The best word I can think of is deprofessionalization. Unfortunately that has been used [1]with a different meaning. Amateurization doesn't work because amateur often means hobbyist. Popularization doesn't work because the status of the activity has changed – from something done as part of a job to something done not as a job. It is one of several ways a job can change:

- More efficient. New tools, materials, etc., make it possible to do the same job in a shorter period of time or at lower cost.
- Higher quality. New tools, etc., make it possible to do a better job.
- More exclusive (= higher barriers to entry). Something (e.g., licensing requirements) makes it harder for others to compete with you.
- Less exclusive. Something (e.g., the Internet) makes it easier for others to compete with you.
- ????. People no longer need to hire you or someone like you to do what you do. They do it themselves.

I care because personal science (science done to help oneself) is an example. For a long time, non-trivial science was done only by professional scientists. Now it is being done by non-professionals.

More What about publicization? Or is it too ugly? I looked up democratization as a possibility but found this under "democratization of photography": "Serious photography has gone from being the preserve of the reasonably well off to something that just about anyone can take up with minimal expense". That isn't what I mean here – that the price of something comes down. Hoipolloization is too long. What about massification?

Still More It really is DIY, I hadn't thought of that. That exactly conveys the transition from job to non-job. DIYing (or should it be DIYization?) has a nice ring to it, is very short, is not pompous, and would not need to be defined. I also like promethization, deguilding, democratization, and deprofessionalization.

1. <http://www.medscape.com/viewarticle/494608>

---

Tim Beneke (2012-02-10 23:25:49)

How about "X democratization" with the domain as an adjective? Or "democratized X"? Democratized scientific research; democratized publishing; or demo-technologized publishing/science/photography...? Or demotechnic?

David Johnston (2012-02-10 23:45:00)

Despecialization seems to fit.

Jim Purdy (2012-02-10 23:51:57)

1. – Meme Break Out (like a jail break) 2. – Idea Break Out (same as 1. above) 3. – De-Walling (like taking down the Berlin Wall) 4. – De-Latinization (like when the Catholic Church in the 1960s moved away from the Latin Mass) 5. – Epidigm or Epidigmia, or Epidigmatic (When a paradigm breaks out and spreads rapidly, like an epidemic)

Seth Roberts (2012-02-11 00:04:32)

The problem with "despecialization" is that it is not the reversal or undoing of specialization. On the other hand, I may not be able to do better...

Seth Roberts (2012-02-11 00:07:20)

"democratization" already has a (different) meaning but yes, that is close to the spirit of it. The specialists no longer have a monopoly.

Seth Roberts (2012-02-11 00:23:07)

Yes, "break out" is how I think of it.

gaspard (2012-02-11 00:25:16)

Democratisation is used to mean this in French, among other things - 'accessibility' is also used in British English. I heard a great soundbite way of expressing this by an open source software guru "zero to expert in zero dollars".

Ian (2012-02-11 00:35:37)

Laification? It's close, but it sounds a bit too much like religion should be involved.

Seth Roberts (2012-02-11 01:37:32)

"laification" is very close in terms of meaning ... it is just too obscure, "laity" being a rare word that I barely can spell.

Keimpe Wiersma (2012-02-11 01:49:32)

DIY

Wilhelm (2012-02-11 01:59:26)

Easyfication ;-)

wobbly (2012-02-11 02:05:53)

Deguilding? As in the science is no longer held by a guild. Maybe there's a better word around 'guild'. Commodification or Commoditization? It implies the limited nature of expertise has been let loose for the masses. A pain to spell. Defrocked? Religious, but more personal.

Jeremy (2012-02-11 02:41:32)

Empowerment is what you mean, I think. Empowering?

LM (2012-02-11 03:45:02)

multiversality?

dearieme (2012-02-11 05:00:15)

de-artisanilisation.

justin (2012-02-11 05:01:34)

"Distribution" is the closest I can get to it.

Mark Cancellieri (2012-02-11 06:26:20)

How about "ubiquitization"? :-) The funny thing is that I thought that I just made it up, but "ubiquitization" and "ubiquitize" are already on Urban Dictionary. :-)

Carl Willat (2012-02-11 09:07:26)

Deprofessionalization is still your best choice. Just commandeer it. "Photography has become deprofessionalized." Sounds just right. Who cares if it has another meaning too? However, mugglefication (adapting a term from Harry Potter) would mean it's not being done exclusively by the wizards anymore. Too cute for my taste, though.

Andrey Shestakov (2012-02-11 09:08:17)

Massification sounds good. For example, in programming, available to virtually anyone with a computer, there is a strong tendency for hobbyist projects to grow into worldwide-accepted tools. Gmail started as a side-project, as several website-building frameworks. I'd call that massification without a doubt (:

Michael D (2012-02-11 09:10:42)

De-skilling

Elizabeth Molin (2012-02-11 09:12:02)

Panification? It doesn't have a definition yet and it's easy to say. To me, massification sounds too much like mastication.

gwern (2012-02-11 09:25:49)

Toffler's 'prosumer' and 'prosuming'?

Nancy Lebovitz (2012-02-11 09:30:53)  
Skill access?

Ken (2012-02-11 09:40:53)  
"Commonification"

Ken (2012-02-11 09:42:43)  
or better, "Commonification", the new verb being "to commonify"

Aaron Blaisdell (2012-02-11 10:23:26)  
prometheitization, prometheitize?

Bryan (2012-02-11 10:51:57)  
I vote for "democratize" too. The second dictionary definition is, "Make (something) accessible to everyone."

Stone Glasgow (2012-02-11 11:46:25)  
Any examples of this occurring where the cause was not borne of improved technology, affordable to average people?

Stone Glasgow (2012-02-11 11:54:54)  
Personal science is more like practicing a religion without going to church; without the blessings of the ordained leaders of the religion. It is today considered blasphemous to examine one's own reactions to change, even if most confounding variables can be eliminated.

Seth Roberts (2012-02-11 12:50:39)

Personal science is more like practicing a religion without going to church; without the blessings of the ordained leaders of the religion.

yes, that's very true. It does have a "how dare you!" (blasphemous) aspect, which other instances of deprofessionalization or whatever you call it – such as digital photography – do not. To answer your question, all the examples I can think of came from new cheap technology.

wobbly (2012-02-11 14:56:21)  
Post-guild.

Darius Bacon (2012-02-11 15:54:46)  
I like 'demotic' better than 'democratic' since it's shorter and avoids political associations. Poor basis for a noun, though, and obscure. Self-help is to the point too, but has a more specialized meaning now.

WCB (2012-02-11 16:21:42)  
How about self-reliafication? Aren't we talking about being less reliant on others so we can be more self-sufficient? "Self-sufficientiation" seems a little too much for one word. -:-)

Jenny (2012-02-11 17:36:21)  
How about 'imspecialisation' as in perfect-imperfect?

Chris U (2012-02-11 21:18:03)  
mass enabling - more positive connotation than de-something

nile (2012-02-11 22:03:39)

Laity (and related terms as lay workers, laymen, laypersons, etc ) is widely used and understood in most Catholic and Protestant congregations. I think it is much more widely used and understood than you might imagine or have experienced. I think "laification" is a good fit. Some congregations have lay pastors or lay preachers - exactly the transition from specialist (priest or preacher) to "something done by the general public, not as a job." that you are looking for.

Christopher Burd (2012-02-12 11:35:41)

My contribution is "vernacularization". But I actually agree with Carl Willat. Just commandeering "deprofessionalization". Linguistic patterns like "de + X + ization" don't typically have precise meanings out of context, but people coin new instances because they need a term for some precise meaning. So, the established meaning of "deprofessionalization" (= a shift in a job's requirements from a high to lower skill level [?]) occupies only one point in the field of potential meanings of that word. There is room for alternative meanings.

Stone Glasgow (2012-02-12 13:45:58)

I think that this process is simply the march of technology, and the growth of wealth in society. Over time, the total amount of valuable things grows, and stuff that was only available to royalty and billionaires eventually becomes ubiquitous. Examples include automobiles (85 % of households below poverty line have one, 35 % have two cars), cell phones, computers, spices (black pepper was worth more than gold at one time), indoor plumbing, medicine (most common drugs are now \$4 per bottle at Walmart), electronics (DVD players, navigation systems), etc. As time passes, we find ways to make everything cheaper, and everyone can afford to do what specialists used to charge a premium for, basically because they had access to expensive equipment that regular people could not afford. I think personal science is a different phenomenon. It's an act of dissension, taking matters into one's own hands instead of asking high-ranking men of science for approval, who have convinced most of us that large double-blind studies are the only way to differentiate causation from correlation. Most people are convinced that anecdotal evidence is worthless, and that the only way to know if a drug or treatment will work is to look to the leaders of the scientific community, in the same way that religious leaders in the middle ages convinced most that they were the only way to decide what is moral and what is not, and the only way to predict the future. In the past, they predicted armageddon; today they predict runaway man-made global warming that will kill us all. It's basically the same religious process. So, in the future, I suspect that more and more of us will realize the nature of scientific religion, as it were, and begin to defect from its grip in ever greater numbers. Today huge percentages of Europeans are agnostic about God, and I suspect that many years from now most of the developed world will be pro-personal-science, and will largely discount the influence of the scientific-religious leaders of tomorrow. Many years from now we will realize that science is today controlling the lives of average people in the same way as medieval priests.

Paleophil (2012-02-12 16:24:58)

folkification, laicization, demystification, detechnicalization, generification, reverse specialization

Peter (2012-02-12 16:57:30)

I think you're looking for "disintermediation".

Maria Droujkova (2012-02-12 17:18:13)

When something that was done by everybody becomes the domain of professionals, it's called "professionalization" - and the opposite would be "de-professionalization." This is similar to, for example, deschooling as Illich used it, which I like in this context. And similar to de-medicalization of breastfeeding which needs to happen, and de-professionalization of breastfeeding consultants back to LLL ideals.

Stephen M (Ethesis) (2012-02-12 20:02:05)

The word is almost automation. Most of these tasks are ones where a computer has taken them over. There ought to be a word for that process, and I think there is, just can not remember it.

Rafael (2012-02-12 23:22:42)

Younification. Reminded me of TIME magazine's 2006 Person of the Year.

Melissa (2012-02-13 08:30:40)

I really like Christopher Burd's suggestion of "vernacularization". I also like the idea of a public skill set that changes and has things enter (and exit, say weaving or sewing) this way. Having language to talk about the public skill set would be useful because I most often see people talking about how we have fewer public skills, when it seems that they just change over time and changing based on technology available is normal flow (eg high literacy)

Christopher Burd (2012-02-16 17:39:37)

"Vernacularization" is also a good Ivan Illich word. DIYization does what Seth want, but makes linguistic purists grit our teeth.

## **Vitamin D3 in Morning Helps Him Sleep Through the Night (Story 16) (2012-02-11 05:00)**

Greg Harrington left a comment on [1]an earlier post:

I have had very similar results [fall asleep more easily] from first-thing in morning D3.(NOTE: I have great flexibility in my schedule – I can sleep/awake whenever I want – so I have been most focused on "restful" sleeping.) Differences: (a) My pre-D3 issue was restless sleep (waking up frequently), not failure to fall asleep. (b) The effect of sleeping all the way through the night was definitely immediate–very first night. (c) Also, most days I also wake up feeling more "rejuvenated". This is not 100 % though.

I asked him for details.

Tell me about yourself.

I've lived Austin,TX since 07/2011. Kansas City, MO before that. I'm a software programmer. 6' 3". 210 lbs. (White male, mostly German, but completely European descent.)

How did you want to improve your sleep?

I want to sleep through the night without waking up 3-6 times in a 6-9 hour sleep. This problem has lasted for 2-3 years. It sort of crept up on me. I go to sleep between midnight and 2 am.

How much D3 do you take? At what time?

I take 50,000 IU between 8 and 9 am. If I forget or wake up later, I don't take it. [2]This is the product I take: Bio-Tech D3 in 50,000 IU capsules.

Why 50k? It was available on Amazon, and I calculated that to be what you'd get from 75-90 minutes of full-body sunlight. Thinking about Paleo lifestyle...that seemed reasonable. This is a LOT more than most SE people are taking but I wanted to maximize the effect! ;-)

Any effects of D3 on something other than sleep?

I often waking up feeling more rested/rejuvenated. But not every day. I tend to feel tired between 11 pm and midnight.

What happened when you started taking D3 in the morning?

1. <http://blog.sethroberts.net/2012/01/24/vitamin-d3-first-thing-in-morning-improves-falling-asleep/>
2. [http://www.amazon.com/gp/product/B000A0F2B2/ref=as\\_li\\_ss\\_tl?ie=UTF8&tag=harrslife-20&linkCode=as2&camp=1789&creative=390957&creativeASIN=B000A0F2B2](http://www.amazon.com/gp/product/B000A0F2B2/ref=as_li_ss_tl?ie=UTF8&tag=harrslife-20&linkCode=as2&camp=1789&creative=390957&creativeASIN=B000A0F2B2)

---

Albert (2012-02-11 09:09:30)

50000 IU seems like way too much to take on a daily basis. (I've never seen anyone recommend more than 5K to 10K per day.) I would recommend that this person get his blood levels checked and make sure they are not too high. Otherwise serious complications could occur.

Chris U (2012-02-11 11:35:01)

Some recommend taking 50k once per week. IMO, if you're taking 3k or more per day get a blood test. Do some research and pick a target level, mine is 100 nmol/L (40 ng/ml), then retest to monitor progress. The units differ according to your location. In Canada our tests are in nmol/L in the USA it is usually ng/ml.

Jean (2012-02-11 13:43:40)

Making vitamin D by exposing skin to sunlight creates a create negative feedback-the skin darkens and makes less vitamin D, so no one is getting 50000 units of vitamin D on a daily basis from sunlight. Wrong assumption, but good guess. Complications of high vitamin D include abnormal bone formation, kidney stones and possibly brain function. 50,000 a week for 8-12 weeks is the medical regimen for true deficiency, then the replacement is based more on geographic latitude than anything else.

Alex Berg (2012-02-11 14:35:26)

I'm wondering if Greg Harrington took the negative feedback effect into account when he computed how much d-vitamin is created from 75-90minutes fullbody daylight. The body has a negative feedback system which cuts down d-vitamin production after some or enough has been produced. I've once heard it said that it only takes 15 minutes sunlight to reach that limit for white people. I tried confirming this number by asking Google + Wikipedia, but none made we wiser. But the negative feedback system definitely exists.

Henk Poley (2012-02-22 05:01:52)

Huhm.. your body can only keep around 200,000 IU total. Taking 50k IU daily is too much, as it uses only about 5k per day.

## Vitamin D3 in Morning Improves Mood But Not Sleep (Story 8 Update) (2012-02-12 05:00)

In [1]an earlier post, Alexandra Carmichael of [2]CureTogether noted that 4000 IU/day Vitamin D3 gave her better results than 2000 IU/day. Her mood was better and her sleep was better. But she'd only taken the larger dose once.

She recently sent me an update:

Since I last wrote to you [8 days earlier], I've been taking 4000-6000 IU Vitamin D3, and I can report that it's NOT having a positive effect on my sleep, but it is balancing my mood significantly, helping me to handle normally overwhelming situations with much more ease, and avoiding mood extremes. This is a wonderful thing!

Anyway, just wanted to let you know I don't fit the sleep-improvement set - I still wake up super easily in the night. Falling asleep is easy, but I attribute that to the blue blocker glasses. Also, 4000 IU is much better at balancing my mood than 2000 IU (no noticeable effect) or 6000 IU (feelings of intensity or overwhelm increase).

1. <http://blog.sethroberts.net/2012/01/26/vitamin-d3-at-7-am-4000-iu-better-than-2000-iu-story-8/>
2. <http://curetogether.com/>

---

Shawn (2012-02-13 08:26:46)

If vitamin D3 tricks the body into thinking it's getting a lot of sunlight, unless someone is seeking to reset their circadian rhythm (for example when traveling) it seems to me that it would be best to take it in the afternoon, or, ideally, small doses throughout the day, with the strongest concentration around during the brightest times of the day.

Seth Roberts (2012-02-13 12:12:20)

If vitamin D3 tricks the body into thinking it's getting a lot of sunlight, unless someone is seeking to reset their circadian rhythm (for example when traveling) it seems to me that it would be best to take it in the afternoon, or, ideally, small doses throughout the day, with the strongest concentration around during the brightest times of the day.

I think the goal is to increase the amplitude of your circadian rhythm so that you will be more awake during the day and more asleep during the night. Perhaps morning sunlight has more effect on circadian amplitude than sunlight later in the day. I've taken D3 at various times in the morning; around 10 am the effect seemed to go away, although I'm not sure of that.

Anima (2012-02-17 19:51:52)

I have bipolar disorder that has been well-controlled for some time now. I recently had an episode of hypomania that seems to have been triggered by upping my morning dose of vitamin D to 5000 IU for several days. I used to take 2000 IU, and I have taken 4000 IU without incident, so 4000 IU may be my sweet spot - or at the very least upper limit - as well. The hypomania lasted longer than what is typical for me and it was not followed by depression, despite the fact that I drank a lot of alcohol (binging on alcohol has always immediately ended a hypomanic episode in the past for me, but would also always cause debilitating depression). It's great that this blog is highlighting the potential benefits of taking vitamin D, but I really wish I had been more careful with this supplement. It seems obvious that a person with BPD should be cautious with anything that effects mood and circadian rhythm, but since my mood has been a non-issue for some time now and I no longer take handfuls

of medication, I've stopped thinking of myself as bipolar (as stupid as that sounds). This was definitely a wake-up call.

### **High Defect Rate in Ultrasound Machines That Scan Pregnant Women (2012-02-13 05:00)**

Two studies in Sweden by the same group have found high rates of defects in ultrasound machines used to scan pregnant women. The line of research began when doctors at the Karolinska Hospital discovered that many of their ultrasound machines were malfunctioning.

[1]The first study examined about 700 machines from 7 manufacturers. About 40 % had defective transducers – the only element tested. "The high error frequency and the risk for incorrect medical decisions when using a defective transducer indicate an urgent need for increased testing of the transducers in clinical departments," the authors concluded.

[2]The second study tried to find out how fast the machines break. The researchers examined about 300 machines all of which were working correctly (or had been fixed to work correctly) a year earlier. The retest showed that about 30 % were defective. Apparently they break easily – and nobody notices.

These are lower bounds on the defect rate of the whole machine because only one part of it was tested. Because one part of the machine breaks so easily without detection, it makes me worry about the part of the machine that determines the strength of the ultrasound. How often is the actual strength much higher than the intended strength?

[3]Caroline Rodgers has argued that ultrasound is a plausible cause of autism. [4]A 2010 epidemiological study found no link between autism and ultrasound but these high defect rates call that study into question. In that study, almost all children (about 90 %) had had experienced ultrasound before birth. This means that lack of correlation with autism means lack of correlation of number of scans (1 or more) with autism. This leaves open the possibility that it only takes one scan from a defective machine to produce autism. If that were true, and each child scanned repeatedly by the same machine (e.g., if a child has three scans, all are from the same machine), there would be no correlation between autism rate and number of scans.

These results scare me. It isn't just ultrasound and autism. I [5]blogged a few weeks ago about gross dosage errors in CT scans, some patients getting 10 times the intended dose of radiation. Here is another example where the operators of dangerous medical devices had no clue about appropriate testing and maintenance.

Thanks to Emily Williams who sent me a paper that mentioned these studies.

[6]More about the ultrasound/autism link. [7]Association between prenatal ultrasound and lefthandedness, which implies that ultrasound affects fetal brain development.

---

dearieme (2012-02-13 08:16:56)

I need ultrasound studies on my heart and CT scans on my head. Should I be worried?

Jim Purdy (2012-02-13 08:27:18)

Why am I not surprised?

Dennis Mangan (2012-02-13 08:47:26)

In the clinical lab, QC is the rule on every piece of equipment for every test, daily or sometimes once every 8 hours. It seems like no one was doing any quality control testing on these ultrasound instruments.

High Defect Rate in Ultrasound Machines That Scan Pregnant Women « Thor Falk's Reading List (2012-02-13 10:48:12)

[...] Seth's Blog » Blog Archive » High Defect Rate in Ultrasound Machines That Scan Pregnant Women.... [...]

Seth Roberts (2012-02-13 12:14:12)

I need ultrasound studies on my heart and CT scans on my head. Should I be worried?

I don't know. But the next time I am asked to have dental X-rays made I will ask to see the maintenance/testing records.

Jim Purdy (2012-02-13 13:47:56)

Are dental x-rays really necessary? BTW, do you remember back in the 1950s when shoe stores had x-ray machines that let you see how well your feet fit in shoes? I think I would prefer that my feet get zapped for that sensible purpose instead of my head getting zapped.

Seth Roberts (2012-02-13 18:05:18)

Are dental x-rays really necessary?

A very good question.

CFortier (2012-02-14 13:20:41)

In regards to dental x-rays, I believe people on the fence about them should look to another theme of this blog: hormesis. I, for one, am not too worried. The ultrasound topic strikes me as altogether more sinister. Has anyone had experience taking a skeptical attitude to these tests? I imagine the pushback from the docs would be extreme.

Seth Roberts (2012-02-14 17:51:10)

In regards to dental x-rays, I believe people on the fence about them should look to another theme of this blog: hormesis. I, for one, am not too worried.

yeah, I am not worried so long as the machine is working properly. If it is not working properly...

The ultrasound topic strikes me as altogether more sinister. Has anyone had experience taking a skeptical attitude to these tests? I imagine the pushback from the docs would be extreme.

Good question. I also wonder what happens if you take a skeptical attitude toward the machines themselves ("when was the last time this machine was tested?").

Nancy Evans (2012-02-22 15:07:20)

Prenatal ultrasound may be hazardous for developing babies because ultrasound involves heat, sound and vibration, all or any of which can interfere with normal brain development. During the prenatal period, the developing human is most vulnerable to any environmental insult, either chemical (pesticides, industrial chemicals) or physical (radiation, ultrasound). The use of prenatal ultrasound has increased dramatically over the past 30 years as has the prevalence of autism. Yet the focus of most research into causes of autism has been primarily genetics and chemical exposures. However, there is considerable research showing cause for concern and you can find abstracts of the studies at [www.ultrasound-autism.org](http://www.ultrasound-autism.org) You can also find Caroline Rodgers excellent powerpoint presentation The Elephant in the Room at <http://iacc.hhs.gov/events/2010/full-committee-mtg-slides-Oct22.shtml> Ultrasound may be safe for adults whose body systems are fully developed but it can severely affect developing babies.

### **DIYization: The Word I Was Looking For (2012-02-13 17:00)**

In [1] a recent post I wondered what's a good word to describe the next step in economic progress after specialization – when making/doing X is done by the general public (not as a job) instead of just by paid specialists (as a job). For example, the introduction of [2] cheap cameras allowed the general public, not just professional photographers, to take pictures. Personal science is an example of such a shift, of course. Thank you for your many suggestions, such as laitization, deguilding, promethization, and several more. The combination of Keimpe Wiersma's suggestion (DIY) and wobbly's suggestion (deguilding) led me to DIYing and DIYization.

DIYing, I learned, is [3] an existing word with a different meaning (to do DIY). Although ordinary DIY (Home Depot) is associated with men, women appear to use DIYing far more than men and they use it to describe traditionally feminine activities (see [4] this). For example, there is a blog [5] DIYing To Be Domestic by a woman. This is irrelevant to whether I use it – it's just interesting.

DIYization is much rarer. It appears in [6] a 2005 essay called "Scandinavian Dreams: DIY, Democratisation and IKEA" where it refers not to a change in an activity but to a change in society – toward more DIY. IKEA, says the essayist, is an example of "the DIYization of society."

DIYing is shorter. DIYization is more self-explanatory, less likely to be confused with dying, and makes clearer the connection with specialization. Not to mention it is more pompous – more Veblenesque. In the last chapter of The Theory of The Leisure Class, Veblen used long rare words to say that academics show off their uselessness using by using long rare words.

Thanks for the credits. I'm glad I could be of service. Love your work!

## Apple Admits It Has a Workplace Problem (2012-02-13 20:39)

From [1]The Independent:

Facing a growing scandal over the working conditions of those making its best-selling gadgets, Apple has called in assessors from the same organization that was set up to stamp out sweatshops in the clothing industry more than a decade ago. The move is an admission that Apple's own system of monitoring suppliers has failed to stamp out abuses, and that the negative publicity surrounding its Chinese operations threatens to cause a consumer backlash against its products.

[2]I blogged about this a month ago. I think this announcement suggests the power of This American Life (which recently aired [3]a show about working conditions at Apple's factories) or Steve Jobs (his ability to "see no evil") or both. It reminds me of the American Civil Rights movement. That movement made considerable progress soon after TV became widespread and Northerners could see Southern brutality on the evening news. Mike Daisey, via This American Life, suddenly made this problem a lot clearer to a lot of people outside Apple, thereby putting pressure on Apple management.

---

Jim Purdy (2012-02-13 23:51:24)

YOU SAID: "...the American Civil Rights movement ... made considerable progress soon after TV became widespread and Northerners could see Southern brutality on the evening news." It's hard for me to think of TV, especially with "reality" shows, violence, and Rupert Murdoch's Faux News, as being a force for good. But what do I know? I don't even have a TV. You may be a little bit correct about TV having an effect on the politics of civil rights. However, I would suggest that the real change came from a repositioning of the political parties, as the Democratic voters shifted to the north and west, and the GOP embraced the views of the Old South. The recent failure of Jon Huntsman showed that the once-mighty moderate wing of the GOP has been replaced by the likes of anti-moderates like Santorum and Gingrich.

Robin Barooah (2012-02-14 01:47:31)

I am uncomfortable about the disingenuous reporting side of this, and I'm very skeptical about the cause-effect relationship. The media attacks anyone who has a vulnerability, whether it's in the interests of society or not. The more high profile the target, the more money the media can make by selling advertising against the attention it attracts. Apple has been openly reporting labor problems on its own, for years, and it very much appears that they called in the FLA voluntarily, before the NYT or NPR pieces. It's flat out dishonest of the media in general (not Seth) to present Apple as a problem case without pointing out that they are ahead of their competitors in this area. If they wanted to help more, they could promote real competition in this area by showing comparisons rather than hoodwinking people into supporting companies with even worse practices.

Seth Roberts (2012-02-14 06:25:38)

Robin, the only media I have seen criticizing Apple lately has been This American Life - is this what you mean by "NPR"? If it is, I am curious why you think it was dishonest. The TAL program started with Apple and emphasized Apple but it did not end with Apple - working conditions at non-Apple factories were considered - and it gave a voice to a defender of these factories

(Nicholas Kristof). To me it was basically a show about how American companies exported jobs overseas but did not export the worker protections that had grown up around those jobs. This is how the show ended – with Daisey saying that.

Adam (2012-02-14 07:55:20)

<http://cache.johnchow.com/wp-content/uploads/2012/01/apple-foxconn.png>

Robin Barooah (2012-02-14 09:53:59)

The main pieces I'm referring to are the two in the NYT which were far less balanced.

Seth Roberts (2012-02-14 17:43:37)

Adam, I take the comparisons in the johnchow.com page differently than you do. They are unadjusted for anything – age, sex, location (e.g., urban/rural), type of work, etc.

Seth Roberts (2012-02-14 17:46:16)

The main pieces I'm referring to are the two in the NYT which were far less balanced.

oh, I see. I probably would agree with you. That happens a lot with the NYT.

Glen Raphael (2012-02-14 21:21:50)

Seth, this really is much ado about nothing. Adjust for whatever the heck you want, you'll be hard=pressed to find \*any\* context that says working at Foxconn is worse than these worker's other available opportunities. Adjusting for location (urban/rural) actually isn't appropriate because many workers flock to the urban factories to escape rural life - their next best option is working on the farm, where they'd have much higher risks of every sort including the risk of causing their family to starve. But as for the rest, the documented suicide rate at Foxconn isn't merely lower than that in china generally; it's also lower than that in the US and lower than the rate at US or chinese colleges (an appropriate comparison since assembly workers tend to be in the 16-21 age group). One way we know that conditions are \*unusually good\* at Foxconn is that one of the problems Apple found (and is trying to stamp out) is that many workers are willing to pay large bribes to third parties in order to get these jobs. Some pay more than a month's salary in advance as a kickback to intermediaries. Near as I can tell, the chief problem here is that people aren't willing to do math. They just say "20 people in a year seems like a lot" without making that a percentage or comparing it to \*anything\*. But Foxconn employs more people than the entire population of Wyoming, so our intuitions about how many should happen are out of whack. If you want to claim "too many" people are harmed in industrial accidents or are committing suicide or are in violation of safety regulations or even in are violation of local child-labor laws, one thing you might try is to find the equivalent numbers for the population of Wyoming. Hint: they'll probably be worse. I have yet to see any such comparison that made Foxconn look bad. (full disclosure: I've worked in a Chinese factory alongside assembly workers; I've also seen Mike Daisey's show. After the show I asked him a clarifying question and he admitted he exaggerates a bit for dramatic purposes.)

Glen Raphael (2012-02-14 21:33:54)

btw, the previously-linked graphic was based on this (pretty good) Forbes article: <http://www.forbes.com/sites/timworstall/-2012/01/29/the-apple-boycott-people-a-re-spouting-nonsense-about-chinese-manufacturing/>

Seth Roberts (2012-02-14 23:04:38)

Adjust for whatever the heck you want, you'll be hard=pressed to find \*any\* context that says working at Foxconn is worse than these worker's other available opportunities.

1. If you have done any adjustments, what were the results? No epidemiologist on earth would seriously compare rates of suicide among Foxconn workers to "Chinese national average". What about comparisons to American workers of similar age,

job, etc.? What about comparisons to Foxconn suicide rates in earlier years? 2. The workplace injury comparison in the graphic was not between "these worker's other available opportunities", it was with US workers. I think it is praiseworthy, not "nonsense" (Forbes), that at least some Americans believe Chinese workers should be as safe as American workers doing similar jobs. Which is blatantly not the case. Not because of the suicides, which are hard to interpret without more comparisons, but because of other problems, such as repetitive strain damage. As Daisey says. I agree with the Forbes writer (Tim Worstall) about wages but not working conditions. I don't think Daisey complained about low wages. 3. Fine to criticize Daisey but pointless to leave out the details. What did you ask him and what did he reply?

Glen Raphael (2012-02-15 07:52:00)

> I think it is praiseworthy, not "nonsense" (Forbes), that at least some Americans believe Chinese workers should be as safe as American workers doing similar jobs. Which is blatantly not the case. What's your evidence that this is "blatantly not the case"? We know the rate of \*fatal\* work injury is \*higher\* for American workers than for Foxconn workers and it often makes sense to use fatal injuries (which are easiest to unambiguously measure) as a proxy for non-fatal ones. I've seen no calculation of repetitive strain injuries per 100,000 there but it seems likely to me that's lower at Foxconn too, based on the additional context that this is work young people do for quite a short period of time. (and also based on my knowledge of the work conditions at a similar plant) > If you have done any adjustments, what were the results? No epidemiologist on earth would seriously compare rates of suicide among Foxconn workers to "Chinese national average". What about comparisons to American workers of similar age, job, etc.? **The Foxconn suicide rate is less than the suicide rate of American college students, who are of a roughly similar age.** (It's hard to compare to American \*workers\* of a similar age/job since many American workers at the same age aren't allowed to work full-time.) I think it's incumbent on those claiming Foxconn's rates are unacceptable to find \*some\* comparison that Foxconn is worse than so we can figure out what rates they \*would\* consider acceptable. In his show, Daisey implied there were much older workers on the factory line, which wasn't true. He did this partly for comic effect when taking about how factories allegedly evade "child labor" restrictions by swapping in their oldest workers when the inspectors arrive. I asked him if he actually \*met\* any old workers (say, older than 26) and he said he hadn't and that he had exaggerated. If repetitive motion injuries are caused by doing the same job for a very long period of time, it's relevant that nobody does this for a full career. Most people don't do this job for long; they're there for, say, 2-3 years and then go do something else. The nearest relevant US comparison might be with working at McDonald's. Or being in the army. Daisey complained that if you were to start work (illegally) at 14 and work the same station the same way continuously until you're 23 it'd be bad for your health, ignoring the fact that nobody does that. The jobs don't stay stable for that long nor do the workers stick around for that long. If you deal with the conditions and problems that actually exist in practice rather than the worst hypotheticals one can dream up, it's not so bad. Yes, you can find sad hard-luck stories there, but you'd be able to do that anywhere given the size of the relevant population.

Seth Roberts (2012-02-15 13:52:18)

What's your evidence that this is "blatantly not the case"?

What Daisey said. Plus what is in China Blue, a movie about blue-jean production in China.

We know the rate of \*fatal\* work injury is \*higher\* for American workers than for Foxconn workers and it often makes sense to use fatal injuries (which are easiest to unambiguously measure) as a proxy for non-fatal ones.

Jobs differ enormously in how often they cause injury. This is why such comparisons (Americans with all jobs vs. Foxconn workers) are not very convincing.

Glen Raphael (2012-02-15 14:29:55)

> What Daisey said. Daisey has made no effort to place the safety at Foxconn in a context that would allow statistical comparison with the US. He did demonstrate that some people (out of a population of hundreds of thousands) were injured, but did NOT demonstrate the injury rate to be unusual or higher than that in the US. He didn't calculate the rate and didn't compare it to anything else. All efforts to actually do so have failed to demonstrate these factories to be unusually bad. > Plus what is in China Blue, a movie about blue-jean production in China. The garment industry is totally different from the

electronics assembly industry. Working conditions in electronics assembly are far, far better. To make electronic products that work, you need a working environment that is clean and cool and dust-free and well-lit and you need to break the tasks into chunks that are really really easy for your workers to replicate *\*flawlessly\**, which involves constructing the right custom fixtures and making sure the exact right tool for each job is close at hand and the work environment generally conducive to the work being done. Jeans (and shoes!) can be made in a hot, muggy, dusty, poorly-lit factory by exhausted and stressed-out workers and the product will still be functional at the end. iPads and iPhones cannot, so it's largely for the benefit of the *\*product\** that the conditions at Foxconn are so good. BTW, the head of the FLA agrees. Quote: "Working conditions at Chinese manufacturing plants where Apple Inc's iPads and iPhones are made are far better than those at garment factories or other facilities elsewhere in the country, according to the head of a non-profit agency investigating the plants." source: <http://www.reuters.com/article/2012/02/15/us-china-apple-idUSTRE81E1FQ20120215>

Seth Roberts (2012-02-15 18:22:37)

Daisey has made no effort to place the safety at Foxconn in a context that would allow statistical comparison with the US.

He said that Chinese workers are not rotated the way American workers are. Surely rotation reduces repetitive strain injuries. That is why I do not need additional evidence to convince me that Chinese workers have more repetitive strain injuries than Americans doing similar jobs. The China Blue stuff goes to make the point that workplace protections are much weaker in China than in America.

Glen Raphael (2012-02-15 20:07:39)

>He said that Chinese workers are not rotated the way American workers are. No, he didn't do that. He did rather dubiously *\*assert\** that Chinese workers never rotate tasks, but he made no effort to evaluate whether American workers doing similar work rotate tasks more often than Chinese workers do. It's vaguely plausible that they *might*, but you'd have to gather evidence to establish it. In fact, you'd have to gather evidence both here *\*and\** in China, since what Daisey did to get this claim was seek out malcontents. He didn't do a random survey, he sought out people who had complaints. I don't doubt that those particular workers made those complaints, but we can be pretty sure the *average* worker's experience was a fair bit better than **the experiences of those who were gathering illegally to try to form a union**. Imagine if you went to a American non-union manufacturing plant and talked to the local union organizers and the people they thought you should hear from. (this is essentially what Daisey did in China to get his RSI story). Do you think you couldn't in that situation find a few people claiming they work too long at tasks that are likely to cause RSI? Would you then extrapolate from their experience and assume it's typical of the half-million other workers you hadn't heard from? Or might you take into account the selection bias that caused you to find those particular workers and conclude that there *might* be a problem but the extent of the problem is as-yet undetermined?

Seth Roberts (2012-02-16 14:18:42)

Glen, okay, you think it is selection bias. You seem to have ignored this sentence by me: "The China Blue stuff goes to make the point that workplace protections are much weaker in China than in America." Do you believe that Chinese workplace protections resemble American workplace protections? That Chinese workplaces are as safe as American workplaces doing the same job? If so, why?

Alex Berg (2012-02-17 12:57:01)

» Glen, okay, you think it is selection bias. Seth it seems to me that at this point you probably should admit that there most likely is a problem with selection bias in the whole Apple story (rather than just stating what Glen thinks). Since you do not I suspect you might be falling victim to various human thinking biases such as: [http://lesswrong.com/lw/jx/we\\_change\\_our\\_minds\\_less\\_often\\_than\\_we\\_think/](http://lesswrong.com/lw/jx/we_change_our_minds_less_often_than_we_think/). The following sentence just struck me: Eliezer Yudkowsky - Knowing about common biases doesn't help you obtain truth if you only use this knowledge to attack beliefs you don't like. Besides that I praise you both for an interesting rational discussion!

Seth Roberts (2012-02-17 14:45:21)

Alex, I should have said I don't think it is ALL selection bias.

Glen Raphael (2012-02-17 21:02:57)

I think *electronics assembly* in China at Foxconn is probably at least as safe as the sorts of jobs done by people of a similar age in the US. This despite or regardless of China having fewer explicit "workplace protection" laws and a more corrupt legal system. My reason for thinking this is as follows: (1) The job itself inherently promotes safety. Unlike most jobs, electronics assembly (especially FOR APPLE) requires ludicrously small error tolerances or else the product doesn't work and building it isn't profitable. People tend to get injured on a job when they make mistakes. People tend to make mistakes when they are in a rush or tired or careless or haven't received proper instruction or don't have the right tools for their task or aren't being well supervised. But people who make mistakes don't produce a consistently high-quality end product. Foxconn's margin on these products is tiny and the value of each product produced is large. If they force workers to work faster or harder than their capacity (or force them to work with inadequate tools or inadequate light or...), the workers are likely not *just* to occasionally injure themselves but also to make mistakes that generate tens or hundreds or thousands of worthless iPhones, wiping out the profit margin for the run or even causing Apple to pick another supplier. In short, Foxconn has every incentive to make the work segments *utterly consistently achievable* which has the side effect of making the work *unusually safe*. Certainly safer than, say, working in a restaurant. (And unusually boring, which explains the high turnover rate). (2) Foxconn in particular has rather ludicrous economies of scale. Every possible mistake that could injure a worker (which invariably costs time and money and holds up production) **has been seen by now** and most have been dealt with. They work on such a scale that even the *tiniest* available improvement in per-worker productivity is worth spending some money and effort chasing down and fixing. (3) I've been on a Chinese assembly line, and it just plain *felt* boringly safe. It's hard to explain, but the fact that everything is being so meticulously measured and controlled is a big part of it. Whereas my intuition suggests that US workers (who don't live on site and have more autonomy) are more likely to goof off or show up at work with a hangover, leading to mistakes and injuries. All that said, I do have a few caveats. My argument does apply to the most visible job that employs the most people - assembly - but the same argument does not apply with the same force to one-off jobs like manufacturing the tooling. There *are* jobs at Foxconn that won't have been so brutally optimized for efficiency (and hence, safety) because these jobs don't have the same leverage as assembly-line work. *Those* jobs might be less safe (albeit more efficient and more convenient to the workers) than their U.S. equivalents. And I saw this in China too - the people who made the tooling at GSL didn't wear their safety goggles (because the goggles were hot and uncomfortable to wear) while cutting metal and there was nobody ordering them to do so. *That* end of production might well be a lot less safe...but that's not where most of the employment is and wasn't what the recent allegations were aimed at. I didn't comment on China Blue mostly because I haven't seen it. I am sure Chinese employers are more abusive in various ways than American employers, because China hasn't got our legal culture - there's no army of lawyers willing to file class-action suits against denial of back pay or what-have-you. I'm sure there's lots of room for improvement in other areas. But the claim that successful electronics assembly-line work could scale up to the size of Foxconn while specifically being *less safe* than other forms of manual labor strikes me as a claim that requires *actual evidence* to establish. "some injuries exist" does not constitute evidence that it's unsafe, since that will always be true for any employer. What would constitute evidence would have to involve an injury **rate** and at least one point of comparison - that Foxconn's rate is *worse than* some other relevant rate somewhere else. Absent that, I tend to give Foxconn the benefit of the doubt.

