might be surprised. Purely in terms of evidence, there doesn't seem to be much controversy that for primary prevention, statins aren't very useful, and certainly aren't justified based on the number needed to treat to prevent a cardiac event. There's controversy about whether or not to change current clinical recommendations, but again, that's not really a scientific controversy. It's a political one. (Side note for anyone reading who found this because of statins: the evidence in favor of statins is much stronger among persons who have already had a heart attack.) I don't object to a healthy skepticism about science. That science often turns out to be wrong is a feature, not a bug. What I do object to is the attempt to delegitimize scientific findings merely because they are inconvenient or unpalatable to a political or cultural viewpoint.

Jason (2014-03-11 21:46:02)

Also, Seth, I'm not able to find a name of your four mutations theory, so I can't read much about it. But even if that were the case, it doesn't increase the plausibility of your alternative theory in the context of the observed data. If anything, it makes the virus-cancer link seem more plausible, since it would provide an additional explanation of how an infection today could set off a chain of cellular change that results in cancer many years later. Seth: Surely you know that cancer increases as the fourth power of age. Look into how that is explained.

Retired now (2014-03-11 23:18:00)

I think what irritates me about the whole vaccination debate is that medicine says it is now evidence based, but what it considers to be evidence depends on the political correctness of the belief. As a now grandparent I would like to see the RCTs which prove efficacy and safety of any vaccine given. But that data is not actually available. Just asking for it raises the hackles of any medical person who can't provide it. They say "trust me" and frankly I no longer do. Association is not causation and while medicine demands proper RCTs for any alternative medical treatment they are more than prepared to accept association when it comes to vaccines. What made me really cautious about the HPV vaccination outcomes is that the doctors in sexual health clinics were claiming reduction in cancer within two years of the vaccine's introduction and various groups of docs have

made that claim at least annually since then. Anecdotal evidence isn't acceptable in the place of RCTs. I want to know that the RCTs have been done over a decade or more for both cancer outcomes and in relation to safety. Noone has been able to give them to me. And I want to compare the numbers who report severe side effects with those who report cervical cancers. Only then can I make an informed choice.

Robin (2014-03-12 00:24:33)

Jason wrote: "Robin: What I mean by misdirection in this case is this: focusing on measles mortality as the sole measure by which we evaluate whether or not the measles vaccine is 'worth it' is a strategy to draw people's attention away from the entirety of the measles disease burden on the infected, their families, and society." Sorry, but public health authorities have set the agenda here with their focus on brain inflammation and death as "possible outcomes" when they are justifying their resource spend on vaccinating against measles. They cite absolute numbers of people infected, and numbers of people taken to hospital. They do not mention the percentage of those infected who are fully vaccinated (a varying yet significant percentage, and in my book a false sense of "security" is of particular concern) and that of those who visit hospital, as it would be very, very rare for these people to not be checked and sent on their way straight away. I should concede that we are probably coming at this from different angles. Although chicken pox can be vaccinated against (at a cost, with scaremongering, and failure rate) we chose not to do this and instead our kids have all had chicken pox. Was it a hassle? Yes. Was it unpleasant and inconvenient? Yes. However, we have some confidence that their resulting immunity is robust, and the negative factors are really not that bad. Chicken pox is referred to as a horrendous, scarring, terrible disease in media by those who are selling or promoting the vaccine. I find this unacceptable, but you might feel this is quite OK to mislead and scare people. Concerning anecdotal evidence, of course it is difficult to establish causality. However, when a healthy 12 year-old girl feels immediately unwell immediately after a Gardasil injection, and goes downhill from there and dies, this indicates to me that as a parent I want to know significantly more about this. Nurses complain about Gardasil that most often the girl faints, breaks out in hives, etc. immediately following. This isn't some random thing I read on the internet. I actually have had these conversations. Recently. I recognise your right to be concerned about the veracity of my claims, though. My general position is that I really don't think we know enough about the immune system, nor do we have enough data to make high-quality guesses. Add this to obviously unhealthy amounts of power held by pharma companies and their consultants, the economics of big health, etc., and the overall picture isn't a good one. I think Seth's post above does a better job of summarising the situation - apologies for the long-winded response.

Robin (2014-03-12 00:35:04)

Briefly, on measles, in NZ, people born before 1969 are considered to be completely immune to measles. Why? Because the measles vaccine was introduced somewhere around then. That is, the first one, that was supposed to provide life-long immunity. Except it didn't. So another one was introduced. A booster. Whooping cough is also an issue. Again in NZ, the situation was that mothers passed antibodies to their infants through breast milk, but this only occurred if the mother had had WC. A problem has arisen whereby mothers who were vaccinated against WC didn't pass the antibodies to their infants, putting their infants at significant risk. The Ministry of Health in NZ has recently realised this and started a programme of pregnant mother vaccination in an effort to address this introduced problem. Many actors in this context take the approach that by the time adverse issue are detected and the impact determined, that they will be long gone, unavailable to take responsibility, or at the most, legally beyond reach.

Seth Roberts (2014-03-12 01:06:28)

But an anecdotal case of a young woman who died within 72 hours of receiving a vaccine is not in and of itself evidence of harm from the vaccine any more than an anecdotal case of a young woman dying within 72 hours of having a bagel is proof of harm from the bagel.

You fear vaccines and bagels equally? Everyone I know fears vaccines more. If someone dies within 72 hours of a vaccination any sane person would increase how much they fear vaccines unless there is a more plausible cause of death. Any person with a good understanding of the logic of science would increase how much they fear vaccines unless it was proved that the cause

of death was something else. I suspect that in the anecdotes you refer to there was not a more plausible cause of death, much less a proven alternative cause.

Jason (2014-03-12 06:36:33)

Anyone with a good understanding of the logic of science? Really? Anyone with a good understanding of the logic of science would have a lot of questions before feeling confident connecting two events related only by proximity in time. Further, people with a good understanding of the logic of science don't demand lower standards of proof for the things they believe versus the things they don't believe. Seth: Science is about degrees of belief, not proof or "standards of proof". Nothing is ever proved or disproved. Evidence pushes belief in Idea X (such as "vaccines cause harm") up or down. If someone died within 72 hours of getting vaccinated that should increase belief in "vaccines cause harm" unless you are sure the person died for another reason. Where does your understanding of science come from? You have been poorly taught.

Joe (2014-03-12 10:58:59)

Jason: "Back to Joe... it really depends on how you define controversy, doesn't it?" Absolutely. Definitions matter. The best example of that is found in the "climate change" field. The climate alarmists began to use the term after it became apparent that the globe hadn't warmed for over 17 years. Another "inconvenient truth"? "Do I consider a few people whose arguments rely on willfully ignoring or misrepresenting evidence to be adequate to call something controversial? No, I guess I don't." Jason, I think you need to expand your list of reading material. It's not a few people, it's from experts around the world. And if I thought they were misrepresenting the evidence, I wouldn't put any credence into their claims or their research. "At least as you've represented them, your arguments refuting the HPV-cancer link a) ignore much of the evidence base, perhaps intentionally;" What evidence base? You have only a correlation upon which to hang your hat. A correlation shared by the vast majority of the population (HPV infection). Of which only a tiny fraction ever get cervical cancer and die. And which can essentially be totally avoided by getting regular Pap smears. And you somehow think it makes sense to "vaccinate" virtually everyone on the planet, with a "vaccination" that's never been proven to protect against anything, and which may have already killed over 100 girls and harmed 20,000 others. I think that's criminally stupid. "b) rely on theories that were flawed even when produced 100 years ago, long before the science behind much of the current evidence was even developed;" What theory would that be, exactly? And what "science" is there behind the current evidence? That somehow correlation now means causation? When did that become science? "and c) don't actually offer much of an argument beyond that you just don't believe the existing evidence." Oh, I believe the existing evidence. Unfortunately, the "evidence" consists of correlation, not causation. And anyone who's ever taken even Bio 101 knows that correlation isn't the same as causation. Your side wants to convict firemen for starting all those fires simply because firemen can be found at the scenes of most fires. My side demands more than that before we blame the firemen. Like real scientific (forensic) evidence. "To me, that's not a controversy. Or at least, it's not a scientific controversy. But people try to call the science in the question to back up political arguments that they know aren't defensible purely on political grounds. As far as I'm concerned (I can't speak for others here), this particular controversy isn't about political arguments. It isn't even about the subject of vaccinations in general. It's about the scientific method. It's about the wisdom of exposing millions of young women (and others) to the potential hazards (including death) of a vaccine that's never been scientifically proven to prevent any disease, including the disease the vaccine is purported to protect them against. A disease that has historically affected only older women, and which takes the lives of only a tiny fraction of them, and even that tiny fraction can be protected by getting regular Pap smears. What ever happened to: "First, do no harm"? "On the statins question, you might be surprised." Nothing surprises me anymore about the subject of statins. "Purely in terms of evidence, there doesn't seem to be much controversy that for primary prevention, statins aren't very useful, and certainly aren't justified based on the number needed to treat to prevent a cardiac event. " Yet one cannot visit a doctor anymore without being strongly urged to take a statin pill. Why? And just recently, the protocol has even been expanded to increase the target base by at least 40 %. Why? "There's controversy about whether or not to change current clinical recommendations, but again, that's not really a scientific controversy. Here's the scientific controversy: Statins were sold to the public as an easy and safe way to lower one's cholesterol, right? Everyone knew that high cholesterol was a risk factor (i.e., correlation) for heart attacks, right? But wait, numerous studies have now shown us that just as many people with "low" cholesterol levels have heart attacks as those with "high" levels. And that there is essentially ZERO difference in overall mortality. Especially if one understands the difference between relative risk and absolute risk. So they better come up with an explanation for that,

right, and quickly? So now they try to claim that for those with previous heart attacks, there is a barely measurable benefit. While they still try to push statins on all the rest of us! Why? Heck, once a person has reached the age of 65, those with higher cholesterol levels live longer than those with lower levels. That is, cholesterol appears to have a PROTECTIVE effect. So why in the heck would anyone want to artificially lower one's cholesterol? I just don't get it, and would you, if you could find a way to be honest with yourself. There may be something about statins that protect a small fraction of us against heart attacks, but it isn't by lowering our cholesterol. That's a scientific fact. It may have a slight anti-inflammatory effect, and more and more scientists are now attributing CHD to inflammation, so statins have been pushed on the public (as a whole) for exactly no good scientific reason. All thanks to an incorrect CORRELATION. Entire books have now been written about all the serious side effects of taking statin drugs (including death). Books such as "The Statin Damage Crisis," by Duane Graveline, M.D., "The Heart Revolution," by Killmer McNally, M.D., "The Great Cholesterol Myth," by Stephen Sinatra, M.D., and Jonny Bowden, Ph.D., "The Great Cholesterol Con," by Malcolm Kendrick, M.D., "The Cholesterol Conspiracy," David R. Hastings Lloyd, "You Will Not Die From A Heart Attack," by David S. Grimes, M.D., "Ignore The Awkward," by Uffe Ravnskov, M.D., Ph.D., "The Cholesterol Delusion," by Ernest N. Curtis, "Low Cholesterol Leads To Early Death," by David Evans and Tom Naughton, "The Truth About Statins," by Barbara H. Roberts, M.D., and many more. I guarantee to you, Jason, if you read all those books, they will have to put a gun to your head to get you to swallow a statin pill. [...] "I don't object to a healthy skepticism about science. I have no skepticism about science. I have a lot of skepticism about the people who claim to practice it. And far too many of them are dangerous to our lives. That's a scientific fact. "That science often turns out to be wrong is a feature, not a bug. What I do object to is the attempt to delegitimize scientific findings merely because they are inconvenient or unpalatable to a political or cultural viewpoint. I see no one here who fits that description. I do see a lot of people who QUESTION those so-called scientific findings, which is what scientists are supposed to do, right? In fact, it's part of their job description! And I object to the people who try to ridicule or belittle them for doing their jobs. For caring about their children. For questioning the "experts." For doing their own due diligence. And I think they should be roundly praised and congratulated.

Joe (2014-03-12 11:05:23)

Jason: "Further, people with a good understanding of the logic of science don't demand lower standards of proof for the things they believe versus the things they don't believe." Yet you're apparently totally satisfied with having correlation essentially mean the same thing as causation, forgoing the scientific method altogether. Sigh.

Joe (2014-03-12 11:17:18)

Jason: "Anyone with a good understanding of the logic of science would have a lot of questions before feeling confident connecting two events related only by proximity in time." But they are not only related by proximity of time. Getting a shot, and then being hit by a car, might fit your description. But getting a vaccination, and then almost immediately (or soon after) suffer symptoms (e.g., seizures, strokes, dizziness, fatigue, weakness, headaches, stomach pains, vomiting, muscle pain and weakness, joint pain, chest pains, hair loss, appetite loss, personality changes, insomnia, hand/leg tremors, arm/leg weakness, shortness of breath, heart problems, paralysis, itching, rashes, swelling, aching muscles, pelvic pain, nerve pain, menstrual cycle changes, fainting, swollen lymph nodes, night sweats, nausea, temporary vision/hearing loss, death, etc.) that could LOGICALLY be connected to having foreign proteins and chemicals injected into your body, would not. No, it's not proof. Any more than any other correlation can be considered proof, but it sure jumps out as something that demands more investigation before going too much further. "First, do no harm."

Joe (2014-03-12 12:17:20)

The next "Big Thing": PCSK9 inhibitors <http://www.ncbi.nlm.nih.gov/pubmed/23652470> They surely must already know by now that statins don't work by lowering cholesterol (and don't prolong life), yet here they are again, looking for yet another way to make money...er...lower cholesterol levels. It couldn't be that most of the statin patents are running out...could it? God help us all.

## Nick Szabo is Satoshi Nakamoto, the Inventor of Bitcoin (2014-03-11 05:00)

There were many funny things about [1]Leah Goodman's claim in Newsweek that a California engineer invented bitcoin. One was her observation that he put two spaces after a period – just like the inventor of bitcoin. Another was her observation that his relatives said he was "brilliant", without giving any examples. His brilliance had remained perfectly hidden – until now. A third was her conclusion that he was obsessed with secrecy and distrusted government – just like the inventor of bitcoin (according to her). Felix Salmon [2]was quite wrong when he said there are some very strange coincidences and the pieces of her argument "fit elegantly together". Actually, her argument is worthless from top to bottom. Salmon was right, however, when he said that the engineer's English shows he couldn't possibly have invented bitcoin. As Salmon says, Goodman ignored this itty-bitty problem.

Who is the inventor of bitcoin? I'm sure it's [3]Nick Szabo, a former law professor at George Washington University. This idea first surfaced a few months ago in [4]an anonymous blog post based on textual analysis. Szabo used certain phrases in the original bitcoin description far more than a bunch of other possible candidates. That is real evidence. The hypothesis that Szabo is the inventor passes several other tests as well:

1. Right time zone. The original bitcoin postings appeared to come from the Eastern (United States) time zone. Szabo lives near Washington, D. C.
2. Prior to bitcoin, he had similar ideas. As far as I can tell, his previous ideas were the closest of anyone's.
3. Yet the original bitcoin proposal didn't reference his work. The usual reason for not mentioning a predecessor's work is that you want more credit. Yet the creator of bitcoin didn't want credit. Failure to mention Szabo's work is so strange it may have been Szabo's way of telling insiders he's the inventor. In other words, this fact makes sense if Szabo is the inventor. It remains unexplained if anyone else is.
4. Szabo failed to get excited when bitcoin emerged. It was based on his work (more or less). Like everyone, [5]including me, Szabo had been [6]told countless times that his ideas were worthless, crazy, stupid and so on. ("Money just doesn't work like that, I was told fervently and often.") Because of that treatment, I greatly enjoy pointing out confirmation of my ideas. It's such a fundamental pleasure there's a word for it: glee. If he wasn't the inventor of bitcoin, Szabo should have gleefully followed its progress, pointing out over and over how this showed his original ideas were right. He didn't do this. Again, this makes sense if he was the inventor – he didn't want to draw attention to how close bitcoin is to his published ideas. It remains unexplained if anyone else is.
5. The clincher, for me, is that he wrote [7]an article about the emergence of money that is compatible with [8]my theory of human evolution. His article says money emerged from collectibles. Collectibles are an important part of my theory. I say they emerged because they helped skilled artisans, who were innovators, make a living. For most people, collectibles are trivial, whereas I've written often about [9]the Willat Effect, which I believe is the psychological rule that created them. It isn't easy to be consistent with my theory. I've read dozens of theories about human evolution. Whenever they explain the same things as mine (e.g., evolution of language), they have been inconsistent with my theory. Two examples are Jared Diamond's ideas and Daniel Dennett's ideas. Szabo's essay is the only the second example I have seen of ideas that fit mine. [10]The aquatic ape theory, which is about what happened before the events of my theory, also fits; Szabo's ideas are about what happened after the events of my theory. Szabo's ideas about the emergence of money are very non-obvious (especially because you have to realize the centrality of collectibles) and are compatible with a theory he cannot have heard of. I doubt anyone agrees with me that compatibility with my theory is a great plus but it is obvious that if you understand how money began, you are in a much better position to invent a new form of money than if you don't. The difficulty of mining bitcoins corresponds to the difficulty of making collectibles. You could randomly pick anyone, including cryptographic experts, and the probability would be extremely low they have a good theory of how money began. Yet Szabo does.

I ignore the coincidence of initials: NS and SN (or NS).

Szabo's achievement is good news for me because we have a similarity. He was a law professor. They are not supposed to invent new and useful things. No law professor before Szabo invented anything remotely as new and potentially important as bitcoin. I am a psychology professor. They are not supposed to make useful discoveries about health. I have made discoveries/inventions about health that are certainly new and might some day be important, such as the Shangri-La Diet and [11]the underlying theory, [12]the effect of morning faces on mood and [13]daily brain testing.

furcio (2014-03-11 07:07:44)

You are right. He is on my list on the top. I think the same.

Seth Roberts thinks it was Nick Szabo | Megalomania:me (2014-03-11 07:43:02)

[...] Seth Roberts thinks that Nick Szabo created bitcoin and he gives a few good reasons to back up his claim. [...]

gwern (2014-03-11 08:46:15)

> This idea first surfaced a few months ago in an anonymous blog post based on textual analysis. Szabo used certain phrases in the original bitcoin description far more than a bunch of other possible candidates. That is real evidence. No, it's bullplop. I criticized it at the time: [http://www.reddit.com/r/Bitcoin/comments/1ruluz/satoshi\\_nakamoto\\_is\\_probably\\_nick\\_szabo/cdr2vgu](http://www.reddit.com/r/Bitcoin/comments/1ruluz/satoshi_nakamoto_is_probably_nick_szabo/cdr2vgu) My criticism has been trapped in moderation since 1 December 2013. Oddly enough, the author has had time to approve 4 or 5 other comments, but \*not\* mine. I wonder why? > The original bitcoin postings appeared to come from the Eastern (United States) time zone. You should check the timezone metadata on the SVN repo & original whitepaper, and look at the location of the IPs in Finney's debug dump of the first Bitcoin transactions... > Szabo lives near Washington, D. C. Really? The address I have for Szabo is in Minnesota. Just because he's affiliated with GWU doesn't mean he lives in DC. > Yet the original bitcoin proposal didn't reference his work. This also 'proves' Wei Dai wrote Bitcoin, among others. > If he wasn't the inventor of bitcoin, Szabo should have gleefully followed its progress, pointing out over and over how this showed his original ideas were right. He didn't do this. Most of the Cryptography mailing list thought it was a questionable idea at best, and Szabo has many projects, just look at his homepage. > Szabo's achievement is good news for me because we have a similarity. He was a law professor. He was a cryptopunk decades before he went into law school. > 5. The clincher, for me, is that he wrote an article about the emergence of money that is compatible with my theory of human evolution. Once one has a theory, anything fits it. You are listing confirmatory evidence for Szabo,

but where's your \*disconfirmatory\* evidence? For example, the \_Sunday Times \_ just posted an article on Satoshi where Wei Dai pans the Szabo theory for the simple reason that no one has seen Szabo write C++ code, much less code dealing with cryptography & IRC & P2P networking. Coding is not a skill you pick up overnight! So, where is the evidence - any evidence - that Szabo knows C++? This is important. This is really really important, given that literally the only thing we know \*for certain\* about Satoshi is that he knows how to write C++ & English. If one's favored candidate can't be shown to be an experienced C++ coder, that's a fatal problem for one's theory. Seth: Szabo asked for help coding his ideas. No one disputes that.

Lively discussion of this post over on Reddit: [http://www.reddit.com/r/Bitcoin/comments/205396/seth\\_roberts\\_on\\_nick\\_szabo\\_being\\_satoshi\\_nakamoto/](http://www.reddit.com/r/Bitcoin/comments/205396/seth_roberts_on_nick_szabo_being_satoshi_nakamoto/)

alphageek (2014-03-11 11:55:30)

Szabo is the author of the paper. Finney is the author of the code.

dearieme (2014-03-11 12:10:32)

I am Spartacus. :)

jason y (2014-03-11 15:20:05)

gwern, if Szabo could write C++ code, what do you think the probability is that you wouldnt have found any evidence of it? i know you're just making up a number, but i trust your judgment.

gwern (2014-03-11 16:11:43)

> Seth: Szabo asked for help coding his ideas. No one disputes that. That evidence has already been explained and screened off: he still needs that help. Interesting as Bitcoin is, if you've read Szabo's papers (and not third-hand summaries), Bitcoin can still only be shoe-horned in as a very limited and partial implementation. Incidentally, does that reply mean you concede all of my other points? > Finney is the author of the code. Alphageek, have you compared the bitcoin-0.1.0 code to some of Finney's code like the RPOW server? > gwern, if Szabo could write C++ code, what do you think the probability is that you wouldnt have found any evidence of it? I don't know. I have not finished looking into the matter to my own satisfaction. My point here is that ability to write C++ is the single most important piece of evidence in favor of being Satoshi, and yet, almost every Satoshi speculator ignores it or dismisses it in a sentence. I'm reminded of [http://lesswrong.com/lw/35d/inherited\\_improbabilities\\_transferring\\_the\\_burden/](http://lesswrong.com/lw/35d/inherited_improbabilities_transferring_the_burden/) and [http://www.gwern.net/Death %20Note %20Anonymity](http://www.gwern.net/Death%20Note%20Anonymity)

anand srivastava (2014-03-12 04:24:45)

What do you think about the utility of gold and other collectibles in the modern times where you can trade with currency. Why do very rich people buy rare works of arts for huge amounts?

Brock in HK (2014-03-12 07:51:19)

I am Spartacus

Todd Fletcher (2014-03-12 10:02:03)

Agree 100 %. I read Szabo's website before reading Nakamoto's white paper and the frame of mind is the same, and it's a singular one; nobody else I have encountered had the same angle on it

Adam (2014-03-12 13:12:40)

About the initials: Szabo is a hungarian name and in hungary you always start with the last name, thus it's Szabo Nick (SN)

dearieme (2014-03-12 06:45:19)

The most important Soviet defector to British Intelligence (sorry, I can't remember his name) said that he chose the UK rather than the USA because he knew that US Intelligence was thoroughly penetrated.

## "Dawn of Genomic Medicine" (2014-03-13 05:00)

According to the headline of [1]a Yahoo News article, "the dawning of the age of genomic medicine" is upon us. There has been little impact of genomics but "that is finally changing," says Julie Steenhuysen, the author of the article.

I was curious how this would be argued. Here's how:

Sambrookes had been very athletic as a young teen, but as she matured, she noticed a heaviness in her legs. By age 20, running left her tired. At 40, she needed a pacemaker, just like her mother did at that age.

"I started thinking there is something to this," said Sambrookes, now 56, who lives in Michigan City, Indiana.

After some dead ends, she found McNally, who cast a wide net, testing for more than two dozen genes that could account for Sambrookes' heart and muscle problems.

The culprit turned out to be a mutation in a gene called Lamin that causes Limb-girdle muscular dystrophy. The disease can cause weakness and wasting of the muscles between the shoulders and knees. The mutation can also cause electrical disturbances of the heart.

McNally recommended Sambrookes replace her pacemaker with an implantable cardiac defibrillator that could protect against sudden cardiac death.

That proved to be the right call. Last August, Sambrookes' heart stopped three times. Each time, the defibrillator shocked her back to life.

"She literally tried to die three times," McNally recalls of her patient. "It still takes my breath away."

Because someone recommended a pacemaker be replaced with a defibrillator, genomic medicine is a good idea. The benefits of genomic medicine must remain elusive if you have to use such a poor example to support it.

1. [http://news.yahoo.com/dawning-age-genomic-medicine-finally-213006405--finance.html;\\_ylt=AwrBEiJE6hhTvjAAKkDQtDMD](http://news.yahoo.com/dawning-age-genomic-medicine-finally-213006405--finance.html;_ylt=AwrBEiJE6hhTvjAAKkDQtDMD)

---

August (2014-03-13 06:02:18)

The forums on 23 &me led me to realize that I had a poor ability to process sulfur. It seems like 'genomic medicine' is all about making a pill or medical process, but the benefits seem to come from sharing experiences. 23 &me tries to discover things by survey, but like most surveys, there are often questions that I can't answer correctly because they've got multiple choice answers that don't quite apply.

Jack (2014-03-13 10:07:05)

What the lady had in common with her mother was that she probably grew up eating the same kinds of foods as her mother, and that they were both going to Medical Doctors who were on commission. Neither one probably tried changing their diet or pursuing natural cures. Chances are it had nothing wjatsoever to do with genetics. Genetics is nothing more than modern day voodoo, and a new scam to milk money out of unsuspecting gullible moroins who will put their health into the hands of modern witch doctors who only know how to prescribe poisons, un-needed tests, dangerous surgeries and dangerous radiation and other procedures.

JV (2014-03-13 11:04:46)

This just shows that the advances are being pushed by those of us interested enough to look for genetic answers. She states she found someone to test and help her "after some dead ends" - she actively pursued answers! For those of us willing to look hard there are emerging answers in our genetics at places like 23 and Me. I have been dismissed by doctors saying it isn't proven science yet but there is lots of information there if you are willing to dig - and a lot backed by research studies that have not become mainstream yet

Allan Folz (2014-03-13 12:16:23)

I'm confused about the defib vs. pacemaker distinction. They say the new defib saved her life on three occasions, but they leave hanging in the air whether the pacemaker had been doing the same thing in a prophylactic manner all along. It's like

saying a parachute saved your life three times, but your old way of making sure the aircraft had enough reserve fuel to reach its destination in event of a stiff headwind didn't accomplish anything. I can appreciate there might be additional advantages to the defib, but saying it saved your life vs. a pacemaker isn't necessarily one of them. I hate reporters. Are they really that logically challenged, or do they think the rest of us are idiots?

Retired now (2014-03-13 14:25:44)

To me the whole point of knowing one's genome is how to avoid turning potentially problematic genes on in the first place and if one has inadvertently turned them on how to turn them off. A drug or gadget isn't going to fix anything.

Seth Roberts (2014-03-13 14:57:42)

"I hate reporters. Are they really that logically challenged, or do they think the rest of us are idiots?" I think they have a job that, like almost all jobs, requires steady output. The fewer questions you ask the faster you can finish the piece. So long as the result is not obviously idiotic, they are okay. There is a tradition in science/health reporting of giving authorities a free pass - allowing them to say anything, no matter how self-serving, without criticism. I do wonder if their critical faculties erode from disuse. If years of not being critical cause them to lose the ability to be critical.

Seth Roberts (2014-03-13 14:59:39)

"The forums on 23 & me led me to realize that I had a poor ability to process sulfur." What happened next? Did you stop eating sulfur-containing foods? If so did anything change?

dearieme (2014-03-13 18:20:32)

When I had my first cardiac arrest I fell on top of my bike and the mechanical shock restarted my heart. Pushing a bike around with you everywhere in life would be inconvenient I admit. And you are not likely to gain advantage from it in bed, for example. But sarcasm aside, I agree with Seth. You don't half weaken a case by citing feeble evidence.

JV (2014-03-13 20:20:24)

Pacemakers and defibrillators are not the same thing - a pacemaker alone will not restart a heart that has stopped completely - they only adjust the pace of a heart's rhythm. Although I believe they now have combined units that can perform both functions but if you don't have one of these types you don't get both benefits

Allan Folz (2014-03-13 21:00:22)

I understand they are not the same thing. What I don't understand, and what I'm asking is would her heart have likely stopped if it was connected to a pace maker. It's suspiciously convenient (well, to my cynical mind anyway) that within weeks/months(?) of her switching from a pace maker to a defib, the defib starts firing away, saving her life three times. OK, it could happen, and that's great if so, but it's just kind of hanging there in the story. I think that's called begging the question. No? Of course, I'm not a paid journalist. I could be wrong.

dearieme (2014-03-14 03:08:56)

I want to know what happened to Ma and Grandma. By implication they carried the gene. Did they suffer atrial fibrillation/cardiac arrests? Because if they did the recommendation to get an implanted defib would have been sensible without the genetic fol-de-rol.

JV (2014-03-14 07:40:17)

Good question about the relatives dearime, I agree the article seems incomplete. Also being saved by falling on your bike after cardiac arrest sounds like a one in a million type thing, you're a very lucky guy! Allan they probably replaced the pacemaker with a defib that could also pace her heart - I have a friend whose defib (after firing several times) was upgraded to one that could also pace - as his heart gets weaker it keeps him in a more regular rhythm to spare the damaged heart muscle as much as possible.

August (2014-03-14 14:33:32)

Initially I dropped anything I could associate with sulfur. I can handle some now, but I had overloaded my system. I started taking molybdenum, which is need for the enzyme. I notice beneficial effects immediately. I think anyone suffering I.B.S symptoms ought to consider sulfur may at least be a contributor to the problem. Seth: Thanks, that's good to know. You mean these two events - (a) stopped sulfur and (b) started molybdenum - happened at the same time? What is "the enzyme"?

dearieme (2014-03-15 12:44:44)

The Old England Journal of Medicine comes up trumps again! You should supplement your bike (for outdoor use) by having a bright wee daughter, for indoor use. <http://www.dailymail.co.uk/news/article-2581537/Schoolgirl-Izzy-McCarron-9-saves-fathers-life-kicking-chest-heart-stopped.html>

Mark (2014-03-14 06:35:47)

Seth, That magnesium study has precisely the same problems as the Willett studies that we had been discussing. Look at Table 1. Across the board, almost every indicator of health (except physical activity, but more on this below) increased monotonically across the magnesium quartiles. The folks in the highest quartile were inherently healthier than those in the lower quartiles. This inherent (i.e., unmeasured) difference cannot be adjusted for in statistical models. Incomplete adjustment for "potential confounders" (or even "known confounders") can just as easily increase the net confounding bias as reduce it. Regarding the physical activity measure, I'm skeptical. They measured it in hours per day, and the averages ranged between 4.5 and 4.9 (hours per day!!) across the quartiles. I'd wouldn't put much weight on that one! I wouldn't use this study as a reason to start taking magnesium!

dearieme (2014-03-14 12:44:23)

Ahoy, Seth [http://pipeline.corante.com/archives/2014/03/14/going\\_after\\_poor\\_published\\_research.php](http://pipeline.corante.com/archives/2014/03/14/going_after_poor_published_research.php)

Seth Roberts (2014-03-14 14:04:44)

The real problem isn't the research that is done (which is easy to ignore), it is the research that isn't done. E.g., the narrowness of research at medical schools. Ioannidis has never shown any sign of understanding that.

dearieme (2014-03-14 14:46:58)

Ahoy Seth, Ben Goldacre seems to be admitting that his study of statin side effects is on a par with much "Climate Science" i.e. it's twaddle based on lousy data. <http://www.theguardian.com/science/blog/2014/mar/14/statins-side-effects-study-placebo-ben-goldacre> Why on earth would he choose to compromise his reputation with such rubbish? There's nowt so queer as folk.

Seth Roberts (2014-03-14 18:53:27)

Ben Goldacre's misunderstanding, as revealed in that article, is epic. First, he doesn't explain how he knows statins do cause muscle pains. I'm sure they do – but how does Goldacre, the evidence snob, know? Second, his explanation for why his study got the wrong answer makes no sense. "Incomplete data"? All studies have incomplete data.

James (2014-03-17 08:42:40)

Antibiotics cause weight gain - but why? Could childhood antibiotic use promote obesity in later life? [http://www.nytimes.com/2014/03/09/opinion/sunday/the-fat-drug.html?\\_r=0](http://www.nytimes.com/2014/03/09/opinion/sunday/the-fat-drug.html?_r=0)

## **The Wisdom of Google: "Dessert", "Honey" and "Fruit" Closer to "Dinner" than "Breakfast" or "Lunch"** (2014-03-16 05:00)

I have [1]blogged many times that bedtime honey improves sleep. I learned this from [2]Stuart King, an Australian musician. He also pointed out we eat dessert with dinner more than with other meals. Which others who have described the honey effect [3]have not said. The dessert observation suggests that other sweets, not just honey, improve sleep. After I repeated the dessert observation, a friend said I of all people should know it isn't universal. The Chinese don't eat dessert, she said. Yes, I said, but where I lived in Beijing there seemed to be lots of sweets eaten in the evening, and lots of street vendors selling fruit in the evening.

The honey-sleep connection helped me improve my sleep in other ways. I found my sleep got better if in addition to bedtime honey I ate fruit (e.g., banana) an hour or so before bedtime. My sleep got even better if I ate something sweet, such as Yakult, an hour or so before that. Both observations implied that honey improved sleep because of the sugar. Nowadays I usually eat three sets of sweets: soon after dinner, mid-evening, and bedtime. I sleep very well every single night, better than ever before. These findings make sense if glycogen (stored glucose) is very important for sleep. My way of eating (three sets of sweets slightly spread out) may produce more glycogen at bedtime than similar ways of eating (e.g., eating the same sweets spread throughout the day).

Recently I realized that Stuart's observation about dinner and dessert made a prediction: the word dessert should be better associated with the word dinner than the words breakfast and lunch. (A lot of talking/writing consists of describing reality.) I used Google to test this prediction. I counted the hits returned when I searched "dessert dinner", "dessert breakfast", and "dessert lunch". The prediction turned out to be true: "dessert dinner" had a lot more hits than the other two combinations, even though breakfast, lunch and dinner are almost equally common.

I checked about forty other food words: Were they more associated with one meal than others? I found several interesting things.

1. It wasn't just dessert. Honey and fruit were associated with dinner more than breakfast or lunch. The size

of the association was very similar in the three cases. For almost all other food words I tested there was little or no association.

[4] 

Here are examples of little or no association.

[5] 

2. There were some surprising associations, shown here.

[6] 

No surprise that tea is associated with breakfast but why is potato associated with lunch? French fries? Why is nuts associated with dinner? Do nuts contain something that improves sleep?

For each food I computed a "dinner effect" meaning the  $\log(\text{dinner count})$  minus the average of  $\log(\text{breakfast count})$  and  $\log(\text{lunch count})$ . Here is a kind of histogram of those values.

[7] 

The outlier status of nuts, fruit, honey and dessert is clear.

These findings support (a) the original idea (because the original idea led to them), (b) the importance of the original idea (because the association is so clear) and (c) use of Google to learn what people do. Word associations are influenced by many things, no doubt; these results suggest actual behavior is a strong influence. Use of Google to study behavior is free, public, fast, and convenient.

I was surprised the results were so clear. I suspect the explanation is that sweets taste better closer to bedtime. Dessert, honey and fruit differ in many ways; the similarity of size of association suggests that the association is due to what they share (sugar).

I hereby give you permission to eat dessert with dinner.

Jeremy (2014-03-16 08:11:03)

Breakfast seems to me the most commonly eaten sweet meal. Often breakfast is nothing but some pastry, cake, or dessert, in many countries (jam is a breakfast food, cereal, pain au chocolate, etc). Dinner is always real food perhaps followed by a desert,

but never just a desert like breakfast often is.

gwern (2014-03-16 08:55:53)

So, in your Anglosphere-customized-search-results, dessert is associated with dinner. ...did anyone actually doubt that? What happens when you look at Google results in, say, Urdu?

Sara (2014-03-16 10:26:53)

Very interesting post.

Adam (2014-03-16 13:57:56)

I got 5.6 million hits for "dessert" and "breakfast" in Chinese; 14.7 million hits for "dessert" and "dinner" in Chinese.

Adam (2014-03-16 13:59:29)

Tons of hits for honey and breakfast though! It seems drinking honey water for breakfast is very popular in the Chinese speaking world. Even my wife does it.

Jeremy (2014-03-16 15:24:58)

The problem is the word "dessert". The definition of that is something that comes after a meal, usually dinner. Do a search for "sweet" and I am sure it will come up more associated with breakfast than dinner. As I said above, breakfast is often primarily sweet while dinner is always non-sweet + perhaps some sweet at the end. Sweet in the morning seems far more prevalent than the other way around. Also, afternoon snacks are often sweet as well. It would seem, then, that traditionally, while dessert would often follow lunch or dinner, those meals were always largely non-sweet, and sweet was far more associated with early morning and afternoon eating and that sweet was only a minor part of evening eating.

Seth Roberts (2014-03-16 16:31:42)

The results for dessert are very close to the results for fruit and honey. All three should be explained the same way. Where is the word dessert defined as you say ("something that comes after a meal, usually dinner")? I cannot find a definition of dessert that includes "usually dinner" or something like that. That is not the meaning I learned.

Seth Roberts (2014-03-16 16:32:16)

yes, drinking honey with breakfast is very popular in China. I wonder if that has something to do with high rates of diabetes in China. Maybe the problem is not how much sweets they eat but when they eat them.

daz (2014-03-16 17:47:27)

another confounding factor, for some people dinner could be lunch... From wiki, "Dinner usually refers to the most significant meal of the day, which can be the noon or the evening meal. However, the term "dinner" can have many different meanings depending on the culture; it may mean a meal of any size eaten at any time of day.[1][2] Historically, it referred to the first meal of the day, eaten around noon, and is still occasionally used for a noontime meal if it is a large or main meal. However, the meaning as the evening meal, generally the largest of the day, is becoming standard in the English-speaking world." <http://en.wikipedia.org/wiki/Dinner>

dearieme (2014-03-16 17:47:28)

My childhood breakfast was porridge followed by either a kipper or bacon and eggs. The Dutch like ham and cheese at breakfast, in my experience. So that's the civilised world covered: maybe the rest eat jam.

daz (2014-03-16 17:59:04)

when i was growing up in the UK in the 70's, from memory, my mum called me in for dinner for the early evening meal, whereas my mates mum called him in for Tea (he had has 'dinner' at lunch time). & then there's the term supper as well, <http://en.wikipedia.org/wiki/Supper>

daz (2014-03-16 18:05:03)

since i've linked the wiki's for dinner & supper, i may as well add the Tea wiki link as well, that's Tea as meal (not as a drink), [http://en.wikipedia.org/wiki/Tea\\_\(meal\)](http://en.wikipedia.org/wiki/Tea_(meal))

mikimoonmouse (2014-03-16 19:39:58)

Seth, you are clearly no cafe drinker !

mikimoonmouse (2014-03-16 19:49:26)

In France there is a saying that breakfast in Germany is the beginning of a laborious day, while in France it is the end of a wonderful night. Maybe breakfast is a belated dessert.

dearieme (2014-03-17 15:40:24)

Ahoy, Seth. The OEJM speaks: <http://www.dailymail.co.uk/health/article-2582867/Saturated-fat-DOESNT-cause-heart-disease-all.html>

gwern (2014-03-17 16:13:05)

> I cannot find a definition of dessert that includes "usually dinner" or something like that. That is not the meaning I learned. I suggest getting a better dictionary. From the OED, first definition of 'dessert': > dessert > > (di'zɜ:t) > > Also 7-8 desert, 8 des-, disart, 9 desert. > > [a. F. dessert (Estienne 1539) 'removal of the dishes, dessert', f. desservir to remove what has been served, to clear (the table), f. des-, L. dis- + servir to serve.] > > 1. a.1.a A course of fruit, sweetmeats, etc. served after a dinner or supper; 'the last course at an entertainment' (J.). > > 1600 W. Vaughan Direct. Health (1633) ii. ix. 54 Such eating, which the French call desert, is unnaturall. 1666 Pepys Diary 12 July, The dessert coming, with roses upon it, the Duchesse bid him try. 1708 W. King Cookery 261 'Tis the dessert that graces all the feast. 1739 R. Bull tr. Dedekindus' Grobianus 96 If the Guests may pocket the Desart. 1834 Lytton Pompeii iv. iii, The dessert or last course was already on the table. 1846 J. Baxter Libr. Pract. Agric. (ed. 4) II. 69 The Medlar when in a state of incipient decay is employed for the dessert. 1875 Jowett Plato (ed. 2) III. 696 Pleasant kinds of dessert, with which we amuse ourselves after dinner. Seth: The quotations do not support the definition. They are consistent with "after a meal".

Kirk (2014-03-17 16:57:14)

I agree that the term 'dessert' is associated with dinner/supper. An alternative analysis would look at the number of 'defined' breakfasts on the published menus of 'diners' such as Dennys. (Note: this is an American analysis.) Glancing at the menu at dennys.com, I see 26 defined items in the Breakfast section (not including the last one, Breakfast Sides). Some are sweet, some are not. The sales figures probably aren't available, so one has to count simply by availability. Without looking at actual ingredients (using the names), I count seven as being primarily sweet (such as the French Toast Slam). But even those customers who order a non-sweet selection could spread jam on their bread and put sugar in their coffee.

## Heart Emergencies by Appointment at Mt. Sinai Hospital (2014-03-18 05:00)

[1]A recent *Bloomberg News* article looked into why Mt. Sinai Hospital in New York did a very large number of heart procedures, making its cardiologists very well-paid. One reason, the journalists discovered, is that patients had been told to lie:

On a pair of representative Sundays in 2012, 10 patients told ER workers they'd been instructed to arrive there before their cath-lab appointments, according to internal hospital correspondence. Two of them said they'd been coached to say they were having acute symptoms of heart disease, according to the exchanges.

Even more remarkable, the journalists found, was that many patients had cardiology appointments before they showed up at the emergency room:

Certain patients who showed up at Mount Sinai Hospital's emergency room on Sunday mornings stood out [because] they already had appointments. Each was scheduled for a procedure at Mount Sinai's catheterization lab, where cardiologists thread wires and tubes into blood vessels to detect disease and insert cardiac stents. The New York hospital's cath lab has regularly scheduled such emergencies-by-appointment, according to three doctors and another medical professional, all of whom said they had direct knowledge of the practice.

Larry Husten, a medical columnist at Forbes, [2]argues that this is an example of a widespread problem.

1. [http://www.bloomberg.com/news/2014-03-06/mount-sinai-cath-lab-takes-nyc-heart-emergencies-by-appointment.html#disqus\\_thread](http://www.bloomberg.com/news/2014-03-06/mount-sinai-cath-lab-takes-nyc-heart-emergencies-by-appointment.html#disqus_thread)
2. <http://www.forbes.com/sites/larryhusten/2014/03/06/what-ails-mt-sinai-hospital-ails-the-entire-us-healthcare-system/>

---

dearieme (2014-03-18 07:46:22)

I originally read "The New York hospital's cath lab" as 'cash lab'.

Joe (2014-03-18 09:11:29)

That's just the tip of the iceberg. Stents now comprise 85 % of coronary interventions. Drug-coated stents cause even more blood clots than the non-coated ones, but, of course, bring in even more money for the hospital. For the past 15 years or so (after all this expensive intervention), heart attack rates have remained relatively constant. First, do no harm? Nah. First, let's make some money.

Karen (2014-03-18 10:11:53)

I don't see why this isn't enough to send people to prison.

Joe (2014-03-18 10:55:21)

Best-selling author Kevin Trudeau jailed for TEN YEARS as judge calls him an 'uncontrollable huckster' for selling fake weight loss tips <http://www.dailymail.co.uk/news/article-2582977/TV-pitchman-Kevin-Trudeau-get-s-10-year-sentence.html> Question: What's the difference between what Trudeau does and what a lot of BigMedicine and BigPharma do today? Stents (and other procedures, like tonsillectomies, Caesarian deliveries, etc.) that aren't needed (or that actually cause harm), drugs that aren't needed (or that actually cause harm), etc. I'm not aware of anyone losing his life because of Trudeau's false claims. The same can't be said of BigPharma and BigMedicine. They all defraud and con the public, but only Trudeau goes to prison? :( PS: Yes, I

know the real reason is that Trudeau violated several court orders, but you know what I'm talking about.

JM (2014-03-18 11:45:11)

Joe has a very good point - we have had Trudeau's case plastered across the Chicago newspapers recently. Part of the problem is that Big Medicine and BigPharma has everyone convinced, from most of the doctors on down through nurses and to the average citizen that things like stents and drugs save lives. And most people, if told that they need one of these things, are too frightened to say no or even ask questions about alternatives because they are convinced they are going to die without them.

Joe (2014-03-18 13:13:14)

I think I'll throw in BigGov, too, for things like "The Food Pyramid," "The Food Plate," "You can keep your insurance company. Period.", mass "swine flu" vaccinations, "global warming" hysteria, etc. Trudeau should have an awful lot of company in the dock, no?

Robin (2014-03-19 00:42:30)

Wow another example of how the "health" system in the US is well and truly f\*! %ed.

### **Truth to Power: Eric Lander's Reddit AMA (2014-03-19 05:00)**

A year ago, Eric Lander, who identified himself as "President and Founding Director of the Broad Institute of Harvard and MIT [and] one of the principal leaders of the Human Genome Project, directing the largest center in the international project" did a Reddit AMA (Ask Me Anything). One of the questions did not go as expected:

Question As an advisor to the President, what is being done or do you think will be done to increase the attractiveness of students finishing PhD programs in science?

Lander We need to shorten the time for getting a PhD and for a first faculty job. Young people should get out into the scientific world early, when they have lots of fresh ideas. We should encourage grants to young scientists and should encourage them to take big risks. When you're taking big risks, science is amazingly fun.

The response to this answer was very negative.

With all due respect, this is a ludicrous statement. . . The true problem is the way in which you fund science. You fund projects and proposals. In order to get these projects funded, the preliminary data has to be essentially the whole project being done. Then you fund at a 6 % percent line. It leads to cronyism in the peer review process and a general sense of despair in scientists. How about you radically change the funding system for PIs?

I too am disappointed with Dr. Lander's response to possibly THE most important question here regarding training basic scientists.

Do you truly believe this? . . . There is no reason to encourage more students to go into science if there is not enough government funding to support their careers.

Alas, this is not important. It just pleased me that someone questioned Dr. Lander's absurd claims, which he makes often. "We should encourage young scientists to take big risks". Yes, I agree, does he really believe this? Do he really believe that someone coming up for tenure should take big risks?

---

Joe (2014-03-19 09:17:17)

"Question As an advisor to the President, what is being done or do you think will be done to increase the attractiveness of students finishing PhD programs in science?" Wear more makeup? Wear designer clothes? Yep, that ought to help. Sorry, I couldn't resist. :)

dearieme (2014-03-19 12:12:28)

I find it hard to see why spirited youngsters would want to be ground in the sausage machine that eventually spits out tenured jacks-in-office. Hell, you could be into your forties before you were able to tackle a project that you had chosen yourself for its intrinsic interest. It's a far cry from the best science lab there's ever been, with Ernest Rutherford's bright young men at the Cavendish. I'm very proud of persuading my daughter not, Not, NOT to do a PhD. Seth: A very smart Berkeley grad student in biology told me she had decided to leave academia after seeing up close what professors had to do – how hard they worked. She had entered grad school thinking she wanted to be a professor.

dearieme (2014-03-19 13:58:49)

Aye, Seth, when I left academia to work in industry my new colleagues could scarcely believe how much work I got through.

### **Cheap Accurate Home HbA1c Test (2014-03-20 05:00)**

Walmart sells [1]a kit for home measurement of HbA1c (brand name ReliOn) that costs \$9 and provides results by email. It's sold only at Walmart. I have been paying \$30 for the same measurement at a test center (about 30 minutes away). If you use insurance, copay might be \$15. Without insurance, a doctor's office test might cost \$90. The reviews suggest the test has roughly the same variability and average as a lab test. A few people had trouble getting enough blood on the dots but at \$9 there is plenty of room for repeat testing.

My blood sugar improved when I started to walk an hour per day and when I started intermittent fasting (eating about half as much as usual every other day). I noticed the effects with blood sugar tests but frequent HbA1c tests (say, once/week) would have been much better.

Diabetes has become an enormous problem in China, where 10 % of adults have Type 2 diabetes, roughly the same as in America. Americans often think obesity causes diabetes but this doesn't explain why smoking – which makes people thinner – [2]is associated with diabetes. People get diabetes who don't smoke and aren't fat. Whether anyone who walks an hour/day gets diabetes is less clear.

Thanks to Shant Mesrobian.

1. <http://www.relion.com/diabetes/a1c-test>

2. <http://www.ncbi.nlm.nih.gov/pubmed/11063954>

---

Joe (2014-03-20 12:38:01)

Seth, this may be another example of how associations/correlations can lead us astray. What if smoking per se has nothing to do with getting diabetes? What if obesity per se has nothing to do with getting diabetes? After all, most smokers and most obese people do not have diabetes, right? "As a young surgeon, Peter Attia felt contempt for a patient with diabetes. She was overweight, he thought, and thus responsible for the fact that she needed a foot amputation. But years later, Attia received an unpleasant medical surprise that led him to wonder: is our understanding of diabetes right? Could the precursors to diabetes cause obesity, and not the other way around? A look at how assumptions may be leading us to wage the wrong medical war." [http://www.ted.com/talks/peter\\_attia\\_what\\_if\\_we\\_re\\_wrong\\_about\\_diabetes](http://www.ted.com/talks/peter_attia_what_if_we_re_wrong_about_diabetes) What do many smokers and many obese people have in common besides diabetes? What do the smokers and obese people without diabetes have in common? Etc.

Adam (2014-03-20 16:39:39)

Smokers and obese people have lower IQs: <http://jaymans.wordpress.com/2013/04/30/obesity-and-iq/>  
<http://www.reuters.com/article/2010/02/23/us-smokers-smarter-idUSTRE61M3UQ20100223>

Parser (2014-03-20 22:38:40)

Seth, perhaps clarify this sentence: "People get diabetes who don't smoke and aren't fat. " I couldn't parse it. Seth: Some diabetics (a) aren't fat and (b) don't smoke.

Jazi Zilber (2014-03-27 19:57:56)

There is a completely done at home within five minutes test <http://www.amazon.com/A1CNOW-SELF-CHECK-BAYER-HEALTHCARE-DIABETES/dp/B004N11OGQ>

Seth Roberts (2014-03-27 23:26:19)

if you buy 10 tests it costs \$15/test. Very interesting.

---

Shelley (2014-03-21 11:35:15)

How are your sinuses? I was helped so much by your Baby Shampoo post. I am anti Komen for many reasons. Komen thinks Mastectomy, radiation, and chemo: Moderate and normal. Not eating meat: Radical and ridiculous. Komen uses 85 % of the \$ \$ they take in to make MORE money, not on "the cure" at all and they focus on drugs and "moderation" instead of what we all already KNOW will help prevent cancer—a low fat, plant-based diet!!!!!!!!! The pink ribbon on the KFC bucket of chicken was the last straw for me.

GB (2014-03-21 14:57:03)

Do we really KNOW that Shelley, or do we just think we know it because of some grand epidemiological studies and confusion over the healthy user effect? I'm certainly unconvinced. I mean, we KNEW 40 years ago that lowering saturated fat and increasing carbs would make us all healthy and free of heart disease and diabetes. Many of us still know it. And now we're all fat. From past presentations, Seth was (is?) eating half a stick of butter a day. I suspect reduction of processed foods and all the inflammatory crap in them is much more important than minimising animal protein.

GB (2014-03-21 15:02:37)

But totally agree with you on KFC, that stuff may well cause cancer

Alex (2014-03-21 19:38:03)

The rant missed other problems with Komen. For an organization that goes after other charities, and not just cancer groups, who use "for a/the cure," it doesn't care that much about a cure. It spends just 21 % of its budget on research. When my friend was diagnosed with inflammatory breast cancer seven years ago Komen didn't even have any information about it on their website. IBC affects younger women, has a high mortality rate, does not show up on mammogram, and is frequently misdiagnosed as an infection. It really needs the awareness push. Komen also decided in 2112 to stop giving money to Planned Parenthood, which for many women is the only place they can afford to get a mammogram. The backlash convinced Komen to reverse course, but it was an eye opener for many people who had supported the group until then.

Shelley (2014-03-21 20:32:08)

GB- Have you read the China Study? The research project culminated in a 20-year partnership of Cornell University, Oxford University, and the Chinese Academy of Preventive Medicine, a survey of diseases and lifestyle factors in rural China and Taiwan. More commonly known as the China Study, "this project eventually produced more than 8000 statistically significant associations between various dietary factors and disease." The findings? "People who ate the most animal-based foods got the most chronic disease ... People who ate the most plant-based foods were the healthiest and tended to avoid chronic disease. These results could not be ignored," said Dr. Campbell.

Tim S. (2014-03-22 02:02:16)

Interesting on the soya... Want to test myself, had been avoiding soya – Seth, can you email me the R code you use for your reaction time testing? Thanks! Tim Seth: I'm no longer distributing it for free. Sorry.

Joe (2014-03-22 08:38:26)

Shelley, have you read these <http://chriskresser.com/rest-in-peace-china-study> "Denise got hold of the raw study data and took it apart with a fine-toothed comb. And what she found is that the claims Campbell made in his China Study book are not supported by the data. She also found important data points Campbell never bothered to mention in the book because they didn't support his vegan agenda" Denise Minger dismantles The China Study: <http://rawfoodsos.com/2010/07/07/the-china-study-fact-or-fallac/>

GB (2014-03-22 12:38:01)

Cover to cover Shelley. When I mentioned 'grand epidemiological studies', that's the chief one I had in mind. I'm all for people doing whatever makes them feel healthiest, so best of luck to you. I've got some great friends who went vegan and feel the

best the ever have (hence why I read the book 5 years ago and did quite a lot of amateur research and self-experimentation afterward). But you shouldn't say 'what we all already know will help prevent cancer' based on that work, it cannot and hasn't proven anything scientifically. And the follow up trials haven't been enough to bring me around as yet. Again, the evidence for removing processed rubbish and large amounts of sugar seem much, much more clear cut. But good luck to you if you've found what works!

Teresa (2014-03-22 19:03:50)

Planned Parenthood does not perform mammograms. Never has. That was a made-up media sob story. Check your facts. That said, Komen's caving to political and media pressure in that widely publicized incident seems to have ticked off both supporters and critics of Planned Parenthood and prompted many to take a closer look at Komen.

James (2014-03-23 04:03:26)

An ethics committee stops an MS patient receiving HSCT (stem-cel transplant) treatment mid-course, and won't allow another to be treated, who then goes to Russia at great cost to receive the therapy: [http://clubtrotppo.com.au/2014/03/15/edicts-from-on-high-ii-ethics-committee-e dition/](http://clubtrotppo.com.au/2014/03/15/edicts-from-on-high-ii-ethics-committee-e-dition/)

James (2014-03-23 04:05:01)

As with CCSVI, the MS organisations aren't supportive of new treatments: <http://www.msaustralia.org.au/news/ms-australia-statement-autologous-hematopoietic-stem-cell-transplant-hsct-treatment> Blog of the second patient: <http://www.movingmountains2013.com/>

Shelley (2014-03-23 07:45:19)

Joe- Denise Minger? I believe she was apx 23 when she wrote her first rebuttal to the China Study, she is not a doctor, nurse or scientist and on one of her blogs she is self described as a tutor, free lance writer and website designer - are those adequate qualifications to provide a rebuttal to decades of unbiased peer reviewed research? I certainly don't think she is qualified. Whoever is backing Denise Minger, is she the best they can do? Can't they find a real doctor with decades of research to provide a serious rebuttal? My question to Denise Minger is, if you are as smart as you say you are and you're "community" gives you credit for, why can't you understand the plant based doctors you talk of are promoting a whole food plant based diet rather than a vegan diet? She is supposed to be brilliant, yet she seemingly cannot grasp the whole food plant based diet concept she is supposedly intelligent enough to debunk. If she was legitimate why not just be honest and straight forward about her information without playing games and trying to deceive? Is Denise Minger really the best the low carbers can come up with in their battle against the plant based doctors? They couldn't find a Dr. McDougall, Dr. Esselstyn or Dr. T. Colin Campbell type with professional stature and decades of research and field work to make their case? These days with the internet, Facebook and Twitter everyone with a camera is an expert on any topic regardless of their qualifications, even Denise Minger. Heeeeeeeere's Denise: <http://www.youtube.com/watch?v=heWprUncqlw> This is an absolutely perfect example of why Dr Mc Dougall refuses to call himself a vegan. In her talk, Ms. Minger never mentions that Dr. M has said many times that there are lots of UNhealthy vegans. The point isn't veganism but healthful eating. Which all the plant based gurus espouse. I can't off hand remember all her arguments but I do remember the one about Seventh day adventist vegans and vegetarians having a higher rate of all cause mortality than seventh day adventists who eat fish. However, if you look at the numbers she gave, the difference appears to be small and they are comparing ovo lacto vegetarians to those who eat fish. Which to me is another reason not to eat milk and eggs. The PrimitiveNutrition videos and HealthyLongevity pretty much counter all her arguments on this video. Minger is a perfect example of a lowcarber nutritionist: she is not a doctor, she is not a nutritionist, she has not enough competence respect to a real nutritionist or doctor, she tricks the articles, she tricks the people, she tricks with all the news that she finds only to adapt the truth to her thought. She's so inarticulate and silly that she may actually be doing vegans a favor. With so many negative things to fight in the world, why spend her energy fighting vegans whose philosophy is harmlessness? It really baffles me. She must feel guilty and this is her way of dealing with it.

Joe (2014-03-23 13:13:32)

Shelley: "are those adequate qualifications to provide a rebuttal to decades of unbiased peer reviewed research?" You're

pulling my leg, right? "She's so inarticulate and silly" That's pretty much the way I feel about McDougall. Plus, he's a pretty nasty guy, too. We're not going to change each other's minds, Shelley. Why not give this topic a rest?

Shelley (2014-03-23 15:53:02)

Oh go on Joe have you ever met Dr Mc Dougall in person? NO I am sure you have not. How can you say he's a nasty guy? For a 70-something you should know better than to say someone is nasty whom you have never even met. I am not pulling your leg about Denise! I listened again to part of a crappy speech of Denise Mingers. There is lots of evidence during it that she is reciting something someone else wrote with all the stumbling she does throughout it. Further this is what she used to have up on her webpage, before she had the sense to take it down: ..... Denise Minger wrote: About Me ... I started college when I was 16, switching majors about ten times but ultimately deciding on English. I currently live in Portland, Oregon and work as a freelance health writer, teacher, and web designer. .... Joe-you are 70 so you surely must know what freelance writers do-right ? They write what they are paid to, when they are paid to, for whoever pays them! In her case I think the stupid jokes, failed irony, and stupid quips are all her, but the cherry picked out of context, and twisted data from studies she cites and the minority conclusions she presents as mainstream research is fed to her. I am sure she is quite well paid for her services and I don't see her as really caring about health - hers or that of others, just like all the other low carb, high animal products, fad diet pushers. It is obvious that the only thing she brings is lame jokes and failed irony, while someone else is feeding her info and paying her bills. I give up on you Joe but perhaps someone with a modicum of common sense can learn from what I posted about Denise. Joe I feel bad for you are 70 and you have been duped.