Seth Roberts (2012-02-18 22:55:14)

The suicide rate at Foxconn. I don't think the owners of Foxconn are stupid. If there were a comparison suicide rate that showed the Foxconn suicide rate to be innocuous, I believe they would have brought it to my (and the world's) attention. Instead I am shown the nonsense of a comparison to overall Chinese suicide rate. As if I am stupid. That alone makes me think something is seriously wrong. What evidence would I like to see? Suicide rates at Foxconn in previous years. Suicide rates at similar factories, including other countries. Safety records likewise. This isn't complicated - but such evidence is absent. I believe it is absent because it would not make Foxconn look good. Again, I am assuming the people in charge of Foxconn are not stupid and are making the best defense money can buy. "The job itself promotes safety." Really? Surely trained workers make less mistakes and are safer than untrained workers. If so - and if the job is as optimized as you claim - why do workers quit so soon, requiring untrained workers to replace them? Why don't they make the job more attractive, thereby increasing the training level of the average worker? I don't know why workers quit so fast but whatever their reasons, they are aspects of the job that do not

promote safety. I am unpersuaded by your Candide-like argument ("Foxconn has every incentive . . . ") that things must be good because margins are thin. Oh yes, Foxconn is safer than other forms of manual labor. I don't think much of the random inspection stuff that Apple PR promotes. It is much more about protecting Apple than protecting the employees. But it is better than nothing. As Apple indicates with their latest announcement, it can be improved. Daisey's contribution, in my opinion, is his attempt to listen to Foxconn employees. To give them a voice. There are many ways to do such a thing. His is only one way, with obvious sampling biases. There are other ways. I hope they are tried. Until someone such as Daisey begins to make clear what can be learned from listening to employees, there is unlikely to be any pressure to do so. The TV show Undercover Boss makes clear episode after episode how much the reality of a job can differ from what people in high places (or distant places) imagine. High-ups at Apple, I'm sure, don't know what Foxconn is like. Jobs made laughable statements ("swimming pool"). Maybe someday they will be forced to know – because the rest of us know. I look forward to a Chinese version of Undercover Boss. After I wrote this reply I saw this: <http://www.nytimes.com/2012/02/19/technology/foxconn-to-raise-salaries-for-workers-by-up-to-25.html> The salary raise argues against your idea that margins are thin ("Foxconn's margin on these products is tiny"). Nor does this quote from the article support your overall view: "the auditor at the Fair Labor Association said recently that he had already found "tons of issues" at Foxconn plants."

Glen Raphael (2012-02-28 10:33:49)

> After I wrote this reply I saw [nyt article] Daisey claims in his show that the last time Foxconn announced salaries would be increased, it was just an accounting trick. The prior convention had been that workers get a very small salary \*plus room and board\*. American journalists have been prone to ignoring the room-and-board part when making cross-country comparison. We just look at the bottom-line salary, ignoring that this job provides "a living wage" by definition - it pays for food and shelter. So the trick is to price that in. In order to get some good press, the company announced salaries would increase by 30 %...but simultaneously started charging for some of the previously-free rent and/or food so that on balance the compensation package was approximately unchanged. Given the sheer amount of services Foxconn provides for its workers, it's hard to know whether this new "up to 25 %" increase is meaningful. > High-ups at Apple, I'm sure, don't know what Foxconn is like. What makes you so sure? When I worked at a company in silicon valley that did its production in China, we sent engineers and management at various levels to the factory on a regular basis. Certainly there are people at Apple who know what it's like better than Daisey does. I spent months in China working alongside the assembly workers when we were debugging our production process and getting the quality level up, as did others in QA, product management, hardware design and senior management. I'd be surprised if Jobs himself didn't visit the factory. Jobs' statements weren't laughable to those of us who have BEEN to a Chinese factory. On the suicide rate: We've heard so far that Foxconn's appears to be much lower than China (overall), China (college students), US (overall), US (college students), and US (auto manufacturing), which ought to be enough to shift the burden of proof to the other side. The rates at "similar factories" are not available because (a) nobody keeps the info indexed that way, (b) it's not even clear what would constitute being sufficiently "similar". > Nor does this quote from the article support your overall view It's ambiguous. I'm sure there are "tons of issues", but having "issues" doesn't mean the job is fundamentally unsafe. "issues" are likely to include things such as long hours and unpaid overtime that aren't relevant to the current discussion. Seth: I am going to post again on this so I will be brief here. "We sent engineers and management at various levels to the factory on a regular basis". Okay, what was the purpose of these visits? I've heard of such visits. If I am not mistaken, their purpose was to make sure the products were being manufactured appropriately – meaning high enough quality. Nothing to do with worker safety or worker complaints. I think there is something to what you are saying here – that it is to Daisey's advantage to exaggerate bad working conditions. Likewise it is to many other people's advantage. But it is likewise to many people's advantage to hide bad working conditions. Which is why I don't take seriously these visits by engineers from your company – who even if they spoke regional dialects (very unlikely) would not be terribly interested in listening to people far below them on the social scale (factory workers).

Glen Raphael (2012-02-29 19:37:25)

I personally liked the factory workers and enjoyed trying to communicate with them. They seemed like happy, healthy teenagers. I was interested in listening to them out of normal human curiosity and to practice my language skills. We didn't have particularly deep conversations because I only spoke a very small amount of Mandarin and they only spoke a very small amount of English, going through a translator was tedious, and we had few points of common experience. (For instance, they didn't know where California was). We mostly communicated non-verbally. For instance, I taught them some magic tricks

involving rubber bands. And we sketched in notebooks to get ideas across. We didn't discuss safety or worker complaints because I had no reason to think this was an issue of concern (this was in 1998/1999). (At my factory the workers spoke Mandarin and the managers spoke Cantonese; we often had a translator assigned to us.) The purpose of our visits was to keep production on deadline, to establish an acceptable quality level and to track down the source of various problems we were seeing in preproduction so they could be resolved in the next run. Toward that end, I brought some specialized test equipment, showed them how to set it up and use it and actually sat on the line and ran my own tests on devices as they came down the line. I consulted with their white-gloved QA people and helped them decide what did or didn't constitute a failure. I debugged some of their software installation processes. At the same time, one of our hardware engineers looked at the steps being followed to assemble a tricky custom component that wasn't working very well and tried to debug what could be done to make it more reliable. While at the factory, we saw up close a reasonable slice of what the job consisted of, both for workers on our line during this preproduction run and for workers on some neighboring lines doing regular production runs. The products I saw produced included PocketMail, the Sharp Wizard, and some electronic language dictionary products, all produced at the GSL (Group Sense Limited) factory in Dongguan. (This one: <http://www.groupsense-sp.com.hk/en/contacts.php> ) Here's a picture of me at my test station - the workers found it hilarious whenever I put on a pink cap since that cap style/color does indicate social status: [http://impel.com/pictures/glen\\_factory.jpg](http://impel.com/pictures/glen_factory.jpg) Here's a shot that shows the scale of the factory floor with a couple lines running: <http://impel.com/pictures/factory.jpg> The workers worked long hours sometimes...but then, so did we. The work I saw didn't seem especially strenuous; the working conditions were obviously MUCH BETTER than those at most of the jobs in that city on account of having good lighting and good air conditioning and reliable power and well-made custom fixtures and the right tools close at hand. Salary aside, it seemed like a decent job. One of the people I work with today grew up near Foxconn and had friends who worked at places like that; her impressions matched mine. As did what I heard thirdhand by way of a coworker who was dating a local at the time. Given the scale on which Apple produces, I assume Apple has people permanently at the factory who have better language skills than we did. If you want to hypothesize that the conditions get worse when there's nobody looking, the trouble is that there's just about always somebody looking. The squeaky wheel gets the grease; in order to get problems resolved quickly you pretty much \*have\* to have people visiting the factory in person on a regular basis. Both my company and Sharp Electronics had people there quite often. It's low-status dead-end transitional employment; the turnover rate is high for much the same reason the turnover rate is high at McDonalds or Disneyland. It's not a career; it's something people do for a couple years until they find something better to do elsewhere.

Glen Raphael (2012-02-29 21:49:44)

The Nightline report on Foxconn is here: <http://www.youtube.com/watch?v=hLuPtMvwwA0> One interesting thing they did was go to the nearby city and see how the dorms compare to where the workers were living before. If I were to do what Mike Daisey did, my questions would include: (a) If you weren't working at Foxconn, what would you be doing instead? (b) what do you plan to do in a few years, and how is this job preparing you for the future? Note that is that according to the Nightline segment the dormitory housing is paid for with <1 day's wages per month. That is extremely cheap, suggesting that it's still mostly paid for by the employer. Note also that if one employer in China were to (as suggested at the end) pay more than double the market rate, this would cause riots among jobseekers and kickbacks and all sorts of corruption - these jobs would end up going to the politically well connected rather than those who need them most and the excess profit would get competed away. Apple can make things a little better - and has - but asking them to double wages across the board seems frankly insane.

Glen Raphael (2012-03-16 12:16:35)

This American Life has decided to officially \*retract\* their story about Mike Daisey and the Apple Factory on the basis that Daisey was simply lying about a lot of what he claimed to experience. Some of the parts I found implausible turned out, in fact, not to have happened. Daisey's defense is that the story he tells is essentially a work of fiction - it makes for better \*theater\* if he pretends to have \*personally met\* with underaged workers and workers injured by n-hexane or who had their hand crushed whereas in fact he appears to be combining stories he's heard third-hand about factories in general and telling them as his own in the context of the Apple factory, adding poignant details here and there so it reads better. Ira Glass now says "I suspect that many things that Mike Daisey claims to have experienced personally did not actually happen." <http://www.thisamericanlife.org/blog/2012/03/retracting-mr-daisey-and-the-apple-factory> Seth: Thanks, Glen. To make up

stuff about those you are criticizing is a huge mistake, at least if you want to improve things. To say it is okay because it is "dramatic license" – as Daisey has – is absurd.

Glen Raphael (2012-03-16 13:43:57)

More details on the retraction here: [http://www.marketplace.org/topics/life/i\\_economy/acclaimed-apple-critic-made-details](http://www.marketplace.org/topics/life/i_economy/acclaimed-apple-critic-made-details)  
Quote: "Daisey claims he met underage workers at Foxconn. He says he talked to a man whose hand was twisted into a claw from making iPads. He describes visiting factory dorm rooms with beds stacked to the ceiling. But Cathy says none of this happened. " The fact that the incidents Daisey talks about are such statistically rare events - something that affects less than one in ten thousand workers. happening at one specific plant, one specific year - makes it extremely unlikely that a single man could have managed to find so many good examples. If one assumes Mike Daisey is telling the truth, it really does cast doubt on the notion that these incidents are as rare as they are. But he was lying. In retrospect, the claim to have seen the workers quarters should have been a tip-off. I never saw the worker quarters at GSL and it's hard to imagine a reasonable pretext for why Daisey would have been shown them. How would that conversation even go? "I'm thinking of using your factory to build my product, but first I need to know...what the worker dormitories look like!" I mean, really? Who does that?

Greg M. (2012-02-14 08:48:03)

I came across this article on better sleep and thought this eclectic group of readers might find it interesting. Anyone want to ground their their bed and see if they sleep better? <http://www.foodrenegade.com/can-earthing-help-adrenal-fatigue/>

steve (2012-02-16 09:09:42)

interesting discussion on atopic and EFA's. It should be noted however, that it is a hit or miss proposition and in most cases the scientific literature shows no benefit from supplementing with EPO for atopic conditions.

### How to Eat Natto (2012-02-15 05:00)

I started to eat natto, a kind of fermented soybean, after I became convinced that we need to eat plenty of fermented foods to be healthy. That was four or five years ago. Recently I learned it is [1]a very good source of Vitamin K2, which is a co-factor of Vitamin D3.

[2]This post about [3]an infographic called World Stinky Foods (in Japanese) complains that the infographic doesn't include natto. In my experience, however, natto has a moderately strong taste but does not stink. If anything it has too little smell, which is why it comes with packets of mustard and sauce. I think it is the texture that some people don't like. [4]Wikipedia refers to this difference of perception: "The flavor of natto can differ greatly between people; some find it tastes strong and cheesy and may use it in small amounts to flavor rice or noodles, while others find it tastes bland and unremarkable, requiring the addition of flavoring condiments."

By ordering it in restaurants, I have finally figured out a good way to eat it: 1. Add both flavoring packets (mustard and sauce). 2. Add a raw egg. 3. Add chopped onion. 4. Mix. The egg adds protein and creaminess, the onion adds bite and crunch. I might try it with scrambled eggs. Ever since I learned that [5]Mr. T (a rat) liked scrambled eggs, I have been eating about one egg per day.

---

Andy (2012-02-15 08:36:04)

I too found the texture of natto a problem at the start, I can barely taste anything from it except a faint hint of burnt coffee or something slightly bitter. I always do a raw egg with natto, and usually just the yolk as I dont think it needs to be any slimier! Good tip on the onions though.

Glen Raphael (2012-02-15 09:15:41)

In my experience, natto seems horrifically stinky. Maybe one gets used to what wikipedia calls the "powerful smell" with repeated exposure. I didn't mind the texture at all, but the smell seemed like ammonia, kind of hard to put up with.

Rashad (2012-02-15 09:54:01)

Sort of unrelated, but I thought you might find this blog post and the linked article interesting, given your focus on specialization and craft production. [http://www.slate.com/blogs/moneybox/2012/02/15/artisanal\\_pickles\\_and\\_the\\_u\\_curve\\_of\\_economic\\_development.html](http://www.slate.com/blogs/moneybox/2012/02/15/artisanal_pickles_and_the_u_curve_of_economic_development.html)

Ashish (2012-02-15 15:34:11)

Timely - I was wondering what to do with the natto in my freezer, since I rarely cook rice any more. I take it you are eating

this "straight," i.e. not over rice. Why do you add a raw (rather than scrambled) egg? Red onion or yellow/white onion? As a complete aside, it's interesting that the styrofoam natto box does not feel cold to the touch even when straight out of the freezer.

Nick Winter (2012-02-21 20:31:25)

3/3 of my friends so far, when asked (or not asked), never want me to microwave or even eat natto anywhere near them because of the smell. Thanks for the raw egg tip; always on the lookout for more places to put those. Double bonus for supreme gross-out when others see me eating it like that. Wonder if I can somehow get the half stick of butter in there, too.

Martine (2012-02-26 17:27:43)

I tried some natto this past week and it was not exactly what I had expected. It didn't smell totally horrific, but a wee bit off-putting. I mixed a bit in with some green onion and soy sauce and served it over rice for breakfast. Slimy, yes, but not bad tasting at all. I can't imagine eating a ton of it one sitting. But I think any taste can be acquired.

## **Vitamin D3 in Morning Improves Sleep Three Ways (Story 17) (2012-02-16 05:00)**

Chris Cappadocia [1]recently commented here:

After the morning D3 entries started to appear here sometime before Christmas, I switched to taking my D3 first thing in the morning too (between 4-7000 IU) and so far I've noticed significantly increased feelings of sleepiness at bedtime, with moderate improvement falling asleep, reduced wakings throughout the night, and much better ability to sleep in.

I asked him for details:

Tell me about yourself.

I am a graduate student. I live in the Greater Toronto Area. I exercise almost daily (6 days a week maybe) with weights (but nothing especially strenuous); most of the year I walk about an hour a day (but not January and February); I try to eat some vegetables every day, I have taken fish oil for at least six years, and in the last 8 months I've started to eat as much fermented food as I can easily obtain (kombucha and apple cider vinegar every day, kefir or yogurt or miso occasionally). Another thing which might be relevant is I've consumed a lot of caffeine ever since I started university. Regarding sleep though, I was off caffeine for six months one time and noticed no improvements (whatsoever!) in sleep.

When is "first thing in the morning"?

For about a month (January 2012) I have been taking D3 when I get out of bed, around 8:00 am. For this month, waking up and getting out of bed have roughly coincided. In December 2011 I took it usually at 9:30 am; if I woke up earlier than I preferred, at say 7:00 am, I would wait to take the D3.

Before you started taking D3 first thing in the morning, what time were you taking it? How long had you been taking it at that time? How long have you been taking it first thing in the morning?

I have been taking D3 daily for about 3 years. My daily intake was in the range 5000-12000 IU. I took the D3 throughout the day with food, and therefore somewhat randomly; a typical day on the high end might have been 2000 IU with a small breakfast, 5000 IU at lunch, 3000 IU at supper. Most often it was more like 5000 IU at lunch,

1000 IU at supper. I have been taking D3 in the morning since about early December 2011.

You say morning D3 caused "moderate improvement falling asleep" – you mean you fall asleep faster?

As an adult it has seemed to take an hour minimum, with two hours not being at all unusual (two or three nights a week). And then I could easily wake up shortly (an hour) after that. These times are all estimates, since I try to avoid looking at the clock. But of course I do look sometimes, so I have some sense of these times, but it's not so reliable. Also sometimes it's not clear whether I've slept or not.

With that said, I would estimate the improvements falling asleep to be that in January it has mostly taken me under an hour, perhaps 45 minutes, to fall asleep. Also, I feel more content to just lie there and wait for sleep, it feels like less of a struggle.

What are the average (median) times taken to fall asleep before and after starting to take your D3 in the morning?

I estimate:

90 minutes to fall asleep before starting morning D3

50 minutes to fall asleep after starting morning D3

over the last 6 months (the last two being the months on morning D3).

You say morning D3 "reduced wakings throughout the night" – Can you estimate the size of the change? What was it before morning D3? What is it now?

Three nights ago I woke up only once in the middle of the night, and it felt like maybe 20 minutes or so. Two nights ago I slept from 9:30 pm until about 7:45 pm, and I don't recall waking up once. Last night 12:00 pm until 7:00 am, and I don't recall waking up once. Before morning D3 I could easily wake up at 1:00 am for 5 minutes, 3:00 am for 30 minutes, 5:30 am for 45 minutes. This January, my impression is that I still do wake up three times a night or so, but remain awake only 5 to 20 minutes each time.

You say morning D3 has given you "much better ability to sleep in" – could you say more about this?

For at least the last 4 years I have been waking up earlier than I would prefer. I might go to bed at 11:00 pm and wake up at 6:00 am feeling very tired, unrested, and in a negative mood. (Due to not sleeping enough during those 7 hours; I am fairly confident I do not have sleep apnea.) Waking up early would not be an issue for me if I fell asleep at 11:00 pm and slept straight through until 7:00 am.

So by "much better ability to sleep in" I meant that I have woken up most days in January at 8:00 am, feeling rested but most notably, not feeling like "Ugh, I need more sleep" yet being unable to fall asleep again. I've felt like when I wake up, it's the right time to get up. By the way, I did not notice this effect at 4000 IU. It showed up around 7000 IU.

What brand of D3 are you taking? Gelcaps or tablets?

Carlson gelcaps. Each cap is 1000 IU, in safflower oil. (I do not eat breakfast, so I take these on an empty stomach and this seems to give me no problems.)

Daniel Lemire (2012-02-16 06:53:46)

"I've noticed significantly increased feelings of sleepiness at bedtime, (...)" This looks like a good description of the effect it has on me. It would be interesting to verify this specific effect over several individuals.

Nate W. (2012-02-16 07:51:32)

Seth, why do you never write about sexual health - e.g., the effect of vitamin d on sexual health? Obviously, it's an aspect of health most people care about, do you not consider it important?

Stone Glasgow (2012-02-16 11:55:13)

D3 is a stimulant with a "crash" for me. The crash happens about 3 hours after ingesting 5,000 IU. I can now time my sleep to coincide with my expected D3 crash, which has improved my sleep tremendously.

ChristianKI (2012-02-17 12:06:00)

@Chris Cappadocia: Maybe it's time to get a Zeo to get better data on falling asleep and night awakenings? @Nate W: If one starts talking about improvement of sexual health the media types who want to report about Quantified Self will use it as the core example. It reduces the seriousness of the media reporting and people see self experimentation as "fringe". Talking about improving sleep is much better for the self experimentation meme.

## **Father Versus Surgeons and New York Presbyterian Hospital (2012-02-17 05:00)**

I decided to read [1]this book review because of a brief description ("A father describes, and rages at, the loss of his teenage son.) in an email. Then I found this:

Weber's story becomes more spirited and urgent when Damon's health begins to fail more seriously, and his father is forced to locate his true enemy: the received wisdom and arrogance of the American medical establishment.

Weber père . . . admits he doesn't trust "any single voice on Damon's illness." And he's wise not to, as he discovers in short order that health care for his son is first and foremost a business, and that surgeons frequently talk out of their hats.

Heart transplants represent big money for hospitals: at half a million dollars each, 20 pediatric transplant operations a year make a significant contribution to the finances of New York-Presbyterian Hos-

pital/Columbia University Medical Center, where Damon's surgery is eventually performed. Hospitals compete to attract patients (every transplant center Weber speaks with wants to perform his son's operation) and stringently guard their surgical outcome data, as Weber discovers when he tries to find out if the blithe assurances of the Columbia transplant team are scientifically valid. He quickly realizes "each hospital is a fiefdom."

Worse still, the medical barons who run the fiefs care as much [i.e., as little] for protocol as they do for patients. Over Christmas of 2004, Damon is casually "listed" as a potential heart recipient — meaning he has to be ready to receive a new heart at a moment's notice — without his father's knowledge. His doctors then disappear for a week and more.

Before Weber can truly blow his stack, he discovers Damon's doctors have also misclassified his son's transplant status as less urgent than it is. Dad bulls [sic] them into fixing the problem, and 11 days later, a heart is found for Damon. The transplant in turn initiates a tragic cascade of doctor errors so egregious that Weber eventually sues both the medical director of pediatric heart transplants at New York-Presbyterian Columbia hospital and the hospital itself for malpractice. (Three years into the lawsuit, the medical director claimed Damon's post-op records couldn't be located.) All this happens at one of the country's best heart transplant centers.

"Passively relying on the medical establishment and trusting them to manage my son's care in his best interest is not . . . a luxury I have allowed myself," Weber writes, with good reason.

Maybe I should start a series called "The Culture of Surgeons". Entry 1: [2]Eileen Consorti, a Berkeley surgeon who told me I should have surgery for a hernia I could not detect. Entry 2: [3]Martin Burton, an Oxford ear nose and throat surgeon whose Cochran Review about the pros and cons of tonsillectomy failed to consider that tonsils are part of the immune system.

JPB (2012-02-17 13:04:49)

One should always be wary of the medical industry, especially surgeons. Too many in that industry are either covering their backside or protecting their income stream...

JimPurdy.blogspot.com (2012-02-18 00:28:04)

As I asked in one of your recent posts about medicine: "Why am I not surprised?" What does surprise me is that so many people blindly trust the medical industry. Maybe it's partly because of all the "gold standard" research studies published in prestigious medical journals. But the "gold" in the "gold standard" seems to refer to all the money involved, from the studies funded by drug companies, the reports published in journals that make huge sums of money selling reprints of those articles to BigPharma marketing departments, all the way down to the surgeons and drug-pushing doctors. As I've discovered through repeated personal experiences, the medical industry isn't very interested in low-cost approaches like simple lifestyle changes, especially when hundreds of thousands of dollars can be made from tests, surgeries and drugs for each patient. If you want to contain escalating medical costs, just shut down the entire health care industry for a year, and watch the sharp decline of prescription

drug abuse deaths, of hospital-acquired infections, and of deaths from botched surgeries and drug prescribing errors. Jim Purdy

Brice (2012-02-27 23:34:32)

Check out this just posted article from WSJ on hernias and operations. <http://online.wsj.com/article/SB10001424-052970203833004577249344022834000.htm> l?mod=WSJ\_myahoo\_module Hernia repair, one of the most common surgical procedures, carries a risk many patients don't consider: chronic pain after surgery. More than 30 % of patients may suffer from long-term chronic pain and restricted movement after surgery to fix a hernia, a bulge of the intestine or body fat through a weak area in the abdomen, studies show. Damage to nerves and muscles from the hernia may cause lingering discomfort. New synthetic mesh devices, though better than traditional sutures at reinforcing the abdominal wall, can irritate nerves and carry a slightly higher risk of infection.

### One Doctor's View of Personal Science (more) (2012-02-18 05:00)

A few weeks ago [1]I blogged about a leukemia doctor's disapproval of self-experimentation ("you won't learn anything and others won't learn from it, either"). What I wrote was [2]reposted at The Health Care Blog, where it elicited this comment (by "rbar"):

Sigh. Mr Roberts did it again, he simply does not (want to) understand that anecdotal evidence is of little value (let me give you an example: I self experiment with traffic signals; I noted that I can considerable cut down on travel times when ignoring red lights and stop signs; there are no drawbacks whatsoever, no one get hurts, and even my gas mileage/carbon footprint got better) .

Individuals who have similar questions as Mr. Roberts should look up the following key words, because they may understand why controlled studies are far superior to anecdotal evidence:

- placebo effect
- regression to the mean
- misattribution error [apparently rbar means error in determining the cause of a change]
- self limited conditions/natural fluctuation of chronic conditions
- and in terms of drawbacks of experimentation: primum non nocere, and also the fact that anecdotal evidence adds relatively little to humanity's knowledge base

Does all that mean that patients should not be well informed, active and making suggestions to their treating physicians? Of course absolutely not. Being knowledgeable about one's condition is different from self experimentation. Is that intellectually challenging?

One reply to this comment said we should be aggregating data across patients. "I believe Mr. Roberts is alluding to the power of aggregating real-world data across patients to generate insights into what may and may not work, not to giving undue weight to any single anecdotal case." No, I was looking at it from the point of view of the self-experimenting patient. If you have a health problem, and you can measure it often (daily, weekly) you can find out what works faster than your doctor – often much faster. You can test many more possible solutions. This is what Richard Bernstein taught the whole world of diabetes, starting in the 1960s, when he pioneered home blood glucose testing. Apparently rbar also objects to that.

Rbar's comment is dismissive ("Sigh", "Is that intellectually challenging?") and partly obscure ("ignoring stop signs and stoplights" – huh?). Because patients who self-experiment may make "misattribution errors" they shouldn't self-experiment? That's like saying because people may make reasoning errors they shouldn't reason.

The true meaning of rbar's comment may be hidden in his statement that it's okay for patients to "make suggestions to their treating physician." Which shows who he thinks should be boss in the doctor-patient relationship. When a patient self-experiments, the doctor is no longer boss. Maybe rbar is a doctor. Maybe he feels threatened by self-experimentation. If so, I hope he's right.

More A later reply to rbar put it well: " Your list of possible pitfalls . . . is similar to lists I remember seeing back in graduate school in various research handbooks. I do not see how you go from the fact that these effects and errors are possible to the conclusion that the whole endeavor isn't worthwhile."

2. <http://thehealthcareblog.com/blog/2012/01/31/one-doctor%E2%80%99s-view-of-personal-science-you-won%E2%80%99t-learn-anything/>

---

Jordan (2012-02-18 06:12:22)

It's very problematic. Everyone self-experiments in different areas of their life. In my time, I have seen too many people make false attribution errors through wishful thinking and other biases to not realize that while it can be useful, self-experimentation has to be done with extreme caution and its conclusions treated with extreme care. I myself have gone through long periods of my life completely convinced that certain factors were the culprits in certain situations, only to later discover to my astonishment how wrong I was, and how my biases have led me to overlook important conflicting data. The problem is, your biases and assumptions can often literally not let you SEE relevant data. It's why \*peer review\* is so important. This has made me extremely careful these days. I now believe that self-experimentation has to be done with the utmost of reservations and care - no conclusions can be treated as anything more than extremely provisional - and that it really is of limited use to people at large.

Jordan (2012-02-18 06:15:30)

I think, really, self-experimentation has more value in areas where we can be reasonably sure that there are a few factors, and that we can isolate those factors. Many situations we must admit are just too complex for that and are just useless for self-experimentation, even if what we do seemingly \*works\* (there are too many factors for us to know WHAT exactly worked. This does not mean we should stop DOING what works until we understand WHAT is working, only that we must be aware that our explanations for WHAT is working and WHY might be completely off base) Also, we cannot expect others to treat our results as anything other than invitations to thought.

Glen Raphael (2012-02-18 07:25:37)

"stoplights and stopsigns" struck me the most relevant point rbar made. If the condition you're trying to treat is "my commute takes too long" and you self-experiment with ignoring stoplights and record the outcomes, the data will tell you that is perfectly safe and gets you where you're going faster...right up until the day you die in a horrible crash. If we apply that metaphor to self-experimentation, his fear is that that somebody just trying random treatments will find a false local maximum - a treatment that \*seems\* to help in the short run but has a worse long-term prognosis than doing nothing, due to a serious secondary effect that takes longer to develop or has some semi-random component. Applied to conventional drug trials (eg: thalidomide), it's a valid concern. But applied to the sort of treatments you're usually exploring/recommending, not so much. He's basically applying a precautionary principle (if it could cause harm, don't do it), whereas you're applying a proactionary principle (if it's broken, try to fix it). Your rule makes more sense for patients trying to get better; his rule makes more sense for doctors trying

not to get sued.

Jazi zilber (2012-02-18 07:43:08)

Let me respond to this guy 1) there are negatives to self experimentation. Likewise, there are negatives to talk with a doctor. Everything has negatives. Of only relevance is the sum of the effects. Indeed, one got to be smart. Always. Albeit self experimentation requires a little more than average wisdom. 2) placebo effects are over rated. It is a cultural prejudice that placebo effects are "nothing" they are very real. And anything that bring about placebo improvements is highly welcome. If self experimentation is an effective method to induce placebo healing, it is a great reason to embrace it. Besides, when someone tries many things and only some work, the odds for placebo effects are quite lower. 3) one MUST look for the statistical significance of self experimentation results. 4) one can only look for the statistical expected value for contribution to the world knowledge. It is childish to ask whether a specific finding will contribute. The question is whether it has some chance to contribute. And it has. Every self experimenter has a tiny chance to add for new knowledge. But it adds up. Besides, the average doctor adds zero to overall knowledge. And since when do patients live for adding for the world's knowledge? How ludicrous it is to even mention this to someone with a condition! People try things to get healthy.

Tuck (2012-02-18 08:41:57)

Two thoughts: Barry Marshall got a Nobel Prize in Medicine for self-experimentation. Any individual who says "anecdote is not data" doesn't understand how science is done. Second thought, if you do the experiment that Glen Raphael described, you might also (tickets aside) come to the conclusion that stop lights are a waste of your time, and actually increase the accident rate. The town of Makkinga in the Netherlands ditched all their street signs and stop lights, and the accident rate went to zero. Other towns are now following their example... So even the type of self experimentation that Rbar would have us not do yields useful results. What does not yield useful results in science is a slavish adherence to precedent. Although that is the way to get through medical school... "European Cities Do Away with Traffic Signs" <http://www.spiegel.de/international/spiegel/0,1518,448747,00.html>

Outis (2012-02-18 10:14:04)

+1 to Glen Raphael's comment (I especially like the last sentence).

JimPurdy.blogspot.com (2012-02-18 10:27:47)

Two more of my off-the-wall opinions, about placebos and what I will call "The Hundredth Patient Effect:" 1/ PLACEBOS: In my opinion, the reason that placebos sometimes look good relative to BigMedicine is not that placebos work. Rather, BigMedicine often doesn't work, so there's not much difference. But sometimes, BigMedicine actually kills the patient. 2. MEDICAL STATISTICS: I think medical statistics conceal a dirty secret of modern medicine, which is that the statistics are applied for the benefit of the doctors, and very much to the detriment of the patient's health. The doctors are gambling with the patients, and the patients are losing. After my bad medical experiences in 2010, when I refused a leg amputation and quadruple coronary artery bypasses (and both conditions got better with simple cheap lifestyle changes), I have often asked myself why doctors could have made such bad recommendations. Let me try to explain my reasoning: Suppose that, over a period of time, a doctor considers whether to perform a major and expensive (profitable) procedure on 100 patients. In the past, I would have thought that the profit motive would have been an incentive for the doctor to operate. I still think that is a factor, but I now think there is another, more important factor: statistics. If the doctor amputates 100 ailing legs, and all the patients live, the doctor make a lot of money, and he is praised for saving 100 lives. BUT WAIT A MINUTE THERE! Based on my experience, the body is capable of healing very sick legs and other body parts. Maybe, if no amputations had been done, one, or 10, or 50, or even 99 of those 100 patients would have recovered fully and kept their legs. So why amputate 100 legs? Because of that hundredth patient, the one that dies. If 100 patients are not operated on, but one dies, that one death will almost certainly result in a major malpractice lawsuit and perhaps even the end of the doctor's career. So, the doctor's options are: (a) amputate and make a lot of money, and be credited with saving 100 lives, or (n) don't amputate, and save 99 legs (and 99 lives), but get one major lawsuit and very bad publicity. Unfortunately, I think there may be strong pressure for the doctor to take the safe (for him) choice and amputate 100 legs just to avoid one messy lawsuit. I call my theory "The Hundredth Patient Effect."

Seth Roberts (2012-02-18 10:52:01)

If the condition you're trying to treat is "my commute takes too long" and you self-experiment with ignoring stoplights and record the outcomes, the data will tell you that is perfectly safe and gets you where you're going faster...right up until the day you die in a horrible crash. If we apply that metaphor to self-experimentation, his fear is that that somebody just trying random treatments will find a false local maximum – a treatment that \*seems\* to help in the short run but has a worse long-term prognosis than doing nothing, due to a serious secondary effect that takes longer to develop or has some semi-random component.

Glen, thanks for explaining that. This happens with modern clinical trials, too – FDA-approved drugs are found to have bad effects later and are taken off the market. So it is unclear that self-experimentation is more dangerous. As you say, I test stuff that has been safely engaged in (such as looking at faces in the morning) for very long times.

Kirk (2012-02-18 10:54:30)

I keep coming back to the concept of risk management. I think these doctors have heard too many stories of patients who died from a burst appendix because the patient had received herbal treatment from some quack who thought he knew Chinese medicine. For high-risk situations, these physicians are right. (The TV show 'Doc Martin' illustrates several such situations in an entertaining fashion.) And yet if a patient goes to a physician who assesses the condition and says, sorry, it's a low-risk issue, nothing I can do, live with it, these things sometimes clear up over time . . . In those situations, where the physician has already assessed it as low-risk, then why shouldn't the patient experiment? Suppose it's a sleep issue. What's the risk with experimenting with light levels at night, timing of Vitamin D, drinking peppermint tea after supper, or standing on one leg? I also argue that these 'obey the physician' advocates do no such thing in the case of their own diet. No matter which diet they follow, the one designed by a physician who clinically treats for obesity, I bet not one of these advocates strictly follows that specific diet. Which is fine. The risk is low.

Seth Roberts (2012-02-18 10:58:22)

I now believe that self-experimentation has to be done with the utmost of reservations and care – no conclusions can be treated as anything more than extremely provisional – and that it really is of limited use to people at large.

Jordan, care to give examples to support these conclusions? My experience has led me to opposite conclusions. For example, I can point to many people who have used self-experimentation successfully. For me, the interesting comparison is not self-experimentation versus nothing – I think it's obvious that some data is better than none. (And, of course, sometimes data is misleading.) The interesting comparison is self-experimentation versus expert advice (e.g., doctor's advice). What has been your experience comparing the two?

Tim Beneke (2012-02-18 14:42:51)

"Self experimentation versus expert advice." To repeat something posted on this site elsewhere: I suffered a great deal of clinical and sub-clinical depression over the years. Between 1975 and 1996, I went through 4 antidepressants, was told that I needed to return to the considerable trauma I felt as a child and relive the experiences and release a lot of repressed emotion. I saw 3 clinical psychologists and 3 psychiatrists. I was a night person during this time staying up to anywhere from 2-4 a.m. on average. No mental health professional told me to start going to bed and getting up earlier as a way to treat my depression, even though I made it very clear that I was a night person. Seth Roberts strongly impressed upon me the notion that going to bed at 3:30 a.m. was my biggest problem. When I finally changed my circadian rhythms in December 2003, I felt a quick mood uplift, about 20 point rise on a scale of 100 in terms of baseline mood, I estimated. With baseline mood improved, I started enjoying music enormously and life became more fun. I agree with earlier posts that self experimentation requires a certain capacity for objectivity, disciplined observation, and engaged reflection and some people probably are not able to do it effectively. But lots of people are, if they are willing to do some work, and it has helped me in many ways. Experts have an incentive to overstate their knowledge.

dearieme (2012-02-18 19:00:32)

All the RCTs in the world won't tell me whether I can tolerate beta-blockers: only self-experimentation can do that.

Jazi zilber (2012-02-19 02:29:33)

Jimpidry, Doctors have good reason not to plan on lifestyle changes. Most patients do not adhere to large lifestyle changes. Even if a doctor is sure that a list of exercises, food etc. will heal the foot, he may judiciously recommend to amputate it, if the chances a patient will do the complex changes is near zero. (assuming the risk from doing nothing is high) It may sound undemocratic etc. but every suggestion you do is related to what are the chances of it being used.

Barcelona psicologos (2012-02-19 05:53:36)

I believe that there is still much research in medicine. Should not be making diagnoses closed. You can always have hope.

Brian Toomey (2012-02-19 16:25:04)

Hi Seth, I've been reading for a while. I've had delayed sleep onset my whole life, and seem to have pretty much fixed it reading this blog. I am still varying the factors but what seems most important is: 1) 5000 IU liquid D3 first thing on waking 2) Blue Blocker Glasses 3) Using the xiser (xiser.com) for what I am seeing as a combination of one legged standing to exhaustion and anaerobic exercise Don't seem to have much effect: 1) 10,000 Lux lamp 2) Niacin to flush 3) Magnesium 4) Cold shower before bed My sleep onset insomnia was terrible, with me often unable to sleep before 3-5am, and now I've been waking between 8am and 9am feeling refreshed. My wakeup time seems to be inching back slowly. Thanks for the help your blog gave me! Best, Brian

Hamish Barney (2012-02-19 16:49:08)

What does this doctor do every single day if not experiments of  $n=1$  on his patients? Doesn't this doctor try and assess the efficacy of the treatments that they dole out? Doesn't this doctor change the drug that he prescribes to his patients if they don't seem to work, even if the clinical data says that the drug is 99 % effective?

Perfect Health Diet » Around the Web; Paleo Summit Edition (2012-02-25 20:09:36)

[...] Seth Roberts explains what Richard Bernstein taught the world. [...]

Nina (2012-02-26 12:46:04)

And that's why Dr Richard Bernstein - former engineer- went on to train as a physician. He continues to amass data from masses of grateful patients. Does that squash the sceptics? Nope. 'No double blind trials... blah de blah de blah'

### **"We're Economists. And We Don't Care About Innovation" (2012-02-19 05:00)**

In a Planet Money show about whether Super Bowls help host cities, a sports economist named [1]Victor Matheson, a professor at College of the Holy Cross, described himself and other sports economists:

We're economists. And we're concerned about equity and we're concerned about efficiency. And what most economists see . . . "

He didn't say "We're concerned about innovation". The way he ignores innovation reflects the whole field of economics. Here's the same thing from Christine Romer. In [2]an editorial about whether manufacturing deserves special treatment, she considers only productivity and equity:

It might be better to enact policies that will make all American businesses and workers more productive and successful. . . Today, we face a profound shortfall of demand. . . We need actions that raise overall

demand. [She doesn't say we are in a period of profound stagnation in most industries, which is also true.] . . . More aggressive monetary policy that lowered the price of the dollar would stimulate all our exports . . . Moving is very costly for dislocated workers with ties to their communities. . . Manufacturing jobs are seen as one of the few sources of well-paying jobs for less-educated workers. . . . Public policy . . . should be based on hard evidence of market failures, and reliable data on the proposals' impact on jobs and income inequality.