Shelley (2014-03-23 15:56:30)

Joe-at 59 seconds you can see Loren Cordain & his book "The Paleo Diet" <http://www.youtube.com/watch?v=2zVxA6yipv4> Where do you get the idea that eating lots of meat and fat lowers cholesterol? When someone is losing weight, their cholesterol lowers. However, at some point the cholesterol has to go up because you are eating lots of meat and fat. On the Atkins diet, the LDL is high. Jimmy Moore who has a website called Livin La Vida Lo Carb has GAINED weight on his paleo low carb diet and now is on a diet that is even higher in fat and is ketogenic. In a talk in Australia which is on you tube somewhere on the net he says his cholesterol is over 340 and his LDL is around 240. He isn't worried. Some people think there is no connection between cholesterol and heart health-!!!! I am wondering how Jimmy got fat on his paleo diet which is supposed to be the best for losing weight (according to the primal diet people). He evidently thinks it is because he wasn't eating enough fat! Esselstyn's book on preventing and reversing heart disease is worth reading - it will make you confident you have the tools and info to talk to doctors & others who spout nonsense. I know the plant based diet helps with not only heart disease but every other chronic condition as well. That is the beauty of the Mc Dougall program. One diet, one approach to combating ALL chronic conditions. Some people hate it to hear that one diet can be the answer for the vast majority of issues but it's completely correct. Getting on board is a win-win proposition. Do not pass up the opportunity to read Esselstyn's book. Great info is in there. Plant Positive has made a series of excellent videos. He provides a lot of citations and points out how Paleo is a FAD diet. this first video is a good one. It's concise and worthwhile Paleo is the latest re-packaging of low carb. <http://www.youtube.com/watch?v=egqf7k5Lzhk&list=PLCC2CA9893F2503B5&index=1> The Mc Dougall way of eating is very simple. My advice to anyone is this: just follow it for 4 weeks and see if you like how you feel. Get your weight before starting, a lipid profile and glucose. And then have another test at the end. It does not matter what other people saw or did not see. It is a sample of one in the end ! Why would you rely on what others report, when you can have the answer in 4 weeks for yourself?

Joe (2014-03-23 17:09:17)

"Where do you get the idea that eating lots of meat and fat lowers cholesterol? When someone is losing weight, their cholesterol lowers. However, at some point the cholesterol has to go up because you are eating lots of meat and fat. On the Atkins diet, the LDL is high? One last time, I couldn't care less about my LDL level! Because it has nothing to do with my health (unless it gets too low). But here's a few things (for those of you who still believe in the lipid hypothesis) that WILL get better, your HDL will go way up, your triglycerides will virtually disappear, and your LDL particle size will be large and fluffy, all of which are supposedly VERY "good things." "Some people think there is no connection between cholesterol and heart health-!!!!" Count me among them! Read these books: Malcomb Kendrick, "The Great Cholesterol Con," David R. Hastings, "Cholesterol Conspiracy," Uffe Ravnskov, "Ignore the Awkward, How the Cholesterol Myths are Kept Alive," David S. Grimes, "You Will Not

Die From a Heart Attack," Kilmer McCully, "The Heart Revolution," Stephen Sinatra and Jonny Bowden, "The Great Cholesterol Myth," Ernest Curtis, "The Cholesterol Delusion," David Evans, "Low Cholesterol Leads to an Early Death, Evidence From 101 Scientific Papers," etc. Those will hold you for a while (actually, I know you will never read any of them, because Dr. McDougall said you shouldn't, but maybe others will). "How can you say he's a nasty guy?" Because I know people who know him very well, plus the fact that I've heard him on the radio. And you act very much like him.

Shelley (2014-03-23 19:53:10)

Adios Joe- your poor long suffering wife has had a tough life with you -I will bet \$ \$ on it. hahah

Joe (2014-03-23 21:13:55)

She hasn't had it nearly as hard as your poor ol' husband, who must feel like he's married to Tammy Faye Bakker herself, EH? The horror. The horror.

GB (2014-03-24 00:53:19)

Shelley, if you want to question the lack of credentials of Minger, this probably isn't the blog to be doing it at. One of Seth's great interests is the advantages that an amateur outsider can have over inside professionals - time and time again they make the breakthroughs in science. Question Minger's processes and conclusions if you wish, but to question her lack of authority is a lazy and ill-thought approach.

Shelley (2014-03-22 06:12:26)

The Modern Diet in Graphs piece was interesting. But wow- "heart healthy" butter? eggs are "nutritious"? On what planet? Do you know that eggs have a caloric density of 1000? That is one thousand calories per pound-! Not what you want to eat if you are trying to lose or maintain weight. Someone I know has been looking at the published research on tests done, including published animal research, before the 1970's, on the use of eggs. He was able to find several studies, and they showed eggs caused more heart disease faster than any other animal foods, in the animals studied. Different amounts of eggs were used, and there is no small amount of eggs that do not harm the body. Any one recommending that even 1 egg a week, is healthy, is just plain ignoring the research, and just does not want to understand the truth. THE ONLY REASON 1 egg a week, or 1 egg a day, is considered safe is because it will take a few decades to do major harm to most people consuming that amount. A slower amount of heart disease build up is considered safe by the people making the nations health regulations. Everyone needs to understand this. This is one more reason why heart disease is still the number one killer.

Seth Roberts (2014-03-22 07:08:21)

this study disagrees with you about the dangers of eggs: <http://www.ncbi.nlm.nih.gov/pubmed/11023006> "When dietary confounders were considered, no association was seen between egg consumption at levels up to 1 + egg per day and the risk of coronary heart disease in non-diabetic men and women." so does this study <http://www.ncbi.nlm.nih.gov/pubmed/10217054> "These findings suggest that consumption of up to 1 egg per day is unlikely to have substantial overall impact on the risk of CHD or stroke among healthy men and women."

Shelley (2014-03-22 07:42:11)

OK Thanks- I will inform my friend and look over the links you posted. I used to eat eggs each day. Loved them. Now the thought of eating an egg makes me want to puke. fish eggs cheese all contain dioxins - which increase your risk of many cancers. <http://nutritionfacts.org/video/dioxins-in-the-food-supply/> Chicken and eggs are the top sources of arachidonic acid in the diet, an omega 6 fatty acid involved in our body's inflammatory response. <http://www.youtube.com/watch?v=-0ap3dVC-LM> <http://nutritionfacts.org/video/eggs-vs-cigarettes-in-atherosclerosis/> Eggs are nasty chicken's "periods". Nobody needs the cholesterol in them, as we produce what we need. There are far superior and less expensive sources of protein than nasty slimey eggs!

Joe (2014-03-22 09:09:33)

Shelley, yes, grass-fed butter is heart-healthy, even if you still cling to the blood lipid theory of heart disease. <http://authoritynutrition.com/why-are-eggs-good-for-you/> And eggs are one on the most nutritious foods you can possibly eat. <http://authoritynutrition.com/why-are-eggs-good-for-you/> On the other hand, lipophobia is one of the more deadly disorders out there. Viva la graisse!

Joe (2014-03-22 09:20:30)

Oops! The correct link for grass-fed butter is: <http://authoritynutrition.com/grass-fed-butter-superfood-for-the-heart/>

Gina (2014-03-22 09:42:06)

Joe: Blog posts are not impressive. I can link you to a thousand that say the opposite of Authority Nutrition (lofty!) if you like. In the US, egg producers are not allowed to advertise eggs as healthy or even safe. Seth posted studies that found that eggs are not detrimental to heart health, but other studies link them to atherosclerosis (<http://www.ncbi.nlm.nih.gov/pubmed/22882905>), cancer progression (<http://www.ncbi.nlm.nih.gov/pubmed/20042525>) and diabetes (<http://www.ncbi.nlm.nih.gov/pubmed/22390963>). It's way too easy to get a bad case of confirmation bias with this stuff. If you want to cite blogs as sources, you can do it with anything (<http://theflatearthsociety.org/forum/>).

Shelley (2014-03-22 09:54:13)

Oh Joe-what I have learned about dairy is that it increases the production of a hormone in the body called IGF-1 (insulinlike growth factor 1). IGF -1 is strongly linked to the development of cancer of the breast prostate, lung and colon. T Colin Campbell tells us (The China Study) that "under unhealthy conditions IFG-1 becomes more active, increasing the birth and growth of new

cells while at the same time inhibiting the removal of old cells - this favours the development of cancer” Also high levels of calcium as found in dairy products lower vitamin D and Vitamin D protects against cancer. Dairy also causes constipation. Our bodies are just not designed to process the milk of another species! It amazes me that humans not only consume milk meant for cows, but infant cows at that. Can you think of any species that consumes the milk meant for infants of another species? The medical community of course dismisses this idea because there’s no money to be made in telling people to eat healthy. Then you have the government and their ridiculous food pyramid telling people to consume lots of dairy. Never mind that the dairy industry heavily influences the government to make those recommendations. So my best advice is to stay away from any dairy, raw or otherwise, it ultimately leads to health problems. Based on study after study the most important change you can make in you diet is to eliminate all dairy products RIGHT NOW. The number of autoimmune and degenerative diseases linked to dairy and cheese consumption is long and very, very scary. An excellent book on the subject, based on peer-reviewed scientific evidence is Joseph Keon’s ‘Whitewash: The Disturbing Truth About Cow’s Milk and Your Health’ It’s available at Amazon : <http://www.amazon.com/Whitewash-Disturbing-Truth-Health-ebook/dp/B004FPZ3D0> You can also watch Keon give a lecture at the Vegetarian Society of Hawaii on the same subject at: [http://www.youtube.com/watch?v=cp9MwjW5 ...](http://www.youtube.com/watch?v=cp9MwjW5...) at a \_player In the “The China Study”, which is considered the most comprehensive study of nutrition ever conducted, one of the biggest points in the book is how casein promotes cancer. Casein makes up 87 % percent of cow milk protein. Casein is the predominant phosphoprotein found in fresh milk and dairy products. here is a quote from the book: ..... The Cancer Casein Connection In fact, the connection between casein and cancer was so profound that the scientists could literally turn cancer growth on and off in the laboratory animals, like a light switch, simply by altering the level of casein protein in their diets. Interestingly, they also found that feeding the animals the same levels of plant based protein (gluten and soy) did not at all promote cancer growth. .... there are about 27.3 grams of casein in 1 liter of whole cow’s milk. Approximate! Casein Amounts: 6.5 g casein in 1 cup whole milk - I think skim milk has even more. 5.7 g casein in 1 oz. cheddar cheese 11.3 g casein in 1 cup plain fat-free yogurt You can do no better than following Dr McDougall’s advice. Go to his home page, click on the link for the free program. <http://drmcDougall.com/> Your health will be immensely improved, I know mine was. I have now been McDougalling for a little over 3 years and will stay with this way of eating forever. My lipids are now excellent, I have no skin issues or sinus issues anymore, my energy is great, I weigh what I weighed in high school. I sleep beautifully and have a clear mind. All because I eat no animal products whatsoever! You get used to eating foods with out greasy butter and your taste buds come alive. I never miss butter anymore!

Nancy Lebovitz (2014-03-22 09:56:28)

I’m pretty sure the doctors/heroin article is substantially wrong, or at least severe pain is very undermedicated. The only way I can conceive of that article being plausible is that maybe it’s easy to get smallish amounts of opioids, and some people find out they’re all too fond of them, but it’s very hard to get enough opioids to treat serious intractable pain. Seth: The article proposes just what you say: It’s easy to get small amounts of opioids, and some people become addicted.

Kevin (2014-03-22 10:07:34)

Many other studies confirming egg safety, including the links in the original article. 1982: <http://www.ncbi.nlm.nih.gov/pubmed/7124663> "It is concluded that within the range of egg intake of this population differences in egg consumption were unrelated to blood cholesterol level or to coronary heart disease incidence." 2009: <http://www.ncbi.nlm.nih.gov/pubmed/19000074> "For the majority of U.S. adults age 25+, consuming one egg a day accounts for <1 % of CHD risk." And, of course, the 99 year old lipid researcher Fred Kummerow: [http://www.nytimes.com/2013/12/17/health/a-lifelong-fight-against-trans-fat.html? \\_r=1 & ...](http://www.nytimes.com/2013/12/17/health/a-lifelong-fight-against-trans-fat.html?_r=1&...) "Cholesterol has nothing to do with heart disease, except if it’s oxidized ... He has never used margarine, and instead scrambles eggs in butter every morning. He calls eggs one of nature’s most perfect foods"

Kirk (2014-03-22 10:09:33)

Talking about pain, the recently published book "A Nation in Pain" (by Judy Foreman) is well worth a read. Apparently there are many legitimate alternatives to meds.

Seth Roberts (2014-03-22 12:45:58)

I just picked the first two studies I found relating egg consumption and heart disease. I didn't have a preconception about it. The first study you cite, about heart disease, found a very small difference:

Plaque area in patients consuming <2 eggs per week (n = 388) was  $125 \pm 129$  mm<sup>2</sup>, versus  $132 \pm 142$  mm<sup>2</sup> in those consuming 3 or more eggs per week.

between groups where egg consumption was about twice as much in the high consumption group. That implies eggs matter little, if at all. The second study about diabetes is more impressive. People who eat lots of eggs are surely different in other ways from people who eat very few – maybe you have heard of the healthy person bias – but at least the association is large.

Seth Roberts (2014-03-22 12:53:46)

Butter tastes good – in many situations, it tastes delicious. So do other animal fats. The notion that they could be bad for us in any amount is hard to reconcile with evolution. If they are bad for us in any amount, why don't they taste bad – so that we won't eat them? Maybe you know that a genetic change that made it hard to digest milk (lactose intolerance) disappeared in some populations. This change – the disappearance – made it much easier for adults in those groups to eat cheese and other dairy. Presumably the genetic change happened because milk and dairy products helped people survive. I tend to agree that ordinary milk is bad – I never drink it. But I eat yogurt and cheese – I think the benefits of fermentation outweigh the problems. I am sure we need to eat fermented foods to be healthy. McDougall hasn't figured that out, as far as I can tell.

Gina (2014-03-22 13:34:02)

"Butter tastes good — in many situations, it tastes delicious. So do other animal fats. The notion that they could be bad for us in any amount is hard to reconcile with evolution. If they are bad for us in any amount, why don't they taste bad — so that we won't eat them?" It seems likely that we only evolved to dislike things that are acutely bad for us (i.e. poisonous), not things that kill us slowly and only past our reproductive primes. Liking animal fat was no problem for people who lived to the ripe old age of 25 and just needed calories. I don't think it's so advisable to apply that to ourselves. "Maybe you know that a genetic change that made it hard to digest milk (lactose intolerance) disappeared in some populations. Making it easier for adults to eat cheese and other dairy. Presumably this was because milk and dairy products helped people survive." Mere survival is not what most people are looking for. When starvation is a threat, any food is health food.

dearieme (2014-03-22 13:58:35)

Different peoples have different diets, but one can be pretty confident that every human in history has experienced being an egg, and has experienced consuming milk. So I'd tend to put the burden of proof on people who wish to argue that eggs, or butter, yoghurt or cheese, are killers.

Joe (2014-03-22 14:01:22)

Gina: "Blog posts are not impressive." Look closely, Gina, those posts provide you with direct links and references to scientific studies, etc. Of course, you're free to ignore them, too. Shelley: You keep referencing the China Study. That study has been debunked so many times now that it's a farce. You're free to ignore the debunkings, of course, but I just can't do that. Here's yet another look at it: <http://www.proteinpower.com/drmike/cancer/the-china-study-vs-the-china-study/> I eat grass-fed butter, a daily dose of grass-fed kefir, and some hard cheeses. No plain milk to speak of. And I'm so regular that the U.S. Naval Observatory sets its clocks by my bowel movements. "My lipids are now excellent" So are mine (how can that be?!), even though I think they have ZERO to do with CVD. Ditto BP, BS, BMI, etc. I'm basically a relatively low-carb-paleo eater, and have been for many years. It helped me lose 100 pounds, and to keep it off. I've never felt better in my life. I'm sorry that you fear fats so much, but I'd fight to the death to preserve your right to do so! :) PS: Gina and Shelley, have you ever had your homocysteine (tHcy) levels checked?

Joe (2014-03-22 14:16:44)

I can hardly believe it. I'm citing Dr. Oz! <http://www.doctoroz.com/videos/5-surprising-ways-live-longer-under-minute> "Dr. Oz's 5 Surprising Ways to Live Longer in Under a Minute 1. Eat Eggs Eggs are a powerful source of protein and cost just pennies.

Many people have been led to believe that eating eggs increases blood cholesterol, but that's simply not true. Eggs contain choline, a B vitamin shown to reduce inflammation in the brain, which may lessen the chance of developing Alzheimer's disease. Eating two eggs comprises 26 % of your daily protein intake, yet contains less than 10 % of your recommended calories for the day. Thus eggs can help you shed pounds. These protein powerhouses protect your bones and fight frailty. Antioxidants and other nutrients in egg yolks help prevent macular degeneration, the leading cause of blindness; they also protect the retina from UV sun damage.

Gina (2014-03-22 14:25:27)

"Gina and Shelley, have you ever had your homocysteine (tHcy) levels checked?" Lower than an omnivore's. I take my B12.

Shelley (2014-03-22 14:46:42)

Joe-My homocysteine is fine. Joe please-hahah Dr Oz? You can not be serious! I swear Dr. Oz is deaf. No matter how many times he hears that fish is unhealthy, he continues to recommend it. A few months ago, Dr. Fuhrman was on his show (again) and explained to Dr. Oz (again) that fish is NOT a good food because of the fat content, saturated fat content, and contamination. Dr. Oz acted as though he had a lightbulb moment and said, incredulously, "But I've been recommending fish to my viewers for YEARS." Dr. Fuhrman then reiterated what he'd just said. And Dr. Barnard was on the show within the last six months, saying the same thing. Yet Dr. Oz continues to recommend fish. It's mind-boggling. Dr Oz is forever flip-flopping. He's in it for the entertainment! He's ridiculous! a older quote, apparently valid, from Dr. Oz: "'We have the science to suggest that if you can make three changes — give up all meat, all dairy, and refined foods including free oils — you can avoid dying from cancer and heart disease. It's being brought to life in a new documentary called Forks Over Knives. I saw it, I loved it, and I need all of you to see it too. This could be the Hail Mary of medicine"- Dr. Mehmet Oz Seems to conflict with his recent comment on his show where he said : "What causes us to die from heart disease and stroke and Alzheimers is inflammation in the body and that's not caused by fats that we've been eating for two and a half million years." I like Dr Oz as a personality. But the problem with following Dr. Oz' advice on diets is that he supports them ALL ! So far I've seen him support, paleo, gluten free, Weight Watchers, low carb (to a certain extent), lacto ovo vegetarian, etc. Jack of all trades, expert at none? he flips-flops all the time. he does present some interesting stuff at times though. I think I stopped watching him regularly years ago- after he said eating yogurt is good for you. Joe-don't you realize that both Dr Oz and Oprah's jobs are to deliver an audience to booksellers and movie producers? If that means jumping on the bandwagon of a different protocol at the drop of a hat, so be it. These shows are mostly about ENTERTAINMENT not health information. It's like getting marriage counseling from Jerry Springer. Do not listen to Dr Oz. Seth - butter does not taste delicious once your taste buds get dialed back. If you get off fat & give your taste buds a chance to clear off the grease you will not be able to tolerate butter. Your both will love the natural taste of real whole foods but you have to give it 30-90 days.

Joe (2014-03-22 15:11:03)

Gina: "Lower than an omnivore's. I take my B12." Not THIS omnivore, and without taking a B12 supplement! Shelley: "Joe-My homocysteine is fine." No supplements? "Joe please-hahah Dr Oz? You can not be serious!" Yeah, I feel pretty much the same way about Dr. Oz, which is why I said I couldn't believe that I was citing him. But even blind dogs can stumble across a bone from time to time. "Dr. Fuhrman was on his show (again) and explained to Dr. Oz (again) that fish is NOT a good food because of the fat content, saturated fat content, and contamination." Fish is a great food! Particularly for its fat content, including sat fat, although some fish can be high in mercury and probably shouldn't be eaten more than a few times per week. I eat wild-caught salmon 2-3 times per week and sardines most days. So I don't worry about mercury at all. I.e., the benefits far outweigh any risks. <http://blog.cholesterol-and-health.com/2010/01/saturated-fat-is-not-associated-with.html> "A recent meta-analysis in the American Journal of Clinical Nutrition pooled together data from 21 unique studies that included almost 350,000 people, about 11,000 of whom developed cardiovascular disease (CVD), tracked for an average of 14 years, and concluded that there is no relationship between the intake of saturated fat and the incidence of heart disease or stroke." So my question is, why do you have such an irrational fear of fat?

Shelley (2014-03-22 16:04:25)

Joe last Aug my homocyst was a 5 or a 6. Yes I take supplements-including B12. read posts on here about homocysteine:

<http://drmcDougall.com/forums/viewtopic.php?t=8627> and this talks about b12 <http://www.veganhealth.org/articles/vitaminb12> I do not think I have an irrational fear of fat. I think you are ignoring the research and the news! You have a ridiculous point of view on fat. And FISH! Holy Christ! The oceans are now contaminated. I live in San Diego and 6 months after the Fukushima disaster they were catching radioactive tuna off the coast of San Diego-! Pollution in our environment is increasing every day so the grass fed animals of today are more polluted than those from 100 years ago. Current seafood is now total garbage. <http://www.nuc.berkeley.edu/forum/218/radioactive-bluefin-tuna-caught-coast-san-diego>.2012-05-28 Mercury in fish and particularly in tuna and other large predators has been known for a while. Here is what the EPA has to say about it after issuing a warning in 2004. <http://www.epa.gov/hg/exposure.htm> #3 [ this is an excerpt from Mc Dougall's newsletter of June 2009 ] Fish is not health food. The truth is fish is an animal muscle made up primarily of proteins and fats, with no carbohydrates or dietary fibers—fish muscles are nutritionally just like the muscles of cows and chickens. They are all loaded with cholesterol and chemical contaminants, and deficient in vitamin C. Fish-fat easily accumulates in the human buttocks, thighs, and abdomen, leading to obesity and type-2 diabetes. All that excess animal protein will cause bone loss (osteoporosis), and the pharmacological activity of the fats (omega-3) will suppress the immune system (cancer and infection) and cause bleeding. Fostering the myth that fish is a miracle food is a slogan many of us grew up with, “better living through chemistry.” In the case of fish, the miracle chemical is omega-3 fatty acids, which have been advertised to prevent and treat diseases ranging from Alzheimer’s disease to strokes. The most thorough review ever conducted (48 randomized controlled studies of 36,913 subjects) of fish and omega 3 fats on health was published in the April 2009 issue of the British Medical Journal and the authors reported, “Long chain and shorter chain omega 3 fats do not have a clear effect on total mortality, combined cardiovascular events, or cancer.”<sup>4</sup> Other research explains the origin of the felonious belief that fish is health food: people who choose fish are the same people who choose an overall healthier diet, consciously avoiding coronary-artery-damaging saturated fats—eating the fish does not prevent heart attacks, it is the not eating beef, chicken, and cheese that saves lives.<sup>5</sup> The erroneous belief that these magnificent swimming animals will improve the health of people is at the root of the decimation of our oceans. People are eating more food from the sea every year and the result is industrial fishing has depleted the world’s fish stocks by 90 % since the 1950s.<sup>6</sup> I love the ocean and am saddened by this loss. Fortunately, I am not demented (from lack of fish consumption) and neither are you. We can stop this runaway destruction of planet Earth and return health to its entire species—but we must act quickly. One major step is to reintroduce the natural human diet of starches to people. If you want to know more about this one big simple solution then read the first chapter of my new book, *The Starch Solution* ( to be published in about a year). 1) Devore EE, Grodstein F, van Rooij FJ, Hofman A, Rosner B, Stampfer MJ, Witteman JC, Breteler MM. Dietary intake of fish and omega-3 fatty acids in relation to long-term dementia risk. *Am J Clin Nutr.* 2009 Jul;90(1):170-6. 2) Kröger E, Verreault R, Carmichael PH, Lindsay J, Julien P, Dewailly E, Ayotte P, Laurin D. Shelley (2014-03-22 16:07:25)

p.s-Joe-Dr. Greger over on Nutritionfacts.org has been doing a series of videos tracing the sources of industrial pesticides, chemicals like mercury, flame retardants, organophosphates, etc. in our food supply (and in breast milk!). In every study FISH comes out as the major source of chemical pollutants in our bodies. Sometimes by a factor of 10 or more over other animal products and 100 or more over vegetable products. The more carnivorous (i.e. higher up in the food chain) the fish - like salmon or mackerel - the higher the contamination. Do yourself a favor and lose the fish. You can get your omega-3 fatty acids from ground flaxseed, hemp and chia seeds, or walnuts.

Joe (2014-03-22 17:08:20)

”Do yourself a favor and lose the fish.” No thanks, Shelley. I’m keeping the fish, the beef, the pork, the lamb, the poultry, etc. The Okinawans are one of the healthiest and longest-lived groups of people on the planet, and they eat fish almost daily. So

do many other populations. And there are countless other studies attributing health and longevity to regularly eating fish, including the Mediterranean Diet. Yes, fish can become contaminated, but so can vegetables and fruits, even the organic varieties. So do your best to minimize it, and enjoy your meal. After a nice glass of wine, of course! Oh, yeah. And don't sweat the small stuff! Stress kills! :)

Josh (2014-03-22 17:25:22)

Interesting debate between Joe/Seth and Gina/Shelley (and the underlying subtext of pro meat/fat vs anti meat/fat). And this debate makes me really wonder about how far nutritional science can take us toward agreeing on what exactly is good for our health, and what is bad for our health. Both sides linked studies that supported their beliefs. So if I can show 'x' is good for our health based on several scientific studies, and you can show 'x' is bad for our health based on several scientific studies, where does the science get us? I'll answer this question - absolutely nowhere. People who believe animal fat is good for their health will search out studies that support this view (confirmation bias). And people who think animal fat is one step below cyanide will search out studies that support their view (confirmation bias).

Joe (2014-03-22 17:51:28)

Josh, not all science is equal. And the data changes over time, as more becomes known. Yes, confirmation bias can be a problem, but only if you let it. It's YOUR life at stake, so just don't let it. Remember that correlation does not equal causation. Use your common sense. And whatever you do decide to do, don't let it stress you out. Enjoy your meals. Try to enjoy them along with friends or family. Unless you have a problem with alcohol, have a nice glass of red wine with your dinner. Get some exercise most days, even if it's just a 30-45 minute walk. Keep your weight down (people with BMIs between 25 and 30 live the longest). That is, enjoy your life! You only get one.

Alex Chernavsky (2014-03-22 18:30:13)

My diet is strictly vegan. I haven't eaten any animal products in about ten years, but my reasons are not based on any putative health effects. I believe that it's wrong to inflict unnecessary harm on sentient creatures. And I don't see how eating them is *necessary* (pleasure, convenience, amusement, habit, or tradition don't really count as necessities). Animal-rights philosopher and attorney [1]Gary Francione makes this argument in his writing.

1. <http://www.abolitionistapproach.com/veganism-and-nonviolence/#.Uy43pv17t8E>

Joe (2014-03-22 19:04:59)

Alex, you're entitled to your beliefs. And I do respect them. I just hope that you will respect the beliefs of those who do not agree with you. You say it's wrong to inflict unnecessary harm on sentient creatures. But have you ever walked behind a farm combine in the field? I have. You should try it once. It's pretty gory. Farm combines kill millions (perhaps billions) of animals each year in the harvesting of crops. Farming also eliminates the habitats of millions (perhaps billions) more (in the preparation of farm fields), resulting in even more animal dislocations and death. I would never think to accuse vegetarians or vegans of "inflicting unnecessary harm on all those sentient creatures" in the fields. Sometimes your side sounds harshly judgmental, don't you think? Frankly, I don't see much difference. Do you?

Alex Chernavsky (2014-03-22 19:21:38)

Joe, I'm quite familiar with your argument. It's debunked here: <http://animalplace.org/1newweb/number.html> Briefly, even if it's true that lots of animals are killed as a result of growing plants, it's *still* better to eat plants than animals, because raising meat is a very inefficient process (e.g., you have to feed a lot of plant matter to a cow to produce a small amount of beef). I do see a big difference. Otherwise, I wouldn't eat the way I eat.

Seth Roberts (2014-03-22 19:46:55)

I ate as you recommend for a long time. No butter, almost no animal fat. During that time I found animal fat repulsive, as you say. Then by accident I discovered that pork fat greatly improved my sleep. Later I discovered that butter improved my brain function as measured by a reaction time test. The anti-animal-fat advocates have no such simple clear evidence on their side, as far as I can know.

Joe (2014-03-22 19:55:15)

Alex: "Briefly, even if it's true that lots of animals are killed as a result of growing plants, Of course it's true! I've seen the carnage with my own eyes. Have you ever even been on a farm? And it only takes a quick google search to see that your debunking has been debunked many times. "it's still better to eat plants than animals, because raising meat is a very inefficient process (e.g., you have to feed a lot of plant matter to a cow to produce a small amount of beef)." So, I'm supposed to stop eating the tastiest, most nutrient dense foods on the planet, because it's more "efficient" to eat plants? Wow. Wouldn't it be even more "efficient" to just stop eating altogether? I kind of think that's where you're heading, Alex, with all due respect. Right down Paul Erhlich Lane. Really, Alex, it's become a religious experience for you, I can see that now. And I do respect it. Up to the point of your side condemning or insulting those of us who don't share those religious beliefs. And then I lose all respect for it. I already have a religion, my friend, it's been around for over two millenia now, and it meets all my needs. If yours meets all your needs, then good on ya. But lighten up on the proselytizing, okay?

Alex Chernavsky (2014-03-22 20:16:34)

Joe, Gaverick Matheny has done the calculations. You can read about it [1]here (Matheny, G (2003). "Least Harm: A Defense of Vegetarianism from Steven Davis's Omnivorous Proposal". *Journal of Agricultural and Environmental Ethics* 16 (5): 505–511.) I do agree with what you wrote further above ("...enjoy your life! You only get one"). But in my view, the word "your" is extended to include non-human animals. Incidentally, for whatever it's worth, I have no religion: I'm an atheist. I strive to base my opinions on reason, not on some sort of mystical principles (I only mention this fact because you raised the issue of religion.)

1. [https://ethik.univie.ac.at/fileadmin/user\\_upload/inst\\_ethik\\_wiss\\_dialog/Matheny\\_\\_G.\\_2003\\_Defense\\_of\\_Veg\\_\\_i\\_n\\_J.\\_Agric\\_Ethics.pdf](https://ethik.univie.ac.at/fileadmin/user_upload/inst_ethik_wiss_dialog/Matheny__G._2003_Defense_of_Veg__i_n_J._Agric_Ethics.pdf)

Joe (2014-03-22 21:15:45)

Alex, I've done my own calculations. Based on what I've seen with my own eyes. And the biggest difference I can see about the way you eat and the way I eat, is that there really is no difference in the amount of carnage. Sentient animals die in the process. By the millions. That's a fact. But the animals I'm responsible for at least get eaten in the end. Not so, yours, although some do get eaten by predators and scavengers. Your view, that animals have the same rights as humans, is essentially a religion (in my opinion). A form of animism, if you will. I believe they have only the rights we grant them. Period. Which of course are open for discussion. I firmly believe, though, that they deserve to be killed (and raised) in the most humane way possible or feasible (so they can enjoy life, too!). And if I were an animal, I'd rather be quickly dispatched by a bolt gun than mutilated by a combine or tractor, and left to die in a field slowly. And painfully. Nota bene: Allan Savory has written about a way to feed all of the world's hungry, and then some, by raising cattle and eliminating desertification at the same time (which would also affect the climate in a positive way). Roughly, it entails letting the cows basically raise themselves. The only human involvement would be to keep them moving, so that the grasslands (after being consumed) get a chance to revive and then thrive. Much like the bison once did in America. Millions of starving African kids, for example (as this was to be an African project) would then have access to all the protein they could handle, the deserts would come back to life, and there would also be a positive effect on the climate. My religion, unlike yours, Alex, puts the lives and sufferings of those African children, and others, ahead of those of animals. Yes, it's a "mystical principle," but it's also based on sound reasoning. PS: I look forward to the day when scientists are able to prove that plants are sentient beings, too. <http://www.greenfudge.org/2009/12/01/plants-display-sentience-and-social-behavior/> That will certainly muck up the party, EH? :)

Gina (2014-03-22 21:30:48)

"But lighten up on the proselytizing, okay?" Oh, the irony! Alex didn't suggest that you or anyone else stop eating meat; he merely provided an explanation for his choice. He neither condemned nor insulted anyone. You, however, are a font of unsolicited advice.

Joe (2014-03-22 22:15:17)

Gina, I'm not trying to convert anyone to anything. I also don't suggest or imply that the way that others choose to eat is somehow unethical, as Alex is doing. At least in my opinion, that's what he's doing. And that's insulting. I also didn't know that

I had to ask anyone's permission to give advice or express my opinion here. Here's more unsolicited advice: If you don't enjoy reading my comments, DON'T READ THEM! But the whining is unbecoming. And unnecessary.

Brock in HK (2014-03-22 22:23:23)

Looks like everyone here is convinced, as I am, that AGW is not proven as fact, and that human causes of climate change should be doubted, judging by the lack of comments on that issue. Whereas whether eggs or meat are good or bad for you - that stirred up 32 diatribe-ilicious comments in a blog where comments are usually short and pithy. The corner has been turned on AGW, but diet dogma can't be left behind.

BRW (2014-03-23 05:45:59)

I worked on a livestock farm in the past and I presently work on an organic vegetable farm. Even though we are small-scale and minimal till- we harvest practically everything by hand, and never use a combine- STILL, I (unintentionally) kill more animals and critters every year growing vegetables than I ever did on the livestock operation. You can't grow plants without animals and you can't grow animals without plants. It is a cycle, believe it or not. Furthermore, most of the animals you hold so dear would not be around today without the farmers who grow them. Vegans certainly aren't doing much to preserve heritage breed pigs. Everything is alive. And you have to consume living things to be nourished. Oh, and eggs are quite good for ye. It sounds like you might just be afraid of the color yellow (butter, yolks, tallow). It is one of the louder ones, isn't it?

Shelley (2014-03-23 07:52:11)

It is correct that there is no study or research that definitively shows that eating a small amount of animal products or oils is significantly more damaging to long term health than eating none. No one can successfully argue on that point. I do tend to agree that eating a small amount of either over the course of a lifetime is probably a reasonably safe thing to do and still be able to live healthy & to a ripe old age. We have proof of that in several cultures. By the way Joe- the Okinawans do not eat fish EVERY single day. They eat a lot of sweet potatoes and veggies and occasional fish. The people on the Mc Dougall way of eating know oil & animal foods carry some risk. Where the line occurs as to when it becomes an unacceptable risk is going to be different for everyone. Just as the number of cigarettes smoked over a certain time period will affect each of us differently so will the amount of animal products and added oils. Do you think it is "OK" to injure your endothelial cells "in moderation"? I don't I am over age 50 and want to protect my health. The forums on drmcDougall.com exist to explain and promote Dr. McDougall's viewpoint which is to eliminate those items from your diet as much as possible. Good people choose to eat meat, dairy and added oils everyday. Dr. McDougall would be the first to acknowledge this. But his position, and the idea he wishes to convey, is to try to eliminate these risks as much as humanly possible. If you go to a McDougall event you will be served food that matches those ideals. He will not endorse consuming small amounts of animal products or oil. His goal, expounded on through his website, is the BEST diet, not an "ok" diet. It's the maximum healing diet, not a diet designed to be just adequate. Many of us appreciate that and make our dietary choices on that basis. Others feel they have little risk in consuming small amounts of these items and make that their dietary lifestyle. Both might be fine but the forum and the rest of the mc dougall website are there to reinforce the idea that these items are not necessary to good health and do carry risks. We will all ultimately make the decisions we feel are the best for ourselves. Those decisions will be different for each of us. We all know there will NEVER be a large research study to demonstrate the validity of the plant diet to minimize risk factors to disease. just who would fund the research at the universities? The farmers ?

Joe (2014-03-23 09:19:46)

Shelley, regarding the Okinawans. I was basically sharing my own experience with actual Okinawans. I was stationed there for a short time. I knew many Okinawans. And the Okinawans I came in touch with ate fish virtually every day. And frequently pork. And, yes, veggies. They're reputed to be one of the healthiest populations, so I was trying to show the contradiction between your claim that fish is supposedly bad for us, with the real-world experience of actual Okinawans. Actually, I think the main reasons they live so long are basically their genetics, their culture, their relaxed lifestyle, and their low levels of stress. Not necessarily their diet. Mañana may be a Spanish word, but I think they borrowed it from the Okinawans. If you have good experience following Dr. McDougall's diet (I'm very familiar with what it entails, and I just don't agree with it, I also don't do well on carbs), then, by all means, hold a steady course. That's precisely what I'm doing. I've found something that works

for me, so I'm sticking to it, too. My health profiles are all excellent. I've never felt so good. So why would I change course? Why would you change course? The short answer is, we wouldn't. "Do you think it is 'OK' to injure your endothelial cells "in moderation"? I don't I am over age 50 and want to protect my health." I agree with you on that point. But eating large amounts of sugar can injure them, too. Which is another reason why I avoid bread, pasta, too many other carbs, etc. I'm in my 8th decade (I still can't believe I've made it this far) and also want to keep on keeping on. Regarding a better scientific study: It's being done. By NuSi. <http://nusi.org/> They aren't trying to "validate" a plant diet. They're just going where the science takes them. Let's hope they finally get it right, or whether there even is a "right" answer.

Shelley (2014-03-23 09:39:27)

Joe- if you made it to age 80 and your health is fine you could be one of those rare genetically gifted individuals who can eat anything and suffer no ill effects. I had an uncle who smoked, drank, ate meat+ cheese + crap and never exercised. He made it to age 88 but I think his last 4 years he was just "existing" & not really enjoying his life. Another uncle made it to age 96. Ate terrible, drank a little, did not smoke and played golf and walked until about age 90. His last 5 years he was miserable. I really don't care to live past age 85. Mostly I want to feel good and be able to do for myself all the time I am on earth. Eating meat displaces nutrients. Cutting out animal-products makes more room in your diet for fruits and vegetables—a goal that most people fail to meet. Meat contains NO fiber, NO phytochemicals, and very little antioxidants. Phytochemicals are angiogenesis inhibitors slowing or stopping the process of a cell becoming cancerous. Antioxidants clean away free radicals. And you don't have to worry about IGF-1 when you eat plants. We all need to eat more fruits and vegetables, as many as we can. Excess protein fuels cancer. Excess protein is hard on the kidneys. Excess protein leaches calcium out of your bones (which is why US has high levels of osteoporosis). Excess protein causes inflammation. All facts - Google if you don't believe me. But despite all this, even if animal foods were the healthiest diet for humans, eating them is simply not sustainable for much longer. On a per calorie basis, they require over ten times as much land, water and energy as a plant-based diet. If everyone ate the way we do in the USA, we'd need two planet Earths to feed us all and we only have ONE. ONE DAY eating meat will be regarded as something as disgusting as smoking is now. One day! You are not built to eat meat. You have no teeth to kill, no claws, not anything to kill other animals with. Nature has not made you a natural killer-meat eater, Your organs aren't built to consume meat and your body hasn't been made to hunt. The fact that you have the technology to kill doesn't justify the fact of murder or consumption of other living beings.

Joe (2014-03-23 11:43:08)

Shelley: "Joe- if you made it to age 80 and your health is fine you could be one of those rare genetically gifted individuals who can eat anything and suffer no ill effects." I'm not 80. I'm in my 70s (i.e., 8th decade). And while it may be my genes, I highly doubt it, considering that I lost my father to a heart attack (when he was 63) and my mother to a heart attack (caused by a stroke) when she was 56. "But despite all this, even if animal foods were the healthiest diet for humans, eating them is simply not sustainable for much longer." Why not? Watch this video: [http://www.ted.com/talks/allan\\_savory\\_how\\_to\\_green\\_the\\_world\\_s\\_deserts\\_and\\_reverse\\_climate\\_change](http://www.ted.com/talks/allan_savory_how_to_green_the_world_s_deserts_and_reverse_climate_change) You sound like you come from the Paul Erlich school, too. And that's just one example of why we almost certainly have more land than we'll ever need, if we'd only use it intelligently. Add in the fact that the rate of global population growth is dramatically (and has been) slowing down, and there is no "population bomb." That's a myth. <http://overpopulationisamyth.com/content/episode-5-7-billion-people-will-ever-yone-please-relax> "You are not built to eat meat." Of course we are! We're omnivores. In fact, our early ancestors had virtually no tooth decay. It wasn't until the advent of the agricultural age that our health (and teeth) began to suffer. "You have no teeth to kill, no claws, not anything to kill other animals with" What we do have is a very large brain, and that's what made us the apex predator that we still are. We make/use tools. We work as a team. That's how we evolved. "The fact that you have the technology to kill doesn't justify the fact of murder or consumption of other living beings." Oh, geez. Here we go again. Insulting my beliefs. What is it about you plant-eaters that compels you (almost all of you!) to constantly proselytize and insult those who disagree with you? I have a hunch why that is. It's because you're not eating enough animal fat! :(

Shelley (2014-03-23 15:45:21)

Joe i am not going to debate endlessly with you about why meat eating and dairy farming are bad for the environment. And why you are not built to eat meat. The evidence is out there for anyone with half a brain. Joe you are not an obligate

carnivore. Do you salivate when you see a cow or a chicken? Like a cat does? Of course not. The paleo diet is discussed over and over on mc dougall forums. It is nonsense. Don't be brain washed. it is not good for anything. it's an excuse so meat eaters can continue eating meat. What we can't find is any experimental support for a "paleo" or "ancestral diet" approach, or deliberate increase in cholesterol, saturated fat, or animal food, doing anything like: Reducing incidence of angina Reducing atherosclerotic lesions Reducing incidence of heart attacks Reducing diabetes Reducing obesity Reducing cancer If these diets are the natural and proper diet for humans, where's the science showing a correlation between increasing cholesterol, saturated fat, or animal consumption and reduced risk or incidence of any of these? As Dr. McDougall puts it in his Starch Solution video, all civilized populations have relied on grains and starches. Agriculture allowed us to achieve the ability to do other things besides forage for food. The Paleos do not have to forage either. They go down to the store and grab a prepackaged, hormone-injected, frozen carcass. In no way is it the same. Going plant-based is a big shift for the body to undertake, ridding itself of the toxins and hormones in animal products, and if someone isn't fully adherent, that process is going to stall or take much longer, and the benefits may not fully materialize. It took most of us years of bad eating to develop health problems, so it's unreasonable to think that it won't take time for our bodies to adjust. The difference is that the Mc Dougall way of eating isn't based solely on how past populations ate or glorifying those primitive peoples. This WOE isn't opposed to progress. Even so, the starches and grains we consume are very similar to what past civilizations consumed. Paleos are in denial that what they're consuming in any way resembles what early man ate, either in quality or quantity. The fresh fruits and vegetables aspect is good, but the meat consumption is much heavier and processed. Early man probably ate more like rural Asians - mainly plant-based with some occasional animal product. If they were healthier (debatable), it was because they ate only whole foods and their animal consumption was still relatively low...especially compared with the SAD diet and how most Paleos interpret the amount of meat they should consume. If Paleo leaders urged their followers to eat mainly fruits, vegetables and an occasional small serving of meat, there'd be no problem, but I don't think that's what's being advised, is it? Diet choices should always be about long term health. The human body can live on an amazingly bad diet for short time periods and even find them enjoyable. It's what happens long term that have driven people to certain cultural preferences. For most of recorded history it's been a starch based diet with the inclusion of small amounts of meat. We have culturally reversed these choices of late and are paying the price. I was listening to a past Coast to Coast interview. George Noory asked why was his doctor saying just the opposite of what Dr. McDougall says in "The Starch Solution". Dr. McDougall explained that his son 4 years ago graduated from Medical School and as when he went to school there weren't any classes in nutrition. George then said you aren't telling anyone not to eat meat? Dr. McDougall said of course not.. but if someone came to me who was smoking and was worried about lung disease, I wouldn't tell him to cut back to two cigarettes a day. Eating animal-derived foods causes our most common diseases for many well-established reasons, including the indisputable facts that they contain no dietary fiber, are filthy with disease-causing microbes (including mad cow prions, and E. coli and salmonella bacteria), and contain the highest levels of poisonous environmental chemicals found in the food chain. Remember, disease-causing red meats, poultry, fish, and eggs are not needed in our diets. In March 2012, the Harvard School of Public Health published results of a study on red meat that followed 120,000 people over more than 20 years. In one sentence, the study found that eating any amount of red meat increases the risk of premature death, and the risk of mortality rises proportionately as you increase your consumption. Substituting other healthy protein sources (nuts, fish, poultry, and legumes) was associated with a somewhat lower risk of mortality. Even a small amount of red meat, with low amounts of saturated fat, was associated with a significantly increased risk of mortality. This raises the question of "why"? Frankly, nobody has a definitive answer. One suspected dangerous ingredient is heme iron (the iron found in red meat), which causes oxidative damage throughout the body. Other suspects are preservatives used in processed meats, which convert to carcinogens inside the body. Here are a couple mechanisms whereby meat causes disease. [http://www.youtube.com/watch?v=p\\_uy4kfQDkA](http://www.youtube.com/watch?v=p_uy4kfQDkA)

Joe (2014-03-23 17:36:17)

"Joe i am not going to debate endlessly with you" And yet, here you are, debating endlessly with me. Can't stop yourself? Maybe if you ate some animal fat, you could, eh? "Do you salivate when you see a cow or a chicken?" Do you salivate when you see a carrot? How inane can you possibly be? "Going plant-based is a big shift for the body to undertake" I can see why that would be. It's because your body is crying out for some good ol' animal fat and protein, the same stuff that humans ate for hundreds of thousands of years! The same stuff we EVOLVED on. "I was listening to a past Coast to Coast interview." So, you believe in aliens and alien abductions, too, eh? That doesn't really surprise me. And yet you make

fun of Minger. "Even a small amount of red meat, with low amounts of saturated fat, was associated with a significantly increased risk of mortality." Not so! <http://chriskresser.com/does-red-meat-increase-your-risk-of-death> But before you read that, make sure you understand the difference between correlation and causation. Ask your granddaughter to explain it to you. I'll finish this off by saying your slavish devotion to your guru and cult leader is unbecoming. In fact, had you lived in San Francisco, back in the 70s, I'm sure you would have been a member of the People's Temple. And you would have probably inhaled the Kool-Aid all the way down to Jonestown and beyond. I feel sorry for you, Shelley, even though you're almost as nasty as McDougall, your cult leader. But then that's to be expected. It's all part of the brainwashing process, right? Sigh.

Shelley (2014-03-23 19:50:59)

Joe- you are not a gentleman. Shame on you. I feel sorry for your poor wife. That's all I have to say to you. Now good night!

Joe (2014-03-23 21:04:54)

"Joe- you are not a gentleman." I am, but only to ladies. "That's all I have to say to you." I'm betting there's more to come.

GB (2014-03-24 01:31:25)

Not sure why I'm stepping into this argument, it's going nowhere. But Shelley, your comment "And why you are not built to eat meat. The evidence is out there for anyone with half a brain" deserves some reply, because it's a half-brained comment itself. We've been using tools to directly hunt for at least 2.5m years, and for scavenge work before that. We've also been outsourcing part of the digestion process through fire for a long, long time (see Richard Wrangham's work). That's why we didn't need to evolve omnivorous teeth and stomachs to become omnivores, and we did do some evolving anyway (stomachs shrunk, for example). We're a different kind of omnivore than the rest, and we got there in a completely unique way. What does seem almost certain is if we didn't go through that meat-eating evolution, our brains wouldn't have encephalized and you wouldn't be able to have this argument with Joe. Our brains would likely be about 65 % smaller. Of course, that doesn't guarantee meat eating is the right approach going forward, but if we didn't eat meat the past 2.5m years, we wouldn't be human. That's important to some of us.

## **Why Do Sweet Foods Taste Good? The Importance of a Simple Observation (2014-03-23 05:00)**

Stuart King writes:

I was very hungry today at dinner and the thought of sweet food wasn't appealing at all, but after filling up on some rice, chicken and coconut cream curry I immediately had ice cream and chocolate slice [= what Americans call a brownie], which had had no appeal 15 minutes or so before!

An everyday observation that anyone can make. Studies have shown what Stuart noticed: When you are hungry sweet foods are unappealing. This is why dessert is eaten after the rest of the meal.

The main way that psychologists explain an experimental effect – choose between explanations – is by finding out what makes the effect larger or smaller. For example, discovery of what makes learning more or less (what increases or decreases the effect of one learning trial) is the main way psychologists have chosen among different theories of learning. Different theories predict different interactions.

Why do we like sweet foods? The usual answers are that sweet foods are a "good source of energy" and they provide "quick energy". But these explanations do nothing to explain what Stuart noticed. If sugar is a good (= better than average) source of energy, we should eat it before other foods (average sources of energy) when we are hungry (hunger signals lack of energy). The opposite is true. You may not want to call it a "contradiction" but there is no doubt the conventional view does not explain what Stuart noticed. Of course many nutrition experts, such as Weston

Price, are/were entirely sure sugar is unhealthy.

As a tool for choosing among theories, Stuart's observation is especially good because (a) it is very large (sweets go from unappealing to appealing) and (b) paradoxical (eating calories should make all calorie sources less appealing).

If you have been reading this blog, you know I explain Stuart's observation by assuming that we need sugar in the evening to sleep well. Sugar (sucrose, fructose, glucose) eaten in the evening increases blood glucose, which increases glycogen. During sleep, glycogen becomes glucose, which the brain needs to work properly. Evolution shaped us to like sweet foods after a meal so that we will eat them closer to when we sleep. (The value of replenishing glycogen close to bedtime also explains why [1]we eat sweet foods after dinner more than after breakfast or lunch.)

I can't think of another case where what experts say is so out of line with what's easily observed. For example, I'm sure cholesterol doesn't cause heart disease, but there is no everyday observation that supports my belief.

I can't think of another case where what experts say is so out of line with what's easily observed. For example, I'm sure cholesterol doesn't cause heart disease, but there is no everyday observation that supports my belief.

If sugar is helpful for sleep, why is it [2]associated with diabetes? My guess is that sugar is almost always consumed in foods that taste exactly the same each time – what in The Shangri-La Diet I called ditto foods. For example, soft drinks. Ditto foods with sugar, because they have a strong precise CS (smell) and a strong fast US (calorie signal), produce an especially strong smell-calorie association. Such an association raises the body fat set point, thus causing obesity. Obesity causes diabetes. It's also possible that eating sugar during the day – at the wrong time – hurts sleep. Maybe sugar during the day raises insulin and thus reduces the conversion of sugar to glycogen. Less glycogen causes bad sleep, bad sleep causes diabetes. My blood sugar levels clearly improved when I started eating sweets in the evening – opposite to what the sugar-diabetes link would predict.

---

Shelley (2014-03-23 05:54:00)

I never ate sweets at night but USED to crave chocolate. Not anymore. I have been liberated from my addiction to chocolate. How? I stopped eating it and 60 days later I lost the craving. The good news is that if you cut out all the added fats, sugars, and salt from your food your taste buds WILL adjust. It takes time. 2 or 3 weeks is NOT enough for most folks. You need 30-90 days. After that you'll actually learn to taste subtle flavors that were overpowered with grease, salt & sugar before. Give yourself some time and your taste buds will adjust. You'll be amazed at how good "real food" really does taste and how satisfying it can be! I did not believe it would happen for me but it did.

Gina (2014-03-23 07:51:16)

Our taste for very sweet would be based, I assume, on dried fruits and honey. Like most people, I only like something that sweet when I am not hungry. However, I only want fruit (more sweet than starch and less sweet than honey) when I am hot and thirsty. I wonder if people who like sweet breakfasts are those who don't have sweets at night and if they started having dessert after dinner they would stop wanting a sweet breakfast.

George (2014-03-23 09:04:23)

This is a good example of using selective evidence. While what he says here is real, there are also lots of times when you crave sweets on an empty stomach. I went through a period where I dieted hard and then binged, and my binges would often start with sweet food and I would often crave sweets. I start the day with a sweet food, and want nothing else in the morning. The ubiquity of sweet food for breakfast as the main meal around the world, which is unheard of for lunch or dinner, also suggests otherwise. (breakfast is not always or necessarily sweet - some people eat bacon and eggs - but it's the ONLY meal where it is common for the main meal to be entirely sweet. Waffles with maple syrup is considered normal for breakfast but if that was your lunch or, worse, your dinner, you'd be looked at as very eccentric) Basically, what he and you are doing is just fitting the facts to your theory.

gwern (2014-03-23 09:37:08)

Agree with George here. Both as a kid and now I loved sweets for breakfast - waffles, pancakes, oatmeal with honey or maple syrup, and of course, regular cereal (loaded with sugar, check the ingredients list sometime). In direct contradiction to this theory. And what do people eat for snacks? When they come home and want something to eat as fast as possible, what do they eat? If it's not fruit (my own standard after-school snack), it tends to be starchy carbohydrates. (Hold a saltine cracker in your mouth for less than a minute and you can start tasting the sugar as it's broken down.) Plus, does the mechanical theory make any sense here? How does eating an ounce or two of sweets before bedtime make a hill of beans' difference to metabolism 8 hours later? Is one's body so dysfunctional it cannot do some basic regulation of blood sugar while asleep? And it's not like one is exercising vigorously while asleep. > I can't think of another case where what experts say is so out of line with what's easily observed. I look forward to hard data, perhaps even randomized data - I realize it will be a great sacrifice to decide whether to have a late-night snack based on a coin flip and then to analyze the data, but posterity will thank you!

Joe (2014-03-23 12:02:27)

Seth: "Obesity causes diabetes." Not in my opinion. In fact you may have it pretty much backwards. There is a correlation, and that's it. And we know what that means, right? Virtually nothing. "Most overweight people never develop type 2 diabetes, and many people with type 2 diabetes are at a normal weight or only moderately overweight." Until you can explain to everyone (and back it up with data to support your claim) why the vast majority of obese people DON'T develop T2D, saying that obesity causes cancer is not too different from saying that cholesterol causes heart disease. We both know how that worked out, right? <http://www.diabetes.org/diabetes-basics/myths/> I think Dr. Attia is on to something: What if we're wrong about diabetes? [http://www.ted.com/talks/peter\\_attia\\_what\\_if\\_we\\_re\\_wrong\\_about\\_diabetes](http://www.ted.com/talks/peter_attia_what_if_we_re_wrong_about_diabetes)

James M. (2014-03-23 13:02:11)

Here is an article/interview with Lewis Cantley, PhD in biophysical chemistry, with commentary on the actions of glucose/fructose/artificial sweeteners, the action on the body/brain, including a thought about why fructose turns readily to fat (found through Mark's Daily Apple). <http://www.biomedcentral.com/1741-7007/12/8> Seth: Thanks, I saw that. When did biologists become climate scientists? (who feel no need to make correct predictions)

Alex (2014-03-23 13:09:47)

Seth, some interesting thoughts in the last few sentences of the post. Hmm... gwern, blood-sugar management seems to be open to great variability between individuals. I've noticed a big difference in my sleep patterns based on blood sugar once I started experimenting. I used to find it impossible to stay awake at 5:00 p.m. I assumed it was some wacky circadian glitch. Once I went paleo (low-carb) that stopped. Just stopped. The honey at bedtime trick (and no other sweets/starches during the day) made a huge difference for my kid. But other people have no trouble staying awake at 5:00 p.m. even if they eat a spaghetti sandwich for lunch, and most other kids sleep through the night just fine regardless of what they ate all day.

babar (2014-03-23 15:01:09)

"sweets" didn't really exist until recently. there was fruit, when it was in season. very little fruit kept long out of season. apples and pears. honey i'd think was very scarce - when did people learn to keep bees? so i doubt that evolution has much to say about this.

Seth Roberts (2014-03-23 17:23:48)

"i doubt that evolution has much to say about this." okay, how do you explain these generalizations: 1. we like the taste of sugar. 2. we don't like it when we are hungry, only when we are not hungry? 3. (bonus question) we like it more in the evening than earlier in the day? I don't think it's a stretch to suggest that evolution shaped when we eat fruit.

Retired now (2014-03-23 17:28:08)

I have noticed that I really want something sweet after dinner at night, but by the time two hours has past I no longer want it (mostly). Not sure how this would fit your theory. And after years of on again, off again, occasions of no sugars and no chocolates I can tell Shelley that one can have totally lost all cravings and then for no apparent reason the cravings return without apparent trigger and without being self indulgent. So don't be too self righteous about it all. If your cravings stay away then be thankful.

George (2014-03-23 18:05:30)

"we don't like it [sugar] when we are hungry, only when we are not hungry" I just don't understand how anyone can say this. Am I missing something? I LOVE sugar when I am hungry. It's fascinating to me that the field of nutrition seems to produce a long line of highly intelligent people who make bold claims that are contradicted by readily available and extremely obvious information - Ancel Keys, Taubes, Guyenet, Seth, etc. I am convinced the field of nutrition functions as a channel for displaced religious sentiments. Something about nutrition seems to recruit mental habits that usually play a role in religion.

Seth Roberts (2014-03-23 19:16:32)

"how can anyone say this?" Elizabeth Capaldi said it based on research she did - data she collected. Perhaps you missed the part where I said studies showed this.

GB (2014-03-24 02:12:34)

Seth, perhaps this is beyond the scope of this post, but do you have any theories about how we sated this hunger for sugars at night in the deep past? I can't see anyone raiding a beehive and then saving the contents until after dinner. Gathering and saving fruit until after dark, perhaps? Does anyone know if any contemporary hunter gatherer tribes save sweet carbs until near bed time? It would be a nice addition to the theory if we could identify such behaviours. Likewise, not being able to identify such behaviours would be an interesting thing, why would evolution offer such low-hanging fruit and yet we're unable to find HGs taking advantage of it?

Anand Srivastava (2014-03-24 03:05:20)

I try to do a thought experiment when I read something like this. My principle is that whatever is supposed to be healthful should not be contradictory to the environment we had during the palaeolithic times. As we are probably much more adapted to that environment than we are to the modern times. My reasoning for this principle is that our environment has changed too fast for us to be able to adapt to the changes. This does not mean that we have not changed, and there is ample that we have changed, but the changes are not universal, and they do not negate the adaptations to the Palaeolithic times. This in a nutshell is the Palaeolithic Principle. Testing Sugar in the night theory with the Palaeolithic Principle, below. In the palaeolithic people, would get sugar from fruits or honey. They would gather them and eat them during their cook-out in the evening, or eat them while they were on hunt or gathering. This means that they were eating sugary stuff either before sleeping or during exercises. They might have also been eating them for breakfast as left-overs. The least sugar would be eaten during the breakfast, as it would be a premium item, and unless you got a lot by luck, nothing would be left over. I think the logic seems very plausible. And maybe beneficial. A little in the breakfast may not hurt. In any case, without some amount of hard work everyday (or at least alternate days), you are not going to be healthy, whatever you do.

Seth Roberts (2014-03-24 06:35:57)

I think people gathered fruit and saved the fruit to eat until late in the evening. They were hungry when they gathered the fruit; it wouldn't have tasted good at the time.

Seth Roberts (2014-03-24 06:42:04)

Surely hunger was very common long ago. If hunger gets rid of or at least reduces our sweet tooth, that is a stunning fact. Having a sweet tooth makes sense – because sugar supplies energy – so not having one...how strange!

George (2014-03-24 06:43:10)

Research has shown that we like sugar ONLY when we are not hungry? Wow, I shudder for the state of scientific research. ONLY when we are hungry, not even just it's more common when we are not hungry? Okay, I'm outta here. This place is a joke. Pure nonsense, and an unwillingness to back off from nonsensical claims. Seth: The research showed people liked sweets much less when they were hungry. I was trying to convey it was a big effect. I see I misled you.