As if innovation (and lack of it) don't exist. Here's an example from Robert Reich, in [3]a post "rebut[ing] the seven biggest economic lies":

Shrinking government generates more jobs. Wrong again. It means fewer government workers – everyone from teachers, fire fighters, police officers, and social workers at the state and local levels to safety inspectors and military personnel at the federal. And fewer government contractors, who would employ fewer private-sector workers. According to Moody's economist Mark Zandi (a campaign advisor to John McCain), the \$61 billion in spending cuts proposed by the House GOP will cost the economy 700,000 jobs this year and next.

Nothing about the effect of shrinking government on innovation. Many types of innovation increase jobs.

This is like [4]doctors ignoring the immune system. Ignoring the effect of this or that policy on innovation is likely to lead to decisions that reduce innovation in favor of something easier to measure or defend, such as productivity or equity. The cumulative effect of ignoring innovation is stagnation and decline, caused by problems that got worse and worse as, due to lack of innovation, they failed to be solved.

Tyler Cowen (The Great Stagnation) and Alex Tabarrok (Launching the Innovation Renaissance) are absolutely right to focus on innovation and the lack of it. The obesity epidemic is 30 years old – a good example of a problem that has gotten worse and worse. Judging by [5]Tara Parker-Pope's reporting, mainstream weight researchers don't have a clue – in the form of empirical results – how to solve it. Outside mainstream academia, the dominant weight-loss idea is a low-carb diet. That idea is a hundred years old (Banting). How little innovation there has been. That Parker-Pope failed to criticize researchers for their lack of progress shows how deep the problem is. She appears not to grasp the possibility.

Matt (2012-02-19 06:50:37)

Maybe I'm a little slow today (or a little overemployed?), but I'm not bridging a gap here. How would the loss of hundreds of thousands of jobs spur enough innovation to be more in favor of losing those jobs? This sounds like Mitt Romney's ridiculous thought process that we should drive families into foreclosure sooner, so that the market could reset faster. No regard for the families that get wrecked in the fray.

Nancy Lebovitz (2012-02-19 09:08:57)

In Murray Rothbard's *Man, Economy, and State*, he assumes that businesses always have more ideas than they have resources to take action on, so the only limiting factor is the availability of capital. I don't know what any other economists have to say about innovation.

MikeW (2012-02-19 10:37:28)

Maybe economics needs a sub-field, "evolutionary economics". Analogous to biology vs. evolutionary biology. One group looks at the way things are, the other looks at how things change over time. From an evolutionary perspective, you could say a healthy economy is a lot like a healthy ecosystem. Species (businesses and individuals) continually adapt to exploit new niches or gain an edge over competitors. Some will thrive, some will go extinct (blacksmiths, elevator operators). And Stephen Jay Gould's "punctuated equilibrium" is obvious when you look at the revolutionary impact of personal computers and the Internet on the overall economy. Where government policy fits in, I don't know. But I think it would be a fun field to study if I were 18 again.

Seth Roberts (2012-02-19 10:57:31)

How would the loss of hundreds of thousands of jobs spur enough innovation to be more in favor of losing those jobs?

If it spurred any innovation, you should be more in favor of losing those jobs. I am not saying consideration of innovation effects would change every decision. Just some of them.

Andy (2012-02-19 11:22:06)

It is incorrect to generally conclude that economists don't care about innovation by citing researchers who aren't in fields (sports and business cycles) that closely deal with innovation and whose research questions don't appear to be greatly affected by the mechanisms of innovation one way or another. Industrial organizational economists and growth economists spent a great deal of time and effort thinking about innovation and productivity growth both at the individual/firm level and at the macro level. The evidence presented here is akin to accusing a cell microbiologist about ignoring macro-ecological considerations in their research and therefore condemning all of biology. While the first claim is likely true by design the conclusion does not really follow. I suspect that you would still find IO and growth economists' attempts at studying innovation limited, but at least consider the attempts of those who are actually working on innovation before condemning all of economics.

Jazi zilber (2012-02-19 11:51:09)

The expected value of innovation is hard to quantify. Hence, economists may have a hard time to analyze it. It is a common habit to ignore things that are not measurable. I wrote about it [1] the academic bias

1. <http://yzilber.blogspot.com/2008/08/academic-bias.html>

Seth Roberts (2012-02-19 12:57:17)

Industrial organizational economists and growth economists spent a great deal of time and effort thinking about innovation and productivity growth both at the individual/firm level and at the macro level.

Is there a book that describes what they have learned from all this "thinking about innovation"? I haven't seen it, but you would know better than me. These efforts have not shown up in the introductory economics books I have seen, which devote very few pages to innovation. That makes me think that my overall summary is fair. Also the way some economists define economics (the whole field) as "how to allocate scarce resources". Nothing about innovation in that definition.

Seth Roberts (2012-02-19 13:00:25)

From an evolutionary perspective, you could say a healthy economy is a lot like a healthy ecosystem.

Yes, in the sense of containing great diversity. Jane Jacobs made this point in her book *The Nature of Economies*.

TMS71 (2012-02-19 15:27:33)

EconTalk with Russ Roberts did an episode on innovation with Alex Tabarrok as the guest. You should check it out.

js (2012-02-19 16:15:21)

I get the sense you don't know much academic economics. Think of Paul Romer's work on the economics of ideas and the huge subfield of endogenous growth theory, or the industrial organization literature on patents, or the economic geography work on agglomeration economies like in Silicon Valley. This is all strictly mainstream stuff, but there is also a rich Austrian tradition on this topic. I'm not sure what the quotation from the sports economist serves to illustrate. Your implicit demand seems to be that economists use the word "innovation" in every sentence they utter.

April Harding (2012-02-19 17:13:08)

I think you may be misinterpreting the absence of innovation from Matheson's and Romer's comments (and implicitly, their conceptual framework for understanding the issues under discussion) as suggesting lack of attention to innovation across the whole field of economics. Until the past few years, economists' training and research did pay too little attention to innovation. Even so, a number of economists have been doing useful research on the issue ever since Joseph Schumpeter's work in the 1940s. And recently, interest in and research on the topic has increased dramatically. Here is a very brief overview of these developments [http://en.wikipedia.org/wiki/Innovation\\_economics](http://en.wikipedia.org/wiki/Innovation_economics)

Seth Roberts (2012-02-19 17:32:54)

I get the sense you don't know much academic economics.

I'm sure you know more than I do. Could you refer me to an introductory economics text that spends more than a few pages on innovation? Or to a book about all the stuff that been discovered?

js (2012-02-19 18:01:03)

You're right, it doesn't feature prominently in introductory textbooks. But introductory textbooks aren't a good indication of what's happening on the research frontier (and economics is hardly unique in this respect - the same is true of physics, for example). At the risk of sounding somewhat curt, perhaps you should explore the field beyond the introductory textbooks before you dismiss it entirely.

Seth Roberts (2012-02-19 21:17:52)

Perhaps you should explore the field beyond the introductory textbooks before you dismiss it entirely.

I'm not dismissing economics! I'm saying they nearly ignore something really important. I am saying the effects of any policy on innovation should be considered when deciding whether it is a good or bad idea. I almost never see that done. Am I wrong? And is there a book that summarizes all the work economists are supposedly doing on innovation? Or is it not just introductory courses, but also upper-level undergrad courses that mostly ignore innovation?

A straffing critique from Seth Roberts « Economic Sophisms (2012-02-19 22:26:19)  
[...] "We're Economists. And We Don't Care About Innovation" [...]

js (2012-02-20 09:46:04)

Here's some of the academic literature: [http://www.nber.org/s/search?restrict\\_papers=yes &whichsearch=db &q=innovation](http://www.nber.org/s/search?restrict_papers=yes&whichsearch=db&q=innovation)

Chris (2012-02-20 23:51:09)

Economists have been paying more attention to innovation albeit indirectly. There's a lot more emphasis today on [1]productivity as a key economic indicator than there was a few years ago. And economists can't seem to answer why productivity increases over the long run, except...technology leading to innovation.

1. [http://en.wikipedia.org/wiki/Productivity#Labor\\_Productivity](http://en.wikipedia.org/wiki/Productivity#Labor_Productivity)

Ragout (2012-02-21 11:46:03)

About half of Christina Romer's article is about innovation. The entire section titled "Market Failures" is about the proper role of government in fostering innovation. Perhaps you feel that her discussion is lacking in some way, but you haven't explained why. You've just ignored it, or perhaps failed to recognize what Romer is talking about. For example, the claim that Romer discusses productivity but not innovation is simply nonsensical. Innovation is the main way to increase productivity, so when an economist talks about increasing productivity, they're talking about innovation. Finally, innovation does not "increase jobs." Innovation can increase or destroy jobs in particular firms or industries, but not in the economy as a whole (excepting perhaps "frictional" and "structural" unemployment). So that's something about innovation that economists know that you don't.

Andy (2012-02-21 13:20:13)

I don't know of any good undergrad level text that covers these issues. That is partly my ignorance as I do neither growth nor IO and partly because I believe that the economics of innovation is underdiscussed at the undergraduate level. My recollection is that the basic coverage in undergrad is to tell students who Schumpeter was and briefly discuss the idea behind creative destruction and then discuss a simple stylized model of the reasons firm may invest in R & D and why patents may be socially desirable. For a richer coverage at the graduate+ level, Zvi Griliches edited a nice book "R & D, patents, and productivity" in the 1980s. Unfortunately I'm not enough of an expert to suggest any more recent work on the subject. Finally, on endogenous growth theory, I recommend 'Wealth and the Knowledge of Nations' which gives a good overview about how innovation and growth were understudied and how David Romer got a lot of people to pay attention to it (by providing a parsimonious model). It also gives an interesting viewpoint on the culture of academic economists.

Seth Roberts (2012-02-21 16:27:29)

Innovation is the main way to increase productivity, so when an economist talks about increasing productivity, they're talking about innovation.

Another way to increase productivity is to spread innovations. For example, there was a time when only a small fraction of workers had knives. Spreading knives made the remaining workers more productive. Same for any tool. A third way to increase productivity is to increase employment. Giving someone a job makes them more productive. So it isn't clear to me why you think innovation is the main way to increase productivity. Both of these other ways are very common.

Ragout (2012-02-21 17:13:41)

Economists have found that innovation is the main way to increase productivity and I assure you that this is what Prof. Romer means when she talks about increasing productivity. Increasing inputs of capital or labor are alternative ways to increase productivity, as you suggest, but they are much less important. The key role of innovation in boosting productivity is mainly an empirical finding, although there are also theoretical reasons to expect this (i.e., diminishing marginal returns to inputs). For more, you could read about the Solow Residual, the Solow growth model, and growth accounting. For example, see the chapters on growth theory in an intermediate macro textbook, such as chapters 7 & 8 in Mankiw, "Macroeconomics."

[http://en.wikipedia.org/wiki/Solow\\_residual](http://en.wikipedia.org/wiki/Solow_residual) bcs.worthpublishers.com/mankiw7/

Seth Roberts (2012-02-21 18:42:59)

Thanks for referring me to the Mankiw chapters.

### **Hot Miso with Cream and Sweetener: Coffee/Tea Substitute (2012-02-20 05:00)**

A few weeks ago, I wondered if I drink too much tea. Is 4 cups/day too much? What about 2 cups/day? To learn more, I needed to drink a lot less tea.

What about miso? I wondered. I had some high-quality miso paste in my refrigerator. I got it in Tokyo at [1]a miso store (thanks to Gary Rymar for taking me there). I made a cup (about 25 g miso paste – 2-3 teaspoons? – mixed with 1 cup hot water). It was delicious. The complex taste reminded me of coffee and chocolate. I added a little cream and a half packet of sweetener (Sucralose). It tasted even better.

I did the same thing with miso from Berkeley. It was still very good.

I cannot imagine not drinking tea. But I can now imagine drinking less tea because miso is much healthier. Replacing tea with miso is an easy way to eat more fermented food. A cup of miso is easier to make than a cup of tea.

Incidentally, don't waste your time with powdered miso. It is much worse than the refrigerated miso (paste) sold in tubs.

1. <http://foodpia.geocities.jp/man9miso/>

---

Not Tony (2012-02-20 08:46:15)

The forums are broken. New users can't create a profile because the image that we're supposed to enter the letters from won't display. This was the only way I could find to contact anybody.

Seth Roberts (2012-02-20 12:26:20)

Thanks for your comment about broken forums. I will look into it.

Jeff M. (2012-02-20 19:46:07)

Why do you use sucralose instead of sugar? My impression was that artificial sweeteners seem eventually shown to be less healthful than natural sweeteners (perhaps depending upon quantity, frequency, other dietary factors, and preexisting digestive & physiological status, e.g. artificial sweeteners are probably less harmful to diabetics than natural sweeteners would be).

Seth Roberts (2012-02-21 02:59:01)

I use sucralose rather than sugar to keep my blood sugar down – although I am not diabetic. Perhaps this is a mistake, as you say.

Alex Chernavsky (2012-02-21 07:37:14)

Seth, do you have any sense of what a dose-response curve would look like for ingestion of fermented food? Also, is your miso

fairly salty? I may try your suggestion (miso with hot water, sweetener, and [soy] creamer), but I wonder about the saltiness.

Oliver Mayor (2012-02-21 07:55:03)

I have a cup of miso now and then in place of tea. When having it this way, I usually mix it with a little coconut oil. For Alex: saltiness is one of the dominant flavors in miso, but there are variations that are less salty. To generalize a bit, if you prefer milder flavor, stick with shiromiso ("white miso"), which has a sweeter flavor, and avoid akamiso ("red miso") which is often stronger-tasting and saltier. But since there are so many varieties; I guess this is a good time to try out side-by-side comparisons. I prefer stronger flavored food, but just to put it out there, the brand I usually buy from my local Asian food market is called "Yamabuki Milder Miso". It has much less sodium for some reason than the other brands, which is not that important to me, but it is also one of the more expensive brands that doesn't have added MSG or additional flavorings.

Chris U (2012-02-21 11:39:58)

Re: Sucralose I've been eating alot of xyllitol for dental health. I suspect that it has other health benefits but haven't done too much research yet. Might be an alternative for you Seth.

Stone Glasgow (2012-02-21 11:48:04)

Tea is a fermented food. Why do you consider it to be unhealthy? You can even find very strongly fermented teas, like "puer," that contain myriad bacteria and related enzymes (one enzyme in puer has a strong ability to digest wheat gluten), and last many years, improving with age like fine wine.

worthwords (2012-02-22 02:10:35)

On what basis is tea unhealthy? Especially a mere 1-2 cups per day.

Seth Roberts (2012-02-22 12:58:12)

I wonder about the caffeine in tea. But not the caffeine in a mere 1-2 cups.

Stone Glasgow (2012-02-22 21:40:59)

Why do you suspect that caffeine may be harmful?

Seth Roberts (2012-02-23 01:56:26)

Caffeine may be harmful because in large amounts it causes sleep trouble. Maybe small amounts also have that effect...hard to say.

## **Vitamin D3 in Morning Makes Waking Up Easier (Story 18) (2012-02-21 05:00)**

David Cramer left [1]the following comment here:

Since you started posting these, I've been taking D3 in the mornings and notice that I wake up much more easily. I started with just 400 IU, then increased it to 800 IU. One day I took 1200 IU and woke up at 4:00 AM the next day. I've gone back to 800 IU since 4:00 AM seems a bit early. For the past week, I've also been giving one of my daughters (11 years old) 400 IU each morning, and she seems easier to wake up in the morning (normally it's quite difficult).

I asked him for details.

Tell me about yourself.

I'm in my 40s and live in Austin, Texas and have two daughters. I first encountered your work when I read about the SLD in Levitt and Dubner's blog. I read the pdf of your papers linked from that blog post and tried the SLD with sugar water. At the time, I was at the high end of my ideal weight, but was not motivated by weight as much as curiosity. I found the irony and absurdity of the SLD appealing. I also liked the idea that it could be tested easily and cheaply. I went from 170 to 145 lb in couple of months, but really only did SLD for 3 weeks. I now occasionally have a nose clipped green smoothie in the morning.

How long have you been taking D3 in the morning? What time do you take it?

I started a couple of weeks ago after you started blogging about it. I take it around 7:00 AM. That would normally be about an hours after I wake up.

The most obvious change since you started taking it is that you wake up more easily? How soon did this start after you started the D3?

Yes, that's the change I notice. It may be improving my sleep quality, but that's very subjective and not something I track closely anyway. The effect started almost immediately.

Could you describe (a) how easy it was to wake up in the month before you started the D3 and (b) how easy it was to wake up after you started the D3?

I would often set three alarms on my cell phone and return to bed for more sleep after dismissing the first two. After D3, I usually wake up before my alarm and don't feel the need to go back to sleep (e.g. after going to the bathroom). Post-D3, when I wake up, I'm awake. Previously, I was still very drowsy for some time, even after getting up.

What time do you usually wake up? get out of bed? do you use an alarm clock to wake yourself in the morning?

Usually 6 or 6:30. Occasionally a little earlier if I have an early meeting at work.

Did D3 have any effect on how easily you fall asleep in the evening? On how often you wake up in the middle of the night?

I haven't noticed any difference in falling asleep. I don't typically wake up in the middle of the night.

How much sunlight do you get on a typical morning?

Although I live in Texas, I doubt I get much in the morning this time of year. I do bike to work a couple of times a week, but my arms and legs would be covered. I might even wear gloves if it's cold. I work inside in an office during the day.

What brand of D3 do you use? what form (e.g., gelcap)?

NOW gelcaps.

How can you tell your daughter "seems to find it easier to wake up in the morning"?

She's a sound sleeper. Normally it requires repeated reminders and threats to get her up. Even after you get her out of bed, she'll fall back asleep on the couch. With 400 IU, I'm noticing less of that. I plan to up to 800 IU this

week to see if there's a difference.

Tim Ozenne (2012-02-21 09:40:10)

In the past, you discussed the effect of morning light—or its absence—on "mood" and such on "normal" individuals (as opposed to SAD types). Any idea if "Daylight Savings Time" has any deleterious effects? I arise early every morning for a swim workout. Right now, it is just barely dawn when practice is over in the outdoor pool, and soon Congress will make it dark again even at the end of the workout. I am wondering if anyone has looked at the effect on mental health of screwing with the clocks to get us up in the dark? Do you know?

beagle3 (2012-02-21 09:41:34)

Just noticed this post: <http://www.gwern.net/Zeo> #vitamin-d n=1, but mostly rigorous proof that vitamin D at night hurts sleep.

carol (2012-02-21 19:47:08)

Maybe this is why I wake up so early! I don't like waking up at 4 am. I never have trouble waking up - I'm too awake. I may drop the D3 for now.

JimPurdy.blogspot.com (2012-02-21 23:32:59)

David Cramer said: "I found the irony and absurdity of the SLD appealing." The absurdity of the Shangri-La Diet? Hmmm ... now there's an interesting thought. David, maybe you've discovered something. Maybe, all these years, the psychologist Seth Roberts has been running a psychology experiment on a grand scale, by proposing absurd stuff (sugar water to lose weight, balancing on one foot, staring at pictures of people in the morning), to see how many people can be fooled into doing ridiculous things. Yup, any day now, Ol' Seth will announce that his whole self-experimentation thing has been a big stunt funded by the propaganda gurus of Madison Avenue. Seth Roberts = the new Allen Funt, with all of America as the unwitting stars of a new Candid Camera program. Seth, does David Cramer get a prize for discovering your secret? Hee Hee ...

gwern (2012-02-22 14:55:08)

Tim: a quick check in Google Scholar with the very most obvious search terms - eg. <http://scholar.google.com/scholar?q=mood+daylight+savings> - suggests that there are many results in that vein.

Seth Roberts (2012-02-22 19:31:23)

Is the Shangri-La Diet "ironic and absurd"? I don't know what "ironic" means but yeah it does seem absurd. 1. Using sugar or fat (olive oil) to lose weight. 2. Making such a small change – all other weight-loss diets involve big changes. 3. Adding foods to what you eat (all other weight-loss diets involve some sort of deprivation – don't eat this or that). 4. Nose-clipping: why should that have any effect? The calories don't change, and calories are what matters. Or: the carbs don't change, and carbs are what matters.

JimPurdy.blogspot.com (2012-02-22 22:22:14)

And of course I was just joking about your supposed hoax. Actually, I am fascinated by how often that you detect things that nobody else seems to have noticed before. It reminds me of how a young child (who still has an open mind, at least until TV kills their brain cells)) will often spot things that adults see every day but don't notice. While I'm in my full-blown "TV-kills-the-brain" mode, Seth, I'm curious about how much TV you watch, and what kinds of TV you watch. As an ultra- liberal, I hope you tell me that you watch MSNBC and CNN, but you'll destroy my theory if you watch Fox News.

Seth Roberts (2012-02-23 02:11:02)

I watch about 2 hours of TV per day. My favorite shows include Homeland, Mad Men, The Bachelor/Bachelorette, Switched At Birth, The Amazing Race, Glee, Survivor, Revenge, The Good Wife, Downton Abbey, 60 Minutes, Work of Art, Episodes, and Suits.

JimPurdy.blogspot.com (2012-02-23 02:45:29)

Interesting, Seth, thanks. Since I gave away all my TVs back in 2005, I'm not familiar with any of those except 60 Minutes.

TomGinTX (2012-02-25 12:51:38)

Seth, have you watched any of the USA Network shows besides Suits? Psych and Burn Notice are my favorites. I also like White Collar, In Plain Sight, Royal Pains, and Covert Affairs. For just plain zaniness, it is hard to beat Psych. The "spy tips" on Burn Notice would come in handy at some odd moment. 8-)

Seth Roberts (2012-02-25 13:18:31)

Seth, have you watched any of the USA Network shows besides Suits?

Thanks for the suggestions. To answer your question: Not regularly. I think I've sampled most of them. Recently I confused White Collar and Suits so I watched a few seconds of White Collar.

TomGinTX (2012-02-25 14:27:53)

Easy to get them mixed up 8-) How to Create a USA Show in Six Easy Steps [http://www.vulture.com/2011/06/usa\\_shows.html](http://www.vulture.com/2011/06/usa_shows.html)  
Seth: Funny article. I am still surprised I like Suits, since on the face of it it's as formulaic as a romance novel.

Amara (2012-03-02 04:35:59)

Hello! i am not into blogging but this time i wanna leave a message that I didn't know that was very effective. I am 27 year old and if I'm going to buy vitamin D3, how many amount of dosage i am going to take? Hope you guys will answer me. Thanks for your wonderful website.

## **Vitamin D3 in Morning (1000 IU) Improves Rosacea (Story 19) (2012-02-22 05:00)**

A reader named Bob H left [1]the following comment:

I'm on 1000 [IU] a day D3 in the morning. I have not noticed any difference in sleep, but my rosacea has cleared up considerably.

Rosacea is not usually believed to be due to Vitamin D3 deficiency. For example, Wikipedia [2]lists many causes, but not that. [3]Here is another list of causes that does not include Vitamin D3 deficiency. [4]The Vitamin D Council says Vitamin D "cannot be used to prevent or treat rosacea" (but without supporting evidence). On the other hand, when people with rosacea consider the question, [5]they find evidence that D3 helps rosacea. If you have rosacea and have tried D3, please comment or email me about what happened.

I asked Bob H for details.

Tell me about yourself.

47 year old, white, IT worker, 230 lbs, runner, beer drinker, Maryland, but I lived in the Netherlands from Jun-2008-Jul-2011.

When did you start taking 1000 IU/day D3 in the morning? Were you taking D3 before this?

I started taking it about 6-8 weeks ago, in the morning, about 9:00 am 1000 IU - my first time for D3.

Please describe your rosacea before you started 1000/day D3 in the morning. please describe your rosacea now.

I've had consistent rosacea for years on my chest. It has not gone away completely, but it's much better.

Please describe your sleep.

My sleep was good before I started taking D3, and is still good.

Most of the success stories about Vitamin D3 in the morning have involved 4000 IU/day or more. Why did you decide to try 1000 IU/day?

I wanted to start out at a lower dose and build up.

What brand and form of D3 do you take?

1000 IU NatureMade gel.

---

Kirsten (2012-02-22 11:09:28)

Funny, I thought everyone knew that-but maybe not. I developed rosacea about 10 years ago, after being sick with a mystery illness that kept me out of work for a month and taking massive antibiotics that, in the end, had nothing to do with getting me better. After that, I developed digestive problems and also a tendency for facial flushing. I noticed it first in pictures-I'd be the person with the bright red nose. I never got the bumps on my skin that some rosacea sufferers have, just flushing. It was aggravated by cold, caffeine, spicy foods, strong emotions, and alcohol. Also, sugar and wheat consumption seems to aggravate it generally-not cause an attack but make me more prone to them. I got laser treatment for it, which helped for a while, though it came back, as the doctor had said it would. Anyway, a few years back I started taking D3 regularly, based on advice on paleo sites and this website, and I noticed that it had a dramatic affect on my flushing-even more than just avoiding my triggers. (That's hard anyway, since I love tea, coffee, and red wine.) I told a friend with rosacea, and he found that it worked too. My D3 intake varies a lot, since sometimes I'm very good about taking it regularly and sometimes I get out of the habit of taking it (like right now). I sometimes take cod liver oil, and sometimes D3 gels. When I stop taking it, the flushing comes back-I notice it after my morning coffee and after wine with dinner. When I start again, the flushing subsides. I've never paid attention to how long it takes-like whether it's instant or whether I need to take it for a while to notice the effect. Perhaps I'll start taking it again and see what happens.

Cliff Clayton (2012-02-22 19:08:06)

For everyone out there reading this, Cooling Inflammation by Dr. Art Ayers has information on rosacea and how D3 works to reduce inflammation. His blog is huge and covers many diseases.

---

Tom (2012-02-23 05:55:48)

It can be hard to get enough magnesium orally, as it's bulky, and ingesting too much can cause diarrhea (the 'milk of magnesia' effect.) Apparently, it is much more efficiently absorbed transdermally, via baths or soaking your feet in water to which magnesium chloride crystals have been added. This is the stuff when marked up as a bath product: [http://magneticclay.com/store/Department s/Ancient-Minerals-Magnesium-Bath-Flakes.aspx](http://magneticclay.com/store/Department%20s/Ancient-Minerals-Magnesium-Bath-Flakes.aspx) But this is the same stuff from an aquarium supply store (about a third the price): <http://bulkreefsupply.com/store/review/product/list/id/648/>

James A Donald (2012-02-23 15:30:20)

Since magnesium disassociates in the body, it is unlikely the form of magnesium supplement makes much difference.

garymar (2012-02-23 20:27:43)

Tom, that's a great link. I just bought some Epsom salts, magnesium sulfate, to put in my bath (besides taking magnesium citrate orally). The magnesium chloride would be a lot cheaper. I can buy it here in Japan in bulk because it's used in the making of tofu (it's called nigari). It costs about \$30 for 50 lbs.

Tom (2012-02-27 18:53:37)

garymar, not sure if you'll see this, but the way to make transdermal magnesium ridiculously cheap is just to dissolve the magnesium chloride in water and apply it with a sponge while in an empty tub. Read a book or email w/ your phone while it absorbs. If the concentration is too strong, you'll feel a mild stinging sensation after about ten minutes (which stops immediately upon rinsing off.) I just can't see the point in diluting it with a tub full of water each day and then losing it all down the drain.

### **Excellent Customer Service From Fidelity Investments (2012-02-23 22:13)**

Because I am in China, I want my new credit card sent here. After 45 minutes arranging this, my credit-card company asked me one last security question: What were the last four digits of the bank account used to pay my most recent bill? I told them. They said my answer was wrong. Huh?

I pay my credit card bills through Fidelity Investments (which is not a bank). I contacted them. I was routed to their BillPay department. The person who helped me, whose name I wish I had written down, said that he was as puzzled as I was. It was not clear at all why my answer was wrong. He suggested a conference call. He started a conference call with my credit-card company. Within a few minutes, he and the credit-card company representative figured out that there was a mistake in the number listed by the credit-card company. Their software had lost the last digit of my account number, so that if my account number had ended in 12345, their records would have showed 1234. (Yet the payment still went through.)

I was greatly relieved. "At least the problem had a solution!" I told the credit-card-company representative. Imagine not being able to control one's money because of a software error. I was/am grateful to the Fidelity representative for quickly solving a problem that had nothing to do with Fidelity.

You might think that such heavily-used software would by now be free of bugs. But it wasn't.

---

Darrin Thompson (2012-02-24 07:18:35)

My dad, who is a very good long term saver, told me that if you are serious about saving your money and investing (the right way, i.e. buy low cost index funds and hold), you either put your account with Vanguard or Fidelity. Everybody else is out to suck you dry with "management" fees.

David Johnston (2012-02-24 08:58:04)

So was it the check digit that was the problem? I can see how software might either conclude that the 'last digit' was the last digit of the account number or the check digit they tack on the end. It suggests organizational incompetence if they can't agree and standardize on these simple things.

dearieme (2012-02-24 10:07:05)

"You might think that such heavily-used software would by now be free of bugs. But it wasn't." Oh very sharp. You do intend it as an analogy, don't you?

Seth Roberts (2012-02-24 15:03:49)

So was it the check digit that was the problem?

It was the last digit. Whether the last digit of the account number is a check digit I don't know.

Seth Roberts (2012-02-24 16:08:28)

You do intend it as an analogy, don't you?

Yes. As another example of the fallibility of experts.

David (2012-02-24 21:02:13)

You might think that such heavily-used software would by now be free of bugs. But it wasn't. No, I wouldn't think that. Not for nanosecond.

### **Lame Response of the AMA to HealthTap (2012-02-24 05:00)**

Many years ago, when I was a professor at Berkeley, I sought out David Freedman, a professor of statistics, for comment on an idea of mine. I knew he would dislike it – he was negative about everything – and I wondered how strong his reasons for disliking it would be. It turned out, as I expected, that he disliked it but – I was glad to see – had no convincing reasons. That was helpful, I thought.

Likewise, it is obvious that the AMA would dislike [1]HealthTap, a website that solicits doctors' answers to medical questions (along the lines of "I have X symptoms. What should I do?"). [2]Here's the AMA response:

Dr. Peter W. Carmel, president of the American Medical Association, says he is concerned about the use of online medical information, which should "complement, not replace, the communication between a patient and their physician," he wrote in an e-mail. With online health information sites, "a medical history is not taken, a physical exam does not occur and any suggested treatment is not monitored or assessed," he said. "Using this information in isolation could pose a threat to patients."

These comments could have been made by someone with no medical training. Practically everything has a hypothetical downside ("could pose a threat"). Since he fails to call into question the obvious upside (patients will get questions answered much faster and cheaper), he is practically endorsing it.

1. <https://www.healthtap.com/>

2. [http://www.nytimes.com/2012/02/05/business/on-healthtap-advice-for-you-and-points-for-doctors.html?\\_r=1](http://www.nytimes.com/2012/02/05/business/on-healthtap-advice-for-you-and-points-for-doctors.html?_r=1)

tess (2012-02-24 10:07:35)

such a thing threatens the AMA monopoly – we can't have that!!! patients MUST NOT have ideas of their own! what are you thinking??? ;-)

Jim Purdy (2012-02-26 00:00:36)

HealthTap sounds very interesting, Seth. Thanks for calling attention to another great (hopefully, anyway) resource.

Bennett Werner, MD (2012-05-04 06:08:01)

The AMA doesn't (want to) understand that Healthtap is not proposing to "practice medicine" in its allotted 400 character answer space. It provides much needed information and there's plenty of need for that!

### **Stephen McIntyre on Gleickgate (2012-02-24 15:57)**

Gleick might as well have signed the fake document. Mosher identified him as the author almost instantly. The fake memo, unlike the actual documents, put Gleick in a position of prominence in the climate debate, whereas, in his actual encounters with skeptic blogs, Gleick has come across as an erratic and even comic figure. The style parallels came afterwards.

From [1]here. I sat next to Peter Gleick at a friend's dinner party about five years ago. He seemed to me staggeringly accomplished, not erratic (or comic) at all. Yet recently [2]I too found him to be comic. Remember that famous New Yorker cartoon – "On the Internet, no one knows I'm a dog"? The bitter truth is "On the Internet, no one knows I'm a nice person." I don't mean Gleick is not a nice person – if anyone is a jerk it is me for what I just quoted – I mean that his recent actions strike me as weirdly uninhibited.

1. <http://climateaudit.org/2012/02/24/heartland-publishes-gleick-emails/#comments>

2. <http://blog.sethroberts.net/2012/01/30/the-great-climate-change-debate-which-side-is-funnier/>

---

mike (2012-02-24 17:06:00)

Check out Gleick's review of "The Delinquent Teenager Who Was Mistaken for the World's Top Climate Expert" and the comments in reply. [http://www.amazon.com/Delinquent-Teenager-Mistaken-Climate-ebook/product-reviews/B005UEVB8Q/ref=cm\\_cr\\_pr\\_top\\_link\\_next\\_2?ie=UTF8&showViewpoints=0&filterBy=addOneStar&pageNumber=2](http://www.amazon.com/Delinquent-Teenager-Mistaken-Climate-ebook/product-reviews/B005UEVB8Q/ref=cm_cr_pr_top_link_next_2?ie=UTF8&showViewpoints=0&filterBy=addOneStar&pageNumber=2)

mike (2012-02-24 17:37:27)

Gleick was one of the authors of the response to the WSJ article. He said that most of those authors have no expertise in climate science. Those authors included the people below: Claude Allegre, former director of the Institute for the Study of the Earth, University of Paris; J. Scott Armstrong, cofounder of the Journal of Forecasting and the International Journal of Forecasting; William Kininmonth, former head of climate research at the Australian Bureau of Meteorology; Richard Lindzen, professor of atmospheric sciences, MIT; Henk Tennekes, former director, Royal Dutch Meteorological Service; Antonio Zichichi, president of the World Federation of Scientists, Geneva.

dearieme (2012-02-25 15:19:31)

Is he mad or just a conceited chump who considers himself above petit bourgeois notions such as propriety and legality? The funny farm or jail?

## **The DIYization of Beer Brewing and Innovation (2012-02-25 03:43)**

The key point – as far as I'm concerned – in [1]this article about the DIYization of beer brewing comes in the middle of a paragraph:

Home brewing is part of a broad spectrum of DIY activities including amateur astronomy, backyard biodiesel brewing, experimental architecture, open-source 3-D printing, even urban farming. . . . Many of these pastimes can lead to new ideas, processes, and apparatus that might not otherwise exist.

Likewise with the DIYization of science: It will produce new ideas, solutions, etc. The Shangri-La Diet is an example.

Thanks to David Archer.

---

## **Vitamin D3 in Morning: 4000 IU Better Than 1000 IU (Story 20) (2012-02-25 05:00)**

[1]Daniel Lemire, a Canadian computer science professor, left [2]the following comment here

I have irregularly taken 1000 UI in the morning for years with no noticeable effect.

For about two years, I have had poor sleeping patterns characterized mostly by the fact that I tend to go to bed at 1am or later (and I get up around 7:15 am [woken up by an alarm clock]). Whenever I would try to go to bed earlier, I would simply fail to fall asleep.

After reading this blog, I increased my intake of D3 to 4-5,000 IU. I'm now falling asleep about an hour earlier. This could be a placebo effect, of course, but I consider it a very significant improvement.

It is unclear whether I have more energy. I don't know how to measure such an effect. I expect that I'm less irritable, but that's a side-effect of getting more sleep.

I asked him for details.

Tell me about yourself.

I'm in my 40's. I enjoy a flexible schedule and often work from home.

You write: "For about two years I have had poor sleeping patterns characterized mostly by the fact that I tend to go to bed at 1 am or later (and get up around 7:15 am [woken up by an alarm so that he can eat breakfast with his family and walk his kids to school]). Whenever I would try to go to bed earlier, I would simply fail to fall asleep." You mean you are still tired when you get up? You want to sleep longer but are unable to?

I was getting about 6 hours of sleep, and yes, I was still tired when I got up. I'm less tired now that I am getting around 7 hours of sleep.

"I tend to go to bed at 1 am or later". What was the average (median) time of going to bed? When you went to bed at this time ("1 am or later"), how long would it take you on average (median) to fall asleep?

The median is 1 am. I fall asleep immediately. I don't go to bed unless I know I will soon fall asleep: I tried to go to bed earlier, but it made me feel worse about my insomnia and I did not get better sleep. I tend to stay up until I feel like I must go to bed.

"After reading this blog, I increased my intake of D3 to 4-5,000 IU." How many days have you been at the new dosage?

2 weeks +/- 3 days.

Was this the only change?

Yes. As far as I can tell. The time did not change. It is around 7:30 am. Soon after I get up. Before coffee.

"I'm now falling asleep about an hour earlier. " What time (median) is that? How long (median) does it take you to fall asleep? What time are you now waking up?

I now fall asleep around midnight. I just instantly fall asleep. So I am getting approximately 7 hours of sleep.

"I expect that I'm less irritable." You've noticed that you're less irritable?

Yes. I feel less irritable.

What brand and formulation (e.g., capsule, gelcap, tablet) of D3 do you take?

Walmart house brand ("equate"). Tablets, 1000 IU/tablet. I take 4, sometimes 5. (Median is 4.)

1. <http://lemire.me/blog/>

2. <http://blog.sethroberts.net/2012/02/08/vitamin-d3-and-sleep-story-14/#comment-949971>

---

Nancy Lebovitz (2012-02-25 07:57:00)

Off-topic, but a striking case of self-experimentation: [1]MS symptoms reversed with scientific-theory based diet change- in the paleo range, I think.

1. <http://www.youtube.com/watch?v=KLjgBLwH3Wc&feature=youtu.be>

Stone Glasgow (2012-02-25 12:11:08)

Seth, have you considered two-stage sleep? We appear to be naturally inclined to sleep in two, four-hour stages per night, with a waking period in between, according to modern studies, historical references, and modern day hunter gatherer tribes: [http://www.bbc.co.uk/news/magazine-16964783?utm\\_source=twitterfeed&utm\\_medium=twitter](http://www.bbc.co.uk/news/magazine-16964783?utm_source=twitterfeed&utm_medium=twitter)

Seth Roberts (2012-02-25 13:22:41)

Seth, have you considered two-stage sleep? We appear to be naturally inclined to sleep in two, four-hour stages per night, with a waking period in between, according to modern studies, historical references, and modern day hunter gatherer tribes:

I am not so sure. What if all those studies involved people who didn't stand much (say, less than 4 hours/day) but long ago people stood much more (say, more than 8 hours/day)? And if you stand a lot the two-stage structure disappears? So it is not so clear what we are "naturally inclined" to do. I admit however that I can get a lot done after I wake up early in the morning but before I later fall back asleep...so it is not so clear there is anything wrong with this two-stage structure.

Stone Glasgow (2012-02-25 15:37:42)

Perhaps the methods that you have used to combat your early-waking have been interfering with our natural tendency to have twin sleeping-cycles. Did you see the side bar in the BBC link? When segmented sleep was the norm: "He knew this, even in the horror with which he started from his first sleep, and threw up the window to dispel it by the presence of some object, beyond the room, which had not been, as it were, the witness of his dream." Charles Dickens, Barnaby Rudge (1840) "Don Quixote followed nature, and being satisfied with his first sleep, did not solicit more. As for Sancho, he never wanted a second, for the first lasted him from night to morning." Miguel Cervantes, Don Quixote (1615) "And at the wakening of your first sleepe You shall have a hott drinke made, And at the wakening of your next sleepe Your sorrowes will have a slake." Early English ballad, Old Robin of Portingale The Tiv tribe in Nigeria employ the terms "first sleep" and "second sleep" to refer to specific periods of the night

Stone Glasgow (2012-02-25 15:39:35)

Why would the Tiv tribe in Nigeria have twin sleep-cycles? They are presumably on their feet a lot and in the sun generating D3.... Perhaps they don't skip breakfast ;)

Seth Roberts (2012-02-25 16:37:53)

you didn't like my first example, okay, let me give you two more: 1. Is whatever language the Tiv speak likely to be the very first human language? 2. Is whatever diet the Tiv eat likely to be the very first human diet (or even the diet of 100,000 years ago)? I don't mean that you're wrong - just that I am less convinced than you.