JV (2014-03-24 07:22:47)

Just a personal observation - I will eat sugar when I am hungry but I realize I don't find it satisfying. If I'm not careful I will look for more sweet foods (the idea of pay attention and don't eat mindlessly) and end up feeling slightly sick but if I eat something not sweet the hunger is more satisfied. I think that is a lot of the problem with our modern society, we often don't pay attention to what our bodies are telling us and sweet foods are way too easily available everywhere we turn.

Kirk (2014-03-24 10:27:53)

I agree that honey just before bedtime improves my sleep. I'd like to know why. But jumping from that personal observation to the theory that people eat sweets after supper so as to improve their sleep ignores other lines of thought. 1) Many people eat their last meal hours before they go to sleep. The honey effect, for me, depends upon honey ingestion within 1 hour of bedtime, not a dessert immediately after supper. 2) People eat sugar throughout the day, when they need to stay awake. One line of proof includes inspecting the menus of breakfast chains such as Dennys, IHOP, and Perkins. Another line of proof: stand in a fast food chain during lunch, the kind where people buy a cup and fill their drink at will from the dispenser. What percentage of customers select a sugared soft drink? From my limited personal experience, I remember it as being a large percentage. 3) Using soft drinks as a measurable product of how Americans consume lots of sugar, using a search engine to look for its consumption before bedtime yields few results. Searches such as: "bedtime coke", "bedtime cola", "bedtime soda". 4) Then again, Americans do love their ice cream. The search phrase, "ice cream before bedtime" yields a wild mixture of positive and negative search hits. Apparently, if you eat ice cream before bedtime, either you lose weight and sleep better, or you gain weight and have nightmares. If I remember correctly, the speculation that desserts improve sleep originated due to a dinner party where dessert was served, thus, it was concluded, it was the dessert that improved sleep. However, there are at least two alternate theories. The first, which is the one I prefer, is that a dinner party is a minor stress event which typically ends well. It is stressful because people might not like your jokes and stories, or you may be stuck talking with a bore. Also, you have to be 'on stage' for a long period of time. It's similar to going on a vacation and exploring a bunch of new places. The second explanation is that a dinner party simulates paleo life; a day of hunting/gathering, followed by sitting around the fire talking with companions and hearing and telling stories. What is similar in modern life? Many people, after a day of work, watch TV, where they see friendly faces and hear stories. A dinner party is a more intense expression because one not only consumes but tells stories.

dearieme (2014-03-24 11:40:41)

Why do people fuss so much about paleo life? The population has grown so much since that it's easy to believe that we've evolved a long way from then.

Seth Roberts (2014-03-24 12:56:42)

"I agree that honey just before bedtime improves my sleep. I'd like to know why." I think the idea that "honey before bedtime improves sleep" is far from proven (although the idea that "sweets in the evening improve my own sleep" is proven beyond doubt). It is also unclear to me how much weight (a lot? none? moderate amount?) to put on what people tell me about their sleep. For example, you tell me that honey before bedtime has improved your sleep. How much weight should I put on that? By looking into associated phenomena, such as the notion that when we are hungry, we don't want sweets, I learn more about both issues (1. is it generally true that bedtime honey improves sleep? 2. Should I trust what people tell me about their sleep?)

If the answer to both #1 and #2 is yes, then the idea that we don't like sweets when we're hungry makes sense. If the answer to both #1 and #2 is no, the idea that we don't like sweets when we're hungry is not explained. I agree with you, this post is no help in understanding why bedtime honey improves sleep.

Joe (2014-03-24 13:36:19)

dearieme: "Why do people fuss so much about paleo life? The population has grown so much since that it's easy to believe that we've evolved a long way from then." I'm not sure that I understand your question. But the people who "fuss so much" about paleo are usually the people who think eating a 100 % plant-based diet is the ONLY way to eat. Which is preposterous, of course. Man evolved while eating animals, animal fat, fish, insects, snakes, etc., and certainly veggies and fruits (when in season) for millions of years. That's why we are omnivores, not carnivores or herbivores. And we've thrived. On the other hand, it's only been about 10,000 years (since the beginning of agriculture) that we've eaten things like grains, especially wheat, year-round fruit, etc. Which is basically a blink of the eye, in terms of evolution. Many of us think our health has suffered for it. Others don't agree. Thus the "fuss." Also, it seems to be a sort of religious experience for one side, saying and implying that those of us who choose to eat animals and animal fat, like we have for millions of years, are now "unethical." You can probably imagine how some of us would respond to that. Hint: Not very well.

Edward Edmonds (2014-03-25 09:02:17)

I think an interesting question to ask would be: Do people who eat deserts after dinner eat big breakfasts, smaller breakfasts, or no breakfast? And do people who eat big breakfasts tend to eat desert after dinner? When I am hungry but not stressed I crave meat and/or fat. When I'm hungry and stressed I tend to still crave meat and/or fat but less of it and only two things as "desert" satisfy my "sweet" craving: yogurt or dairy (e.g. milk) or something sweet. Another question I'd be interested in knowing the answer to is do people who eat more full fat yogurt crave less sugar?

David (2014-03-25 10:06:39)

Just a few thoughts: 1. i think we crave sweets after meals because we didn't get sugar during the meal, not because we naturally prefer it after a meal. In other words, if you have steak and potatoes, you may crave dessert. If you have a Moroccan meal with meat, rice, figs and honey, you may not crave sweets after a meal. (This would be easy to test). 2. No one craves just sugar. They want dessert, which is fat, starch and sugar together, so i see sugar as part of a balanced diet. 3. Almost all starches and meats are more palatable when eaten with sugar. Breakfast cereals are loaded with added sugar, meats like barbaque are covered in sugary sauces. I mean is there anyone when hungry who likes plain oatmeal??? No, we love it with brown sugar and fruit or honey. 4. There is a lot of discussions of what Paleo ancestors ate. First, I've been following the Paleo diet for over 10 yrs and it changes every few years. It was high protein and veggies, then they added more saturated fats, then they added more tubers like sweet potatoes. For a diet that hasn't changed in a million years, it changes about every 2 yrs with a new recommendation of how we misunderstood something. 5. Which brings me to #5, Paleo people say we would not have had access to sugar but traditional peoples have collected honey throughout history. Honey can be stored indefinitely, so i kind of roll my eyes when a Paleo advocate says that we should only eat honey if you've gone through the trouble to climb a rope ladder, beat off bees, recover the honey and sprint away from the bees. Those same people never say you can only eat meat if you have run for miles, tracked an animal, killed it, skinned it, and carried it back to your tribe. My point is just that i think we have to be careful creating narratives for why we should or should not do something. 6. Finally, we don't live a Paleo life. We struggle under a 10 hour cognitively demanding job with more chronic stress which has been shown to damage the brain, given sugars role in providing energy for the brain (mostly through the liver), it makes sense that we might crave (and therefore need) more sugar than we had during Paleo times.

Strauss Vasconcelos (2014-03-26 01:21:42)

Seth Roberts, I believe your theory how about sugar improves is correct, but I do not quite agree with the explanation for diabetes. To me, a simpler explanation would be that our livers need a certain amount of micronutrients to digest properly high amounts of sugar, including magnesium, complex B, coenzyme q10 and choline (choline is needed in liver to properly export triglycerides produced by excessive ingestion of alcohol and sugar, see this post made by Chris Masterjohnson: <http://blog.cholesterol-and-health.com/2010/12/meeting-choline-requirement-eggs-organs.html>). So the brain prefers to

ingest sugar after a meal because half of it is glucose, who can provide immediate energy for brain, and the another half, fructose, is metabolized exclusively in liver, providing a stable source of glucose for a brain whose body cannot store high amounts of glucose. My proposal to fix your theory is that sugar (and honey) helps improve not only sleep, but our health and brain function as well. But if we ingest insufficient ammount of those mentioned micronutrients and high amounts of sugar, we'll develop metabolyc syndrome and inexorably DM II. Of course, like traveling to Rome, there are many ways to develop DM II, not just this one.

David (2014-03-26 05:56:39)

Strauss, i agree with your points, and its a reason why i think there is confusion on the issue. Fructose is incorrectly seen as bad, but its really the refined sugars and their lack of nutrients that cause problems. Honey and fruit have a ton of nutrients that accompany the sugars and help them metabolize. Second, the glucose and fructose are free and not bound together like in sucrose. Third, i agree that the primarily benefit of sugar is supporting the brain. With only 2 % of body mass and yet consuming 20 % of the calories, keeping the brain healthy with a steady supply of fuel seems paramount.

George (2014-03-29 15:40:02)

"Seth: The research showed people liked sweets much less when they were hungry. I was trying to convey it was a big effect. I see I misled you." Fair enough, Seth. I still think you're ignoring lots of readily available evidence. You've ignored the point about breakfast, which as the name implies is breaking a long fast, being the most commonly eaten sweet meal. That alone poses a serious challenge to your theory. That the ONE meal eaten after a long fast every day in all cultures around the world tends to be sweet, or is often sweet, and that this isn't the case with lunch or dinner, massively does not support your theory. There there is the well known fact that heavy dieters almost always binge on sweet foods - they don't binge on steak and bacon and eggs, but donuts and ice cream and chocolate. Again, massive un-evidence. Sorry, it's a nice theory but it just doesn't add up. Do the right thing and move on. Truth is more important than our pet theories. Seth: You might want to read the research I mentioned, by Elizabeth Capaldi.

Nancy Lebovitz (2014-03-30 02:30:04)

David, I'm quoting this because I like it: "4. There is a lot of discussions of what Paleo ancestors ate. First, I've been following the Paleo diet for over 10 yrs and it changes every few years. It was high protein and veggies, then they added more saturated fats, then they added more tubers like sweet potatoes. For a diet that hasn't changed in a million years, it changes about every 2 yrs with a new recommendation of how we misunderstood something." As for the rest, honey is easy to store, but I don't have a feeling for when people invented a way (ceramics?) to store it. Could they have used animal bladders? If so, I don't think there'd be a fossil record. It's true that people don't want straight sugar for dessert. Hard candy is for snacks, not dessert. Still, dessert varies a lot in it' fat/starch/protein/sugar ratio. Your basic cake is sugar/refined flour/a little egg and dairy. Cheese cake is mostly cheese and sugar. Let to themselves (no theory about nutrition), people don't use whole grains in dessert so far as I know. I believe we need more investigation of dessert.

Patti (2014-04-02 08:55:46)

I have been experiementing with a ketogenic diet. Recently my blood sugars upon rising have increased to well over 100. Within a couple of hours upon rising my blood sugars drop to 90. That was not the case before I started the diet,

Patti (2014-04-02 09:05:44)

continuing... as my blood sugars were normally around 90 upon rising. I have been reading about the Somogyi Effect and Dawn Phenomenon for diabetics as a possible clue to why my bs have shifted. I am beginning to think the SE and DE are not mutually exculusive to active diabetics. From this post, and the one about honey before bed, I am wondering if being in a state of nutritional ketosis might just only be beneficial during the day. This thought comes about because last night I just went crazy with eating sugar before bed, and I awoke in very good spirits after having a wonderful dream. For the last several months this has not been the case. I usually had very uncomfortable dreams. I think for me my hours of rest have increased to 8 hours due to the time change. During the winter I usually will awake at 3am and stay awake for a couple of hours. Today I am going to experiment with eating a ketosis diet through out the day and tonight I am going to have honey.

Seth Roberts (2014-04-02 11:17:20)

"I am beginning to think the SE and DE are not mutually exclusive to active diabetics." I agree. I found this in Wikipedia: "Clinical studies indicate that a high fasting glucose in the morning is more likely because the insulin given on the previous evening fails to last long enough." I had/have a high fasting glucose in the morning but don't take insulin (and am not diabetic). So the explanation of the high glucose in the morning, at least in my case, cannot be my insulin didn't last long enough.

Patti (2014-04-03 20:34:09)

I tried the honey last night, and it did not work. I actually awoke at 12am in a panic. This also happens when I have fruit. I am thinking the fructose in both is the culprit.

Seth Roberts (2014-04-04 13:40:31)

If bedtime honey causes you to wake up too early, try a smaller dose.

Danny (2014-04-04 16:01:47)

Humans are born loving sweet, fatty and salty foods. Scientists think it is evolutionary because we didn't get much of this stuff when we first evolved so people who ate this whenever they found it lived longer and passed on liking this in their genes to their offspring. The human brain takes a lot of energy to keep it going, as well as our body, and snacking on a few plants just won't do. Humans who ate sweet things (fruits, etc.) and fats (meats, nuts) got more nutrition and lived longer.

Seth Roberts (2014-04-04 19:21:15)

This does not explain why we eat sweet foods separately (dessert) and after the main food.

## **Treat Everyone As Smart, Capable and Motivated? (2014-03-25 05:00)**

A Vancouver drug center has started an unusual program: [1]alcoholics bottle homemade beer.

The Drug Users Resource Centre, the Downtown Eastside non-profit famous for housing Canada's first crack pipe vending machine, is also behind what may well be North America's first program teaching severe alcoholics how to brew their own beer and wine.

Now the alcoholics just do bottling but the people behind the program intend to expand it to include other parts of the beer-making process, such as fermentation.

What's interesting is that they are not treating severe alcoholics as passive or disabled – as recipients of treatment. At least not entirely.

This program reminds me of several things. Geel, a town in Belgium, [2]treats people with mental illness as valued caregivers. [3]Zeynep Ton says low-level retail employees should be treated as people who can learn many jobs, give good advice to both customers and management, make good use of free time, and so on. [4]I treat my students as people who want to learn – who do not need to be scared into learning by threat of a bad grade – and are capable of inventing their own assignments.

Is there a general lesson to be drawn from these examples? (All are complicated, in spite of brief descriptions.) Could it be a good idea – as a default – to treat those you deal with as smart, capable and motivated? It is no great leap to treat alcoholics as motivated to make beer but it is a slight leap to treat them as capable of making beer. Is the next step is to treat them as smart?

What if doctors, before they saw a patient, told them: Please search the Internet for possible remedies. Bring a list of the ones you want to consider to our meeting. Is that crazy? The slightly subtle point is this may make the doctor happier.

---

Brandon Berg (2014-03-25 05:59:09)

My impression is that doctors are not generally happy with patients doing this. I may be wrong about that, but I feel as though I've heard a lot of doctors complaining about patients who self-diagnose before coming in, but have no recollection of any doctor ever speaking positively of the practice.

Alex Chernavsky (2014-03-25 06:29:34)

I do have a little bit of sympathy for doctors. One of my responsibilities at work is to troubleshoot computers. My non-techie colleagues (that is to say, almost all of them) sometimes have totally ridiculous theories about what's wrong with their PCs and how to fix the problem. Seth: In contrast to the completely non-ridiculous theories of psychiatrists. If you were paid by the visit you might be happy if a client wanted to test a ridiculous theory. It would mean two visits rather than one.

Peggy (2014-03-25 07:46:01)

I'd say the general lesson is that accepting someone as they are can provide them with a foundation from which they can go on to change and to become whole. Perhaps a lack of belonging actually propels people toward self-destruction.

Edward Edmonds (2014-03-25 08:44:24)

I work in a histology laboratory where we have a yearly flux of new students doing clinical rotations as a part of their academic programs. Different senior histologists have different methods of teaching. Most of them train in an authoritarian manner essentially writing off any new ideas new students almost always have using the excuse that because they have no clinical experience they can't possibly have any real world ideas that are of use. Or my favorite excuse is when I hear a student that has a good idea the senior histologist will say "we don't do things that way at this facility"... I remember when I was a student, I had good ideas, and I remember questioning whether or not I got into the right field of work whenever I heard

that kind of discouragement. I never forgot that feeling. When I train students I always expect that they will do things a little differently or that they will have new ideas, so instead of treating them like they have something to learn from me, my first question is always show me what you have learned or show me how you'd like to do this procedure, in other words they went through the same training I did maybe at a different facility but there are a lot of different ways to approach things we do in the lab, so I let them develop their own "style". Then after they do it in their own way I show them how I do it my way and I explain step-by-step why I'm doing it this way just as I have them explain why they choose to do a procedure in they way they choose. The entire thing is an enjoyable experience we are learning, and laughing, and undoing the dogma learned from the academic setting. In the end it makes more confident and competent histologists, they know why they do the things they do instead of just memorizing steps... all of my students end up being excellent troubleshooters and problem solvers.

andrew (2014-03-25 09:28:20)

That is the basis of libertarian philosophy.

Gina (2014-03-25 09:31:04)

The problem with bringing a list of possible remedies to a doctor appointment is that the doctor will only be familiar with the pharmaceutical options. I've done this with my grandmother and my cat. All I got was a glassy stare from the human doctor and complete sarcasm from the vet. Both were dismissive without even listening. The vet wouldn't even take the paper (published in a peer-reviewed journal) that I printed off.

C.M. Mayo (2014-03-25 09:41:06)

My teaching philosophy exactly. And over the years I have found that everyone, yes everyone, is capable of writing more and wilder and more vivid fiction- or whatever kind of writing they fancy. Love your blog. It is always such a surprise.

nicole (2014-03-25 10:59:26)

article in this month's harper's about just this topic: <http://harpers.org/archive/2014/04/diagnose-this/> i can get it for you Seth if you don't have access.

Alex Blackwood (2014-03-25 11:29:56)

Same experience here, Alex Chernavsky. Having been on the other side makes me more patient with doctors when they get that look of, Oh, no, another PhD from Google University.

Joe (2014-03-25 12:29:22)

Alex Blackwood: I have zero patience with doctors who don't know how to listen to their patients. And I've been known to walk out the door when they don't. I've also had doctors thank me for providing them information they didn't know anything about. First, the internet is what you make of it. It's just a tool. You can get bad information from the internet, and you can get good information there. And doctors don't always have access to the good information, or the time to find it. I'd even go so far as to say that doctors FREQUENTLY have bad information. An example of that (I can give you dozens of them), in my opinion, regards statin drugs. Doctors essentially get their information regarding statin drugs from the drug companies. What incentives do you think come into play there? The vast majority of doctors don't even know that statins have ZERO efficacy on patients without a previous history of heart attacks, yet they prescribe them anyway. For virtually everyone! Why do you think they do that? This information is available to anyone with a computer. Frankly, I think anyone who takes the time, has the interest, etc. to do their own due diligence should be applauded, not ridiculed. If for no other reason than to be better informed.

Seth Roberts (2014-03-25 12:30:26)

" the general lesson is that accepting someone as they are can provide them with a foundation from which they can go on to change and to become whole." I agree, that's part of it. I'd also say that treating alcoholism, retail sales, etc., are difficult tasks and that, because of that difficulty, two brains (e.g., boss and employee) are better than one (e.g., boss).

Seth Roberts (2014-03-25 12:56:34)

"That is the basis of libertarian philosophy." yes, the basic assumption of libertarian philosophy is that government consists of people who are not smart, not capable and not motivated telling people who are smart, capable and motivated what to do.

AI (2014-03-25 13:16:24)

If doctors were always correct in their diagnoses and always offered the most effective known treatments, and if doctors were available 24/7 to offer their service to each patient, then, yes, this would be a crazy idea. But, in the current environment, it may still be a crazy idea because: 1. What kind of a defense in a medical malpractice lawsuit is: "Well, my patient thought it was a good idea ..." ? 2. The internet, (even with PubMed, WebMd, NIH), is not good enough, user-friendly enough, deep enough. Doctors should also tell patients to research their condition in a decent medical library at a hospital or university. A lot of the knowledge in those libraries is not yet easily and cheaply available online (e.g. I don't know a way to access a selection of the vast number of books and journal articles housed in UCLA's Louise M. Darling Biomedical Library online as cheaply as I can on site. It sure seems like a lot of stuff there is not available in PubMed or on Amazon, etc.)

dearieme (2014-03-25 13:25:13)

There's an absurd new habit sneaking into the NHS. You walk in to talk to your GP and he says "we only have ten minutes so restrict yourself to one problem". Observe that this requires the patient to guess whether his symptoms add up to one problem or more. Bonkers, eh?

Joe (2014-03-25 13:41:22)

AI: "1. What kind of a defense in a medical malpractice lawsuit is: 'Well, my patient thought it was a good idea ...? That's why it shouldn't end with that. How about: "Due to my patient's request, I checked his information out more thoroughly, and other experts in the field thought it was a good idea. So I gave it a try, and lo and behold, my patient was very happy with the results." "2. The internet, (even with PubMed, WebMd, NIH), is not good enough, user-friendly enough, deep enough." It's easy to find great information outside of those sites (which are often part of the very problem we're discussing, not the solution). The internet is a very, very large (and deep) resource. It can lead you to great books, papers, journals, articles, etc. on many subjects, written by other experts or knowledgeable people. Especially if you're looking for more information about a specific subject. One doesn't have to graduate from medical school to learn the truth about statin drugs. In fact, medical schools may be the worst places to learn about them. Medical libraries are just tools, too. You can find good information there, and you can find very, very bad information there. Kind of like the internet.

GeoffD (2014-03-26 05:00:58)

As a Dentist, I would love it if people took some level of ownership over their problems. My least favorite patient response is an apathetic "Do whatever you think is best." The info is all out there now. Most people don't want to be bothered.

Dragan (2014-03-28 18:42:31)

I always thought that the Pygmalion effect is worth thinking about. This isn't quite the Pygmalion effect, I think, but the idea - treating everything as smart, capable, and motivated - strikes me as similar.

## **"Why Fuss About Paleo Life?" (2014-03-26 05:00)**

[1]dearime asks:

Why do people fuss so much about paleo life? The population has grown so much since that it's easy to believe that we've evolved a long way from then.

Jared Diamond wrote a paper about rapid evolution on an isolated island. When modern (factory) food was introduced to the island (in the 1940s?), there was a very high rate of diabetes, presumably due to the new food. Since

then, the rate of diabetes on the island has gone way down, although they still eat modern food. Diamond took this to be due to evolution (people with diabetes-resistant genes had more offspring), supporting dearime's point of view.

After the first Ancestral Health Symposium, Melissa McEwen commented how unhealthy many of the top people looked. On the other hand, Tucker Max commented how healthy the attendees looked in general. I agree with both observations. A paradox.

When I was an assistant professor, and wanted to sleep better, I believed wondering about paleo life was unhelpful because (a) we knew so little about it and (b) it must have differed in thousands of ways from modern life. Should I spend an hour trying to find out about paleo life and/or what paleo gurus recommend for bad sleep? Or should I spend an hour trying to find out how ordinary people have improved their sleep? My answer was the latter. I ignored paleo life.

Looking into how ordinary people improved their sleep did help. I eventually reached a non-trivial conclusion: Eating breakfast made my sleep worse. No paleo guru had said that – I had been right to ignore them. Yet it made evolutionary sense. Cavemen did not eat breakfast, I was pretty sure. (No refrigerators.) After that I paid more attention to what evolutionary thinking would suggest. This led to [2]several discoveries: the effect of faces in the morning on mood, the effect of standing on sleep, and the Shangri-La Diet. It is incredibly hard to discover big new experimental effects (such as the effect of morning faces), especially in fields you know little about (my specialty in psychology was animal learning, not mood, sleep or weight control). I was impressed.

[3]The effect of bedtime honey (more generally sweets in the evening) on sleep emphasizes the paradox or puzzle or whatever you call it. I found out about the honey effect by paying attention to what works. No paleo involved. Stuart King told me it improved his sleep. Here are three reasons to look at ordinary experience and avoid paleo theorists: 1. It turned out to help. 2. It's a huge effect and very easy. 3. Paleo theorists have said the opposite: avoid carbs, avoid sugar. If you followed their advice, you would do the opposite of what helped Stuart and me. On the other hand, I increased my belief in the effect because it made evolutionary sense: 1. It makes sense of why we like sweets. 2. It makes sense of why our liking for sweets goes down when we are hungry (surely due to an evolved mechanism). 3. It makes sense of why we eat sweets more in the evening (presumably due to an evolved mechanism that makes sweets taste better in the evening).

The short answer to dearime's question is that, in my experience, it is incredibly hard to learn anything about health. There are so many possibilities and evolutionary thinking helps choose among them – decide which to take the trouble to test.

---

Jake (2014-03-26 09:14:25)

When you are young, anything you do health-wise seems to work. When you are over 60, you have no room for error. That is when you must mimic your evolutionary past. I am 71 and my wife and I have followed a strict paleo low-carb lifestyle for the past 5 years which resulted in great improvement in our health. In the last two years I have mimicked paleolithic meal frequency including hunting failures and seasonal famines. This has resulted in even more dramatic improvement in our health.

Joe (2014-03-26 09:18:32)

Seth: "The rate of diabetes has gone way down." 'According to the CDC, the rate of diabetes has roughly DOUBLED in just the last 30 years.' <http://www.cdc.gov/diabetes/statistics/prev/national/figage.htm> And it was rising in previous years. And it's projected to DOUBLE again in the next 30 years. So if there are such things as "diabetes resistant genes," it appears that diabetics are reproducing far faster than non-diabetics. Seth: "I believed wondering about paleo life was unhelpful because (a) we knew so little about it and (b) it must have differed in thousands of ways from modern life." We know quite a bit about it. We can also assume many other things about it. Such as HOW it must have differed in the "ways of modern life." For example, that our ancient ancestors certainly didn't eat fast food. For a long time, they didn't even eat cooked food. They didn't eat processed or refined foods. They didn't eat sugar. They didn't eat grains. They probably didn't eat three meals a day. They probably were forced to fast from time to time. They ate what was available to them, e.g., meat, fish, insects, snakes, seeds, veggies and fruits, when they could find them. They spent most of their waking hours hunting and gathering. They were outside a lot. They got lots of sleep. Etc. Which is pretty much what "paleo" life today is all about. Eat only REAL foods. Don't eat sugar. Don't eat grains. Don't think you need to eat three meals a day. Exercise. Get a good amount of sleep. And that's about it. Our ancestors managed to live pretty healthy, relatively disease-free lives living that way (or we wouldn't be here today), and we can today, too. Are there other ways to "skin the cat"? Yes. But why "fuss" about a way of living that served us so well for hundreds of thousands of years? Seth: "3. Paleo theorists have said the opposite: avoid carbs, avoid sugar. If you followed their advice, you would do the opposite of what helped Stuart and me." Maybe the purists would say that. But the vast majority of them would say that a 80/20 rule is good enough. That is, feel free to tinker around the edges. If you can tolerate a little sugar, and not gain weight, go right ahead. If you can eat a lot of simple carbs and not gain weight, go right ahead. But some of us can't do that without gaining weight. Seth: "If you followed their advice, you would do the opposite of what helped Stuart and me." Have you ever eaten a strict paleo diet? Unless I misunderstood you, you previously said that you ate pretty much the way Alex C. eats. Which is apparently a strict vegan diet. But you decided to "tinker around the edges" yourself, and try a little animal fat. Which helped you think better and faster. So the question is, if you had been eating a paleo diet, would you have been thinking better and faster all along? :) Seth: "The short answer to dearime's question is that, in my experience, it is incredibly hard to learn anything about health. There are so many possibilities and evolutionary thinking helps choose among them — decide which to take the trouble to test." At least we can agree that there are many possibilities, and that taking the trouble to test them is extremely beneficial. That's precisely how I found paleo and lost 100 pounds. But I think we can learn more by looking back in time (what we already know worked pretty well), than trying to forecast where evolution will take us (what we hope will work for us)...because that may not be a place we really want to go.

Maarten (2014-03-26 10:22:25)

Evolutionary thinking is reverse engineering. It's creating a narrative for an observation that can't be explained by logic, filling the gap with theories that can't possibly be proven. It's what humans do when the world becomes too complex or unpredictable to understand. Finding a narrative is important, so in that way I'm attracted to paleo thinking. However, it should never get in the way of (self-)experimenting and observations. As you point out, when your observations conflict with a theory, just abandon it and find a new one. And one day, I hope to be okay with not understanding, or lacking a clear narrative for most observations in my life, and just live it.

dearieme (2014-03-26 11:40:19)

"We can also assume many other things about it." Why would I base my diet on someone else's guesses? "But why "fuss" about a way of living that served us so well for hundreds of thousands of years?" "us"? We are not them; we have evolved. Our numbers have shot up so far since the beginning of the neolithic that we are bound to have many differences from them. Still, if you want to mimic what you fondly imagine is the diet that kept 'em going to the ripe old age of 35, I admire your pluck.

Joe (2014-03-26 12:22:41)

dearieme: Why would I base my diet on someone else's guesses? What then do you base YOUR diet on? "We are not them; we have evolved." Do you think we have "evolved" to eat fast food, processed and refined foods, sugar, grains, etc. in just 10,000 years? If so, why all the obesity, diabetes, heart disease, cancer, etc? That sounds like we may be DEvolving. "Still, if you want to mimic what you fondly imagine is the diet that kept 'em going to the ripe old age of 35,

I admire your pluck." I do have a lot of pluck! I attribute it to eating like Grok. But to your question, should I assume then that you think eating lots of fast food, sugar, processed and refined foods, industrial oils, grains, getting little or no exercise and sleep, etc. is helping us to lead longer lives? By what mechanism? Paleo man didn't get to enjoy our present lifespans, but the reasons for that are pretty obvious, aren't they. They didn't have life-saving medicines, like antibiotics. They didn't have doctors. Many of them probably starved to death. They also died from rampant infectious disease. They spent much of their time fighting each other over limited resources (warfare). Hunting and gathering in paleo times was a very dangerous business. Injuries (and deadly infections) were commonplace. It's surprising they lived as long as they did. How long do you think we'd live today without medicines? Without life-saving procedures? Without doctors? Answer: Not long.

Joe (2014-03-26 12:43:00)

Dearieme, as you can see from this graph, as recently as the early 20th century, lifespans were still only 39 years (average of males and females) or so. <http://www.beyondveg.com/nicholson-w/angel-1984/angel-1984-1a.shtml> What else happened in the late 19th and early 20th century? Could it be the development of Modern Medicine? [http://en.wikipedia.org/wiki/History\\_of\\_medicine](http://en.wikipedia.org/wiki/History_of_medicine) Hmmm.

Seth Roberts (2014-03-26 13:45:28)

When I wrote "the rate of diabetes has gone way down" I meant the rate on this particular island – the island that Diamond was writing about.

dearieme (2014-03-26 14:15:45)

"What else happened in the late 19th and early 20th century? Could it be the development of Modern Medicine?" Probably it was overwhelmingly caused by greater wealth bringing clean water, sanitation, and plentiful foods, plus the wonderful fluke of the discovery of antibiotics.

Joe (2014-03-26 14:32:35)

Sorry, Seth. I was focused on your suggestion that just in a few years, people had actually EVOLVED to eat modern foods. I'm not a geneticist, but I'm unaware of any evolutionary theory that would account for anything like that, so quickly. I think the more reasonable explanation is that the vast majority of diabetes goes undiagnosed (if this is in fact the island of Papua New Guinea). "CONCLUSIONS: The vast majority of persons with type 2 diabetes in PNG are undiagnosed and are not receiving treatment: based on the lower of two country prevalence estimates, less than 3 % of the diabetic persons in the country are seen at health facilities. Services are limited, with only a handful of health professionals specially trained in diabetes. Expansion of services and awareness and prevention programs are urgently needed." I don't know when "modern foods" were introduced, or even what "modern foods" really means. And I hope they didn't use obesity as a proxy for diabetes, because the vast majority of obese people do not have diabetes.

James M. (2014-03-26 14:36:01)

Looks like a great debate. Personally learning from Paleo/Primal (and even other sources like Weston Price for traditional foods, Raw foodists, vegetarians) and trying to keep it 80/20 has allowed me to: drop 30 lbs; maintain my weight; cleared up my skin, allowed me to get off an expensive medication; reversed health issues; gave me more energy; a clear mind; and so on. There are a lot of Paleo/Primal promoters who are saying to try different things and tweak the diet/lifestyle as one goes, and not be an extremist about it. Paleo/Primal also lead me to this website which put out there alternative approaches and the benefits of self-experimentation. By experimenting with Paleo/Primal I benefited. It's quite possible some other approaches may have given me the same results, but then again if it works, don't break it. Still learning as I go. I did note that Seth was talking about diabetes rates on the island and not the population as a whole. If people can be healthy on a diet high in sugar and carbohydrates, good for them. I've found its doesn't work for me. Keep up the interesting writing. I don't necessarily agree with everything, but it does open the door to re-thinking on issues, and maybe a change in opinion.

Joe (2014-03-26 14:36:12)

Dearieme: "Probably it was overwhelmingly caused by greater wealth bringing clean water, sanitation, and plentiful foods, plus

the wonderful fluke of the discovery of antibiotics.” That too. So it’s wasn’t really fair to compare lifespans between paleolithic and neolithic eras, right?

Gina (2014-03-26 14:41:11)

”I do have a lot of pluck! I attribute it to eating like Grok.” You eat nothing like Grok. Grok wouldn’t even recognize the meat and vegetables that you eat. Eat some cattails and bugs and wash it down with some untreated water and you might be getting closer to Grok’s ballpark. Avoiding processed foods is a great idea, but it doesn’t mean anyone is really eating ”paleo”. <https://www.youtube.com/watch?v=BMOjVYgYaG8>

dearieme (2014-03-26 14:46:46)

”Do you think we have ”evolved” to eat fast food, processed and refined foods, sugar, grains, etc. in just 10,000 years?” I think it most unlikely that we haven’t evolved to eat grains in the last 10000 years. We know for sure that we evolved to drink milk in adult life in a much shorter period than that. As for ”fast food, processed and refined foods, sugar”: since I don’t eat an Americanised diet I’m personally probably not much affected. Perhaps I have evolved to thrive on fish-and-chips, a wonderful fast food unavailable to my ancestors before the 19th century, and a perfectly reasonable part of a mixed diet. I particularly enjoy it with mushy peas with a squeeze of lemon on them. Allow me to recommend it to you. Or perhaps it’s more likely that some fast foods, such as f- &-c, are nutritionally beneficial without any need for massive recent evolution. If what you are asking is why Americans like their food and drink so sweet, I have no polite answer to offer, unless it be that it could be a response to the government’s War on Fat in the diet. ”If so, why all the obesity, diabetes, heart disease, cancer, etc?” Rather than being so excitable, take them calmly in turn. Heart disease rates have collapsed: the mysterious rise from the 1920s to the 1960s has been followed by a mysterious fall since. There’s no explanatory theory yet available that’s backed by good evidence. The scale and timing of the changes rule out age distributions, the rise and fall of smoking, and changes in diet as explanations, and (I’m tempted to say ”of course”) medical intervention. Cancer is the subject of much hysteria. Last time I looked (about ten years ago) it was quite clear that talk of cancer epidemics in developed countries was rubbish. Once you’d corrected for the rise and fall of smoking, and the ageing of the populations, there was no increase in rates. Nil. Nowt. There was nothing to explain. Diabetes: there I have less knowledge. In the UK it is very hard to know whether there has been much or any intrinsic growth in Type II because (i) the population is ageing, but that never seems to be allowed for in consciousness-raising articles in the papers (ii) the racial composition of the population is changing: this may be a big deal because South Asians are particularly prone to the disease (iii) the threshold for diagnosis of Type II has been reduced, and (iii) the government pays GPs for each diagnosis diabetes. So higher rates of diabetes are of course reported. Whether that has happened on a like-for-like basis is unknown to me. But if there has been no change like-for-like, there is again nothing to explain. As for obesity, who knows? Perhaps it’s caused by an infection that stops the feeling of satiety working properly? Most aspects of human biology seem to be complex and little understood. Consequently quasi-religious doctrines on food strike me as inevitably short of evidence. I see two rational responses. (i) Eat a mixed diet, in moderation; certainly avoid slurping large beakers of brown sugar-water; probably include far more fish than is, for example, the American norm. (ii) See whether you can learn by self-experimentation, such as that advocated by our blogger, but don’t assume that the lessons that apply to you necessarily apply to everyone else.

Joe (2014-03-26 15:02:10)

James M: ”There are a lot of Paleo/Primal promoters who are saying to try different things and tweak the diet/lifestyle as one goes, and not be an extremist about it.” Exactly, James. As Seth says, this blog is about personal science, self-experimentation, and the scientific method. It also shouldn’t be about what works on an island somewhere; it should be about what works for YOU. I personally believe that most of what ails us is related to what we consume (and what our parents consumed while we were in the womb). Yes, I’m sure that our individual genes come into play, too, but the field of epigenetics shows us that we can also influence our DNA by what we eat. <http://advances.nutrition.org/content/1/1/8.full>

Joe (2014-03-26 15:27:19)

Dearieme: ”Heart disease rates have collapsed: the mysterious rise from the 1920s to the 1960s has been followed by a mysterious fall since.” You’re absolutely right! It peaked in the 70s and has been plummeting ever since. And well before anyone ever heard of statin drugs. For more about this phenomenon, read this book: ”You Will Not Die of A Heart Attack,”

by Dr. David S. Grimes. Smoking appears to be the main suspect, but there is no clear answer. "Allow me to recommend it to you." I have no problem at all with fish and chips that are made without industrial oils and wheat flour. Know of any? :) "I think it most unlikely that we haven't evolved to eat grains in the last 10000 years." I disagree. Read Dr. Davis's great book, "Wheat Belly," for all the details. Also, the wheat being grown today is not the wheat your grandmother ate. "Cancer is the subject of much hysteria." Unfortunately, that's true, too. We have no idea what causes cancer (in general). And now we're blaming relatively harmless viruses for it. :( "As for obesity, who knows? Perhaps it's caused by an infection that stops the feeling of satiety working properly?" I think the vast majority of obesity is caused by what we eat, and how we live. Ditto diabetes. "I see two rational responses. (i) Eat a mixed diet, in moderation; certainly avoid slurping large beakers of brown sugar-water; probably include far more fish than is, for example, the American norm. (ii) See whether you can learn by self-experimentation, such as that advocated by our blogger, but don't assume that the lessons that apply to you necessarily apply to everyone else." I have no problem with any of that, Dearieme, accept perhaps with the word "moderation." That's what seems to trip a lot of folks up. And especially if it works for you, and your health markers are okay. Good luck!

Joe (2014-03-26 15:45:05)

Gina: "You eat nothing like Grok. Grok wouldn't even recognize the meat and vegetables that you eat." How do you know what I eat? Was that you peeking in the kitchen window the other night? You were wearing a pointed cap and carrying a broom, right? I eat as close to what Grok ate as I can, only better. I eat grass-fed meats (including organ meats and bone marrow), wild game, like venison, elk, rabbit, wild-caught fish, organic veggies and fruits, even some so-called exotic foods, like snails, oysters, etc. "Eat some cattails and bugs and wash it down with some untreated water and you might be getting closer to Grok's ballpark." I've eaten cattails, and a lot of other stuff you wouldn't touch with a ten-foot pole. Like snakes, maggots, grubs, bugs, lizzards, etc. In the service, I was taught to eat just about anything, if anything was all I had to eat. Including untreated water, which is pretty easy to do if you know how. Grok knew how. And so do I. "Avoiding processed foods is a great idea, but it doesn't mean anyone is really eating 'paleo.'" It means they're on their way, and that's a "good thing"!

Joe (2014-03-26 16:35:57)

Dearieme, one reason (I'm sure there are more) for the plunge in heart attacks since 1970 could be this: "When there is increasing traffic volume on a highway, it may make sense to make the highway into a larger freeway to allow a higher traffic volume. In short, the same happens to the coronary arteries: When blood flow is increased, the inner layer of vessel cells (endothelial cells) sense this necessity and start the process of enlarging from capillaries into genuine collateral vessels. In response to endurance exercise training (such as running, bicycling, swimming, and hiking), blood flow is increased, which leads to a conversion from capillaries into collaterals. This is a very elegant treatment everybody can accomplish. It reduces the chances of the occurrence of angina pectoris, myocardial infarctions, and death. Beyond the interventional, surgical, and medical treatments against coronary artery disease, this collateral training is a natural and valuable therapy that many patients can apply by themselves, for themselves, if only they are aware of it. " <http://circ.ahajournals.org/content/116/11/e340.full> In short, exercise can create new collateral arteries, which is akin to giving yourself your own by-pass operation! I don't know exactly when the fitness craze started (the 70s, it seems), but perhaps that has had more of an effect than we thought?

dearieme (2014-03-27 05:25:56)

But lots of countries exist where it is or was normal for people to take far more exercise than Americans do or did. The rates peaked for them around 1970 too.

Joe (2014-03-27 07:59:56)

Which countries?

David (2014-03-27 10:17:39)

The issue with the 80/20 rule was initially put forth as a way of making Paleo easier to follow, now its a way to say, "we might be wrong so experiment." Paleo is an entire lifestyle change and therefore virtually impossible to know what is really causing improvements in some people's health. The problem i have with Paleo is that's its a narrative, a belief system about what to eat. If Grok only got honey infrequently because he would have to scavage it from bees, then you should not eat honey at

night - even if we discover it helps. I don't find that logic compelling, and one thing i have noticed about the Paleo diet over the last decade is that it keeps evolving. First it was protein and veggies with low fat, then they added saturated fat, then tubers, i recently saw a paper on legumes being Paleo. At this rate, Paleo will involve eating bread in the next year. Pioners like Mark Sisson have said they would change certain things in their books. Robb Wolf has been making big changes in his understanding of Paleo. We do not fully understand Paleo. I find using evolutionary history as a valuable framework, but i'm more into finding an optimal diet and lifestyle, and i believe some answers might be outside the current Paleo understanding. That's why i like Seth's blog, he's into experimenting, not following an idea.

Joe (2014-03-27 11:01:39)

David: "The problem i have with Paleo is that's its a narrative, a belief system about what to eat. If Grok only got honey infrequently because he would have to scavage it from bees, then you should not eat honey at night - even if we discover it helps." That's simply not true, David. If it helps you to take a little honey at night (say, to sleep better), go ahead and have a bit of honey. I get a good amount of sleep, but I tried it anyway, and it didn't help me at all. On the other hand, there are many reasons that some people sleep poorly, right? Maybe there are other ways to "skin the cat"? Magnesium, potassium and Vitamin D deficiencies can easily wreak havoc with your sleep. Why not check that out, too? Or carefully review your daily routines. Anything there that might be affecting your sleep? But a little bit of nightly honey is not even close to being a deal breaker, as far as paleo goes. It might, however, cause you to gain weight and/or affect various health markers. "We do not fully understand Paleo." Agreed! But that doesn't mean it's not a great place to start, does it? That is, eat what YOU think paleo is. For example, eat real foods, eat no processed or refined foods, no industrial oils, no sugar and no wheat. See what that does for you. More importantly, see what it does to your health markers. Then decide if you want to add or subtract any foods. See what THAT does for you. See what THAT does to your health markers. Etc. For some strange reason, you've come to think of paleo as a rigid system. It's not! Compared to diets like vegetarianism and veganism, which eliminate entire food groups(!), paleo is about as permissive and logical as a lifestyle can get. It's all about experimenting. Also, paleo isn't just about what you eat, it's about how to live a healthier life; it includes getting more exercise, and getting it outdoors (whenever possible). Getting good sleep. Etc. "I find using evolutionary history as a valuable framework" Indeed it is!

David (2014-03-27 11:37:10)

Joe, i appreciate your view of Paleo, but i followed the Paleo diet for several years and for most Paleo advocates, it's a belief system, a lens that you need to review everything through. Did Grok do it? If not, then you probably should not either. I later abandoned Paleo after several years because 1) was slowly gaining weight 2) stopped making progress in the gym 3) sleep got worse and 4) had low energy and it was affecting my work, 5) eating so much meat gave my clinically high serum ferritin levels. I was very healthy before Paleo and got less and less healthy during Paleo, so i dropped it after about 7 yrs although i bought into it for far too long and believe it really affected my health. Most damaging in my opinion was the low carb recommendations and the lack of cardio vascular workouts. I really like many of the Paleo principals, but I don't consider eating real food, lowering your stress, exercising and getting more sleep to be anything more than common sense. The issue of grains and dairy are still debatable in my mind (my wife is 100 % gluten free by choice). I agree that Paleo has helped many people, but many of those seem to have had health problems before finding Paleo. The point of Seth's post was "why worry about Paleo". I agree with him and you that its a valuable framework, but i'm much more willing to ignore the Paleo advice if my personal experience differs. In the past, it was: "No, high carbs are bad. You just need to get through the carb flu and get fat adapted." After almost ten years of playing that game, i finally gave up.

dearieme (2014-03-27 12:27:02)

"Which countries?" Read the fourth para. <http://www.drdaavidgrimes.com/2013/07/an-epidemic-of-coronary-heart-disease.html>

Joe (2014-03-27 13:11:34)

David: " I was very healthy before Paleo" Then why did you try paleo??? "Most damaging in my opinion was the low carb recommendations and the lack of cardio vascular workouts." David, I can see by those comments that you don't know much if anything about paleo. First, paleo doesn't have to be "low-carb." You can essentially eat all the veggies you want! You can eat

fruits, too! Especially if you don't have a weight problem. I average between 100-150 grams of carbs per day. That's an awful lot of carbs, David. And sometimes even more. And in no way is cardio exercise discouraged! Just the opposite, in fact. What IS discouraged, is something called "chronic cardio." That's basically the marathon and half-marathon type runners. Repeat after me: Chronic cardio is bad. Cardio is good. I run 5k about 5 times per week. Sometimes I just briskly walk it. I never go further than 5k. And I always do it outside. And I don't stress out if I happen to miss a couple days. Note: Just about anyone can do 5K. "I really like many of the Paleo principals, but I don't consider eating real food, lowering your stress, exercising and getting more sleep to be anything more than common sense." Semantics, David. Call it what you want, but paleo is all about common sense. Eating REAL food. Not eating processed or refined food. Lowering your stress. Exercising. And sleeping. Note: saying you work 10 hours a day and can't find the time to run or walk for 30-35 minutes each day is known as bull ca. "The point of Seth's post was "why worry about Paleo"." The only ones here who appear to "worry about Paleo" are the folks who aren't doing paleo, or don't appear to understand what paleo actually is. And isn't "eating so much meat gave my clinically high serum ferritin levels." Have you been checked for hereditary chromatosis or liver disease? Do you have RA? Some solutions : eat less red meat and donate blood from time to time (which is a good idea anyway). Stop being so rigid, David! "After almost ten years of playing that game, i finally gave up." That's too bad. I wonder if you were ever really on paleo? But it's definitely your prerogative! Good luck!

Joe (2014-03-27 13:23:46)

Dearieme: It was just a guess anyway. But the fitness craze wasn't isolated to the U.S. Do you really think that the UK took "far more exercise" than we Yanks? Really? But isn't it interesting to know that you can effectively give yourself a coronary bypass operation (increasing the flow of blood to your heart) with the right kind of exercise? I do!

dearieme (2014-03-27 13:36:58)

The only time I lived in the US was for three months in 1966. I was struck that the young men took no exercise - no cricket, no rugby, no soccer, no walking or cycling to work. People in Britain took far more exercise. I lived in a YMCA with a good gym. Only four people ever used it: two young Britons in the US for their university long vacations, and two young Italians ditto.

Joe (2014-03-27 14:12:55)

Well, I'm not surprised you saw no cricket, Dearieme. :) But no baseball, no softball, no field hockey, no hockey, no soccer, no football, no flag football, no rugby, no bicycling, no jogging, no lacrosse? Wow. Even in the 60s, those were pretty popular activities. Not like they are today, but still very popular. What city or cities? I've spent some time in your country (mostly in London), and the most exercise I saw Brits getting was by staggering from pub to pub. Not that there's anything wrong with that! :) PS: One of your countrymen, Dr. Malcomb Kendrick, thinks heart disease is caused by dysfunction in the HPA axis. You can read about it in his book, Then Great Cholesterol Con, The Truth About What Causes Heart Disease and How You Can Avoid it." I tend to agree with him.

David (2014-03-27 14:20:01)

"Then why did you try paleo???" Because i was trying to be like Grok. Joe, these days Paleo has a lot of variability, you could argue an all meat Inuit diet is Paleo as is a super high carb Kitavan diet, but i started Paleo back when it was more low carb, when everyone talked about the carb flu and getting passed it, about being fat adapted, when you had to watch fruit intake because too much would be too much sugar, etc. It was mostly veggies for carbs and i don't consider veggies carbs. No way broccoli gets me through the day the way potatoes do. I followed the likes of Cordain, Sisson, Art Devany, and others and it was lower carb. I felt it was more strict back when i was following it and i admit that i kept trying to go low carb to get fat adapted and break through the carb flu. I'm aware of the chronic cardio vs moving slowly distinction in Paleo, but i've been doing a little more "chronic cardio" and i feel better. I'm sure someone will say i'm damaging my heart and should be walking and not jogging, but i feel better and i'm not over doing it. I'm not training to be a marathon racer. (I do agree with the Paleo idea on that being harmful). As for blood iron levels, i don't have a genetic disease but i do give blood frequently now. I ate so much red meat on Paleo (I bought it from a local farmer where his cows were 100 % grassfed) that i began to detest it. Today i had leftover potatoes, lima beans, and pot roast for lunch, when i was doing Paleo the potatoes and beans would have not been allowed. I find i feel much better with higher starch and sugar content like potatoes, beans, corn and grains. I also had horrible sugar cravings during Paleo that never went away and i

would binge on chocolate sometimes. Now i just eat honey or drink fruit juice if i can. Are they Paleo? Well they weren't a few years ago, maybe now they are. My point is it goes back to Seth's post where he said: "Eating breakfast made my sleep worse. No paleo guru had said that — I had been right to ignore them." I got some good ideas out of Paleo, but at some point, like Seth mentioned, i needed to ignore the paleo gurus and try some things that were not part of the Paleo doctrine.

Joe (2014-03-27 14:56:14)

"Because i was trying to be like Grok." I'll take that to mean: just for the hell of it. But if you can't live without eating lots of potatoes, beans, corn and other grains, fruit juice, etc., then paleo isn't for you. And if you are doing "chronic cardio," yes, you ARE damaging your heart, but jogging vs walking has nothing to do with it. It's the amount of time and miles you put in. The actual science behind this is all over the internet, so you don't need to listen to paleo gurus. So I'm not really sure that you know what chronic cardio is, either. I have a bit of chocolate, myself. But only really dark chocolate (88 %). It's actually good for the heart. The way I usually satisfy my own sweet tooth, the part that remains, is to eat various paleo treats made with sweeteners like stevia and xylitol. But infrequently. Mostly just on holidays. So, now that we've seen that paleo isn't for you, and because I really have no idea how you are currently eating, all I can do is wish you good luck! So...good luck!

David199 (2014-03-27 16:08:54)

I'm going to try and get back to the original question, about why we obsess over Paleo life. The short answer, is that many people believe we are best adapted to Paleo life and the further we move away from it, the further we move away from optimal health. Second, because its impossible to test every single aspect of health, it helps to have a framework. Did Paleo man have access to high fructose corn syrup in handy little aluminum cans? No, then maybe we shouldn't either. No need to wait until a bunch of studies come out, we can use the Paleo framework right now to make the decision. My specific issue is that we need to be careful and not over-rely on a single framework because its based on our best guess of what happened a million years ago. That doesn't mean its worthless, it just means that its one of several potential possibilities. So Joe, let me ask this question: If someone followed a Paleo diet (which i'm going to assume still prohibits grains) and then that person as an experiment ate grains for a 6 months and felt better and had better biomarkers, would you: 1. Recommend that they keep eating grains because it appears to be good for them even though Paleo man didn't have them. 2. Recommend they don't eat grains because Paleo man did not have access to them and therefore there may be other harmful things going on that are not represented in the way they feel or their test results (i.e. silent evidence). I would say #1 and i'm guessing you would say #2. And don't get me wrong, i fully understand position #2 and believe silent evidence is very important to consider. Joe, you and i began to disagree over a few points, but i want you to know that i still use the Paleo framework quite a lot. It's not something i completely dismiss, but i'm willing to consider that things outside the Paleo framework, even opposite to it, may be more healthy.

dearieme (2014-03-27 17:12:13)

London, Joe, is scarcely in Britain at all. No, back in '66 it was striking to this foreigner how little exercise Americans seemed to take. I know that much of your climate is unsuitable for the sort of country walks, and the more testing hill-walking, that are so popular here year round. I understand that gardening for nine months of the year would be pretty brutal in much of the US. But heavens, your population even plays golf largely sitting on its bums. And, in that one three month spell (and many short visits since) everyone has emphasised to me that nobody walked anywhere. They even drive to the gym!! I don't know about you but for most of my career I cycled to work. You can in our climate (though it's kinder in the dry east of the country).

Joe (2014-03-27 17:28:29)

David, those are valid questions. I don't eat grains not because of paleo, but because grains are bad for me. Grains, especially wheat (rice isn't so bad, which is why I eat a little sushi from time to time), provide almost no nutrition (which is why it always needs to be "fortified." I concentrate on eating NUTRIENT-DENSE foods. I want as much nutrition as I can get out of a food. Eating grains is much like eating sugar (as far as I'm concerned) - it's just empty calories. And they'll just help to make you fat. There is no way that eating grains can improve your health profiles (BS marketing by the grain companies aside), simply because it brings nothing good to the nutritional party. It does, however, bring some bad things, and if you're interested in learning about them, you can't beat Dr. Wm. Davis's book, "Wheat Belly." In short, today's wheat is nothing like the wheat your

grandmother ate. I would never recommend that anyone eat grains, especially wheat. On the other hand, if that was all I had to eat (which has happened at times to various populations in our history), of course I'd eat it. I'd eat just about anything if my very survival was at stake. But we have choices today, perhaps too many choices, and I think we should be thankful for them, and exploit them to the fullest. You say that you still use the paleo framework a lot. I think by eating lots of potatoes, beans, corn and other grains, and things like fruit juice, and bingeing on chocolate, etc., you've left the paleo "framework" in your rear view mirror. It's much like a vegan regularly eating meat and still claiming to be a vegan. Tweaking a "framework" on the edges is one thing, but that's not what you're doing (IMO). Look, just by eating real foods, avoiding processed and refined foods, and sugar, you may somewhat improve your health markers. You sound like that may be good enough for you. It's just not good enough for me. But whatever you do, don't stress over it. Grab the bit and run! And good luck! PS: If you do find anything outside the paleo framework that's more healthy, please let me know! I've been looking for many years and I can't find anything even close.

Joe (2014-03-27 17:49:11)

Dearieme, I may not know your country as well as you do, but I do know that London is in Britain. And I have no idea why you'd use the word "scarcely" there. Perhaps you're just trying to pull my leg? :) You won't tell me what U.S. city you visited, but I need to tell you that you have a very narrow perspective of my country. It's a VERY big place. You're painting us with a very narrow brush. Yes, we have places where the people rarely walk. But we also have places where we seldom do anything else. I always drove to work or took the train. Mostly because I didn't exactly want to walk or ride a bicycle the 30-40 miles to the office and back. Like I said, we're a VERY big country. But that didn't stop me from jogging 5-6 miles when I got home, etc. You've probably heard of the blind men and the elephant story? [http://en.wikipedia.org/wiki/Blind\\_men\\_and\\_an\\_elephant](http://en.wikipedia.org/wiki/Blind_men_and_an_elephant) Well, the next time you come over here, you really do need to grab more parts of the "elephant." :)

Nancy Lebovitz (2014-03-30 02:35:20)

Joe, I have a friend who gets sick (he describes it as his digestion shutting down) if he doesn't eat a lot of wheat, and it's the same for at least one of his relatives. While I think there are tendencies in what foods are good and bad for people, I think the only advice I'd give to everyone is "give some attention to how your food affects you". Fish seems to be very good for me, but it's deadly for some people.

Possible relationship between early abuse and obesity: <http://www.sciencedaily.com/releases/2014/03/140320134722.htm>

Gina (2014-03-27 07:56:26)

Thanks so much for linking the the Gessen interview, Seth. I can't wait to read the book.

Joe (2014-03-27 08:17:31)

A study on the effect of medications on falls in the elderly, and not one word about statin drugs? Amazing. Simply amazing.

Andrew (2014-03-27 11:21:38)

Great article on why the mouse as control animal has proved disastrous for medical research: <http://slate.me/rA6eqo> Seth: I agree, great article. thanks.

Al (2014-03-27 14:16:02)

Thank you for the link to the page by the guy who is a speed reader with cancer. It's interesting that this particular guy did \_not\_ say "I'm a speed reader, therefore I went on the internet and tried to find a bunch of web pages to speed read." Instead, he said: "I have the ability to speed read very technical material, so I went to the library at Duke and read over 800 papers on melanoma ... " It's really interesting that he found a promising new (to him and his doctors) idea for his own therapy. It's also extremely interesting that there are comments on that page where people talk about their own success stories fighting cancer, despite their doctor's gloomy prognosis. In addition, there is this: "...in Latvia, Melanoma is treated by virotherapy drug name Rigvir. Basically you ingest a virus that is deadly to melanoma but harmless to humans." There are articles about Rigvir and Oncolytic Viruses on Wikipedia. Also, here are some resources described (but not necessarily available online) by the UCLA library catalog. <http://catalog.library.ucla.edu/vwebv/search?searchArg=oncolytic+virus&searchCode=GKEY^&searchType=1>

Charles (2014-03-27 15:14:12)

Only those that survive cancer have the ability to tell you about it. What's hard to determine is exactly what helped, if at all. That indeterminable thing is the only thing that would help another patient

Nancy Lebovitz (2014-03-30 02:36:51)

Andrew, thanks for the link to the mouse article(s). I'm working my way through them, and this is a very serious situation.

## **Larger Lesson of "We Were Wrong about Saturated Fat" (2014-03-28 05:00)**

My sister sent me a link to [1]an article ("Butter is Back") by Mark Bittman, the *New York Times* food columnist, about a recent review that found saturated fat didn't cause heart disease. I told my sister I had clicked on the link but had forgotten to read the article.

My sister was incredulous. *How could you not want to say "I told you so"?* she wondered. (In [2]a 2010 talk I questioned the danger of butter.)

Here is the relevant passage, according to my sister:

A meta-analysis published in the journal *Annals of Internal Medicine* found that there's just no evidence to support the notion that saturated fat increases the risk of heart disease. (In fact, there's some evidence that a lack of saturated fat may be damaging.) The researchers looked at 72 different studies.

I told you so. But this part interests me more:

No study is perfect and few are definitive. But the real villains in our diet — sugar and ultra-processed foods — are becoming increasingly apparent.

Uh-huh. The experts were staggeringly wrong about saturated fat...but they couldn't possibly be wrong about "sugar and ultra-processed foods". That makes no sense, but that's what Bittman wrote ("increasingly apparent"). To me, what is increasingly apparent is that nutrition experts shouldn't be trusted.

I don't know what "ultra-processed foods" are but I am beginning to believe the experts are utterly wrong about sugar, too. As far as I can tell, sugar in the evening improves sleep – by a lot, if you get the details right – and nothing is more important than good sleep. If you have read *The Shangri-La Diet*, you already know that sugar alone cannot have caused the obesity epidemic. It is more complicated than that.

1. <http://www.nytimes.com/2014/03/26/opinion/bittman-butter-is-back.html>
2. <http://quantifiedself.com/2010/09/seth-roberts-on-arithmetic-and/>

---

David (2014-03-28 06:02:21)

Great post. I am always amazed at how confident people are in answers that turn out to be wrong. I find it depressing that journalists continue to make these errors, instead of saying "Finding out that we were wrong about saturated fat makes me question whether we are right about other supposed 'angles and demons' in our food supply."

nicole (2014-03-28 06:27:00)

"To me, what is increasingly apparent is that nutrition experts shouldn't be trusted." Made me spit out my coffee laughing...so true.

RAD (2014-03-28 07:20:07)

Seth, I'm with you that nutrition experts shouldn't be trusted on macronutrient research (fats, carbs, proteins) but I'm much more inclined to trust micronutrient research (e.g. Vitamin D, Zinc, etc.).

Nancy Lebovitz (2014-03-28 07:20:39)

Workplace wellness programs are designed to get people to follow theories of what causes health– there's no feedback from the person about whether the program is making them healthier. <http://www.newsworks.org/index.php/thepulse/item/64755-whats-next-for-workplace-wellness-lifevest-health-wellnow> <https://www.lifevestthehealth.com/> How sure are you that obesity is a disease? That losing weight will make fat people healthier?

Gina (2014-03-28 07:23:09)

Maybe it's too soon for a victory lap?: "The meta-analysis of dietary fatty acids and risk of coronary heart disease by Chowdhury et al. (1) contains multiple errors and omissions, and the conclusions are seriously misleading, particularly the lack of association with N-6 polyunsaturated fat. For example, two of the six studies included in the analysis of N-6 polyunsaturated fat were wrong. The relative risks for Nurses' Health Study (NHS) (2) and Kuopio Ischemic Heart Disease Study (KIHD) (3) were retrieved incorrectly and said to be above 1.0. However, in the 20-year follow-up of the NHS the relative risk for highest vs lowest quintile was 0.77 (95 percent CI: 0.62, 0.95); p<sub>trend</sub> = 0.01 (the authors seem to have used the RR for N-3 alpha-linolenic acid from a paper on sudden cardiac death), and in the KIHD the relative risk was 0.39; 95 % confidence interval [CI], 0.21-0.71) (the origin of the number used in the meta-analysis is unclear). Also, relevant data from other studies were not included (4 and 5). Further, the authors did not mention a pooled analysis (6) of the primary data from prospective studies, in which a significant inverse association between intake of polyunsaturated fat (the large majority being the N-6 linoleic acid) and risk of CHD was found. Also, in this analysis, substitution of polyunsaturated fat for saturated fat was associated with lower risk of CHD. Chowdhury et al. also failed to point out that most of the monounsaturated fat consumed in their studies was from red meat and dairy sources, and the findings do not necessarily apply to consumption in the form of nuts, olive oil, and other plant sources. Thus, the conclusions of Chowdhury et al. regarding the type of fat being unimportant are seriously misleading and should be disregarded." <https://www.hsph.harvard.edu/nutritionsource/2014/03/19/dietary-fat-and-heart-disease-study-is-seriously-misleading/> I love coconut milk dishes, but I probably won't be having them every night just yet. I do agree that nutrition experts shouldn't be trusted, but that includes the authors of the meta-analysis.

JV (2014-03-28 08:03:58)

This just supports the work of Fred Kummerow the 99 year old researcher at the University of Illinois. (I know his work has been mentioned here) His method of dissecting arteries removed in heart bypass operations showed that it was not saturated fat he found but trans fats that caused atherosclerosis - and he has been saying it for 30 years! I find his research more compelling than some of these nutrition studies.

dearieme (2014-03-28 08:52:18)

I want to be appointed Sugarfinder General.

jimk (2014-03-28 09:16:17)

I'd be careful about confidence in "micro nutrients" as well, here's just a few examples, there's lots more. <http://gettingstronger.org/2012/11/why-i-dont-take-vitamin-d-supplements/> <http://joshmitteldorf.scienceblog.com/2014/03/25/life-extension-supplements-a-reality-check/> Some of this is about unknown or unexpected confounders, some are about cause and effect like does low Vitamin D cause poor health or does poor health cause low vitamin D.

Todd Fletcher (2014-03-28 09:33:41)

A lot of the knowledge about diet we need was embedded in traditional cuisines. Reviving those and the husbandry practices around them seems to me a safe way to make improvements in our health.

Joe (2014-03-28 09:49:25)

Seth, this may sound a bit like blasphemy on your site, but I must admit that I find your fascination with sugar to be very puzzling. It has zero nutrients (just empty calories), zero fiber, it can lead to obesity, it damages the endothelium (the lining of the arteries), it can be addictive, yadda yadda yadda. You know the rest. If a dose of sugar before bedtime causes you to sleep better, why not EXPERIMENT with ways to essentially "have your cake and eat it" too? By getting your nightly carb injection from a real food source that at least provides you with some nutrition and fiber too, like a banana, some almond butter, a small bowl of oatmeal and warm milk, magnesium and potassium supplements during the day, etc? Also, isn't it just possible that your current diet may be causing you to have difficulty sleeping? I'm definitely with you on questioning the experts, self-experiments, the scientific method, etc., but sometimes they're right, right? They can't be wrong all the time. I think they're right about sugar. But even if they aren't, it would be healthier for you to get your sugar from some real foods, with real nutrients and real fiber. And isn't that why you want better sleep? To be healthier?

Joe (2014-03-28 10:03:44)

Gina, Willet's attempt at "rebuttal" is not surprising. There will be others to come. How can they not try to rebut that study (of course, there have been other studies, which arrive at precisely the same conclusion?: <http://ajcn.nutrition.org/content/91/3/5-35.full.pdf> People like Willet, and schools like Harvard, are so heavily invested in the lipid theory of CVD that they really have no choice but to go down swinging, much like climate alarmists. To admit that they've been wrong all along would essentially mean that their careers are over, their reputations damaged beyond repair.

Matt (2014-03-28 10:03:50)

Seth's fascination with sugar is probably exactly because it has zero nutrients, zero fiber, can be damaging in certain circumstances, etc. That the observed results are so at odds with conventional wisdom are particularly interesting to me, and I'd guess to Seth as well.

Joe (2014-03-28 10:24:16)

Matt: "That the observed results are so at odds with conventional wisdom are particularly interesting to me, and I'd guess to Seth as well." But there is no conventional wisdom to be at odds with. Quite the contrary. Many, maybe most, experts would conclude that a little sugar (or other forms of carbohydrate) at bedtime, in and of itself, is relatively harmless, and may even improve sleep. And even I would have to agree. On the other hand, why not totally eliminate the potential for damage (which isn't unsubstantial), by eating some real food, some real fiber, and get some real nutrients, and also improve his sleep? If improving Seth's health is his main objective (by getting better sleep), I fail to understand why he doesn't think more nutrients, fiber, etc. wouldn't be better at accomplishing that. And I'm pretty sure that he'll be along shortly to explain that to me. :)

Mark (2014-03-28 10:59:41)

I've said it before and I'll say it again... Walter Willett is a hack. All of his Harvard nutritional epi group's studies have clear, obvious flaws. So, as Joe said, his rebuttal is not at all surprising.

John (2014-03-28 11:09:20)

@Joe the whole point of eating food is to get energy and refined sugar is great for that. All the nutrients you get from food are pretty damn useless without some "empty calories" ( yea I think saying empty calories is really stupid). I expect the "experts" to reverse course on their opinions of sugar. The "experts" opinion of fiber I think is pretty damn laughable also. I have very little fiber in my diet and yet somehow manage to have 3 quick bowel movements a day.

Seth Roberts (2014-03-28 15:10:53)

I found in an experiment that Vitamin D in the morning improved my sleep. Others found the same thing. Experimental evidence does not have the problems of the evidence discussed on Getting Stronger. <http://blog.sethroberts.net/category/sleep/vitamin-d3-and-sleep/>

Joe (2014-03-28 15:27:34)

John, I really don't know what to say. I'm almost speechless. That said, I think just about everything you just said is "really stupid." And trying to debate someone who says really stupid things is...really stupid. So...

kxmoore (2014-03-28 17:38:01)

" But the real villains in our diet — sugar and ultra-processed foods — are becoming increasingly apparent." (Bittman) One little interesting study that echos this sentiment found that the form a food took had vastly different impact. See Kindke's post "Powdered food ( carbs? ) appears to be very evil" <http://kindkehealthnotes.blogspot.com/2013/04/powdered-food-carbs-appears-to-be-very.html> Seth: Reminds me of several of Israel Ramirez's results. For example, that adding water to chow made it more fattening.

Stu (2014-03-28 17:49:05)

If sugar is so bad for your health and causes obesity then why is Robert Lustig (the guy leading the anti sugar movement) overweight? He also has a red face (malar flush), bags under his eyes, a swollen face and a thinning outer third of his eyebrows (and thinning eyebrows in general) which are all symptoms of hypothyroidism. A zero carbohydrate diet is know to contribute to thyroid problems and hypothyroidism. Don't believe me? Then just do a google image search. I once had someone tell me that they were avoiding eating carrots and onions because of the sugar content which is ridiculous. Maybe refined sugar isn't ideal due to a lack of nutrients, but I don't think people should be avoiding fruit and vegetables because of sugar. The days where I have felt the best and slept well are often the days I eat the most fruit and sugary/starchy vegetables.

Nancy Lebovitz (2014-03-29 06:56:59)

Joe, why do you think such small amounts of sugar are dangerous to most people?

Adam (2014-03-29 08:26:00)

I was traveling for work this past week and left my honey at home. Normally I dip a spoon in it and twirl it around a bit, then eat whatever is left on it about 20 to 30 minutes before sleep. While I still slept well, I did wake up during the night and experienced not one but two nightmares. I can't remember the last time I had a nightmare before this.

Joe (2014-03-29 08:31:12)

Stu: I don't really think that Lustig is overweight. He's got a little bit of padding, yes, but for someone his age, that's pretty normal. A BMI of 27-28 is the sweet spot (relative to longevity) for men his age. On the other hand, Lustig has said many times that's he's NOT a fan of low-carb (you can look it up). So those "extra" pounds you see may be due to eating too many carbs, too many calories, etc. And I agree with you. I don't think people should be avoiding fruit and vegetables. Quite the contrary. Refined sugar, yes. But fruits and veggies come with nutrients, fiber, etc. That is, they're real foods. Nancy: On the assumption that we're talking refined sugar, here's what I think: One of the discoverers of insulin, Fred Banting, discovered that among sugar plantation owners who ate the refined version, diabetes was rampant. But among the native cane workers, who only got to chew the raw cane, there was no diabetes. Yes, it's only a simple observational study, but I think there is a strong message there. I just don't think that humans are able to deal with refined sugar. But do I think small amounts of sugar are dangerous to most people? That would depend on what you mean by dangerous, and by small amounts. Do I think that a single teaspoon of sugar at bedtime is dangerous? No, not really. Not for most people. But do I think eating processed and refined foods all day, foods that are usually heavily laden with sugar, are dangerous? Absolutely. In fact, I think it's deadly. That's why I stick to real foods, foods that don't require an addictive drug (which means, by definition, that it's very hard to keep it to "small amounts") be added to it to induce me to eat it. I also think that too much sugar (of any variety) can seriously damage the endothelium, the lining of the arteries. Over time, that can lead to heart disease, diabetes, renal dysfunction, Lupus, etc. And the more damage, the more cholesterol that's needed to repair it. So you can see why I think that artificially lowering one's cholesterol level with statin drugs is counter productive. And dangerous. It's just doesn't seem logical to me, in this age of obesity, diabetes, etc., why we would want to add something like refined sugar to our diets, knowing how addictive it is, without at least getting some actual nutrients and fiber in return. Our food stuffs today are already short of nutrients (thanks to modern farming techniques), then we often cook the remaining vitamins and minerals right out of them, so the part we actually consume often lacks any nutrients at all. So, to someone like me, it's just another lost opportunity to improve one's health. That's probably more than you wanted to hear, but sometimes I just can't help myself.

Seth Roberts (2014-03-29 12:37:05)

I think fruit and Yakult (which is sweetened with glucose) are good substitutes for honey. I wouldn't take honey on a trip - too messy.

babar (2014-03-29 15:43:32)

i think you can get honey in little packets like they have jelly in at ihop. just don't forget them in your coat pocket when you put it in the wash.

daz (2014-03-29 16:14:29)

Seth Says "I found in an experiment that Vitamin D in the morning improved my sleep"... Hi Seth, on the Vit D subject, have you made any changes since you started your D3 supp routine... ie. do you vary your dose at all, possibly depending on how you feel, or the season (sun exposure), etc also, do you ever bother getting your Vit D blood levels tested (if so, what are/were your numbers & do/did you adjust your D3 supp based on the result). cheers Seth: No I haven't made any big changes. I will get my Vit D blood level measured soon.

Nancy Lebovitz (2014-03-30 02:44:48)

Joe, based on what you've said, it sounds like you're overly worried about sugar. I agree that it's a bad idea to use it as a staple, but that doesn't mean there's a reason to avoid the teaspoon or even tablespoon of honey before bedtime. There's at least one confounding factor in Banting's research- amount of exercise. Also, do you have information about lifespans for workers vs. plantation owners?

fi (2014-03-30 13:39:53)

Where's the high5-icon? I totally agree with you, Seth. Sure too much sugar, probably like too much of anything is bad, but I find it really hard to believe that nature would evolve such an enduring love of the taste of sugar if it really was that "toxic". It just doesn't make any sense to me. Plus, if I recall correctly, our brains (and pretty much our bodies) run on sugar. And I agree that nutritionists are not to be trusted. They have been wrong about a lot, like 180 wrong, so how are we ever supposed to trust anything they say? I have seen dietitians and nutritionists on tv say they make their recommendations based on the evidence, but honestly, at some point you have to wonder if they are really understanding what they are reading. It's like the whole field has no b.s. detectors at all.

Joe (2014-03-30 13:42:05)

Nancy, yes, I am worried (concerned would be a better word) about sugar, but I don't think I'm overly concerned about it. "Given its many links to obesity, diabetes, heart disease, etc.) And I think I said that one daily teaspoon is probably no big deal - for most people. But like with any addictive drug, self-limiting the daily dosage can be problematical. I don't think Banting's research looked at exercise. But, yes, it certainly could be a confounding factor. I don't think it looked at lifespans (although T2D can usually be expected to knock off 10 years, on average), or other aspects of the diets, or even things like vitamin D levels, for example. It was just one factor, but a pretty startling one, in my opinion. You might be interested in reading the book "Sugar Blues", by William Duffy, just to name one.

Joe (2014-03-31 10:20:22)

fi, actually, our brains and body do very well on relatively small amounts of glucose. <http://www.marksdailyapple.com/the-definitive-guide-to-sugar/> #axzz1zRCTnHV4 The excess goes to your liver. See: non-alcoholic fatty liver disease. <http://authoritynutrition.com/sugar-liver-diabetes/>

Jack (2014-03-31 10:37:28)

Seth, Thanks for posting this. Any way you look at it, you, seth Roberts, are a genius and way ahead of your time!

Patti (2014-04-02 11:08:07)

## Teaching Histology: Lessons for Other Teaching? (2014-03-29 05:00)

Edward Edmonds is an [1]histologist at the Albany Stratton VA Medical Center, Albany, New York. He has been an histologist since 2002. Previously he worked at the Landstuhl Regional Medical Center, Landstuhl, Germany, the Ehrling Bergquist Hospital Offutt AFB, Nebraska, and the Armed Forces Institute of Pathology (now Joint Pathology Center),

Washington D.C.

Recently he left [2]an interesting comment on this blog:

When I train students I always expect that they will do things a little differently or that they will have new ideas, so . . . my first question is always show me what you have learned or show me how you'd like to do this procedure. In other words they went through the same training I did maybe at a different facility but there are a lot of different ways to approach things we do in the lab, so I let them develop their own "style". Then after they do it in their own way I show them how I do it my way and I explain step-by-step why I'm doing it this way . . . The entire thing is an enjoyable experience. We are learning, and laughing, and undoing the dogma learned from the academic setting. . . . All of my students end up being excellent troubleshooters and problem solvers.

I asked how he came to this way of teaching. He replied:

Through experience. People like to feel good about themselves, no matter their status. If that person feels they have some sort of insight or knowledge that other people don't have – when that person is queried about their knowledge or has an opportunity to discuss it, they light up, becoming a teacher themselves (regardless of the quality of the information). There is a level of confidence there.

What if someone came along and challenged the quality of that information? Let's say the person challenging the information was an arrogant prick who did have better information but nonetheless put the ignorant person in their place? The quality of the information might be good, but nothing was actually learned that was relevant to the subject. Instead what was learned was how that prick made the other person feel and the prick feeling unchallenged felt empowered. If there were witnesses to the exchange the information learned was not bidirectional it was *omnidirectional*, everybody in the setting learned more about each others' behavior but nothing relevant was retained because the environment was authoritarian. That is an extreme example but it happens in degrees and often it is subtle.

Now that person who was challenged might go home and for spite try to find things to improve the quality of their information. But the learning is motivated not by genuine interest but by spite which has a tendency to cloud judgment (as we can witness in heated academic debates). Are they learning (understanding) in that state of mind? Probably not.

That is partly where my teaching style comes from. It comes from recognizing the "state" in which learning occurs and that someone that learns well who is "smart, motivated, and capable" is so, not because they have some inherent grasp on a subject, but because they have confidence in their ability to learn. In other words they are smart because they recognized as being "smart, motivated, and capable of learning". I want to learn from the students just as much as they want to learn. That really is key.

He also explained the difference between histologists and pathologists:

The histologists/cytologists are the people who develop the microscope slides you often see in studies with different "stains" we have a background in chemistry, biology, and anatomy, we do grossing (dissecting specimens), and autopsy, immunohistochemistry, electron microscopy, etc. A pathologist is some one who makes the diagnosis on the specimens we prepare. We work very closely together and in some facilities our disciplines overlap. However, they are actual doctors. There are also pathology assistants, they

typically just gross and do autopsy. So whenever you have surgery or a biopsy it comes to histology to be processed, we do that and then the pathologist makes a diagnosis and puts their signature on it.

Nancy Lebovitz (2014-03-29 06:58:58)

Off-topic: <http://www.psmag.com/navigation/books-and-culture/killing-pigs-weed-maps-most-ly-unread-world-academic-papers-76733/>

Alex Chernavsky (2014-03-29 08:40:09)

Following-up on Nancy's off-topic post, I'm reminded of the fact that some significant percentage of songs on Spotify have never been played – ever. There's a cool web app called [1]Forgotify that will randomly choose an unplayed song and play it for you. I actually haven't used that app, but there's another, similar one called the [2]Spotify Random Song Generator that plays a totally random song (whether it's been played in the past or not). I've used it a number of times, and it's quite interesting the music it selects.

1. <http://gizmodo.com/you-can-stream-those-4-million-spotify-songs-that-have-1512468463>

2. <http://www.karnhuset.net/demos/spotify/randomSong/>

AI (2014-03-29 09:54:53)

Thanks for this post. I like the description he gives of the state of mind one is in after being "put in one's place" by someone arrogant. It's not conducive to an open minded exploration of the facts. It's not a learning state of mind. At that point, you're just trying to save face in the group. Certainly, I have experienced this state of mind too many times. Not fun. But, it is the real world. There are always arrogant pricks out there. So, it is a great skill to be able to deal constructively with those types of people. But it's difficult. Some of these arrogant people are really skillful at evoking fear and anger. And it's a winning strategy for them because once you become fearful, you are no longer thinking as clearly, reasonably, honestly as you are when you're calm. I sometimes think it is their main rhetorical technique: make the other person fearful, angry, resentful, predominantly emotional, and then make them look really stupid in front of the group.

dearieme (2014-03-29 12:58:36)

O/T lesson from life: today I happened across an article in an old Telegraph. On a brief visit to Washington D.C. a journalist decided to go and look at the White House. This proved surprisingly difficult because everyone from whom she asked directions assured her that it was beyond walking distance. When she got there she had, she said, covered a distance that most British people would consider a short stroll.

Nancy Lebovitz (2014-03-30 02:55:09)

More off-topic– This place has a good commenting community, but with only the three most recent comments listed in recent comments, it's hard to know which threads are still active. The best simple system I've seen for keeping track of comments is at <http://nielsenhayden.com/makinglight/> Making Light– give access to the last 1000/2000/4000 comments, and if you click on a comment in one of those lists, it changes color. The best complicated system is at [1]Alas, a Blog.

Corrected link for Making Light: <http://nielsenhayden.com/makinglight/>

## More Cereal Fiber, Much Less Heart Disease (2014-03-30 05:00)

In Vitamin D and Cholesterol: The Importance of the Sun (2009) by David Grimes, an excellent book, I came across [1]a 1977 study of healthy middle-aged men. The researchers measured their diet and watched them from 1966 to 1976. The question: What diets were associated with better health? There turned out to be associations with cholesterol (lower better) and systolic blood pressure (lower better), but these were less interesting than two strong dietary associations. One was between energy intake and heart disease. Men in the lowest third of energy intake had 23 cases of heart disease; men in the highest third had 7 cases. That's probably due to exercise: the more you exercise the more you eat. We already know exercise is good.

The other association was with cereal fiber. Men in the lowest third of consumption (2-7 g/day) had 25 cases of heart disease; men in the highest third (8-34 g/day) had 5 cases. (A Wasa cracker has about 2 g cereal fiber.) You might dismiss this as healthy-person bias: healthy people do many healthy things, such as eat fiber. However, there was no association of heart disease and fiber from fruit and nuts. They're healthy too. "The advantage of a diet high in cereal fibre cannot be explained [by us]," said the authors.

Later studies have found the same thing. For example, [2]a 2006 review reached a similar conclusion: "There is an increasing body of evidence, including that from prospective population studies and epidemiological observational studies, suggesting a strong inverse relationship between increased consumption of wholegrain foods and reduced risk of CVD." [3]A study of health-conscious people – to reduce healthy-person bias – found a similar association: "Persons who habitually ate wholemeal bread had a lower mortality from cerebrovascular disease." [4]A 2002 review and [5]a 2013 review provide even more evidence for the association.

[6]Shant Mesrobian has emphasized the importance of fiber for health. Whereas paleo gurus usually say grains are bad. [7]Here, for example, are "10 reasons to avoid grains".

---

dearieme (2014-03-30 05:58:33)

There are still parts of Scotland where people eat lots of oats (porridge, oat cakes), eat lots of fish, and take plenty of exercise. I've never seen any suggestion that they are exempt from the high rate of heart deaths in Scotland. But maybe they are. (Decades ago my wife attended a seminar on heart attack rates in Glasgow. The figures differed strikingly from one apparently identical neighbourhood to another, where a "neighbourhood" was tiny - just a few streets. The investigator had no explanation to offer.) Seth: The study I describe was done in London. Grimes would emphasize the lack of sunlight in Scotland as a cause of heart deaths.

kxmoore (2014-03-30 07:28:19)

Perhaps it is not the consumption of whole grains giving the positive effect but the fact that the whole grain eaters tend to eschew highly processed flours.

kxmoore (2014-03-30 07:43:26)

re: heart attack rates in Glasgow. Heart disease has been associated with air pollution. Pollution rates can vary strikingly in a city. Strangely an environmental group has just released an air pollution study naming a street in Glasgow as the most polluted in Scotland. Scotland's most polluted streets identified in Friends of the Earth league table <http://www.dailyrecord.co.uk/news/scottish-news/scotlands-most-polluted-streets-identified-3063791>

Adam (2014-03-30 07:45:36)

Some flavors of paleo are open to including gluten-free grains. For example, the Perfect Health Diet advocates eating up to a pound a day of white rice. Robb Wolf talks regularly about eating corn tortillas. There's a good list of gluten-free grains here: <http://www.listproducer.com/2011/08/30/list-of-10-gluten-free-grains-for-everyone/> Perhaps people could have it both ways, gluten-free AND whole grain?

libfree (2014-03-30 07:54:50)

I agree that lots of paleo people ignore the importance of plant fibre. A couple of things that I think might be important. You might be able to get that fibre from other sources but these just weren't measured properly. My friend from Lao eats far more whole food than I do and I've wondered if my western take of throwing out parts of our food might reduce our fibre intake. He doesn't throw the apple core away, he eats it. When he eats chicken wings and ribs, he cleans the bones more than anyone I've ever seen. I saw a study that found animal fibre being close to scFos in terms of helping pass probiotics.

RAD (2014-03-30 08:18:38)

Interesting. I don't see how it fits with the observation that the traditional Greenland Inuit diet was associated with low CVD rates. I think this goes back to macro vs. micro nutrients. To convince me of a macronutrient claim it has to be compatible with both the Inuit low-carb diet and the Okinawa low-fat diet.

kxmoore (2014-03-30 09:55:18)

A common denominator of whole grain, Inuit and Okinawa diets is sparsity of high-processed flours.

Joe (2014-03-30 13:20:09)

IMO: Too small of a study to garner much information. Too much information was missing or excluded, etc. And it's about the only study I've ever read that posits there's no benefit to eating whole grains and unrefined starches over their refined counterparts. (Someone should alert the authorities!) It's hard to tell how they even controlled for that. I also wonder what they mean by "clinical coronary heart disease"? And using death notices for cause of death is notoriously unreliable. "Heart disease" is usually the go-to, absent an obvious gun-shot wound, blunt force trauma, etc. It also turns on its head, the current conventional wisdom, which is that low triglycerides, high HDL, and large LDL particles are protective. Grains (and too many carbs) cause triglycerides to go up, HDL to drop, and LDL particle size to become small and dense (all the better to attack your endothelium). Ditto for sugar. And, of course, they didn't even have a "no grains" arm. That would have been interesting, I think. It's also interesting to note, however, that saturated fat is NOT implicated. Huzzah! And that it's better to be short than tall. I can't do much about the latter, but I'm sticking to my game plan: Eat saturated fat, veggies, fruit, and don't eat grains or sugar.

RAD (2014-03-30 16:06:19)

@kxmoore, I agree that Inuit and Okinawa diet both lack high-processed flours but the study Seth links to shows that neither sugar intake nor refined flour intake was correlated to CVD incidence. The only dietary factor that seemed to count was fibre from brown/whole-grain bread and breakfast cereal. I find that weird, really weird. @Joe, I thought the study showed that whole-grains was basically all that counted.

kxmoore (2014-03-30 21:15:37)

@RAD I should have read more carefully. Yeah, the first study Seth mentioned showed no refined carb cvd correlation. Perhaps the cereal fiber afford a "second meal effect" that mitigates a harmful effect of refined carbs?

daz (2014-03-30 22:21:59)

some of the Scottish 'cuisine' should be enough to give anyone a heart attack...? deep fried mars bar anyone...  
[http://en.wikipedia.org/wiki/Deep-fried\\_Mars\\_bar](http://en.wikipedia.org/wiki/Deep-fried_Mars_bar)

Joe (2014-03-31 07:01:38)

RAD: I may be wrong, but I think that's what this means: "Straight tabulations of coronary cases against white bread eaten showed no trend. Thus our data do not support the hypothesis that the incidence of CHD is related directly to intake of refined carbo- hydrates" I agree with you, it's weird.

kxmoore (2014-03-31 07:35:57)

You want to see weird? This complicated experiment suggests we should be eating spaghetti for breakfast.  
<http://ajcn.nutrition.org/content/69/4/647.full>

RAD (2014-03-31 08:37:21)

@Joe, I think the accepted wisdom goes something like "replace refined carbs with whole grains" and the statement you quoted says something like "it doesn't matter whether or not you eat refined carbs" but the paper addresses the whole grain part elsewhere. Eating whole grains reduces CVD even if you prefer your grains soaked in high fructose corn syrup (poetic license with causation/correlation). That's the bizarro part for me.

Joe (2014-03-31 09:04:45)

RAD, I couldn't find it, but I'll take your word for it. And, yeah, ain't nothing like a little "high fructose corn syrup" for breakfast! New advertisement: Eat Kellogg's Cocoa Krispies, now with HEART-HEALTHY high fructose corn syrup!

Joe (2014-03-31 09:08:50)

kxmoore, did you notice the study was funded by a CEREAL group? I guess that helps to explain the lack of an eggs and bangers arm.

Jack (2014-03-31 10:34:35)

In all fairness, I would have liked to see an article named "10 reasons to avoid meat" right along side of the article "10 reasons to avoid grains". No doubt more people who do not get enough grains and fiber are having medical problems because they are constipated, which impairs the circulation of their blood and energy, which may lead to cerebrovascular disease and other problems. Who knows? Not me.

Joe (2014-03-31 11:08:36)

Jack, constipation is a complicated matter. But the amount of fiber you eat may, or may not, be a contributing factor. "Stopping or reducing dietary fiber intake reduces constipation and its associated symptoms" <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3435786/> Things like lack of exercise, taking certain medications, not drinking enough water, not eating enough fat, etc., all can contribute to it. Eskimos eat almost zero fiber and they have little to no constipation. People who are forced to eat liquid diets for weeks and longer can still have regular bowel movements. Etc. I always try to "have my cake and eat it," whenever I can, and I eat a good amount of veggies and fruits (along with animals and fish), mostly for the nutrients, but also for the fiber. And it all goes through me like you-know-what goes through a goose.

### Questions for Jeffrey Sachs (2014-03-31 05:00)

On [1]Econtalk, Russ Roberts recently [2]interviewed Jeffrey Sachs, author of *The End of Poverty* and head of the Millennium Village Project (MVP). I enjoyed it but thought Roberts was too easy on Sachs. Here's what I wished he had asked:

Your book, *The End of Poverty* – did you get anything wrong?

What mistakes have you made with MVP?

You say Nina Munk [[3]author of *The Idealist*] chose a non-representative village. [Sachs said that Munk spent her time in the only village in "a war zone."] Did you tell her that? If not, why not?

Munk was on your side when she began reporting, but changed her mind. Why is that?

Why was the project set up in such a way that evaluation is difficult? Why not pick ten villages and randomly select five for treatment?

You say the MVP project is successful because people are copying it – but those people are government officials. Is it plausible they are copying it because they see it as a good way to make money for themselves or improve their career? You must know many worthless medical treatments have been widely copied. Is this your best evidence of success?

No doubt your employees have often told you what you wanted to hear rather than the truth. What's an example? What have you done to get honest assessments of how things are going?

What did you learn from Nina Munk's book?

[4]Roberts says he didn't ask Sachs certain questions because there wasn't enough time.

1. <http://econtalk.org/>
2. [http://www.econtalk.org/archives/2014/03/jeffrey\\_sachs\\_o.html](http://www.econtalk.org/archives/2014/03/jeffrey_sachs_o.html)
3. <http://blog.sethroberts.net/2014/02/14/the-idealist-jeffrey-sachs-and-the-quest-to-end-poverty-by-nina-munk/>
4. [http://www.econtalk.org/archives/2014/03/postmortem\\_on\\_s.html](http://www.econtalk.org/archives/2014/03/postmortem_on_s.html)

---

dearieme (2014-03-31 06:18:31)

Is Sachs one of the people who pillaged Russia just as it was re-convening after the USSR, or am I mistaking him for someone else?

Dominic Frisby (2014-03-31 07:44:45)

Seth, I am trying to contact you. Would you be able to drop me a line - frizzers at gmail dot com Thanks Dominic

Seth Roberts (2014-03-31 12:29:54)

Sachs describes his work in Russia: <http://jeffsachs.org/2012/03/what-i-did-in-russia/> The Harvard economist accused of wrong-doing related to Russia: <http://www.thecrimson.com/article/2006/2/10/tawdry-shleifer-affair-stokes-faculty-anger/>

dearieme (2014-03-31 13:45:16)

Perhaps you meant "A Harvard economist accused of wrong-doing related to Russia"? I mean, Summers is a Harvard economist too. Seth: Right. "A" not "the".

Jeremy Cherfas (2014-04-03 07:13:16)

Did you hear the interview of Nina Munk by Owen Barder? I thought it was particularly interesting as they both tried very hard to give Sachs the benefit of the doubt, and yet ...

Seth Roberts (2014-04-04 13:49:23)

No I didn't know about that interview, thanks.

## 9.4 April

### The Trouble with Critics of Science, Such as John Ioannidis (2014-04-01 05:00)

I haven't been interested in the work of John Ioannidis because it seems unrelated to discovery. Ioannidis says too many papers are "wrong". I don't know how the fraction of "wrong" papers is related to the rate of discovery. For example, what percentage of "wrong" papers produces the most discovery? Ioannidis doesn't seem to think about this. Yet that is the goal of science – better understanding. Not "right" papers.

Almost all important health discoveries are discoveries of new cause-effect relationships. If you do X, Y happens. My view of the problem with modern health science is nothing like what Ioannidis and other critics (such as the "couldn't replicate Finding X" critics) say. It is lack of progress on major health questions (e.g., what causes depression?), emphasized every year by awarding of the Nobel Prize in Medicine to research of little or no practical value. Almost every year, the Nobel Prize press office says the honored research will be useful in the future. The lack of progress shows no sign of ending.

The best that can be said about recent critics of science, such as Ioannidis and Danny Kahneman, my former colleague, is they see there's a problem. The worst that can be said about them is they fail to understand the cause of the problem. This is why their proposed solutions could easily make the problem worse.

Whenever you do an experiment – psychology and the health sciences are almost all experimental – you "use up" the effect you are studying (X causes Y). You can do an experiment to learn if X causes Y only so many times. After that, you know the answer and a new experiment is pointless. Professional scientists are only able to test ideas (cause-effect statements) that are fairly plausible. With such ideas, a publishable outcome is likely enough to be worth the cost of testing. They are unable to test implausible ideas, because such experiments are not likely enough to produce a publishable outcome. With limited resources, they must generate a certain number of published papers per year, at least if they want a career.

To have a viable system, you need to generate new plausible ideas at at least the same rate you are using them up. Otherwise you will run out. You must design your experiments so that they accomplish this. Not necessarily every experiment, but your experiments in aggregate. It isn't easy to find new plausible ideas. If you think I'll just get on with my career, generating papers as fast as possible and leave it to someone else to come up with new ideas worth testing, then your field will run downhill as plausible ideas are used up and not replaced. This is what has happened in several fields, including mine (animal learning). In psychology much greater concern about both fraud and lack of replicability have started at about the same time. I believe both (more fraud, more lack of replicability) stem from the increasing difficulty of honest (or more honest) research.

A friend who is a psychology professor agreed with me that psychologists – at least him – didn't know how to generate new ideas worth testing. "Do you?" he asked. I said I did:

1. They [= psychologists] should modify their data collection. In my experience, new ideas almost always come from carefully collected data. They don't come from introspection, talking to friends, reading the newspaper, watching TV, going to talks, etc.
2. Finding new ideas worth testing means finding new ideas that are plausible enough to be worth the cost of testing. To find new ideas with sufficient plausibility to test you need to test implausible ideas. A small fraction will pass the test, gaining plausibility. They will become sufficiently plausible to be worth testing.
3. To test implausible ideas in a career-consistent manner, you need to be able to test them very cheaply. Few if any psychologists have thought about this. They don't realize how important it is.

When you have very cheap tests, you can test far more ideas than you can if you only have expensive tests. You need a "test set": very cheap tests, cheap tests, almost-cheap tests, and so on. Ideas that pass a very cheap test become worth testing with a cheap test, those that pass a cheap test become worth testing with an almost cheap test, and so on. With current methods (all tests are expensive), perhaps social psychology professors who want to publish have a set of 50 ideas that are plausible enough to be worth the cost of testing. Those ideas get tested over and over, using them up. Were cheap tests available, perhaps the same professors could choose from a set of 1000 ideas those they want to test. Of those 1000 ideas, 950 were too implausible to test with expensive tests. Among those 950, I believe, would be some ideas that when tested seemed to be true.

I came to these beliefs trying to understand why [1]my self-experimentation did a good job of finding new ideas worth testing. [2]I concluded that the secret was this: I was able to test implausible ideas very cheaply – thousands of times more cheaply than professional scientists. Self-tracking – keeping track of my sleep, for example, and looking for outliers – was a very cheap way of getting new ideas about what controls sleep. Self-experimentation was a slightly more expensive (but still very cheap) way to test ideas that self-tracking came up with.

Many people have complained about a lack of replicability problem in psychology, including my friend and co-author [3]Hal Pashler. An obvious solution is to raise the bar for publication: require better (= stronger) evidence. Sure, this will improve the quality of testing, but how will it affect the rate of production of plausible new ideas? My cost-of-test proposal suggests it will reduce that rate of production. I am saying that cheap tests are all important. Raising the publication bar will make the only test you have more expensive. What if the replication problem is a response to lack of plausible new ideas? Then this solution to the problem would make the problem worse.

---

Nancy Lebovitz (2014-04-01 08:12:53)

Good points about the importance of science being on a path to doing something useful, though pure science can pay off in the long run. Who'd have thought that observing the movements of the moon and planets would pay off centuries later in

communications and observation satellites? Back to medicine.... I think you're pointing at serious problem, but if the field didn't have so much fraud and incompetence, there's be more good information (and less bad pseudo-information) to base hypotheses on.

Adam (2014-04-01 08:23:17)

Aside from discovery, medical science also must support the pledge all doctors take to "first, do no harm". This is the main danger with wrong studies. We assume that the results are right because the P-value is small and then we go out and treat millions of patients based on it. Years later we find out we were killing thousands of people.

dearieme (2014-04-01 10:30:06)

We did an accidental experiment this week. We made lots of apple sauce for the roast pork on Sunday, but that left me with no apple to chop up for breakfast the next day. So I took some of the surplus sauce and stirred it up with half a banana and a couple of tablespoons of Greek yoghurt to mimic my usual meal. I felt so full all morning that I could scarcely eat lunch at my usual time. I reckon the secret was that when the apple sauce was made it had been reinforced with some of the pork fat. I suppose it's ancient knowledge that a bit of fat at breakfast saves you from the desire for a mid-morning munch, but I was struck by how firm the lesson was here. It seemed to be clearer than I've ever had it from nuts at breakfast, for instance.

Joe (2014-04-01 12:18:39)

"I felt so full all morning that I could scarcely eat lunch at my usual time." Ah, the wonders of good ol' animal fat.

Seth Roberts (2014-04-01 13:47:11)

"Years later we find out we were killing thousands of people." One big reason medical treatments do harm is that the theory behind them is wrong. For example, cholesterol theory, chemical-imbalance theory.

Seth Roberts (2014-04-01 13:53:42)

"Back to medicine.... I think you're pointing at serious problem, but if the field didn't have so much fraud and incompetence, there's be more good information (and less bad pseudo-information) to base hypotheses on." That's what a friend of mine says. I think he's wrong. I think the problem lies elsewhere - failure to discover big new effects.

Joe (2014-04-01 14:38:46)

Game...Set...Match? "Vegetarians were twice as likely to have atopy (allergies), a 50 percent increase in cancer and a 50 percent increase in heart attacks." <http://www.plosone.org/article/fetchObject.action?uri=info:doi/10.1371/journal.pone.0088278&representation=PDF> I watched FOX News this morning, and they were heralding a new study where it was discovered that 1 out of 3 American children, between the ages of 9-11, had "high" cholesterol levels, and that "something must be done about this!" [No mention of Hippocrates' warning to: "First, do no harm."] What do you suppose that certain "something" will inevitably be? It doesn't take Nate Silver to forecast the probable answer: more statins! Maybe mix them right into the kids' boxes of CoCo Puffs and fruit juice? Or the next "big thing," PCSK9 inhibitors (currently in Phase III clinical trials), which lower cholesterol levels even MORE than statins. All that, while study after study shows that people with "high" cholesterol levels live longer than those with "low" levels! <http://www.ravnskov.nu/the%20benefits%20of%20high%20C.htm> How do we stop this runaway train before it takes most of us right over the cliff with it? I have no idea. :(

AI (2014-04-01 16:59:54)

I'm not a vegetarian, but I took a look at that study from plosone.org, and I found the following statement near the end: "Potential limitations of our results are due to the fact that the survey was based on cross-sectional data. Therefore, no statements can be made whether the poorer health in vegetarians in our study is caused by their dietary habit or if they consume this form of diet due to their poorer health status. We cannot state whether a causal relationship exists, but describe ascertained associations. Moreover, we cannot give any information regarding the long-term consequences of consuming a special diet nor concerning mortality rates."

Joe (2014-04-01 17:50:56)

Al, that same claim can be made for just about any cross-sectional study, unless they control for those factors. And that's almost impossible to do. And the opposing disclaimer could be that vegetarians are usually MORE health conscious (have healthier habits) than your average bear. Here's another study that comes to roughly the same conclusion: <http://jnci.oxfordjournals.org/content/early/2010/04/06/jnci.djq072.abstract> So the next time you hear someone say how healthy a vegetarian lifestyle is, think back to these studies. A vegetarian diet will usually lower your LDL and TC, but it will also substantially raise your triglycerides and lower your HDL level (the so-called "good" cholesterol). The latter two are supposedly risk factors for heart disease. So you're damned if you do, and damned if you don't. Which is why the diet-heart theory of heart disease is absurd, in my opinion. And is making some of us do really stupid things, like take statin drugs.

dearieme (2014-04-02 02:21:28)

I suppose it will soon be the case that the effects of statins will start showing up as a reversal of the heretofore ever-increasing life expectancy. It seems to me unlikely that such powerful drugs, with such pronounced adverse side effects, won't promote earlier death. Of course, cause of death is unlikely to be reported as "statination".

Alexis Gallagher (2014-04-02 11:12:25)

Seth, my apologies if you are already aware of this connection, but you should know that the way that you talk about idea-generation in science is \*extremely\* similar to the way people in the "lean startup" movement talk about starting businesses. The core idea of lean startup is that instead of investing the time and money to start a business based on a hunch of whether there is demand for its product, you should progress through a sequence of progressively more expensive stages of data gathering to validate your idea. So first do the cheapest possible thing that you can do to test an idea, such as basic analysis and discussions. Then do the next most expensive thing you can do to test it further (such as customer surveys, or trial ad campaigns). Proceed along this path, ramping up your investment gradually, in a way shaped by evidence you are discovering. People in the lean world like to talk about "de-risking" the process, by proceeding in this incremental and empirical way. This is just like the progression you describe, from cheap idea generation, to cheap tests via self-experimentation, to more expensive research trials. I mention not only because it's interesting, but because the lean startup movement is large and quite influential in certain circles. It might help you to spread your ideas in some quarters, if you pointed out this parallel. I think this is one of the main books used to describe this approach: <http://theleanstartup.com>

I like Ioannidis (2014-04-02 20:35:15)

I think Ioannidis serves the important role of deconstructing the temple. I don't think he is trying to say that too many papers are wrong, rather he is saying that we underestimate how many are wrong, and this leads to counterproductive practice. He is not trying to point out the solution, he is only pointing out the errors. There's nothing wrong with that. Ioannidis is the garbageman of medical science.

Seth Roberts (2014-04-02 21:54:35)

He's pointing out the wrong errors, thus distracting attention from the important errors. Far more damaging than "wrong" published papers – which can be ignored – are papers that are not published but should have been.

Hap (2014-04-02 07:58:18)

On the subject of bread, popularly demonized in Dr. Perlmutter's book "Grain Brain," as leading – along with glutinous and simple carbohydrates – to decaying brain health, dementia, and Alzheimer's: Does a bread with a "starter culture" in it count as fermented? I'm thinking of the wonderful breads from Acme Bread here in Berkeley. I am hooked on Cranberry-Walnut.

Seth Roberts (2014-04-02 11:20:41)

does (fermented) bread count as fermented food? Maybe. I suppose there are a lot more bacterial fragments in bread than in non-fermented food and maybe these bacterial fragments help protect you against dangerous bacteria. I don't know.

Evelyn M. (2014-04-04 07:20:38)

Talking about bread. I tried the fashionable "no-knead" bread recipe last year and had good results (that's just flour, salt, water, and a very small amount of yeast with a very long rising period). When Cooks Illustrated offered a new take on that recipe specifically to increase the taste of fermentation, calling their loaf "almost no-knead bread." That recipe adds beer and vinegar and produces a delicious loaf. As everyone liked the result of my experimentation, I bravely ordered sourdough starter and gave that a go, but didn't have much luck until I cut the amount down to about 2 tablespoons (considering it part of the liquid in the recipe) and kept the 1/4 teaspoon of yeast that was in the original recipe. (Remaining sourdough starter can be frozen with great success.) That process created a very flavorful loaf. Reading your blog post about the importance of feeding the good intestinal bacteria, I replaced two tablespoons of the King Arthur European-style bread flour that I have been using with high gluten corn flour as recommended and let the dough rise for a full 24 hours. Everyone loves it.

fitness (2014-04-29 14:45:56)

Wow that was odd. I juust wrote an very long comment but after I clicked submit my comment didn't appear. Grrrr... well I'm not wrting all that over again. Anyways, just wanted to say excellent blog! Checkk out my blog :: [1]fitness

## **Journal of Personal Science: Molybdenum and Avoiding Sulfur Helped My IBS (2014-04-03 05:00)**

by August Hurtel

I live in Shreveport, Louisiana and work in the interlibrary loans department at Shreve Memorial library. I am 39 years old.

I believe, due to experiences I will expand upon below, that excess sulfur compounds, especially sulfites, may contribute to and even cause irritable bowel syndrome (IBS). If you have IBS, you can try to verify this in a few ways.

1) Try molybdenum. I take Carlson Lab's Moly-B 500 mcg tablets (one tablet/day).

2) Avoid [1]foods and supplements high in sulfur.

3) If you have already purchased the services of 23 &me or want to, you can look at this thread in the forums – [2]“Reactions to food containing sulfites, sulfur dioxide, bisulfite, metabisulfite. SUOX gene” – and see if you have the same polymorphisms, though if you just do the first two, you'll be able to guess.

The woman who started that thread at 23 &me goes by the name Red Ringlets. She asked if anyone with four polymorphisms involved in sulfur processing experience reactions to sulfur compounds commonly added to foods as preservatives and/or for antibacterial purposes. I have three of these polymorphisms. I knew I was allergic to certain medicines, but I had not thought about the effect of sulfur coming from my food and supplements largely because I associated reactions to sulfur with hives and headaches.

Several years ago [3]once the appetite suppression the Shangri-La diet kicked in, I adopted what most would consider a paleo template for my diet. This means I generally avoid grains, legumes, and dairy with caveats (like rice, now that I work out, and butter because it is animal fat and therefore good according to evolutionary thinking). Additionally a substantial amount of the meat that I buy comes from conventional sources.

Despite not being technically paleo, I enjoyed coffee, chocolate, and red wine, which are all high in sulfur. Sulfur is also added to various coconut products, shrimp, fish, dried fruit – many products a person trying to eat paleo might eat. I ate them. And I would have gastrointestinal distress that I could not explain despite getting leaner.

In the summer of 2013 after a few social functions that served grilled hamburgers, grilled shrimp, and other summer party foods a paleo dieter might think would be okay, I went to the emergency room. I had a serious pain where my appendix should be. Sometimes the pain would get worse after eating, and I would often get diarrhea. I thought I had appendicitis, but the doctors found nothing wrong. They took regular X-rays and did blood tests, and came back and said they found nothing. I got really angry about that, so they ordered a CT scan. The CT scan also showed nothing. They told me I had IBS because they had gone through a list of other things it might be and eliminated all of them.

When I went to the emergency room, I also inadvertently took with me a large amount of sulfur. I had a couple of 90 % Lindt bars with me. My chocolate intake had risen during that time, too. I had stuff to do, places to go – and an excuse to treat chocolate like a food group.

I was aware, from reading on the internet, of FODMAPs, which are osmotic carbohydrates that draw water into the gut, causing gas, bloating, cramping and diarrhea. They seemed a likely culprit because these were the symptoms I experienced. Following a [4]low FODMAP diet seemed to help, but not perfectly so.

There is some overlap between the two lists of foods to avoid (high sulfur and high FODMAP), so avoiding FODMAPs might have helped because it made me avoid sulfur. It also made it possible for me to have days where I didn't eat any FODMAP foods but I would eat something like shrimp and then I'd have symptoms despite not eating any FODMAPs. So, looking back on it, I think of attending a wedding, eating nothing but shrimp, and drinking a little bit of red wine, and then having IBS problems and not understanding why because it doesn't fit in well with the FODMAP story. I think FODMAPs are problematic in a gut that has already been compromised, but FODMAPs are not evolutionarily novel, and thus are unlikely to be the original cause of the problem.

Since it was summer and I just gotten through that ER experience, I stopped eating a lot of fruits, chocolate, wine, etc. One of the things that figures largely for me as a source of sulfur during this time though is shrimp. I kept thinking it was a safe food to eat, and didn't realize until later it was a source of sulfur. Additionally, I was

taking several supplements that contained sulfur: gelatin, biotin, glutathione, NAC, ALA, MSM. I had gotten into the habit of trying different supplements since 2010 because of a neuralgia that neither doctors nor dentists could explain. Though I was not taking all of them at once, I did supplement enough to assume I kept my sulfur level high throughout this time period.

I noticed the thread Red Ringlets posted at 23 &me in August of 2013. In October I asked whether or not sulfur could cause a dehydrating effect. I asked this because I've noticed wine can take more water out of me than other drinks containing alcohol do. I didn't get an answer to that question, but I began to explore some of the links people had put into the thread. I read through this site: [5][www.learningtarget.com](http://www.learningtarget.com). I found the following page particularly helpful because it mentioned that molybdenum is a vital part of the [6]sulfite oxidase enzyme: [7]Vitamins and Supplements for Sulfite Problems.

I still had not made a connection between sulfur and irritable bowel syndrome, but I decided to supplement with fucoidan, which is a sulfated polysaccharide found in some seaweeds. I thought it would help my gut, but it caused diarrhea. It was as if I had decided to supplement with cholera. The effect was large and obvious enough for me to realize it was probably the supplement I had just taken. Once I accepted that, I put together what I had learned from the 23 &me thread.

Now, in retrospect, I think fucoidan may have caused diarrhea for completely different reasons. I learned in my 23 &me health report that I am norovirus resistant, and I have subsequently read that this has something to do with my ability (or inability) to make fucose. I can't remember where I read this, but it made me think fucoidan could have destabilized my gut flora for reasons unrelated to its sulfur content.

Whatever the reason for the extreme reaction to fucoidan, I decided the beneficial reaction to molybdenum meant that I had a genetically limited capacity to deal with all the extra sulfur in my food and supplements. I threw out my high sulfur supplements and tried to stick to low sulfur foods. Within about two weeks I started having normal bowel movements. This was better than what I was achieving before the entire fucoidan fiasco. I had migrated to a diet of rice and fish which helped me approximate normalcy, but any time I tried to have any variety in my diet, I would run into problems. By avoiding sulfur, I was able to eat a larger variety of foods without incident.

Eventually I found if I was very careful, I could eat small amounts of high sulfur foods, but this is hit or miss because I can't reliably gauge what the potential dose is, nor is it always clear whether a food has sulfur in it. I still supplement with molybdenum but I think the long term strategy here is both molybdenum and at least avoiding high sulfite foods because my genetics suggest it is doubtful I am going to be able to process as many sulfites as other people do regardless of how much molybdenum I have.

As I mentioned before, I think once the gut is compromised, many things become irritants. Removing excess sulfur has increased my health a lot, but I suspect I need to improve gut flora, and possibly heal some tissue damage. The doctors may not be able to see it, but I still have residual pain in the region where my appendix is.

August (2014-04-03 07:51:57)

"I read through this site: sulfite oxidase enzyme:" Originally was "I found the page below particularly helpful because it mentioned Molybdenum is a vital part of the sulfite oxidase enzyme" And it looks like this other link completely disappeared: <http://www.learningtarget.com/nosulfites/>>[www.learningtarget.com](http://www.learningtarget.com)

JM (2014-04-03 12:03:50)

August, great example of using careful observation and personal science to diagnose and treat yourself - and I think it's pretty obvious that traditional medicine would never have figured this out. And thanks for sharing, maybe this will help someone else who is having similar problems.

August (2014-04-03 13:50:43)

Thanks JM. It looks like I need to correct my correction. The link is: <http://www.learningtarget.com/nosulfites/>

dr j (2014-04-03 14:52:40)

Dear August, Thank you for taking the time to write about your inspiring detective work! Its is extremely valuable to be able to mull over your process in approach; i am starting on a Lynch Syndrome path. best john

Steve (2014-04-03 18:22:13)

August: I just checked my 23 &me data. My results are the exactly the same as Red Ringlets and yours: SUOX rs10876864 AA, rs705703 CC, i5000977 AA, i5000976 AA . That would finally explain why I get such intense headaches when I drink red wine.

Seth Roberts (2014-04-04 13:48:39)

Sorry. It appeared correctly in the visual editor.

JRM (2014-04-06 09:27:20)

I started supplementing with molybdenum after I did a hair minerals analysis test which showed very low levels of molybdenum. I felt better. 23andme said that I was a slow metabolizer of caffeine. Molybdenum is used in caffeine detoxification via xanthine oxidase. Supplementation helped reduce caffeine withdrawal symptoms the next day. The farmer who I buy almost all of my beef from commented that my hair test was similar to his soil minerals test. A different local farmer commented that her soil minerals test showed a deficiency in molybdenum. When I go to the farmer's market, I find that asking farmers if they do soil mineral tests and supplementation is a good indicator of whether their food will taste good. The best farmers test beyond ph, Ca, Mg, N, P, K to a plethora of micronutrients Mo, Se, Fe, Cu, Zn, B, Mn, Cr, Co, etc. Soil mineral deficiencies become mineral deficiencies in the plants and animals grown on that soil. People can't go to nutritiondata.com, plug in their daily diet, and assume that their diet contains all the necessary minerals because the website says it should. One of William Albrecht's themes was that the soil quality in the South is compromised due to heat and precipitation leaching out the minerals from the soil. Maybe it is coincidence that the author is from the South. I don't know. Other minerals which were low on the test like lithium (5 mg/day) and magnesium (via MgCl foot baths), I also noticed a benefit from supplementing. But I haven't noticed a benefit from supplementing selenium.

JRM (2014-04-06 09:33:04)

My markers are SUOX 56398711 i5000976 AA SUOX 56397916 i5000977 AA SUOX 56391486 rs705703 CC intergenic 56401085 rs10876864 AG I haven't noticed a reaction to sulfites or sulfur containing foods.

Louis (2014-04-15 10:41:58)

Hello, August, Thanks for writing this article. I imagine you might be helping many people; perhaps you've helped me at least. If nothing else, it's another hypothesis for me to test. I believe I could have this issue with sulfites, so I've begun a low sulfur diet. I too have IBS that got slightly better on a low FODMAP diet, but by no means took care of it completely. I'm wondering a couple things: 1. You say that you had normal BM's after two weeks. Did that two week period include supplementing with

molybdenum or was that on the low sulfite diet alone? 2. I have a number of symptoms that I think are related to the IBS such as insomnia and difficulty concentrating. Did you too have symptoms related to your IBS? If so, did they go away or show improvement in two weeks too? Thanks!

Anne (2014-04-18 00:08:56)

Hi August Thank you for taking the time to write down this post. It was really interesting, and I will try this out over the coming weeks. I will start today and take away MSM and instead put in some molyben. The last entry from Louis was really interesting and I am very intressted in your comments on that, because that is a big thing even for me. 2. I have a number of symptoms that I think are related to the IBS such as insomnia and difficulty concentrating. Did you too have symptoms related to your IBS? If so, did they go away or show improvement in two weeks too? Kindly Anne

August (2014-04-30 13:43:11)

Louis, The two week period included both molybdenum and the low sulfite diet. I can say I had problems sleeping at various times, but I had not associated it with I.B.S. because of stress in my life. I did not track my sleep during the two weeks and I can't remember if it improved specifically during those two weeks. I have my windows covered and I try to avoid blue light at night, but I notice sleep changes depending on the season, stress, and I assume the more pain I am in, the more likely I will stay awake too, so I.B.S. must have had some effect. I can say I am sleeping reasonably well now. I wake up before my alarm, possibly in anticipation of the loud birds who inhabit my neighborhood.

MJB (2014-04-04 07:15:04)

Researchers Debunk Bubonic Plague of Black Death In Europe, Classify it As a Pneumonic Plague Instead Growing up, children have been taught that the Black Death, which spread throughout London in the mid-1300s and killed roughly 60 percent of the population, was caused by fleas off the backs of rats traveling on boats from Asia. However, researchers believe the disease, previously thought to be bubonic and spread through fleabites from human to human, was actually an airborne virus given its fast-spreading nature, according to the Washington Post. Such a pattern of transmission would make the black death a pneumonic plague, not a bubonic one. [http://www.latinpost.com/articles/9864/2\\_0140401/researchers-debunk-bubonic-plague-of-black-death-in-europe-classify-it-as-a-pneumonic-plague-instead.htm](http://www.latinpost.com/articles/9864/2_0140401/researchers-debunk-bubonic-plague-of-black-death-in-europe-classify-it-as-a-pneumonic-plague-instead.htm)

Andrew (2014-04-04 07:50:30)

Re: side effects, it wasn't surprising to find out that the Fort Hood shooter was on antidepressants.

Nancy Lebovitz (2014-04-04 10:45:31)

I was hoping the side effects website was evaluating typing speed and errors and such so that people could find out side effects from drugs they were taking.

GB (2014-04-04 11:13:53)

Re the University of Sydney study on macronutrient contents in mice. See the comments below the article from Rory Robertson, he's the sort of economist I wish they all were - useful. Also note the protein used - casein. Not exactly a balance of amino acids.

## **Bedtime Honey and Motivation (2014-04-05 05:00)**

A friend writes:

[1]The honey has been the biggest improvement in my life in several years. It's not just the energy, I think I'm more motivated to do things.

I started the honey with 1 tablespoon, but like others who commented, I had some trouble getting to sleep, so I reduced the dose to about 2 teaspoons. I take the honey about 15 minutes before bedtime, and I have not missed a dose since starting.

The first morning after the honey I felt much more alert and rested. I had no trouble getting out of bed even on 5 hours sleep at around 6:30 – 7:00 AM PDT.

The motivation that has come since starting the honey doesn't feel primarily psychological. It doesn't wax and wane or change in response to events. It feels raw (no pun intended), more like a drive.

The motivation improvement (that might be due to honey) seemed to begin a few weeks after I started it. The main aspect of the motivation is that I feel impelled to do things. This feeling lasts all day. It's not a manic feeling, because I still have priorities, and I can bail out of a task if I'm not making progress.

I noticed a similar change. After I started the bedtime honey, it became easier to do everything. Not a big change, but noticeable. When it started is hard to say.

1. <http://blog.sethroberts.net/category/sleep/honey-sleep/>

Andrew (2014-04-05 08:37:25)

Maybe a dumb question, but do you brush your teeth after the honey? Or before?

Nathen (2014-04-05 10:42:33)

I've started to collect reaction-time data. Is your bar for an unusual score a certain number of standard deviations out? Have you determined how important the time of day of the test and consistency of timing is? I've been testing every hour for a week and so far it is not at all clear.

Seth Roberts (2014-04-05 12:32:43)

To determine an unusual score I look at the data. I don't do any calculations. The time of day seems to have a small effect. I don't know what you mean by "consistency of timing" but if you mean the time between tests that appears to matter little. For example, if I stop for 3 days after doing the test daily it will not change the score by much.

Seth Roberts (2014-04-05 12:33:03)

I brush my teeth after the honey.

Retired now (2014-04-05 17:07:05)

I have to get rid of my residual candida infection first - honey exacerbates it. In the meantime I find that a starchy dessert or rice or potato starch helps with the sleep without setting off the thrush.

ML (2014-04-06 06:03:20)

FWIW, I've experimented with other sources of sugar besides honey and bananas and found a similar effect. I've been following Seth's schedule of taking a dose right before bed, an hour or so before and about two hours before bed. I've slept better when I've taken the equivalent of two TBS of honey 2 hours before bed and one TBS the next two times. I also find my sleep is improved if I've had some sugar around mid-afternoon.

shtove (2014-04-09 16:40:48)

The one invariable effect I find from 1 Tbsp of honey before bed: no matter how little sleep, I get up in the morning without intolerable fatigue. Recently I varied other beneficial sleep factors - reduced the carbs, no relora - and achieved the grand total of 12 hours sleep over 3 days. Previously that would have had a dreadful effect on me, but I was waking fairly easily and able to perform well on each day. Amazing - although I did have to catch up on sleep late in the week. I have now restored my previous routine, but this honey effect seems constant over the past few months. Eradication of that fatigue is helpful with anxiety over sleep onset.