Stone Glasgow (2012-02-25 19:35:41)

So you think that perhaps even 500 years ago, we were eating and acting outside of the natural behavior of our ancestors, which was (and is) disrupting our sleeping patterns? Seem plausible to me. Seth: Yes, that's what I think. One reason the Tiv may have segmented sleep is that they don't eat enough animal fat.

Kirk (2012-02-26 13:12:43)

I am skeptical about most claims about what might be considered normal human sleep. For example, the entertaining and fascinating book "Don't Sleep, There are Snakes" is one of several accounts I have come across where hunter-gatherers slept according to odd schedules. And the health blogs constantly talk about keeping your room pitch-black so as not to affect melatonin levels. And yet didn't hunter-gatherers camp under full moons? Seth: yeah, and did they or didn't they sleep in the shade of trees? and did they or didn't they cover their eyes while they slept? I don't think we'll know the answer to these questions any time soon. However, my many attempts to make my sleep deeper did eventually improve my ability to fight off colds.

Chris (2012-02-26 14:45:29)

I can see how this can happen. For most people 1,000 i.u is not enough and it has been proven in many case studies. The ideal amount of D3 consumption can range from person to person, but it should be around 5,000 i.u - 10,000 i.u. I was

reading an article on: <http://whatvitaminsshoulditakeinfo.com/> and it basically explained this is due to changes in society; electricity, working inside for long hours, sunscreen..etc Kirk, it is recommended to sleep in complete darkness. Any form of light immediately signals to your body to stop producing melatonin. However, you did bring up a very valid point that I have not yet studied. I'll have to look into that.

Iwan (2012-03-08 08:42:15)

Has anyone else noticed this? I have been taking 4 x 1000 u in the mornings for the past 6 weeks. In the past 2 weeks, 4 people have asked me if I've been on holiday as I appear 'tanned' and healthy. I live in Canada. We have limited daylight at this time of year and I do an office job. Blood pressure is okay and I eat mostly paleo, and I have had no other significant lifestyle changes in the period. Has anyone else seen similar effects?

### **Carl Willat Suffers From the Willat Effect (2012-02-26 05:00)**

[1]Carl Willat, for whom [2]the Willat Effect is named, wrote to me:

I had two cartons of half and half in the fridge, neither had reached its expiration date but one was three days newer. I wondered if I could taste the difference between them, and I found that I could. Neither was sour, but one tasted fresher. I made a batch of vanilla ice cream out of each of them, figuring that together with the other ingredients I was adding (vanilla, egg yolks, cream, salt and sugar) the difference in taste would be less noticeable. After putting both mixtures through the ice cream freezer I tasted them [side by side] and one tasted a lot better. I gave a friend of mine a spoonful of each and she immediately noticed the difference. She correctly identified the good one and described it as tasting fresher and lighter. I can't bear to eat the less good batch and I don't know what to do with it. I don't want to give it away for fear someone will think it representative of what my ice cream tastes like. I'm sure in the past I've made plenty of ice cream of this same quality that I and everyone else thought was perfectly acceptable, even delicious.

The fascinating part is "can't bear to eat the less good batch". Same thing with me and tea: In the last half year or so, I've made hundreds of side-by-side comparisons of tea. I now throw away cups of tea I don't like. I never used to do that.

1. <http://www.carlsfinefilms.com/>

2. <http://blog.sethroberts.net/category/human-evolution/my-theory-of-human-evolution-directory/willat-effect/>

jeff (2012-02-26 05:57:24)

I had an experience with this just this week. I brought a cup of starbucks to a meeting that had a carton of Dunkin Donuts coffee. After having the starbucks the DD tasted awful. I am seeing many more examples with this effect in real life.

Adam (2012-02-26 06:24:10)

I am interested in knowing which was the best tasting ice cream. The one made from the freshest ingredients or the one made from the fermented? Is it fermented or just on its way to spoiled. I have also noticed this effect, especially with coffee, and it's not always the one that I assume to be the "freshest".

Alex Chernavsky (2012-02-26 07:32:30)

Then there's something that I would call the reverse Willat effect. I recently bought a new brand of kim chee that, at first, tasted much better to me than my usual brand. But when I compared them side-by-side, the two brands tasted remarkably similar to me. See also: [1]Double-Blind Violin Test: Can You Pick The Strad?

1. <http://www.npr.org/blogs/deceptivecadence/2012/01/02/144482863/double-blind-violin-test-can-you-pick-the-strad>

Brian (2012-02-26 12:44:39)

Hi Seth, I wonder what your thoughts are about when we should and should not avoid the Willat effect. On the one hand, nicer things are nice, but on the other I don't want to need the best of everything. Looking at the Willat Effect next to the Hedonic treadmill what do you think is optimal? I already can't stand normal chefs knives, produce, yogurt, speakers, music, movies, and books! - Brian Seth: In my experience the Willat Effect both increases (tea) and decreases (sake) consumption. Of course when it decreases consumption it decreases enjoyment - since I don't drink sake, I no longer enjoy it. But I don't miss sake, there are plenty of substitutes. So, in my experience, there has been no serious downside. The upside is really noticeable: I do side-by-side tea comparisons every day.

Kirk (2012-02-26 12:59:48)

I'm tied in knots in a fierce debate with myself as to whether I should continue with the comparison tea tasting. You see, I had grown bored with a regular black tea (organic Assam, brewed 2.5 minutes, served with cream). A month ago I tried another round of tea comparison with a variety of samples, and the winner was the one I had settled on three years ago. But it's still kind of boring. Given this state of boredom with black tea, several years ago I started making chai tea out of a random blend of spices, grinding the spices myself with a granite mortar and pestle. And the tastes have been reasonably pleasurable, like adding fermented foods to soups and steps. But as I contemplate taking on a half-year investigation into what makes the best chai blend, I have to ask myself, "Do I really want to shun all those other almost-good-enough blends?" On the other hand, at the end, I'll have the perfect chai blend.

dearieme (2012-02-26 17:35:12)

You give the inferior ice cream to the cat. Life isn't all that complicated.

---

Tuck (2012-02-27 12:28:54)

Fallon and Enig's "Nourishing Traditions" cookbook contains a similar recipe for mayo. In their recipe whey is optional, and if excluded reduces the life of the mayo, but if included a period of fermentation is not required. I've made mayo with and without whey, and with whey it lasts a lot longer, even if you put it directly in the fridge. Homemade mayo is well worth it, and once you get the procedure down takes very little time.

Not Tony (2012-02-28 15:01:19)

Sorry to keep posting in here, but the now the forums won't send the verification email to new posters, so no more new posters can register. Seth: after you register for the forums, send me your username and I will approve your registration. I do it this way to prevent thousands of spam registrations.

Stone Glasgow (2012-03-01 14:09:20)

What did she report regarding apple vinegar? Have you found an effective cure for toenail fungus?

## **Personal Science and Varieties of DIY (2012-02-29 19:48)**

How does personal science (using science to solve a problem yourself rather than paying experts to solve it) compare to other sorts of DIY?

Here's an example of personal science. When I became an assistant professor, I started to wake up too early in the morning. I didn't consider seeing a doctor about it for several reasons: 1. Minor problem. Unpleasant but not painful. 2. Doctors usually prescribe drugs. I didn't want to take a drug. 3. Sleep researchers, based on my reading of the sleep literature, had almost no idea what caused early awakening. They would have said it was due a bad phase shift of your circadian rhythm. They often used the term circadian phase disorder but never used the term circadian amplitude disorder – apparently they didn't realize that such a thing was possible. I decided to try to solve the problem myself – an instance of DIY. Except that, if I made any progress, that would be better than what the experts could provide, which I considered worthless.

There are thousands of instances of DIY, from fixing your car yourself to sewing your own clothes to word processing. Here is one dimension of DIY:

1. Quality of the final product. Better, equal, or worse to what you would get from professionals. Richard Bernstein's introduction of home blood glucose testing led him to much better control of his blood glucose levels than his doctors had managed. Same as my situation: DIY produced acceptable results, the experts did not.

In contrast to Bernstein, who reduced his blood glucose variability within months, it took me years to improve my sleep. That is another dimension:

2. Time needed. Personal science, compared to other DIY, is orders of magnitude slower.

Here are some more dimensions:

3. Training needed. I don't know how much training personal science requires. On the face of it, not much. I had acne in high school. I could done self-experimentation at that point. It just didn't occur to me. On the other hand, I think effective personal science requires wise narrowing of the possibilities that you test. For most health problems, you can find dozens of proposed remedies. How wise you need to be, I don't know.

4. Commercialization. Some forms of DIY are entirely the creation of businesses – cheap cameras, home perms, IKEA, etc. Bernstein's work happened because of a new product that required only a drop of blood. The company that made it wanted doctors to do DIY: measure blood glucose levels in their office (fast) rather than having the measurement made in a lab (slow). When I started to study my sleep, no business was involved. Now, of course, companies like Zeo and the makers of FitBit want users to do personal science.

5. Price. My sleep research cost nothing, which in the DIY world is unusual. The term DIY is almost entirely a commercial category: Certain books and goods are sold to help you DIY.

6. Customization possible. Some kinds of DIY give you the tools to build one thing (e.g., IKEA, home perms). Other kinds (e.g., Home Depot, word processing) give you the tools to build a huge range of things. This dimension is variation in how close what you buy is to the finished product (Ikea = very close, word processing = very far). Personal

science allows huge customization. It can adjust to any biology (e.g., your genome) and environment (your living conditions).

7. Benefit to society. If I or anyone else can find new ways to sleep better – especially safe cheap easy ways – and these solutions can be spread, there is great benefit to society, by comparison to DIY that allows non-professionals to reproduce what a professional would create (e.g, IKEA).

You might say that personal science isn't really DIY because, compared to other DIY, (a) it is much slower and (b) the potential benefit to society is much greater. But those features are due to the nature of science. Any form of DIY has unique elements.

My mental picture of DIY is that there are two sides, producers and consumers, and in many domains (health, car maintenance, word processing, etc.) they creep toward each other in the sense that what producers can make slowly increases and what consumers are capable of slowly increases. When they meet, DIY begins. In some cases, the business has done most of the changing; the DIY is very easy (e.g., Ikea). In other cases, the consumer has changed a lot (literacy – not easy to acquire). Either way, the new DIY causes professionals who provided that service or good for a living to lose business.

## 7.3 March

### Tucker Max on How to Eat an Egg (2012-03-01 05:00)

A few months ago I blogged that [1]a rat had persuaded me to eat more eggs. This particular rat liked scrambled eggs. Rats are omnivores, like humans. Unlike humans, they ignore advertising, nutrition fads and disinformation. Related to this, [2]Tucker Max emailed me:

Have you thought about eating your egg raw? It sounded weird to me at first, but after looking extensively into it, there was a lot of good evidence that cooking an egg destroys a lot of the beneficial nutrients/enzymes in it. Once I started doing this, I noticed a HUGE increase in energy from the egg. It was like I almost eating a different food. In fact, the very first time I did it was at night, like 9pm, and I couldn't get to sleep until 3am I had such a huge burst of energy. It's not quite like that anymore, but I take it about an hour or two before I work out, and its like taking a red bull (I may be a bit vitamin B12 deficient, which would explain this).

As to how I do it, I just crack the egg into a coffee cup, and swallow it whole. It has pretty much no

flavor. I also only do it with organic pasture-raised eggs. I don't think I'd do this with normal, crappy store bought eggs.

I replied:

On my blog I said that butter and egg were in that way different from other foods – butter or at least milk must be a complete nutrient since it is the only food the baby gets. Other foods are under no such evolutionary pressure.

Tucker replied:

Which is why its SO important to get raw milk/butter from grassfed cows. Almost a completely different food than normal grocery store milk.

Yeah. When I get back to California I will compare raw and cooked eggs. In Beijing I eat mainly fermented eggs.

1. <http://blog.sethroberts.net/2011/11/30/an-unbiased-view-of-what-we-should-eat/>

2. <http://www.tuckermax.com/>

---

Tomas (2012-03-01 06:58:07)

I don't agree that raw eggs have no flavor, I specifically eat eggs raw for flavor. Usually I discard whites though, which have inferior nutritional value compared to yolks. Many people including me have noticed that eggs eaten alone strongly decrease blood sugar. My BG tends to be lower in the morning, so I prefer eating eggs later on. I haven't noticed any effect on energy levels.

Tomas (2012-03-01 07:00:29)

... and my main concern is that cholesterol oxidizes quickly when heated and becomes toxic

MetaThought (2012-03-01 07:33:13)

Sunny side up is the best of both worlds.

Tony (2012-03-01 08:08:46)

Hi, In case you never saw this article on the glutathione boosting benefits of raw milk and eggs: <http://www.westonaprice.org/blogs/2010/09/11/the-biochemical-magic-of-raw-milk-and-other-raw-foods-glutathione/>

Eric (2012-03-01 08:42:34)

I eat my eggs scrambled OR raw, but when I eat'm raw I only eat the yolk. It's a Spanish snack: Huevo con miel ( <http://www.spain-in-iowa.com/2011/04/huevo-con-miel-raw-egg-yolk-with-honey/> ) I don't think that raw egg whites are good. I'm not sure about it, but I think I read somewhere that the egg white should be heated before consumption. I like the taste of a raw yolk, it's basically the same as "sunny side up"! I don't like the taste and texture of the egg white. Just the yolk for me, with some salt most of the time!

beagle3 (2012-03-01 09:11:06)

How and where do you get eggs you trust to be salmonella free? I'm living in NYC, and I can't seem to find in-shell pasteurized eggs anywhere. Given how horrible chicken raising conditions in the US are (even the so called "cage free" ones - 15 minutes a day outside the regular cage is enough for that designation), how do you trust your eggs to be disease free?

gwern (2012-03-01 09:31:00)

> the very first time I did it was at night, like 9pm, and I couldn't get to sleep until 3am I had such a huge burst of energy. It's not quite like that anymore Yeah, that's how the placebo effect works for me too.

Brad Czerniak (2012-03-01 09:46:10)

There may be side benefits to eating raw eggs, but eating them raw means only about half as much bioavailable protein.

Cap (2012-03-01 09:58:48)

@beagle3, I recall reading somewhere that people know techniques to tell by inspecting an egg whether it is likely to have salmonella; sorry I can't recall any details, but it's worth looking into maybe.

Tony (2012-03-01 10:10:23)

@beagle3, I get safe eggs at ShopRite in Upstate NY. Search for locations here for NYC: <http://www.safeeggs.com/store-locator>

Alexian (2012-03-01 10:19:13)

@gwern Your life must be amazingly energetic if every single new thing you try gives you a burst of energy for 7 hours. The problem with citing the 'placebo effect' is that most stuff you'll try will never trigger any placebo effect, whether you expect it to work or not. Not to mention, why would anyone have a pre-expectation that eating a raw egg would give them a burst of immediate energy?

aretae (2012-03-01 11:41:44)

I concur with Tucker Max, at least on the difference between pastured eggs, and not. We have chickens in our backyard...they live on grass, bugs, weeds, etc...and the eggs aren't even recognizeable as the same type of food as store fed, even "Free Range" ones. 1. The yolks are impossible to describe as yellow. I'm pretty sure yellow yolks are a strong indicator that the chicken producing them is undernourished. Think orange, like the fruit. 2. My wife has an egg allergy, getting pimples if she eats many store-bought eggs. Not true of our backyard chickens.

dearieme (2012-03-01 12:14:11)

The principle is well known. <http://www.youtube.com/watch?v=eqvddpX1uYA>

Mike deCock (2012-03-01 13:41:09)

I don't worry about salmonella (the odds are something like one in 10,000 - 30,000) and most healthy adults won't suffer greatly from an occasional exposure. I do avoid raw egg whites as avidin can cause biotin depletion. Mark Sisson has a good article explaining it. It seems like the best of both worlds is sunny side up or poached. <http://www.marksdailyapple.com/drinking-raw-eggs/>

Tom (2012-03-01 14:10:04)

The yellow in commercial eggs comes from tumeric or other compounds which are added to the feed. Commercially-raised chickens do not get enough beta carotene in their food for their yolks to become yellow. If the feed were not adulterated, the yolks of commercially-raised eggs would be gray. [www.universaloleoresins.com/natural.php](http://www.universaloleoresins.com/natural.php)

Tom (2012-03-01 14:10:38)

The yellow in commercial eggs comes from tumeric or other compounds which are added to the feed. Commercially-raised chickens do not get enough beta carotene in their food for their yolks to become yellow. If the feed were not adulterated, the

yolks of commercially-raised eggs would be gray.

Paleophil (2012-03-01 19:17:09)

Like humans, monkeys, prefer yolks, though some will eat whites too, and they don't have frying pans, so they of course eat them all raw: Monkey eats a raw egg <http://www.youtube.com/watch?v=6wPuS3ozmWM> A monkey eating a raw egg in Bali <http://www.youtube.com/watch?v=X9FrFK6FbNU>

Conor (2012-03-01 19:39:06)

Raw eggs are great, however it's worth being aware of the possibility of creating a biotin deficiency if you're eating them a lot and eating the whites as well as the yolk. There is a quick run-down here: <http://www.marksdailyapple.com/drinking-raw-eggs/#axzz1nvGj1Z31>.

Paleophil (2012-03-01 21:05:25)

I tend to eat more raw egg yolks than whites myself, but I don't currently discard all raw egg whites. Here is some info to consider that's counter to the standard view of raw egg whites as mostly or completely harmful and cooking as a total solution to the alleged problem: Even Mark Sisson says at that above link: "If you like raw eggs, I'd say have at it – with the above info in mind." "Let's start with one simple idea: Mother Nature isn't stupid. She didn't make human beings the only species that prefers foods that will kill us." -Tom Naughton Cooking doesn't destroy all egg white avidin: "It is a myth that light cooking completely destroys the avidin. According to this study (<http://www3.interscience.wiley.com/journal/119344834/abstract?>), poaching eggs only destroys one third of the avidin while even frying leaves 30 percent of it behind." (The Incredible, Edible Egg Yolk, July, 2005, by Chris Masterjohn, [http://www.cholesterol-and-health.com/Egg\\_Yolk.html](http://www.cholesterol-and-health.com/Egg_Yolk.html)) Raw egg whites may actually provide benefits: "Heck, even — shudder — raw egg whites may give a glutathione boost in some people comparable to that given by raw milk! .... Raw Egg White — The Trusty Sidekick? The researchers searched over thirty publications identifying the sequences of edible plant and animal proteins and concluded that the only two types of protein in the food supply containing these unique bonds are whey proteins and egg white proteins. They noted the following: 'It may also be noteworthy that from time immemorial, whey from raw milk and/or undenatured raw egg white have been administered to children and to the sick as prophylactic or therapeutic measures in folk medicine.'" (The Biochemical Magic of Raw Milk and Other Raw Foods: Glutathione, September 11, 2010, by Chris Masterjohn, <http://www.westonaprice.org/blogs/cmaterjohn/2010/09/11/the-biochemical-magic-of-raw-milk-and-other-raw-foods-glutathione>) Wild animals and hunter gatherers don't restrict themselves to eating only infertile eggs, the way most modern Americans do. One difference between conventional supermarket chicken eggs and the wild eggs that primates and other wild animals eat in the wild, is that most supermarket eggs are infertile and restricted to a narrow range of egg development. It turns out that fertile eggs contain less avidin than infertile eggs (The Merck Veterinary Manual, <http://merckvetmanual.com/mvm/index.jsp?cfile=htm/bc/171406.htm>). Wild animals don't restrict themselves at all to any particular stage of development in the egg cycle. They eat anything that won't fight back so much as to be a serious threat. Thus, they eat some of their eggs in the fertile stage or beyond (see also Balut [http://en.wikipedia.org/wiki/Balut\\_\(egg\)](http://en.wikipedia.org/wiki/Balut_(egg))), maybe most of them. Luckily, fertile eggs are increasingly available in the USA. "Maybe fertilized eggs would be helpful for folks who want to down a lot of raw whites without worrying about inducing biotin deficiency." -Denise Minger "An egg seems intuitively analogous to a seed, so it seems like fertilization should neutralize the anti-nutrients like sprouting does to seeds. That's a good topic to research for another blog post perhaps!" -Chris Masterjohn "Dr. Sharma, PhD, who is a biochemist with Bayer, contacted me about this issue. His investigation into the matter revealed that there is not enough biotin in an egg yolk to bind to all the avidin present in the raw whites. He found that 5.7 grams of biotin are required to neutralize all the avidin found in the raw whites of an average-sized egg. There are only about 25 micrograms – or 25 millionths of a gram – of biotin in an average egg yolk." <http://articles.mercola.com/sites/articles/archive/2005/02/09/raw-eggs.aspx> It will be interesting to see what results Seth's raw vs. cooked egg experiment produces. It's refreshing to find someone who doesn't jump to conclusions before he has done any testing. For it to be a relatively fair test, he should presumably use fertile, pasture-raised chicken eggs, or perhaps other high-quality eggs like free-range duck eggs.

gwern (2012-03-02 15:00:30)

Alexian: unfortunately the effect only works for things I have loudly and repeatedly publicly committed to believing and

practicing - since I don't write on the paleo diet nor eat it, nothing in the diet gives me a rush...

Evelyn M. (2012-03-02 22:05:24)

When I was a very little girl in the - gulp - 1940s, it was common knowledge that anyone feeling under the weather should take a raw egg whisked into a glass of milk to regain his strength. (Kind mothers added a bit of vanilla and sugar.) I have no idea why such a sensible idea went out of fashion.

www.hydroxatone.com (2012-03-03 05:33:07)

Maybe I'm being a bit slow...but where does the rat reference come in..have I missed something? Mmmmm eggs are good though...fish-finger sandwich with a cooked egg with runny yolk..the food of kings...!.. Seth: A rat liked scrambled eggs. I thought that translated into good advice: eat eggs.

### **Coconut Oil Cures Foot Fungus (2012-03-02 05:00)**

About ten years ago my doctor pointed to a thin white line on my foot: That's fungus, he said. Huh. He prescribed an antifungal medicine, previously available only by prescription, that had recently become over-the-counter (OTC). I tried several OTC remedies from my drugstore. None worked. According to the directions, they were to be applied twice per day. My doctor said the reason for the failure was that I hadn't precisely followed the directions. This reminded me of a doctor who said that fat people know what to do about being fat (eat less) and simply fail to do it.

Years later I discovered that socks matter. [1]With a much larger number of socks, my foot fungus got much better. Apparently the fungus died if it didn't come in contact with my foot within a week or so. (I had it only on one foot.) With a large number of socks, my foot fungus never got really bad. But it did not entirely go away.

I discovered that tea tree oil works. When my foot fungus got noticeable I would put on some tea tree oil and it would get better.

In January I went back to Berkeley for a month. Without doing anything, my foot fungus seemed to vanish. Apparently being away from my apartment for 4 months was enough to get rid of the fungus. When I returned to Beijing in February, the fungus returned within a day or two. The shape of a particularly bad spot matched exactly where a plastic sandal touched the upper part of my foot. A sandal I'd worn in the shower to prevent foot fungus.

All this is to show how little I know about foot fungus in spite of having it for years.

In November (3 months ago) a reader of this blog named Chuck Currie wrote me:

Sometime in the spring I noticed that I was getting what looked like a rash around the large toe of my right foot. It began spreading, first under and between my toes and then across the top and then under my foot. There was a definite line with little bumps that showed its progression. And, it itched really bad - like bad athlete's foot.

In July I was prescribed Nystatin and Triamcinolone Acetonide cream. [I tried this - Seth] I was told to put it on twice a day, which I did. Because I wear flip flops all summer, I didn't need to cover it. The cream did not work at all. It actually seemed to make it worse.

I have been interested in coconut oil since going paleo, even though I can't eat it, or coconut milk - they really upset my stomach. I was reading an article on coconut oil that mentioned its anti-fungal properties

and I remembered reading this before. So I thought I would give it a try on my foot.

After showering, I cover my foot with coconut oil, place a plastic bag over my foot (the kind you put produce in) to keep it from being wiped off and then place a sock over the bag to hold it on. I leave it on for two or three hours and then take everything off and lightly wipe my foot with a paper towel and go to bed.

I do this three or four nights a week and have been doing it for three months. I knew immediately that it was doing something. My foot became very warm, almost like it was on fire, the first time I did this. It didn't have this effect the second time. My fungus/rash started to retreat. My skin would dry out and flake off between sessions, like I was using an exfoliate.

Then I noticed that my [toenail fungus] started to clear up and I could see the nail growing from the cuticle on my big toe was clear, not yellow and thick. By now the line has progressed two thirds of the way up my toe. At this rate, it should be completely clear in another couple of months.

I still get small flare ups of the rash/fungus on my foot, but it has almost completely cleared up. You can still see where it had been. The skin is dryer and lighter in color than the rest of the foot.

I think if I had done this every night the progress would have been faster. I'm now starting to put a small amount of coconut oil on the top of my foot in the morning and letting it air out for a while before putting on my socks and shoes. When the fungus was on the bottom of my foot this was not possible, but now that it only seems to be on the top, this works and I think this will speed up the process. The best thing is there are no bad effects. I use extra virgin, cold pressed, unprocessed coconut oil. My understanding is that heat processed coconut oil does not have the same anti-fungal properties.

Pretty convincing, huh? In Berkeley I bought Whole Foods house brand coconut oil (cold-pressed). Edible was cheaper than non-edible. In Beijing, after my foot fungus had gotten quite noticeable, I started to use it. At bedtime, I rub it all over my foot, put my foot in a thin plastic bag, and put on a sock. When I get up, I take off the sock and the plastic bag.

After doing this once, my foot was much better. After five applications, I couldn't detect any fungus. Application is pleasant (without trying, I don't miss a night) and, as Chuck says, obviously safe – I could eat what I am spreading on my foot. It costs a few dollars/month. Tea tree oil works, too, but it wasn't easy to spread all over my foot, wasn't pleasant to apply, wasn't edible, and cost \$15/tiny bottle. On the internet you can find many home remedies, such as soaking your feet in apple cider vinegar. Apparently they work. This is much easier.

If you try this, please tell me your experience, whether it works or not.

---

1. <http://blog.sethroberts.net/2010/05/23/foot-fungus-revisited/>

Darrin Thompson (2012-03-02 07:09:22)

Let's not forget to give the Doc a cookie for noticing and correctly diagnosing "foot fungus." Seth: yeah, good point.

Margaret (2012-03-02 07:31:37)

I recently got 2 spots of what appeared to be Ringworm on my shoulder. I tried coconut oil on them daily for about a week and a half, but it didn't help. Of course, I didn't cover it up, maybe that would have helped. Tinactin (2x a day) worked in a week. Natural cures so seldom work for me. It's frustrating, I try them often. So far the vitamin D hasn't helped my sleep much, either. It may have helped my rosacea, but that always goes away when warmer weather starts, and so I can't be sure why it's finally gone for the winter. I've been taking Vitamin D for about 6 weeks, starting with 2000 iu a day, and working up to 6000, the same Trader Joes brand that Primal Girl uses. I haven't noticed much of a difference, but it's hard to measure it much in my case as I have rather little control over when and how long I sleep. I co-sleep with my 3-year-old, who wakes me up often to nurse in the night, and of course when she wakes up in the morning I have to get up, and I can't go to sleep at night before she does... The help I need with my sleep, is being able to go back to sleep again after having been awoken. Also, being able to go to sleep quickly when we go to bed is sometimes a problem. The vitamin D may be helping a bit with these things but it's hard to be sure.

john lushefski (2012-03-02 09:38:26)

I would guess that processed coconut oil should still have the same effects, as I think the anti-microbial/fungal/etc properties are from the fatty acids. Is there a proposed reason as to why processing/filtering would remove those properties? Seth: Heat might destroy the crucial enzymes or whatever. Filtering might remove them. It's easy to think of reasons.

Maria (2012-03-02 11:06:15)

This is why I so appreciate your blog: such a wide range of topics, such practical information, such detailed personal evidence. I've read in a number of places that coconut oil was anti-fungal, but references were so vague that I didn't know what to do with that information. This is so specific with real life evidence. Thank you so much! I will try it.

Tom (2012-03-02 11:17:36)

It's fascinating, yet it makes sense. Coconuts have to hang in the blazing sun for weeks without being eaten alive by all manner of life.

Kirk (2012-03-02 12:00:55)

I forced my toenail fungus into a major retreat by switching to the Perfect Health Diet (which added more carbs, which, according to Paul, supplies the body the glucose needed to fight fungal infections). I also added in a number of their recommended supplements. And I soak my feet daily in Epsom Salts and apply an over-the-counter anti-fungal cream. Although most of the fungus has disappeared, some remains; I can feel numbness when I lightly tap my toes on the floor. (Plus there is visual evidence.) I'm glad you brought up the story about the socks; I have been wearing Chinese cotton slippers this winter, without socks, which makes me think that perhaps the fungus has settled into them. I started the cider vinegar treatment several days ago, followed by drying my toes in the sun, and then topping with coconut oil. However, the coconut oil I have been using is refined and doesn't say anything about being cold-pressed. I will change to virgin, cold-processed, unprocessed coconut oil, and also try the plastic bag technique. Will let you know if anything changes. Seth: Yeah, I think there is something to the idea that a low-carb diet makes you more susceptible to fungal infections. I am beginning to think I don't eat enough carbs.

Coconut Oil Cures Foot Fungus | Health Impact News (2012-03-03 17:07:07)

[...] by Seth's Blog [...]

susan (2012-03-03 23:58:48)

i wonder if it is because the coconut oil is preventing the fungus from getting oxygen to live? sort of like when you want to get a tick out, you rub it with crisco?

Leila (2012-03-04 21:19:51)

I've never heard of the crisco trick to get rid of ticks but I bet it works great. A warm bath will make them let go, so that's what we use. There is definitely a link between low carb diets & skin problems. I started a very low carb diet in the fall of 2010. About a year ago (spring 2011) I developed skin problems on my arms, back & scalp. I don't have a definite diagnosis, but based on appearance & from what I can find online, I think it's keratosis pilaris on my arms & psoriasis on my scalp. I've added carbs back into my diet, have vastly increased my vitamin A intake, & I'm sitting here with coconut oil on my scalp & hair. It feels good, sure hope it helps! I did it once before but have trouble sleeping with a plastic on my head, so it's tough to do often.

Phoenix (2012-03-05 14:05:57)

I developed toenail fungus after a couple years of vegetarianism; I think there's something to be said about zinc deficiency and nail/skin susceptibility to infections. Anyway, I turned to a Perfect Health Diet-ish diet and starting supplementing zinc. I've been rubbing coconut oil on my foot and nails every night. I also mixed some rubbing alcohol with some apple cider vinegar, put it in a little spray bottle, and spray it all over my foot every morning (it smells pretty bad, but the smell dissipates fairly quickly). It's been about 10 months, and my toenails look close to perfect. Hard to say which thing made it work (zinc, diet, alcohol+ACV, coconut oil). Normal toenails are awesome!

Michael (2012-03-06 20:24:57)

That's pretty fascinating, actually. I've never heard of coconut oil being used in this way (as a medication, more or less). I bet your foot (or feet) were silky smooth after these treatments as well!

Jon (2012-03-09 13:44:23)

After reading this blog entry I started using coconut oil instead of olive oil as a moisturizer (I get cracks in my hands). It works much better, hands aren't getting cracks any more. I'll see if it keeps working.

JPB (2012-03-17 15:50:19)

How long and how often do you need to apply the coconut oil?

## **Vitamin D3 in Morning: Mixed Evidence From PaleoHacks (2012-03-03 05:00)**

Paleo Hacks has [1]a thread about timing of Vitamin D3. Better in morning (my and several other people's experience) or evening (Robb Wolf's experience)?

This answer supports morning:

I prefer taking it in the morning. I think it helps set my circadian rhythm.

This answer supports night:

I prefer it at night. I find I sleep better.

This answer supports morning:

I had trouble sleeping when I started Paleo and was taking my D3 at night before bed. Was nervous and couldn't seem to settle down. No problems since I went to morning, I have them with my fish oil right after breakfast.

By the time you read this there will probably be more evidence.

Thanks to [2]Melissa McEwen.

2. <http://huntgatherlove.com/>

---

Alrenous (2012-03-03 08:38:34)

What's not mixed is that doses of Vit-D five times the Canadian RDA (sometimes higher) help sleep when properly timed.

TalkingRat (2012-03-03 11:47:24)

I used to take my D3 at bedtime, with the rest of my vitamins and fishoil. I was curious whether I'd notice anything with morning timing of D3, so I changed to morning supplements at first light, and as on that same day, I started yawning around 7:30 pm. I noticed because I don't normally yawn, except that yawning is an effect I get from my bedtime melatonin supplement. So I suspect the switch to morning D3 aids in the body's changeover to melatonin production. I can't say I notice better sleep, because the dog's been having a hard time sleeping past 5 am. But I'm sticking with morning D3 timing because it appears to trigger melatonin production with the end of daylight. I take 2000 IU D3 on top of 900 IU in multivitamin and calcium pills.

Peter (2012-03-03 19:25:49)

I've always taken my D3 early in the morning. Last fall, I decided to stop eating breakfast because, much like Seth's experience, my body was waking me up earlier and earlier, usually associated with a growling stomach. Skipping breakfast helped me sleep until 6:30 or 7:00 a.m. on the weekends, which is a significant improvement. Even without breakfast I continued to take my D3 in the morning (8K IU). Two weeks ago, I tried taking D3 at lunch. I slept through the night but felt as if I hadn't slept at all when I woke up. It was the worst week of sleep that I can remember. Last week I reversed the experiment, taking D3 in the morning, and my sleep returned to being restful.

Nick (2012-03-04 09:03:26)

I like the idea of nutrient timing especially aligning with the circadian rhythm. Vitamin D in the morning and vitamin C before bed. Anyone else experiment with this combo?

Patrik (2012-03-04 23:25:28)

I happen to take Vitamin D3/K2 combo in the morning – and at night, I drink some magnesium. Anyone else try this?

### **"Thou Shalt Not Testify Against Another Doctor" (2012-03-04 05:00)**

First do no harm . . . As [1]Robin Hanson has said, what does that mean? In contrast, the rule illustrated by this story, from Bryan Castañeda, who works for a Los Angeles law firm, is quite clear:

At the old firm I used to work at, I was talking to one of the senior attorneys and the topic of medical malpractice cases came up. He said he avoids them. Why, I asked. He said – I'm paraphrasing here – "Because you won't find a doctor who will testify against another doctor in open court. They may advise you in private, 'Oh yeah, so-and-so definitely screwed up,' but you won't get them to say that on the stand. They all protect each other."

Judging by this story, if your doctor makes a mistake, the only person who will suffer consequences is you. Thank heavens the rest of us [2]have more power than ever before. [3]A recent survey of doctors found that "more than a 10th (11.3 %) admitted to telling patients something that was not true." The survey did not ask about lies of omission (when silence is misleading); unwillingness to testify that someone else made a mistake is that sort of lie. [4]The survey also showed that doctors (at least, those who took the survey) have a self-serving interpretation of the term not true. Although only about 10 % said they had said something "that was not true" – meaning something that they knew wasn't true – "more than half had described a patient's prognosis more optimistically than warranted." Apparently they consider such descriptions not instances of "not true".

In *Systems of Survival*, Jane Jacobs described two moral systems (lists of rules/values): The guardian syndrome and the commercial syndrome. In certain areas of life (e.g., military), the guardian syndrome prevailed; in other areas (e.g., small business), the commercial syndrome prevailed. Loyalty (e.g., "never testify against a fellow doctor") is a guardian value – indeed, the main guardian value. In contrast, honesty is the main commercial value. Jacobs said that the two syndromes corresponded to two ways of making a living: taking and trading. Doctors do not represent themselves as predatory (= taking). But, according to Jacobs, this sort of rule ("never testify against a fellow doctor") puts them squarely in that camp.

I asked Jim Jacobs, one of Jane Jacobs's sons, for comment. He replied:

Exactly right. Jane experienced this herself, unfortunately. It's really a major problem. I see the very same behavior among medical researchers too.

4. <http://well.blogs.nytimes.com/2012/03/01/when-doctors-dont-tell-the-truth/>

---

Stone Glasgow (2012-03-04 13:09:06)

Doctors are squarely in the "guardian" group, and (mostly) operate under its morality as described by Jacobs. This includes accepting money only at arm's length (indirectly via insurance), and active deception "for the greater good," as you have described here. This is fine if we trust these men as the most intelligent, moral, and capable beings on earth. If not, we have a serious problem, which is further exacerbated when doctors begin operating under a blend of both moralities—protecting each other and maximizing profits—without concern for the welfare of the patients they are sworn to protect. If understood in light of Jacobs' theory, this is the most rational argument, in my mind, for placing healthcare completely in the hands of (local) government, along with all other guardian functions, like military and police. As I argue at length at my blog, there is little difference between viral invaders that plan to kill us, and men with guns planning our demise. We need guardians to protect us from both dangers, regardless of their size.

Stephen M (Ethesis) (2012-03-09 17:57:59)

The other thing that doctors do is give you a negative diagnosis, deliberately saying things are worse than they are. If you survive or do well, then you have done better than expected and will be happy. If you don't, then you did as predicted and are less likely to blame them. This, in spite of the research indicating that positive predictions improve patient health. I remember sitting there, listening as a faculty member at a medical school explained that to me, in between his classes teaching ethics.

### **The Parable of the SAME (2012-03-05 05:00)**

SAME is a drug well known to help depression. [1]For example, "a popular dietary supplement called SAME may help depressed patients who don't respond to prescription antidepressant treatment, a new study shows." But there's something important few people know about SAME.

While talking to a Seattle woman about how Vitamin D3 first thing in the morning helped her with depression, she told me the following story:

When I was 47, I just wanted to be healthier. I kept gaining weight. I knew what foods are healthy. I just didn't seem to eat them. A naturopath suggested SAME. I tried it – Twin Labs SAME. That was really fabulous for me. For the first time I got a glimpse of what being not depressed was like. Cravings weren't there any more. Went from a size 24 to a size 14. Lost 70 pounds. I'm 5' 8". I didn't feel deprived. I was eating plenty of food. going to yoga. Feeling really great.

Then Twin Labs discontinued it. It was [2]made in Japan. I tried every other SAME out there, eight different brands. None of them worked. I gave each of them a month. I tried different dosages.

I started slipping back into depression. Not being able to cope. I was sleeping more. Sugar cravings returned.

[why did Twin Labs stop making it?]

It wasn't a good seller for them. So fucking wrong. I wrote letters to try to get them to start making it again. I did a campaign. People found pockets of what was left in the country and sent it to me. But it finally ran out.

The moral(s) of the story? 1. So much for word of mouth. You might have thought it would make the good SAME sell well, better than the bad SAME. Apparently not. 2. So much for the placebo effect. 3. Clinical studies (e.g., of SAME) may higher-quality versions of what they are testing than the versions available to the rest of us. 4. So much for quality control in the supplement industry – except maybe in Japan. There can be substantial quality variation among supplements, undetected by the industry. I have to believe the companies selling the useless SAME didn't realize it. Surely they thought that good SAME would be a better product for them than bad SAME.

This resembles [3]the Vitamin D3 story I have been telling. [4]Tara Grant said she'd heard countless times that Vitamin D is good. She hadn't heard once that it must be taken in the morning. I've heard countless times that SAME is good. This was the first time I heard about huge quality control issues. In both cases individual self-observation uncovered a crucial truth that an industry had overlooked. They didn't want to miss it. The Vitamin D Council didn't want to miss the time-of-day effect. They just did.

This also resembles [5]what I said about ultrasound machines: A lot of them are broken, unbeknownst to their operators and the people (often pregnant women) being scanned. The countless "experts" (doctors) who recommend

ultrasound don't seem to know this.

Which is why personal science (trusting data, not experts) is more valuable than experts want you to think.

---

gwern (2012-03-05 09:00:02)

> 2. So much for the placebo effect. Que? I see zero mention of anything like blinding. Seth: All brands should have been equally effective placebos. (Some Muslims get so upset about some cartoons being drawn or books being burned they will kill dozens of people over it. Proof that paper is a drug more powerful than testosterone or steroids at inducing rage!)

Stone Glasgow (2012-03-05 11:02:12)

What brands did she try? Surely someone makes a high quality SAME today. Did she try Jarrow? Consult [consumerlabs.com](http://consumerlabs.com)? Perhaps twin labs' version was actually the wrong chemical? Seth: She tried all brands for sale in the US.

Kim Øyhus (2012-03-05 14:06:09)

Market forces driving real quality, is a myth. The places I have worked, have confused quality with satisfying and fooling customers. This is often called TQM, Total Quality Management. The bosses have also been mainly concerned with having alpha primate status, and considers real quality improvement to be a threat to their status. All this nonsense of the pharmaceutical industry, the climate scam, the military industrial complex, corrupt doctors, etc., are not aberrations. They are rather typical of most work today, in my experience.

Jenny (2012-03-05 17:26:05)

When I trained as an Occupational Therapist, one of the things we were warned about was that not all prescription drugs are equal - sadly the fillers and colours can change the drugs affect/ absorption rate etc. I was working in the NHS at the time NICE came into being, which was going to limit people's (and their doctors') choice of manufacturer of their drug, and we knew that many people were going to get a less satisfactory outcome. I personally have a problem with drugs with a pink colouring - it slows the absorption rate for me. I found this out with Indomethacin - our British 'cheap' indomethacin has bright pink colour on it, and takes about 45 mins to start to help me, whereas the 'white' ones start to work in 10 mins. This is a serious delay for any drug with a time base to it. Luckily I have a very on-the-ball pharmacist who hunts out and stocks the 'right' coloured medication for me.

Stone Glasgow (2012-03-05 23:30:33)

It must have been that the Twinlab product contained something active other than SAM-e, or consumerlab's tests for SAM-e are dreadfully inaccurate. They tested about 15 different brands and only a few failed; the rest contained the stated amounts of SAM-e according to their method: <http://articles.latimes.com/2000/mar/27/health/he-13037> Seth: That's fascinating. Thanks.

Perfect Health Diet » Around the Web; PaleoFX Edition (2012-03-10 17:49:47)

---

Darrin Thompson (2012-03-06 07:29:29)

Why is that a scary thought? Seth: It is a scary thought because of the emptiness – lack of overlap between what is taught and what students want to learn – it might expose.

Tom (2012-03-06 08:07:14)

If I had been asked that question, I would've replied yes to only about 5 % of my classes. I don't think college is about educating people anymore. I think at this point it exists just to feed millions of unsuspecting people into gigantic loans that cannot be discharged by bankruptcy. It is the new slavery. [latimes.com/business/la-fi-student-loan-delinquencies-20120306,0,6387032.story](http://latimes.com/business/la-fi-student-loan-delinquencies-20120306,0,6387032.story) Undergraduate colleges are no more legitimate than law schools.

Stone Glasgow (2012-03-06 16:18:47)

Tom, I agree completely. It is no longer a good idea to attend most modern universities. I suspect that in the future, college will become compulsory in the same way that American grade-school was at one time provided by the private market, and has since become a forced part of every American child's life.

w (2012-03-06 17:00:26)

If no praise had ever been written about Rush, too much praise would already have been written. Seth: What about this example?

w (2012-03-07 08:30:47)

When you cast about for a good to say in a person's defense and the best you can come up with is a single instance of epistemic luck, well, as I said: no praise is plenty. Seth: I wasn't casting about. I posted that link weeks before Rush's current problems. There is a backlog of posts, that's why it appeared recently

Leslie (2012-03-09 12:17:15)

Biologists are saying it will take years for the fallout from the BP oil spill to develop (<http://gulfofmexicooilspillblog.com/201-1/02/21/gulf-of-mexico-oil-spill-blog-effects-10-years-and-10-cm-thick/>), and "Despite low concentrations of oil constituents in Gulf of Mexico waters from the Deepwater Horizon spill, fish were dramatically affected by toxic components of the oil." ([http://www.nsf.gov/news/news\\_summ.jsp?cntn\\_id=121786](http://www.nsf.gov/news/news_summ.jsp?cntn_id=121786)). But if Rush Limbaugh says everything is fine, then the biologists must be wrong.

### **More About the Lawsuits Against Law Schools (2012-03-06 05:00)**

New York magazine has just published [1]a long article about the lawsuits against law schools for deceptive reporting of job prospects. This is the most radical (in the sense of challenging what "every reasonable person knows") article I've seen in a major magazine in a long time. Gary Taubes's article ([2]"What if It's All Been a Big Fat Lie?") is a good example of such an article. It was published in 2002. Long long ago The New Yorker published a series of articles by Paul Brodeur (published as a book in 1989) arguing that power lines cause cancer. So long ago that Brodeur [3]has retired. Unlike what Taubes and Brodeur wrote, the New York article is not investigative journalism. It was much easier to write. But that does not change the similarity of basic message – that powerful respected people have been lying to us.

Beyond the sheer existence of this article, it's also interesting that nobody interviewed for the article said the allegations were false. For example, here's a dean at New York Law School, one of the defendants:

"We teach critical thinking, and writing, and so forth," Buckler said. "And that's always been the case, and those skills have always been useful. I guess I would say that it's never been a good reason to go to law school or any grad school, because you think there's a guarantee at the end. Whether that was twenty years ago or ten years ago or this year."

In other words: It doesn't matter if we publish false or misleading data because (a) we teach useful skills and (b) the data don't matter – right-thinking people ignore such data ("it's never been a good reason to go to law school" because you think it will provide a job). Recent graduates of New York Law School do an even worse job of defending the school:

"Mathematically, it's a ton of graduates, yes, and no, there aren't enough jobs for them," Daniel Gershburg, a 2006 graduate of NYLS and an attorney with a successful practice in Manhattan, says. "At the same time, what are schools supposed to say? 'No, no, don't come here! Run for your lives! . . .'" [That is: Of course they lied.] Julia Shapiro, who graduated from NYLS in 2007—and who works as a lawyer in Los Angeles—puts it this way: "Suing the school is not going to help them find a job. I would not put my energy into wallowing in my sorrows." [That is: Get over it.]

In contrast, it's easy to make a case that the schools intentionally deceived prospective students. One of the lawyers behind the lawsuits said:

"NYLS [New York Law School] has to put students in seats," Strauss said. "That's the system they set up for themselves. They've got a huge new building, gleaming classrooms, but they're cutting corners on transparency. They've created this reality where the only way they can put [enough] people in seats is by misleading them."

A commenter put it like this:

Over the past 20+ years (since the advent of the U.S. News Rankings, really), the non-elite law schools have perpetrated a pervasive and dynamic fraud aimed at luring unsuspecting college students to throw away their financial futures [due to] reliance upon utterly fraudulent salary-and-employment data. The goal is obvious: to keep the student-loan teat gushing into administrative pockets.

[4]

As I said earlier, there's an old joke: Why do students go to law school? They're bad at math. Apparently law school administrators are also bad at math. The existence of this story suggests that average reader of New York magazine is not inclined to forgive them.

---

JPB (2012-03-06 07:41:01)

The real crime is that not only are there NOT enough jobs out there but that these students have been encouraged to go over \$100K in debt...

Andrea (2012-03-06 08:14:14)

My brother attended a "non-elite" law school and has spent the last decade working as a paralegal.

Tom (2012-03-06 08:39:13)

I don't think college is about educating people anymore. I think at this point it exists just to feed millions of unsuspecting people into gigantic loans that cannot be discharged by bankruptcy. It is the new slavery. [latimes.com/business/la-fi-student-loan-delinquencies-20120306,0,6387032.story](http://latimes.com/business/la-fi-student-loan-delinquencies-20120306,0,6387032.story) Undergraduate colleges are no more legitimate than law schools.

dearieme (2012-03-06 08:43:13)

"It is the new slavery." Don't be so silly. It would, however be the new indentured labour, if only they could find jobs.

Gary Wolf (2012-03-06 17:37:09)

Peter Thiel recently said in an interview that the for-profit education companies were the sub-prime mortgage dealers of the education bubble. But the dynamics of education fraud are doubtless not confined to for-profit colleges. (That the emergence of large scale fraud is a normal phase of a bubble is well argued in Kindleberger's classic "Mania's, Panics, and Crashes.")

### **An Example of Predatory Medicine (2012-03-06 20:29)**

I [1]recently posted about how doctors act like predators, in the sense of having what Jane Jacobs called "guardian values" (e.g., loyalty to other doctors is more important than honesty to patients). [2]Here is an example of medical

behavior that coming from an ordinary business would be shocking:

On February 21 [2012], I had my evaluation for a kidney transplant at a university-affiliated medical center about 100 miles from where I live. The way this institution operates, it takes about 8 months to get from initial referral to evaluation and there are all kinds of diagnostic tests in between (see previous blogs for more details). Once you are an approved transplant candidate and an organ becomes available, you go to the hospital and have surgery. The average stay for a kidney transplant is about 3 days and then you are discharged to a local hotel for 5-7 days. During that time, you return to the hospital every day for blood work, monitoring of the immunosuppressive medications and patient education. Also, you must have a full-time caregiver. That can be a friend, family member, stranger off the street corner, but they must be with you at all times to ensure that you are eating, taking meds, bathing, etc. Also, driving is prohibited until about six weeks post-transplant so the caregiver is also a chauffeur and attends the educational activities as a back-up in case the patient becomes incapacitated or symptoms of rejection appear.

In short, your caregiver must be able to put their own life on hold for about two weeks with as little as two hours notice. When you think about it, that's a pretty tall order to fill. I have a caregiver, he happens to be a member of this forum. He is a dear, dear friend and always will be if only for the fact that he is willing to undertake this role with only the merest of acquaintance. He is more than willing to put himself and his home at my disposal if necessary. I won't call him out by name, he obviously knows of whom I speak, but I truly feel as though Karma has smiled on me since our paths have crossed.

So the evaluation finally rolls around. Caregivers must be present during the evaluation. We check in at the medical center and are shown to an exam room. We are seen by a barrage of clinicians; dietitian, nephrology resident, nephrology attending (the doctor in overall charge of my medical care while at the transplant unit), and the transplant surgeon. There are physical exams (kind of interesting since my caregiver knows me pretty well, but not THAT well), an EKG and a side trip to the lab. At the lab, the phlebotomist doesn't pay any attention to my advice about using a butterfly catheter and proceeds to draw 20 (count 'em, 20) vials of blood for type, cross match, antigen levels, etc, etc through a Vacutainer. About halfway through, my vein collapses and she has to switch to the other arm, this time with a butterfly. After that, a chest x-ray. Back up to the 9th floor for our final meeting of the day; the social worker.

Up until this time, everything had been encouraging. I can't say enough good things about the clinical staff, they were all wonderful, professional, warm, willing to answer questions, etc. My transplant surgeon looks like he should be on a TV medical drama, he can unzip me any time! The good vibes ended the minute we sat down with the social worker. She informed me that I would be required to have a second caregiver, a backup so to speak. WTH? People that can call a halt to their lives don't grow on trees. Talk about hitting a brick wall. Here's a sample of the conversation:

Social worker: What will you do if you are discharged to home and you can't take care of yourself?

LadyDoc: Well, if I can't take care of myself then I guess I shouldn't be discharged, should I?

Social worker: Well, you could always go into a nursing home.

LadyDoc: Over my dead body.

And there you have it, the standoff. I have looked through every single printed word and email that I have ever gotten from this institution (and I keep very good records) and there is NOT A SINGLE WORD about having a second caregiver. The only family I have in the area is my daughter and she has two little boys under the age of five at home, so I can hardly ask her. My circle of friends is painfully small, many are disabled and not up to the challenge and the others

have lives of their own.

The social worker called me a few days later to see if I had changed my mind and it suddenly began to sound like a sales pitch. She was touting all the advantages of this particular institution but I just don't see it. I am now turning my attention to medical centers where the inpatient stay is closer to 5-7 days and then the patient is discharge directly to home, none of this stay-in-a-hotel stuff. I can't think of too many places where germs and nastiness run more rampant than a hotel. I am so frustrated, I feel as though the last 7 months of my life have been an utter waste of time. Furthermore, the evaluation day was wasted; if we had met with her first we could have simply gotten up and walked out and said "Thank you for playing, please try again".

In case you needed any convincing that customers for health care differ from customers for other services. (The difference: they are more desperate.) Think of this example if you are sure that government-run health care must be worse than the current system. You can learn what happened next at the link.

Tuck (2012-03-06 21:32:59)

Or they could put her on a ketogenic diet for a few weeks and cure her kidneys. But where's the money in that?

Michael 2 (2012-03-07 01:05:25)

I second Tuck's comment. There are anecdotes about people doing a paleo diet (low carb, low protein (high protein is bad for those with kidney disease), high fat) and regaining kidney function. The blog nephropal which contained one such anecdote is now hidden. It was written by a paleo friendly nephrologist, Ken Tourgeman.

Wilbur (2012-03-07 04:22:32)

Wow, there are anecdotes??? Man, I'm sold. Hey doc, cancel my chemo! I read on a blog the there are anecdotes that this fad diet will cure me. Signed, Steve Jobs Alta Mesa Memorial Park Seth: what if the fad diet was harmless? And takes only a few weeks to try

Dennis Mangan (2012-03-07 08:44:07)

"Reversal of Diabetic Nephropathy by a Ketogenic Diet [in mice]... ..Diabetic nephropathy, as indicated by albumin/creatinine ratios as well as expression of stress-induced genes, was completely reversed by 2 months maintenance on a ketogenic diet." Paper can be found at PLOS One. Seth: Thanks, Dennis, that's good to know. [1]The paper was published in 2011. Three of the authors are from a neurobiology department.

1. <http://www.plosone.org/article/info:doi/10.1371/journal.pone.0018604>

Ginna (2012-03-07 18:40:17)

Wilbur, yes, anecdotes are not necessarily clinically valuable. But as Seth points out, if the alternative treatment suggested does no harm on its own, there's only upside. I really don't get this attitude. My mom's kidneys were beginning to lose function last year. For various reasons, I suspected she had a problem with gluten. Her doctor offered no real advice, other than 'when they actually fail you will need dialysis etc.' He offered no other treatment possibilities. He suggested she lose a little weight, although she wasn't particularly overweight. (Maybe 15 extra lbs.) I insisted she adopt a paleo-ish diet, with gluten avoidance being the priority. A year later, she feels better in many ways, and has improved her kidney performance substantially. Her GFR has improved from 31, which is moderate-to-severe, to 62, which is mild kidney disease. Apparently this kind of improvement

is vanishingly rare for a 70-yr old. So I'll take that anecdote, thank you very much.

Tuck (2012-03-08 06:23:09)

In mice (as mentioned above): <http://lavinlavidalowcarb.com/blog/dr-charles-mobbs-diabetic-kidney-damage-can-actually-be-reversed-with-a-high-fat-low-carb-ketogenic-diet/10660> You'll get a kick out of that one. Of course he doesn't want to put actual \*humans\* on a ketogenic diet, he wants to develop a drug... In humans: "Pete is a 30 YO male, 175cm tall, 110kg (I can't tell you how depressing and embarrassing it is that the US can't figure out the metric system) and pretty much a mess. He is sedentary, stressed, has terrible sleep and exists on packaged pastry products and beverages with "DEW, Pepper" and similar monikers. Recently Pete had to get a physical and he had: high blood pressure, elevated: blood glucose, BUN, creatinine. Given that his condition was obviously not good it was recommended that his renal function get checked out. Tests indicated Pete was operating on approximately 10 % of normal kidney function. Pete was pretty shaken up by his condition...peri-diabetic, facing dialysis ( his doctor wanted to start dialysis IMMEDIATELY) and all at the ripe old age of 30. Fortunately for Pete, his employer was a member at a wacky little gym called NorCal Strength & Conditioning and the employers offered to not only pick up his gym membership for a few months, but would pay Pete on an incentive basis: \$5 for every pound lost. This is a small IT company, and I'm sure this situation violated multiple California state "fair employment" laws...but it's what happened here. Pete went through an initial assessment at NorCal, and it was recommended that he work with Amy Kubal on his nutrition. The course of action involved a low protein (10-15 % protein) low carb ( less than 10 %) high fat (mainly from coconut products), ketogenic diet. Pete's doctor was horrified, but we petitioned for one month of "tinkering" to see how things went. Three weeks later Pete's GFR was 80 % of normal instead of the previous 10 % and his BUN was within normal ranges. His doctor was interested...but baffled. Pete has subsequently titrated up his protein intake with no ill effects on kidney function." <http://www.robwolf.com/2011/06/16/clearing-up-kidney-confusion-part-deux/> "Anyway, the first thing to do with a paper like this is to check whether the authors cited Nielsen's 2006 case report of a human being having their diabetic renal failure halted and partially reversed. I mean, this might be relevant... They didn't." <http://high-fat-nutrition.blogspot.com/2011/04/diabetic-nephropathy-and-lost-swede.html> I hadn't kept up with the comments on your post... Sorry for being unnecessarily cryptic. The fascinating thing from Mobbs work was the importance of keeping protein very low, since protein in excess of dietary requirements was converted to glucose, which is what was poisoning the kidneys... Remove the glucose, kidneys heal. And to Wilbur: All case reports, or any published science, is an anecdote. What's important in science is reproducibility.

Catherine Shaffer (2012-03-12 11:57:54)

This person misunderstands the purpose of a hospital. Patients are kept admitted to the hospital for medical care, not help with activities of daily living. If a patient can't manage ADLs, they need a caregiver or nursing home. She will not find a hospital that is willing to keep her admitted for the entire recovery. This is her own fault for being unwilling to use a skilled nursing facility/rehab center, which is a very common and normal thing to do, and not the fault of the hospital for providing poor "customer service." Rather, the hospital would have been negligent to perform a procedure on a patient that had no way to meet her care needs at home. Another option would have been to hire a visiting nurse or home health aid.

## **How Accurate are the QuackWatchers? Mercury Amalgam Fillings (2012-03-08 05:00)**

From [1]Amalgam Myths and Facts (amalgam here means mercury-containing amalgams used by dentists):

Myth 10: Amalgam has been banned in Germany and Sweden and therefore should be banned in the United States.

Fact 10: Dental amalgam has not been banned in any country in the European Union.

From [2]a 2009 press release:

The [Swedish] Government today decided to introduce a blanket ban on mercury. The ban means that the use of dental amalgam in fillings will cease.

In response to the Swedish ban, the American Dental Association put out [3]a press release that said such a ban was "not necessary" in America because dentists do such a good job recycling the amalgam that doesn't go into your mouth. Moreover, "a recent economic impact study published in the journal Public Health Reports indicates dental care costs in the U.S. would increase up to \$8.2 billion in the first year alone if amalgam use was discontinued." I don't know what "up to" means. Perhaps it means that dental care costs would increase by a trivial amount "up to" \$8.2 billion. Mercury-containing amalgam fillings are about half mercury.

[4]Soon after I had two mercury fillings removed, I slowly became faster at arithmetic.

1. <http://www.dentalwatch.org/hg/myths110.html>
2. <http://www.sweden.gov.se/sb/d/586/a/118550>
3. <http://www.ada.org/3298.aspx>
4. <http://blog.sethroberts.net/2011/06/26/damage-due-to-mercury-revealed-by-brain-test/>

---

Adam (2012-03-08 05:25:32)

Dental amalgams are also banned in Denmark, which has been a member of the European Union since 1973. <http://nyhederne-dyn.tv2.dk/article.php/id-9868029:slut-med-kviks%C3%B8lv-i-t%C3%A6nderne.html>

Tom Passin (2012-03-08 06:30:18)

What happened to you accuracy in the mental arithmetic tests? I remember you wrote an earlier post (not about mercury) that mentioned that your speed increased but the accuracy decreased. How much did your speed increase? Seth: About 50 msec? From an average time/problem of 600 msec to 550 msec. Something like that.

Margaret (2012-03-08 07:10:42)

Quackwatch makes no effort to be accurate, it's merely a website put there to scare you away from any healthful natural remedy or lifestyle change and into your doctor's arms. I really hate that guy!

Kim (2012-03-08 09:54:34)

I had a mouthful of amalgams (12+) removed last fall at the insistence of my functional medicine doctor, and my autoimmune (Hashimoto's) symptoms are finally improving. My endocrinologist has been fiddling with my medicine for years, but they never helped. I absolutely believe amalgam fillings are deleterious to health.

Char (2012-03-08 10:01:19)

I asked my dentist about fillings last time I had to have one put in. Now, granted he is probably pretty "main stream" but he said something that made me think. He said "we have a history with the metal fillings but we don't with the new fillings." I.E. we know what happens with the metal fillings but what will all the material in the new fillings in our mouths do to us? Aren't they a form of plastic? Seth: Yes, they are [1]thermosetting plastics. I'd ask your dentist: what does that history show? There's an even longer history of tonsillectomies. Long history does not equal safe. Tonsillectomies were recently found to be associated with a 50 % increase of risk of heart attack.

1. [http://en.wikipedia.org/wiki/Thermosetting\\_plastic](http://en.wikipedia.org/wiki/Thermosetting_plastic)

Char (2012-03-13 17:35:46)

No, just because we've always done something a certain way does NOT mean we should keep doing it that way if something better comes along. But the thing that I've noticed is that the "new thing" ends up being worse for us than the old. Butter and margarine are examples. We are told to not eat butter because of the saturated fat then we find out that margarine is very bad for us due to trans fats. We hear of a new drug that is supposed to really help people and five years down the line we find out it causes strokes. We are told to take/eat more of a vitamin and then find out that higher rates of cancer are correlated to higher intake of that vitamin. It's confusing. So should I remove what is already in my mouth which I don't think is causing me harm (I could be wrong though!) , an expensive proposition, and replace it with an unknown substance? Will we find out in 20, 30, 50 years that it's leaching out chemicals into the body? That is the question.

Elise Mattu (2012-03-15 14:17:22)

Here's the thing about dental amalgams - they do reduce the metal that they are made out of at the rate of something like 1 % of that metal to 2.1 % of that metal per year. Now the big problem is that when people get all concerned about the amalgams, they go into their local dentist, and demand the amalgams get removed. There is a right way to do it. This right way involves there being an cannula providing oxygen from a canister to the nasal passages of the person having the mercury and silver fillings removed. Otherwise, without the cannula, the person is breathing in somewhere's between 5 to 15 % of the amalgam itself! Depending upon how the dentist drills out the material. No one should ever have more than one filling removed at a single time. And make sure you have a dentist who understands that his drilling away at the filling will be essentially vaporizing the filling. Make sure you are not going to breathe in any of the amalgam. The dentist must be careful to provide you with you protection. Otherwise his or her actions will hurt you more than help you. To say nothing of his or her health, and the health of the staff.

Mark (2012-03-19 21:08:47)

Given how heavy metals remain in the body, wouldn't any harm from them be more-or-less permanent? In other words, wouldn't you expect your arithmetic ability to stop falling further, but not to recover? Seth: "Given how heavy metals remain in the body..." That my arithmetic score improved after my amalgam fillings were removed suggests your theory is wrong - that a substantial amount of heavy metals are removed. Mercury is excreted in hair. Maybe it is also excreted in other ways.

Mickie Roller (2012-03-22 07:04:50)

Read my website: [www.strokesurvivorswithsavvyideas.com](http://www.strokesurvivorswithsavvyideas.com), "Mercury Fillings". Thanks. Seth: you spelled it wrong. I fixed it.

DonDDP (2012-04-19 15:48:13)

Yes it is true that amalgam has been banned in Sweden and Denmark, this month there are meetings in Europe to create more restrictions on the use of this mercury filled material, it is true that mercury comes off silver fillings all day long in small doses. The largest amount of mercury is when it is placed in and taken out of a tooth. Mercury is a toxin, our body is not built to defend against a chronic exposure to mercury. The EPA demands that this filling material be delivered and picked up from dental offices in special hazard material containers but it is ok to put in peoples mouths, that makes no sense. All consumers should atleast be informed and sign a note of consumers consent upon knowing that what is being placed in there teeth is 50 % mercury and small amounts come out into the body on daily basis.

## **Vitamin D3 in Morning: 7000 IU Improves Sleep (Story 21) (2012-03-09 05:00)**

Someone who wishes to be anonymous wrote me:

I had been taking 400 IU D3+calcium morning noon and night for years. I usually fell asleep fitfully. My sleep was rarely uninterrupted throughout the night.

After reading your blog, I started taking all three pills in the morning. Getting to sleep was easier, but

sleep was still usually fitful.

After more reading of your blog, I stopped the D3+calcium and switched to 7000 IU of D3 every morning. Within a couple days, my usual pattern became that I fell asleep quickly and slept soundly through the night.

It is now three weeks, and I continue to enjoy excellent sleep. I noticed no changes in energy or mood.

I asked some questions.

Tell me about yourself.

I'm an academic (professor of decision sciences), 52 years old. I live in Philadelphia.

What you mean by "I fell asleep fitfully"?

Even if I was tired, sleep did not come easily. I had no worries, so it wasn't that.

How long did/does it usually took/take you to fall asleep under the three conditions?

Original 400 IU D3+ calcium 3 times/day: 1/2 hour was usual.

All 3 are taken in morning: 15-30 minutes, but still awakening in the night frequently

7000 IU in morning: 10-15 minutes, and sleeping like a log.

What time do you wake up? What time do you take the 7000 IU?

I usually wake between 7 and 7:15. Sometimes I head straight for the kitchen (where the vitamins are stored) and I take them immediately. Other times I head for the shower and then to the kitchen, whereupon I take the vitamins.

What brand of Vitamin D3 do you take now?

[1]Vitamin Shoppe

1. [http://www.vitaminshoppe.com/store/en/browse/sku\\_detail.jsp?id=VS-2463](http://www.vitaminshoppe.com/store/en/browse/sku_detail.jsp?id=VS-2463)

---

disgruntledphd (2012-03-09 05:30:47)

Seth, you should probably remove the place of residence for your anonymous person, I found it quite easy to identify them given the information provided. Seth: Thanks for letting me know. I have identified him as he chose to be identified.

Joe (2012-03-09 11:24:39)

That brand of D3 contains soy oil, which is bad for the gut (increases gut permeability), according to Dr. Loren Cordain. A better way would be to use Vitamin 3 drops, which are pure vitamin D3. It would be interesting to see the results of using drops compared to using gel caps on sleeping patterns. I use them, and have always used drops (I sleep like a log, too), so I can't be a

n-1 experiment.

BlueMorrissey (2012-03-09 11:26:10)

First of all, I am bipolar, so things fluctuate in my moods and sleep patterns. I was hesitant to post on the D3 experience. I have been taking D3 for over a year, because of my lack of sunshine. I was taking much less than what has been recommended by Seth and had been taking it at various times of the day. A few weeks ago I began increasing the amounts from 5,000 to 10,000 IU and first thing upon waking. My sleepiness at night has gradually increased during this time, but remarkable so during the past week since I've upped my dosage to the 10,000 to 15,000 IU. This is very rare for me to become sleepy before midnight. I work until 10 pm. Usually, I would fall asleep between 2 to 3 am and sleep until 10:30 to 11:00. Now I wake up closer to 9 am. Most importantly I've been able to stop taking ambien and/or benedryl on a nightly basis. I'm excited about this result, and hope to give future positive updates.

Jenny (2012-03-09 13:29:59)

One of you earlier D3 story tellers, I have been sleeping consistently well - until last night when I made the mistake of having a snack at 10pm, instead of supper at 7-8pm. I woke at 2am, had great difficulty going back to sleep - and then was thoroughly woken by one of our computers turning on loud at 3.30am!! By the time I had stared at that blue screen, trying to work out how to turn the damn thing OFF (it wasn't my computer - it's owner was snoring peacefully) I was wide awake. No snack tonight for sure.

Jenny (2012-03-10 13:11:22)

Last night, I made sure I didn't snack, and sure enough I slept all night very soundly. Nice to experiment...

## **The Value of Moodscope (2012-03-10 05:00)**

In 2007, Jon Cousins started tracking his mood to help NHS psychiatrists decide if he was cyclothymic (a mild form of bipolar disorder). After a few months of tracking, he started sharing his scores with a friend, who expressed concern when his score was low. Jon's mood sharply improved, apparently because of the sharing. This led him to start [1]Moodscope, a website that makes it easy to track your mood and share the results.

I was curious about the generality of what happened to Jon - how does sharing mood ratings affect other people? In January, Jon kindly posted [2]a short survey about this. More than 100 people replied.

Their answers surprised me. First, in a survey about sharing your mood - not about tracking your mood - most respondents did not share their mood. It is as if, in a survey about being tall, most respondents were not tall. Second, although Jon's mood sharply rose as soon as he started sharing, this was not the usual experience. Sharing helped, some people said, but other people said sharing hurt. For example, one person said her mood was used against her in arguments. Finally, the respondents gave all sorts of persuasive reasons that rating their mood helped them. To me, at least, the value of mood rating isn't obvious. I can list a dozen hypothetical benefits but whether they actually happen is unclear to me. [3]I rated my mood for years and did it only to learn about the effects of morning faces. MoodPanda, another mood-rating site, [4]gives a few brief vague unenthusiastic reasons to track your mood. And their site is all about mood rating.

In contrast, Moodscope users were clear and enthusiastic about the value of tracking. Here are some reasons they liked mood-tracking:

It is useful to look back sometimes to help you find ways of 'keeping up' a positive mood/outlook.

My mood range has definitely narrowed since starting mood stabilizers, so using Moodscope has

given me solid evidence that the treatment is working well. I also run statistical analyses of my mood charts against variables like sleep, medication use, and alcohol consumption. The correlations were not particularly meaningful using a 9-point Likert-like scale from a standard mood chart. When I used my Moodscope scores instead, I suddenly found that some of the correlations are (ridiculously!) statistically significant, which also made me feel more certain about what I need to do and change to better manage my mental health.

I could express my miserableness in total safety, without leaning on anybody else. It has proved wonderful. My profile has risen from a score of 7 on day 1 (11 months ago) to the 90s now. Being able to track my reasons for feeling better or worse has been part of this. The patterns are visible, ditto the triggers that send me up or down.

The great benefit of Moodscope has been to confirm the advantages of my own lifestyle management for coping with bipolar disorder. It has shown that what I felt was bad for me, is indeed bad, and what I felt was good for me, is indeed good. (I know that I have to take the meds.)

It helps that I can post things about sleep hours in the comments and see the correlation to the chart.

I have found the tool immensely helpful in gaining insight into how my own behaviour and thoughts can impact upon my mental health. I have gained more control.

It helps me to gain insight into my moods, take responsibility for them and steer a calmer, more productive course through life.

It allows me not to panic when I am low as I can see that ups and downs are all part of life.

Pre-Moodscope, I would not realize I was on the way down until 10 or so days had passed, and so I had done nothing. But with Moodscope, I can see if it's a trend and do something immediately. It means I deliberately intervene earlier.

I use my scores, and comments, to understand what triggers my low mood and take steps to stop it getting lower, in so far as I am able.

I view it as a diary of sorts, private for my own contemplation.

I want to catch myself before I make a deep plunge and stay down too long. I do use the info with my doctor. I love having something concrete to show and talk about.

It has helped me feel like there is a greater safety net there, and given me a greater awareness of when I'm slipping back into my treacle pit; I now know that any score between 20 and 30 means I am in dangerous territory and need to take some remedial action, and if I get below 20 then I'm really in a bad way.

Moodscope has helped me identify incidents in my life with my mood. For example if I have to assert myself strongly with someone, I feel exhilarated and very proud of myself for about two days then gradually my mood will lower and a week later I will feel apathetic and down. I love that it is helping me make sense of my emotions and as a result I am not judgmental of them.

I've found Moodscope really useful in finding out what influences my moods. I am bipolar and af-

ter 20 years on lithium I'm managing without any meds. Don't worry, I came off it slowly, under medical supervision!

I use Moodscope as a sort of diary of how I am feeling. Looking back I can see what really pushed my mood down and oddly it's not always the major things that you'd imagine. In my case depression is brought on more by physical health problems - I am a CFS sufferer.

I sum up their reasons like this: 1. Helps understand causality (what causes mood to be low or high?). 2. Immediate guidance (should I take action to raise it?). 3. Self-expression (similar to diary). 4. Reassurance (low moods are "part of life"). [5]Alexandra Carmichael wrote about the value of mood-tracking and mood-sharing. Her experience did not repeat Jon's: She found little initial benefit of sharing, but great eventual benefits ("a kind of deep, healing therapy"). This was the main benefit of tracking for her - that it allowed this sharing. [6]Kari Sullivan also tried Moodscope. She didn't share her mood. The benefits she list fall under the heading of Reason #1 (helps understand causality). For example, she learned "most social interaction lowers my mood," which surprised her.

Not everyone liked tracking:

My girlfriend . . . stopped using Moodscope. In her words, "I don't want Moodscope to remind me how terrible I'm doing."

She has now decided to give up on taking the test as it just reinforces her feelings of general greyness and sometimes despair.

At a website devoted to collecting new ideas about health, [7]Moodscope ranked #1 out of about 500 ideas.

When I started my self-experimentation I didn't get anywhere for a long time (after initial success with acne). After 1990, however, I was astonished at the progress I made. One useful discovery after another - how to lose weight, sleep better, be in a better mood, and so on. Over the next 20 years, I improved my health considerably more than all the other scientists in the world put together. I came to see what was happening as a kind of catalysis. The useful information was already there; my personal science was the catalyst that turned it into something useful. (Lack of people like me was why the discoveries were so abundant - a counter-example to Tyler Cowen's lack-of-low-hanging fruit explanation for stagnation.) Professional scientists were too restricted in what they did.

The Moodscope story is similar. Psychologists have been studying and measuring mood for a long time. The Profile of Mood States is an important result of their research. But no psychologist saw it as an agent of change. It was simply a research tool, albeit a popular one. Only when Jon Cousins started using it for his own selfish purposes did it become clear how useful it could be. He was the catalyst.

Both my story and Jon's are examples of what I say about DIYization of science: It gets tools into the hands of a larger and more diverse group of possible innovators, who are less "stuck" - less committed to old ways of doing things - than the professionals. They are also more motivated to do something useful than the professionals, who are weighed down with other big concerns - about status, job security, money, and so on.

Stone Glasgow (2012-03-10 11:25:09)

Well said! And this applies to innovation and improvement in all areas of life. It is exactly why economies "stagnate" - because industries gradually come to organize themselves as if they were government departments, often with explicit support from governments. Modern medicine and public schooling are good examples of this process, but it can happen to any business, any time the focus is removed from individuals. Guardian syndrome morality does not allow innovation except by elite leaders. Commercial syndrome morality allows for more innovation (wealth creation) by allowing everyone to create innovative products and ideas - not just the men at the top of the pyramid. If individuals lose their ability to innovate and create solutions to problems, the growth of the economy slows - precisely because a "growing economy" is just another way to say "lots of people finding ways to make life better for each other." And this is why half the nation feels that reducing government is stimulating to an economy - because they recognize that wealth (new and useful stuff) depends on the creativity of individuals, not just leaders.

Seth Roberts (2012-03-10 13:04:50)

Thanks, Stone. I agree with what you say. What you say about guardian syndrome morality ("does not allow innovation except by leaders") is a perfect description of modern medicine.

Chris (2012-03-10 21:50:08)

Oh my god I hate people who use my mood against me in constructive debates. Like any argument is moot just because I'm not super happy at that exact moment? Even my mom does it at times, "I'll come back when you're in a better mood" I mean, why are my opinions of less value at that point? Anyway, it's very interesting to see the effects of a scientific study of moods, although I would imagine there's quite an ambiguity among people - like how would you define your moods? For some you need to be REALLY pissed off to be angry, whilst some find it easy and natural. In any way it's something to look out for, particularly in the field of mood related disorders - let's just not hope that everyone starts seeing bipolarity in themselves. PS: Very nice blog Seth, I just found you today via Google :-)

Alasdair (2012-03-12 02:06:52)

I used Moodscope for a few months, as I was learning to cope without SSRI's after a 4 year period with miserable, life-limiting depression. I haven't used it for about 3 months now - principally because its user interface is REALLY IRRITATING! For those who don't know it, Moodscope presents a set of 20 choices to make in random order. Half of these are positive ("inspired", "attentive"), and half negative ("hostile", "nervous") on a scale of 1..4, from "Not at all" to "very". I know WHY the interface is this way, but selecting a score is VERY TEDIOUS for this late-50's computer scientist. Each card has two scores on each of two virtual faces and is presented in a random orientation, so to select a score, I need to "flip" and "rotate" the card until the score I wish to select is at the top and then click on it. At the end of the process, Moodscope presents a score, between 0 % and 74 %, which used to pretty closely mirror the way I was feeling. So, for me personally, the pain of clicking irritating cards outweighed the benefits of getting an objective measure of my mood. The graph of mood over time was interesting, but not compelling. I see Moodscope is now advertising paid subscriptions for premium services. I haven't played with those. The value of sharing? Sharing a mood is a VERY intimate thing to do. I experimented it for a while - one person was simply not interested, and another was interested enough to respond, but I didn't find the interactions helpful or unhelpful. I think I'd have carried on with Moodscope, but not with sharing, had it been possible for me to enter the data more conveniently. Typing this has (almost) encouraged me to set up a google spreadsheet for the purpose...

## Ten Years of Weights, Including Two Years on the Shangri-La Diet (2012-03-13 05:00)

[1]

Here's a new graph I've made of Alex Chernavsky's data. In 2001, he started weighing himself and recording his weight with the hope that it would help him lose weight. His data shows several interesting things:

1. Long walks really helped. The walks lasted 1.5-2 hours. They weren't sustainable but the weight loss they caused lasted a remarkably long time – years, apparently, in the sense that it took years to regain the lost weight.

2. A low-carb diet worked well, but only at first. Alex lost a lot of weight initially but then started to regain it. Just before he became vegetarian, he was regaining weight quickly. I don't know if this is typical. The popularity of low-carb diets has not been matched by availability of data about long-term effects, where by "long-term" I mean four years. Even though low-carb diets are 150 years old (Banting wrote in 1863).

3. The Shangri-La Diet is working better than other alternatives. There's a difference between (a) showing that a diet causes weight loss and (b) showing that it works better than other ways of losing weight. In this comparison, it appears more sustainable than long walks and the weight loss it causes appears more sustainable than the weight loss from a low-carb diet.

Alex originally used Shangri-La Diet principles by ingesting 4 tablespoons of flaxseed oil washed down with water. ([2]Details here.) He lost weight but then started to slowly regain it. I suggested he increase his intake of flavorless calories so he started to eat 1 tablespoon of coconut oil (about 100 calories) each day with his nose clipped. He stopped slowly gaining weight.

I asked Alex why he has persisted weighing himself so long. He replied:

I had at best a vague idea of what I wanted to do with the data. When I was in graduate school [in neuroscience], I enjoyed plotting the results of my experiments, so I thought it would be fun to have a dataset that consisted of my own weight measures. After I started the SLD, I had a more-concrete reason why I needed to collect the data. I explicitly set out to test the diet.

1. <http://blog.sethroberts.net/wp-content/uploads/2012/02/2012-02-27-Alex-Chernavsky-color.jpeg>

---

John W (2012-03-13 06:40:39)

It would be interesting to see an update on your weight, and your current implementation of the diet.

Alex Chernavsky (2012-03-13 07:27:51)

John, I have an update here: [1]<http://www.astrocyte-design.com/shangri-la-diet/index.html>

1. <http://www.astrocyte-design.com/shangri-la-diet/index.html>

Andrew (2012-03-13 08:25:00)

When did he stop walking the first time? It's not listed in the chart. Seth: I think he stopped when winter came.