Antonis (2014-04-14 16:00:20)

I would like to share my experience about honey. I brush my teeth using honey and it kills harmful bacteria in mouth because I know it is antibacterial effect. When I burn my skin, I apply honey after cold applying. It recovers the skin speedily, but you should cover of it. Same for scars and cuts. And now it is interesting to hear honey helps for losing weight and good sleep. I think it is a miracle food for people. Why I started to use honey: I read some verses from the Qur'an and it triggered me to search honey. Related verses says: "And your Lord inspired to the bee, "Take for yourself among the mountains, houses, and among the trees and [in] that which they construct. Then eat from all the fruits and follow the ways of your Lord laid down [for you]." There emerges from their bellies a drink, varying in colors, in which there is healing for people. Indeed in that is a sign for a people who give thought." Nahl 68-69 verses

## **What is Teaching? (2014-04-06 05:00)**

[1]Russ Roberts says:

Great teaching is more than passing on information. For that you can read a book or watch a video. A great teacher provokes and takes you on a journey of understanding. That requires grappling with the material and making it your own. Usually that means applying your knowledge to a problem you haven't see before. At least that's often the case in economics. I think Doug Lemov said it in his EconTalk episode – you haven't taught it until they've learned it and learning is more than just hearing the facts or the answer to a problem.

This was the view I heard at UC Berkeley among faculty – when they weren't complaining about teaching.

I disagree with this. The best teachers bring out what is inside their students. They provide the right environment so what is inside each student is expressed. How to do this will be different for each student, so you have to learn about them – not just generally, you have to learn about each one. (Or at least you have to grasp their diversity and allow for it.)

Learning is natural. Every student, in my experience, wants to learn something. What makes the situation much more difficult, is the false assumption that every student wants to learn the same thing or can be cajoled into learning the same thing. One of my Berkeley students said that in high school he had had a "great teacher" of philosophy, much like the teachers that Roberts praises. He had made philosophy so interesting that my student had originally majored in it. That had been a mistake, said my student.

I believe [2]human nature has been shaped in many ways to make our economy work. Human economies center on trading. You make X, I make Y, we trade. If everyone made X, that would be bad economics. So we have been shaped to want to go in different occupational directions – you want to be an Xer, I want to be a Yer. This is deep inside us and impossible to change. When healthy students have trouble learning, I think the underlying problem is their teacher wants them to be an Xer (like the teacher) – but they want to be something else. A great teacher finds that something else.

Even the term *great teacher* is misleading, because it seems to imply that being a great teacher (= every student learns a lot) is difficult. I have found it's easy, just as swimming with the current is easy. It requires a certain psychological ingenuity to fit this way of teaching into a system that doesn't understand it. But after I figured out how to do it, it was so much easier than teaching the traditional way. I used to try to make all my students learn the same thing. That was really tiring – like swimming against the current. After class I'd be exhausted. Now I feel fine after class.

Zach H (2014-04-06 06:13:57)

How would you adapt your teaching style to something like math, where the thing the student might want to learn requires a great deal of knowledge they might not be interested? It seems unavoidable that a certain core of mathematical subjects

is necessary while the students do not want that knowledge for its own sake. A big difference is that you have the luxury of teaching a subject where the particular knowledge and experience acquired in your course does not have to satisfy as many prerequisites. Additionally, the material in such subjects is artificial with respect to human experience. Adapting it to a format where it aligns with what people want to learn requires many acts of ingenuity.

Scottt (2014-04-06 08:13:56)

Along the same lines as what Zach says... My wife and I are very involved in the elementary teaching sphere. There are fundamental things that people simply need to know, whether they are particularly interested in knowing them or not. It's the price of admission to civilized society. How to add, subtract, write, etc. To use an extreme example from the opposite end of the teaching continuum from where you practice, when a kindergarten child shows up in school not even knowing his own name (happens every year - parent issue), then he needs to learn it or he can't function. Doesn't matter whether he wants to. I think your philosophy finds a home at the (perhaps) high school and university level, but probably not earlier than that. In the early grades, the genius of teaching is being able to get kids to engage in and be excited about learning what must be learned. Until they have been exposed to the broad range of all that has been learned before, they can't know what may interest them.

Roger Sweeny (2014-04-06 08:14:36)

Every state now has "learning standards" that say, "Students will learn X, Y, and Z." Teachers are legally supposed to have no choice: they must get students to know X, Y, and Z. So legally, a "good teacher" HAS TO "make all my students learn the same thing." State learning standards don't care whether "every student wants to learn the same thing." Students don't have a choice. So one of the tasks of a "good teacher" is to try to get all students "cajoled into learning the same thing." (Of course, one of the results of this is that students don't learn a whole lot of what they are supposed to, though almost all do a certain amount of "learn, get a grade, and forget." But "Students will learn X, Y, and Z" is the official policy of all states, and all of them pretend that's what is actually happening.)

Andrew (2014-04-06 09:24:49)

Great post. So much of civilization is the attempt to force people to adapt to the constraints of mass production, rather than the reverse.

AI (2014-04-06 12:54:58)

If one person is an X-er, another a Y-er and still a third is a Z-er, there is probably a collection of knowledge and/or a set of skills they all need in order to conduct economic transactions with each other. For example, a natural born visual artist may not be as quickly able to learn to read as a natural born journalist, but learning to read benefits both the economy and the visual artist if the visual artist. It's more efficient if the visual artist can, say, understand a written agreement to sell her artwork to the journalist, and so on. If the visual artist has to pay someone else to read and interpret that written agreement, then some efficiency is lost and the visual artist is less well off. But in a society where the visual artist is forced to learn to read by a rigorous school system she benefits by being more efficient, and having a lower cost of doing business than if she were illiterate. On the other hand, maybe this idea is just wrong. Maybe it's a waste of time to teach a visual artist to read. She could, instead of wasting time understanding written agreements to sell artwork, be actually creating artwork, which would benefit her more than the savings she experiences from reading her contracts herself. How is an educational system supposed to know which skills to teach all people and which skills to teach only to certain specialists? What if the educational system gets the mix wrong? And, what if you are, by nature, a visual artist, but not good enough to be economically viable? What should the educational system do for you in that case?

Terri Fites (2014-04-07 05:09:00)

Good post. Thank you for sharing it. We homeschool, and I see lots of what you said in both my kids and the kids I teach chemistry to in our homeschool group--and myself as I teach them! Take care.

aretae (2014-04-08 21:55:08)

Seth, As someone outside of the schools, who has been teaching for 20 years (dozens of unrelated topics, hundreds of

audiences), and considers himself a philosopher of education... What you've said here is very important, and I would refactor it substantially...to make both your and Russ Roberts' statements basically true. 1. Motivation is the core of learning. When someone wants (badly) to learn something, one can't keep them from learning it with a team of horses...teacher or no. When someone actively doesn't want to learn a topic, the greatest teachers in the world cannot teach them. Normal education is the business of trying to make a recalcitrant student learn something they don't care about. Your model, as far I've been able to piece together over the course of the last couple years on your blog, centers around letting students learn about things they do care about. As such...you maybe shouldn't take the title "teacher". You are perhaps instead an education sherpa...you help a student to take their own journey. I think the gap is huge between what you're talking about and what "teaching" is understood to be. My line: teaching and helping the student learn are effectively unrelated topics. I'm into the 2nd, not so much into the 1st.

aretae (2014-04-08 22:06:39)

Zach, I'm in the fields of math and computer education. You asked Seth: How do you adapt your method to a topic like math. My shortest answer is: I don't. I can teach K-8 mathematics ( $1+1=2$  through fractions/decimals/percent) to a group of interested previously math-free homeschool students Aged 10-14, in one hour a week for a semester...and I have. Once I know that that's the parameter against which I'm working (K-8 math for an interested student takes 20 total contact hours)...why would you? Almost everyone at one point or another decides that knowing some math is better than not knowing any. Home-/un-schoolers find it pretty easy to teach then. It's only fitting that approach into traditional big-box schooling that is hard.

Dragan (2014-04-10 19:16:06)

Seth, I don't think the comparison is fair. Roberts is obviously talking about teaching of some particular subject, in the way the word is usually used. You are using teaching in the sense of bringing out a person's potential... I think? Why is one of these superior to the other? I met a wonderful teacher of First Aid, CPR and AED. I mean, he was truly excellent. He didn't bring out any of my latent potential or anything of the sort, though. But I see nothing wrong with that.

Seth Roberts (2014-04-10 20:02:45)

Not a fair comparison? You mean: we are talking about different things? I doubt it. I think Roberts is talking about most formal education. For example, economics classes at a university, high school classes. So am I. Roberts describes the usual view of teaching: take what is in the teacher's head and put it in the student's head. I am not saying that's wrong. I am saying there is another goal that deserves more attention than it gets: helping each student achieve his/her goals. In the discussions of how to teach I've heard – for example, I attended lots of workshops at UC Berkeley on how to be a better teacher – this never came up.

Dragan (2014-04-11 14:33:33)

Yes, my take was that you are talking about different things. I think I misunderstood. I was thrown off by your comment that being a great teacher is not difficult. I suppose I agree, if we're talking about those of us who teach a relatively small number of eager undergraduates whose goals are not altogether different from ours. Coincidentally most educational research at the very least pays lip service to constructivism, the idea that students construct their own knowledge. A typical advice for teachers, then, would be to meet students where they are and work from there. Unfortunately, details are seldom given.

daz (2014-04-08 22:00:30)

hi Seth, just reading an old post of yours from back in 2011 here, <http://blog.sethroberts.net/2011/07/30/science-in-action-why-did-i-sleep-so-well-2/> just wondered (when you have time) what your current dosings & timings are for, butter, flax oil & coconut butter...? after dabbling with honey for a bit, i'm now interested to try other things before bed to see how my sleep is affected. thx

B.B. (2014-04-10 07:33:47)

I have issues with the Ignored Expert site, real life examples. There are three models of The Prophet. The first is Cassandra, the accurate forecaster who gets repeatedly ignored by stupid and greedy Suits, who often work for oil companies. Cassandra likes to feel superior when the forecasted disaster finally happens; often the Suits get killed. Al Gore likes to think of himself as Cassandra. The second model is the Boy Who Cried Wolf. The boy dishonestly makes opportunistic forecasts for his own agenda. The result is no one believes him when the wolf actually arrives. The third model is Chicken Little. There are those who are always in an hysterical model, forecasting catastrophes which never arrive. Which category do global warming advocates belong in? Instead of Ignored Expert, I see the Stopped Clock fallacy. A flawed clock is always wrong, but can still be useful because it may give the approximate time. A Stopped Clock is almost always wrong, but it is right exactly two times per day. Unfortunately, someone looking at the Stopped Clock cannot know if that is one of the right times. A Stopped Clock is utterly useless even though it is sometime right. There are always Cassandras forecasting, for example, a stock market crash or an earthquake. Like a stopped clock, they are almost always wrong. Sometimes, the disaster will happen. Then they will congratulate themselves on being geniuses, and everyone will ask why were they ignored. They were ignored because they are almost always wrong. Did Elizabeth Warren, a lawyer, really make a forecast in the 1980s that the stock market would crash in 2008? She could have become very wealthy investing on that basis. I wonder if she forecasted the crash in 1987, in 1990, in 1998, and in 2000-2002 along the way. Did she also forecast the stock market booms of the 1990s, the mid-2000s, and 2009 to 2012? Did she also forecast that the "affordable housing" initiatives she has long advocated helped create the subprime mortgage bust? I want to be an Ignored Expert also. I forecast that the stock market will suffer a major crash sometime in the next 30 years. I can't tell you when, where, how, or why. When the market crash comes, I expect to be called a Genius. I forecast a recession will start sometime in the next 15 years. Finally, I forecast a really hot Summer sometime in the next 10 years. Yes, I am being sarcastic. There is a world of difference from an engineer discovering a potentially dangerous flaw in the Shuttle using valid testing procedures, and someone making a forecast. For every Ignored Genius you can find who wasn't listened to, I can find an Expert who made a prediction that turned out ridiculous, like a prediction that man could never fly faster than sound. How are we supposed to separate experts who make foolish predictions from those who are Cassandras?

Seth Roberts (2014-04-10 10:14:24)

"For every Ignored Genius you can find who wasn't listened to, I can find an Expert who made a prediction that turned out ridiculous." I'd go much further. For every Ignored Genius you can find a thousand Experts who made a prediction that turned out to be ridiculous. Global warming experts who predict disaster are the Boy Who Cried Wolf (the prophecy involves self-interest) except that they don't know there isn't a wolf. The models on which they base their prediction are likely to be wrong but they don't understand this.

Fred Silva (2014-04-09 11:16:59)

Unfortunately the New York Times article is paywalled :( Seth: Sorry, I didn't realize the paywall varies from country to country. I was in Korea when I read it.

Seth Roberts (2014-04-09 17:41:32)

you can see most NY Times articles, including this one, by opening them in what Chrome calls "incognito window". Firefox has something similar.

Nancy Lebovitz (2014-04-09 18:15:09)

What advantage does resistant starch have over potatoes?

Alex (2014-04-09 20:55:14)

No, that article is only for premium subscribers. It's paywalled even in incognito mode.

Seth Roberts (2014-04-09 23:38:03)

that's odd, because I read it using incognito mode. More: The NY Times paywall varies from place to place. Using incognito mode, I can read it in Korea but not in America (and Australia).

Adam (2014-04-10 08:04:20)

Nancy, potatoes that are cooked and cooled will contain a small amount of resistant starch, but not much. If you are shooting for a certain intake target, it is much easier to take pure resistant starch in the form of potato starch than to get it from whole foods.

JM (2014-04-10 08:09:23)

Nancy, it has to do with cooking the potatoes. When you cook potatoes to a certain temperature (I think it's about 140 F) the starch granules burst and become regular starch which your body digests as such. Cooked and cooled potatoes, green bananas and other food that contain undigestible resistant starch which then feed the gut bugs in your lower digestive tract. Lots of info at Mark's Daily Apple which ran the self-experiment post (which I thought had a nice outline of how to do your own self-experimentation). Also there is a lot of info at Free the Animal blog.

Jerry (2014-04-10 18:26:16)

The evidence indicates that asthma is an infectious disease caused by Chlamydia pneumoniae. I successfully treated mine using the Hahn Protocol. Check out <http://www.asthmastory.com/steps/> for info on how to do it. I use my inhaler very seldom now.

harold (2014-04-12 17:16:24)

At the end of the Honey health benefit article there is a link to •10 uses for honey outside the kitchen. " #9: Fight insomnia: If you don't have much trouble falling asleep, but tend to wake up in the middle of the night, it could be totally natural (for centuries many people had a two-sleep schedule) or it could be due to stress hormones, adrenaline and cortisol, being out of tune. A bit of salted honey (you need both sweet and salty) can help reset these hormones and get you back to sleep. You only need a small amount (this shouldn't be a snack!), so use a teaspoon or egg spoon to keep yourself from overindulging."

### **Hobby versus Job: Casa Pepe Guest House, Seoul (2014-04-10 05:00)**

Yesterday I was in Seoul, at [1]Casa Pepe Guest House. Sensationally good at a very low price. It really is a guest house – attached to a house – with a separate entrance. There are four rooms, with shared kitchen and bathroom. The owner is an renowned chef. The first evening he brought salad and wine from his (Japanese) restaurant. The first morning, he invited me to come with him to buy fish at the Seoul fish market. Every morning, he made breakfast – something different each time.

I found it through hotels.com. On their map, it was off by itself. I thought that meant bad location, but the opposite was true. It is the sort of good location you cannot normally get. It is near the Blue House (Korea's White House) and many foreign embassies and is very safe. Dozens of interesting restaurants and cafes are nearby. (Even more than the rest of Seoul.) The neighborhood is the Beverly Hills of Korea, with better (and cheaper) restaurants and less pretentious architecture. Casa Pepe started about a year ago, with a remodelling. Everything is new and clean. The floor is heated. The building is up a steep path and has a nice view of streets, hills and houses. Free laundry. All for less than \$50/day.

During my stay I briefly overlapped with a *Tsinghua student* (how could that possibly happen?) but otherwise I was the only person.

Why is it so nice? The owner said, "It's my hobby." I think that explains it.

[2]I've said that doing a job and doing science are fundamentally incompatible. Any job requires steady and repeated output. You do the same thing over and over. The goal of science is discovery – and a discovery is inherently unpredictable and unrepeatable. (Art is a job with science-like elements – and [3]artists were the first scientists.) Casa Pepe Guest House illustrates another side of the job/science conflict: A job is inherently conformist. You give people, especially customers and your boss, what they expect. Science is inherently nonconformist. The more a discovery challenges "what everyone knows", the better. Hobbies make this point because they can vary more than jobs. If you make tables as a hobby, for example, your tables can vary more than if you make tables for a living. Casa Pepe is way outside (better) what one expects from a rented room.

Another way Casa Pepe is unusual is that it is very hard to find, even if you study [4]the directions. I found it by knocking on a neighbor's door. The neighbor called Casa Pepe. Someone from Casa Pepe came to meet the neighbor and me on the street – it was too hard to tell the neighbor where it was. Here are better directions. From Incheon Airport, take airport bus 6112 to the Hangsun University stop. Go to Exit 6 of the nearby subway station ([5]Hangsun University Station on Line 4). Walk up the street (Seongbuk-ro) indicated by Exit 6 – toward the hills. After walking about 13 minutes, where the road veers right, you will see a sign that says Seongbuk-ro 19-gil (gil = side street), which points almost exactly to a steep concrete path on the left perpendicular to the street. It is the width of a driveway. Go up about 40 meters. Casa Pepe is on the right – a white house with a red door, with a sign that says "casa pepe". Don't be misled by the fact that the listed address is not on Seongbuk-ro 19-gil.

Alex Chernavsky (2014-04-10 08:20:20)

I work for a non-profit organization, and we depend a lot on volunteer labor. In working with IT volunteers, I find that the best, most-capable volunteers are those for whom computers are both a hobby and a job. The volunteers who are IT professionals ONLY, and who don't "mess around with" computers much at home, tend to be much less knowledgeable and less adept at problem-solving.

Dragan (2014-04-10 18:43:26)

Lovely story. I had both awful and pleasant experiences in Seoul. Not a place I intend to return to, but if I did I'd be certain to visit this guest house. Interesting how an earnest story like this can sell something so well.

Nancy Lebovitz (2014-04-11 09:14:28)

Off-topic: person finds considerable health gains from drinking more water. <http://andrewducker.livejournal.com/3074-958.html?thread=28953230#t28953230>

kxmoore (2014-04-13 08:26:41)

I just got into the beer-making hobby. I go to a monthly beer swap at a brewshop in Brooklyn. The best beers I have ever tasted were made by the hobby brewers at these events.

Seth Roberts (2014-04-13 11:31:50)

Beer making is a very interesting example. I suppose there is a set of products where we tend to think that small scale production = better: beer, cheese, wine, sausage (?), book-binding (?), others. The word artisanal is used. In other cases, we think bigger = better: flat-screen TV, car, and so on.

## **Burnt Sugar Grapefruit: Give Thanks for South Korea (2014-04-13 05:00)**

A Marginal Revolution commenter [1]wrote:

South Korea being prosperous has had no benefit to me, yet I have borne the cost.

I say: Wait ten years. No country combines innovation and quality like South Korea. Samsung illustrates quality but the innovation is less clear. Here are examples.

1. Food preparation. In Seoul, a friend took me to an American-style buffet. Nothing could be worse, I thought. But I was blown away by original treatments of familiar things. One was an octopus salad. It was truly chewy and crunchy, in contrast to most restaurant salads. Whoever designed it understood underlying principles – they weren't just mindlessly copying. The fruit on offer included burnt sugar grapefruit – small pieces of grapefruit with a little bit of added sugar, then torched. The burnt sugar adds complexity. A simple small cheap attractive practical dish – not grilled grapefruit with too much brown sugar.

2. Cafes. Seoul is bursting with little cafes that are pleasant places to spend a few hours. They are well-decorated (many individually-decorated), serve interesting food and drink, and make Starbucks look cold, hard and stodgy. You can easily spend \$6 on dinner and \$6 on a drink afterwards but the \$6 drink seems worth it. One Korean explained the profusion of beautiful useful cafes on competition ("Koreans are very competitive"). Another Korean said it was the TV series Sex in the City ("The characters spent a lot of time in cafes"). There are two Korean cafes near where I live in Beijing.

3. Bakery. [2]Korean bakeries have what Americans expect in a bakery, such as bread and croissants, but also have many more products, both baked goods and other food, than American bakeries. There are many Korean bakeries in Beijing.

4. Airport. Incheon Airport was voted the best airport in the world for 7 years; in the most recent two years, it was voted second best. I'm not sure this reflects innovation that future airport architects will want to study; new airports have a huge advantage for which I cannot adjust. But Incheon has free wifi that works; Beijing International Airport has free wifi that doesn't work.

5. Door lock. Nice houses and apartments in Seoul have a kind of digital door lock I haven't seen anywhere else. Via Google I found [3]this – which, lo and behold, comes from South Korea. These locks are better in several ways than other electronic door locks. For example, the keys are lit. My guess is that new houses and apartments in America don't have these locks because Americans don't even know they exist. Apparently a South Korean company (Milre) figured out that substantial improvement was possible. There isn't even an English Wikipedia entry for Milre, yet it will have more effect on your life than, oh, 99.999 % of the current entries.

6. Pop music. Gangnam style, obviously; K-Pop, slightly less obviously, if you don't live in Asia. Gangnam style = K-Pop plus humor.

Keep in mind South Korea is small (population 50 million; the population of Japan is 130 million). A country that is a lot more prosperous now than 30 years ago is a good place to innovate because all the crummy old stuff is being replaced – that is clear. It is also a big plus for innovation if its citizens are well-educated. If you understand that, and how bad the United States is at innovation (housing, health care, cars, education . . . ), you will see that helping South Korea become prosperous was a great investment. Inadvertently great, but great nonetheless.

In *Start-up Nation: The Story of Israel's Economic Miracle*, the authors (Dan Senor and Saul Singer) argued that Israel is unusually innovative because no one defers to their superiors, everyone challenges everyone else ("The Israeli said, "What does "excuse me" mean?"). In *The Ethnic Theory of Air Crashes*, a chapter in *Outliers*, Malcolm Gladwell repeated the theory that Korean Air had a lot of crashes because co-pilots were too deferential. Which is only to say we have a lot to learn about innovation and South Korea.

kxmoore (2014-04-13 08:21:23)

There are several Korean bakeries here in NYC. They are in Koreatown and have French names and are often crowded. The baked items look good but everything tastes like wonderbread to me. Awful. There is also a huge Korean-owned buffet restaurant. The food is superior to American buffets except for the desserts.

Andrew (2014-04-13 10:39:17)

Tons of Korean cafés and restaurants in Los Angeles, too. The cafés help family members immigrate to the US by creating jobs that can be given to cousins, etc.

Seth Roberts (2014-04-13 11:22:56)

Two of the Korean bakeries near me in Beijing are Tous Les Jours and Paris Baguette.

No One (2014-04-13 13:16:42)

I have friends who work at the Israeli branch of Samsung (which is Korean). They have interesting culture clash stories. One of the things that happens often is that Korean teams come to Israel to learn the "Israeli Creativity" style, and come back confused how that thing could ever work anywhere.

dearieme (2014-04-13 16:03:43)

"South Korea being prosperous has had no benefit to me, yet I have borne the cost." In what sense has the complaint borne the cost, I wonder, and in what senses has he had no advantage from it?

dearieme (2014-04-13 16:14:05)

Ah, forgive me for answering my own question, but the commenter seems to be thinking of the cost to the American taxpayer of the Korean war and the American military deployment there ever since. Plus the cost to the casualties and, presumably, their families. It's a fair point, and so I withdraw my cantankerous remark.

jeff (2014-04-13 21:20:08)

Seth, On any topic that compares peoples, you risk ruining your career if you actually are interested in digging for truth (not that I claim to know the form of the latter), so you might considering staying away. When you compare Starbucks to Korean cafes, I am sure your observations are spot-on. But the superiority of the Korean cafes only partially stems from Korean character, the gulf is made wider because the United States is a socially atomized place of extreme diversity. By now, only dolts deny that diversity equals reduced social cohesion, so you are comparing a unified people against an atomized people and declare the unified people do things better. No duh; this is a worthless comparison and you should be ashamed for advancing it, given the general tone of your blog. You can't compare S. Korea to the USA or any European country because all but Korea are increasingly factioned. But if you compare Korean cafes to French cafes of the 1920s and adjust for technology, I am sure that you will find the former to be nicer but the latter to be more inspiring, and more importantly, a place more likely to result in copulation, which if you are like me, really can't be beat for life enjoyment. So which would be better Korean or French cafes? For me, it would be the latter, because once a certain level of comfort is attained, then the physical pursuits are where life begins. Moreover, when you say the USA is bad at innovation, you are being myopic beyond all imagination. The USA along with many Western nations is in the midst of an inventive and enormous scientific experiment, replete with controls, to see if various peoples from around the world are interchangeable and what will be the consequences of pushing diverse populations nearer to Malthusian limits. Since we already know the answers to these questions on a small scale, one scientific test is, will our massive educational interventions make all peoples equal and interchangeable to arrive at the expected resultant had no population replacement, and/or augmentation programs been initiated? Change your vantage and you will see that the wealthy people of the USA gave up on advancing some forms of innovation and turned to social engineering for the hobbyist science that you advocate. You may not see social engineering as experimental, but it is, and it is of the highest and most profound importance as once it begins, it never ends. As regards overall Korean innovation, I am sure it is great, but it will be within the same limits as other high-IQ agrarians. The reason that Korean Air pilots suffered many crashes most likely resulted because, despite their fiery personalities, they are a people genetically disposed to obedience and compliance to a slightly higher level than a mixed pastoralist/agrarian people. To be a good pilot, you need both adherence to rules and a cowboy confidence. After the crash in San Francisco a year or so ago, an American trainer shared his experiences training East Asian pilots. He marveled at their mastery of the air operations manual, declaring it far better than his, but he said they were generally deficit when it came time to improvise. Compare this to Feynman who opined that it was important not to study too much, the works of others, as it might impede your ability to innovate.

Dragan (2014-04-13 22:28:29)

My favorite memory of my summer in Korea (Seoul mostly) is the food. For the young, the party scene is fantastic, as well. Lots of places to go to, lots of young people dancing, and a very safe environment. Interesting stuff, too: breakdancing shows and video game competitions as serious as high school basketball games in the US. A guy I met in Seoul told me that in his hometown of Manila, everyone brings guns and knives to dance clubs. So he flies out to Seoul whenever he feels like enjoying himself at a reasonable price without fearing for his safety. Outside of wonderful food and nightlife, the rest of my impressions weren't as favorable as yours, Seth. (Well, I did think that Incheon was wonderful.) I've met welcoming and helpful Koreans while there, but I did not feel welcome in the country overall. I do not think I'd like to visit it again. For comparison, I'd be happy to travel through Japan again, or China, at least the parts I previously visited. A few years ago, one of the traveling websites (maybe Lonely Planet) had a poll for "Least favorite city" and Seoul was 3rd on the list. I thought this a bit ridiculous, as I've been to far worse cities, but had to admit there's logic to the madness.

Brock in HK (2014-04-14 07:08:53)

The commenter clearly favors tyranny of all being harmed against their will vs free people fighting for liberty. He undervalues the benefits of freedom, which is why his calculus is wrong. Think of the cost to the world of South Korea in a Kim dynasty-led Stone Age.

George (2014-04-14 16:57:03)

Nearly all Asian countries are infinitely superior than America at the "art of living well" - food, nightlife, cafes blow American versions out of the water. The funny thing is Asians are scene as "boring" in America, but in their own countries they have

magnificent tradition of unbridled hedonism and excitement seeking that makes our pathetic Puritan attitude to fun seem utterly lame. Which it is. We're pathetic when it comes to food and nightlife and fun in general. Asians drink more than us (waaay more), party harder and better, and eat waaaay better. Arguably these things are what really matter in life (In my view they are!). It's because Asia, like Europe, has a "culture" - a set of traditions created over centuries through a process of tinkering to maximize human enjoyment. America does not have traditions (i.e a culture), we have "science" - a habit of starting from scratch and finding that we simply can't invent a good lifestyle using "science". We can't even figure out how to stay thin using this start from scratch "science" - once we got rid of thinness-promoting traditions, all our science couldn't replace it. Outside of things like food and nightlife, I think its fairly obvious that America is infinitely more creative and innovative. But living is simply better there, the little things in life that make it fun and exciting. Now compared to Europe its a bit more complicated.

Adam (2014-04-14 21:17:31)

Having lived in China for 3+ years and having Asian friends in Korea and Japan as well, I have to say you are dead wrong about Asians knowing how to party. My friends back in the States are much better at it than anyone I ever saw in China. Japanese and Koreans drink a lot, but it is a sort of hierarchical thing forced on them by the work environment. You get drunk because the boss is getting drunk. It isn't fun, it is a mandatory work event.

George (2014-04-14 22:55:21)

Sure, Adam, clubs closing in LA at 2, capital of entertainment for chirssake - yeah, we Americans really know how to party. Not to mention you have to drive so you can't really drink. It's barely better in NYC with closing times of 4. China kind of sucks though, that's true. Maybe there was a whole scene I didn't tap into. But then there's the endless prostitution, the late night clubs, the heavy drinking, the great food - give me a break. Asians do debauchery and dissipation on a scale that would make our Puritan ancestors roll over in their graves. Europe's better at it too, much better. Berlin has parties that last till Monday. No, we're about work in America, and buying stuff. We're dull, but comfortable, and we own lots of stuff. Clearly we have our priorities right.

Dragan (2014-04-16 17:56:29)

"Asians do debauchery and dissipation on a scale that would make our Puritan ancestors roll over in their graves. Europe's better at it too, much better. Berlin has parties that last till Monday. No, we're about work in America, and buying stuff. We're dull, but comfortable, and we own lots of stuff. Clearly we have our priorities right." I completely agree. "We can't even figure out how to stay thin using this start from scratch "science" - once we got rid of thinness-promoting traditions, all our science couldn't replace it." I really liked this line. In fact I think I'll steal it, the highest form of flattery. :)

## **Pregnancy Gingivitis: Failure to Look for the Cause (2014-04-14 05:00)**

A few days ago, I learned from a Crest ad that a large fraction of pregnant women, such as half, suffer from gingivitis (inflamed gums). It's called [1]pregnancy gingivitis. The ad recommended better dental hygiene, such as brushing your teeth more.

Thirty years from now will people think *how could they* [meaning us] *havebeen that stupid?* Faced with pregnancy gingivitis, they brushed their teeth more? Pregnancy gingivitis is supposedly due to "hormones" that increase during pregnancy. In other words, a health expert actually thinks - or claims to think - that pregnancy gingivitis has a different explanation than other gingivitis. Yet he doesn't know what causes other gingivitis. For example, [2]here is what Mayo Clinic experts say causes gingivitis. This makes no sense. But it is worse than most nonsense, since fetal health is at stake.

Several years ago, I greatly increased my flaxseed intake because I discovered it improved my balance. [3]My gums suddenly went from red (inflamed) to pink (not inflamed), no doubt because flaxseed has lots of omega-3, which is

anti-inflammatory. Gingivitis is – usually? always? – caused by too little omega-3.

My theory: pregnancy gingivitis happens because pregnant women need more omega-3 than usual. A growing brain needs lots of omega-3. If this theory turns out to be true, the gums of pregnant women should be monitored to make sure they are getting enough omega-3. Nowadays pregnant women are given omega-3 to take but there is no test to make sure it is enough. That pregnancy gingivitis is common suggests it often isn't enough. Actually, everyone's gums should be checked to make sure they are getting enough omega-3.

1. <http://www.oralb.com/topics/gingivitis-during-pregnancy.aspx>

2. <http://www.mayoclinic.org/diseases-conditions/gingivitis/basics/causes/con-20021422>

---

Mark Sanders (2014-04-14 11:16:40)

I like to read your blog for the articles on self-experimentation. However, simply because something works for you is not scientific proof that your cure, or your explanation for your own cure, is true for everyone else. There is a list of things that go out of whack in a pregnant woman's body, most of which resolves once the baby is delivered. This is not to say your idea is wrong, maybe it is. But just because it worked for you doesn't mean it will work for a pregnant woman or that the Mayo Clinic should change it's explanation of gingivitis, an explanation that makes sense to me.

Seth Roberts (2014-04-14 12:44:40)

Many (10?) other people told me that their gingivitis went away when they took 1-2 tablespoons of flaxseed daily. Nobody told that this amount of flaxseed failed to reduce gingivitis. My confidence about this is not based only on the fact that something worked for me. It is also based on the fact that it worked for many other people and the research showing that omega-3 is anti-inflammatory. Of course, my idea about pregnancy gingivitis is just a theory, a theory that can be tested. But at least it is a theory that explains ordinary gingivitis and pregnancy gingivitis in the same way.

Adam (2014-04-14 14:18:06)

That is funny. It seems like they just figured women's hormones are something that changes during pregnancy and arbitrarily said that that is what causes pregnancy gingivitis. Which hormones specifically and in what way do they cause inflammation of the gingiva?

Tom Metz (2014-04-14 14:38:56)

Self experimentation and anecdotes are, in my opinion, some of the best sources of information we have as long as what we resolve to experiment and what we try isn't dangerous and used in place of what we know also works. Suggesting that pregnant women should take flax oil or eat more flax (it's just a food) is not dangerous. Self experimentation is not even in the same league as a clinical trial yea I know. But lets look at the prospect of a clinical trial to see if pregnant women with bad gingivitis need more omega 3... who on earth would fund that study? Nature's Bounty? Bob's Red Mill? Colgate? Colgate would lose money if there was a connection. "Hey ladies you don't need colgate... you need flaxseed!" Omega 3 isn't prescription and therefore would provide no benefit to the companies with adequate money to actually fund studies. It will simply never happen. Mr.Heisenbug (don't know his actual name) said on his blog that he cured his hand eczema with a specific type of probiotic. Because of this countless others with eczema have tried this probiotic with great success in curing their eczema. No clinical trials exist that establish the connection between eczema and this probiotic. The standard treatment here in the U.S. for eczema is to go to your doctor, then get a referral to a dermatologist, then get a prescription for a steroidal hand creme that's going to have a plethora of side effects, cost your insurance an obscene amount of money and probably smell terrible. The sad thing is... the creme will always be the medical systems treatment of choice because

there is much money to be made on it. As for the topic... I would think a pregnant would need more omega 3 because it is essential for brain development and well the woman is essentially developing someone else's brain for them. According to this article... <http://www.sciencedaily.com/releases/2012/06/120609152436.htm> omega 3 in breast milk is important for infant development. It would make sense that, if there is a connection between gingivitis and omega 3, the gingivitis would be worse for a pregnant woman. Most American adult women are already deficient in omega 3 because of the high amount of omega 6 oils used in processed foods. A pregnant woman would have to defer their amounts of omega 3 to the developing baby thereby depleting their own stores. An interesting (and safe) test would be to examine food diaries of pregnant women and see if at any point they crave foods high in omega 3 (fish flax etc...) Love your blog Seth and, as an educator, look forward to all of your posts.

Gina (2014-04-14 15:11:14)

You can count me among those whose gums improved with flax. I don't do oil, but 1-2 tbsp of ground flaxseeds a day. How do you know it's the omega-3 and not the lignans or something else in flax?

Seth Roberts (2014-04-14 16:26:03)

how do I know it's the omega-3 and not the lignans or something else? because the flaxseed oil I used didn't have lignans. and plenty of research shows that omega-3 is anti-inflammatory.

Amol (2014-04-14 19:03:26)

It is incredibly interesting to me that dosage is an incredibly important factor for generally accepted medical drugs but no one ever applies it to food. After reading your blog, I started experimenting with honey immediately after waking up and before going to bed to absolutely amazing results in sleep at night and appetite control during the day. When I tell people that I eat 60 grams of honey a day, they almost always ask as to why so much without realizing that 60grams is only 3 tablespoons. My guess would be that Omega-3/ Fish oil or Flax seeds probably fall into this category where people make random statements about dosage without any meaningful evidence, self-experimental or otherwise, to back it up.

Leslie (2014-04-14 20:09:22)

Hi Seth, I stumbled on this interesting bit of info on cannabinoid like anti-inflammatory in flax (<http://www.ncbi.nlm.nih.gov/pubmed/22706678>), so perhaps that also contributes to the positive effects seen with flax?

Allan Folz (2014-04-14 20:28:59)

I have what I think is an interesting self-experiment wrt O3 & pregnancy. My wife had some pretty bad post-partum depression following the birth of our first. It lasted more or less until he weaned, a little over two years. With our second, for the whole pregnancy there was some underlying tension whether she would experience it again. Quite fortunately and thankfully it did not. About the only difference I noted at the time was the first was a boy and born with some moderate complications during delivery while the second was a girl, no issues. I chalked it up to the complications (depression is well-known among heart-attack survivors and IVF recipients, which IVF is, IMO, by-definition a complication). For the third pregnancy I had "discovered" Paleo eating and so we were on a low-moderate carb diet. We were also supplementing vitamin D and a little fish oil. She was averaging 5K IU of D a day, but only about one, 1g capsule once or twice a week of the fish oil. All in all, not much fish oil as I was generally skeptical at the time of how much was really necessary for people otherwise eating traditionally healthy, home-cooked meals. Late in the third trimester she started experiencing a certain amount of moodiness. In and of itself, it would not be atypical for any woman in her third tri, but with my wife's history it us more sensitive and take notice. Paying close attention (and long before discovering your blogging about self-experimentation) I eventually correlated the moodiness to those times we'd skip taking fish oil. If she didn't take any mid-week, by Saturday it was very noticeable that her mood was down and she would be on the short-tempered side. Once I noticed the connection, and without telling her what I was doing ie. single-blind, I'd deliberately skip her mid-week one week note her weekend temper and mood. The next week I'd be sure she took a cap mid-week. Next week back to skipping. Then a week of double-dosing, 2 caps twice in the week. It had the best results yet. At first I was amazed. It was neat: so mechanical, like flipping a switch. But then it occurred to

me that if two capsules in a week vs. one was enough to change her mood then she was obviously deficient as every mg was being put to use with no spare capacity "in the tank." I wondered if her body was scavenging it from her own brain, kind of a sobering thought. After that she went to supplementing daily and had no mood issues through the rest of the pregnancy or while breast feeding. I can't remember if she had the typical "baby blues" at the three day mark. I am convinced O3 is a vital part of nutrition for mothers both pre-natal and while nursing. I share this story about every time the subject comes up. I also have an interesting story about my son and fish oil, but for another time. :)

Jim (2014-04-14 20:32:15)

In reply to Mark: I have always had poor gums. When I saw, years ago, Seth using flax oil to help with gums - and other bloggers saying that it helped (Marginal Revolution) I tried it. My gums were much improved. The last time I went to my dentist his comment was "Who has been taking care of my teeth?" My gums were much improved. I told him that he was taking care of my teeth - every 4 or 5 years. For me flax oil is really good. It really ups my HDL cholesterol levels also (from the 30's to the 50-60's).

sam (2014-04-15 05:56:04)

the esteemed chris kresser is not that keen on flaxseed oil. he prefers fish oil. <http://chriskresser.com/why-fish-stomps-flax-as-a-source-of-omega-3>

Tom Metz (2014-04-15 11:11:09)

To Allan, Wow that appears to be quite a connection between the Omega 3 and depression during or after pregnancy. Through such an idea we can ask the question- is Omega 3 deficiency during pregnancy the primary cause of postpartum depression? A pretty significant reality if true seeing that postpartum depression is very common. Now if there was only a way to connect the postpartum depression to gingivitis. That would be pretty wild.

Allan Folz (2014-04-15 12:14:30)

Tom, I really think it is. I also think it extends well beyond pregnancy. I wonder how many pre-adolescent boys struggling with ADHD and teenage boys struggling with depression, and so many of them on one big pharma prescription or another, really are suffering from an O3 deficiency.

Seth Roberts (2014-04-15 13:28:52)

yet flaxseed oil works. and does not have mercury contamination problems.

Allan Folz (2014-04-15 18:49:31)

I don't have an opinion on flax vs. fish. At the time I didn't even know there was an efficacy debate. We were taking a fish-based supplement because it was most readily available. Heck, even among fish oils there's a huge debate between molecularly distilled esters and the natural triglycerides. I don't know which is necessarily better, except that the distilled esters did work for us. So, I call it omega-3 at let folks decide which they want to take. Now that I'm thinking about it, yes, I should do a self-experiment - put the family on flax for a month and see if anyone can notice a difference. Unfortunately, I don't have any pregnant or nursing mothers for a real test.

Bill Johnson (2014-04-18 05:56:28)

My wife's been Oil pulling for several years now and during pregnancy she does it even more than usual. She finds it very effective in avoiding this mouth problem. How about giving it a try for all mothers there.

Cord (2014-04-18 07:10:14)

The state of medical knowledge about pregnancy is shameful. We basically haven't progressed much beyond "hysteria" when it comes to diagnosing and treating woman-specific medical problems. I'm working on my second pregnancy. Gingivitis is not a malady I have encountered so far, but I do take cod liver oil and eat a ton of eggs (pastured, from my own flock). The one that gets me is the chronic constipation. Every pregnancy guide will tell you that constipation is common in pregnancy, and there

are lots of cute theories about how this is adaptive because it helps you extract the most possible nutrients from your food. Not a whisper about what happens to me: total cessation of gut motility from the day before the positive test until 18 months after the birth of the baby. People who say "just eat more fiber" (like my OB) make me livid. Whatever is causing this, it's NOT adaptive to be dependent on Milk of Magnesia for two years with each kid. I actually got a blockage with my first pregnancy, and the thought of doing that again terrifies me. I was determined to find an answer this time around, but my OB was no help, and even the internet is extremely squeamish about recommending \*anything\* for pregnant ladies other than an extra pillow and a sedate walk. I tried a chewable probiotic, with no results. Then tried the Jarro-dophilus (whose thick shelled capsules are supposed to make it past the stomach intact), and later added potato starch with it ala Free the Animal, and things are not entirely back to normal, but lo and behold, I am off the milk of magnesia!! All this says to me that the problem may be hormone related, but if it were just "hormones", a probiotic wouldn't fix it- it's got to have something to do with gut health, and probably gut flora. Pregnant or not, intractable constipation is not normal and not healthy. So why doesn't my OB know about this? Why do all mainstream sources of pregnancy info shrug this problem off as "just hormones" and recommend totally ineffective solutions?

Seth Roberts (2014-04-18 07:36:28)

I agree. Calling it "hormones" makes no sense. You might try steel-cut oatmeal, that's a good source of fiber.

Terri (2014-04-20 13:53:12)

As a medical doctor taking time to read on nutrition, GI health, food intolerances, and pregnancy for myself and my own issues, I have learned way more than I ever did before. But at least I have the tools to make sense of what I am reading so I won't complain much. I don't have gingivitis, but I have definitely realized that many of us females head into pregnancy deficient in omega 3, iodine, vitamin d, vitamin k2, magnesium, and micronutrients. Sadly, my own OB didn't even take time to make sure I was on a decent prenatal vitamin. On flax vs seafood vs supplement, I think each person has to find their own way. I have the commenter Cord's issue, and flax, despite trying it, made the GI motility much worse. Seafood is feel good food for me.

### **Mo Ibrahim: My Third Year of Teaching (2014-04-15 05:00)**

By the start of my third year of teaching, in 2007, half of my New York City Teaching Fellows cohort had quit teaching. Some for health reasons, some due to differences with their school's administration, and some due to the difficulty of teaching during the day and going to graduate school at night. Teaching poor students, writing fifteen-page papers on pedagogy and compiling lesson plans proved to be too much.

The day before classes began that year, the principal told me that our students needed to earn an economics credit to fulfill graduation requirements. He asked if I wanted to teach the class. I hadn't taken economics since freshman year of college, but I reluctantly agreed. The principal said he had an economics curriculum in his office and he would return shortly with the material. He didn't return and never gave me the material. . However, I was able to develop a curriculum on the fly. I had read Gladwell's *The Tipping Point* and watched Gopnik's *Lighting Up New York* documentary. I got the idea to make a curriculum based on Gopnik's four theories of New York City crime reduction: Broken Window, Abortion, Child Boom and Korean Immigration. To supplement my curriculum I read *Freakonomics* and Park's *The Korean American Dream*. I didn't have to teach math anymore, because I was teaching economics, but I was still teaching English. My class focused on reading poetry and short stories and writing short essays.

By that time I had earned my Master's degree from the City College of New York, and had learned two principles that proved helpful. During an evening class, an African-American female professor, who insisted we call her Doctor, advised us to use the don't ask, apologize principle to get around policies with school administrators. For example, instead of asking if I could take my English class to read poetry in Central Park, I should take them knowing that I could simply apologize if I were reprimanded by an administrator. She also told us about a research study done by Lisa Delpit, an education researcher, who advised teachers not use please with inner-city male students. According

to her study, when students in that demographic hear the word please they feel they have a choice. For example, a teacher should say, "Go back to your seat," instead of "Go back to your seat, please." In my experience, she was right. The command without please worked better.

I can't recall using any other teaching techniques that I was exposed to during graduate school. There should have been more instruction on how to motivate students to study and how to get parents to make their children do their homework. Talking to my students, I learned that, when they get home, most of my female students took naps and most of my male students played video games. Very few of them did any homework, read or studied.

I didn't give any homework or quizzes in my English class, which had about 20 students, because most of my students didn't do any schoolwork at home. I had my English students do all of their writing assignments during class time. I didn't give any homework in the economics classes as well, which had about 30 students, but I had felt compelled to give quizzes to assess how well the students understood my lessons. I knew that the majority of my students weren't going to study at home, but I hoped that I had explained the material well enough that they would be able to do well on quizzes. I initially did a quiz review the day before the quiz, but that didn't seem to help the dismal passing rates. I tried doing the quiz review immediately before the quiz, but that didn't help. I eventually moved to telling my students exactly what was going to be on the quiz, but surprisingly even that didn't help. When students don't understand a lesson or do well academically, teachers are supposed to take responsibility, but that's very difficult to do when most of the students are very apathetic.

---

dearieme (2014-04-15 06:39:09)

State education is a failed experiment.

Gina (2014-04-15 11:48:32)

I have a friend who just quit teaching due to student apathy. It's sad, because at one time she was so excited about teaching. She said she was out of ideas for how to make her students care. She was teaching at a small rural school where half the students ended up dropping out.

Banh Li (2014-04-15 13:15:37)

dearieme: Data from some countries (e.g. Finland and Poland) do not support your claim.

AI (2014-04-15 17:58:53)

A lot of people in low income areas have higher priorities than studying economics. Many of these young people live in a dangerous, overcrowded environment. And their parents and peer groups can't or simply don't place a high emphasis on academic learning. Given that reality, what kind of results can we reasonably expect teachers, schools or even government to deliver? (Even in solidly middle class schools, many students are apathetic when confronted with academic economics.) The older I get, the more difficulty I have in believing that we can just slap an "education system" on top of a free, loosely regulated, highly individualistic collection of people (i.e. America) and expect high quality results. For most of us, learning a complex academic subject requires patience, focus, time, and work. In our system, a lot of that is solely under personal control. Sure, a government program in a free society can help with some of these things. But we don't live in a totalitarian, Soviet-style system where we can force kids to spend ten hours a day reading a physics textbook and working out homework problems. We live in a free society. The school police are not allowed to come to my house and force me to read about the law of cosines. I have no doubt that we Americans - across the board - could excel at quantum mechanics, organic chemistry, and writing just-in-time compilers if we wanted to spend ten hours a day doing those things. But that's not what we're in to.

Brock in HK (2014-04-15 18:47:29)

I think the dismal passing rate is a sign that the material was too sophisticated for the students level of ability, rather than their lack of desire to study. Strong evidence is that the review immediately prior to the quiz did not have an impact on their scores relative to other times of quiz prep. There is a body of research, especially as relates to Khan Academy, that indicates where people are learning most efficiently, and that is not the point where they are getting many to most of the answers wrong. Totally separate is how that came to be that the material was too sophisticated for this specific group of students.

WW (2014-04-15 21:00:01)

Dearieme, why is this an example of failed state education? it seems to be apathetic students being the cause. why would non state education fix that?

dearieme (2014-04-16 04:17:10)

"Data from some countries (e.g. Finland and Poland) do not support your claim." Then it's not a failed experiment in those countries. They'll do very well to keep it that way. "why would non state education fix that?" Because doing away with a monopoly run on rigid doctrinal lines has every chance of leading to the sort of experimentation that will lead to improvements. In other words, much the usual reason for trying to abolish monopolies.

Dragan (2014-04-16 18:35:29)

Thanks for the review, Mo. I have a question. "I can't recall using any other teaching techniques that I was exposed to during graduate school." Since you're not using any techniques from your graduate school training – yet you are teaching – how/where did you pick up your teaching "know how"? Is it modeled on what you observed your own teachers do, or...?

Terri (2014-04-20 14:11:58)

Thinking aloud: WHY are students apathetic? Why? How do we draw those kids in? How do we get them to learn the basics needed to just be motivated, dedicated citizens? Is there anything you see which helps? Smaller classes? More structured class? Less structured class? Presenting it as it will appear to them in real life? Anything? Loved the mention of the act now, ask forgiveness later. Not really great thought, but seems very applied and sometimes necessarily so. And I had not heard of the "please" one, but I will store that away for sure. Good post.

## **Korean Bakery Opens in Berkeley (2014-04-15 05:00)**

After I wrote [1]my recent post about Korean innovation, I noticed an example in downtown Berkeley. A few months ago, the Korean bakery Paris Baguette opened a branch in a good location (next to a BART station) that has seen two businesses – two different cafe chains – fail in the last 5 or 6 years. It seemed to be doing well. There were more customers than I'd ever seen with the previous business (Tully's Coffee). [2]Paris Baguette has about 20 American branches.

Jane Jacobs once called Berkeley a "pretentious suburb" but it is where Peet's – the original of Starbucks – began and where Chez Panisse is. It had a farmer's market and an emphasis on organic food long before the rest of America. ([3]A new survey suggests the health benefit of organic food is small or zero.) If you could call a location an "early adopter" Berkeley would qualify, but that would be understating it. Via the Free Speech Movement and the whole notion of student protest, little Berkeley shaped an entire decade (the Sixties). But it seems to have been a long time, like half a century, since anything important started here. The Bay Area, however, remains enormously innovative (Google, Twitter, Intel, and so on).

---

Cathy (2014-04-15 06:25:59)

Not surprised Tully's coffee failed, that is awful tasting coffee! I'm sure there are other better places to get a good cup of coffee in Berkeley. Also, it is possible that the Korean bakery will have decent coffee. I find it strange that it is a French bakery. I have been seeing a few articles recently where the French connection is made to cuisine in Vietnam, especially Hanoi which makes sense since it was a colony of France. Let us know what you think of the place, it sounds intriguing!

dearieme (2014-04-15 06:40:23)

I remember strolling about the Berkeley campus in the summer of '66. It smelt funny.

George (2014-04-15 07:39:30)

It's funny you list twitter and google as paradigm examples of innovation - they're my go-to examples of what I consider the utterly trivial nature of what people call "innovation" these days. Korean bakeries aren't nearly as good as Vietnamese sandwich shops (Banh Mi). I'm sure you know about them, everyone does - some are lame, but the good ones are awesome! What I like about the Korean (and other Asian) coffee shops is that they somehow provide a really tranquil and soothing atmosphere. I'm not even sure what it is, but they've figured that out. Maybe it's the clientele - Starbucks in America are filled with yuppie strivers focusing away with incredible intensity on their computer screens - grim faces, serious looks, they just ooze tension, effort, and striving. No one smiles. No one looks up. The original European idea of the coffee house as a relaxed social space where you go to share an idle hour (or three) chatting with friends, or read some light book, has been perverted in typical American fashion into workaholic spaces where grim people gather to energize themselves with shots of strong coffee while they conquer the world. It's quite hideous. The lack of relaxation and ease is palpable. Asia, I believe, has managed to preserve the European concept of the coffee shop much better.

Andrew (2014-04-15 07:43:23)

I can't believe I bothered to read all of George's comment. :-/

Sam (2014-04-15 11:22:59)

What I like about the Korean (and other Asian) coffee shops is that they somehow provide a really tranquil and soothing atmosphere.

I've noticed this as well. I think part of it is the interior decor. The Korean shops tend to be warmly and brightly lit inside. Starbucks tends to be dark with moody lighting inside. Also the focus in Korean shops seems to be on the snacks, deserts, cakes, etc. rather than on coffee. With Starbucks and other American coffee shops, the focus is mostly on coffee. People going to eat pastries and snacks will be in a lighter mood than people going for coffee.

kxmoore (2014-04-15 19:40:24)

If you have ever had a baguette in Paris or for that matter one from a real French bakery anywhere in the world "Paris Baguette" will disappoint.

Seth Roberts (2014-04-15 21:47:26)

What's interesting about Paris Baguette is the innovation. Not the quality of the baguettes. The innovation is not disappointing.

dearieme (2014-04-16 04:13:48)

"yuppie strivers focusing away with incredible intensity on their computer screens – grim faces, serious looks, they just ooze tension, effort, and striving. No one smiles. No one looks up." And yet much of what they do is doubtless worthless piffle. It's a funny old world.

George (2014-04-16 06:57:39)

Oh, it's undoubtedly worth piffle dearieme. The things they waste their youth on and take so seriously are indescribably trivial. But in a world that glorifies "work", to be busy is to be cool. Every civilization before us glorified the life of leisure and idleness and contemplation. Perhaps you worked so you could achieve leisure, but work itself wasn't cool. I pity these kids.

Andrew (2014-04-16 07:04:28)

Yawn. Congrats on knowing exactly what your millions of imagined whippersnappers are up to. Could you sneer a bit more efficiently, please?

kxmoore (2014-04-16 10:12:43)

"What's interesting about Paris Baguette is the innovation" I didn't see innovation at Paris Baguette. Just a bad imitation of a French cafe. But then again, McDonald's is a bad imitation of a burger joint.

Sam (2014-04-16 11:05:23)

I didn't see innovation at Paris Baguette. Just a bad imitation of a French cafe. But then again, McDonald's is a bad imitation of a burger joint.

I suppose the innovation would be the different tastes and the different items they have. If the tastes don't appeal to you, then I suppose it would just seem like a bad imitation rather than innovation. Personally, I like both real baguettes and Western baked goods, as well as the kinds at Paris Baguette and other Korean bakeries. The latter tastes different and good to me. One thing I like in particular is how the deserts are much less sweet and less richer than French deserts. Though the ordinary breads tend to be sweeter than ordinary French breads. Incidentally, McDonald's is much closer to a traditional burger joint than the newer burger joints popping up these days. McDonald's started as an old school burger joint, and its burgers are still closer to the traditional burgers than the newer, monstrous gourmet burgers that are popping up these days.

Seth Roberts (2014-04-16 14:35:42)

"Just a bad imitation of a French cafe." You underestimate what was necessary to win the Cafe Wars in Seoul.

In case anyone is interested, here's the NHS's webpage on NSAIDs. <http://www.nhs.uk/conditions/Anti-inflammatories-non-steroidal/Pages/Introduction.aspx>

dearieme (2014-04-16 05:57:07)

When I was a fresher our University Principal held a Nobel Prize in Physics. Nowadays almost every university boss I read about seems to be a creep, a twerp, or a crook, of little or no academic distinction. It's been less than two generations, for heaven's sake.

Joe (2014-04-16 09:34:19)

Dearieme, universities were also once bastions of free speech and non-conformity (e.g., compare Berkeley circa 1966 with Berkeley circa 2014). Not anymore. Orwellian newspeak, doublethink, thoughtcrime and PC propaganda rule the roost today. Even historically Catholic universities have been infected with this horrible virus. And it's not by accident. That "long march through the institutions" is proceeding exactly as planned.

Dragan (2014-04-16 18:53:01)

Fairly grim stuff about Brandeis. Probably the biggest disappointment of my professional life was realizing that Universities are not very much like what I imagined them to be.

Gina (2014-04-16 19:16:29)

Interesting story about the Hadza gut biome. From what I can tell, we know almost nothing, since, on paper, their gut biomes seem awful despite their good health.

Terri (2014-04-20 14:19:39)

What interested me was perhaps their overall health despite quite a bit of honey and tubers. Their diet didn't seem all that diverse as stated in the articles I have read. I kind of mull that over in my mind as I think about how it is recommended to us to eat a diverse diet. Is diversity overrated? But then without diversity how do they/we acquire select nutrients.

Terri (2014-04-20 14:20:38)

My comment was regarding the Hadza article.

best (2014-05-10 07:14:05)

{ i'am finally find good url shortener this is best link shrinker with lot of awesome features. give it a try.

## High-Frequency Trading and Health Care (2014-04-17 05:00)

High-frequency trading is a misnomer. It's actually short-latency trading, a name that makes clearer why it is so unsavory. As Michael Lewis explains in *Flash Boys*, short-latency traders use a buy order on one exchange to quickly buy that stock on other exchanges before the original buy order reaches the other exchanges. Lewis writes:

The deep problem with the system was a kind of moral inertia. So long as it served the narrow self-interests of everyone inside it, no one on the inside would ever seek to change it, no matter how sinister or corrupt it became – though even to use words like "corrupt" and "sinister" made serious people uncomfortable.

I thought of health care. Our health care system – centered on treating symptoms with drugs you take for the rest of your life – serves the narrow self-interests of those inside it, such as doctors and medical school professors. That is surely one reason its predatory aspect is rarely mentioned.

But I also noticed how poorly Lewis, an excellent writer, describes the problem. "Moral inertia"? No, the problem is not that Person X or Person Y is slow to get outraged. "Corrupt"? No, no one is being paid off to look the other way or vote a certain way or introduce a certain bill. "Sinister"? It's unclear what that means. Is Lewis just using a fancy synonym for "bad"?

Elsewhere Lewis uses the word *predatory*, which seems accurate. Short-latency traders preyed on those who sold stock, taking advantage of their ignorance. Of course, no one is forced to buy or sell stock and the loss on one trade is small. But everyone gets sick.

---

Andrew (2014-04-17 06:07:01)

I think Lewis was almost forced to use inaccurate language. To call these pricks what they are would, over the length of a book, become wearily coarse and shrill.

MC (2014-04-17 06:51:27)

It's difficult for outsiders to follow, but Lewis' book is essentially a fiction. What's really happening is that one rich group of guys is furious at another rich group of guys that are eating their gourmet lunch. How does that affect you and me and grandma? Not at all.

AI (2014-04-17 07:42:57)

Almost everyone with a little money saved is more or less forced to participate in the market, through vehicles like the California Public Employee Retirement fund, their 401K or their IRA. These vehicles are pretty much designed by law to be invested

exclusively in stocks and bonds. A few people with truly self-directed IRAs do have a chance to invest retirement money in other vehicles (e.g. real estate, small private businesses, etc). But these are neither widespread nor easily available to employees at most organizations. And, with interest rates so low and food, fuel, and education prices rising at faster than "inflation" these days, it's very hard to justify parking your cash in a money market account over the long term. Don't forget that Wall Street sometimes tries to force you to put more of your cash into their market. (Remember George W. Bush's attempt to privatize social security?)