Alex Chernavsky (2012-03-13 15:06:07)

Yeah, I never really walked during winters (I live in Upstate New York).

BlueMorrissey (2012-03-13 15:07:52)

I've had success on and off on the shangri-la diet. I usually stop because of stress in life leads me back to old habits of anxious snacking and bad habits of diet soda and smoking at night cut into that 1 hour window of non-flavors. I've tried every diet imaginable, but really do prefer the SLD due to its simplicity, cost effectiveness and only small amounts of exercise. My only curiosity is whether or not it works because of the aspect of our paying more detail to our diet and true hunger or the actual flavorless calories. All in all, I do want to enjoy my food, and seem to be losing out on the positive effects of tasty foods. Also, is it the fat content that suppresses appetite. Lately I have found my best formula in a long time. I take about 10 grams of fish oil first thing in the morning, then a couple of eggs with some cheese on Scandinavian Bran Crispbread. This combo leaves me filled and satisfied throughout the day. Only diet soda, tea and maybe some peanuts during the rest of the day. I'm single and work nights, so it has not been a social problem. I would imagine I'll continue to make changes, but I have lost 25 pounds since early January. I usually weigh around 250 and am 6' 2". I do want to add the SLD in combination again and see what happens. By the way, my sleep has been much better than in a long time. I think the vitamin D and late sleeping has been beneficial, along with the high Omega 3 content, which I take for my bipolar. I will add the SLD and give a later update. Thanks Seth.

Joanna (2012-04-15 02:50:40)

Hi Seth! I have just read your book and I could not put it down!! I had been complaining recently that no one had yet made sense of the whole weight loss puzzle. People have got close but no one has put all the pieces together to make a coherent theory. And then I find this book - it is a mind blower and truly does make sense of all the facts about weight loss, everything fits and makes sense in this theory. I really do believe you've hit the nail on the head. I'm so glad you have because I had set myself a project to figure it all out - but I could never have come up with this - as it's coming from a different angle to the purely physiological. Quite honestly - I think you ought to be up for a Nobel prize or something - this information will be priceless to millions - once it becomes better known. I had just started 'The Carbohydrate Addict's Diet' book before I read this and this is probably the second closest thing I have found to getting the full picture after your book. Your theory makes sense of all the observations about food cravings described in their book, for example; MSG, which intensifies flavours, leads to intense food cravings and weight gain. Totally brilliant - it's all starting to make sense :) Thanks so much - reading your book is one of the best things I've ever done! I'll be back to post my own success with the diet - started yesterday and definitely noticed some appetite suppression already. Seth: Thanks, Johanna, that's nice to hear. From your lips to God's ear.

Ross (2012-04-18 17:51:07)

Dr. Roberts, When I consume 2 tablespoons of coconut oil at a time, it doesn't feel right and I get a stomach ache. Is there a way to consume the coconut oil in one fell swoop and somehow mitigate this mild nausea? I imagine the issue is consuming the oil on an empty stomach, but isn't that the point? Thanks for your blog! - Ross Seth: The issue may be lack of the right enzymes for digesting it. Your body doesn't make enzymes it doesn't need. Start with a tiny amount of coconut oil - that doesn't cause a stomach ache - and gradually work up to 2 tablespoons.

ob (2012-04-19 17:14:46)

## **This American Life Retracts Daisy Show (2012-03-16 15:33)**

[1]This American Life has retracted the Mike Daisy show it did a few months ago because it turns out several details - not trivial ones - were wrong. Daisy knew this, and kept the TAL producers from finding out by concealing the cellphone number of his translator. He told them it no longer worked. TAL producers didn't ask for her email address,

apparently. It is a lot like Gleickgate – Daisey/Gleick believing it was okay to stretch the truth in pursuit of some greater good (better Foxconn working conditions/less global warming). At least, I would like to think that is why Daisey did it. I hate to think he needed the money.

The position of This American Life is more complicated than their press release reveals. A few years ago [2]Alex Heard revealed that parts of David Sedaris stories were made up. Sedaris is one of TAL's biggest contributors. He is also their most famous. He probably owes his success to TAL. Did TAL retract his stories? Did it even mention the new information? Uh, no. But TAL remains a great show. These are missteps.

A few weeks ago I complained about Sedaris in a comment on the New Yorker website: Why does The New Yorker publish his stuff as memoir rather than fiction? What exactly is funny about making up derogatory stuff about living people (e.g., Sedaris's guitar teacher) and spreading the false info far and wide?

1. <http://www.businessinsider.com/ira-glass-heres-everything-that-was-made-up-in-our-big-apple-foxconn-story-2012-3>

## More About the This American Life Retraction (2012-03-17 06:02)

Mike Daisey had a perfectly good point about the shallowness of Steve Jobs. Too bad he took "dramatic license". The more interesting part of the story for me is why This American Life (TAL) producers were fooled by Daisey and how they reacted when this became clear.

Suppose I make a short film in which Michael Jordan misses ten free throws in a row. Ten separate free throws, spliced together. Every detail is true, but the whole is false. Mostly he made free throws. You are never going to learn how false my film is by fact-checking it. Because every fact is true. That was the first big mistake made by TAL producers. They assessed Daisey's story by fact-checking. In their retraction they say nothing about this point and seem unaware of it. Had they assessed it more broadly they might have become aware of the exaggerations.

The second big mistake made by TAL was to accept the standard journalistic view that you should get "both sides" of a story. If Person X claims Y, try to find someone who disagrees. If a Democrat says such-and-such, find a Republican to comment. In the Daisey story broadcast in January, the TAL producers took Daisey to be saying "Chinese factories are bad" and countered this, in standard journalistic practice, by finding someone who would defend Chinese factories: New York Times columnist Nicholas Kristof, of all people. Yeah, the salaries are low but they are better than rural jobs, said Kristof. I could have said that. Kristof knows almost nothing about Chinese factories – that was perfectly clear. Thinking they needed "the other side" confused TAL producers and wasted their time. Instead, they should have asked someone who knows a lot about Chinese electronics factories to comment. Again, if they had done this they might have realized that Daisey was not telling the truth. Most journalists know not to demonize. But many of them haven't learned not to polarize.

From [1]the retraction broadcast it is obvious that Ira Glass is furious. He lied to us! was the dominant note. Given how furious he is it is perfectly understandable that he and the rest of TAL didn't manage to reach even one interesting conclusion the entire show. They simply wanted to set the record straight quickly, which is fine. If there are more stories about this, in-depth ones, I am afraid Glass is going to conclude We wanted to believe. That is going to be his deepest comment on this. I hope I'm wrong. I don't agree with that assessment. I think the real problem is We wanted things to be simple. In particular, they wanted (and still want) the simple-minded view of the world taught in

journalism school to be correct. The one in which experts can be trusted, every story has two sides, and truth can be ascertained by fact-checking.

A medium-sized scandal in American journalism is the mainstream journalistic view of global warming – of course humans have caused it (= AGW). To say otherwise is "anti-science". The question has complexities (e.g., how models are tested, how scientists distort stuff) that journalists ignore. I don't think journalists "want" to believe anything about global warming. I think what they really want is simplicity. It makes their jobs easier. A considerably larger scandal is the free pass given to medical schools and drug companies and [2]their first, let them get sick attitude. The recognition that that this is horrible and there are alternatives seems beyond the thinking of most journalists who cover the subject. Again, the notion that our health care system is predatory is complex. Much simpler to believe it is good and not question basic assumptions. Both scandals – AGW and health care – are well in evidence at The New Yorker, an even more respected outlet than TAL, where Elizabeth Kolbert blindly accepts AGW and Atul Gawande, Michael Specter, and Jerome Groopman accept the first let them get sick way of doing things.

1. <http://www.thisamericanlife.org/radio-archives/episode/460/retraction>

2. <http://blog.sethroberts.net/2011/09/18/first-let-them-get-sick/>

---

Robin Barooah (2012-03-17 06:58:38)

Honestly, I don't see why you are defending Daisey in your opening here. Are you not aware that Apple's supplier responsibility report began while Steve Jobs was CEO, and that the only things that Daisey added to what they publish turn out to be lies? Seth: I don't think Daisey's lies are interesting. He lied to make a better story. He took "dramatic license". Not the first person to do that – see David Sedaris, James Frey, and so on. TAL's failure to catch those lies is more surprising, that's why I discuss it at length. I think I have more to learn from it.

Nancy Lebovitz (2012-03-17 08:17:01)

"First, let them get sick" is partly appropriate modesty. Sometimes a treatment which seems plausible (like hormone replacement) isn't such a brilliant idea. Seth: Yes, there is something to that. By first, let them get sick I mean three things: (a) Too little attention paid to fixing small problems, which become larger problems. Small things wrong are ignored until they become big things wrong. Because drugs are so dangerous, they cannot be used on small problems – the risks outweigh the benefits. An example is gingivitis. I believe it indicates too much inflammation all over your body, not just in your gums. (b) Too little interest in nutrition, which is a major cause of illness. (c) Too little interest in prevention.

Tom (2012-03-17 09:42:34)

Not quite correct: – There was no hexane poisoning – There was no mangled hand – There were no guns at the gates when Daisey arrived at the factory. – There were no bunks stacked to the ceiling. I certainly agree with you that not every story has two sides (or can be intelligently "polarized"), but if the fact checking had been done, the problems with his narrative would have been caught, and the broadcast would never have happened. I also think Daisey is a major-league bastard who doesn't haven't the decency to feel shame when he lies to millions of people. That puts him a few rungs below James Frey, which isn't saying a whole lot.

Nancy Lebovitz (2012-03-17 09:52:32)

Also, Daisy apparently doesn't get that what he says on the stage matters. And that getting people to care by lying to them can lead to not believing information about actual atrocities. Back to the need for medical modesty, not to mention the risks of using surrogate measures of "health": [1]Hazards of lapbands. [2]What gets ignored when obesity is considered to be a primary risk factor.

1. <http://www.diabetesselfmanagement.com/Blog/David-Spero/gastric-bands-too-dangerous/#comments>
2. <http://danceswithfat.wordpress.com/2012/03/17/jumping-to-conclusions-is-not-great-exercise/superflat>

superflat (2012-03-17 11:13:29)

i agree generally, but think you're very wrong when you say the problem isn't that journalists tend to want to believe certain things – many if not most journalists at reputable, influential press believe a certain narrative about the world and see their job as political, speaking truth to power, etc.

Dr. Tim Hadley (2012-03-17 11:57:44)

One of the mistaken assumptions here is that "New York Times columnist Nicholas Kristof" might shockingly get something wrong. Just because he works at the NYT, he knows something? Or anything?

Kirk (2012-03-17 13:07:06)

It is a continuing trend: Gleick and his fabricated Heartland memo, Breitbart and his out-of-context editing of Sherrod's speech, and now Daisey and his spin on Apple factories. These people created lies to tell what they consider to be the true underlying story; they were motivated to influence the world to make it better. Interestingly enough, the brilliant David Simon in his 'The Wire' series developed the character of a reporter, Scott Templeton, who also wrote articles based upon lies, but Scott had different motivations. Scott Templeton did not care to influence the world to make it better; he simply craved money and glory. Sometimes professional storytellers anticipate reality and yet just miss.

Tom (2012-03-17 14:59:36)

Nancy, agreed. Interestingly, the Public, the theater where Daisey is currently performing (the show closes Sunday) revealed yesterday that they also hadn't known that he was lying in his monologue about what he had witnessed, saying "...we wish he had been more precise with us and our audiences about what was and wasn't his personal experience in the piece." So even the playhouse was expecting a higher level of integrity. Seth: "So even the playhouse was expecting a higher level of integrity." That's a good way of putting it. There is such a thing as too much dramatic license. And Daisey's defense that his work is "theatre" does not please an actual theatre owner.

Jim (2012-03-17 18:38:42)

Wonderful post Seth! I think you are correct. A bias for the simple story is behind a lot of this. Life is complicated! That takes a lot of the "conspiracy type thinking out of the equation." I had as default model "journalists are dumb" but I have had some really sharp students as declared journalism majors so I was always troubled by my "simple story". p.s. Thanks so much for Shangri-La! The flax oil has raised my HDL, allowed me feel in control of my weight, and improved my gums. My dentist after a 2-3 year absence by me asked "who is taking care of my teeth." No one but the flax oil, brushing, and Seth! Thanks!

Kirk (2012-03-19 10:37:06)

I like this guy's analysis of of the Daisey lies. [www.insidehighered.com/blogs/education-oronte-churm/mike-daisey-liar-and-so-a-m-i-Advocates-like-Daisey, Mortenson, Frey, Breitbart, and Gleick make it difficult to understand the truth when looking at issues like the Keystone oil pipeline](http://www.insidehighered.com/blogs/education-oronte-churm/mike-daisey-liar-and-so-a-m-i-Advocates-like-Daisey-Mortenson-Frey-Breitbart-and-Gleick-make-it-difficult-to-understand-the-truth-when-looking-at-issues-like-the-Keystone-oil-pipeline). Each side spins a believable tale. But what source can we trust, when no news organizations pay for decent fact-checking any more?

Glen Raphael (2012-03-19 11:16:48)

I really like your Michael Jordan example and will probably use it elsewhere. Firsthand testimony is a powerful thing. Or imagine applying Daisey's technique to the US military. Take the worst examples of injured soldiers that you could find in the news anywhere in the country over a few-year period. Tell a story in which you personally met all of these people as individuals, in a context that suggests the injury rate must be many orders of magnitude higher than it is. Give those soldiers words and actions that fill out the needs of your story to make it especially poignant and close with a call-to-action to email some high mucky-muck to "do something". Come to think of it, I'd be surprised if this hasn't been done yet. Somebody call Michael Moore, I've got a pitch for him... :-)

Elisa (2012-03-19 17:16:48)

TAL's audience wants to a) feel good about liking This American Life and b) feel OK about using Apple products. Scapegoating Daisey kills two birds with one stone. But it seems to me the producers are just as much to blame as Daisey for this story being presented as "journalism." Tom, if you listen to the retraction show, Daisey quite evidently feels shame. Seth: "The producers are just as much to blame." I agree and have yet to see this point made even once in all the journalistic comment (e.g., James Fallows, The New Yorker). Apparently journalists prefer to blame non-journalists (Daisey) for bad journalism. It doesn't make complete sense but there it is.

## **Genomics Confidential: Iceland Not So Wonderful (2012-03-18 05:00)**

Many people think that personal genomics will change medicine. Doctors will choose treatments based on your genome, learning your genome will tell you what diseases you are at high risk of so you can take precautions, and so on. One person who believes this is Eric Topol. In his new book, [1]The Creative Destruction of Medicine, he writes:

The biggest leap came in the first decade of the twenty-first century. The six billion bases of the human genome were sequenced, and this led to the discovery of the underpinnings of over one hundred common diseases, including most cancers, heart disease, diabetes, autoimmune disorders, and neurologic conditions.

[2]Here is the founder of a company that makes sequencers: "I believe that the impact on the medical community of whole human genome sequencing at a cost comparable to a comprehensive blood test will be profound."

I disagree. I have seen nothing that suggests genes make a big difference in any common disease and plenty that suggests environment makes a big difference. My self-experimentation led me to one powerful environmental factor after another, for example. Biologists have invested heavily in the study of genes for reasons that have nothing to do with practical applications, as Thorstein Veblen would be the first to point out.

In 1999, New Yorker staff writer Michael Specter wrote [3]an admiring article about a neurology professor named Kari Stefansson. Stefansson had returned to his native Iceland to take advantage of Iceland's genetic homogeneity to find genes for common diseases. "In the past, drugs were discovered almost by chance," Specter wrote, as if this would soon change. The wishful thinking involved is indicated by passages like this:

[Stefansson] and Gulcher selected the five per cent of Icelanders among the hundreds of thousands in their genealogical database who had lived the longest— most of them over ninety. The database allowed the two scientists to seek an answer to a simple question: Are these people who live so long related to each other more often than the average in Iceland? The answer quickly became apparent. People over ninety are much more closely related to each other than people in the general population are, and their children are more likely to live longer than the children of others. That provides strong evidence that the trait is inherited.

"Strong" evidence? The "people over ninety" observation is strong evidence that longevity is inherited only if relatives share nothing but genes. The "their children are more likely" observation is strong evidence of genetic control only if parents pass on to their children only genes. Both assumptions are highly unlikely. For example, surely an Icelandic person lives closer to his relatives than to randomly selected Icelanders.

The article quotes no one with my view (geneticists are overstating the practical value of their work), but it does

say that "Stefansson set out to raise capital at a time [1996] when investors had become skeptical about the many unfulfilled promises made by companies claiming that genetic research would solve the ills of humanity."

Will reality overtake hype? Here is [4]an indication this is happening:

Kari [Stefansson], a neurologist, was a Harvard professor when he co-founded deCODE in 1996. Two years later, Iceland's parliament gave deCODE access to one of the country's unique resources—health records of the genetically homogenous population. DeCODE debuted on the NASDAQ stock exchange in 2000, and it made dramatic discoveries of genetic factors associated with cancer, heart disease and other conditions. But the company never turned a profit and filed for bankruptcy protection in 2009.

---

Albert (2012-03-18 06:51:36)

Michael Rose found that he could breed longer living fruit flies by natural selection (<http://www.nytimes.com/2005/12/06/science/06conv.html?pagewanted=all>), so it is not that far-fetched to think there could be something in the genome to account for longevity. Seth: No doubt genes influence longevity. But how much – the size of the effect – is important. Is the genetic influence on longevity like pieces of gold laying on the sidewalk (high benefit/cost ratio) or like the gold found in seawater (low benefit/cost of extraction ratio)? In other words, how does studying genetic effects on longevity compare to studying other effects (e.g., nutritional effects) on longevity?

Alex Chernavsky (2012-03-18 07:08:02)

See also this: "[1]Personality Without Genes?"

1. <http://neuroskeptic.blogspot.com/2012/03/personality-without-genes.html>

mike (2012-03-18 09:17:53)

Parents increase their child's risk of coronary heart disease through their genes and not through the family's diet or lifestyle a study of more than 80,000 men and women who were adopted as children showed that susceptibility to the disease is transmitted in the womb and not in the home. They found that adoptees who had at least one biological parent with CHD had up to 60 per cent more chance of suffering the disease themselves, compared with a control group. In contrast, growing up in a home with adoptive parents who suffered from CHD resulted in no additional risk for the child, even if both parents had the disease. <http://www.telegraph.co.uk/health/healthnews/8725739/Heart-disease-risk-inherited-through-genes-not-behaviour.html>

JRM (2012-03-18 11:34:57)

Maybe it won't change medicine, but it is extremely interesting nonetheless. I just got my 23andme results back. One of the things they look at is warfarin sensitivity. I have a gene that reduces the efficiency of vitamin K recycling. Guess what? Liquid vitamin K2 drops is one of the few supplements where I notice the effects. Before, I always had chapped lips. Personal genomics has the potential to indicate which supplements would be most useful. What else? I apparently have some gene variants for increased intelligence. Over time, personal genomics will help break the taboo on differences in IQ. I am a carrier for cystic fibrosis. The gene affects transport of chloride ions. Personally, I am neurotic about salt intake. It has to be just right. If I eat fruit, I need to balance it with salt because the potassium in fruit throws off the electrolyte balance. CF sufferers produce

mucus in excess. So, I imagine that carriers still produce abnormal amounts of mucus. This would provide an explanation of why I suffered chronic ear infections as a child. Mucus would block the Eustachian tube creating a breeding ground for bacteria. Of course, it wasn't the sole cause. Mucus producing foods such as dairy would also be a cause. Since going paleo, it is not a problem anymore. What else? One of the reasons I got tested was to see if I had genes for hemochromatosis. I don't. So I can keep on eating my 1.5 pounds of meat a day. Seth: You sound like an extremely sophisticated consumer of genetics information. Yet even for you the only practical benefit seems to be what you say in the last three sentences: "One of the reasons I got tested was to see if I had genes for hemochromatosis. I don't. So I can keep on eating my 1.5 pounds of meat a day." I wonder why you think we know everything about "genes for hemochromatosis". How much variance do the hemochromatosis genes we know about explain? what if they explain only 10 % of the variance? If I were worried about too much iron in my blood I would simply have it measured. So even your one practical example doesn't make sense. I'm not saying the info isn't interesting...but the defenders of its practical value seem to have a hard time being convincing.

threepipeproblem (2012-03-18 18:37:18)

This guy has a bunch of anecdotes of the kind you said you haven't seen. [http://www.ted.com/talks/richard\\_resnick\\_welcome\\_to\\_the\\_genomic\\_revolution.html](http://www.ted.com/talks/richard_resnick_welcome_to_the_genomic_revolution.html)

Pauline (2012-03-19 03:44:10)

This is a nice article reminding us of the limitations of the scientific method. <http://everythingyouknow-iswrong.blogspot.co.uk/search?updated-max=2011-02-25T04:37:00-08:00&max-results=2&start=18&by-date=false>

Sadie (2012-03-20 08:49:18)

"I have seen nothing that suggests genes make a big difference in any common disease and plenty that suggests environment makes a big difference." You are dead right about this. The more we learn about epigenetics, the less our previous model of genetic determinism makes sense. We know beyond a doubt that gene expression can be turned off and on (it's an essential part of how we determine a gene's function in the first place). Any given gene's function is affected by other genes and by the cellular environment. What we learn from genetic studies in the future may help us understand the mechanisms of how gene expression can be modified by behavior, but it's missing the big picture- that behavior can change gene expression, and thus every bodily process! I'm interested in JRM's example: "I have a gene that reduces the efficiency of vitamin K recycling. Guess what? Liquid vitamin K2 drops is one of the few supplements where I notice the effects." Did you experiment with vitamin K2 drops before you received your genetic analysis, or after?

## **Vitamin D3 in Morning: Moving D3 & Fish Oil from Evening to Morning Improves Sleep (Story 22)** (2012-03-19 05:00)

A few weeks ago I got an email from a reader named Alexander Vinther:

I take Vitamin D3 (2000 units) in the morning (between 7 and 9 am) together with fish oil. My sleep is deeper and I don't wake up at odd times during the night. I tried increasing my intake 3-fold [= to 6000 IU] but felt too energetic/restless when going to bed (regardless of the time). I stopped taking Vitamin D3 (the regular dose) for a while to check my results only to start waking up in the night (or waking up early). Before this, my intake of D3 and fish oil was usually in the evening (everybody seems to recommend taking vitamins in the evening). The change from evening to morning was with both fish oil and D3 (I have always been taking them simultaneously) with huge improvement in sleep.

This is especially interesting because he made the evening-to-morning change long before I blogged about it. I asked for details.

Tell me about yourself.

Male, 24 years old. I live in Denmark and study philosophy. I exercise a lot (6 times a week, crossfit).

What were your sleep and energy like before you started taking D3 and fish oil in the morning?

My energy levels during the day would change a lot, sometimes with a huge surge in energy in the evening making falling asleep difficult. This would lead to few hours of sleep or a general feeling of not having slept at all (this in comparison to what I feel now, the feeling of "deep" sleep). [This is what happened when he was taking D3 and fish oil in the evening. -Seth]

Have you tried other D3 dosages?

I started out with 1400 units of Vitamin D3. I now take a multivitamin which has a small amount of D3, hence the 2000 units. I didn't notice a difference between 1400 and 2000 units, but 6000 made me giddy/restless for the first week, which is for as long as I tried that particular dosage. 4000 units seems to have the same effect as 2000 units, but it is a dosage I haven't taken for more than a week.

How long have you been taking Vitamin D3 in the morning?

I switched the time (from evening to morning) of my D3 intake about a year ago. Stumbling upon your blog confirmed my belief in or underlined the evidence for a difference in morning/evening intake.

How soon after you started D3 and fish oil in the morning (instead of the evening) did you notice better sleep?

I would say I see improvements in my sleep 3-4 days after D3 intake

What brands of Vitamin D3 and fish oil do you use?

My D3 brand is Danish: Naturdrogeriet D Mega. My fish oil brand is Biosym EPA-GLA+. I take 2 capsules containing a total of 1200 mg fish oil (DHA, EPA, GLA), 600 mg Borago oil and 700 mg soyalecithin.

---

Åse (2012-03-19 05:58:35)

This is all so interesting. When I read about the vitamin D on your blog this fall, I went out and got me a bottle from the local supermarket (in Sweden). What caught my eye then was that I hoped it would help with my around 3 pm slump, which was so bad I basically could not work beyond it. OK, maybe I could, but it would be hard concentrating, and I would need a nap, and by that time I needed to go home anyway... I started taking 1 in the morning, with my cup of sugar water, and fish oil capsules that I use for the SLD (which has gotten me down from slightly overweight, to normal weight, and my waist is now roughly where I expect it to be). And, I do think it improved the afternoon slump rather quickly. But, nothing for the night. I never had sleeping problems earlier (except during pregnancy). It took 3 kids for me to become sleep-deprived. But, I have been having a hard time sleeping, and also of waking up multiple times. I upped the intake to 4 tablets - but that just hurt my stomach. I have eased back - between 2 and 3. And, there may be an improvement. Not back to where I used to be, but fewer waking up in the night. But, not as noticeable as the lesser afternoon slump (or finding my waist).

Boris (2012-03-19 15:31:53)

I 38 tried 2000 D3 and 4000 for 2 months with my regular multivitamins and did not notice anything different. Seth: Thanks for reporting your experience.

BlueMorrissey (2012-03-19 15:36:23)

I began taking mega doses of Barleans fish oil in the morning a few weeks after increasing the D3 to 5000. I've never fell asleep so fast and deep as I have now. I'm 38, bipolar and am off ambien and benedryl just recently. I do take a small amount of melatonin. The only problem is I sleep at least 9 hours a night and am quite slow in the mornings. It'd take this anyday over the chronic insomnia. Thanks for the article Seth and the sharing Ase. Seth: Thanks for reporting your experience. Your immune system is probably working much better now than when you had chronic insomnia.

Jared D (2012-04-05 11:11:56)

First and foremost; Seth, I thank you for sharing. May of last year til August of last year, I was on 4000IU D3 and 1000mg/q12hr. I was ok but still sluggish and work at night and sometimes with an OT. Since I am diabetic II and loosing weight it isn't working on my favor. October of last year, I was tweaking with OTC med for a month. I increased my D3 to 10,000 (q12hrs) and Lovaza 2gm(q12hrs) and Multivitamins with D 400IU as well as cooking mushrooms as meat substitute. this one works for me quite well my energy is back 200 %. Being said, I have lost almost 20lbs in two months. Addendum: My Dr is well aware of my OTC and Rx meds.

### **"Seth, How Do You Track and Analyze Your Data?" (2012-03-20 05:00)**

A reader asks:

I haven't found much on your blog commenting on tools you use to track your data. Any recommendations? Have you tried smart phones? For example, I have tried tracking fifteen variables daily via the iPhone app Moodtracker, the only one I found that can track and graph multiple variables and also give you automated reminders to submit data. There are other variants (Data Logger, Daytum) that will graph one variable (say, miles run per day), but Moodtracker is the only app I've found that lets you analyze multiple variables.

I use R on a laptop to track and analyze my data. I write functions for doing this – they are not built-in. This particular reader hadn't heard of R. It is free and the most popular software among statisticians. It has lots of built-in functions (although not for data collection – apparently statisticians rarely collect data) and provides lots of control over the graphs you make, which is very important. R also has several programs for fitting loess curves to your data. Loess is a kind of curve-fitting. There is a vast amount of R-related material, including introductory stuff, [1]here.

To give an example, after I weigh myself each morning (I have three scales), I enter the three weights into R, which stores them and makes a graph. That's on the simple side. At the other extreme are the various mental tests I've written (e.g., arithmetic) to measure how well my brain is working. The programs for doing the test are in R, the data is stored in R, and analyzed with R.

The analysis possibilities (e.g., the graphs you can make, your control over those graphs) I've seen on smart phone apps are hopelessly primitive for what I want to do. The people who write the analysis software seem to know almost nothing about data analysis. For example, I use a website called [2]RankTracer to track the Amazon ranking of The Shangri-La Diet. Whoever wrote the software is so clueless the rank versus time graphs don't even show log ranks.

I don't know what the future holds. In academic psychology, there is near-total reliance on statistical packages (e.g.,

SPSS) that are so limited perhaps they can extract only half of the information in the usual data. There are many graphs you'd like to make that it is impossible to make. SPSS may not even have loess, for example. Yet I see no sign of this changing. Will personal scientists want to learn more from their data than psychology professors (and therefore be motivated to go beyond pre-packaged analyses)? I don't know.

1. <http://www.r-bloggers.com/>
2. <https://www.ranktracer.com/>

---

Darrin Thompson (2012-03-20 05:57:27)

One thing that might help would be if someone could identify a book or resource that would educate work-a-day computer programmers on data analysis. I think we're special and deserving of a special book just for us. We are capable of implementing analysis if it's described to us, but woefully incapable of applying it to real data. It's a painful blind spot for me. For instance, I find this very interesting: <http://blog.linkibol.com/2010/05/07/how-to-build-a-popularity-algorithm-you-can-be-proud-of/> But the best I could do would be to pick one and implement. I don't get much insight from reading it. Painful to admit...

Joe Harris (2012-03-20 13:29:39)

Just wondered if you're familiar with KXEN and whether they're making inroads into academic circles. Also have you tried Tableau for going over the data visually? It's my personal favourite.

Brian Toomey (2012-03-20 13:53:58)

Hi Seth, I am learning R now, and finding that having a Google form synced to my iphone, which I can then read into R is a flexible way to collect data. What tools or publications would you recommend for learning more about data analysis and visualization. I've been reading the R blogs. In my psych education I received the SPSS approach you critique. Thanks, Brian  
Seth: Exploratory Data Analysis by John Tukey is pretty good. It is a strange subject, data analysis: Those who do it all the time (practicing scientists) don't write about it – they don't write statistics books or even articles – and those who write about it (the authors of statistics books) appear to do not much of it. For a long time statistics textbooks used made-up examples, presumably because their authors had so little contact with actual examples. Psychology professors don't seem to entirely realize their advantage (considerable experience with actual data) because when they write about statistics they often imitate statistics professors – e.g., most intro stats texts written by psych professors imitate intro stats texts written by stats professors.

Nancy Lebovitz (2012-03-21 04:15:39)

Off-topic: [1]They're only testing drugs they think they can understand, and that's part of why we aren't getting miracle drugs.

1. <http://wavefunction.fieldofscience.com/2012/03/unstoppable-moore-hits-immovable-eroom.html>

Paleophil (2012-03-24 08:39:19)

It would be nice if there was an effective simple way to track and analyze our brain function data for those of us who aren't computer programmers. Has anyone come up with good simple methods other than Moodtracker?

MikeW (2012-03-21 10:00:57)

Off-topic, but that "long-term SLD success" link points to one of the ugliest websites I have ever seen. I can't imagine a worse combination of text/background color and font style. Makes my eyes hurt. That blogger could use web design tips from you in addition to the dietary advice.

Ethan Fosse (2012-03-21 22:17:33)

Excellent post. Most medical doctors know very little about nutrition (or more generally how to interpret the statistical models and graphs commonly used in epidemiological studies), so even those who aren't lured into giving questionable advice by private companies are still usually not reliable sources of information on these nutrition and diet.

Bryan (2012-03-22 17:14:26)

I posted the "doctor gravy train" story on Facebook and two people commented. Both said the story is overblown: one said the dinners are little more than "cold cuts and a boring lecture," the other said they were nothing but "cold noodles and pens." Neither seemed to address the fact that those who went to these lectures were more likely to prescribe the drugs in dangerous or risky ways. Also, incidentally, both are attorneys whose significant other is a doctor: one is married to an ER doc, the other is engaged to a psychiatrist. Seth: Interesting. Yeah, what about the main finding?

## Gary Shteyngart is a Very Funny Guy (2012-03-22 05:00)

I heard Gary Shteyngart (latest book [1]Super Sad True Love Story) at the Beijing Bookworm. No better job of authorial self-promotion have I seen. He was born in Leningrad in 1972, he grew up hearing jokes from his parents. For example: The 1980 Summer Olympics were in Moscow. At the time, Brezhnev was in charge. He was going senile. At an Olympic ceremony, he gave a speech. His hands shook holding the text of his talk.

"Ohhhhhh....." he read.

He paused.

"Ohhhhh....."

He paused.

"Ohhhhh....."

An apparatchik ran up to him. "Senior Comrade Brezhnev, those are the Olympic Rings!"

The moderator asked Shteyngart what he thought of Putin's plan to require every Russian teenager to read a specified 100 great books by graduation. "These things never work," said Shteyngart. "American cities have done this. Everyone's supposed to read a certain book, usually *To Kill a Mockingbird*. Never tell someone what to read." However, he said one of his favorite authors is Karen Russell. (For a New Yorker podcast, he read a story by Andrea Lee.)

I asked about his favorite TV shows. He mentioned *The Sopranos*, *The Wire*, and *Breaking Bad*. "Who would have guessed that TV would become a great art form?" He is writing a show for HBO about Brooklyn immigrants.

I learned that he was [2]interviewed by a magazine called [3]Modern Drunkard. The interviewer – not Shteyngart – mentions an Russian saying: "The church is near, but the road is icy. The bar is far away, but I will walk carefully." How true.

1. <http://supersadtruelovestory.com/>
2. [http://www.drunkard.com/issues/06\\_06/06\\_06\\_gary\\_shteyngart.html](http://www.drunkard.com/issues/06_06/06_06_gary_shteyngart.html)
3. <http://www.drunkard.com/>

Tracy (2012-04-27 21:45:27)  
I like bookworm too!!

### **Flavour, a New Scientific Journal (2012-03-22 12:01)**

A new online open-access journal called Flavour has just started publication. The first issue has [1]three articles and an editorial.

The journal

encourages contributions not only from the academic community but also from the growing number

of chefs and other food professionals who are introducing science into their kitchens. . . . often in collaboration with academic research groups.

The first set of articles has an example of a collaboration between chefs and professional scientists – [2]how to get a strong umami flavor from Nordic seaweed. Then you add the flavor to ice cream. Which reminds me of dessert at a friend's house where he poured expensive balsamic vinegar on vanilla ice cream.

Thanks to [3]Melissa McEwen.

David (2012-03-22 12:04:20)

Off topic: Seth, in a video of a lecture you gave, you were wearing orange goggles, presumably because it was after sunset. Do you have a source for those goggles? Seth: I got mine from Amazon. They cost about \$7.

Andrey Shestakov (2012-03-23 02:19:21)

David, following Seth's advice I decided to buy myself similar goggles, but was unable to find anything like this within my reach. So I decided to order custom glasses from an optician's shop (my eyesight is good, so lenses are not corrective). I chose the biggest frame I could find, but it was small nevertheless. After getting my glasses I found out that my eyes hurt when I wear them! I contacted the optician's and they told me that never did they hear about someone's eyes hurting when wearing non-corrective lenses. I don't know yet what causes this. Probably the frame is too small. I just wanted to warn you that it's sensible to try the lens for 5-10 minutes before buying.

### **Another Unintentionally Revealing Response From the American Medical Association (2012-03-23 05:00)**

A few weeks ago [1]I blogged about the lame response of the American Medical Association to HealthTap, a website that solicits doctors' answers to medical questions. Their criticism was so weak it amounted to praise.

More recently, the AMA was asked about its position on doctor rating websites. [2]Here's what happened:

Robert Mills, a spokesman, sent me a statement that he said was from the A.M.A.'s president, Dr. Peter W. Carmel, that read, in part, "Anonymous online opinions of physicians should be taken with grain of salt and should not be a patient's sole source of information when looking for a new physician." This, however, is almost exactly the same statement [3]it provided to its own publication, American Medical News, in 2008, when it was attributed to Dr. Nancy H. Nielsen, the president-elect of the A.M.A. at the time.

Such plagiarism is more consistent with what Jane Jacobs in *Systems of Survival* called guardian values (where honesty is unimportant) than commercial values (where honesty is very important). When you grasp that doctors follow guardian values rather than commercial ones their behavior becomes far more predictable – and plainly in need of

control by outsiders. That doctors are allowed to charge for their services resembles allowing policemen to write as many parking tickets as they like and pocket the fines.

Thanks to Bryan Castañeda.

---

Glen Raphael (2012-03-23 06:11:37)

I do not understand why people keep trying to apply the concept of "plagiarism" to domains in which it's not relevant. There is nothing wrong with saying something that other people have said before. It is quite common that a company (say, Apple) or some other organization (say, the AMA) has its PR people come up with a set of "talking points" to answer particular kinds of questions. After that has been done, no matter who you ask, you're likely to get something resembling that answer. So the AMA president either did say this line himself (and it wasn't original) or was willing to have it said on his behalf in his name. Nobody ever claimed this statement was "original research" so there's no dishonesty here. The correct term for this sort of reuse is not "plagiarism", it's "consistency". An earlier place I noticed this odd trend was in connection with the Wegman Report - when Congress asks somebody for a summary of technical information it seems to me like a downright \*bad idea\* for it to be all original research - copying from whatever the best sources available are and saying "I stand by this" is the best way to efficiently get good information into the record. Originality is nice and all, but it doesn't trump accuracy. If you ask a question and get an answer, the important issue is whether the answer is \*accurate\*, not whether it is \*original\*. Indeed, the more "original" the answer is, the less likely it is to be accurate.

Tuck (2012-03-23 07:01:04)

"That doctors are allowed to charge for their services resembles allowing policemen to write as many parking tickets as they like and pocket the fines." LOL. I wouldn't have a problem with policemen like that if I was allowed to fire them and hire their replacement. I think a big part of the problem with the medical industry is that it's been distorted by a government-mandated payment scheme that makes absolutely no sense (insurance through the employer). Many folks have noted that the medical industry works much better in those realms, like plastic surgery and laser eye treatment, which are outside the government scheme, i.e. are forced to operate more like an auto-repair business. +1 to Glen's comment, also.

Jim (2012-03-23 10:42:06)

I agree with Glen as well. "Plagiarism" does not apply to that (repeated?) statement. Also, the statement regarding online ratings seems pretty fair. He just says they shouldn't be a patient's sole source of information when selecting a doctor. Sounds fair to me. As for the grain of salt, I agree as well. I'm sure if we look at the online reviews for the SLD book, there will be quite a few, ahem, "outliers." Seth: I would like to think the president of the AMA is not brain-dead. He could have said "This has come up before. Our position is...". As for the actual content of the statement (e.g., shouldn't be sole source of info), it reminds me of scientists who say "I think we should be cautious when interpreting this result." Oh really?

Nancy Lebovitz (2012-03-23 16:08:09)

The quoted statement is so cliched that I really can't worry about plagiarism.

Tom (2012-03-23 22:02:51)

*I think a big part of the problem with the medical industry is that it's been distorted by a government-mandated payment scheme that makes absolutely no sense (insurance through the employer)* I don't get where all weirdo libertarians spouting

these bizarre falsehoods are coming from. Insurance through the employer is not and never was "government-mandated". It was something employers came up with after WWII to attract workers in short supply. They kept it up because it reduced worker mobility, keeping an artificial ceiling on wages. The group-buying power of large employers vis-a-vis insurers enabled them to buy insurance far cheaper than an individual could, making changing jobs extremely risky and expensive. Further, despite the vastly higher health premiums paid by individuals, the coverage in reality is practically non-existent for major health problems. My late father was a heart surgeon. He was always reimbursed immediately with no problems by a given insurance company when the worker was employed by a large employer (say, General Motors.) When the *same insurance company* insured an individual who needed the *same operation*, it was pulling teeth to get the insurer to honor the policy. Blue Cross simply didn't dare fuck with General Motors. But individuals were dead meat. And this was thirty years ago. Forgive me if I doubt that insurers are more ethical now. Sorry if that doesn't jibe with your fantasy of how magnificently corporations always behave, vis-a-vis the moustache-twirling government.

### **The Hunger Games (2012-03-23 20:52)**

I recently read The Hunger Games and liked it a lot. I finished it in a few hours – couldn't stop reading. In contrast, I read a few pages of the first Harry Potter and stopped. When I was ten years old, I read The Hobbit, The Fellowship of the Ring (the first book of The Lord of the Rings trilogy), and stopped halfway through the second book. I never went back and have not seen the movies. I have never read a book by Stephen King, John Grisham, Robert Patterson, Anne Rice, Stephanie Meyer, and so on. None of them appealed to me. The Hunger Games is different than other books that have sold huge numbers of copies. When it came out, Stephen King reviewed it in Entertainment Weekly [1]and gave it a B. The second book in the trilogy, [2]reviewed by someone else, got a C.

Sentence by sentence, even scene by scene, The Hunger Games is mediocre. It is not quotable. There is no vivid writing. The characters are barely interesting. It is not Jonathan Franzen, much less Vladimir Nabokov. But it does a wonderful job of supplying the four basic elements of a good story: a hero, a villain, making you care about the hero, and putting the hero in jeopardy.

Beneath the surface, also, is something I rarely find in novels: the author feels strongly about her subject matter. Collins, the author of The Hunger Games, has said she is writing for teenagers about war. Her father, who was in the Army, cared deeply about this and taught his children about it. "A family trip to a castle, which [the 13-year-old Collins] imagined would be "fairy-tale magical," turned into a lesson on fortresses [given by her father]," says [3]an article about Collins. Did Vladimir Nabokov know this much about child molesters (Lolita)? No, it was a literary device. Did Tolstoy or Flaubert have the events of Anna Karenina or Madame Bovary drilled into them in childhood? Unlikely. Both novels are built on basic novelistic subjects (actually, the same subject – infidelity). Somehow Collins's deep connection comes through. I have no idea if you can write a good book simply because you love something. But you can definitely write a good book if you hate something: The Devil Wears Prada.

1. [http://www.ew.com/ew/article/0,,20419951\\_20223443,00.html](http://www.ew.com/ew/article/0,,20419951_20223443,00.html)

2. [http://www.ew.com/ew/article/0,,20419951\\_20300507,00.html](http://www.ew.com/ew/article/0,,20419951_20300507,00.html)

3. <http://www.nytimes.com/2011/04/10/magazine/mag-10collins-t.html?pagewanted=all>

FredR (2012-03-23 21:13:04)

"Was Tolstoy or Flaubert personally affected by the events of Anna Karenina or Madame Bovary?" Seeing as a lot of Anna Karenina is autobiographical, this seems like a pretty weird question. Seth: Maybe I'm wrong. Maybe "personally affected" is the wrong way to put it (and I will change it). Sure, many pieces of Anna Karenina are autobiographical – details of the marriage proposal, for example. But I never got the sense that the overall theme of the book was something Tolstoy had studied. On the other hand, The Death of Ivan Ilych seemed incredibly heartfelt.

gesher (2012-03-23 21:31:38)

The Hobbit is not the first book in the Lord of the Rings trilogy. It's not part of the trilogy at all.

Ryan Holiday (2012-03-23 21:43:39)

Just finishing the 3rd book now, I started the series 4 days ago. Honestly, they could do a lot worse than teaching this book in middle or high school English classes.

Bryan (2012-03-23 22:20:21)

Flaubert famously said "Madame Bovary c'est moi." so he may have been more personally invested than you think.

Yogesh (2012-03-24 00:35:58)

"When I was ten years old, I read The Hobbit, the first book of Lord of the Rings trilogy, and stopped halfway through the second book." Did you mean you read \*The Fellowship of the Ring\*, which is the first book in the LOTR trilogy? \*The Hobbit\* is the prequel to the trilogy. Seth: I read two and a half books: The Hobbit (the prequel), Book 1 of the trilogy, and half of Book 2 of the trilogy.

w (2012-03-24 07:45:27)

Surprised by your surprise that authors feel strongly about their subject matter. I read the first two and found them a bizarre combination of bland prose, predictable plotting, and high entertainment. They were also the most morally irresponsible books I'd ever read. Same league, perhaps, as the Bible, Celine, etc, but the target audience is young adult. Take one case: none of the "good" main children are ever placed in a situation where they have to kill, except in self-defense. Highly convenient that all of the other good/innocent children are murdered by the "bad" ones, who thereby become worse in our eyes and can thereafter be acceptably dispatched by a protagonist. Zero meaningful psychological reflection by the about this situation. Seth: Yes, The Hunger Games is mediocre in so many ways – zero interesting psychology is one of them, as you say.

Eugene Woodbury (2012-03-24 08:07:07)

I'm reminded of this by Philip Pullman: "We need stories so much that we're even willing to read bad books to get them, if the good books won't supply them." Seth: Yeah, good point. Week after week I am puzzled that the short stories in The New Yorker ("good books") are not more fun to read.

Allen K. (2012-03-24 08:11:21)

I haven't read the Hunger Games yet, but if you want a writer who unquestionably supplies the four ingredients you listed, plus can actually write, try Lois McMaster Bujold (multiple Hugo and Nebula winner). All her back catalogue is on-line, e.g. [http://baencd.thefifthimperium.com/24-Cr yoburnCD/CryoburnCD/Novels/Cordelia's %20Honor/index.htm](http://baencd.thefifthimperium.com/24-Cr%20yoburnCD/CryoburnCD/Novels/Cordelia's%20Honor/index.htm)

T.D. (2012-03-24 11:11:04)

First off, there is no way for you to know whether the authors mentioned above cared less for their stories than Collins. There is no way for you to equate Collins' upbringing with the way her story is told. You just used what you read about her extraneously to make judgments about the text, and any text should always work alone if put under scrutiny. I would put forth that the main reason why I, and most everybody else, found the Hunger Games enjoyable, apart from the premise, is that every chapter ends with RAISING THE STAKES. Collins does this masterfully. But this is a function of structure, of weaving a narrative, and nothing to do with the premise of warfare itself. It's the process of reading it that appeals. When I devoured the

trilogy in two days, I had to step back and determine whether I had read a great series or if my senses had been manipulated by perfect execution of narrative. Was there something really there? I am doing the same after watching the film, although I'd recommend you hold out for as much as possible after finishing the trilogy before you watch it. Seth: "As much as possible"? You mean as long as possible? Why? I don't remember this "raising the stakes". Given that the narrator faced death, the stakes were high early. I don't remember them going higher. Maybe the appropriate comparison of Collins is not with high literature (e.g., Flaubert) but with Ann Rule (true crime). Rule is a terrific writer and several of her books I could not stop reading. Her best book is *The Stranger Beside Me* – and that is the book of hers where she had the most personal involvement. I still believe that Collins's personal involvement with warfare (through her dad) has a lot to do with why I enjoyed *The Hunger Games*.

Aaron Blaisdell (2012-03-26 11:07:30)

I think Tolkien knew quite a bit on a deep personal level of the subject matter of his books. He was a WWI veteran and witnessed first hand a lot of trench warfare, and subsequently became a philologist with an expertise in Anglo and Norse language, history, and mythology. I found his books gripping and addictive and have read his trilogy about 6-8 times all the way through since my teenage years. I also plowed through the Harry Potter books. Couldn't put them down. I'm rereading them out loud to my daughters who love them, too. I also raced through the *Sword of Truth* series by Terry Goodkind. Another series I reread every few years is Asimov's *Foundation* novels. The original trilogy is fantastic pulp fiction.

Kayode (2012-03-29 08:31:09)

I think there's a lull in the middle of the "2 towers" (*Lord of the rings* book 2) because I stopped there too and never went back. As for the HP books, you could give them another chance. The first two are slow but Rowling starts to hit her stride at book 3. That's where all the grand themes of the series start to show up. Well, that's where I started noticing at least.

## **Sleep and Mood Strongly Linked (2012-03-24 05:00)**

I recently came across [1]a 2005 survey, done in Texas, that found people with poor sleep were far more likely to be depressed or anxious than people with better sleep. Huge risk ratios:

People with insomnia . . . were 9.82 and 17.35 times as likely to have clinically significant depression and anxiety [than persons without insomnia.]

Other studies have found similar results. For example, [2]a 1979 survey interviewed the same people twice, one year apart. People who had insomnia both times were 40 times more likely to be newly diagnosed with major depression during the intervening year than those who did not have insomnia at either time.

A simple thing to say about the sleep/mood correlation is that it supports [3]my theory of depression, which says depression is often due to malfunction of two circadian oscillators (one controlled by light, the other by faces). If they are working properly (in sync, with large amplitude) you sleep well and are in a good mood when you are awake. If they are not working properly (e.g., not in sync) then you do not sleep well and are in a bad mood at least part of the time while you are awake. What is called depression (e.g., not wanting to do anything) is actually a good thing in the middle of the night. Not wanting to do anything – being still – is necessary to fall asleep.

A sad and more complicated thing about this correlation is that it is ignored. It is not explained by any theory of depression popular among psychotherapists, such as cognitive-behavioral therapy, not to mention a dozen other explanations of depression (psychoanalytic, etc.) that psychotherapists favor. Nor is it explained by any pharmacological theory of depression. In other words, if you seek treatment for depression within our healthcare system the treatment you will receive will derive from a theory that cannot explain this result. Yet the correlation is so strong it must be telling us something important.

You can read endlessly about the high cost of health care. What if the high cost is not the core problem? What if it is only a symptom of something less obvious? What if health care costs a lot because we have a poor understanding of health and disease (as the failure of popular theories of depression to explain the sleep/mood correlation suggests)? What if we have a poor understanding of health and disease because health research is too concerned with allowing healthcare providers to make money?

---

JPB (2012-03-24 07:27:04)  
Your final paragraph says it all!

Tim Beneke (2012-03-24 09:09:29)

To repeat what I've said before. I suffered a lot of clinical and sub-clinical depression that was unsuccessfully treated by the medical/psychological establishment for many years. When I stopped being a night person, I got a lot of relief and began to turn it around! None of the 3 psychiatrists or 3 clinical psychologists, all of whom knew I was going to bed at 3:30 in the morning, advised me to go to bed earlier. Seth told me that my biggest problem (I was also obese at the time but that is another story) was going to bed at 3:30 in the morning. I said that I got my best writing done starting around midnight when I really came alive. He said that no one should be coming alive at midnight. Boy was he right! Seth: Thanks, Tim.

Brian Toomey (2012-03-24 13:17:57)

Hi Seth, Interesting post. I suspect you are also familiar with the research that sleep deprivation is a potent anti-depressant: <http://opinionator.blogs.nytimes.com/2010/04/07/in-sleepless-nights-a-hope-for-treating-depression/> With your theory we would say that the extra wakefulness puts the two oscillators into sync, but they fall out soon after if the problem remains (blue light, stress based elevation of cortisol, whatever). Some questions though: There are plenty of other things that seem important for depression like mercury levels (<http://www.ncbi.nlm.nih.gov/pubmed/16891999>) or trauma. How do you theorize these with respect to your theory. Seth: Yes, depression has other causes. I am saying that people need to see faces in the morning (plus other things to make them effective) for their mood oscillator to function properly. Without this, they don't necessarily become depressed—they are more vulnerable to a hundred things that can push them over the edge into depression. Like the way HIV destroys the immune system. Roughly everyone is lacking what I say is necessary (morning faces). In contrast, only a small fraction of the population is poisoned by mercury. Imagine an entire population with a grossly malfunctioning immune system. That's what I'm proposing, substituting mood-regulation system for immune system. With a non-functioning mood-regulation system – which is what I think almost everyone has – all sorts of things will go wrong and will be considered the "causes" of depression and other mental and behavior problems. For example, I think a large fraction of addictions are due to bad mood regulation. What other factors do you think are important? How do you theorize interaction and causation across the levels? Perhaps, as UK researcher Richard Bentall claims with respect to psychosis, looking for the cause of depression is like looking for the cause of coughing. There are many, but some major players. Also, I wonder how important you think \*seeing\* faces is as opposed to other methods of interaction (touch, smell, talking). Perhaps people are differentially dominant across sensory modalities, with you and the people who seem helped being visually focused? Anecdotally, my girlfriend seems much more touch focused as a mood moderator. Seth: I would be surprised if something that seems so important – mood synchrony via faces – is absent in a large fraction of people. The effect of morning faces on mood is profoundly different than the mood alteration you are familiar with – e.g., "I feel better after a drink" and so on. thanks, Brian

Dr Cory Annis (2012-03-24 14:31:31)

Sleep is second only to oxygen in terms of essential "nutrients". We can go longer without water and food than we can without sleep. The "energy" that the brain regenerates during sleep has to be made up somewhere but all our substitutes pale in comparison. People who don't sleep well consume more calories, more caffeine, more alcohol, more tobacco, and more drugs, legal and otherwise. What might happen to our collective health and it's monumental current costs if, instead of protracted political battles and expensive regulation, the government simply shut off the electricity at sundown. Seth: An idea that is more practical than you might realize. In Chinese college dorms, the electricity goes off at midnight. This would be a reasonable experiment in an American college: randomize dorms so that some have their electricity turned off at midnight and others don't. Compare the health and grades of the students in the two sets of dorms.

shtove (2012-03-24 18:24:16)

Final paragraph is powerful. Very pleased I found this blog.

April (2012-03-24 18:34:16)

I have observed this pattern in myself. I didn't realize what the underlying mechanisms were. When I switched to "being a morning person" (actually, I got a dog...who insisted on getting up reasonably early every morning) - my insomnia mostly disappeared, and my depression diminished considerably. I suppose I get exposure to "morning faces" too, in the form of my pals in the park, whom I see most morning when we walk our dogs.

April (2012-03-24 18:36:59)

It is a real pity this mechanism is not more widely known though. I have suggested to other people with insomnia/depression to try going to bed earlier, and I am unable to convince them to try it. Seth: I think it's hard to force oneself to go to bed earlier - by sheer force of will. But it isn't hard to get more sunlight in the morning and more exposure to faces in the morning, both of which will make you tired earlier.

TMS71 (2012-03-24 20:35:03)

I think you nailed it. My biggest beef with the state of understanding of mental health issues is that their explanations for different disorders don't even seem to be slightly influenced by evolutionary theory. Emotions aren't even put into their proper functional context (from an evolutionary standpoint) before theorists try to understand what has gone wrong with them. I like the circadian theory. How would you suggest bringing these 2 circadian rhythms back into synchronicity? Seth: get sunlight and faces in the morning, avoid sunlight (and fluorescent lights) and faces late at night. That's the basic solution.

Ken Snyder (2012-03-25 06:06:30)

Seth, enjoyed reading your post and your "faces" oscillator has me intrigued; I've added your depression paper to my reading list.

Alex Chernavsky (2012-03-25 10:04:38)

April - perhaps the companionship of the dog was the reason your depression diminished considerably. "[1]Could A Dog Benefit Your Mental Health?"

1. <http://psychcentral.com/blog/archives/2009/03/04/could-a-dog-benefit-your-mental-health/>

TMS71 (2012-03-25 20:01:04)

Why do you rule out the straightforward explanation for the correlation, that anxiety and depression make it difficult to fall asleep? Seth: Here are four reasons that your proposed explanation does not strike me as likely: 1. In the 1979 study, the insomnia preceded the diagnosis of depression. 2. It isn't interesting to explain a correlation between A and B by saying, without data, A causes B. That's too easy. 3. Why should depression make it hard to fall asleep? 4. The insomnia involved is not restricted to difficulty falling asleep.

Rob (2012-04-14 10:44:19)

Seth, Do you think there is any connection between Anxiety, eye-contact avoidance, and mood oscillators? Disliking eye contact is a common occurrence in people with social anxiety and autism. (Though avoiding eye contact also has cultural differences) Do you have any thoughts on the implications of night time socializing on couples? Since it seems that direct face viewing is important, perhaps most socializing doesn't necessarily fulfill the face viewing requirement. One last thought.. Has anyone tested the difference between real faces and television / mirrors. I seem to recall from infants that eye contact entrains the right hemisphere

Rob (2012-04-14 11:11:06)

I'm reading through Self-experimentation as a source of new ideas: Ten examples about sleep, mood, health, and weight and had a bit of an insight. In western society to take a break from standing....we sit. However... more often than not if a chair isn't available here in Thailand.. I see people squatting. As squatting doesn't displace weight onto an object, do you suspect it would be a reasonable alternative to walking or standing? Seth: No, I don't think squatting substitutes for standing or walking. I think the crucial feature of standing and walking is that they stress the muscles. Break muscle fibers. The more breakage, the more time necessary for recovery. Squatting doesn't break muscle fibers, I suspect.

js (2012-03-25 15:39:51)

Yeah I was surprised about how you didn't repudiate the " $n=1$ " rhetoric before. It's simply wrong. The number of observations is not equal to the number of people with self-experimentation, since it's not cross-sectional data. Self-experimentation means a possibly large and growing " $n$ ", all on the most relevant subject - yourself. Seth: It's a subtle thing. Experiments with one subject are called " $n = 1$ ". Yet experiments done in only one lab are not called " $n = 1$ ". Is " $n = 1$ " derogatory? Or does it just serve to identify a certain kind of experiment? Not obvious.

minderbender (2012-03-26 22:51:47)

The Smithsonian piece is okay, but it's bizarre that it identifies *Lactobacillus sanfranciscensis* as a yeast. Seth: good point.

## The Future of Email: What I Want (2012-03-27 05:00)

In [1]this essay, which I learned about from [2]Alex Tabarrok, Paul Graham complains about email. Too easy for someone to send him email. Also slow. He thinks of email as a todo list. Here's what he wants:

More restrictions on what someone can put on my todo list. And when someone can put something on my todo list, I want them to tell me more about what they want from me. Do they want me to do something beyond just reading some text? How important is it? (There obviously has to be some mechanism to prevent people from saying everything is important.) When does it have to be done?

Here's what I want: A price per email. A service that charges people for each email they send me (e.g., \$1/email). I get most of the price, the company providing the service gets a small percentage (1 %?). With two additional features: 1. The initial charge is just for me to look at it. Then, after I read the email, there is a mechanism that allows me to easily charge more to do what they ask, such as give them Shangri-La Diet advice. 2. I can easily put people on a list that allows them to send me email for free.

Since Google already has Google Checkout, it might be relatively easy for them to add this to gmail.

1. <http://paulgraham.com/ambitious.html>
2. <http://marginalrevolution.com/marginalrevolution/2012/03/at-the-frontier-of-personalized-medicine.html>

---

August (2012-03-27 06:07:33)

A great feature would be allowing people to pay more and being able to see that in the inbox. The \$40,000 email gets answered first! Seth: Yes, rank them in your inbox by how much was paid. More paid, closer to the top.

Darrin Thompson (2012-03-27 07:47:28)

I'll put this on my list of fun things to build. It's currently in position 2, behind Trailers for Netflix, which is currently in development. Important detail: if someone builds this do you swear on your honor that you will use it? I should also send you this by email just for the awesome irony.

Damon (2012-03-27 10:57:43)

Makes no sense. Why don't you just open a new email address and keep it private, your Majesty?

Bryan (2012-03-27 14:20:46)

Seth, if I'm sending you too many messages, just say so. No need to go through this whole charade. Seth: ha-ha!

garymar (2012-03-27 14:34:49)

When email first got popular in Japan, I remember reading about old-school CEOs who would delete unread any emails from people they didn't know personally. I laughed at his backwardness then. Now I'm not so sure.

Bryan (2012-03-27 14:35:30)

BTW, Paul Graham is an excellent writer. All of his essays are worth reading.

Hit 'n Run Commenter (2012-03-27 16:30:06)

Would this idea apply to blog comments? Seth: I have never gotten too many blog comments.

Steve | Web Direct (2012-03-28 04:39:28)

This would certainly focus companies into making sure any email they sent to you was totally relevant and worthwhile.

Alrenous (2012-03-28 05:59:44)

That is an excellent idea. Now I want that too. Bravo.

JRM (2012-03-28 10:17:46)

I wish people could do this for telephone calls, too. There is an analogy to this in trading. The person who posts the bid or the offer doesn't pay the exchange fees, but the price taker who hits the bid or lifts the offer pays the exchange fees.

garymar (2012-03-28 14:42:31)

Now that I think about it, this is what *secretaries* are for. Someone who knows your needs and wants and can sort your mail by order of importance. Stem the tide of disintermediation! Time to re-intermediate.

## Nick Winter's Big Success with Percentile Feedback (2012-03-28 05:00)

I have<sup>[1]</sup> posted several times about using what I call percentile feedback to boost productivity. Percentile feedback means comparing your current performance to your previous performance using a percentile. If the current performance is in the middle of your previous performances, the percentile is 50, for example. Percentile feedback is easy to understand (scores above 50 are better than average) and is sensitive to small improvements – so even small improvements are rewarded. My implementation had three other helpful features: 1. It adjusted for the time I woke up to make different days more comparable. 2. It measured efficiency (time working/time available) to further improve comparability across days. 3. It was graphical. I made a graph of efficiency throughout the current day versus previous days. It greatly increased how much I worked every day.

I love it and wish I had it for everything I measure. Unlike so many feedback systems, it is realistic and encouraging. I found it worked extremely well – to my surprise, actually. It's not so surprising I would think of it because it vaguely resembles an animal-learning procedure. (Animal learning is my area of expertise within psychology.)

Nick Winter, one of the developers of <sup>[2]</sup>Skritter (which I use), recently started to use it. He gave <sup>[3]</sup>a much-too-short QS talk about it in Pittsburgh a month ago. I asked him about his experience. He is as enthusiastic as I am. He wrote:

The percentile feedback has been a huge success—I'm getting way more done than I ever did, and I'm much better at prioritizing toward my main project. Seeing the graph going in real time has been much better at making me aware of what I need to do to hit high targets each day. I will do a full writeup on this, and on my self experiments, when I finish this iOS app and stop focusing so much on work. The short teaser goes something like this:

Phase 0: just tracking normal work at end of day in a Google Doc, average 2 hours a day on iOS development

Phase 1: tracking normal work and iOS dev separately in the Google Doc, average 4 hours a day on iOS development

Phase 2: using Beeminder to have better graphing and goal incentive for iOS dev, average 5 hours a day

Phase 3: first three weeks of using percentile feedback, average 6.4 hours a day

Phase 4: second three weeks of using percentile feedback, deciding to really push it based on the positive feedback from my metrics (more productivity, more happiness), average 9.4 hours a day

So now I'm getting close to averaging 70 hours of focused iOS dev a week and it feels great. In a normal work place, "time spent working" != "productivity", but for me they're very similar as long as my energy is good, which it almost always is now.

The surprising insight is that changing the way that I measured my work performance—from spreadsheet, to better spreadsheet, to graph, to better graph—has had such a huge impact. I have been working on maximizing work productivity for four years, ever since starting the startup, but in the last six months I've become radically more effective. I love the percentile feedback graph design!

You can see his implementation on <sup>[4]</sup>his homepage.

4. <http://www.nickwinter.net/>

---

Tom (2012-03-28 08:10:29)

Seth (or anyone), Any suggestions for an iPhone app that's a good tool for this method?

Ben B (2012-03-28 09:16:58)

Is he gathering his data in R like you do, and then presenting it via this Highcharts API?

Andrey Shestakov (2012-03-28 22:33:32)

The percentile feedback actually worked very well for me. I used your R scripts on Max OS X. I have a two-display set-up, so I dragged the window with the chart to the second display, so that it wasn't obscured by other windows. This was a critical factor for me to make this system effective. When I started to see the productivity chart all the time, it started to be much more motivating.

Nick Winter (2012-03-29 12:39:46)

Ben, I'm not using R for this (although R is cool). I put a start/stop button on my site when I'm logged in, and the data lives on my App Engine server.

Alexis (2012-03-30 14:33:02)

I'm very interested in this but I'm not sure it's a feature or a bug that the system results in feeling "great" about working 70 hours a week. Perhaps it is a way to become pleasantly addicted to extremely hard work, but that's a dangerous power. I was working about 60-75 hours/week doing ios development over Jan & Feb, and in the end I was sick (but I'm not in my exactly young). Also, I worry that using monitoring to drive up efficiency means you get very efficient at what you can monitor, and crowd out all slack which is valuable over the longer term for creativity even if it's benefit harder to monitor. Reading this post, for instance, would not count as productive. That said, if there were a good app for this, I'd be trying it tomorrow.

Tom (2012-04-01 01:05:31)

Same here. I think a ton of people would buy that app.

Nick Winter (2012-04-06 07:17:28)

Alexis, I can see your point about motivation hacks potentially cutting off useful signals sent by unmotivation, and about blindness to the unmeasured areas of life. I use other tools (like daily journaling, happiness/health tracking, and time set aside for faraway thinking) to be strategic about those things, which I think is better. But certainly it should be pointed out that one should not blindly hack productivity without another way of getting perspective.

## Assorted Links (2012-03-29 05:00)

- [1]All about kefir
- [2]Fraud and waste at a New York hospital. From the comments you can see that the problems have lasted decades. If someone is always sick, year after year, it means there is something about their sickness (about health in general, actually) we do not understand. Likewise, the decades-long persistence of huge problems at this hospital suggests there is something fundamental about regulation (and perhaps health care) we do not understand.
- [3]This paper about how well blood uric acid level predicts mortality, which appeared in 2004, did not get nearly the attention it deserves. I was shocked by its existence – American medical school professors are almost incapable of good research. Well, it's from Finland.

Tuck (2012-03-29 05:14:26)

The study on uric acid and mortality isn't surprising, as gout and metabolic syndrome are highly correlated: "Gout, Diet, and the Insulin Resistance Syndrome": [http://www.jrheum.org/content/29/7/1350.full.pdf+html?ijkey=f725dc5a637823eb123e4ef812a42f23f988a51f&keytype=tf\\_ipsecsha](http://www.jrheum.org/content/29/7/1350.full.pdf+html?ijkey=f725dc5a637823eb123e4ef812a42f23f988a51f&keytype=tf_ipsecsha) Have you seen this: "Gout: The Missing Chapter from Good Calories, Bad Calories" <http://www.fourhourworkweek.com/blog/2009/10/05/gout/>

dearieme (2012-03-29 16:47:25)

"...whether its relationship to cardiovascular events is circumstantial or causal remains to be answered." Has it been answered?

garymar (2012-03-29 16:57:21)

Serum uric acid levels serve as an easily available and inexpensive risk marker, but whether it is an "innocent bystander," a "partner in crime," or even a protector in proximity to CVD cannot be answered based on observational studies.

These guys are too reasonable for their own good. Since they didn't shout "Stop eating meat!" to the media they were simply ignored.

## **Fermented Foods Improve Irritable Bowel Syndrome (2012-03-30 20:38)**

It's hard to get scurvy. If you eat anything resembling an ordinary diet you won't get it. The existence of scurvy, produced by extreme conditions, led to the discovery of Vitamin C. From the case of scurvy and Vitamin C we learned – well, most people learned – that some diseases are clues to what we need to eat to be healthy.

There is no lab test for irritable bowel syndrome (IBS). It is diagnosed if you have "abdominal pain or discomfort in association with frequent diarrhea or constipation," [1]says Wikipedia, and a dozen other things (colon cancer, lactose intolerance, celiac disease and so on) can be ruled out. It is common. In the United States, one study found that 14 % of those surveyed had it. Surveys in other countries produce even higher values – the United States is not a hotspot. "It is one of the most common diseases diagnosed by doctors," says [2]an NIH webpage.

What is it telling us? According to the NIH webpage, "medications are an important part of relieving symptoms." Those medications include anti-depressants. If you treat the problem with drugs, you completely ignore the possibility that a digestive problem is due to eating the wrong food. You might think that would be obvious – but no. Of

course, people with IBS are less interested in taking medicine so they often believe they are "intolerant" to various foods. But they have a hard time figuring out what those foods are, and their problems persist. The Wikipedia section about causes is a monument either to the ignorance of medical school professors or Wikipedia contributors:

The cause of IBS is unknown, but several hypotheses have been proposed. The risk of developing IBS increases sixfold after acute gastrointestinal infection. Post-infection, further risk factors are young age, prolonged fever, anxiety, and depression. Publications suggesting the role of brain-gut "axis" appeared in the 1990s, such as the study "Brain-gut response to stress and cholinergic stimulation in IBS" published in the *Journal of Clinical Gastroenterology* in 1993. A 1997 study published in *Gut* magazine suggested that IBS was associated with a "derailing of the brain-gut axis." Psychological factors may be important in the etiology of IBS.

That's all. Nothing about eating the wrong food. And people wonder what to do about the cost of health care! My suggestion: get rid of everyone (especially medical school professors) too blind or biased to consider that a digestive problem may be caused by the wrong food.

Fortunately not everyone is rushing to treat IBS sufferers with drugs. In an obscure journal called *Molecular Medical Reports*, [3]an open-access article recently appeared about diet and IBS ("Diet and effects of diet management on quality of life and symptoms in patients with irritable bowel syndrome"). [4]The authors are from Norway, which makes the sanity more understandable. The article looks at the effect of dietary advice on IBS symptoms. It compares three groups of patients (IBS patients given dietary advice, IBS patients not given dietary advice, and people without IBS). Patients with IBS eat quite differently than everyone else (for example, they eat less dairy, thinking they might be lactose intolerant), but they are still bad off.

The main point of the article is that the dietary advice was helpful. IBS patients given the advice two years before the study were better off than IBS patients not given the advice, although even those given the advice were considerably worse than normal. Looking at the difference between the diets of the two IBS groups, the better-off group ate a lot more probiotic dairy:

The guided IBS patients reported a consumption of sour milk products containing probiotics almost twice as often as the unguided IBS patients and one and a half times that of the controls. The products used were supplemented with *Lactobacillus rhamnosus* GG, *Lactobacillus acidophilus* La-5 and *Bifidobacterium* Bb-12. Patients with IBS were found to have fewer *Lactobacillus* spp. and *Bifidobacterium* spp. in their intestinal flora than healthy individuals (44). These bacteria have been shown to bind to epithelial cells and inhibit pathogen binding, and to enhance barrier function (46). Furthermore, these bacteria do not produce gas on fermenting carbohydrates, an effect which would be amplified as they also inhibit *Clostridia* spp. (46). A number of studies have shown an improvement in flatulence and abdominal distension with a reduction in the composite IBS symptom score, following probiotic intake (45,46) [emphasis added]

It is highly unlikely that we need to eat sour milk products containing probiotics to be healthy – such products are new in evolutionary history. But it is entirely possible that we need to eat plenty of microbe-laden (e.g., fermented) food to be healthy, [5]as I have said countless times on this blog. The big improvement in IBS symptoms produced by probiotics supports my belief that we need to eat plenty of fermented foods to be healthy. (The Wikipedia entry about IBS mentions probiotics and yogurt, but not fermented foods.) Maybe IBS, like scurvy, is a clue to something really important.

Thanks to Melissa McEwen.

---

Txomin (2012-03-30 21:27:17)

How do (non-dairy) fermented foods fit in our evolutionary history? Seth: Early in evolution, I believe more fermented foods were chosen over less fermented foods, when both were available – because the more fermented foods tasted better. Call it accidental fermentation. For example, old fruit was chosen over fresh fruit. Later in evolution, I believe foods were deliberately fermented, as they are now.

Tom (2012-03-30 23:21:28)

Seth, Art Ayers had a great post on this earlier this month: [coolinginflammation.blogspot.com/2012/03/dr-oz-constipation-soluble-fiber-foo d.html](http://coolinginflammation.blogspot.com/2012/03/dr-oz-constipation-soluble-fiber-foo-d.html) Seth: Thanks for the recommendation. I learned a few things but his weird idea that "there are no genes for food intolerance" makes me wonder about everything else he says.

Alex Chernavsky (2012-03-31 04:31:35)

My wife suffers from chronic digestive problems, probably IBS (other possible diagnoses have been ruled-out by tests). She finds significant relief from drinking kombucha. Before trying kombucha, she tried various drugs – to no effect. She also tried soy yogurt and various probiotics sold at health food stores, but none of those treatments had any effect. Drinking kombucha is not a cure. She drinks eight or ten ounces every day, but she still has flare-ups of her symptoms. Nevertheless, she's much better now than before. She also eats kim chee and miso soup, but we haven't tried to isolate the effects (if any) of those foods, and she doesn't eat them daily. Seth: I suggest eating several fermented foods daily, not just kombucha. Kefir is easy to consume and easy to make.

Tuck (2012-04-01 14:02:11)

"I learned a few things but his weird idea that "there are no genes for food intolerance" makes me wonder about everything else he says." I like that idea. I've often explained to people who tell me that celiac is a genetic condition that this is logically equivalent to saying that a person who falls to his death died of a genetic condition: his genes didn't give him wings. Wheat's a toxic plant. It's hardly surprising that we can't digest it, but that fact doesn't mean there's a gene that's responsible for gluten intolerance. On a related note, you might find this interesting: "IBS and Gluten Intolerance" <http://www.ibstreatmentcenter.com/Newsletters/MidMar2008.pdf> My IBS is food-triggered. Either wheat or seed oils sets it off, wheat is worse. I suspect IBS is simply one manifestation of wheat poisoning (goat-grass poisoning, to be correct), and celiac is another. Which effect you have is determined by your genes, of course... Seth: yes, it is misleading to call celiac disease a genetic condition. But unlike wings, a certain gene that makes you more susceptible to celiac disease is quite common.

Ethan (2012-04-07 05:47:54)

So why not update/fix the wikipedia article?

## Does Kerrygold Butter Improve HDL and LDL? (2012-03-31 14:13)

More: Greg used Kerrygold butter in the results given below. I now see that he omitted data from other butters that did not agree with his conclusions. This makes his results considerably more doubtful and his whole post (in which Kerrygold butter is called "butter") misleading. I have changed the title of this post to reflect this.

A New York lawyer named Greg [1] reports remarkably clear evidence about the effect of butter on blood lipid levels: It improved them. For a few years he measured his HDL and LDL regularly with a home cholesterol device. For unrelated reasons, he started eating more butter. He ate a half stick (about 60 g)/day, like me. Here's what happened.

The first five measurements are from lab tests. The rest are from his home machine.

I asked Greg for details.

I'm 36. I bought the cholesterol meter last July after my doctor said he couldn't figure out why my numbers were a bit high. We both agreed it was not something to worry too much about and that there was no point charging my insurance company for a VAP test every 6 months. We both also agreed that going on a statin was a bad idea. I picked up the meter out of curiosity. I had previously been monitoring my blood sugar (since 2009) and found it to be very interesting, so I thought I could have some fun with the numbers. The result is all the more surprising because I did not expect it. I was tracking my numbers around the time of the experiment [with butter] to make sure they did not go the wrong way like everyone says they should.

The machine is a [2]CardioChek PA [about \$600], which is designed for use in doctors offices, not for the consumer market. The device is "CLIA-waived", which means that the FDA considers it so simple that the user does not need any special training in clinical chemistry (home glucometers fall into the same category). The machine gives significantly different numbers for different people, suggesting it is measuring something real and not spitting out random numbers.

I asked what the reaction to this data has been.

Most people I've spoken to have been receptive to the idea [that butter improves blood lipids], but I got no sense that they would be willing to try it for themselves. Most people I know seem to be quite willing to accept the fact that the old stories about cholesterol are not true. In contrast, one conservative cardiologist said I must have "unique genetics".

1. <http://kneelelessmegafauna.blogspot.com/2012/03/is-butter-as-powerful-as-statin.html>

2. <http://www.cardiochek.com/>

---

Tom Passin (2012-03-31 19:41:13)

That home device sure has a lot more scatter than the lab tests. I suppose we'd like to have the lab be more precise than we can be at home, wouldn't we? Seth, I don't remember your figures. How do these results compare with your own changes?

Seth: I didn't measure the effect of butter on my HDL, etc.

peter (2012-04-01 08:37:18)

seth, when you consumer butter is it by cooking or just eating it raw? does it matter? Seth: I don't know if it matters. I eat it raw (with small pieces of meat.)

dustin (2012-04-02 21:37:08)

I had a similar result with butter consumption. I did a brain function month trial of eating a half cube a day and (w/out planning) ended up getting a lipid profile pretty much exactly at the end of it. Both LDL and HDL were the best they have ever been for me. In fact on my whole blood report there was only one thing in the "warning" column and humorously that was a note that my risk of a heart attack was less that 1/2 of the average. On a related note I always find it funny when people ask how can you possibly stand eating that much butter in a day. I vaguely remember having to hide the butter in bread or other things the first week or two, but by the end of the month I was totally addicted to plain butter by the slice. In fact, while I'm happy that it is good for my brain and my body I now find it hard to pass by the fridge w/out sneaking a slice of butter (at least several times a day). My kids are slowly acquiring a butter addiction as well.

Greg (2012-04-04 17:08:33)

Tom: I believe the scatter you see in HDL reflects actual physiological changes. The device has very little variance from test to test in that measurement. Part of why the skew in HDL reflects other experiments during the red time series (my second post is about that). I have an idea about where the rest of the skew comes from and will post a follow-up if I can figure it out. The non-HDL number (i.e. the total cholesterol measurement minus the HDL) is much less accurate and the device seems to contribute considerable variance. With enough data points I think the readings are useful. Dustin: my doctor told me some of his patients have had similar results from butter consumption.

Peter (2012-04-06 13:43:20)

Greg also ate coconut oil with his butter, which is likely a confounder given coconut oil's known ability to increase HDL.

## 7.4 April

### Moderate Alcohol Consumption Associated With Less Cirrhosis (2012-04-01 12:50)

Alcohol is bad for your liver, we're told. However, moderate amounts may be good for your liver. [1]A recent meta-analysis found that men who drank moderate amounts of alcohol had considerably less risk (a risk ratio of 0.3) of liver cirrhosis than men who drank no alcohol. It wasn't clear if some forms of alcohol (e.g., wine) were more protective than others. I came across this study because [2]another article called the association "biologically implausible", whereas I think it is highly plausible due to vast experimental literature on hormesis (animals given small amounts of poisons are healthier than animals given none).

The findings about cirrhosis join a much large body of evidence that moderate drinking is associated with less heart disease. [3] A recent meta-analysis reached this conclusion once again and found, in addition, that moderate drinking is associated with less all-cause mortality.

These are more examples of the health benefits of fermented foods, one of my favorite subjects. It is unfortunate the liquor industry does not run long-term human experiments on the effects of moderate amounts of beer, wine, and so on.

1. <http://onlinelibrary.wiley.com/doi/10.1111/j.1465-3362.2009.00153.x/abstract>
2. <http://www.bmj.com/content/344/bmj.e2276?etoc=>
3. ---

Leila (2012-04-01 14:37:29)

Paul Jaminet has posted about alcohol - "the harmful effects of alcohol on the liver occur only when it is combined with polyunsaturated fats" - <http://perfecthealthdiet.com/?p=509>. Definitely a worthwhile research topic!

Tim Beneke (2012-04-02 09:34:12)

As I understand it, there is substantial evidence that people who consume a lot of alcohol also exercise substantially more than people who don't. This is certainly true among people I know.... Perhaps it's a matter of compensation. <http://www.livescience.com/7910-exercisers-drink-alcohol.html> "Michael French, a health economics professor at the University of Miami, and his colleagues dug into data from the 2005 Behavioral Risk Factor Surveillance System, a yearly telephone survey of roughly 230,000 Americans, and found a surprisingly strong positive correlation between the levels of alcohol intake and exercise. For both men and women, those who drank at least some alcohol exercised 7.2 minutes more per week than non-drinkers. While that may not seem like much, the study showed that the more booze, the more minutes spent sweating. Light, moderate, and heavy drinkers worked out 5.7, 10.1 and 19.9 minutes more per week, respectively. Also, drinking resulted in a 10.1 percent increase in the probability of vigorous physical activity." Perhaps this confound has to be integrated into any analysis of the putative health benefits of alcohol... Seth: A surprising correlation.

MetaThought (2012-04-02 17:49:59)

Could it be that people with very weak livers just don't drink alcohol at all, because of negative effects, and so skewing the results somehow?

Jordan (2012-04-02 19:51:50)

I think the associations beg a question: What are the alcohol drinkers "not eating" because they are consuming a glass or wine or other spirits? Maybe those not drinking alcohol are replacing it with an extra large serving of ice cream. Seth: Yes, associations always raise the question of what is causing them.