Glen Raphael (2014-04-17 07:58:48)

Maybe Lewis does a poor job describing the problem because he doesn't understand it and it's not clear what's wrong with it. HFT involves a great many strategies - not just that one - and it's not at all clear there's anything "predatory" about that one. There is no universal human right to have orders filled across every market simultaneously at the same price. If you don't want to be "preyed on", there's a simple solution: don't place orders that large. Trades that are so large they can't be fulfilled on one market are big enough to move the market. When the market moves, entities that trade across many exchanges need to either quickly adjust the prices they offer or lose a lot of money. This "predation" makes markets more efficient price-finders as it enhances a small preexisting diseconomy of scale. Yes, HFT can make it slightly more expensive to make truly massive moves in the stock market than it might otherwise be. But that's only a \*bad\* thing if you think there's some moral reason why huge trades over many markets should be exactly as cheap to carry out as tiny trades on one market.

Seth Roberts (2014-04-17 09:27:34)

"It's not clear what's wrong with it"? It's clear what's wrong with it to the persons who want to buy or sell - they pay more. You mean it's not clear what's wrong with it to you? That's what you seem to be saying but maybe I am misunderstanding. A larger reason that HFT is bad is that it makes the stock market less attractive. HFT contributes nothing to the economy and to the extent it makes the stock market less attractive it is destructive.

Joe (2014-04-17 14:09:11)

Al: "Don't forget that Wall Street sometimes tries to force you to put more of your cash into their market. (Remember George W. Bush's attempt to privatize social security?)" I'm no fan of Dubyah, but his plan was VOLUNTARY. No force at all. And for the sake of my grandchildren, etc., I wish he had succeeded. Wall Street can't force anyone to do anything, but the government can, and does. Given the FREEDOM of putting my money under the care of the government, or investing it in the market (thus being able to leave those assets to my children, etc.), I'm going with the market. Every. Single. Time.

Andrew (2014-04-17 14:47:01)

Unfortunately they tried to sell social security privatization at the exact moment it became clear that Wall Street was behind the trillion dollar mortgage fraud that cost so many their homes. Oopsie.

Joe (2014-04-17 15:18:20)

Andrew, Wall Street wasn't behind it, but they weren't blameless either. They allowed the government to shove them around, by threatening them with more regulation, disallowing mergers, expansion, etc., if they didn't loosen credit standards. You've heard of the Community Reinvestment Act, right? That's when it started, and it only got worse over time, with Freddie and Fannie gobbling up anything the banks could throw at them. The heavy hand of government caused the meltdown, and that's a fact. Note: There's another meltdown yet to come, which the US taxpayer will also have to bailout: Student loans. About a trillion dollars worth. Just about anything the government touches turns to c & \$p. And just wait until you see what it does to health care!

Andrew (2014-04-17 22:19:40)

Very simple world you got there, Joe. Looks a bit cramped.

stocksandstartups (2014-04-17 23:40:54)

Seth said: " It's not clear what's wrong with it'? It's clear what's wrong with it to the persons who want to buy or sell — they

pay more. " "They pay more" - Maybe, maybe not, this is far from clear, especially for the proverbial "little guy" (e.g. anyone who doesn't trade multi-million dollar blocks of stock). And even if people are paying more, it's tiny. HFT traders are looking for pennies per share on a trade. If a penny or two per share is going to have any effect on your retirement, then you're also worrying about what color to paint your Gulfstream Jet because you are super-rich. For the rest of us, this makes no difference. Still mad about a penny difference? Remember, until 2001 stocks traded by the sixteenths, so you couldn't even change your buy/sell price by 1 cent, you had to do it by 1/16th of a dollar (6.25 cents)! Not to mention all this investment in bringing technology to the stock market is why you can sit at home and get real-time price quotes in your pajamas, and why you can get \$8 stock trades. Just because someone else is getting rich doesn't mean you're getting ripped off.

Joe (2014-04-18 06:44:02)

Simple, Andrew? Blaming everything on Wall Street is simple. But how could you leave out the part the government played? Surely you weren't unaware of it, right? Did you follow the Cliven Bundy situation in Nevada? If so, you got to see the heavy hand of government in action. Should a desert tortoise be able to effectively put a rancher out of business? A rancher who has been peacefully ranching those lands since 1874? Was it really necessary to have armed federal agents, along with K-9s and armored vehicles, remove Bundy's herd? Couldn't the government have simply filed a lien on his ranch? Yes, legally, Bundy was in the wrong. But the government breaks the law every single day. They also simply ignore many laws they don't like. Only the government can get away with c & \$p like that. I think that's wrong. YMMV.

dearieme (2014-04-18 07:01:22)

"legally, Bundy was in the wrong": jeeze, that was a lot of words to camouflage a simple point. The answer to your complaints about The Government is, of course, to have them sell off most federal land. Alas, they would handle it so that Harvard advice would result in most of it ending up in the hands of oligarchs. Just as Harvard advice managed to bring that about in Russia. Comparing the USA to Russia: can that be valid? Probably not; Russia is run with greater intellectual rigour.

Seth Roberts (2014-04-18 07:39:34)

Another thing that's wrong with HFT to people who buy and sell is that the prices they see on their computer screen at the moment they do a trade are not the prices they end up paying.

Joe (2014-04-18 07:46:56)

Dearieme, I wasn't trying to camouflage anything. That should have been obvious, no? And no "point" is simple around here, apparently. Selling off federal land is, of course, one solution, especially when considering our 17+ trillion debt (and growing by the day). But it won't happen. It makes too much sense. The real question is: How did they end up owning all that land to begin with, and why do they still own it? Our Constitution actually prohibits it. But our Congress enjoys ignoring the Constitution. And so they refuse to divest it. Ah, the wonders of government. Also, how much "intellectual rigor" must the Russians have if they were stupid enough to take advice from Harvard "economists"? How do they think WE ran up our 17+ trillion debt? Russia is essentially a banana republic that happens to have a lot of oil. Let's see how that works out for them in the long run.

stocksandstartups (2014-04-18 11:24:49)

Seth said: "Another thing that's wrong with HFT to people who buy and sell is that the prices they see on their computer screen at the moment they do a trade are not the prices they end up paying." This is exactly how it is for any individual (you or me, e.g. non-professionals) who buys or sells stock. If I'm placing an order to buy a stock, just because the screen says the "ask" (what someone is trying to sell their shares at) is at \$50.27, doesn't mean I'll be able to buy at that price, and this makes complete sense. By the time my computer screen loads the price information, and I enter my sell order and click "Submit", the market may have moved. The \$50.27 ask may have already been filled (someone else bought it), and the next cheapest ask is now \$50.35. So now I have to up my bid. This is far from 'bad' (or 'good' for that matter), it's just how markets work. And this just as often can work in your favor with the price dropping as you enter you bid, and thus you get a cheaper price than you were expecting. Thus if HFT traders were guaranteed the price they saw on their screen they would have a significant advantage over non-professionals/individuals. So I'm confused by the point you're making here. The only explanation I can think of is you've never bought or sold stock, or if you have, you were hands-off about it and didn't pay attention to the price movements

as you were placing your order. Seth: HFT caused prices to move away from sellers and buyers. For example, if you are buying, the price goes up. This is different than random fluctuation.

dearieme (2014-04-18 12:44:15)

"How did they end up owning all that land to begin with": well, in Nevada they stole it from Mexico, fair and square.

dearieme (2014-04-18 12:46:20)

The Russian government improved its intellectual rigour by expelling Harvard economists, and having a drunken president retire. You may be able to think of equivalents that the US federal government would benefit from.

Joe (2014-04-18 14:16:59)

I prefer to think of it as stealing it back from the Europeans, dearieme. Stealing land is something you Brits are familiar with, no? I think we should do with Harvard economists what the Mormons do. Send them out into the world on missions, for not just two years, but for the rest of their lives. Let them help other countries run up mountains of debt, devalue their currencies, and generally screw up their economies, like they did to ours. They won't go voluntarily, or pay their own way, like Mormon missionaries do. But a guy can dream, can't he?

Noah Motion (2014-04-19 08:11:07)

*High-frequency trading is a misnomer. It's actually short-latency trading, a name that makes clearer why it is so unsavory.* The fact that the trades are short-latency means that they can be, and are, if I'm not mistaken, made with high frequency. And it's unclear to me how 'short-latency' is any more or less unsavory than 'high-frequency.' Seth: The term short-latency makes clearer the problem (from the point of view of ordinary traders): use of very short latency to front-run. Frequency has nothing to do with it. The trades could be high frequency without the extremely short latency. It is the extremely short latency that matters.

how to do a liquid diet (2014-04-27 23:04:22)

However, in most of the time, these two age groups largely depend on vitamins supplements. For example, there is evidence that patients with Crohn's disease, which causes inflammation in the gastrointestinal tract, can benefit from a high-calorie liquid diet. Dependent upon what the options are, you can combine fruits and vegetables. my blog post: [1]how to do a liquid diet

1. [http://kelleyxomyvqwruw.beeplog.com/658289\\_3974659.htm](http://kelleyxomyvqwruw.beeplog.com/658289_3974659.htm)

liquid diet weight loss recipes (2014-04-28 04:44:49)

These days there's a great number of speak about liquid protein diets. Thus, responsible use of the substance must be observed. The liver produces proteins that help maintain the volume of the blood and the clotting factor. Also visit my site: [1]liquid diet weight loss recipes

1. <http://darrelgzcd.wordpress.com/2014/04/21/while-many-of-the-other-shake-liquid-diet-plans-come-in-vanilla-chocolate-or-strawberry-the-hollywood-diet-is-a-fruit-shake/>

myaree led lighting (2014-05-01 16:16:23)

Today, I went to the beachfront with my kids. I found a sea shell and gave it to my 4 year old daughter and said "You can hear the ocean if you put this to your ear." She placed the shell to her ear and screamed. There was a hermit crab inside and it pinched her ear. She never wants to go back! LoL I know this is entirely off topic but I had to tell someone!

Lindsey (2014-05-03 00:35:13)

The travel - A maker is normally lightweight and portable so it can easily be taken along on your travels, so there is no need to get fussing over big espresso machines. Coffee lovers usually buy grounded coffee beans within the market. For most single-serving coffee machines you can use warm water only or domestic hot water and mild dishsoap to completely clean the exterior.

## Universities: Expectation versus Reality (2014-04-18 05:00)

A recent Ph.D. from Berkeley named Dragan [1]commented here:

Probably the biggest disappointment of my professional life was realizing that Universities are not very much like what I imagined them to be.

I asked him to elaborate. He replied:

My peers dreamed of being in the sports or movies, of being lawyers, of being rich. Those dreams didn't seem so great to me. Instead I fantasized about being a scholar and later in life climbed up the educational ladder towards a PhD at a leading research university. The closer I came to becoming a professor – my professional goal in life – the more disappointed I became.

I am somewhat embarrassed to remember this, but I used to say things like: "Universities are places where people can devote themselves to a life of study, investigation, and imagination. In exchange for a home like this, we provide society with ideas. And, of course, we teach." I guess I thought that there should be a home for people who are capable and devoted to intellectual pursuits, a rather naive notion it seems.

I wanted a place where I would be judged primarily by my intellectual and creative ability. Instead I have been made keenly aware of the importance of networking, of doing favors for the right people, of who to cite, whose criticism to acknowledge and whose to ignore. I used to despise such things, now they're second nature. The irony, that I now know far more about popularity than I did back in high school. One of the first things I learned is that it is imperative to do research that brings money and/or prestige. In other words: popular research. I didn't know such a thing existed.

What if I don't want to do popular research? The most common advice I received during my graduate studies: "Wait till you're tenured to do that," always said with good intentions.

Only one person told me: "Do what you believe in. Tenure and accolades will come in time." I liked this advice more. But the professor who gave it was fully tenured before I was born. Perhaps things were different in his time? I suspect they were. Last year, two retired professors, each from a major research university, assured me that they would never get tenure in this day and age. They took years with their research and published few yet original papers. "You have to wait until tenure nowadays," they said.

This is not what I thought I'd find. Nor did I expect to find that efficiency and money-making are priorities here. I love what I do, or at least what I want to do. If I could afford to, I'd do it for free. I mean that as an academic, money seems relatively unimportant. Yet universities seem to be run by people who aren't academics and whose primary interest is making money, rather than fostering research. It occurs to me that these two aims may be in conflict.

Don't get me wrong: I am not saying that academia is altogether bad. I can honestly say it beats unemployment and the handful of low-wage jobs I had as a teenager. And there are days when all the things I just wrote about seem less important and I focus on my research or my teaching. But other times I think, silly me. If only I was smart enough to get rich in the first place, I could have done anything I wanted to – like pursue research that actually interests me.

As a professor (with tenure) at Berkeley, I was fascinated by how mediocre I was. By the usual metrics, I was in the bottom quarter of the distribution. Yet I had made discoveries that I knew were important – for example, [2]a surprising way to lose weight, a *really* surprising way to improve mood. Although these discoveries impressed me, they [3]did not impress my colleagues.

dearieme (2014-04-18 06:52:41)

Allow a nit-pick; if you were bottom quartile then by definition you were not mediocre. Unless you were being described by a sports commentator, for whom "mediocre" = "average" = "ordinary" = pretty poor.

Joe (2014-04-18 07:12:40)

Glenn Reynolds, a law professor, has written a good book about the coming "purge" in academia. Up to 50 % of our universities will not survive it. Since most people do not belong in college (my opinion), and moreover, can't afford it these days (also my opinion), other ways to "get educated" and/or develop meaningful skills will be found. Yes, "creative destruction" is coming to academia, and soon. The Higher Education Bubble <http://www.amazon.com/Higher-Education-Bubble-Encounter-Broadside/dp/1594036659> I also think tenure is part of the problem, not the solution. It basically protects bad teachers (and some really bad teachers) and gives them a place to hide. And, as usual, government involvement has only made the situation worse. Yep, that's my opinion, and I'm sticking to it.

dearieme (2014-04-18 07:25:35)

"Glenn Reynolds ... has written a good book about the coming "purge" in academia": a book? It doesn't need a book. For years I've just said "Dissolution of the Monasteries", which seems to me to sum up the position reasonably well.

dearieme (2014-04-18 07:27:11)

P.S. I'm hoping my pension will survive: even the monster Henry VIII pensioned off nearly all the monks, rather than leaving them to starve.

Joe (2014-04-18 08:06:42)

"For years I've just said 'Dissolution of the Monasteries,' which seems to me to sum up the position reasonably well." Maybe you should have written a book?

Alex (2014-04-18 08:22:00)

What are the usual metrics for a professor? Do they emphasize teaching or research? Seth: At Berkeley, research. Number of papers in good journals and top journals, such as Science and Nature, is very important.

Andrew (2014-04-18 12:07:21)

Has anyone ever applied "moneyball"-type statistical analysis to tenure-likelihood and grant-getting success? Ie, what are the "sleeper" journals, buzzwords, co-authors, etc.? It seems like much of the data that would be needed is publicly available. Whatever the results, the ensuing publicity from publishing that research would itself make someone's career. :-)

Alex (2014-04-18 12:47:22)

Did that align with your own goals for yourself? Seth: No. I wanted salary increases.

jason y (2014-04-18 16:54:21)

Joe, you illustrate the problem. If someone writes a book he's an authority. If someone condenses the essence of a book's argument into a couple sentences he's just another guy with an opinion. The demand for impressive windiness is one of the reasons academics remain powerful. I keep reading that college is becoming a bad investment for the bottom x percent, but the culture is such that I think many people would take a long-term income penalty in order to prove they aren't uneducated. We have a long way to go before this "bubble" pops, or before this system fundamentally changes, esp. with the coming increase in ZMP workers.

Alex (2014-04-18 17:48:09)

It's not that college is becoming a bad investment for the bottom x percent; it's that some majors are not good investments, and are becoming financially suicidal as the price tag rises. A degree in engineering or computer science is an excellent investment. But a degree in English, history or anthropology? Fine if you have a trust fund, but if you're going to college and expecting to support yourself after, you'd be better off using that time and money to start a business. At least that debt can be discharged through bankruptcy.

Joe (2014-04-18 18:15:04)

Jason, college is becoming a bad investment for much of the top x percent, too. The quarter of a million dollars (and up) it takes to get a decent degree (at a decent school) these days could be invested (say, by someone's parents), and over time that should more than offset any "long-term income penalty." [The "investor" should have somewhere between 2.5 and 3.0 million dollars after, say, 35 years, with even a modest rate of return.] And possibly even allow the "student" to do something he or she actually wants to do, like create a business, write a killer program, learn a rare skill, invent something, etc. And the culture will change once parents and students realize that, for the vast majority, paying \$250,000+ for an education is a bad investment. And the coming increase in ZMP workers only makes the need for change more urgent. Academia got greedy. And in the immortal words of Rev. Jeremiah Wright, "the chickens are coming home to roost." Maybe not this year, or next, but soon...says just another guy with an opinion.

jason y (2014-04-18 18:34:31)

Pardon me, I was thinking in terms of the distribution of IQ, or something very much like IQ. Your distinction is the right one. That said, baristas would rather live a life of debt peonage than admit they can't hack it in university. Like I said, there's nothing worse these days than being anything less than smart, and as long as you need a college diploma to be above suspicion young people will remain only too willing to commit financial suicide.

jason y (2014-04-18 18:45:11)

Joe, I don't disagree with you. We only disagree on how much I think people are willing to spend or give up to have a piece of paper that proves they aren't ignorant. Intellectual insecurity is rampant. I am utterly bemused by its ubiquity. Until everyone stops worrying how smart other people think they are, especially members of the credentialed class, universities will continue to jack up the price of token diplomas and kids will continue consigning themselves to the poorhouse to protect their egos.

dearieme (2014-04-19 02:14:58)

The cheap answer would be to run standard IQ tests for all eighteen year-olds and give them a lapel badge to wear with their score on it. Bingo: no need for silly credentials.

dearieme (2014-04-19 02:15:54)

In fact, not even the exact score: probably displaying the decile would do the trick.

CC (2014-04-19 06:29:27)

Seth, that last link was interesting to me. I liked this: <> You point out that you never advocated eating bad-tasting food. But even if you had, is expecting people to stick to this any crazier than expecting people to permanently cut calories every day for the rest of their lives?? The normal diet advice figuratively pits people against their own brains and tells them to keep up the fight for (say) 60 years. Oh yeah, and the success rate is near 0 %. I often tell people who think that we've already "cured" obesity (just have a little self-discipline, stop shoveling food down your throat) that I've invented a cure for heroin addiction: Stop using heroin! Yet any doctor who proposed this would (correctly) be laughed at.

CC (2014-04-19 06:30:04)

Sorry, that last comment was supposed to have this excerpt inside the angle bracket: The committee went on to criticize my weight-control ideas: "Eating bad-tasting food may lead to sustained weight loss, but only in those who have the self-discipline to adhere to such a regimen." My conclusions were not likely to generalize, in other words, because hardly anyone will have enough self-discipline.

Seth Roberts (2014-04-19 14:14:32)

Drinking sugar water was not "eating bad tasting food". To claim I discovered that "eating bad tasting food" causes weight loss was highly inaccurate.

CC (2014-04-20 04:43:52)

"Drinking sugar water was not "eating bad tasting food". To claim I discovered that "eating bad tasting food" causes weight loss was highly inaccurate." Right, I was agreeing with you.

Terri (2014-04-20 14:28:09)

This is true in medical academics as well. Very, very, very frustrating. Angering. Sad. Detrimental.

Jack (2014-04-21 11:41:06)

Seth, Dr. Seth Roberts, you are a Genius, an individual, an adventurer and a trailblazer. Your unique insights and personal investigations have helped so many people, most of them who are not even known to you. Please continue to be YOU! And "don't let the turkeys bring you down"! Thanks for sharing your great work and personality with us all.

Dragan (2014-04-22 18:00:26)

A bit overwrought, but complaining feels good sometimes. Coincidentally, the 2012 article Seth linked in his commentary ("did not impress my colleagues") is very useful in defending oneself from accusations of "introspection." Can't praise it enough for that.

Serwis GSM (2014-04-28 06:22:15)

Seth Roberts | The Story's Story (2014-04-29 12:30:12)

[...] Seth Roberts died (H/T Tyler Cowen), though unlike Cowen I didn't know him. But in 2013 he did link to The Story's Story and I consider that a small but significant achievement. He too was interested in cities and how cities function; he knew so much but was open to talking to strangers: his contact page still says, "Ask Me Anything/Contact Me," which is often a sign of an active, open mind. Of his recent posts this is my favorite. [...]

## Lyme Disease and Bad Medicine (2014-04-19 05:44)

I got *Cure Unknown: Inside the Lyme Epidemic* (2008) by Pamela Weintraub from the library and found something surprising: an angry foreword. Weintraub is a science journalist; the foreword is by Hillary Johnson, another science journalist and apparently a friend of Weintraub's.

In her anger, Johnson says several things I say on this blog.

The more Weintraub investigated, the more virtually everyone with a shred of authority was losing their credibility. . . . The so-called "objective" scientists were sending an entire disease down the river and over the cliff [meaning they ignored it] for reasons that seemed frequently to have more to do with mere opinion and crass external forces — cash, prestige, careerism — than with scientific erudition.

She rejected the science writer's inbred habit of relying on the government official with the highest pay grade or the scientist with a job at Harvard as the final word on a topic. . . . I think of her, with enormous respect, as a "recovered" science journalist.

As one who also suffers from the disease I chronicled with kindred passion in *Osler's Web*, I sometimes wonder if the only investigative writers who will possess the necessary temerity to remove the white gloves and tackle those putative experts to the ground will be those . . . whose personal experience demands they follow the rocky trail that leads to the truth.

The last point is the most important, I think. You can curse the careerism of Harvard medical school professors and the servility of science writers but that does nothing, or not much, and what you are upset about (careerism and servility) is unsurprising. Less obvious, at least to me, is that there is a way to overcome the careerism and servility. It *still* surprises me that I was able to figure out [1]interesting stuff about sleep, obesity, depression and so on that the experts in these fields hadn't figured out — and that sometimes contradicted what they said. (For example, I found sugar *isn't* fattening.) As Johnson says, one reason I was able to learn so much was that I wanted to sleep better, lose weight, be in a better mood, and so on. Unlike the experts in those fields, for whom research was a job.

1. <http://escholarship.org/uc/item/2xc2h866/>

---

Alex (2014-04-19 07:19:28)

Foreword Seth: Thanks, I fixed it.

dearieme (2014-04-19 12:08:11)

"I wanted to sleep better, lose weight, be in a better mood, and so on. Unlike the experts in those fields, for whom research was a job." Approval of what is approved of is as false as a well kept vow.

Garcinia Cambogia Extract (2014-04-29 14:23:35)

Hi there friends, its impressive post regarding educationand fully explained, keep it up all the time. Here is my weblog;

## Teaching Children: Adjustment to Individual Differences (2014-04-20 09:29)

After [1]I blogged about my belief that a good teacher tries to bring out what is inside their students (not just transfer brain contents), a reader named Terri Fites [2]commented:

We homeschool, and I see lots of what you said in my kids.

I asked her to elaborate. She replied:

Here is where I learned the most starting on day one of kindergarten with my first child five years ago; it is my job to identify strengths, weaknesses, and to help the learner achieve the goal using what they can. For example, I was embarrassed and appalled that my first child didn't read or show any interest in reading to herself until about second grade (7 years old). However, I continued to provide the necessary environment—reading wonderful books aloud, having her read a sentence from our selections, occasionally forcing her to read from her own readers. She had a great verbal understanding and would listen to anything I read aloud to her. Eventually, slowly, she transitioned and has NO issues with reading now. Her strength is verbal understanding and listening comprehension. Her weakness is focus on her own activities and sitting still.

My second child came along and was strong in different ways that I had to discover and appreciate. Her verbal skills, although perfectly normal, are not her strength, but music rises out of her at every moment. Clearly we have to do more than music. Using this strength, I make sure to provide plenty of musical CDs in Spanish for Spanish (which she struggles with—we have had tutors come for years with the intent the girls become fluent). We memorize and recite poetry routinely as part of our lessons, and she "sets" hers to song/music. When we do math facts (addition, subtraction, multiplication flash cards), she does best if she hears them in a sing-song voice. Her strengths are effort, music, rhythm, and art. Her weaknesses are verbal reasoning and remembering verbal types of things (not so prominent in math and geography skills so her spatial and math skills overcome this problem remembering things).

I would say, particularly in elementary school, that although the reading, writing, and arithmetic skills needed should not be optional—the timing of learning them and the method of learning them ought to be fluid to a degree. Everybody should learn to read but we're losing kids because they're not developmentally ready until second or third grade for some of these verbal/reading things. By then the bulk of the spelling and phonics rules have been expected to have been learned and the child is probably destined to be a poor speller, decoder, and poor at reading aloud. (This would be my husband. Obviously he was able to overcome this, but his spelling and read aloud are not pleasant. He says he remembers the year when words and reading just started coming together for him. Unfortunately, that was fifth grade. Did he need to learn to read and spell then in fifth grade!? I'd argue NO! But, in this case, recognition of a child/type of child is important. He is very, very logical, and the way that spelling/phonics is taught now/then is NOT so logical. A rule is given here. It is broken here. It is ignored here. No explanation is given. A kid learns long A as a \_e here or -ay there, but not all the other combinations that make the long

A sound- and certainly not all together in a lesson sequence!!!: ea, ae, ei, eigh, ai, etc. The logical child gives up. There are programs out there like Orton Gillingham, for example, designed to teach the "rules" of English in such a logical manner. Or I design my own curriculum. But this is not an option for most school teachers. Autonomy is being denied.) And now, multiplication is being moved forward in school grades, too. And analytical, thinking math is being moved forward. I think we'll lose students! Good students! "I'm no good at math." Geesh. Because you can't do story problems in second grade? Because you're still mastering the facts and you're being pushed into application too early?

1. <http://blog.sethroberts.net/2014/04/06/what-is-teaching/>

---

dauids (2014-04-20 11:10:41)

Couldn't agree more. I've long held a belief that we should do away with fixed time lengths for grades (as in, Third Grade is a nine month length of time). This doesn't make any sense, and we don't need a very advanced appreciation of different learning styles to understand this. Some kids learn math relatively faster than others, some develop reading comprehension faster, etc. We should split up reading, writing, math into separate classes. When a student displays mastery of a certain level of, say, math, that student moves on to the next level of math. It shouldn't matter whether that mastery is achieved at the same time as other students, or whether it takes one month or 18 months. Moving between levels should be fluid. Any given math class may contain older students who are learning math at a relatively slower pace, and younger students who are learning math at a relatively quicker pace. Additional benefit: outlier students learning any particular subjects at extremely slow rates can much more easily be identified and assisted, then would be the case when a block of students move from grade level to grade level every year, all together, in all subjects, at the same time. A system like this should theoretically work fairly well until high school, when students begin selecting their own courses and specializing with languages, arts, AP courses, etc.

Seth Roberts (2014-04-20 11:37:38)

I skipped fourth grade but it shouldn't have taken such a massive dislocation to make the work challenging for me. Likewise, I remember one student was held back a grade. That was awful. I still remember what a good artist he was. Much better to start with the idea that everybody has their own strengths and their own speed.

Terri (2014-04-20 14:43:14)

Reply of dauids sounds great! Why can't it be done this way? Seth's reply reminds me of how I don't allow my kids to use the word "smart." Makes me cringe. They can say...John knows his chemistry or Janie plays piano like a champ or Sally uses the biggest words I have ever heard. But not "smart." That artistic student described could draw anything and Seth could obviously spell well, read well, and get all his math work right--each child "smart" in their own right. Sadly, both probably felt so alienated by the handling of their strengths by the academic institution.

Allan Folz (2014-04-20 19:53:24)

*first child didn't read or show any interest in reading to herself until about second grade (7 years old) FWIW, that's the Finnish model. Waldorf too. Students of both systems seem to do OK for themselves. The standard American education model seems to have the idea that brains are empty buckets into which we pour knowledge at some pre-ordained and invariable, X. Ergo, if we want smarter people we must begin pouring knowledge sooner. Of course, the truth is smarter people are able to learn and remember at rates far greater than X, multiples in the case of geniuses. And dumber people retain at rates far below X. And then there is the difference in capacities. Finally, on top of those, as Terri's story illustrates, different people learn and remember things differently depending on how the material is presented and conveyed. It's all so messy when your goal is to use early 20th century mass production techniques to optimize throughput.*

Elizabeth (2014-04-21 06:28:12)

dauids: what you're describing is pretty much the Montessori method used by the elementary school my daughter attended in the Netherlands. Each child works independently, either individually or in small groups of two or three, on modules of math, reading, etc., which are identified by colors and flora/fauna rather than any visible hierarchy (1, 2, or A, B, etc.). The teacher checks your progress when you've finished the green fish module in math, for instance, and tells you to go on to the pink tulips. Each child progresses at their own pace, with as much help from the teacher as they need. First through third grade are all in the same room, working through the same modules. Of course this is very demanding of the teachers!

Dragan (2014-04-22 18:23:29)

I liked this story. One of my sisters could read before first grade, the other struggled for some time. They are both of them very smart, and very different, individuals. Not too long ago it occurred to me that the educational system in this country is a disaster. I went from being generally against home schooling in most circumstances to supportive of it in most circumstances. It's not the teachers, the vast majority want to be good teachers, but even great teachers in our system are only allowed to be good. Nor do I think that the upcoming for-profit reforms will improve things for most kids. So when I heard my nephew will be home schooled, I thought, great.

Joe (2014-04-21 08:10:13)

Sovaldi! Sounds like the name of an Italian-made violin, right? It's a very fitting name. Because, once again, the public is being played like a fiddle. An \$84,000 "treatment" for a "virus" that no one can even prove exists. And brought to us by the usual

suspects. This will probably invite scorn again, but, yes, IMO, HCV is another one of those phony viruses (HIV, HPV, FIV, etc.), brought to us by those intrepid "virus hunters" at the CDC. Sigh.

Gina (2014-04-21 09:20:20)

At least Solvadi actually cures something. When was the last time that happened? I was beginning to think that drug companies only focused on erectile dysfunction and depression. The ADHD link should be labeled "omega-3 helps children with ADHD... just not very much."

Al (2014-04-21 09:34:29)

Re the patent system for medicines, there is some discussion about alternative systems, for example, here: <http://www.cepr.net/index.php/Publications/Reports/financing-drug-research-what-are-the-issues>

Joe (2014-04-21 10:26:22)

The "cure" claimed by Sovaldi is: that 90 percent of the participants had undetectable levels of the virus after 12 weeks taking Sovaldi plus the older pill-and-injection cocktail. Not one word about extending even one life by even one day. Approximately 15,000 Americans are said to die each year from "HCV-related diseases." Watch that number remain at 15,000 for decades to come. Want an easy way to avoid dying from "HCV-related diseases"? Never take an HCV test.

Andrew (2014-04-21 14:45:06)

Joe, you are an absolute moron. The reason they are charging that much is because it actually cures the disease: <http://hopefulgeranium.blogspot.co.nz/2014/03/on-participating-in-phase-iii-trial-of.html>

Joe (2014-04-21 15:40:15)

Thanks for keeping it classy, Andy! I've come to expect no less from you. This story is about something called "viral load." Do you know what PCR is? That's how they measure viral load. It's the same process they use in HIV patients. But it does NOT measure the VIRUS itself: "The latest diagnostic disease indicator, 'viral load,' is an indirect measure divorced from any actual symptoms at all, which means that the efficacy of a drug is judged according to the observed change in a number deemed to be a 'surrogate marker,' and whether you're actually better, worse, or felt fine to begin with has got nothing to do with it. It's based on the 'Polymerase Chain Reaction' method of amplifying formerly undetectable amounts of molecular genetic material—in this case, fragments of RNA that are said to be from HIV—by copying them in enormous numbers. Forbes magazine called it biotechnology's version of the Xerox machine But errors are amplified too, by the same amount. The PCR process will indiscriminately copy dud HIVs that have been neutralized by antibodies, defectives that never formed properly in the first place, scraps of free-floating RNA, all of which end up being counted. And incredibly, these counts are presented as if they represented active viruses detected in the patient and not creations of the PCR process itself. The Australian mathematician Mark Craddock has shown the mathematical basis of the model to be fatally flawed and based on wrong assumptions about what the number of RNA fragments says about the number of free viruses." <http://www.duesberg.com/viewpoints/aids-heresy-hogan.html> Ditto for HCV. In other words, he ain't cured. It was interesting, however, to note that the author had apparently been cleaning up his life, his diet, taking supplements, etc., and was doing very well...way before he contemplated becoming a guinea pig for Big Pharma. It would also be interesting to know more about how he originally came to test positive for HCV antibodies. And about the lifestyle he lived. Was he an alcoholic? Abuse recreational drugs, etc? PS: The reason they are charging that much is simple: Because they can. Ever since the advent of HIV, they've known that they can always count on the ignorance of people like you. PPS: "HCV has some immunosuppressive effects that protect the liver, together with the virus, from the host immune response to some extent. You don't necessarily want to lift that protection without good reason." That statement may go down in history as perhaps the dumbest words ever spoken. Now HCV can even PROTECT the liver! Sounds like something you would say...Andy.

Dragan (2014-04-22 18:26:08)

Someone forwarded this article to me and I thought of this blog. Give your ideas some legs: The positive effect of walking on creative thinking doi: 10.1037/a0036577

George Henderson (2014-04-24 19:14:12)

Hi Joe and Andy, HCV infectivity depends on its presence in serum, because it rides on the VLDL → LDL-R cycle. This is why carbohydrate restriction is a worthwhile method to control HCV. And why PCRs are accurate predictors of clearance. My PCR count predictably dropped and rose according to the carbs in my diet. I don't doubt that Sofosbuvir + GS-5816, or any similar combo, will clear the virus and save lives IRL, which is not to say that other methods won't also save lives. I doubt that interferon-based therapies could ever have had the same effect. During treatment my ALT and AST went to normal and have stayed there. And my fibroscan score shows significant reversal of scarring. Pharma gets precious few things right, but this is one of them. Don't risk adding Sovaldi to some toxic old brew, wait for the all-new combos.

## **The Link Between Lead and Crime (2014-04-22 05:00)**

In the 1960s, a Caltech geochemist named Clair Patterson made the case that there had been worldwide contamination of living things by lead, due to the lead in gasoline. There were great increases in the amount of lead in fish and human skeletons, for example. More than anyone else he was responsible for [1]the elimination of lead in gasoline. (By coincidence, this was just shown on [2]the new Cosmos TV series.) A professor of pediatrics at the University of Pittsburgh named [3]Herbert Needleman did some of the most important toxicology, linking lead exposure (presumably from paint) and IQ in children. Children with more lead in their teeth had lower IQ scores. The importance of this finding is shown by the fact he was accused of scientific misconduct.

When lead was eliminated from gasoline, blood levels of lead went down – and so did crime. The idea that childhood lead exposure causes crime many years later explains so many otherwise-hard-to-explain facts, especially worldwide declines in crime rates, that I conclude it's true: lead exposure does cause criminality. Kevin Drum wrote [4]a long article about this in Mother Jones a year ago and followed up his original article [5]in many ways. [6]A BBC radio show yesterday covered the topic.

This interests me for two reasons. One is simple. It shows the value of [7]monitoring your own brain function by using something like the brain test I have often blogged about – e.g., to notice that [8]butter made me smarter or [9]mercury in my teeth fillings made me stupider. There's still lots of lead in the world – in old windowpanes, for example. And you are exposed to thousands of other modern chemicals (e.g., in cleaning products) whose effects on your brain are essentially unknown.

The other reason is complicated. It involves the context of this discovery. Mostly, the health research establishment has been unable to get anything right. Heart disease has been the #1 killer for decades; doctors still claim (and vast number of people, including New York Times health writers, believe them) that it is caused by cholesterol. Depression and bipolar disorder might be the single greatest cause of suffering nowadays – and psychiatrists are still claiming it is caused by "chemical imbalance" in the brain. (For my view of what causes depression, see [10]this.) Beyond figuring out that lung cancer is caused by smoking, there has been almost no progress understanding what causes cancer. The "oncogene theory" of cancer turned out to be a dead end. There have been little bits of progress here and there but on the big issues, there has been nonsense decade after decade – and lack of realization that it is nonsense.

In contrast, taking lead out of gasoline was a big step forward in public health and pointing out the link to crime a big step forward in understanding crime. Rare examples of progress. What can I learn from that? I have stressed [11]the importance of insider/outside – people close enough to understand but far enough away to have freedom. The lead/crime case supports that. Clair Patterson was a geochemist, not a toxicologist. Rick Nevin, the first person to argue that lead causes crime, was an economist, not a criminologist. Both of them had a good methodological understanding and used this to shed light on a different area than their original training. (Obviously I have used my background in experimental psychology, especially my methodological knowledge – how to experiment, how to measure brain function – to shed light on many health questions.) The lead/crime link also supports my view that the

notion that "correlation does not equal causation" does more harm than good. The immediate response of many many people to the lead/crime evidence was exactly that – putting them on what turned out to be the wrong side. Whatever truth correlation does not equal causation might have is outweighed by the damage it does when it is used to ignore evidence. How smart do you have to be to realize "correlation does not equal causation" is stupid? To me don't ignore evidence is the most important principle of science. But many university professors don't agree with me.

I'm also impressed – in a good way – by Drum's article. At least it exists. Anyone can read it and then look further, for example at [12]original scientific articles. I wouldn't say it was easy to write but it did not require expensive travel, extensive interviews, or months of research. It did require original thinking. In contrast, the New York Times and The New Yorker, which do allow expensive time-consuming journalism, haven't published anything nearly as good in decades. The New York Times's idea of high-quality journalism seems to be [13]a series about the high cost of health care while The New Yorker weighs in on [14]the harm done by Dr. Mehmet Oz.

Thanks to James Keller.

Xav (2014-04-22 05:40:12)

Seth, what shows and Youtube channels do you (and other blog readers) currently use for providing a dose of "morning faces" ?

Seth Roberts (2014-04-22 06:08:27)

I use bloggingheads.tv.

dearieme (2014-04-22 06:18:10)

I think you're wrong about causation and correlation. The simple belief that correlation must imply causation does, I guess, far more damage than ..... well, than what? For many problems it's perfectly reasonable to demand that an observed correlation be backed up by controlled experiments - whether on a population sample or on an individual. The problem arises where you can't perform experiments - nobody is going to impose lead or cigarette smoke on a sample of people. There you can turn to Bradford Hill's criteria - which seem to me superior to an uncritical supposition that correlation must imply causation. [http://en.wikipedia.org/wiki/Bradford\\_Hill\\_criteria](http://en.wikipedia.org/wiki/Bradford_Hill_criteria)

Seth Roberts (2014-04-22 07:28:10)

In my experience few people assume that correlations must imply causation. Whereas many people use "correlation does not equal causation" to ignore evidence.

sam tanyonevski (2014-04-22 08:01:32)

the complete state should read: "Correlation does not imply causation, but it does demand explanation."

gwern (2014-04-22 08:21:33)

> The problem arises where you can't perform experiments - nobody is going to impose lead or cigarette smoke on a sample of people. Dearieme, yes yes, everyone knows you can't experiment on people - \*that\* way. There's still ways you can try to experimentally confirm it: for example, instead of focusing on \*adding\* lead, focus on \*removing\* it; you can go find an area with lots of lead in its building, pay for random buildings to be renovated and de-leaded, and monitor outcomes of their inhabitants. This will require a lot more money and data than if you could add big doses of lead (since generally there's not that much lead you can remove so the effect will be small), but it's doable if there's will. Unfortunately, there isn't. Most people don't appreciate the value of this sort of research. (How much would an experimental confirmation or debunking of the effect of lead on crime be worth over the next century? Billions, at a minimum. Is anyone running these sorts of experiments? Nope.)

Joe (2014-04-22 09:08:31)

People who think the "correlation does not equal causation" principle does more harm than good, would certainly DEMAND that they NOT be tried for a capital crime (i.e., punishable by death) in a court of law, based solely on correlation. Or I would hope not. And real lives are also at stake here. There would be a demand for EVIDENCE, wouldn't there? Just because there is a far stronger correlation between men and murder than women and murder, a good criminal investigator would never automatically discount the idea that a woman may have committed a particular murder, and not a man. He or she would still look for EVIDENCE, right? Just imagine how many men would unjustly lose their lives if it were otherwise. It's the basis for the Hippocratic rule of: First, do no harm. The reason so many scientists and researchers like to use correlations rather than actual scientific evidence is this: \$ \$ \$ And it's easy to find a correlation. But actual EVIDENCE? Not so much.

Jack (2014-04-22 09:59:36)

In grammar school I was taught that the ancient Romans used lead pipes in their cities for plumbing, which poisoned them. Later I discovered that most if not all major cities in the United States use lead pipes throughout the cities to distribute water to homes. The city water, of course, is also filled with poison: arsenic. chlorine. chlorates and flouride (flouride is rat poison). Many of the weights that bodybuilders and weightlifters use are filled with lead, with no lead warning label whatsoever on them. Either city planners never went to school, refuse to learn from history, or don't care; or there is a gigantic conspiracy to keep people sick to keep them physically and mentally weak and submissive and trapped in the modern health care system,

which is actually a Death Cult. It is amazing that any of us are still alive, considering all of the poisons that exist in our air, water, food and "medicines". Good article!

Adam Long (2014-04-22 11:31:08)

Seth, I hope this is not a hijack but I had a few questions about the practicalities of morning faces. Apologies if you have covered these questions elsewhere, but I've read through your (extremely helpful!) summary page and couldn't find answers. 1) When you say morning, have you or others found that earlier is better? I get up around 7 am but as a practical matter, it would be easiest to do this while at my desk, around 9:30 or 10. Of course I will endeavor to self-experiment and find out, but would be curious to know if you have any thoughts on this question. 2) Do you find that you need to be staring directly at the faces for this to work? I ask because as a practical matter it would be easiest if I could have this running on my computer screen while I'm doing other things.

Seth Roberts (2014-04-22 13:17:38)

Is earlier better? There is an ideal time, where moving the faces earlier or later produces weaker results. The only way I know to figure out the ideal time is trial and error. Do you have to be staring directly at the faces for this to work? Yes. My guess is that the sensitive period is roughly 2 hours long. During this period you need at least 30 minutes (ideally 50 minutes or more) to get a big useful effect. So you need look directly at the faces for at least 30 minutes during the sensitive period. While looking at the faces you can listen to whatever you want – music, podcast, book, etc.

Xav (2014-04-22 15:56:26)

Thanks for the pointer to bloggingheads. Did you ever do any experiments with looking at still images of peoples faces versus videos to see if there was any impact ?

dr j (2014-04-22 16:45:23)

The only problem with removing lead is that lead has been replaced with other additives that mimic the behavior of lead in controlled gasoline combustion. As a chemist friend of mine said, okay remove lead, remove that as one source of stupidity and replace with partial pyrolysed benzene and other aromatic ring structures in early morning start-ups and by exhaust catalysts that are sub optimal.

bjk (2014-04-22 18:21:29)

30 minutes sounds like a long time to stare at faces. How about getting a dog? Your unconscious can't tell the difference between human and dog faces, right? The assumption is already that it can't tell the difference between virtual and real faces.

Seth Roberts (2014-04-22 19:09:48)

I can't imagine staring a dog straight in the face for 30 minutes. 30 minutes isn't a long time for a conversation.

Seth Roberts (2014-04-22 19:11:11)

I've never tried still images. If I didn't have a computer monitor, I'd use a mirror.

Seth Roberts (2014-04-22 19:12:22)

ethanol is a good substitute for the lead in gasolines.

Alex Chernavsky (2014-04-23 04:14:03)

There's also the interesting theory that legalized abortion lowers the crime rate: [http://en.wikipedia.org/wiki/Legalized\\_abortion\\_and\\_crime\\_effect](http://en.wikipedia.org/wiki/Legalized_abortion_and_crime_effect)

Andrew (2014-04-23 07:30:38)

Watching a talk show like bloggingheads for 30 minutes doesn't seem hard.

dearieme (2014-04-23 14:04:12)

But, gwern, it's so easy for your sort of experiment to miss the point. For example, people gathered the statistics for one of the big Australian lead-mining towns. (Broken Hill, I imagine.) People there were as healthy as you like - no sign of lead cutting a swathe through them. But, it seems likely, that if lead in gasoline was the problem then you need to study not the rather large particles ("dust") emitted by ore mining, but the tiny particles emitted from internal combustion engines. dr j: "As a chemist friend of mine said, okay remove lead, remove that as one source of stupidity and replace with partial pyrolysed benzene and other aromatic ring structures in early morning start-ups and by exhaust catalysts that are sub optimal." That may be why there was then a war against aromatic compounds in gasoline. Benzene, once used to wash grease off your hands in the chem lab, was discovered to be far more dangerous than had been understood.

dearieme (2014-04-23 14:09:22)

"The idea that childhood lead exposure causes crime many years later explains so many otherwise-hard-to-explain facts, especially worldwide declines in crime rates, that I conclude it's true: lead exposure does cause criminality." But that might extend to having exposure to lead being used to explain every otherwise inexplicable rise or fall over time. Does decline in lead explain rises in divorce rates, bastardy, and so on? Does the lead argument satisfy Bradford Hill's criteria?

Seth Roberts (2014-04-23 15:00:29)

Nevin goes over how his argument satisfies Hill's criteria here: [http://www.ricknevin.com/uploads/Nevin\\_-\\_2009\\_Env\\_Res\\_Author\\_Manuscript.pdf](http://www.ricknevin.com/uploads/Nevin_-_2009_Env_Res_Author_Manuscript.pdf) Few things rose a lot and then fell a lot over the period of time we are talking about. For example, divorce rates only rose.

B.B. (2014-04-25 09:51:47)

For pure health reasons, there is plenty of cause to "get the lead out." We need to do more and faster. But that is different from pinning the blame for violence on lead. Here is an article which takes a skeptical look at the lead-violence link. The issue is not so obvious. The article gives academic references. <http://www.samefacts.com/2014/04/crime-incarceration/lead-and-crime-a-hole-in-the-theory/> Here is another idea. Modern chemicals reduce testosterone in males, and that reduces aggression. And another theory. It is well known that heat, particularly humid heat, put a burden on the body, which must keep the brain cool. If it is too hot, people become "hot heads." An overheated brain will far more easily commit acts of violence. It is why violence is higher in summer. The widespread adoption of air conditioning and new dress standards which allow cooler clothing may have reduced violence. Could not greater incarceration contribute to lower social violence (outside of prisons, that is)? New York has had an exceptionally large drop in violent crime. Is it not PC to say that aggressive policing made a difference?

York (2014-04-25 10:47:04)

Lactobacillus plantarum CCFM8661 alleviates lead toxicity in mice. <http://www.ncbi.nlm.nih.gov/pubmed/22684513> Protective Effects of Lactobacillus plantarum CCFM8610 against Acute Cadmium Toxicity in Mice <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3591948> Dead L.plantarum -as in heat-killed- works as well as alive cultures.

York (2014-04-25 10:48:32)

It may boil down to lack of probiotics.

## **Value of Salt Reduction Supported by Four Studies (2014-04-23 05:41)**

For a long time, researchers have found links between high sodium intake and higher blood pressure, and between higher blood pressure and increased risk of stroke. At the same time, critics, [1]including Gary Taubes, have argued that the data do not support the idea that most people should reduce their salt intake.

New evidence suggests the critics were wrong. Four different studies support the idea that high amounts of salt

intake are generally bad.

[2]One study recently appeared in BMJ Open. "The UK initiated a nationwide salt reduction programme in 2003/2004. The programme has been successful and resulted in a 15 % reduction in population salt intake by 2011," write the authors. That might not seem like much but the reduction was in the salt in processed foods, which for most people is most of their salt intake. The more processed food you ate – and the more extreme your salt intake – the greater the reduction.

The main finding of the study was that over the same period, there was a large and steady decrease in both blood pressure and strokes in the UK. Mortality from stroke and ischemic heart disease (IHD) went down by 40 %!

There were small changes in other environmental variables over the same period: people ate slightly more fruit and vegetables, weighed slightly more, smoked somewhat less, and so on. Maybe these other changes were what led one critic to dismiss the results in [3]a *New York Times* article:

Dr. Niels Graudal, a senior consultant in the department of internal medicine at Copenhagen University Hospital, said that connecting the two events "is meaningless."

"This paper describes two independent incidents," he added. "That these incidents should be in any way connected is absolutely unlikely."

Consistent with the low quality of science journalism in the *New York Times*, it seems the reporter, Nicholas Balakar, did not ask Dr. Graudel any hard questions – for example, for an alternative explanation of the decline.

The BMJ study did a poor job of determining the *a priori* likelihood of such a big decline. It could have looked at year by year changes in stroke and IHD mortality before 2003, for example. Was stroke and IHD mortality rising or falling? It could have looked at changes in stroke and IHD mortality in similar countries without a salt reduction program over the same period. Such comparisons would have helped a lot. But the BMJ study did report the results of other nationwide salt reduction programs.

Japan, in the late 1960s, carried out a government-led campaign to reduce salt intake. Over the following decade, salt intake was reduced, particularly in northern areas from 18 to 14 g/day. Paralleling this reduction in salt intake, there were falls in BP and an 80 % reduction in stroke mortality in spite of large increases in fat intake, cigarette smoking, alcohol consumption and obesity which occurred during that period. Finland, in the late 1970s, initiated a systematic approach to reducing salt intake through mass media-campaigns, co-operation with the food industry and implementing salt labelling legislation. This led to a significant reduction in the average salt intake of the Finnish population from  $\approx 14$  g/day in 1972 to less than 9 g/day in 2002. The reduction in salt intake was accompanied by a fall of over 10 mm Hg in systolic and diastolic BP and a decrease of 75–80 % in stroke and IHD mortality.

Again, reductions in salt intake happened just before huge decreases in stroke and IHD mortality. It is the triple repetition of an unlikely event (big reductions in mortality) and the experimental aspect (something was specifically changed) that convince me. The critics are not going to come up with a plausible alternative explanation of all three cases (UK, Japan, Finland) any time soon.

[4]A paper co-authored by the same Dr. Graudal who dismissed the new findings found that high sodium intake

was associated with increased mortality. It also found that low sodium intake was associated with increased mortality. This is why a reduction in the salt in processed food makes so much sense: 1. It's easy. You don't have to do anything. 2. It reduces salt intake the most in people who eat the most salt – exactly where it is likely to be the most beneficial.

Just to be clear, this data also says that if you don't eat a lot of salt, there is no good reason to reduce your salt intake (unless you have high blood pressure).

---

Charlie Currie (2014-04-23 07:26:26)

The big confounder here is processed food... As Gary Taubes says, "MOST" people do not need to reduce their salt intake. And, I would add, "MOST" people need to reduce their processed food intake.

Adam (2014-04-23 08:38:00)

Here the same Dr. Graudal says CDC salt guidelines are TOO LOW: <http://www.webmd.com/food-recipes/news/20140402/cdc-salt-guidelines-too-low-for-good-health-study-suggests>

CC (2014-04-23 09:10:41)

The Japanese decreased their salt intake from 18 \*grams\* to 14 grams/day? That's a huge amount of salt! In the linked article from Adam (in the comments), Graudal says that the safest intake is between 2,645 and 4,945 mg. Maybe the opponents don't really disagree after all?

Seth Roberts (2014-04-23 10:30:44)

yes, Japanese food is very salty.

Charlie Currie (2014-04-23 11:03:21)

I think in most cases, not all for all people, very salty food is self limiting. The problem with the salt content of highly processed foods, or at least one of the many, is that it is right in the "salty enough" zone, so it is not self limiting, which is certainly not the goal of food manufacturers. And, it's pervasive, just like soy, wheat, sugar, corn (starch & HFCS) and other un-spellable / un-pronounceable ingredients.

bea (2014-04-23 11:20:28)

I'm a 54 year old woman 5'6". On the sad diet I weighed 175 lbs and BP was creeping up to slightly above normal. Fast forward 4 years Paleo style diet 135 lbs and BP low. Sometimes 80 over 60. I now make sure I get enough salt daily. I put some salt in my water and liberally salt my food. That upped my BP to 115 over 75. I also don't drink water excessively as I can tell it depletes my sodium. When you switch to a real food diet you need to seek out salt.

Gina (2014-04-23 11:23:52)

Could iodine be playing a role in this? I don't know if the salt in processed food is regular, iodized salt or what's in salty Japanese food. I know that some people who go on low-sodium diets get into trouble with iodine deficiency, just like people who use

non-iodized sea salt. But, like most things, too much iodine is trouble.

Seth Roberts (2014-04-23 11:27:30)

"The problem with the salt content of highly processed foods, or at least one of the many, is that it is right in the "salty enough" zone." The amount of saltiness you think is "just right" depends on your salt intake. When your salt intake is higher, you want more salt in your food. Presumably this was a long-ago adaptation to salt scarcity. When salt was abundant, you wanted more of it – just like the theory behind the Shangri-La Diet. (When calories are abundant, you want more.) This means that the salt in processed foods has two effects: it increases the salt in your blood; and it increases how much salt you want in the next food you eat. This is another reason that simply reducing the salt in high-salt foods is worth trying – because it has two effects.

Bill (2014-04-23 12:10:18)

Dr. David Brownstein has been advising his patients to \*supplement\* unrefined salt for years and has found no increase in BP and substantial health improvements. He has written a book about salt and health based on his clinical experience. Unrefined (real) salt may be very different in its biological effects than refined salt. And the observational epidemiology cited here is not, to me, convincing. Beyond the obvious confounder of salt correlating with processed food, there are doubtless many others. Very easy to draw the conclusion you expect or want when establishing real causality would require far more rigorous methods. If you believe this kind of epidemiology then why not listen to the Harvard School of Public Health and avoid animal fats? Also, the effect sizes cited here strain credibility. How could a 10 point drop in BP explain an 80 % decrease in stroke and heart disease mortality? Other things are going on, and I don't think anyone really knows what they are.

Joe (2014-04-23 12:37:58)

"Other things are going on, and I don't think anyone really knows what they are." I agree. Too many moving parts. "Dr. David Brownstein has been advising his patients to \*supplement\* unrefined salt for years" Yes, and Light Grey Celtic sea salt in particular. Far more minerals. Plus, it tastes great! I can't stand the taste of refined salt anymore.

Joe (2014-04-23 13:34:10)

14 grams of salt was normal in those places!? I got a lot of benefit from deliberately increasing my sodium intake to 4 grams and that tastes like a lot to me. I can't imagine how people were managing to get down so much more in Finland and Japan.

Seth Roberts (2014-04-23 15:05:00)

"How could a 10 point drop in BP explain an 80 % decrease in stroke and heart disease mortality? Other things are going on, and I don't think anyone really knows what they are." The big decrease is plausible because it is only extremes of salt intake that are dangerous – that is, it isn't linear – and the decrease was greater among people who ate a lot of salt. "Other things are going on." If you have an alternative explanation of the UK, Finland and Japan results, what is it? A vague claim of "other things" is no help.

George (2014-04-23 16:21:01)

"Other things are going on." If you have an alternative explanation of the UK, Finland and Japan results, what is it? A vague claim of "other things" is no help." Stupendous intellectual error. I can perceive an error in your logic without having to come up with an explanation of my own. As a piece of logic this is terrible (really shockingly so), as a piece of psychology this is one of the best things I've seen in a long time. It's very hard for the human mind to simply admit ignorance and suspend judgement. People would rather believe a bad theory that has little supporting evidence than simply say "I don't know". The human incapacity to simply say "I don't know" when there is insufficient evidence is probably responsible for most of the silliness that passes as nutritional advice these days and does grave harm to our prospects for ever figuring out true causes. If you simply can't suspend judgement until good evidence shows up and feel irresistibly compelled to adopt the first vaguely plausible theory, you are unlikely to persevere in getting at the true cause.

dr j (2014-04-23 17:46:55)

Ah George, loosen up! Seth provides us with "brain morning faces" and I'd be a tad lost without his and others' reactions and anecdotes. I've spent 20 years at morning teas with academics and my old dept head would say something like this to goad somebody to go spend the week after hours reading up on the literature to create more outrageous discourse at morning tea the following week- might even lead to a paper or two for the dept. :-)

Jack (2014-04-24 10:10:33)

The sinister movement to demonize salt and destroy the health of the world's population has been in full swing for a while now. By getting people to believe that salt is bad, and to limit salt, the agenda for population control thrives. Wars have been fought just to obtain salt. Gandhi led the native people of India in a walk to the sea to make their own salt from saltwater, to protest the British governments monopoly on salt. The body needs salt to retain life giving fluids in the body, and to transport life giving fluids through the body for nourishment and to flush wastes out of the body. For thousands of years, Chinese Doctors have known that salt is absolutely essential to health. In Chinese Medicine, salt is known to strengthen bones, strengthen teeth, strengthen kidneys, strengthen sex organs & performance, strengthen ears and hearing, strengthen brain fluid and strengthen and increase the hair on the head. It is also used to cure problems and diseases associated with the same things it strengthens. Yes, the Chinese know that too much salt or too much salty taste in the diet is not good for the heart and may increase blood pressure. But to demonize salt, to encourage people to cut back too much on salt will make people weak and lead to illness, increased doctor and dentist visits, and early death. Every person's body is different, and people's health conditions change all of the time. Salt is necessary for life. How much salt is needed depends on common sense and the needs of the individual. Personally, I would not take any government study seriously or any World Health Organization study seriously, because their agendas are the same. They are Death cults designed to trick people into submission and to cull the human population.

Gina (2014-04-24 14:18:19)

Is it just me, or is it getting weirder here?

George (2014-04-24 18:30:48)

I know, dr J, but seriously! There's limits to bad thinking and this kind of thing permeates nutrition and diet advice in this country. It has to stop. I have no idea why the quality of thinking in the field of nutrition seems particularly bad as practiced by highly intelligent people, but it is. There's a mystery here.

Bill (2014-04-25 06:27:38)

"The big decrease is plausible because it is only extremes of salt intake that are dangerous — that is, it isn't linear — and the decrease was greater among people who ate a lot of salt." Seth, are you saying that four out of five strokes and heart attacks take place in people who eat "extreme" amounts of salt? Maybe that's true, and maybe it could make credible that an average 10 % BP decline could cut CVD mortality by 80 %, but I'd be very surprised. "If you have an alternative explanation of the UK, Finland and Japan results, what is it? A vague claim of "other things" is no help." I don't think anyone knows. As you've pointed out, the underlying causes of CVD aren't even known. And hasn't CVD dramatically decreased in recent decades in general? Dr. Nortin Hadler has pointed out that CVD now poses a pretty low risk of shortening our lifespans, just as the hysteria about avoiding sat fat, salt, etc. and taking stains is peaking. If we don't know why life-shortening from CVD is declining, just picking one thing that correlates with that decline doesn't seem convincing to me. For now at least, I'll keep bringing my own salt to restaurants (since it's on the table less and less) and supplementing my 1 teaspoon of Celtic salt per Dr. Brownstein.

libfree (2014-04-25 12:29:44)

Aren't we just discussing levels here? I don't see that "The value of salt reduction supported by 4 studies" doesn't really help me determine if my salt levels are good or bad. Since going on Paleo, I have to fight to get my salt levels up to 5g a day which is where I feel the best (based on various markers). I do live in the american south and I sweat heavily and exercise heavily daily. I am a little shocked by how much salt is listed on processed foods. I've been paying attention the last few days when I go through the grocery store and it's pretty shocking. I just looked up the old meal I would eat at Taco Bell in the bad old days it comes in at a shocking 3.4G. I still don't see how I could have come close to the 14g number that Japanese had even on my old

diet. I checked my old diet log and found the number to be closer to 10g.

Justin (2014-04-25 12:54:08)

What about other minerals? E.g. potassium and magnesium (among others)? Having an aggressively high sodium intake without counter-balancing other minerals could cause for some issues as the body reels to re-balance. Laser-beam focus on just sodium, which seems to be the "salt" du jour seems to ignore a considerably more complex system.

Sara Lake (2014-04-25 19:54:27)

I'm (still) researching autoimmunity in a bid to cure my ITP. I've just come across a link between high salt and increased expression of IL17 (a high, or under-regulated level of which is linked with autoimmune disorders). [http://www.the-rheumatologist.org/details/article/4797501/Salt\\_as\\_a\\_Promoter\\_of\\_Th17\\_Cells\\_and\\_Autoimmune\\_Disease.html](http://www.the-rheumatologist.org/details/article/4797501/Salt_as_a_Promoter_of_Th17_Cells_and_Autoimmune_Disease.html)

sam tanyonovski (2014-04-26 01:30:55)

okinawans have been living till 100, illness free, for centuries in spite of a plethora of salt. of course, once they started with western food longevity decreased and illnesses increased.

George (2014-04-26 14:36:23)

The problem with what you're saying that in the world of nutrition Japan doesn't actually exist. If Japan *existed*, then Taubes theories would have been laughed to scorn. If Japan *existed*, then Stephen Guenets theories of high palatability leading to obesity would have been considered a joke. If Japan *existed*, then the theory that processed food leads to obesity would have been discarded long ago as a poor joke. No, sam tanyonovski, Japan simply *does not exist*. So stop inventing countries that don't exist to illustrate your nutritional theories. Only one country actually exists when it comes to nutrition; the United States.

Tom Metz (2014-04-27 10:51:24)

I don't know if the two go hand in hand but since losing over 100lbs years ago my taste for salt went through the roof. I don't know if it's some kind of psychological addiction but I love salt. In the past I would probably get, not even kidding, 20+ grams a day. I never actually measured it to be that much but when I did make an effort to measure I remember weighing out 10 grams and looking at it saying "whoa this is nothing..." then I proceeded to eat the 10 grams and a lot more without weighting it throughout the day. It doesn't increase my blood pressure (maybe by 10pts max to an already low blood pressure)... at least not according to the cuff I bought. What does happen, however, is that I retain an ungodly amount of water. Always. I can retain, and I am not kidding, 15lbs of water if I have an extreme salt intake for a couple of days in a row. That's finally the point when I HAVE to cut back because I will literally feel heavier when I walk around. My shoes get tighter and I just look really really fat. People have even made comments that I've put on weight. They don't believe me when I tell them it's water weight. For that reason I HAVE to watch my salt intake... which I hate because I really really really love the salt which is funny because I never cared about it when I was super overweight. I really do think salt sensitivity is very very individual. I can't tell you how many times I've read that the body adjusts homeostasis and fluid balance to match CONSISTENT levels of salt intake. Not in my case. For years it's been- eat a little salt consistently, hold a little water. Eat a lot of salt consistently for a couple of months, hold a lot of water for a couple of months.

Justin (2014-04-28 06:26:59)

@Tom, I, too, take in a lot of salt. I've not measured it to date, but I salt like a fiend. Usually sea salt but I'm not afraid of typical table salt. I also take in a decent bit of magnesium daily. Like you, I can tack on some serious water weight under the right circumstances. The most consistent water-weight add is related to carb/glycogen replenishment-something I've blogged about here: <http://justinowings.com/understanding-bodyweight-and-glycogen-de/> One thing I've noticed that I'm curious about in your experience is that while my salt intake is high, I think my potassium intake can be low at times \_relative to other salts\_, which can lead to cramps/issues that seem to be dealt with by adding some "NoSalt" to water or literally licking it off my hand (doesn't taste the best as far as salt goes but seems to work). I've also noticed that alcohol consumption can lead to some serious water retention - not unlike what you describe with people noticing weight gain. I can clearly see the impact of water retention on my "softness" when I see a material change in the scale. For example, yesterday I started the day at 164.

Ate a high protein diet that was low in fat and low in carb (call it 200g protein, 30g fat, 70g carbs but probably 40 of that was dietary fiber). ALSO had 6 oz of tequila – 68 g of alcohol. Weight this morning = 169. By tomorrow morning my weight will probably be around 163 if I had to guess. Crazy, right? Maybe not to you. I hate water weight fluctuations though — they're just annoying. I prefer looking more lean to puffy and the worst I've had it on water retention was at the tail end of a week at the beach where my legs literally got swollen from the water weight. Given my body comp at the time was only about 10-12 % BF, that kinda water retention made for serious swing in my appearance – particularly on my legs. TL;DR – water weight is a major force to be reckoned with! And it seems pretty poorly understood. Btw, I have very low BP (and a low resting HR), too.

Tom Metz (2014-04-28 10:17:56)

Thanks for your reply Justin, I'll get to potassium but first I want to talk about alcohol consumption and water retention. It's really interesting that you mention alcohol because I, unfortunately, have a lot of personal experience with this. I use to drink a lot during my college days. Thankfully, though it was hard to completely stop... once I did finally stop I haven't been tempted to go back. This was many years ago. The first time I ever got pretty drunk I woke up the next morning feeling light as a feather and feeling the best I had in months. Alcohol is a natural diuretic as it inhibits anti-diuretic hormone. It's well known in bodybuilding circles that drinking some hard liquor before a show can help drop water weight and increase muscle definition. Aside from that I never noticed alcohol to CAUSE water retention. Of course I was really obese at the time so it may have happened. I would imagine it's possible, probably from an overcompensation effect from it greatly inhibiting anti-diuretic hormone while the body is metabolizing the alcohol. As for the potassium... I started using lite salt mixed with nu-salt to combat the high sodium. I'm probably using %75 potassium and %25 sodium while measuring everything out carefully. Excess potassium can be dangerous. It takes a lot though. I don't think the potassium does anything special to help eliminate excess salt. The decrease in sodium intake as a result of the potassium replacement probably helps reduce water retention a lot more than taking in potassium does. Interestingly I find that the potassium does make me quite thirsty but I don't hold the water. I'll drink like crazy then urinate a lot over the next couple of hours. One thing that I swear works... eating a lot of cranberries. There doesn't seem to be a lot of research on this but a lot of people swear that cranberries help with water weight. My experience has been that when I make a cranberry smoothie (with real cranberries I don't use the juice) I get a dull, almost uncomfortable, mild sensation in my midsection followed by increased urination for a couple of hours. Of course if you really really want to eliminate water weight... eliminate carbs for a couple of days, like you mentioned, lower salt, sweat a lot, be in a calorie deficit etc... the body loses a lot of what it uses to hold on to the water this way.

Sam (2014-05-06 13:21:14)

Japan carried out a government-led campaign to reduce salt intake ??

thhq (2014-05-09 04:02:34)

The super saltiness of Japanese diet is probably due to liberal use of soy sauce. Finland I don't know but salt licorice pastilles (salmiakki) are popular. They're so salty that they burn my tongue.

## **Journal of Personal Science: Omega-3, Nursing a Baby and Postpartum Depression (Part 1 of 2)** (2014-04-25 05:00)

by Allan Folz

My wife had moderately severe postpartum depression (PPD) after the birth of our first child, a boy, in 2004. The depression lifted at the same time the nursing stopped, when he was about two years old. The pregnancy itself was without major or even minor problems so the depression was a big surprise. It was frustrating because nothing we did to alleviate it actually helped.

With our second child, born in 2007, for the whole pregnancy we were worried she would experience it again. Thankfully she did not. There were a couple of differences between the two pregnancies. Our first baby was a boy and born with a complication during delivery. The placenta did not release. This caused to be transferred to a

hospital, as it was a home birth. At the hospital she was given two units of whole blood. Our second baby was a girl, also born at home, and this time with no issues.

Her third pregnancy was in 2010 and this is where the story begins.

A couple months before she became pregnant, I had discovered paleo dieting following a link to [1]Richard Nikoley's blog. I read about his experience and followed links to other sites in the paleosphere. The diet, the rationale behind it, and the numerous reports of other people having their health remarkably improved by it really resonated with me, so we adopted a lower-carb, paleo-style diet.

We didn't have health problems that we were trying to correct for ourselves or a particular need to lose weight, outside of a few pounds for my wife relative to how much she weighed prior to her first pregnancy some six years before. However, I've always had an interest in health, medicine, and how the body functions. I even considered becoming an M.D. back in my undergrad days and minored in biology alongside my major in electrical engineering. I have a strong skepticism towards experts and what is the conventional wisdom in mainstream media sources. I think that's why I almost immediately found Seth's blog so intriguing, he questions the conventional wisdom and pushes people to take personal responsibility over their health and well-being. So, we were on a low to moderate carb diet, but weren't fanatical about it. I remember that after my wife's first visit with her midwives they were concerned by the ketones in her urine and strongly suggested she start eating more complex carbs. She followed their advice to be conservative. We were also supplementing Vitamin D and a little fish oil (a Mega-EPA omega-3 supplement). She was averaging 5K IU of Vitamin D a day, but only about one, 1 gram capsule once or twice a week of the fish oil. All in all, not much fish oil as I wasn't sure how much was really necessary for people otherwise eating traditionally healthy, home-cooked meals, and I'm very skeptical of the diet supplement industry.

Late in the third trimester she started experiencing some moodiness. By itself, it probably would not have seemed atypical for a woman in her third trimester, but with my wife's history we were far more sensitive to it and quick to take notice. Paying close attention (and long before discovering Seth's blogging on self-experimentation), I eventually realized the moodiness happened when we'd skipped taking fish oils mid-week. If she didn't take any mid-week, by Saturday it was very noticeable that her mood was on the short-tempered side. Once I noticed the connection, and without telling her what I was doing (i.e. single-blind), I'd deliberately skip the mid-week dose one week and note her weekend temper and mood. The following week I'd be sure she took a capsule mid-week. Next week back to skipping. Then, just to be sure, I had her double-dose one week. The double-dose had her in the best mood of all.

At first I was amazed. It was so neat, so mechanical – like flipping a switch. But it occurred to me that if two capsules in a week vs. one was enough to noticeably change her mood then she was obviously deficient as every mg was being put to use with no spare capacity in her system. I wondered if her body was scavenging omega-3 from her own brain for the developing fetus. That was a sobering thought. After that she went to supplementing daily and had no mood issues throughout the rest of the pregnancy or while breast feeding. She did have some of the typical “baby blues” that set in at the three day mark, but they did not last long. Also, she had good days and bad days, like anyone would. I'd say the omega-3 returned her to her normal bearing, irrespective of the demands of pregnancy and nursing.

There is zero doubt in my mind that omega 3 helped both my wife deal with a severe and yet all too stereotypical mental health problem. I'm a pretty sharp, pretty well-read guy who's always had an interest in biology and medicine. After the experience with our son's weaning, I wondered if nursing could cause or complicate PPD.

Seven years ago, when my wife was pregnant for the second time, I had searched the web for material related to those two (nursing and PPD) and came up empty-handed. I know I've never read something dealing with those two in mainstream outlets because it's the type of thing I would mentally file away for future reference if the

situation ever came up. It seemed like I was the only one willing to consider there might be a connection between them. Diet suggestions for nursing mothers are full of the usual bromides about getting enough complex carbs, fiber, and protein. Search engine auto-completes on “postpartum depression” don’t offer “omega-3” or “diet” anywhere in the top 10. You have to type the first two letters of each before they pop-up as auto-complete options. Today, the first hit for “postpartum depression diet” (I use Bing) is <http://www.postpartum-living.com/depression-diet.html>, which makes absolutely no mention of fats or lipids. It mentions vitamins, of course, but, incredibly, nothing specific.

During the two years my wife had PPD after her first pregnancy, no one suggested omega-3. At the time, I attributed her PPD to the delivery complications and the blood transfusion. I knew that depression is well-known among heart-attack survivors and IVF recipients, and, in my opinion, IVF is a pretty severe complication. Among the health professionals she saw about her PPD, the only thing the MD did was give her a prescription for Prozac or something similar, which she didn’t use because, well, of course – she was nursing. Had she quit nursing to take the prescription we would have attributed the improvement to the drug when it actually came from ceasing nursing. The naturopathic practitioners – she saw two different ones – gave her B-12 shots, SAM-e, melatonin, and a bunch of useless diet advice that one could read at all the usual places. The B-12 was good for a 24-48 hour energy boost. Other than that, none of them made the slightest difference.

*Part 2, about using omega-3 to treat ADHD, will appear tomorrow. Allan Folz is a software developer in Portland, Oregon. He recently co-founded [2]Edison Gauss Publishing, a software house that makes academically rigorous educational apps for children in grades K-8. Their apps are suitable both classroom and home use, and have proven to be particularly popular among homeschoolers that appreciate a traditional approach to practicing math.*

nicole (2014-04-25 07:44:26)

Did you see this? <http://www.theatlantic.com/health/archive/2014/04/postpartum-depression-can-happen-to-any-parent/360918/> I wonder what would account for Dad’s getting PPD...

Allan Folz (2014-04-25 14:48:02)

Wow, crickets. :) Let me guess tl;dr? Sorry. As for the Atlantic article (and I thought I mine was long), not impressed. Didn’t make a clear enough distinction between “blues” and depression. Beyond that, sure, Dads are sleep-deprived too and experience negative effects. No surprise there. However, it didn’t offer any prescriptive advice beyond the usual “communicate, get rest, eat well, brush your teeth well and floss.” Ok, maybe not that last one, but I didn’t read the whole thing so maybe it’s in there after all. :)

Andrew (2014-04-25 15:30:53)

Hi, Allan, it’s a good article. Maybe people are waiting for part two before commenting? Anyway, I enjoyed this, and I’m very much looking forward to reading the second part.

Allan Folz (2014-04-25 15:52:32)

Thanks Andrew. I was a little worried I missed the mark with it.

Thomas Johnson (2014-04-25 16:36:57)

Did the midwife note anything about prenatal vitamins? Nearly all prenatal vitamins include omega-3, and all of the doctors my wife and I have talked to suggest continuing to take prenats during nursing. Here's the nutritional information for one of the most popular prenats (one-a-day): <http://labeling.bayercare.com/omr/online/oad-womens-prenatal.pdf> Note that it includes 223mg of omega-3. It seems like traditional medical advice could have saved some self-experimentation here.

Seth Roberts (2014-04-25 17:12:30)

I'm guessing that 223 mg of omega-3 is not nearly enough.

Allan Folz (2014-04-25 17:27:34)

Thanks for your question Thomas. It is a good one. With our first she took the Rainbow Light pre-natal all through the pregnancy and the whole time she was breastfeeding. It was a hard multivitamin so certainly had no O3. 10 years ago I'm not sure any of them did. Also, "Does your prenatal vitamin have O3?" was certainly a question no one asked us. Nor is it all that far from "Are you taking an O3 vitamin?" which definitely no one asked, much less recommended. With our third, she took the same pre-natal multivitamin. After three children, I know the routine. They ask, we tell them yes, Rainbow Light, they smile, nod, and say OK, good. But I'll respectfully dispute O3 is traditional, or even contemporary, medical advice. DHA is "a thing" now, but is it ever linked to mental health of the mother? Please show me where. I only see it marketed as important for the baby's development, akin to Folic Acid and Vitamin D. If the baby is healthy, who is going to know to take O3 for mom's benefit? Finally, the One-a-Day of 200mg of DHA and 23mg/day of EPA is very questionably adequate. From the Bloch/Qawasmi paper that Seth linked to on Monday we know EPA has greater efficacy than DHA. It's why O3 was discredited for ADHD treatment early on – all the early studies used DHA and the effects were mixed at best. For my wife, 400/200mg of EPA/DHA respectively, ie. 1 capsule a week, was not enough to keep her mood level, and twice that amount was the bare minimum. OaD is 1500/wk. If the woman is lucky enough to have the DHA work for her, she might be fine, but if not I think she'll have a very hard time knowing how to fix it if she is relying on conventional advice (switch to EPA and 2-5X the dosage) . My fear is doubling up on her OaD, a reasonable thing to attempt, is unlikely to help. So she'll give up on O3 for the wrong reasons.

Allan Folz (2014-04-25 17:32:53)

Seth, you beat me to it. For the record, the [1]Bloch-Qawasmi paper.

1. [http://www.jaacap.com/article/S0890-8567\(11\)00484-9/abstract](http://www.jaacap.com/article/S0890-8567(11)00484-9/abstract)

Thomas Johnson (2014-04-25 17:53:12)

Regarding links to mental health of the mother, I don't have a link to the original study, but a quick search found this article on WebMD: <http://www.webmd.com/baby/news/20110412/omega-3s-may-cut-risk-of-postpartum-depression> The study mentions 300mg of DHA 5 day/week in the experimental group. There's also this <http://www.medscape.com/viewarticle/775013> and this more recent article: <http://www.plosone.org/article/info%3Adoi%2F10.1371%2Fjournal.pone.0067617>

Seth Roberts (2014-04-25 18:41:51)

"she'll have a very hard time knowing how to fix it if she is relying on conventional advice (switch to EPA and 2-5X the dosage)" this isn't clear. what is the conventional advice? apparently YOUR advice is switch to EPA and 2-5X the dosage.

Allan Folz (2014-04-25 20:03:00)

Sorry. What I meant to say... She'll have a very hard time knowing how to fix her depression if she is relying on conventional advice, which either completely ignores O3, or at best recommends 1000-1500mg of DHA a week, which is too low an amount to make a difference. Instead, I believe women should be ready to take 400-800mg of EPA *a day*, which works out to 2800-5600mg/week.

Max (2014-04-26 07:24:04)

Excellent article, thank you Allan. I encouraged my wife to take 2 capsules, daily, of the Nordic Naturals pro-omega/ultra-omega product, which has 650mg EPA / 450mg DHA. Through two pregnancies (2011 and 2013) and breastfeeding, we had excellent

results - calm, alert babies and and no PPD. It's impossible to know how much to credit the O3 but your report reinforces my belief that it helps.

milly (2014-04-27 06:03:48)

Thanks for the post, very interesting. I suffered from terrible insomnia (and PPD/moodiness) since my son's birth, and once I weaned him at 2.5 years a few months ago, my sleep (and thus, mood) drastically improved. I took fish oil while pregnant (in addition to my prescription, iron-heavy prenats which I continued taking until weaning) but less vigilantly while breastfeeding. Conventional advice warns mothers of potential depression post-weaning, and bracing myself for that, was shocked to find the complete opposite.

Stephanie Pires (2014-04-28 00:39:01)

I had a very severe PPD with my first son, who has very mild autism. I feel that I am lucky to be alive. I noticed that the less I nursed, the less depressed I was. When I finally quit at 11 months, I was back to normal within a month. It was like a miracle. I too had complications and thought that I might die during his delivery. I always assumed the PDD was actually a form of PTSD. I didn't know anything about omega 3's 30 years ago, but I have to say, it was the single most awful event of my entire life. I can understand now who something like that would have helped. At the time, no one took me seriously, except my mother. She called me every day twice a day and finally, when my son was 3 months old, I went and spent a month with them. I was somewhat better after that. I think my strange labor and delivery were related to oxytocin.

Orthomol world vitamin (2014-04-30 09:17:44)

Orthomol Vitamins for teenagers i join, all above told the truth.

mcx realtime data provider (2014-05-01 10:47:14)

Thank you for the auspicious writeup. It in fact was a amusement account it. Look advanced to more added agreeable from you! However, how can we communicate?

## **Journal of Personal Science: Omega-3 and ADHD (Part 2 of 2) (2014-04-26 05:00)**

by Allan Folz

My story of omega 3 and self-experimentation did not end with my wife and her pregnancy. As I mentioned, I discovered the paleo diet, Vitamin D, and fish oil all about the same time. Mostly for reasons of general good health we began supplementing with vitamin D and fish oil (Mega-EPA Omega-3 supplement). I ordered some of each from the same place online and we began supplementing both at the same time, around January-February of 2010.

At the time my son was in kindergarten and having problems socializing at school. He had them at home too, but we'd all adjusted to them at home. He exhibited a lot of what would be called typical spectrum issues, though I was certain he didn't have anything approaching Asperger's. Things that interested him, such as building with Legos playing outside with or without friends, he did quite well. It struck me that he was a high-energy boy who didn't appreciate receiving directions, desk work, or anything requiring moderation and self-reflection. I like to joke that Tom Sawyer is hardly a modern archetype.

Nonetheless, he was having problems. The Vitamin D Council web site had a number of very persuasive anecdotes from parents about autistic children cured by Vitamin D. Our son wasn't autistic, but autism involves several behaviors, and he had a few of them. He didn't make good eye contact when talking or being talked to. He wouldn't follow directions if he didn't feel an intrinsic motivation to follow them. He could not fall asleep and would often lay in bed restless for an hour or more at night. The Vitamin D Council recommended 2000 IU per 50 lb/day, so that's what we all took. We also took one fish oil capsule a week. At the time I thought of omega-3 only being for heart health. This made me a little skeptical about how much was really required. We seemed a healthy family, so I figured

our needs were modest. One capsule a week seemed well beyond the norm so we should be good.

Almost immediately after beginning the supplements my son's behavior improved. I was pleasantly surprised and attributed it to the Vitamin D based on what I'd read on the Vitamin D Council web site. It wasn't a cure by any means, but it was a very noticeable improvement. He would still have bad days, and I was a little bummed that after the initial improvement the Vitamin D didn't seem to be helping any further. However, I figured such is real-life outside of attention-grabbing headlines.

Two years later, January and February of 2012, second grade for him, and about a year and a half after the self-experiment with my wife during her third pregnancy, my son's behavior dramatically worsened. We were all still taking D, but at that point it was obviously not showing any benefit for my son. He was in a worse place than when he was in kindergarten. I resigned myself to Vitamin D not being his problem, and at his teacher's demand signed him up for outside testing.

I didn't notice at the time, but we had run out of the "fish oil" over Christmas break. The second week of January we visited family in the Midwest. When we returned, school was a nightmare for him and us. My wife and I attributed it to too much TV, bad diet, and not enough sleep while we were visiting family. However, even two and three weeks after our return his problems were worsening. Around the beginning of February, I finally got around to ordering another bottle of the omega-3. I thought of it as mostly being for my wife, who was doing fine, so I didn't feel any immediacy. When it finally arrived, we all started taking it again. Immediately his behavior improved. It was such a night and day difference the connection was impossible to miss. It was like kindergarten when he first started taking Vitamin D, only far more so. For the first time in two weeks he wasn't angry and crying at the end of the day. That's when it occurred to me that in kindergarten he started taking fish oil at the same time as Vitamin D. For the last two years I had been attributing to Vitamin D what was due to the omega-3 supplement. I felt like an idiot.

After that, I did some research on omega-3, fish oil, and ADHD. When I knew what to look for, I found that there were, in fact, a few studies about using omega-3 for ADHD treatment. It seemed that EPA was effective while DHA was not, or at best, less effective than EPA. When I took a closer look at our "fish oil," I remember thinking to myself, "Oh wow, this stuff is Mega-EPA. How lucky is that." I had chosen it almost at random. It had the best per-dose price and was listed as a top seller.

In retrospect, were it not for the pain and difficulty experienced by my son, it would be funny how the answer was under my nose the whole time. I was slow to appreciate it because of my own prejudice and not treating the problem as something to scientifically test. I thought of omega-3 as being for heart health. I'd never seen it mentioned in relation to emotional health or brain development, outside of the usual bromides about eating walnuts and so forth. Plus the recommendations are always couched in generalities without specific dosage guidelines. Even after I discovered it made a difference for my pregnant wife, it didn't occur to me to test it seriously on my son. Their symptoms and nutritional needs seemed unrelated.

A few weeks later we saw the professional who had tested our son to go over the results. A few weeks had passed between the evaluation and when we met to discuss the results; it was during that time that I made the omega-3 discovery. I told the professional that our son was getting really good results from the omega-3 supplement. I said that after noticing his results I'd done some online searching and there were a few scientific studies supporting the use of omega-3 supplements for ADHD. The professional said he was aware of the studies, but the efficacy wasn't as certain or as strong compared to the prescription drugs so most people choose the prescriptions. (He sent me the same Bloch & Qawasmi paper Seth linked to in his April 21 Assorted Links.) I wondered if most people were even made aware of the possibility of omega-3 deficiency – he certainly didn't bring it up with us. I would not have found the research papers without first knowing what to look for. I knew what to look for only because of the discovery I made with my son.

The omega-3 supplement, while a huge improvement, was not an immediate cure. We started giving him two capsules daily which consisted of 800 mg EPA and 400 mg DHA. That seemed to me a lot of omega-3, relative to what one could consume through normal dietary intake.

I was not overly comfortable with that level of dose long-term despite it clearly working. So every couple months or so I'd have him skip a day or whole weekend. Without fail, his mood noticeably worsened. By the early evening he would be overwhelmed and frustrated to the point of tears by little things that weren't going his way, things that were really just the usual complications of life in a household with two parents and two siblings.

A poignant instance of the effects of missing a dose happened in the Fall of the following school year, still 2012. My wife's mother came for a visit. The break from routine caused my wife to forget to give our son his omega-3 supplement for three or four days in a row. He might have had them on Sunday, but not on any of the weekdays. By Thursday I had gotten a note and phone call from his teacher about his behavior at school. We had to go and meet with her the following week. At the meeting I shared that we had forgotten to give him the omega-3 capsules due to his grandmother visiting. I saw this as proof it was working. The teacher didn't know we had forgotten, and yet his behavior had noticeably regressed. She did not share my awe, and tried to imply that he should be on a prescription. I said that kids can forget prescriptions just as easily and the side effects from a missed prescription are going to be far worse than three days off an omega-3 supplement.

Last month we again ran out of the omega-3 supplement. Except for the accidental occurrence when my wife's mother was visiting, this is the first time he's been off it for more than a few consecutive days in the two years and two months since I first discovered it helped him. I'm quite pleased that he seems to be doing OK. There's been virtually no difference in his behavior since stopping. However, it's not a true cold-turkey quit. We have some of the Green Pastures FCLO infused coconut oil, so he's been taking that instead. The manufacturer is vague about its omega-3 content, but my rough estimate is that he's taking, a third to a half of his previous dose with the Mega-EPA capsules. Then again, it's in the triglyceride form which is supposed to be 50-70 % better absorbed on a per-gram basis. Perhaps it's a wash.

I've thought about having him try flax oil. There is considerable debate about the efficacy of flax oil and the body's ability to synthesize EPA and DHA from ALA, the omega-3 in flax oil. It might be a little late to test efficacy now. The best time to test was one and two years ago when the Mega-EPA supplement was clearly working and had an "efficacy" half-life of 24 hours. The thought never occurred to me until recently when reading Seth's blog.

I can't end without sharing some of my frustrations with the state of health science. There is no doubt in my mind that omega-3 helped both my son and my wife deal with some severe and yet common mental health problems. I'm a pretty sharp, pretty well-read guy that's always had an interest in biology and medicine. Outside of a few esoteric corners of the web where you have to know what you're looking for in order to find it, omega-3 is something you take for heart health.

I think the comparison with statins is apt. When "heart-healthy whole-grains" don't fix one's blood makers, and why would they, it's very quickly on to prescription drugs (statins). When "use your words" doesn't fix a young boy's interactions with classmates and teachers, and why would it, it's on to prescription drugs. Boys especially are put on incredibly strong pharmaceuticals with well-established risk factors that include stunted growth and suicide. Pharmaceuticals should be tried last, but they are clearly being tried first by frustrated parents and suspect practitioners. It's a national shame and a personal outrage.

*Part 1, about using omega-3 to treat postpartum depression, appeared yesterday. Allan Folz is a software developer in Portland, Oregon. He recently co-founded [1]Edison Gauss Publishing, a software house that makes academically rigorous educational apps for children in grades K-8. Their apps are suitable both classroom and home use, and have proven to be particularly popular among homeschoolers that appreciate a traditional approach to*

practicing math.

Alex (2014-04-26 06:53:06)

Thanks for sharing your story, Allan. I'll be doing some trials.

babar (2014-04-26 07:32:22)

thanks for sharing your story. your boy sounds a lot like mine with respect to where he sits with respect to "spectrum" behaviors. (my kid is 6.) we haven't tried anything with omega-3 (and knowing him, he would refuse a new "vitamin".) i'm glad you have found this link but in my brain the problem in many cases is with the school environment and not the kid. your kid is probably intrinsically fine and if he grows up with his self intact he will do quite well in life.

Max (2014-04-26 07:32:43)

Thank you again. This is going to help a lot of people. My wife's 8 year old boy is in a similar situation and I will encourage them to try EPA at these doses. One question: it's hard to imagine a young boy being able to swallow the big capsules or liking the taste of the liquid. How do you manage delivery?

C.M. Mayo (2014-04-26 07:47:54)

An especially interesting read. Thank you for your generosity in sharing this story. My own sense is that oily fish must have been a more important part of the human diet, so our bodies need that oil and with the modern diets we have, we usually don't get it unless in a pill. Ditto fermented vegetables. I share the frustration at how quick-on-the-trigger so many doctors are to prescribe pharmaceuticals, many of them on the market with very dubious data behind them, and when there are alternatives without dangerous side effects.

Alex Chernavsky (2014-04-26 08:53:27)

Interesting story. You were very wise to avoid psychotropic drugs. If you are interested, you should check out a book called, [1]*Anatomy of an Epidemic: Magic Bullets, Psychiatric Drugs, and the Astonishing Rise of Mental Illness in America*, by Robert Whitaker. A portion of the book deals with the harmful effects of drugging children. See [2]here for an interesting Ritalin-related excerpt from that book.

2. [http://books.google.com/books?id=XhPp\\_o6bB3EC&pg=PA225&lpg=PA225&dq=%22robert+whitaker%22+ritalin&source=bl&ots=JvGz2mAkdf&sig=D0PNMMyn7FKbVhvsEOUqMaeyF3o&hl=en&sa=X&ei=eMtbU7b1E\\_DLsQSCxIKoBg&ved=0CIEBE0gBMak#v=onepage&q=%22robert%20whitaker%22%20ritalin&f=false](http://books.google.com/books?id=XhPp_o6bB3EC&pg=PA225&lpg=PA225&dq=%22robert+whitaker%22+ritalin&source=bl&ots=JvGz2mAkdf&sig=D0PNMMyn7FKbVhvsEOUqMaeyF3o&hl=en&sa=X&ei=eMtbU7b1E_DLsQSCxIKoBg&ved=0CIEBE0gBMak#v=onepage&q=%22robert%20whitaker%22%20ritalin&f=false)

Adam (2014-04-26 08:56:38)

To offer something of a counterpoint, for those of us without ADHD or Depression, there is an argument that supplementing with Fish oil may be harmful: <http://chriskresser.com/when-it-comes-to-fish-oil-more-is-not-better>  
<http://www.westonaprice.org/know-your-fats/precious-yet-perilous>

Andrew (2014-04-26 09:46:43)

Max, Carlsons "Very Finest Fish Oil" with lemon flavor in the pint bottles, while expensive, is surprisingly good tasting. I recently read someone on the net recommending just drinking small gulps of the Carlsons directly from the bottle. I haven't done that yet, but it definitely seems more convenient than pouring it out every time I want to take a dose.

Mehmet (2014-04-26 10:58:54)

In a bbc documentary, i have seen a child's school problems are resolved by omega 3:  
[http://www.bbc.co.uk/science/humanbody/mind/articles/intelligenceandmemory/omega\\_three.shtml](http://www.bbc.co.uk/science/humanbody/mind/articles/intelligenceandmemory/omega_three.shtml)

dearieme (2014-04-26 12:36:51)

We are regular eaters of mackerel pate, sardines on toast, and smoked salmon. We also enjoy the occasional kipper. I trust that these will satisfy our needs for fish oil. As for other fish, I had a nice piece of whiting yesterday. Yum, yum.

Allan Folz (2014-04-26 12:46:35)

Thanks everyone. I really appreciate it. I prefer to be the private type, but I feel helping people by getting the word out about O3 is important. @babar - I feel very much the same way about schools' treatment of boys today. However, he was not functioning well at home either. To a certain extent I'm sure school wore him down and that spilled over into home life, but life wasn't grand prior to kindergarten either. Regardless, O3 makes a huge, noticeable difference. @babar & max - Concerning delivery, they are large pills that the kids chew up. Our oldest son has always been adventurous towards foods and eating, and the others started young enough they didn't know a difference. When our youngest was a baby I would pierce it with a fork and let him suck it out while I held the capsule. Seemed gross to me but he loved it. The capsules pop loudly and squirt in your mouth when you bite into them. I call them firecrackers and they like that, complaining even when they occasionally don't get a good pop for whatever reason. Finally, though we take fermented cod liver oil straight and quickly chase it with food, I've read of people mixing it with just enough peanut butter, yogurt, or ice cream to carry it across the tongue and down the gullet. I think the same should work for any liquid oil. @Alex & Mehmet - Thanks, I'll check them out. One thing I've learned is that many parents who have gone the prescription drug route really don't like hearing about alternatives. @Adam - While I haven't seen those specific links, I do share concern about over-doing the O3. It's partly why I was under-dosing for so long, and repeatedly testing my son's response to taking him off it every couple or few months. My preference is for as small a dose as he can tolerate, though I see Seth has discovered what seems to be large, bordering on incredible, doses make a commiserate improvements. It's also possible unrefined flax seeds are metabolized differently whereby overdosing it not a concern. @Andrew - I guess whatever works for somebody, but if one is aiming for a specific physiological effect, I think the dose needs to be more carefully measured than a "swig." :)

Deb (2014-04-27 09:38:20)

Great article. I'm going to try it with my 12 yr old son. And that Adam dude who posted fish oil harmful articles obviously does not have a child with ADHD. If he did he would understand that you will try ANYTHING to help your child.

Robert (2014-04-27 11:15:46)

You may want to look into some of the new EPA-only supplements - Nordic Naturals EPA Elite, RenewLife EPA 1000 and OmegaVia EPA 500. The one by OmegaVia is the smallest (kid-friendly) pill.

Charles (2014-04-27 11:31:54)

I was taking Wellbutrin for "adult" ADD. It had pretty much saved my life when I finally realized that I had ADD when I was 40, and had been experiencing it for most of my life. After a number of year, though, I wanted to get off the drug, and read a Purdue study that indicated 50 % of boys with ADD had Omega-3 deficiencies. So I started taking fish oil caps, and was able to stop the Wellbutrin. It's true that it's probably not great to take unlimited amounts of fish oils. But given the alternatives, I would recommend erring on the side of getting enough, then start cutting back until you find the correct amount. And adding fatty fish to the diet, as well as getting the gut microbiota in good shape with pre- and probiotics. 90 % of the neurotransmitters produced in the body are produced by intestinal bacteria. If your gut is screwed up, your brain will be, too.

<http://tinyurl.com/bbwwebcams25441> (2014-04-27 20:58:38)

Thanks for finally writing about > Seth's Blog

krol (2014-04-28 00:56:47)

Its that you go through my head! You appear to be aware of a great deal of close to this particular, just like you published the hem ebook within it or something. I have faith that you only need to can do by w. g. to drive a car the message residence somewhat, however other than that, that is amazing web site. A superb understand. I'll certainly be back.

Vitamin shopppe orthomol (2014-04-29 02:54:48)

orthomol Vitamin c serum at me a similar situation, let's discuss.

Dave (2014-05-01 14:01:14)

Awesome article Allan. I (and my family, co-workers, etc.) also notice (!!!) when I stop taking my fish oil. I've been through several cycles of self-experimentation on this, and I can say w/o a shadow of a doubt that it makes for a large positive difference in my mood, outlook, level of anxiety, speed of thought, etc. I'm 50 y/o now and often wonder what life would have been like if I would have discovered Omega-3 supplementation sooner. My first-born son is the "spitting image" of me at that (teen)age, both good and bad, and this article FINALLY put it all together for me regarding my son's behavioral challenges. So, while I'm still able to have a strong influence over his choices, I'm going to insist that he start supplementing as well. With all of the information out there (now) on ADHD and the "spectrum", I recognize some of those symptoms in myself and son, so there seems to be some of that correlation with us as well. Finally, I've found Krill Oil to be particularly effective for me. I do think the "phospholipid carrier" (vs. triglyceride) marketing of Krill Oil suppliers is more than hype in my case. BTW - Is there a strong Northern European component to you or your wife's lineage? If so, I would not be surprised. I gather others have noticed a correlation of omega-3 / behavior / mood for people w/ that ancestry as well.

## **Seth (2014-04-27 19:15)**

Hello, this is Seth's sister, Amy, with the sad news that Seth died on Saturday, April 26, 2014. He collapsed while hiking near his home in Berkeley, CA. He had asked that any memorial gifts be made to [1]Amnesty International. Thank you to all for following and sharing Seth's work.

1. <http://www.amnestyusa.org/>

---

Gretchen (2014-04-27 19:34:14)

Seth was an extraordinary person and will be missed. Thanks for letting us know.

James Babcock (2014-04-27 19:39:11)

My condolences. I'm stunned; I've been reading his blog for awhile and never suspected his health was failing. I know this is a rough time, but I'd like to ask: if you don't already know for certain, please preserve any evidence, digital and physical, that might indicate why he died. If it was the result of one of his self-experiments, then I think he would want us to know.

Gerry Mandel (2014-04-27 19:40:24)

I am deeply saddened to lose my dear friend of 35 years. Brilliant, curious, kind, supportive – Seth was a treasured friend who I looked forward to sharing ideas and experiences with for many years. I will miss him a lot. My condolences to Seth's family.

Katie (2014-04-27 19:47:30)

I'm so sorry for your loss. He will be missed.

Graham English (2014-04-27 19:47:35)

So sad. RIP Seth.

Alex (2014-04-27 20:01:59)

Amy, I'm devastated to hear this news. Seth has been an incredible inspiration for improving my family's lives. Please accept my condolences.

Dimitri (2014-04-27 20:17:52)

How sad. Seth was an amazing person. So honest and inspirational. My sincere condolences.

Terry Stewart (2014-04-27 20:32:02)

I am so sorry to hear this. I followed his work closely both here and in my academic career (Roberts and Pashler, 2000 should be required reading for all scientists). His passion for the science and understanding the world around us shone through in everything I read of his. I'll miss him.

JRM (2014-04-27 20:47:14)

I am deeply sadden to learn of his death. Amy, I would like to know if he died of a brain hemorrhage (or other sort of hemorrhage) and what his level of omega 3 intake was. Please fill us in on the medical details. In October, I emailed him this: "I left a comment because you underestimated your omega 3 consumption by a factor of 10. The denominator is 10 g for flaxseeds, not 100 g. <http://blog.sethroberts.net/2013/10/18/omega-3-and-omega-6-in-common-foods-and-my-consumption/> #comment-1152121 " [That is, his omega 3 intake was about 13 grams/day] And he responded with the next day with "thank you for your comment (and the additional info in your email), I took your comment VERY seriously. I have already gone down from 60 g/day to 30 g/day. But it is not so obvious what to do because if I remember correctly I found that 60 g/day produced better results than 30 g/day. I'm not sure about that however. Maybe I am misremembering. Maybe I will stay at 30 g/day for a while and then see if there is any difference when I go to 15 g/day. Seth"

Gerry Mandel (2014-04-27 20:51:00)

I am deeply saddened to lose my dear friend of 35 years. Brilliant, curious, kind, supportive — Seth was a treasured friend who I looked forward to sharing ideas and experiences with for many years. I will miss him a lot. My condolences to Seth's family.

Nick (2014-04-27 20:52:42)

Wow. Unbelievably tragic. I've always been intrigued by Seth and his ideas. I admired him. I wish you and your family the best in this difficult time.

Adam Long (2014-04-27 20:54:54)

As others have already written, and I stunned and devastated by this news. I am so sorry for your loss. My condolences to you and your family. I never got the chance to meet Seth in person, but I learned so much from his writing. What an inspiring person. I am at a loss for words. RIP Seth.

Richard Starr (2014-04-27 20:59:12)

Count me among the many terribly saddened readers of this blog. Condolences to Seth's family.

Melissa (2014-04-27 21:06:23)

Seth's creativity, courage, kindness, and integrity have inspired and helped me more than I can say. We've lost a very fine man.

Shar (2014-04-27 21:12:39)

On April 21 Seth was interviewed extensively by Super Human Radio's Carl Lanore. Condolences to all who cared for and loved Seth.

Lauren (2014-04-27 21:23:20)

This is tragic and shocking news. I've been a reader for years and learned so much from Seth and this site. There was still so much more to learn from him. Please accept my condolences.

Sean Estey (2014-04-27 21:37:14)

I'm absolutely shocked that this happened to Seth. I've never met him, just interacted via a few comments on his blog and an email conversation, but I feel like I just lost someone I know. Seth had such a curious, bright mind and was never afraid to challenge the status quo. A great loss...

Lars Thurfjell (2014-04-27 21:37:25)

My condolences. I met Seth at the 2011 Ancestral health symposium. Very interesting and cool person.

Dragan (2014-04-27 21:46:57)

A very thoughtful and unique person, I'll miss his insights. Dragan

Nancy Lebovitz (2014-04-27 21:49:30)

I'm very sorry to hear of Seth's death- he found and pursued a non-standard and useful way of making people's lives better. I admire his gusto and optimism about how much could be discovered.

Aaron Blaisdell (2014-04-27 21:55:33)

I am shocked. I am in shock. I can't bring myself to believe Seth is gone, and feel like this is some elaborate hoax. Seth has been a dear friend for a long time. My collaboration with him, and my conversations with him, have made a profound impact on my life. His warm companionship, unique intellect, insatiable curiosity, and infinite creativity will be missed. A bit of Seth will live on in me for the rest of my life.

Bryan (2014-04-27 22:02:55)

I'm shocked and saddened. RIP, Seth.

emini\_guy (2014-04-27 22:04:23)

I am stunned and saddened too. I found his ideas refreshing and stimulating. I will be missing him and this blog that he kept posting to so often. Condolences to his family and friends. RIP Seth.

Andrea (2014-04-27 22:05:19)

EVERYTHING that Nancy said, which was perfect. Seth was curious, persistent, and an asset to the human community. I met him once at the Ancestral Health Symposium and he was just as I'd imagined: quiet, shy, curious, and studious. A complete person, at one with his path, it seemed. May his work live on.

Patrick Vlaskovits (2014-04-27 22:08:14)

RIP SETH.

Stu (2014-04-27 22:25:40)

I'm very sad to hear of this. Seth and I never met in person but we communicated over email regularly and became friends.

RIP Seth I will miss our friendship.

Robin Barooah (2014-04-27 22:31:23)

I'm shocked and saddened. I considered Seth to be a personal friend, and will miss him.

JC (2014-04-27 22:43:14)

This is terrible news. Prof. Roberts taught me much about science and health. This is truly a deep loss for the world. My condolences to his family.

R.I.P. Seth Roberts | Uncouth Reflections (2014-04-27 22:48:21)

[...] saddened to learn that scientist, professor, self-experimentation advocate, and best-selling author Seth Roberts has died. I was an avid reader of Seth's blog for years and even met him in person a couple times. [...]

Martha Rotter (2014-04-27 22:51:25)

Thanks for letting us all know, Amy. I'm so sorry for your loss. I am absolutely devastated. Seth made such a huge difference in my life and the lives of so many others, he was an incredibly visionary and forward-thinking researcher. I will truly miss reading his insights & research. So sad to have lost such a brilliant mind. RIP.

Ellis Reppo (2014-04-27 22:54:23)

I learned a lot from Seth by reading this blog. He has helped me in numerous ways. My condolences go out to his family and to those that knew him personally or through this blog.

RIP Seth Roberts | Ben Casnocha (2014-04-27 22:58:36)

Brian (2014-04-27 23:02:35)

Thank you, Seth, for always listening to us and for helping us. Our thoughts and prayers are with your family and loved ones.

Alexander in Sweden (2014-04-27 23:13:03)

R.I.P. Seth, you will be missed by a lot of people.

Allan Folz (2014-04-27 23:27:38)

Wow. Just wow. So sorry for your and your family's loss. I hope you can find some solace that his legacy, heterodox questioning and self-awareness through self-experimentation, touched many tens of thousands of people and made their lives better for it. RIP Seth.

Angel Mac (2014-04-27 23:29:57)

Thank You Amy and So Sorry for your loss. Seth was a Real Human BEing at it's best. Question: Would it Help for readers to "Continue to Donate" To Help KEEP this Blog ONLINE for All to Read ? If not Please POST and let us know what would help Keep this Blog HERE Thanks May Seth continue to send messages to many on this plane.

falconcy (2014-04-27 23:30:32)

Sad to hear that Seth has moved to Shangri-La in the Sky. We met online and knew each other virtually - it was a pleasure to have known him and my thoughts are with his family at this sad time. I'll be drinking a shot of EVCO in his memory tonight.

Jusin (2014-04-27 23:37:19)

Seconding James' comment. I really want to know why he died, if there was a link to one of his self-experiments.

David (2014-04-27 23:38:33)

What terrible news. The world has so few independent thinkers. My condolences to everyone.

Allan Folz (2014-04-27 23:58:17)

It's hard to think about right now, but I agree: if his passing was related to his heavy omega 3 intake, I think he'd want his friends, acquaintances, and readers to know. I am so sorry for all our loss.

Robin (2014-04-28 00:10:27)

This is very sad to hear. A part of me always hoped he'd find a way to hack himself to immortality! Rest in peace Seth.

Anand Srivastava (2014-04-28 00:13:25)

I have been following this blog for a long time. The news is a shock. I thought it was some kind of a joke. He was always self experimenting to figure out how to fix whatever he didn't like about himself. I guess whatever this problem was sneaked up on him. It would be useful for all his followers to know what went wrong. I think he would like it as well. He was a true researcher. We need more people like him. RIP Seth.

Hilly Billy (2014-04-28 00:16:14)

About time.

Kasim (2014-04-28 00:32:16)

He was always self experimenting to figure out how to fix whatever he didn't like about himself. I guess whatever this problem was sneaked up on him. It would be useful for all his followers to know what went wrong. I think he would like it as well.

Jon (2014-04-28 00:55:20)

How sad to hear this news. Best wishes to all those that were close to Seth and his family during this difficult time.

Hamish barney (2014-04-28 01:32:48)

My sincerest condolences to you and the rest of your family. Seth's writing was very important and influenced me deeply. He was an original and deeply original thinker and even though I never met him I will miss him deeply.

Resurgent (2014-04-28 02:04:30)

This is devastating news..! I have had several email exchanges with him - What a fine man..! A terrible loss!! Rest in peace, dear friend...!!

John N (2014-04-28 02:06:13)

Very sad news. I didn't know Seth and I wasn't a poster here, but I'm a longtime reader and a big admirer, his blog has been educational and inspirational. He was a force for good. I hate death.

Daf (2014-04-28 02:11:19)

Such terrible news. Seth's blog has been a "must-read" for me for several years and it's sad to think there will be no more. Please accept my sincere condolences.

Sara Lake (2014-04-28 02:24:16)

Amy, I am so very sad to hear about your loss. Seth was such a bright light, a unique voice for personal science and also just a lovely person. I emailed him 'out of the blue' one day, never expecting a reply, with a request that I never thought he'd be interested in (to publicise my health issue on his blog, so that anyone with info could contact me). Not only did I get an answer almost immediately, but he was enthusiastic about my idea, did it that day, and asked me to keep him updated on my progress. And when I did, he always replied with encouragement and ideas. People just aren't like that, especially busy, quite famous professors. Sad day. :(

Jay August (2014-04-28 02:52:11)

This is really sad news. RIP Seth.

Jo tB (2014-04-28 03:10:58)

So very, very sorry to learn of Seth's death. I only recently discovered his blog and enjoyed reading and learning from it. My condolences to the entire family at the loss of Seth at much too early an age. I wish you all every strength in the coming months in coping with your grief. My heart goes out to you all.

Kasim (2014-04-28 03:15:25)

So sad. RIP Seth.

Daniel (2014-04-28 03:15:51)

So sad. He will be missed greatly - what an original thinker, a true inspiration!

Glen Raphael (2014-04-28 03:18:12)

Ouch. I was not expecting that and am very sad to hear it - thank you for letting us know! (Seth and I had corresponded over the years due some overlapping interests, but hadn't met in person.) How old was Seth? Wikipedia doesn't list his birth date but seems like it ought to.

Laura B. (2014-04-28 03:18:43)

Hi Amy, When is Seth's funeral and viewing? Where will they be located? I would like to go. Thank you. -Laura

Seth Roberts has passed away (2014-04-28 03:50:24)

[...] sad news is here, from his sister, he collapsed while hiking. This is a shock, as I had email with Seth less than [...]

BenSix (2014-04-28 04:06:43)

I was sorry to hear this. My sympathies to those who loved him.

Dan Maldonado (2014-04-28 04:13:19)

Seth was brilliant, and kind. Rest in peace, friend.

Alex Chernavsky (2014-04-28 04:15:12)

Amy, my deepest sympathies to you and your family. I never met Seth in person, but we corresponded for several years, and I spoke with him over Skype a few times. Recently, we started the "Brain Tracking" group for people who were interested in self-experimentation. Seth was a unique individual, and I'm greatly saddened by his death. The loss is profound. I'm co-moderator of the Google+ Group for people who are interested in tracking their reaction time. Although Seth was the main driving force behind the project, I do think that we should continue his work. If anyone is interested in joining the group, you can do so here (you have to have a Google+ account before you can request membership in the group): <https://plus.google.com/communities/114619130176100669530> @Glen: A *New York Times* article listed his age as 52 in September, 2005.

Michael Bishop (2014-04-28 04:17:40)

Amy, I'm deeply sorry for your loss. Seth, Thank you for pursuing truth and sharing the journey.

GB (2014-04-28 04:22:35)

Seth was unique as both an innovator and educator, and generous in how he shared his knowledge and findings in ways that improved the lives of people he'd never meet or who could never thank him. What a tragic loss. RIP Seth and my condolences to his family and friends.

Paleophil (2014-04-28 04:23:14)

Sorry for your loss, Amy. I will miss Seth's interesting take on things.

Morex (2014-04-28 04:28:50)

Amy, please know that you have a couple of SLD successful people in Mexico that are thinking of you, your family and in deep and infinite gratitude for Seth's work and kindness. He changed my life, made think, laugh and realize there is a vast world of knowledge to discover right in front of me. This is a huge loss for humanity. Thank you, thank you, thank you Seth. You left this world a better place and changed the life of thousands.

Steve (2014-04-28 04:48:43)

My life has improved greatly from rigorous application of his insights. I now share them with others as food for thought. His work will forever impact the future. Of all the things he suggested and that I tried – morning faces, nighttime honey/dessert, increased butter consumption, Vitamin D in the morning, introducing fermented foods into my diet, flaxseed for better gum health – I have benefited from, and experimented with. Sometimes it was less the case that the suggestion solved a problem and more the case that it opened my mind to the possibilities of tinkering with and understanding my body more. I've also valued the insights on teaching posted to this blog. /salute

Mark L. (2014-04-28 04:49:14)

RIP Seth! Seth made quite an impact around the world. And I am thankful for his influence on me.

Morex (2014-04-28 04:54:03)

Amy: I just posted about the sad news on the SLD forums. Sorry to bother you with this, but please let me know if you need help running the forums or maintaining them. I own a small web hosting service and I could host the forums for you. Even if they are not so active, a lot of people benefit from those forums. I don't want all that knowledge to disappear. Thank you.

Chase Saunders (2014-04-28 04:59:44)

Seth was a great man. Rest in peace.

Noah Slater (2014-04-28 05:03:48)

I discovered Seth's Shangri-La diet through Aaron Swartz, and unlike so many other things, it made me feel as if I had some control over my weight. His approach to self-experimentation inspired me to start thinking about my life in a similar way. And in fact, I have been working on a percentile feedback tool (with the help of Nick Winter) that helps me make better use of my time. This was directly copied from one of his experiments. Seth has had a profound effect on my life, and I am shocked and saddened to learn of his passing. Thank you for everything, Seth.

Christian Kleineidam (2014-04-28 05:10:02)

Rest in peace. Seth did work that mattered.

Peter Breton (2014-04-28 05:20:24)

I'm shocked and saddened to hear this. Deepest sympathies to you and to his family. Seth affected a lot of lives through his work and his many lively interests. I never met him in person, but I felt that I knew him through this blog. Truly a great loss for all of us.

Mathew Ferguson (2014-04-28 05:22:23)

Seth's work improved my sleep (and life) immensely and I'll forever be grateful for his particular brand of personal science. He was an original thinker and not willing to accept something just because someone said it was so. We've lost a great mind but the people he inspired will continue to self-experiment and step-by-step improve the world.

Dirk (2014-04-28 05:25:41)  
Sad news, rest in peace Seth...

Grant (2014-04-28 05:40:35)  
That's so sad. His was one of the few websites I visited every day for fear that I might miss a fascinating post if I didn't. Rest in Peace, dear Seth

Nassim N. Taleb (2014-04-28 05:44:21)  
Sad, very sad news. I feel deep sorrow. A man of integrity, of intellectual thirst, a friend.

My "Total Fat Loss Solution" Talk - Perfect Health Diet | Perfect Health Diet (2014-04-28 06:06:28)

WW (2014-04-28 06:11:35)  
Seth, rest in peace my friend. We'll miss you. Amy, our condolences. Seth made a difference in our lives by making us think and question.

Mark Levison (2014-04-28 06:12:04)  
Amy thanks for giving us the sad news. May his memory be a blessing. Please share our heartfelt condolences with your family. Seth - thanks for inspiring us, challenging us and making us think.

Brian Beaven (2014-04-28 06:12:29)  
I'm very sorry for your loss. I have been following Seth's blog for a couple of years. I enjoyed his thoughts and experiments.

dearieme (2014-04-28 06:28:28)  
Condolences to all his family. I knew Seth only from his blog and some e-mailing but I'll badly miss our online "conversations". He has added to the sum of human knowledge, and done so with spirit and pluck. RIP.

Christopher Sturdy (2014-04-28 06:33:09)  
My deepest condolences to you and your family, Amy. Seth made a lasting impact with his initial research discoveries about timing and animals. This work has been, and will continue to be, textbook material that generations of professors will teach and generations of students will learn. He continued to make an impact in his more recent work with self-experimentation, as can be seen by the number of posts before this one. His critical thinking and spirit of inquisitiveness and discovery will be missed by all.

Geoffrey (2014-04-28 06:36:15)  
Never commented before, but have read this blog for many years. My sincere condolences, he will be missed.

AI (2014-04-28 06:41:41)  
Very sad to hear this news today. I have always appreciated Seth and his willingness to express views which ran counter to conventional wisdom and political correctness if he thought they were backed up by sound evidence and reasoning. Most of all I appreciated his ideas about the meaning and importance of personal science.

vimal (2014-04-28 06:50:09)  
Amy, I'm so sorry for your family's loss. Seth was a truly innovative thinker and helped many improve their health and well-being.

RIP Seth Roberts | Rhymes With Cars & Girls (2014-04-28 06:56:11)  
[...] Another one of my favorite bloggers. [...]

Scott Pierce (2014-04-28 06:56:16)

Wow. Seth touched a lot of people including me. He was never afraid to say what he believed was right. He'll certainly be missed.

Wil and Judy B (2014-04-28 07:00:58)

Very sorry to hear this, we will miss his writing and his unique way of thinking!

Natan (2014-04-28 07:01:54)

Amy, this is terrible news. Condolences.

Bryan (2014-04-28 07:06:37)

Terrible news. Loved his blog, ideas and his quantified truth-seeking experiments. Not much more to say, but THANK YOU Seth for everything you shared with us.

MJB (2014-04-28 07:07:57)

A great loss. Seth was an original thinker with great integrity.

Max (2014-04-28 07:13:12)

Really stunned and sad to see this news. :( Deepest sympathies to Seth's family and friends. His passing is such a loss, for all of the reasons mentioned above. I hope we can celebrate and continue his spirit of profound inquiry. It feels especially startling given the care Seth obviously gave to his own health (though perhaps this extra attention grew out of a condition we, or he, didn't know about.) Someone mentioned his dosage of ground flaxseed. By my calculations, it would take 22 (large, Nordic Naturals pro-omega) fish oil capsules to match the 13g of flax-derived Omega 3s he took daily. That's a lot. Unrelated to Seth's experiment, I took around the same amount of 4 tbs ground flaxseed for a few weeks but developed spontaneous bleeding in my eye and stopped. (until seeing these calculations today, I had no idea 4 tbs had that much omega 3) Checking this blog had become a treasured nightly ritual for me. Seth's wisdom will be greatly missed.

SM (2014-04-28 07:14:33)

I am so sorry for this loss. Seth was quite unique in his empirical approach to medical problems and blog posts (which I've followed for years now) will greatly be missed. I believe it is unfortunate that his untimely passing might now cast doubt on the efficacy of particular regimens he followed. To those who might think this, remember that there could be other causal factors we did not know regarding his health that could have encouraged him to become active in this field. Amy, again I'm so sorry for your loss. If you ever do decide to release more information about causes that lead to his passing, please let us know. I believe it's an extremely personal topic, but also feel that such information is something that Seth believed could help to advance both the medical field and humanity, in general. Warm Regards, SM

Cliff Styles (2014-04-28 07:16:07)

What utterly wretched news. Seth was an inspiration, he had a lot of work left to do, and now we will all miss both the man and his work. From my contact with him, only through email and this blog, he made me aware that being a good man and a true scientist were one. My condolences to all of those who will miss him.

Kim Kirkpatrick (2014-04-28 07:18:10)

This is a great loss. I include Seth's work in so many of the things that I teach and that I write. Although he and I were never close personally, his work clearly had an impact on my thinking in a major way. He will truly be missed. My sympathies go out to all whose lives he touched.

space (2014-04-28 07:22:06)

I cannot believe Seth is gone... I'm so sorry for your loss. I've been reading him for a long time. What a great scientist he was. Very inspiring human. Whenever you find the strength, if you think he would have liked that, please share the medical reasons why he left us.

Gerry Mandel (2014-04-28 08:09:28)

I am deeply saddened to lose my dear friend of 35 years, Seth Roberts. Brilliant, curious, kind, supportive — Seth was a treasured friend who I looked forward to sharing ideas and experiences with for many years. I will miss him a lot. My condolences to Seth's family.

Charles (2014-04-28 08:12:00)

Sad ;=( A great loss to personal science, and one less good person in the world.

Jazi Zilber (2014-04-28 08:13:57)

What a loss!! RIP Seth. We will miss you. And Amy, any way I can contact you?

Martyn (2014-04-28 08:14:23)

My condolences, as a longtime reader, too. A great and premature loss.

Kelly Valenzuela (2014-04-28 08:17:43)

Please accept my sincere condolences! Seth was a very interesting and kind person, and his presence will be greatly missed. =(

LisaBL (2014-04-28 08:21:26)

OH!! I'm completely shocked! Seth was one of the my favorite QS speakers and we were always really happy when we could get him to make the trek to QSSV. He inspired and challenged so many assumptions. My condolences to your family!

Tim Steele (2014-04-28 08:23:12)

Seth - Thanks for everything! My condolences... Tim

Sarah Madden (2014-04-28 08:30:21)

Just truly shocking news. What a great loss to the world. His memory will live on in the hearts of all the people he has touched with his knowledge and will to make the world a better place. Rest in Peace.

Gina (2014-04-28 08:38:41)

I think for the rest of my life I will continue to wonder what Seth would think about things. I can't believe he's gone.

CeeKay (2014-04-28 09:26:45)

That is terrible news. RIP.

Tucker Max (2014-04-28 09:28:23)

Amy, I am so sorry to hear about this. I am deeply saddened and I can't imagine how it must feel for you. I wrote a tribute to Seth, he had a huge impact on my life: <http://tuckermx.me/rip-seth-roberts/>

Tom Metz (2014-04-28 09:38:09)

Seth changed my life in many ways and I know he's changed the lives of others with his book. The fact that he was so enthusiastic about sharing his thoughts and his experiments was a reality I took great satisfaction from. I feel like all of his blog posts and work are way ahead of their time. Fifty years from now science and public understanding will catch up and those of us here now will point back to this blog. "I think for the rest of my life I will continue to wonder what Seth would think about things." Me too Gina

Mehmet (2014-04-28 09:41:19)

I am deeply sorry and it is hard for me to believe that Seth has gone. He very much influenced me with his scientific thinking and he opened a new door to me through this blog. I will miss his posts and I think the world has lost an important critical thinker.

Ryan Holiday (2014-04-28 09:41:38)

A terrible loss. Someone suggested that we post our tribute here for his family, along with what I believe is Seth's final column. He changed my life in many many ways, and I thank him for that. <http://betabeat.com/2014/04/personal-science-pioneer-seth-roberts-passes-away/> / <http://betabeat.com/2014/04/seth-roberts-final-column-butter-makes-me-smarter/>

nborlaug (2014-04-28 09:42:34)

I agree with a previous poster that to truly honor Seth's work we should ask for a detailed understanding of how and why he died as soon as it's appropriate. I think it's safe to say that is what he would have wanted. Many of us have followed his prescriptions, and is it possible that some of his ideas led to short term benefits but long term consequences? Or did he suffer from some condition, and his experimentation led him to live longer than he otherwise would have? Perhaps we'll never know. But it's worth asking questions when the time is right. If you're interested in joining me in making sure we get answers, email me at [nborlaug@outlook.com](mailto:nborlaug@outlook.com)

Allen Neuringer (2014-04-28 09:43:46)

My condolences to Amy and to all those who valued Seth's friendship, inspiration, creativity, and research – as did I.

Tara Grant (2014-04-28 09:44:00)

Seth I started that journal of personal science you asked me to do. I'm so sorry I didn't write you back last week. I figured out a way to map my mood that you would be very proud of. Thank you for being my mentor. You have changed my life and the way I think and I will be forever grateful.

Craig Fratrik (2014-04-28 09:51:14)

I am so sorry for your loss. Seth fundamentally changed how I view the world. He will be greatly missed.

Gary Wolf (2014-04-28 10:01:06)

Dear Amy, Please accept my condolences as well. I'm shocked and so sad to hear this news. Seth spoke at the very first meeting of the Quantified Self, in 2008, and his supportive advice shaped the community in many ways. If there is to be a public memorial will you let us know? There is a good QS community in the Bay Area; if there are any practical things that are useful, let me know and I'll assist. Gary Wolf

Kelly Barratt (2014-04-28 10:02:36)

I am so very sorry to hear this; Seth's blog has been one of my go-to reads every morning and I've learned to think about a lot of things very differently because of his research and writing. Please know how very much we all appreciated him.

Jacquie (2014-04-28 10:03:55)

Amy, my heartfelt condolences to you and your family. I am so terribly saddened by this unexpected news. Thank you for taking on the unwelcome task of informing us of his passing. I will greatly miss Seth's unique perspective on the many diverse topics that were of interest to him and his readers. He, and the commenters on his posts, challenged my thinking, in the best possible ways, on my notions of health, personal responsibility, fairness, convention and conviction. Most of my days included a visit to Seth's Blog and I am a better educated person for the time I spent considering his ideas, reasoning and criticisms. Seth's sudden absence in my daily routine will be felt for a very long time. His inspiration and the example he set will be with me always.

Mark Frauenfelder (2014-04-28 10:18:22)

Seth was a great inspiration, and an exceedingly generous person. What a shame that his life was cut short when he had so much more to offer. I'm going to miss him very much.

Mo Ibrahim (2014-04-28 10:37:42)

Wow, this is absolutely unbelievable! My condolences to Seth's family.

jseiger (2014-04-28 10:41:24)

Amy, you might be the wrong person to do this, but you or someone Seth would have trusted should try to take some of his blog posts and papers and turn them into a book. Seth was a thinker, and for such people a book is the ultimate testament to their lives.

Omega 3 Fatty Acids for my Brain | Juraj Karpis (2014-04-28 10:47:12)

[...] Seth Roberts was a great teacher who changed my life. [...]

John Eels (2014-04-28 10:51:19)

I'm sad to hear the news. I didn't know Seth personally. I visited the blog often. Seth's ideas have had a great effect on my life. Especially the morning faces.

Joe (2014-04-28 10:52:47)

Like so many others here, I'm shocked. Amy, I'm so sorry for your loss. You have my deepest condolences. Godspeed.

Ashish Mukharji (2014-04-28 11:04:45)

How very sad. Seth made a big difference to my life, as he did for so many others. Amy, I'm so sorry for your loss.

Aaron Blaisdell (2014-04-28 11:05:11)

Seth has a paper in press and should appear in print in a week or two in a special issue of the International Journal of Comparative Psychology on Behavioral Variability that my colleague Dave Stahlman and I are editing. Please check here: [http://escholarship.org/uc/uclapsych\\_ijcp](http://escholarship.org/uc/uclapsych_ijcp) where it will be published. I will forward the link again once the issue has been published.

Andrew (2014-04-28 11:09:32)

A brilliant man who improved so many lives.

as (2014-04-28 11:19:41)

I am sorry for your loss. I know he helped many people with his life's work. What happened?!

Richard Nikoley (2014-04-28 11:29:40)

Seth Roberts. A man I often had a question for and was always honored and surprised that he had questions for me. A truly insatiably curious man, the very definition of a man in my eyes. When I did my AHS11 presentation, he was the first person to the microphone for the Q &A. Every now and then, I'd get an email asking if and when I was going to blog about some thing or the other that I had said (and forgotten) I would blog about. He probably had 3x5 cards or something to keep track. :) What a tragedy. What a loss.

Shant (2014-04-28 11:36:07)

I am devastated by this news. Seth and his work had a profound impact on me, and I owe him quite a bit. It was great getting to know him and work with him, however briefly. I put down my own personal thoughts about Seth here: <http://mrheisenbug.wordpress.com/2014/04/28/seth-roberts/> Rest in peace, Seth. You will be dearly, dearly missed.

Claudia (2014-04-28 11:37:09)

Like all the others posting here, I was stunned to read of Seth's passing. What a vibrant, questioning, questing voice that has now gone silent. I too checked in daily to read the latest posting – a habit that will be very difficult to give up. Thanks to all his friends and family for nurturing that inquisitive, productive mind. RIP, Seth Roberts.

Andrew (2014-04-28 11:40:08)  
It's always about you, isn't it, Richard?

C.M. Mayo (2014-04-28 11:52:25)

My deepest condolences to you and your family. I am one of the many who did not know Seth personally but avidly followed his blog and occasionally entered the fray of the comments section. There are a zillion blogs out there, but Seth's so enriched my life that, from the time I discovered it, I made it a daily ritual to check in- and was almost always astonished by whatever he had posted, and astonished at his continuing generosity. Seth's creativity, courage, generosity, and quest for excellence were truly an inspiration to me-and so many others. His passing is a great loss.

Richard Nikoley (2014-04-28 12:16:05)

Andrew, We value people because they value us. You can look at it any way you like. I lost. You lost. I'm simply telling people how I lost.

Nassim N. Taleb (2014-04-28 12:25:18)

Sad, very sad news. I feel deep sorrow. A man of integrity, of intellectual thirst, a friend.

Sheila (2014-04-28 12:29:52)

Dear Amy, I cannot imagine what your family is going through right now. I am one of the many people (all of us strangers) who tried to help Seth. I called 911, and was on the phone with them until the medics and fire came. I am available to you and your family with a very open heart and with great sadness for your loss. Please contact me if you would like to. I am so very sorry. I have been thinking about your family, hoping to let you know that I am available if I can help with anything around closure, but not knowing how to contact anyone, since Saturday. In humanity, Sheila

Eliezer Yudkowsky (2014-04-28 12:37:11)

I am shocked and horrified. Seth Roberts was responsible for 20 pounds of personal weight-loss for me via Shangri-La, and when I reported that the diet mysteriously stopped working after that, he personally Skyped and emailed with me on suggestions trying to get it working again. His personal spirit of investigation was an inspiration to all of us and is probably to some extent responsible for my trying to compose my own ketogenic Soylent now. I'm sad.

Jack Harris (2014-04-28 12:38:46)

Just stunned at this terrible news. Though I knew him only from this blog, it was obvious Seth was a brilliant and courageous guy with a unique perspective to share. My sincere condolences to his family and loved ones.

Rachael (2014-04-28 12:45:14)

Amy and family, I am so sorry for your loss. I had many an interesting conversation with Seth, and have enjoyed his blog very much. I will be thinking of your family and wishing you peace.

Leroy (2014-04-28 12:46:40)

I came to Seth's blog every day. He greatly enriched my life with his many unique approaches to life's problems. I will miss him greatly.

Paul Langford (2014-04-28 12:49:24)

A real loss. Condolences to all the family.

Ross (2014-04-28 13:07:12)

This is so sad. I will miss his writings very much. Every day that I fired up my RSS reader, I would check for his posts first and many in my family have seen an email from me with a link to his postings. He was a seeker of truth. I wish the best to his family

and close friends.

Seth Roberts: The Best Way To Learn Is To Do | Quantified SelfQuantified Self (2014-04-28 13:17:21)

[...] self-experimenter and personal scientist, died last Saturday. Seth's sister Amy, made the announcement yesterday on his blog. The news was unexpected and very sad. A few things Seth taught [...]

Martin (2014-04-28 13:21:39)

This is really tragic. I am a long time reader and his blog was a never ending source of inspiration. Thanks Seth

Oliver Mayor (2014-04-28 13:23:59)

My condolences to the family. Seth's ideas, curiosity, and compassion helped and inspired me and so many others. I'd hoped to meet him in Beijing some day. This is quite a loss to the world, that Seth left us so soon.

Well this sucks: RIP Seth Roberts | Free The Animal (2014-04-28 13:38:20)

[...] I dropped this comment on the post by his sister, on his blog. [...]

David Smith (2014-04-28 13:48:46)

Very tragic. I've been think about this all day. I didn't know him personally but his blog was probably the most inspirational one that I follow. He'll be missed.

Seth Roberts | Hunter Gatherer (2014-04-28 13:54:17)

[...] was deeply saddened to learn that Seth Roberts suddenly passed away. Many people knew Seth better or longer than I did, but I'd like to share a few [...]

Richard Nikoley (2014-04-28 13:55:26)

Seth let down a lot of people by going and dying. Express how much he let you down, here and anywhere.  
<http://freetheanimal.com/2014/04/sucks-seth-roberts.html>

John Durant (2014-04-28 14:12:45)

Seth inspired me and so many people to improve their lives – in ways large and small. I loved to walk and talk with him. I wrote a short remembrance of Seth: <http://huntergatherer.com/seth-roberts/>

B.B. (2014-04-28 14:18:58)

To Amy and all other family members, I am so sorry to hear of Seth's passing. What a bold and imaginative thinker he was. I always looked forward to his postings. He cared very deeply about finding the truth about things, about what are the causes of illnesses, and truly about evidence-based treatments. I learned so much from his references and observations and speculations. Who can fill such shoes? We need more people like Seth.

Nile (2014-04-28 14:20:43)

Amy, Please accept my very deepest condolences. I spoke with your brother a few times and carried on several email "conversations" with him - the last just a few days ago. I thought he was a brilliant man ahead of his time. I hope you and the rest of your family and Seth's close friends can find some solace in the fact he discovered so much, helped so many people in his far too short life. You are in my prayers.

Duncan (2014-04-28 14:26:59)

My condolences to you and the rest of the family, Amy. I checked the blog every day or two because Seth's posts were always stimulating.

Sue Breedlove (2014-04-28 14:30:11)

Amy, I'm so very sorry to hear the sad news. Seth was a dear friend to me and my sons. Let me know if I can help in any way. Take care.

Tom (2014-04-28 14:30:52)

Seth transformed the world with his brilliance, curiosity and generosity. What a profound loss.

Nile (2014-04-28 14:32:42)

Richard- Using Seth's death to promote your web site is beyond the pale. Andrew was right but far too kind.

Ash Simmonds (2014-04-28 15:02:38)

Well, that sucks. :(

Seth Roberts has died | Economic Sophisms (2014-04-28 15:11:37)

[...] He died on Saturday. [...]

Michele (2014-04-28 15:35:41)

RIP. I am so sorry to hear of this. I feel it as a personal loss as well. I only recently learned of this site. I have done a lot of my own personal health experiments but have gotten mostly open hostility from the world over trying to share that info. I had hoped to talk with him but could not readily find an email and then got busy with life. I feel like another door has closed and nothing will ever come of what I have learned other than my own improved health.

Donald (2014-04-28 15:51:18)

I'm so sorry, what a loss, he made a big impact on my life and no doubt many others.

Jay (2014-04-28 16:38:32)

Such sad, sad news. I didn't know Seth, but I read his blog all the time. There were many things I learned from his writing and self-experiments that improved my health. My sincere condolences to his family.

BRW (2014-04-28 16:56:33)

I wish Seth's loved ones the best. He provided such a valuable platform for new ideas to be explored and information to be shared. His thirst for understanding was contagious, I always looked forward to his posts. I hope he was at peace in the end. Condolences, BRW

Steve Hansen (2014-04-28 17:06:03)

I followed Seth's blog for years and, like so many others, benefited from his approach to science and knowledge. Not just from his personal experiments, but from the ideas he was open to. His blog led me to Nikoley's and to Dr Sarno (Healing Back Pain) and a complete cure of 20 years of back pain. Free. No drugs no surgery – just thinking. Truly life changing. We became friends here in Beijing, where I teach at the university just down the road from his Tsinghua. Amy, if there is anything that needs to be done in Beijing I am happy to do it (steve.hansen@gmail.com). My condolences. Steve

Marian Lizzi (2014-04-28 17:11:42)

Amy, my sincere condolences. I was lucky enough to work with Seth on The Shangri-La Diet. As an editor and a friend, I will miss him deeply. Seth was one of a kind, and a great inspiration.

Peter Eckersley (2014-04-28 18:00:36)

This is terrible news. Will information about Seth's funeral be posted here?

Israel Ramirez (2014-04-28 18:16:44)

I have never met Seth in person but corresponded with him, spoke with him a couple of times on the phone, and read several of his academic research papers. I encountered a smart, gracious gentleman, who was willing to entertain novel ideas. I am very grateful for having encountered him and deeply regret hearing about his passing away.

Dickbutts (2014-04-28 18:27:33)

I'm just going to put this out there, maybe there's a correlation between eating a stick of butter every day and dying while exerting. Just another novel idea I'm sure he would have appreciated studying.

Kudzu Bob (2014-04-28 18:40:30)

His intellect and good humor cannot be replaced. Rest in peace, Seth.

Jim Keller (2014-04-28 19:38:29)

Seth, You were a great thinker and blogger. I read your blog everyday, for insight, outrage and sometimes a laugh. Thank for helping us all look past conventional wisdom, question all the bad answers out there and actually supply some good ones of your own. You helped me certainly and I know many others. Thanks for the quick responses to emails. I found myself thinking "Seth would like this" when I found a gem on the internet. I'll still think that. I'm really sad about your passing. All the best to your family and friends. Goodbye, Jim

Jim (2014-04-28 20:47:25)

Seth, Thanks for your help. You will be missed.

DBH (2014-04-28 20:52:14)

Seth improved the quality of my life. I am grateful for his blog and saddened by his passing.

Robin Benson (2014-04-28 20:56:59)

Can't believe he's gone. Somebody wrote above that Seth "cared very deeply about finding the truth about things". This was my experience also. Thanks Seth, and farewell.

Anon (2014-04-28 21:40:09)

Heart issues eh? Just looking at this blog I can easily tell you why. Fish oil consumption and Salt limitations. Really? You're just begging to die of heart issues.

TSINGHUA\_hyx (2014-04-28 21:46:38)

R.I.P an excellent teacher for me

Viorel (2014-04-28 21:49:14)

So sad to hear about this! RIP, Seth, you will be missed.

Melody McLaren (2014-04-28 22:09:48)

Amy - Like man others, I am stunned and shocked by this news. I've known Seth since we met back in 1978 - when he first joined the UC Berkeley Psychology Department as a young assistant professor and I was a second-year grad student. I think Seth introduced me to you during that early period. We had a long, fascinating friendship that lasted right up to last Thursday, when we were trading emails about the OPTIMA breast cancer trial I'd just joined. I will always remember him for his refreshing, honest outlook on scientific research and his love of experimentation - including wild and wacky projects with food and exercise - as long as I live. He will be deeply missed by me and no doubt man others.

Drini (2014-04-29 00:41:13)

My condolences to the family. I discovered Seth's blog and writings early this year. I loved his theories and his experimental

approach. It's sad that such a brilliant scientist and self-experimenter is gone. This kind of tragic loss really forces you to put things into perspective. We still have a lot to learn and we need to approach the quest for the ultimate health truth-if such thing exists-with humility, positivity and patience. For, even the best of us aren't infallible. Seth, thank you for your work and experiments, for making it available to others and for improving the lives of many. You will be missed. May you rest in peace.

Jason (2014-04-29 03:58:29)

I never met Seth, but his work changed my life for the better. His spirit lives on in each of us who is healthier, happier, and more curious because of him.

Alice Lee (2014-04-29 04:20:28)

Hi Amy, I'm an student from Tsinghua University and Positive Psychology Center at UPenn. Seth has always been my favorite professor, since the very first lesson. I'm flying to San Francisco today. Would it be possible for you to let me see his last place? I appreciate your help. Please contact me at [lixingyu1993@hotmail.com](mailto:lixingyu1993@hotmail.com), if at all possible. Thank you.

Peter Andrews (2014-04-29 05:19:34)

My ongoing life is diminished because I will never again get to click with anticipation because 'Seth has a new post!'. Although I am not religious, i hope against hope that Seth is somewhere now happily observing his new situation, already trying to figure everything out. Miss you already, Seth.

Bill Stuart (2014-04-29 06:53:42)

I am so sorry Seth is gone. His keen intellect, courage and imagination are all too rare. He was a great influence on how I live and see the world. My heartfelt condolences to his mother and family.

Ashley (2014-04-29 06:57:58)

I was beyond shock when I heard the news last night. I took 3 of Seth's classes back at Tsinghua University, and he was the one who introduced me to R and agreed to write a recommendation letter for me 3 days before the deadline, when I had no one else to turn to. He was a great scholar, teacher, as well as a friend. RIP Seth.

Terri Fites (2014-04-29 07:51:00)

Thank you for letting us know. I am sorry for your loss. We will miss his blog and how he reached out to us. Thank you to Seth.

Åse Innes-Ker (2014-04-29 08:50:25)

I am so sorry to hear this.

Brian Toomey (2014-04-29 09:32:12)

What a terrible, horrible loss! I had just emailed with Seth on Friday night putting the finishing pieces on a piece I was writing on how self experimentation had improved me in sleep. Not only had Seth's ideas been the original impetus for my sleep improvement, but he had also mentored me in the design and data analysis in R of my self experimentation, and also been a fabulous correspondent and entertaining writer. I'll miss Seth in all these ways: - As a generator of novel ideas - As perhaps the most rigorous thinker in QS around design & data analysis - As an entertaining blogger - As a friendly, approachable correspondent What a gigantic loss. Thanks, Seth, for all you did.

Matt (2014-04-29 10:39:49)

Shocked and saddened. Seth's writings had a huge impact on me. RIP

Nassim (2014-04-29 11:04:47)

Seth was a great man, an independent and fearless thinker, a person of integrity. But above all he was a loyal friend. A huge, huge loss.

robin (2014-04-29 11:38:14)

Shocked and will miss his insight and Outlook on life

A Note about Seth Roberts | Patrick Vlaskovits (2014-04-29 11:52:18)

[...] Seth Roberts has unexpectedly passed away. Others who knew him more intimately than I did, have already penned, quite eloquently, why he will be missed. See John, Tucker, Ryan, and Richard. [...]

mark johnston (2014-04-29 13:08:35)

RIP Seth

Igor Carron (2014-04-29 13:20:33)

Amy, I am sorry for your loss. Seth was a truly gifted person and we collectively won't be the same without him. Tonight, we will have a heavier heart, I know I will. Godspeed Seth.

Ashish Mukharji (2014-04-29 16:37:30)

How very sad. Seth made a big difference to my life, as he did for so many others. Amy, I'm so sorry for your loss.

Evolutionarily (2014-04-29 18:24:23)

Tragic news, Seth improved my life with his thoughts and will be sorely missed.

Tim Beneke (2014-04-29 18:54:21)

Hi All, I am so stunned and saddened by Seth Roberts' death. We'd been friends since 1997 and had many fascinating conversations. He helped me in so many ways. Specifically, his Pavlovian analysis of weight control and his crucial insight that consuming calories with little or no flavor would reduce hunger, enabled me to lose, on average, about 20 % of my weight and keep it off over the past 15 years. Shortly after I first met him I described my problems with over-eating and pigging out on sweets and fats. He stunned me when he said, "Interesting that no one ever pigs out on fruits and vegetables." Interesting indeed! And his insistence that if I stopped being a night person and went to bed earlier, and tried to get morning sunlight, my baseline mood would improve, turned out to be true, and did far more than anything else to help me come out of depression. I learned so much from Seth – about how to think and how to listen. He was the most intellectually fearless and tenacious person that I've known. He used his brilliance to attack very core problems that caused a great deal of human suffering – obesity, sleep problems, depression – and came up with concrete solutions that truly helped people. His blog was also a site through which many interesting ideas were funneled. He delighted in being able to help people. He was scientific in the best sense – science is simply a method of being rigorously and flexibly sensible and intelligent and open; it was a joy to watch Seth become intellectually excited and pounce upon an idea, a finding, a realization. He became possessed and fascinated at such times. He was unafraid to ask questions or appear dumb. He had such a freshness of mind that at times he appeared to start all over from scratch in approaching a problem and re-think it. I once told him of research about how to improve one's memory; he said that he did not want a better memory. His ability to forget and see things freshly was part of his creativity. I knew him mostly in Berkeley, but more recently in China where we both taught at Tsinghua. In November of last year, I had dinner with Seth and three of his Tsinghua students – it was apparent how much they liked and admired him, and how much he appreciated them. One student said to me, "His students love him." He frequently spoke and blogged about the brilliance and decency of his students at Tsinghua. Ten days before his death we had dinner in Berkeley. He said he wanted to write 8 hours a day until September when he returned to China; he was excited about starting a column on personal science for the New York Observer. The world is worse off without him in so many ways. He had a sweetness that was both personal and intellectual. He had so much more to give to the world, so much more to teach us – it is so sad that we will be deprived of Seth. He was a truly original thinker; such people are rare. A certain original sweetness and a certain original brilliance has left us. My condolences go out to everyone who knew him. Timothy Beneke

K O (2014-04-29 19:29:25)

I always appreciated that he listened to students and lay people with the same respect and attention that he accorded to other researchers. Truly a loss.

Katherine S. (2014-04-29 22:20:02)

I am so sorry to hear of Seth's passing. I learned a great deal from him. So many of us will carry a small piece of him with us, and to us, he lives on in this way. Please everyone, be respectful.

Jonathan Shewchuk (2014-04-29 22:27:22)

After a long time following his blog, I met Seth once, last fall at Nefeli Cafe on UC Berkeley's Northside. We discussed ideas for personalizing courses at Berkeley so that students would learn better. Seth was one of those very rare men who genuinely personified the cliché "thinking outside of the box" instead of mouthing the words. It was brilliant of him to look past his field's staid view of the scientific method to the little-explored question of how to generate hypotheses worth testing. His arguments for why self-experimentation can accomplish some things that large controlled intervention studies cannot accomplish are dead-on. And I have to admire his powers of observation, both in spotting interventions that seem utterly unlikely (in weight loss, depression, mental performance, etc.), and in finding ways to motivate the students in his courses to give unique performances. I'm as stunned as anyone that he died so young. Is there anyone else who thinks like he did?

Aya (2014-04-29 23:24:26)

Thank you Seth, I have many many things to thank you for... Rest in peace.

Mark (2014-04-29 23:50:10)

Wow. Haunting words from his last post: "It was nice to know all that but I did wonder: Was I killing myself? Very sad. My condolences.

dedicated server seedbox (2014-04-30 00:58:18)

I feel this is one of the so much important information for me. And i'm satisfied reading your article. But wanna commentary on some normal issues, The web site style is ideal, the articles is truly excellent : D. Just right task, cheers

sam tanyonovski (2014-04-30 01:17:24)

Seth was an iconoclast of the highest order. Brave, imaginative, and brilliant. I will miss him sorely.

Troy (2014-04-30 04:50:22)

RIP Seth - you were a unique person with a great message that you lived. You've changed a lot of lives and I just wanted to thank you. Condolences to Amy & Family

Justin (2014-04-30 06:20:46)

My condolences to Seth's family. As is evident by responses here and across the Internet, Seth impacted many people's lives in profound ways. While not the only way, Seth did an interview once with a blogger about Uggs. That interview got me thinking about creating a blog about minimalist footwear – FiveFingers, specifically – as I was looking for other blogging outlets outside my of my (considerably less focused!) personal site. The result was BirthdayShoes.com, which has reached a few million eyeballs over the last five years and changed my life in many, many ways. Oh how the ripples grow! Seth once asked me why I blogged and while the reasons are many, his death makes one extremely poignant: your life scales to touching the lives of others in ways you can barely realize. Thank you, Seth, for changing my life in so many ways.

Alice Lee (2014-04-30 06:22:33)

My deepest condolences to your family. Seth was my teacher in Tsinghua University. His ideas were always brilliant and inspiring. He's my favorite professor since the very first lesson. I will miss him.

Julia (2014-04-30 08:52:08)

I'm really sorry to hear this. He was a great guy—even though I never met or corresponded with him, it was thanks to his blog that I was able to stop taking prescription sleep medication. (Vitamin D in the morning makes a huge difference.) His blog also

introduced me to the wonderful paintings of Red Hong. I know he's helped a lot of people, and he seemed totally resistant to dogmatic thinking. What an awesome guy.

Cord (2014-04-30 13:47:25)

My condolences to Seth's family. I can't claim to have known him personally, but I have loved this blog for being so consistently fascinating, literate, and civil: a rare thing in the wilds of the internet. I'll miss it. May his memory be eternal.

Arrigo Benedetti (2014-04-30 14:17:00)

Rest in peace, my friend.

as (2014-04-30 19:41:16)

How I wish I had met him. Is there an obituary? What happened to him? How did he die?

Digby (2014-04-30 19:53:46)

So sad to learn of Seth's passing. I have followed him for several years, enjoyed his experiments and encouragement.

Huan (2014-04-30 22:57:02)

My condolences to Seth's family. I know him in 2010 when he gave a talk at Tsinghua about his self-experiments of changing diets. I was an undergraduate there and very intrigued by his thesis. After that I came to talk to him about my acnes and I thought maybe I could try to identify the reasons for it by adopting his methods. Then we started a spreadsheet to track my diet, sleeping time and other potential factors. I remember it was not easy to get omega 3 oil in Beijing and sometimes he got some for me. I guess there were so many other factors than diet playing role in this experiment and I moved to Shenzhen later in 2010, so we never went deep into the data and analysis. I was a journalism major in undergrad but used quant models to do my thesis. He was surprised at first but then he wrote long emails listing why journalists should learn statistics. Working with him definitely changed my way of thinking and his intellectual curiosity is always an inspiration. I just wish I could have spent more time chatting with him and know him better. RIP Seth.

Primal Retreat (2014-05-01 02:26:30)

RIP Seth - your wisdom will be missed.

Mike Bowerman (2014-05-01 07:53:48)

Shocked and saddened to learn of Seth's passing. Condolences to his family and friends. Seth's unique intellect found insights which improved many lives and will doubtless help still more people as others learn of his work. That he won't be continuing this work is a loss to all. On a personal level, Seth generously spoke and corresponded with me on several occasions which I greatly appreciated. I had always thought I would have another chance to get his thoughts on his work, or have a chance to meet in person. I hope his blog will continue as a legacy and tribute.

nicole (2014-05-01 11:04:28)

This is so sad.

Steve Johnson (2014-05-01 17:55:25)

Amy, Although I never knew Seth he touched my life through his discoveries - every morning I wake up more refreshed due to what he learned and shared. I'm very sorry for your loss.

Stirner (2014-05-01 19:41:05)

How tragic. What more is there to say? Seth was a rare independent thinker and I have every confidence that many of his hypotheses will be decisively confirmed in the long run. In the meanwhile, his legacy lives on in all those he inspired. RIP.

statcruxdumvolviturorbis (2014-05-01 20:58:36)

how old? sounds like cvd. if he didn't have familial hypercholesterolemia then what? why, in god's name, did he die from a heart attack? but, no worries, you'll see him again. if you have any doubts read this: [http://en.wikipedia.org/wiki/Being\\_and\\_Time](http://en.wikipedia.org/wiki/Being_and_Time)

Stephen Yeh (2014-05-01 21:54:55)

I'm stunned. Seth was a bright light. I sat in on his Psych 1 class when I was 17 and followed his career since then, including interviewing him for a paper. He was one of my heroes and role models.

April (2014-05-02 01:43:45)

So astonishing! Seth is a great teacher, I still remember my first course in Tsinghua, he taught us "Current topics in Psychology". He is really really great! RIP. Miss u forever.><

Saul Sternberg (2014-05-02 11:55:41)

Seth and I became interested in each other's research about thirty-five years ago, when he was a graduate student at Brown. In the years since then we were collaborators and friends. (Each of us has attested to how much we learned from the other.) I followed his work in detail, and as you'll see from my comments elsewhere (<http://www.psych.upenn.edu/~saul/about-seth.roberts.pdf>) his scientific accomplishments, I admired them greatly. Except for occasional visits, our interchanges were long-distance ones, phone or email. We discussed many topics – from how to make thicker yogurt to the fairest procedure in considering a tenured professor for dismissal. And of course, various aspects of science. My interactions with Seth contributed greatly to the enjoyment of my scientific life. I am deeply grateful for all that he gave me. Hearing about his untimely death, another friend said: "What a tragedy. I am so sorry to hear that. I know he was a dear friend of yours and a kind of intellectual child. And such a brilliant and brave intellect. This must leave a hole in your world." Indeed, it does.

Clay Kik (2014-05-02 13:42:58)

Seth featured me once. We exchanged e-mails and a few calls. He helped me cope with my bipolar which I am forever grateful. I will be missing him. I checked this blog first thing every morning. I'm so sad we lost a true original. My thoughts and prayers are with you Amy.

Amy Rogers (2014-05-02 18:51:14)

One of Seth's oldest friends today sent an email to Seth's address inquiring about a comment she posted but it hadn't appeared on the blog. I then realized that there were many more comments awaiting approval. Now they are. We are truly touched by your comments and I know Seth would have loved reading them, too. (I hope he is.) As soon we have more information about Seth, we will share it. I can be reached at [twoutopias.amy@gmail.com](mailto:twoutopias.amy@gmail.com). Please note that while I will read your emails, I will not be able to reply to all. Thank you. -Amy

Alex Chernavsky (2014-05-03 03:28:51)

I'm starting to gather remembrances at <http://www.seth-roberts-memorial.com/>. I just started the site last night, so it's a work in progress.

Remembrances on Other Sites | Seth Roberts Memorial (2014-05-03 04:56:06)

[...] Seth's blog — post by Seth's sister Amy (the comments section contains many remembrances): [...]

Jonathan (2014-05-03 06:57:18)

Dear Amy, I am so sorry to hear about Seth's passing. I send healing wishes to you and family. You probably remember me from Tam, where I first met Seth - the brightest kid in a group of very bright classmates. He and I connected from time to time over the years, although not enough and not recently. I was always intrigued by his research and I will follow up via the links on this blog. At this sad time, the outpouring of sympathy and support from so many people who benefited from knowing Seth and his work is a wonderful tribute.

Martin (2014-05-03 07:23:37)

I am another long-time reader of the blog who has never commented before. Seth was a very special person. I am sure there are thousands like me who never met him but who will greatly miss him.

Kurt Miller (2014-05-03 08:09:25)

This is incredibly sad news. I've been a reader of Seth's blog (and book) for many years. I didn't know him personally, beyond brief interactions online. His curiosity, intellect and unconventional ideas have been very inspirational. All the best to those around him. He will be remembered.

ayeppo (2014-05-03 09:45:48)

RIP Seth. Thank you for the inspiration and courage to live your life without the shackles of science, a true explorer. You will be missed.

Agatha (2014-05-03 14:13:16)

Very sad to hear this news. Seth's self experiments were an inspiration. He will be missed. Blessings to his family and friends at this time.

Matej (from Slovenia) (2014-05-03 15:08:18)

I am stunned. My condolences to Seth's family and friends. I was following his blog for many years and I admired him for the unconventional ideas, self-experimentation and original research and blog posts. I was inspired by him. I feel so sorry. Even though I didn't know him personally I will miss him. RiP Seth.

Nassim N. Taleb (2014-05-03 17:18:40)

(I apologize for the duplication but my posts were not showing up).

Anne (2014-05-04 02:04:11)

My deepest condolences to you and your family. Seth was the light to me since many year. I have learned so much from him and all the followers comments. As some earlier wrote, when emailing a question Seth responded very quickly I hope you will find a way to keep the site up, as there is so much wonderful work and articles here posted by Seth We will miss him very much. RIP SETH

Ashu@Kathmandu (2014-05-04 05:00:57)

I followed Seth's blog religiously for the past several years. It was among the first things I read everyday. I learnt a lot from his thoughts on general science and personal science, on how to learn, and even on how to sleep soundly on airplanes! He was someone who never let anything get in the way of his pursuit of the verifiable truth. He was indeed a searchlight of a man, who illuminated many things with simple experiments backed by profound questions! May he rest in peace. I will greatly miss him.

Peggy (2014-05-04 05:37:32)

I'm going to miss Seth; I've been reading his blog daily for several months. He convinced me to try skipping breakfast (something I had never tried before), looking at faces in the morning instead of being surly and avoiding eye contact, and eating honey or other carbs before bed to improve sleep. His recent posts on Omega-3's were also very interesting to me. My condolences to all his family, friends, and followers.

shtove (2014-05-04 05:44:00)

So sad. My condolences.

Weekend Link Love - Edition 294 | Mark's Daily Apple (2014-05-04 07:37:45)

[...] Seth Roberts has died, and with him goes an interesting, brilliant man, a fearless self-experimenter and a platform for new

and useful ideas. Others have shared their remembrances of Seth here. Honor him by always being curious about everything, even the things you know to be true. [...]

Seth Roberts | Megalomania:me (2014-05-04 13:45:45)

[...] Roberts died on Saturday. This is very sad news for me. Dr. Roberts was a huge inspiration and I'll miss [...]

Patti (2014-05-04 15:01:08)

I loved his uniqueness.

Jenny (2014-05-05 02:23:44)

I am terribly sorry to hear about Seth. I have read his blog for years and will miss him and his ideas enormously. My condolences to all of you who knew him personally - he is someone I had always hoped to meet.

Jan (2014-05-05 06:51:37)

My deepest condolences. I too am shocked. Whenever I was tired by all the dogma around me, I opened his blog, read some of his entries and suddenly everything was more bearable. Jan from Slovakia/Austria

Anna (2014-05-05 10:24:55)

I was stunned when I opened the blog a few days ago and saw the news. I didn't know or correspond with Seth but I read his original paper that eventually became the SLD book and followed his blog whenever possible. He was brilliant and so good at puncturing inflated claims made by the medical establishment. I always wanted to tell him that most of the things he did for himself did not work for me at all but he taught me how to find the things that do. The world needs a lot more people like Seth. My deepest condolences to the family and friends. And please let us know what happened.

JohnG (2014-05-05 11:08:45)

Seth's dedication to science regardless the outcome meant so much to me. We corresponded a few times and even spoke over the phone once. He was so amazingly pleasant and caring. I'm terribly saddened for the loss. He was a hero in my eyes. JohnG

john (2014-05-05 12:29:25)

Thank you, Seth, for the invaluable things I learned from you by reading this blog! I miss you... RIP

Gianna B. (2014-05-05 15:58:50)

I've followed Seth's blog for years and always admired his critical thinking, curiosity and lack of complacency to blindly accept conventional wisdom. It's so hard to believe he is gone. I guess part of me wishes that he really hasn't died, that this was another QS "experiment" of Seth's ... to see how many web hits could be generated quoting from a single 50-word post ("Hello, this is Seth's sister, Amy, with the sad news...") without any other corroborating sources such as published obituaries, mortuary listings, a Berkley press release, a hospital reference or news articles from even a small or local newspaper, an alumni newsletter, other public family statements ... anything. But I'll keep watching and keep google-ing, hoping it's just a bad dream.

Everette Twining (2014-05-06 00:29:52)

I have, admittedly, only a vague sense of awareness when someone mentioned to me that he had died. Regardless, I'm sorry to hear of his passing - every death leaves an emotional tear in the fabric of friends. No mention of a couple of things: how old was he when he died, and what was the cause of death?

Sam (2014-05-06 00:36:03)

These are really bad news! I hope this is not some side effect from the self-experimentation - I remember some study stating that too high Omega-3-dosage could lead to epileptic seizures (but never found that study again). Most important: My condolence to you, Amy, and the rest of Seths family and friends! Seth will be missed!!

Rachael (2014-05-06 21:05:55)

Amy and family, I just stopped by to say that I am thinking of you, I know how sad it is to lose a brother. I hope you are having some comfort in the number of lives your brother has touched, and that you feel joy in the number of people he has changed and influenced. I continue to miss Seth, and hold you all in my thoughts. I wish you peace.

Rachael (2014-05-06 21:06:24)

Influenced, I meant.

Kim Øyhus, physicist (2014-05-07 01:16:29)

Seth was a real genius, making real original discoveries, unlike those fake geniuses having misleading high scores on such as IQ and grades.

Ben Rubin (2014-05-08 17:56:40)

Seth was a friend, mentor, and inspiration. He made a difference - and we won't forget him.

Alexis Gallagher (2014-05-09 12:25:19)

This is truly heart-breaking news. Such a loss. Two things always amazed me about Seth. First, that he was such an original thinker - really, truly, genuinely original, in a deep and intelligent way. Second, that he managed to remain so optimistic and so cheerful! He did this despite facing the incomprehension and neglect which comes from being so original. I am sure he could have made his life much easier, professionally, by doing work that was more conventional. But he did not. In this way, he has been a model to me both intellectually and emotionally, a model I do not expect to live up to. I was working on a project that I was very keen to share with him (an app inspired by his blog posts on Magic Dots), and it's hard to believe now I will never have the chance to show him. I am sure his passing is a great loss not only for us but for the many people who do not know him at all, but certainly would have benefited from his curiosity and his courage.

Iris Lamb (2014-05-12 17:53:02)

I am shocked and saddened. My heartfelt condolences to Seth's family, and to the world at large, which has lost an innovative, creative, courageous man. He will be missed.

Galen Cranz (2014-07-07 09:44:40)

Seth! I just learned tonight why you failed to show up on the 26th of April as we had planned. I didn't want to bug you so I didn't call or email to ask what happened. Now I know. I finally sent an email tonight asking if you were alright-'cause it wasn't like you to disappear. I am in shock to know that my worse fears are true. Seth came to see me after the publication of *The Chair* in 1998. No other colleague sought me out on the basis of ideas. Turns out we were both Reedies, and I proposed that we teach a course together, "The office of the future" (which we thought of as neolithic). We did, twice, once with others from the business school, "The Post-Dilbert Office." We were both interested in nutrition and food and ate together in NYC and the Bay area intermittently. We had dinner at the new restaurant that replaced O Chame on April 24. He offered to help me with some computer issues on the afternoon of the 26th. Seth, my friend, this is your friend Galen, saying farewell--and re-opening to the depth of appreciation I have for you. You'd love the book I'm reading now. Dang, I wish we could talk about it after you read it. Love, Galen

## 9.5 May

### Cause of Death (2014-05-10 07:00)

Hello, this is Seth's mother Justine. I'd like to offer what little information I have to try to answer some of the questions that were posted about Seth's death. We're told that we'll get a full coroner's report in about 6 months. In the meantime we were given only "Cause A: Occlusive coronary artery disease" and "Other significant conditions: cardiomegaly."

Most of you won't be surprised to learn that Seth had not visited his doctor in Berkeley in many years, and, responding to a recent question, said that he hadn't been to a doctor during his stay in Beijing either. We are left with 3 sets of paper records. The earliest, dated 2009, reports a Coronary Calcium (Agatston score) screening which he discussed [1]here last October. He obtained a second screening 1-1/2 year later. The first report showed his coronary artery occlusion to be about average for a man his age, with an accompanying risk of heart attack, but no cardiomegaly. The second report, following his conclusion that butter was beneficial for him, and his heavy ingestion of it, showed an improvement in his score: "Most people get about 25 % worse each year. My second scan showed regression (= improvement). It was 40 % better (less) than expected (a 25 % increase)." The report showed the calcification to be unevenly distributed, with most found in his left main coronary artery, and none in all but one of the other arteries. Again, no heart enlargement was reported.

The second medical report set, done in December 2011, was from Beijing and covered an exam that may have been required by his employer, Tsinghua University. This included a physical exam, an x-ray and EKG. All reports were negative, i.e., no abnormal findings and no cardiomegaly.

The third set of reports, from a laboratory in St. Charles, Ill., used data collected in Berkeley. They list toxic and essential elements in his hair. The latest report, dated July 18, 2013, showed one element rated "high." This was mercury, "found to correlate with a 9 % increase in AMI [acute myocardial infarction]" according to the report. His level was assumed to indicate exposure gained from eating fish. Presumably Beijing's toxic smog contributed directly both to the mercury level of the fish that he ate there, and to the level in his hair.

The only information about his blood pressure was in the Beijing report where it was recorded at 117/87. I could find no information about cholesterol levels, though it has not been a familial problem. Of the remaining Framing-

ham Study risk factors: Seth did not smoke or have diabetes. He was not overweight and was physically active. Seth's father died of a heart attack at 72.

Of course, I can't end this posting without sending my deepest thanks for all of the kind notes posted here. They were hurtful to read because of the reminding. They were healing to read because of the solace gained from learning about his friends and that he was able to help many people.

-Justine

Aaron Blaisdell (2014-05-10 07:15:51)

Hi Justine, I am truly sorry for your loss. It is still hitting me very hard as well. Thank you for taking the time to provide us with the details of what you know regarding Seth's death. You and Amy are in the collective hearts of everyone who's life Seth touched in a meaningful way. We all miss him very much.

Alex Blackwood (2014-05-10 08:40:29)

Justine, my condolences to you on the loss of your son. You and Amy have been incredibly kind to share information about what happened to Seth. Thank you.

Melissa (2014-05-10 09:05:01)

I cringed every time I saw someone ask for this information in sympathy for your family at this time of such loss. You've made an incredibly gracious gesture at a time when no one had any right to expect such a thing from your family. It is very much in keeping with how I imagine Seth would have wanted it handled and it's clear that he gained a great deal of what made him so special to so many people from you and your family. Thank you so much.

Alex Blackwood (2014-05-10 09:55:43)

For those of us who want to continue the conversation from Seth's blog, I have started Seth Roberts Community on Google Plus. It's a place to share and discuss interesting items you might have found on Seth's blog. Feel free to join. <http://plus.google.com/communities/101301560863575453174>

Adam Long (2014-05-10 10:11:22)

Thank you so much for posting this information. I am so sorry for your loss, and my thoughts and prayers are with you and your family during this terribly difficult time. In trying to explain to friends who were unfamiliar with Seth what the loss meant to me, I realized that the best way to express my thoughts is to say that Seth was one of my heroes. "Hero" is a word I don't use much anymore, but it certainly applies to him. Thank you.

Martin (2014-05-10 10:43:50)

A hero indeed! Condolences again to Seth's family and thank you to them for caring about the rest of us who did not know him as well but who also miss him very much.

emini\_guy (2014-05-10 10:56:06)

Thank you for this information and condolences to Seth's family and friends once again. He will be missed.

Natan (2014-05-10 12:00:32)

Thank you, Justine.

Philip Kilner (2014-05-10 15:01:38)

Hello Justine, I'm very sorry for your loss, and very grateful that you have been able to give us this update. I'd just like to say that Seth's writings helped me lose five stone in weight with the Shangri-La Diet, and - more importantly - helped me to take ownership of my own health issues, and to think about them in a new way. I will miss reading his work, but he has made a lasting change for the better to my life, and that will stay with me as long as I live. Not many of us can make that sort of difference to the lives of strangers. Thinking of you and your family at this difficult time, Philip

Patti (2014-05-10 16:02:27)

Justine - thank you for your post about Seth.

Pauline (2014-05-11 01:57:11)

Thank you for sharing this at such a time of loss...brave, generous and compassionate, I can see where Seth learnt these qualities.

Robin Benson (2014-05-11 02:46:03)

Thank you Justine. Apples do not fall far from the tree.

Danielle (2014-05-11 16:00:05)

Dear Justine, I am so sorry for your loss. Seth was loved by so many. You have my deepest Sympathies. Danielle

Suzanne (2014-05-11 17:06:02)

Justine, Thank you for going to so much trouble at this difficult time for the family. I'm so sad for the loss of Seth. He was a remarkable man in many ways. His forthright views and willingness to investigate scientifically AND listen to other people's opinions was great. I benefitted much from the posts, the news snippets he posted links to, as well as his great stories. I learnt about aspects of life in China too. We have lost a great champion of academic ethics in Seth and I deeply regret that few will take up the fight that he bravely waged against corruption and distortion in universities. I'll continue to experiment with methods for better sleep, weight loss and health, but will miss these daily 'chats' with Seth (as that's what his blog felt like to me.) Happy Mother's Day - you did a great job!

Sara Lake (2014-05-11 17:30:36)

Justine, thank you so very much for your touching openness in sharing with us. I know Seth would have wanted that, he never held back, even when what he had to say was controversial or contradictory.

Steve Greenleaf (2014-05-12 04:35:34)

My condolences to Seth's family and friends, as well as fellow readers. We will all miss his voice among us.

Bob (2014-05-12 06:12:11)

My condolences. Modern medicine will likely point to blockages as the cause, but even that conventional wisdom may be inherently flawed. <http://www.westonaprice.org/cardiovascular-disease/what-causes-heart-attacks>

space (2014-05-12 08:36:23)

I'm deeply sorry for your loss. Thank you so much for keeping us updated. We will all try to understand what happened.

JohnG (2014-05-12 08:44:40)

Thank you Justine. It was thoughtful to release that information.

nicole (2014-05-12 11:05:12)

Justine, Thank you for this post. I really appreciated it. I also remembered Seth posting about getting medical labs done near his house: <http://blog.sethroberts.net/2014/03/20/cheap-accurate-home-hba1c-test/> Maybe you can find more data from those tests. Thinking of you and your family and this great loss.

Morex (2014-05-12 15:05:18)

Justine, Thank you very much for posting this and keep us informed. Seth was a hero for me in many ways. He saved my life through his work and kind words. Rest assured that like many people here, we won't let his memory fade away. All my love and thoughts to you and your family.

Kirsten (2014-05-12 16:48:53)

Justine and Amy (and family)– I am so deeply sorry for your loss and appreciate your posts here. I've read Seth's blog regularly since 2006 and was for a short time a participant in the SLD forums. And I will always be glad that an exchange with Seth just a few months ago led to an e-mail where I explained what I had learned from his work and how I had put the principles from his blog into action. Since learning of his death, I have felt a real sense of loss. I miss his point of view–I looked forward to seeing where his inquiry took him and the way his thoughts developed. I can only imagine what it's like for those who knew him in real life. He was one of a kind. Deepest condolences– Kirsten

Laura B. (2014-05-13 22:39:28)

Dear Justine and Amy, Thank you for taking the time to write about Seth. –Laura

Althea T. Kippes (2014-05-14 14:10:54)

Dear Justine and Amy, I am so sorry to hear of Seth's passing, and please accept my deepest sympathies for your loss. I met Seth when I was living in Berkeley and in law school. He was such an intelligent, creative, and caring person, as well as quirky and fun. Doing things with Seth was always an interesting adventure. I can't believe that he is gone... Seth's spirit will continue to live on in all of the people that he touched in his life and in all of our memories. –Althea

JiPé (2014-05-16 20:37:17)

I've been reading Seth blog for about a year, but recently stopped for a couple of months. I read his posts from a RSS reader and just begun reading from where I left of. I could not have expected something so tragic could happen. I can feel your pain and the pain of all the readers who have found in Seth the hope of a solution for their health problems. I'm very sorry for your lost and I wish to thank you deeply for informing us about the cause of his death. Something you would not have to do, but probably did knowing your son would have liked it so. Thank you. I send you all my love. Maybe someday, this blog would become a book. I think it should, so we could remember him more deeply, like we had a part of him in our home, and our hearth.

Jeff Baird (2014-05-16 23:30:59)

Hello, A note for Seth's family – I'm so sorry for your loss. I work for the BBC World Service in London. We interviewed Seth for a radio program we did a few years back on the new breed of self-trackers. If you would like a copy of an mp3 of the interview please drop me an email (jeff dot baird at gmail) and I'll try to dig out a copy of it from our archives. best regards, Jeff

Dave in Berkely (2014-05-18 13:16:56)

Justine - I am a friend of Seth's here in Berkeley. I have already been in touch with Amy, and want to communicate my condolences to you also. His passing came as quite a shock to me. I can't imagine how it might have been for you. Since you

have brought up the issue of the hair test (actually, there were multiple), and since I am the one who was involved with Seth on this issue, perhaps it is now appropriate for me to say something about it. Seth had a mouthful of amalgam fillings. Worse, he also had gold in his mouth; and when differing metals are in combination like this in the same mouth, the less noble one will just dissolve into the saliva. Dental text-books are quite clear that these combinations should be avoided, but dentists routinely ignore it. While I had talked to Seth for a long time about the issue, it was only when I got him access to a Jerome mercury vapor meter that he took it seriously. The level of mercury vapor in his oral cavity was astronomical. If I remember correctly, it was measured at nearly 60mcg/m<sup>3</sup>, some 200x EPA limits for long-term exposure. (That's off the top of my head. If relevant, I can check those numbers.) As a result, he had his amalgam fillings removed. Subsequently, Seth began to do hair tests, which were uniformly and over a period of years, high in mercury. I tried to tell him that the problem was not gone. That the half-life of mercury in the brain is some 25 years, and so he needed to consider the question of detoxification. Particularly as some of his symptoms, including the insomnia, were certainly consistent with mercury toxicity. And, his need for so many omega-3 oils seemed to indicate a high rate of oxidation of these oils in the body. He listened, but never really did anything about it. Since the main targets of mercury toxicity are the electrical tissues (brain & heart) and the detoxification organs (liver, kidney & skin), I can't help but think that this must have been a factor in his untimely death. I am sorry to have lost a good friend. I encourage others to consider this aspect of health quite seriously. To explore it further, you can contact DAMS at [amalgam.org](http://amalgam.org). They keep a list of amalgam-free dentists and sympathetic MD's. (Though beware of their detoxification advice.) You might also join the [adult-metal-chelation@yahoogroups.com](mailto:adult-metal-chelation@yahoogroups.com) and [frequent-dose-chelation@yahoogroups.com](mailto:frequent-dose-chelation@yahoogroups.com) lists, and have a look at the books "Amalgam Illness: Diagnosis and Treatment" and "Hair Test Interpretation: Finding Hidden Toxicities" by Andrew Cutler ([noamalgam.com](http://noamalgam.com)). These latter resources provide a slow, low dose, physiologically appropriate detoxification protocol. (It's not just the detests who are failing to read their textbooks. When it comes to chelation, the MD's don't do follow their own advice on the proper dosing of pharmaceuticals.)

Sheila Buff (2014-05-21 08:42:09)

Dear Justine and Amy, I was deeply saddened to learn of Seth's untimely death. I worked with Seth on the writing of The Shangri-La Diet. We had a lot of fun and learned a lot from each other. Seeing the book succeed and help so many people was very gratifying for us both. Seth's legacy will live on through the people he has helped and through his inspiring teaching.

Digby (2014-05-25 15:12:51)

My condolences on the death of your son. We all have lost a wonderful, open, sharing, and brilliant man. I've sampled Seth's blog and papers for fifteen years, and was always struck by his comity and generous spirit. The best always die way too young.

Steven Jonas (2014-05-28 11:56:29)

Like Melissa, I cringed while reading comments demanding to know the cause of Seth's death. Still, as someone who has adopted several dietary changes based on his work (and tested their efficacy), I have to admit to wanting to know those details because they seem important. But I know that I have no right to that information, and can imagine that as a family member, it must be hard to publish it. I really appreciate that you did so, when you didn't have to.

Noumenon (2014-05-29 00:10:30)

Hey, thanks so much for posting. While we on the Internet don't have any right to know this stuff, we sure are curious and interested. This is a much better capstone to the blog than just trailing away.

Anna Purna (2014-06-01 04:44:18)

Quote from post above: "The only information about his blood pressure was in the Beijing report where it was recorded at 117/87. " That indicates a rather narrow pulse pressure. [http://en.wikipedia.org/wiki/Pulse\\_pressure](http://en.wikipedia.org/wiki/Pulse_pressure) 117 systolic minus 87 diastolic = 30 pulse pressure 30/117=25.65 % Quote from Wikipedia:"A pulse pressure is considered abnormally low if it is less than 25 % of the systolic value. The most common cause of a low (narrow) pulse pressure is a drop in left ventricular stroke volume. In trauma a low or narrow pulse pressure suggests significant blood loss (insufficient preload leading to reduced cardiac output). If the pulse pressure is extremely low, i.e. 25 mmHg or less, the cause may be low stroke volume, as in Congestive Heart Failure and/or shock. A narrow pulse pressure is also caused by aortic valve stenosis and cardiac tamponade.

## How Little We Know: Big Gaps in Psychology and Economics (2014-05-22 12:18)

Seth's final paper "How Little We Know: Big Gaps in Psychology and Economics" is published in a [1]special issue of the [2]International Journal of Comparative Psychology (Vol 27, Issue 2, 2014). This issue is about behavioral variability and is dedicated to Seth. Abstract of the paper follows:

A rule about variability is reducing expectation of reward increases variation of the form of rewarded actions. This rule helps animals learn what to do at a food source, something that is rarely studied. Almost all instrumental learning experiments start later in the learning-how-to-forage process. They start after the animal has learned where to find food and how to find it. Because of the exclusions (no study of learning where, no study of learning how), we know almost nothing about these two sorts of learning. The study of human learning by psychologists has a similar gap. Motivation to contact new material (curiosity) is not studied. Walking may increase curiosity, some evidence suggests. In economics, likewise, research is almost all about how people use economically valuable knowledge. The creation and spread of knowledge are rarely studied.

The family is grateful to Aaron Blaisdell Ph.D. who completed final edits to Seth's final manuscript for publication.

Joe (2014-06-15 12:43:50)  
Does anyone know why there has been no obituary for Seth in The Daily Californian, the UC Berkeley newspaper?

peter (2014-06-27 12:18:28)  
readers of this blog should find a way to continue Seth's work by contributing interesting articles and self-reporting. the problem is finding someone to sort thru all the submissions. any thoughts?

Joe (2014-06-29 12:18:40)  
Peter, I'd like to see it, too, but I have no idea how that could actually be done.

peter (2014-06-29 13:05:24)  
seth's family controls the web site; so we'd have to start with them (after an appropriate period of time); then perhaps a like-minded colleague at Berkeley. Alternatively current readers, although it's not clear if anyone is qualified to sift thru the

articles. Also, there would have to be one person in charge (if everyone is in charge, then no one is charge).

Alex Chernavsky (2014-06-29 18:52:20)

Alex Blackwood started a [1]Google+ Community for people who are interested in continuing Seth's work.

Amy Rogers (2014-07-01 15:34:10)

Hi all, I appreciate all the interest in continuing Seth's work. I want to help where I can. I do need to make a decision what to do with this site and the sethroberts.net forum. I am open to all suggestions what you want to see happen to them. Please send your suggestions to [twoutopias.amy@gmail.com](mailto:twoutopias.amy@gmail.com). If you wish to debate an idea with others, please take it to the [1]Seth Roberts Community on Google+ or, for non-Google users, start a topic in the [2]forum under "Self-Experimentation > General." I'll be listening. @joe An obituary was placed only in one major newspaper, [3]*San Francisco Chronicle*. Amy

Geraldine (2014-07-10 11:02:34)

I am stunned to read of Seth's passing, just found out about it this morning when someone left a comment on my book review of the Shangri La Diet. My sincere condolences to all of Seth's family and friends. He was a unique individual and a very caring, giving person, from what I knew. We corresponded by email for a few months when I read, used and wrote about the Shangri La diet, several years ago. This makes me so sad...may he RIP.

## 9.7 July

### Assorted Links (2014-07-31 05:00)

These final assorted links were found in draft mode. - Amy

- [1]Postdoc leaves academia (fMRI emotion research). "I actually ran into that process in three different labs, two of which were at TopUniversityA with PIs who I highly revered and respected. It's just how it goes in those fields...remove all of the negative results, don't actually report the ridiculous number of fishing expeditions you went on (especially in fMRI research), make it sound like you mostly knew what you were going to find in the first place, make it a nice clean story. When my colleagues (from a well-known, well-respected emotion research lab) were trying to talk me into removing all of the negative results and altering what my original hypothesis was, literally saying "everyone does it..." that was it for me. I had a sinking feeling that everyone did do it that way and that I couldn't trust the majority of work I had to depend on/reference myself. The level of denial in psychology and human neuroimaging research that this process just clogs the system with useless BS is something I just can't stomach." Devastating criticism – especially finding the same thing in three different labs. I believe nothing involving fMRI and psychology. My friend Hal Pashler [2]wrote about this. At UC Berkeley, the fMRI machine used by psychology researchers malfunctioned for years. Nobody noticed. Only when someone from UC Davis got different results at Berkeley was the problem detected.
- [3]interview with me about the Shangri-La Diet. The questions do a good job of making the mechanism clear.
- [4]Little or no benefit of antidepressants when children are asked

Thanks to Nile McAdams and Alex Chernavsky.

gwern (2014-08-01 07:35:33)

BTW, I finished my randomized experiment investigating Seth Roberts's claim that using a walking treadmill helped his spaced repetition scores. I found that it did not help, but it hurt: [#treadmill-effect-on-spaced-repetition-performance-randomized-experiment](http://www.gwern.net/Treadmill) > Little or no benefit of antidepressants when children are asked Fulltext: <https://pdf.yt/d/ip9cxFsWLNiTpymo> / <https://www.dropbox.com/s/d0k4gz0sj6a28yg/2014-spielmans.pdf> I was under the impression that the depressed are poor at noticing improvements even other people notice in them, so I'm not sure whether this shows anything.

Laura (2014-08-02 07:52:30)

Thank you so much for posting these. The interview is great. I really miss Seth's blogging.

JP (2014-08-16 04:05:58)

Thank you SO much for keeping Seth's blog up and running. His year's of posting are a treasure trove of insight and research that I refer to often. If it's not too much trouble, could you give us some notice if you ever decide to take it down?

## 9.8 August

### Videos of Seth Roberts Memorial Talks (2014-08-20 07:10)

Video recordings of [1]Ancestral Health Society's public talks on August 10, 2014 honoring Seth's life and work are posted at [2]<http://bit.ly/1v33kbM>.

Many thanks to Tess McEnulty for putting together these videos, adding captions, and making them accessible. - Amy

Dan Maldonado (2014-08-20 20:06:44)

Thank you for posting this.

Robin (2014-08-25 01:20:07)

Thanks for this. We miss him.

GB (2014-09-16 11:26:44)

Thanks Tess and Seth's family for posting these. I still check the blog occasionally but it's not a daily ritual any more, I didn't know Seth but I miss him. Thanks to everyone who contributed to the talks, and of course thanks Seth for your body of work.