D (2012-04-02 20:40:07)

"Paul Jaminet has posted..." The guy is awesome. His book is fantastic. And no, I am not Paul Jaminet nor associated with him in any way other than being a fan.

Tom (2012-04-02 20:41:59)

...found a surprisingly strong positive correlation between the levels of alcohol intake and exercise. **Seth: A surprising correlation.** I think they're just talking about what young people do. I bet young people socialize more, drink more, and exercise more. They probably get laid more, too. :-)

D (2012-04-02 21:16:34)

My interpretation of this: Moderate drinking signifies conscientiousness. High conscientiousness is one of the BEST predictors of longevity. Seth: Interesting idea. Why are people who drink moderately more conscientious than those who don't drink at all? That puzzles me. I suppose I'm an example of the correlation in the sense that I am more conscientious than average and I drink moderately. But I see no connection between the two. I'm not saying there isn't a connection, just that I don't see it.

Aaron Blaisdell (2012-04-02 21:33:54)

Yet another possibility from the strong correlation between heavy drinking and exercising; both can be addictive. Perhaps individuals more prone to addiction are more prone to comorbid (multiple) addictions, such as drinking, endurance exercise (for the runners high), gambling, smoking, sugar, etc. Seth: Good point. There is certainly something to the concept of an addictive personality.

Alex Chernavsky (2012-04-03 04:53:15)

Seth wrote: "Why are people who drink moderately more conscientious than those who don't drink at all? That puzzles me." Possibly because (some) people who don't drink at all used to drink excessively and had to give it up after getting themselves into trouble.

D (2012-04-03 07:56:28)

Hi Seth, What Alex said. Someone who can regularly eat just 10 potatoe chips or have just one glass of wine, are people who know they can touch these things without overindulging. Someone who abstains entirely may also have good discipline, but they may not, and that's why they avoid it all together. So that cohort is a mixture of high and low conscientiousness. But the cohort who can cut themselves off doesn't include people with low high conscientiousness.

### Assorted Links (2012-04-02 20:51)

- [1]Where are they now? J. S. Boggs, profiled by Lawrence Wechsler in The New Yorker. Boggs made small paintings closely resembling money (e.g., a \$100 bill) that he offered in place of real money. He sold surrounding details (e.g., the receipt) to a collector who would try to get the bill Boggs had drawn from the merchant in order to "complete" the work of art.
- A SLDer (Shangri-La Dieter) [2]loses 80 pounds in 18 months. That's 1.0 pounds/week.
- [3]More medicine does not equal better medicine. I agree with every word of this critique by a Glasgow general practitioner named Des Spence. For example, "The prescribing of powerful antipsychotic and potentially addictive stimulant drugs to children is a societal norm. . . . A quarter of US women are taking mental health drugs." As Spence says, these are signs of a healthcare system biased toward those who make money from it and against everyone else (including children). One way to sum up why this is a mistake: Your health is too important to be left to those who only make money if you are sick.
- [4]Japan: from rice to wheat to rice.

Bryan (2012-04-03 09:37:28)  
I'd love to read that BMJ piece, but THIRTY BUCKS for one article?

Mary (2012-04-07 07:28:23)  
Part of your quote from the Des Spence article, "A quarter of US women are taking mental health drugs," does not appear to be supported by the actual facts. I believe it is true that psychiatric drug usage is high and growing, the statement that "over 25 % of US women are taking them" overstates the case a great deal. The source of that assertion apparently traces to the study described here: <http://blogs.wsj.com/health/2012/03/19/womens-use-of-psych-medications-rises-other-health-regimens-lag-men-studies/> Although the study examined records of 2 million patients, those patients were hardly a representative cross-section of the US population. The study was carried out by Medco, a large mail-order pharmaceutical company which caters to patients covered by prescription drug coverage plans. The only patient records to which Medco has access are those of its own customers, that is, a pool consistently entirely of people with prescription drug coverage who have actually filled a prescription for a long-term prescription drug of some sort. Patients who do not have prescription drug coverage or those who do have it, but who do not use it for long-term medications, will not be in the Medco database. So, women who do not take any prescription meds of any sort, or those who take only take the occasional short term course of antibiotics for an acute infection (of the sort they would fill at a local pharmacy rather than through the mail order drug company) were not included in the study.

### **Lack of Repeatability of Cancer Research: The Mystery (2012-04-03 13:30)**

In [1] a recent editorial in Nature (gated), the research head of a drug company complained that scientists working for him could not repeat almost all of the "landmark" findings in cancer research that they tried to repeat. They wanted to use these findings as a basis for new drugs. [2] An article in Reuters summarized it like this:

During a decade as head of global cancer research at Amgen, C. Glenn Begley identified 53 "landmark" publications – papers in top journals, from reputable labs – for his team to reproduce. Begley sought to double-check the findings before trying to build on them for drug development. Result: 47 of the 53 could not be replicated.

Yet these findings were cited, on average, about 200 times. The editorial goes on to make reasonable suggestions for improvement based on differences between the findings that could be repeated and those that could not. The Reuters article goes on to describe other examples of lack of reproducibility and includes a story about why this is happening:

Part way through his project to reproduce promising studies, Begley met for breakfast at a cancer conference with the lead scientist of one of the problematic studies. "We went through the paper line by line, figure by figure," said Begley. "I explained that we re-did their experiment 50 times and never got their result. He said they'd done it six times and got this result once, but put it in the paper because it made the best story.

Okay, cancer research is less trustworthy than someone just barely outside it (Begley) ever guessed. Apparently careerism is one reason why. What is unexplained in both the Nature editorial and the Reuters summary is how research

can ever succeed if things aren't reproducible. Science has been compared to a game of Twenty Questions. Suppose you play Twenty Questions and 25 % of the answers are wrong. It's hopeless. In experimental research, you generally build on previous experimental results. The editorial points out that the non-reproducible results had been cited 200 times but what about how often they had been reproduced in other labs? The editorial says nothing about this.

I can think of several possibilities: (a) Current lab research is based on experimental findings of thirty years ago when (for unknown reasons) careerism was less of a problem. Standards were higher, there was less pressure to publish, whatever. (b) There is a silent invisible "survival of the reproducible": Findings that can be reproduced live on because people do lab work based on them. The other findings are cited but are not the basis of new work. (c) There is lots of redundancy – different people approach the same question in different ways. Although each individual answer is not very trustworthy their average is considerably more trustworthy.

Leaving aside the mystery (how can science make any progress if so many results are not reproducible?), the lack of reproducibility interests me because it suggests that the pressure to publish faced by professional scientists has serious (bad) consequences. In contrast, personal scientists are under zero pressure to publish.

Thanks to Bryan Castañeda.

Jim (2012-04-03 17:31:50)

Wow. They did it six times and got the result they published once!? I'm generally a skeptic of medical research, but I still find this amazing. Seth: I agree. That this sort of thing is perfectly legal – goes undetected – is one illustration of the fact that enormously prestigious journals, such as Science and Nature, employ peer reviewers with major gaps in their understanding. It's like an accounting system with a big hole that allows fraud.

Alex Chernavsky (2012-04-03 18:09:01)

This post reminds me of [1]this excellent article about the shenanigans used by Bristol-Myers Squibb (pharmaceutical company) to gain approval for their antidepressant drug, Serzone. "In testing results submitted to the FDA, Serzone failed to show a clear benefit in six of the eight clinical trials." And the two positive trials were suspect.

jbug (2012-04-03 19:17:18)

Integrity seems so rare in research anymore...sigh....

James A Donald (2012-04-03 21:10:01)

You don't seem to consider the obvious possibility: That science, in most fields, is simply not making progress, that such "progress" as is reported is accomplished by rewriting the past and imposing official consensus. Seth: If "science, in most fields" is no longer making progress, what changed?

James A Donald (2012-04-03 21:10:45)

As to what caused the problem: Peer review caused the problem. It is career suicide to discover that someone else's research is irreproducible. Seth: Your second sentence ("It is career suicide...") is an excellent point. I don't see the connection with your first sentence ("As to what...").

garymar (2012-04-04 00:09:12)

Is it really career suicide? Depends on the case. Everybody jumped on "cold fusion" immediately and multiple labs rushed to replicate it but were unable to. The reputations of none of these labs were harmed by failure to replicate. Of course this was a celebrity case, and a media event.

Stone Glasgow (2012-04-04 00:34:42)

The reason most drug and disease studies are done is only to support or discredit various products. Professional science today is an advertising war – and has nothing to do with reality. Even government-funded studies are likely corrupted by lobbying efforts. Labs are funded with an expected outcome. And are repeated, apparently, until that outcome is achieved, with failures discarded anonymously.

Tom (2012-04-04 07:04:06)

Remember how we used to think that people who believed that the country was a giant invisible criminal conspiracy were cranks?

Andrea (2012-04-04 07:13:52)

It seems to me that some of the best research is being done by self-taught bloggers like Denise Minger and Paul Jaminet, neither of whom has credentials in nutrition. Almost every professional field has now become a guild that exists primarily to perpetuate itself and not to seek the truth. Education, psychotherapy, literary studies, the arts, and even many of the sciences have become disconnected from the joy of learning.

Tony (2012-04-07 02:54:18)

It's not completely correct to believe that experiments are just done once and then blindly believed to be true if in a respectable paper. A proper explanation of research methods and equipment used is standard part in scientific articles, so it's easy to snatch that and make your own things with it. Hence, results are often reproduced in following studies by various researchers, when experiments are built by using previous research methods as a starting point.

gwern (2012-04-07 08:27:51)

garymar: The difference is that cold fusion wasn't \*supposed\* to exist. New successful drugs are supposed to exist; if they didn't, how do these fields & the scientists they employ justify themselves?

Alrenous (2012-04-07 10:22:34)

I see the situation only slightly differently than James. I see peer review as reproducing the pre-existing status hierarchy. When Richard Feynman submits a paper, it is career suicide to reject it. Reviewers are supposed to be anonymous, but in practice cannot rely on that formal reality. If they repeatedly reject papers due to science instead of sociology, they take the risk several times. For example, I keep hearing about reviewer shenanigans, such conflicts of interest, which should be impossible to discover. When J random submits a paper, it is career suicide to accept it. When J random, Ph.D submits a paper, it is decided based on [1]whether it makes Feynman look bad. As per the link, if it makes Feynman look bad, the journals will reject it, and get legalistic if J random insists, strenuously pursuing plausible deniability. Feynman will be able to publish multiple replies without difficulty. Under certain conditions, s/Richard Feynman/Michael Mann/g

Jason H. Moore, Ph.D. (2012-04-12 06:08:53)

Great post. This is a very real concern in biomedical research. One valid explanation for why some results don't replicate is complexity. Under a model of complexity and nonlinearity you don't necessarily expect some things to replicate. I wrote a paper several years ago showing how and why real genetic association results might not replicate as allele frequencies change slightly from study to study. The paper was published here in PLoS One (open): <http://www.plosone.org/article/info:doi/10.1371/journal.pone.0005639>

Elizabeth Iorns, PhD (2012-04-16 14:31:10)

Hi Seth, great post! I think this is a major issue. To address it will require changes in the incentive system that promote collaboration and reproducibility of preclinical academic research. Any new set of incentives should focus, in part, on the funding agencies and journal publications that support academic research. For instance: - Funding agencies should allocate some proportion of a grant to allow research groups to include independent replication in their project work flow. - Journal editors should encourage and acknowledge independent replication of key results (either pre or post publication). Seth: Thanks. I agree with your broad point and I like your specific suggestions.

### **What is "Unnecessary" Medicine? (2012-04-04 15:28)**

An organization called the American Board of Internal Medicine Foundation has launched a campaign to reduce the cost of health care by reducing "unnecessary" tests, drugs, and procedures. [1]A bare-bones website lists them. For example:

Don't routinely do diagnostic testing in patients with chronic urticaria [hives].

Here is the explanation of that recommendation:

In the overwhelming majority of patients with chronic urticaria, a definite etiology is not identified. Limited laboratory testing may be warranted to exclude underlying causes. Targeted laboratory testing based on clinical suspicion is appropriate. Routine extensive testing is neither cost effective nor associated with improved clinical outcomes. Skin or serum-specific IgE testing for inhalants or foods is not indicated, unless there is a clear history implicating an allergen as a provoking or perpetuating factor for urticaria.

Not clear. Are they trying to say the tests are useless ("not associated with improved clinical outcomes")?

My broad question about the campaign is: What does "unnecessary" mean? This is not explained on the website nor in [2]a Washington Post article about the campaign.

A nearby article on the Post website is about "the downside of mammography". It says:

[3]A study published Monday in the Annals of Internal Medicine adds to a growing body of [4]evidence that the potential risks of routine breast-cancer screening via mammography might in fact outweigh such screening's benefits.

That's clearer. It seems to be saying the costs outweigh the benefits. (What are "potential" risks? I thought all risks were potential.) But that doesn't mean that breast cancer screening is "unnecessary", it means it is a bad idea.

If the foundation is trying to say that a lot of medicine does more harm than good, then, please, say so. If they are trying to say that a lot of medicine is useless, then, please, say so. Stop being polite.

I contacted the foundation to ask them about this.

Thanks to Bryan Castañeda.

What they will say is that unless you are an MD, you do not have the knowledge or intelligence to decide if you should have the tests....

### **Do Sonograms Cause Autism? New Evidence (2012-04-06 13:30)**

A female American engineer named Parrish Hirasaki has started [1]a website devoted to the idea that prenatal ultrasound is a major cause of autism. It includes a long list of supporting research. In spite of all this research, "as of spring 2011, analyzing the ultrasound results was not among the 23 hypotheses [about the cause of autism] being tested by the National Children's Survey", says the website.

I first heard this idea from Caroline Rodgers, a science writer, and [2]have blogged about it several times. Nevertheless, the website's home page taught me several things I didn't know:

1. "A recent major study of twins supports earlier studies in concluding that environmental exposures during or shortly after gestation cause a majority of autism cases." This is inconsistent with many other explanations (e.g., vaccine, genetic).
2. "In a recent study, autistic children had reduced connectivity between the two sides of the brain." Which supports the idea that neural misdevelopment is a cause of autism.
3. "Twenty years ago, the FDA increased the allowable intensity of prenatal ultrasound 8-fold to improve images. Autism rates have risen dramatically since that time."
4. There is "widespread misunderstanding among ultrasound operators of the safety guidelines."
5. "A fast-growing commercial business is keepsake ultrasound photos. Franchisers advertise that no medical background or certification is required."

I asked Hirasaki a few questions.

How did you become interested in this?

My age and my profession led me to the theory that the rise in autism is caused by exposure to prenatal/neonatal ultrasound.

1. When my last child was born in 1978, there was one ultrasound machine serving the entire population of Houston.
2. My work experience in the industrial and aerospace industries was extensive in heat and vibration.
3. For several decades, my work included industrial instrumentation in chemical plants and refineries. Most such instruments require routine calibration to stay accurate.
4. In the space program, there are always redundant devices because mechanical and electrical equipment may malfunction.
5. A first cousin died at age 6 of cancer caused by x-ray overdose in the 1940's. I am old enough to remember getting my feet x-rayed at the shoe store.

Who else, in addition to Caroline Rodgers, has independently had this idea and written or posted about it?

Manuel Casanova, a neurologist. Nancy Evans, a science writer.

When you started looking into possible causes of autism, did you look into other possible explanations?

No. I asked myself what had changed about having a baby. Ultrasound seemed to be the obvious major change. Exposure to caffeine, smoking, alcohol and medications had all decreased.

Was there any particular evidence that you found especially persuasive?

On my website, there are 37 papers pertinent to the topic. My primary theory is that overexposure is the cause. The most persuasive evidence that points to this is:

1. The girls in [3]the Kaiser-Permanente study who have the highest exposure to ultrasound during the second trimester have more than double the expected rate of autism.
2. Interruption of the neural migration patterns in the brains of the overexposed mice in[4] the Yale study.
3. A known cause of autism is the mother having an infection. One theory is that as the mother's body fights the infection with a fever, the rise in temperature of the fetal brain causes the damage. The temperature rises in tissue exposed to ultrasound are reported in [5]a paper which calls for the FDA to examine the current allowable limits.
4. The much higher rate of autism for children who weighed less than 4.5 pounds at birth. [6]The medical and AIUM protocol for infants this small is an immediate head ultrasound.

What has made it difficult for the research community to find this?

1. The researchers have education and experience [and funding – SR] in medicine, biology, genetics. This is where they look.
2. In the 1950's, the FDA turned the regulation of medical ultrasound over to the American Institute for Ultrasound in Medicine (AIUM) which is funded by the government and the manufacturers. In November 2011, I expressed my concerns via email to the AIUM Bioeffects Committee. The chair responded that the AIUM monitors the topic and has conducted a thorough [7]search of existing literature (2008) and found no link except the "weak association" in the Kaiser-Permanente study. The report states that there are potential risks to administering

ultrasound tests, which include “postnatal thermal effects, fetal thermal effects, postnatal mechanical effects, fetal mechanical effects, and bioeffects considerations for ultrasound contrast agents.” Another section says “the long-term effects of tissue heating and cavitation have shown decreases in the size of red blood cells in cattle when exposed to intensities higher than diagnostic levels. However, long-term effects due to ultrasound exposure at diagnostic intensity is still unknown.” In 1992, the AIUM and the FDA increased the allowable intensity of prenatal ultrasound 8-fold without knowing whether it was safe. Twenty years later, they still don't know.

3. Engineers who could do such research receive funding from the manufacturers. Such a researcher would be unlikely to propose research that could decimate the industry.
4. This is the classic search for a needle in a haystack. Less than 1 in 300 ultrasounds is causing noticeable brain damage.

I would add that links between sonograms and left-handedness are more evidence that sonograms can cause important brain changes. [8] Here is a doctor who does sonograms dismissing the connection but what I find important is that the connection has been found repeatedly.

gwern (2012-04-07 06:52:11)

> The girls in the Kaiser-Permanente study who have the highest exposure to ultrasound during the second trimester have more than double the expected rate of autism. Is this consistent with the claimed 20x increase? Seth: Yes. The 20x increase happened over a period of time at the beginning of which many fetuses got no exposure. Now no exposure is rare. The Kaiser-Permanente study compared girls with high and low exposure to ultrasound. > what I find important is that the connection has been found repeatedly. So has crystal healing and sympathetic magic. Seth: I am unaware of even one study showing the efficacy of crystal healing much less repeated studies. Same for sympathetic magic.

David (2012-04-08 10:52:18)

Gwern feels skeptical of a link. Does gwern know of studies that compare the rates in populations with no prenatal ultrasound exposure? The idea that 1 in 300 machines might be running 'hot' is disturbing. The fact that the idea that ultrasound generated bubbles might get hot enough when collapsing to trigger nuclear fusion is even considered is another reason to exercise caution. Nuclear reactions need 1000000 more energy to trigger vs chemical.

David (2012-04-08 11:45:53)

The other consideration is the reward. In any risk reward or cost benefit situation, you can't neglect the reward half of the equation. What is the chance your baby will benefit from the ultrasound? Perhaps gwern could provide a table, giving each

potential benefit, and the probability it will occur for a given baby.

Adam (2012-04-08 16:01:45)

Although I'm in medicine, I don't know much about labor and delivery. A friend who is a nurse said sonograms can help identify children in the womb with heart defects. They sometimes will actually do surgery on the child while it is still inside the mother to repair it, so that when the child is born, he has a healthy heart. I don't know what heart defect they're fixing, what the incidence is or what other benefits of sonograms there are, but I'd like to know!

Adam (2012-04-09 16:07:53)

I found this article: <http://www.cnn.com/2011/HEALTH/02/09/surgery.spina.bifida/index.html> Which is possibly what my nurse friend was talking about. It is not a heart defect and they don't "cure" it, but it seems to help. The incidence of this disease is about 1 in 3000. The incidence of autism is though to be about 1 in 110. If sonography allows us to identify kids with spina bifida early and start treating them, it could prevent parents from choosing to abort the child.

## Gene Linked to Autism? (2012-04-08 05:00)

[1]An article in the New York Times describes research that supposedly linked a rare gene mutation to autism:

Dr. Matthew W. State, a professor of genetics and child psychiatry at Yale, led a team that looked for de novo mutations [= mutations that are not in the parents] in 200 people who had been given an autism diagnosis, as well as in parents and siblings who showed no signs of the disorder. The team found that two unrelated children with autism in the study had de novo mutations in the same gene — and nothing similar in those without a diagnosis.

"That is like throwing a dart at a dart board with 21,000 spots and hitting the same one twice," Dr. State said. "The chances that this gene is related to autism risk is something like 99.9999 percent."

It is like throwing 200 darts at a dart board with 21,000 spots (the number of genes) and hitting the same one twice. (Each person has about 1 de novo mutation.) What are the odds of that? If all spots are equally likely to be hit, then the probability is about 0.6. More likely than not. (Dr. State seems to think it is extremely unlikely.) This is a variation on [2]the birthday paradox. If there are 23 people in a room, it is 50/50 that two of them will share a birthday.

When Dr. State says, "The chances that this gene is related to autism risk is something like 99.9999 percent," he is making an elementary mistake. He has taken a very low p value (maybe 0.000001) from a statistical test to indicate

the likelihood that the null hypothesis (no association with autism) is true. P values indicate strength of evidence, not probability of truth.

One way to look at the evidence is that there is a group of 200 people (with an autism diagnosis) among whom two have a certain mutation and another group of about 600 people (their parents and siblings) none of whom have that mutation. If two instances of the mutation were randomly distributed among 800 people what are the odds that both instances would be in any pre-defined group of 200 of the 800 people (defined, say, by the letters in their first name)? The chance of this happening is 1/16. Not strong evidence of an association between the mutation and the actual pre-defined group (autism diagnosis).

Another study published at the same time found an link between autism and a mutation in the same gene identified by Dr. State's group but again the association was weak. It may be a more subtle example of the birthday paradox: If twenty groups of genetics researchers are looking for a gene linked to autism, what are the odds that two of them will happen upon the same gene by chance?

If the gene with the de novo mutations is actually linked to autism, then we will have insight into the cause of 1 % of the 200 autism cases Dr. Smart's group studied. When genetics researchers try so hard and come up with so little, it increases my belief that the main causes of autism are environmental.

Thanks to Bryan Castañeda.

jbug (2012-04-10 14:33:01)

for some reason scientist keep banging their heads against the same genetic door. why do they want this to be genetic so badly? There's no such thing as a genetic epidemic! as a parent with a child who has autism, I find this a frustrating waste of energy, time, and funds. its environmental folks. time to come out of denial. its epigenetics. the toxins/pollutants in the environment are changing the way genes are expressing the cells of the brain during gestation and altering the structure and developmental trajectory of the brain. the timing, duration, and intensity of exposure during specific critical windows of development dictate the level of damage done and where that individual will fall on the autism " spectrum" and its in us. these toxins are already in us. so this will be only be getting worse. time to take all those funds and work on trying to isolate the worse toxic offenders and clean up the environment if its not already too late... I'm not hopeful though.

Matthew Ackerman (2012-04-16 11:11:02)

This is a fabulous post, and I whole heartedly support your analysis. [nitpicking] Never the less, I wouldn't be in the sciences if I didn't love nit-picking and correct people. While your number of 1 de novo mutation is doubtlessly the right number to use for your analysis, there are about 175 de novo substitutions per diploid genome, and you can't forget that there are many other classes of mutations. Whole gene duplications and deletions are quite common and likely occur at per base rates comparable to substitutions. Since, of course, the authors were only sequencing the exome, which entails roughly 1 % of the human genome, they were only able to identify 1 substitution mutation per individual. [/nitpicking] I would call their results somewhat suggestive (after all, they did only have 15 nonsense mutations), but certainly the press release and the paper itself oversell their results. I'm not really sure why people are looking for genetic factors when it seems so obvious that an environmental change must be associated with the rise in rates of incidents, since genes simply do not change in frequency

that fast without strong selection. Oh well, yet another case of marginal science getting too much press attention.

## Science in Action: Unexplained Changes in Brain Speed (2012-04-09 05:00)

[1]

This is me a few days ago. I did a choice reaction time task many times. Each dot is a session with enough trials to supply 32 correct answers. The y axis is in "percentile" units, meaning speed relative to recent performance. If my speed was at the average of recent performance, the percentile would be 50, for example. Higher percentiles = better performance = faster (shorter reaction time). Each point is a mean; the vertical bars are standard errors. The dotted line is the median of the means.

The graph shows that Friday afternoon I was suddenly unusually slow. After dinner, I returned to normal. A change from 60 %ile to 20 %ile to 60 %ile resembles an IQ change from 105 to 87 to 105 (an 18-point change).

At the same time accuracy was roughly constant:

[2]

Because accuracy was roughly constant, the change in speed was not due to a shift on a speed-accuracy tradeoff function.

There are two puzzles here. 1. Why were my scores low Friday afternoon? 2. Why did they recover after dinner? On Friday I didn't feel well. As a result, I didn't eat much. Maybe my blood sugar was lower than usual. I usually eat 30 g butter twice/day. On Friday I didn't have any. At dinner I did have moderate amounts of pork fat (but not butter) and sugar (in lemon citron tea). Friday 6 pm I had a cup of black tea. Although I haven't noticed effects of tea on these scores, there's a first time for everything.

Here is a clue to what makes my brain work well (= fast), I conclude. Butter causes sudden improvement, I have found; which makes it plausible that lack of butter (and other animal fat) could cause sudden degradation. Another possibility was that my blood sugar was low Friday afternoon. (I didn't think of this at the time, and didn't measure it.) I'm surprised that something as important as brain function would be as fragile as these results imply. When various nutrient deficiencies are studied with conventional measures, it generally takes weeks or months without the nutrient for the bad effects to become apparent. It takes many weeks without Vitamin C to get scurvy, for example.

These results raise the intriguing possibility that everyone has sudden ups and downs in brain function and that these ups and downs can be detected at high signal/noise ratios. If so, we can use these ups and downs to learn how to make our brains work well. These results also imply – because my choice reaction time test required only a laptop – that anyone can detect them, study them, and learn what causes them. No experts needed. What a change that would be.

Kevin Burton (2012-04-09 20:51:30)

I'm currently running some similar tests. I noticed that in the morning my responses are pathetic. But tend to improve around noon and peak around 6pm. I need to find a way to make the tests FASTER so I do them more often. But it would be nice to get even responses ...

G.H. (2012-04-09 21:18:05)

I've noticed that my performance of tasks involving manual dexterity is best when my normally chilly hands ( 75°F) are closer to body temperature. I have seen this effect in my typing and guitar playing, as well as in my times on tests at the website 'cognitive fun' (e.g. the reaction time and flanker tests). The effect seems to be the same no matter whether I warm up my hands by exercising, considerably overconsuming calories, or hanging out somewhere hot, and with respect to my typing speed the difference is roughly equal to one standard deviation. So, hand temperature might be an interesting variable for you to track, at least for a period, if you haven't done so already.

yiedyie (2012-04-10 03:36:34)

Can you try the same experiment with fish oil (or other omega 3) Did the butter contain omega 3' ALA, EPA, DHA (the grass fed contain omega 3)? Seth: "The same experiment"? what do you mean? I don't know about the omega-3 content of the butter.

David (2012-04-10 04:26:50)

Perhaps your immune system was fighting a low level infection. The body prioritized that fight over general quickness.

dustin lee (2012-04-10 06:54:49)

I'm curious what a "choice reaction time task" is. Is there software for this? Web apps? I searched on the term and saw a few things similar to some lumosity.com games. Just interested in what people are using and what this is proposed to measure.

Kirk (2012-04-10 13:57:17)

I second what David said. I have noticed a number of times that my body prioritizes fighting an infection over other tasks, especially those self-initiated initiatives which require willpower.

There needs to be a Journal of Personal Science. Seth: I hope so. Thanks for the suggestion.

Alrenous (2012-04-10 13:42:29)

Herring is my fish of choice. This is measured entirely by how it feels to eat it. Now the science tells me it happens to be optimum. I recently did a Willat test of oysters vs. mussels and mussels won. As a bonus, mussels are cheaper. Also fond of crab, and planning to do a proper test of squid. Cod liver oil might be good at mercury and omegas, but in any significant quantities it will give you an overdose of vitamin A. It feels bad to eat.

somebro (2012-04-10 16:50:16)

You also want to look out for persistent organic pollutants in fish. Personally, I don't eat any fish.

Phil (2012-04-11 10:38:21)

Funny, on the day you made your post saying that you haven't seen comparisons between models and predictions except by skeptics, the top entry on RealClimate, the single most prominent global-warming-related blog that is not run by skeptics, was "Evaluating a 1981 temperature projection": <http://www.realclimate.org/index.php/archives/2012/04/evaluating-a-1981-tempe-rature-projection/> Of course, the models have improved a lot since the 1980s but it is still good to look back. You might also want to look at the second plot on <http://web.archive.org/web/20070323005914/http://www.ghcc.msfc.nasa.gov/MSU/musuci.html> which shows global tropospheric temperature anomaly for a longer series, starting in 1979. See if you can figure out why Evans chose to look at how much the temperature has changed since 1988 rather than choosing predictions from a different year. Think it has anything to do with 1988 having the highest measurements of the entire temperature record up to 1998? Nah, gotta be a coincidence, right? After all, he's a climate change skeptic, and we can trust those people to give us the straight truth every time.

### **Paging Dr. Google: Magnesium, Constipation, and Subarachnoid Hemorrhages (2012-04-11 05:00)**

Did you know that magnesium can reduce constipation? I didn't. Did you know that constipation can cause bleeding under your skull (subarachnoid hemorrhages), which are earth-shatteringly painful? Apparently a lot of doctors who treat subarachnoid hemorrhages don't know this. Here is [1]a story from Metafilter:

A year after [cancer] chemo ended I had . . . 4 aneurysms (subarachnoid bleeds) in 12 days. These aneurysms (subarachnoid hemorrhages) were serious agony, the most pain I've ever experienced. . . .

It's like the World Trade Center falling down in one's head, involuntary non-stop screaming, passing out from the pain kind of thing. . . . None of the docs could figure out what these aneurysms were from. They all seemed totally mystified. They gave me a very risky test, brain surgery basically, a brain endoscopy that meant putting a probe into my brain. I had to sign papers that it wasn't their fault I came out a vegetable.

Several lumbar punctures. 2 CT scans then an MRI. Then my neurologist wanted me to do a really risky test, that involved stopping my heart momentarily. . . . The chances of surviving just one of these aneurysms isn't good: "An estimated 10-15 % of patients die before reaching the hospital. Moreover, mortality rate reaches as high as 40 % within the first week, and about 50 % die in the first 6 months." So I felt forced to take this dangerous test. . . .

[I] looked at when the aneurysms happened and the relief I experienced in the Emergency Ward when I'd been injected with magnesium. I googled magnesium and realized its help in treating constipation. I'd been constipated for over a year from the chemo and pain meds for the chemo pain. I realized I had these aneurysms after trying to go to the toilet, from straining. The neurologist didn't want to hear about constipation . . . . None of the docs asked me about constipation. . . .

I self medicated with magnesium citrate, which relieves constipation in a different way than laxatives, it brings water into the colon, which helps the evacuation process a lot. Calcium and magnesium citrates combined, to be exact. And that did the trick, instantly. No more aneurysms. No more dangerous tests. No more brain surgeries.

I wonder if blood tests showed she was magnesium deficient. I also suspect fermented foods would have helped. Chemo causes constipation, I'm guessing, because it kills intestinal microbes, which fermented foods replace.

If you are nickyskye (the author of this) I hope you will contact me, I would like to write more about it and I have some questions.

Thanks to [2]Melissa McEwen.

1. <http://www.metafilter.com/114586/This-is-not-a-necessary-test#4279773>

2. <http://huntgatherlove.com/>

---

Paul Jaminet (2012-04-11 06:10:09)

Wouldn't it be equally logical to infer that magnesium deficiency causes aneurysms, hemorrhage, and constipation, as to infer that constipation causes hemorrhage? I can see the constipation-induced blood pressure elevation increasing the rate of bleeding, but there might need to be a vascular injury to begin with.

Nina (2012-04-11 12:05:32)

You sound surprised that head docs don't look below the navel. We live in an age of the specialist and medics rarely stand back to get an overview. I think we always have to do our own research and take responsibility for fighting our own corner, rather than assuming that busy medics will see connections and act on them. Nina

JeffR (2012-04-11 14:40:31)

"chemo causes constipation, I'm guessing, because it kills intestinal microbes, which fermented foods replace." How is this any better than what you complained about other doctors doing. Why would there be any reason to think that constipation due to chemo is related to intestinal microbes? Additionally, why wouldn't you learn about this so you can say why chemo causes constipation and how intestinal microbe death might or might not be related? I don't know why you seem so committed to commenting from a position of ignorance. Not ignorance as in stupid, but ignorance as in a lack of relevant knowledge. Seth: I'm assuming chemo kills intestinal microbes.

Andrew Morrison (2012-04-11 20:04:45)

While well-absorbed forms of magnesium, such as citrate, are better for raising blood and tissue levels, bowel-motility boosting is another distinct project that may work better with less-well-absorbed forms of magnesium, such as oxide. Because less is absorbed, larger doses can be taken safely, and most of it stays in the gut sucking in water until it is dumped.

JRM (2012-04-11 23:26:19)

I knew magnesium was a laxative. Also, calcium acts as an anti-laxative ie it causes constipation.

LB (2012-04-12 00:07:10)

A bit confusing. The original poster seems to be equating aneurysms with subarachnoid hemorrhages. If the former ruptures, the latter happens. However, it is possible to have the latter from other reasons. Also, straining because of constipation may cause an aneurysm to burst. It will not cause an aneurysm to form where there wasn't one before. So... four separate aneurysms burst? Or one bled four times? Because of straining? Anyway... she's very, very lucky to be alive.

peter (2012-04-14 17:33:16)

a number of things, taken at a sufficient dose, will loosen stool. Magnesium is one, potassium is another. as i recall sufficient dose of Vit. C has the same effect, as does epsom salts probably many supplements

## **The American Dietetics Association Wants No Competition (2012-04-11 05:00)**

Michael Ellsberg has [1]an excellent article about the American Dietetic Association's attempts to make it illegal for anyone they haven't approved to give nutritional advice. In [2]this document, they are frank that this is their goal. After Ellsberg drew attention to it, [3]it was taken down. I look forward to learning why it was taken down.

The [4]Washington State chapter of the ADA, now called the Washington State Academy of Nutrition and Dietetics, is responsible for taking down the document. The organization has this mission statement:

Empowering the people of Washington to improve health with safe, effective and reliable food and nutrition information.

Our Vision: Optimize the health and well being of Washington State individuals through food & nutrition.

Our Mission: Empower members to be Washington State's food and nutrition leaders.

Long ago, in the civil rights or suffrage movements, for example, empowerment meant removal of barriers. This organization preaches empowerment by creation of barriers. Their empowerment is someone else's disempowerment.

1. <http://www.forbes.com/sites/michaellellsberg/2012/04/05/american-dietetic-association/>
2. <http://www.reallyeatright.org/wp-content/uploads/2011/11/MarketPlaceRelevanceBackgrounder.pdf>

4. <http://www.eatrightwashington.org/>

---

LB (2012-04-11 23:58:13)

"Make it illegal for anyone they haven't approved to give nutritional advice" is inaccurate, misleading, and a gross oversimplification of the issue. And yes, I read both the Forbes piece and the PDF to which you linked. Seth: What was inaccurate or misleading? It's awfully easy to criticize if you don't give examples.

LB (2012-04-12 09:59:09)

Misleading/inaccurate: you make it sound like they want to be able to sue me for telling my friend that an easy way to cut out hundreds of calories a day is to skip the morning and afternoon mochas. I see where you're coming from on this issue, but your post is, as I said, a gross oversimplification. Seth: Thank you for clarifying that. I thought it was clear that they want to eliminate competition and that free advice isn't competition. Competition is other people charging money for nutritional advice.

Kirk (2012-04-12 10:03:03)

The ADA isn't going to like this, but they're going to lose this fight because of technology. The Silicon Valley folks are busy building devices and software so that people can measure their own internal systems. And the Internet allows for consumers to send that information to a nutritional consultant based somewhere out there on the net, whether that consultant is based in the States or in Thailand. Technology is going to blow a hole through many a business plan based upon obtaining rent-seeking gatekeeper status. In the meantime, libertarian-influenced lawyers might successfully fight the rent-seekers.

Floyd (2012-04-22 13:21:32)

I followed there diet gained 39 pounds, had no improvement in blood or sugar went Paleo, no more, lost 40, pounds, blood normal,BP normal its a big con, my Dr said keep up with what I am doing,he had no answers? really

## **Interview with Daniel Wolfson of Choosing Wisely (2012-04-12 07:46)**

The new [1]Choosing Wisely campaign is centered on lists of "unnecessary" medical tests and procedures. The hope is that these lists will reduce waste in the health care system. [2]I wondered what "unnecessary" meant so I interviewed Daniel Wolfson, who is Executive Vice President and Chief Operating Officer of the American Board of Internal Medicine, located in Philadelphia.

At the heart of my question was: why these procedures and not others? Each list has five items. How were they chosen? Here is how the five items on [3]the American College of Physicians' list were selected:

The American College of Physicians (ACP) formed a workgroup of eleven experienced internal medicine physicians with specific skills in the assessment of evidence. . . . The group collaboratively identified and narrowed down screening or diagnostic tests commonly used in clinical situations where they are unlikely to provide high value or improve patient outcomes. The results were further reviewed and narrowed by clinically active ACP staff physicians before being placed for review into a randomly selected internal medicine research panel. Representing 1 percent of ACP members, the panel selected five scenarios that represented the greatest potential for overuse or misuse of a diagnostic test leading to low value care.

I said this sounded like a popularity contest. Mr. Wolfson said, no, the recommendations are based on evidence. "Do you know what a randomized trial is?" he asked. What evidence? I said. It's not on your website.

Yes, it's there, said Mr. Wolfson. He pointed me to the "sources" at the end of the ACP list. Here is one of those sources:

2011 USPSTF screening for coronary heart disease with electrocardiography (draft) guideline; 2011 AAFP recommendations for preventive services guideline; 2010 ACCF/AHA assessment of cardiovascular risk in asymptomatic adults guideline.

This is evidence? I said. It's very vague. At this point Mr. Wolfson ended the interview.

So I continue to think it is a popularity contest. Who knows how the doctors on that "randomly selected internal medicine research panel" made their decisions.

I think the Choosing Wisely campaign is worthwhile, in spite of Mr. Wolfson's implausible claims (he also said the doctors who created these lists were "courageous"). Here's what I would say: The items on these lists are things that many doctors in that specialty think are done too often. The lists are like a free second opinion.

1. <http://choosingwisely.org/>
2. <http://blog.sethroberts.net/2012/04/04/what-is-unnecessary-medicine/>
3. [http://choosingwisely.org/wp-content/uploads/2012/04/5things\\_12\\_factsheet\\_Amer\\_College\\_Phys.pdf](http://choosingwisely.org/wp-content/uploads/2012/04/5things_12_factsheet_Amer_College_Phys.pdf)

---

Sam (2012-04-12 12:04:18)

I agree that the "evidence" is vague, but at the same time, I just googled "2011 USPSTF screening for coronary heart disease with electrocardiography" and found the USPSTF's 2004 guidelines (which do not appear to have changed in regards to screening exercise ECG testing). That page is here: <http://www.uspreventiveservicestaskforce.org/uspstf/uspsacad.htm> And here is the accompanying "summary of evidence", which looks pretty thorough (though I admit I've looked at it for all of 15 seconds) <http://www.uspreventiveservicestaskforce.org/3rduspstf/chd/chdsum1.htm> Seth: Thanks, that's helpful. I've looked at it for more than 15 seconds. Here's part of what it says: "when the risk for coronary heart disease events is low, most positive findings will be false and may result in unnecessary further testing or worry. The risk level at which the benefits of additional prognostic information outweigh the harms of false-positive results is unclear and requires further study." I think that it is true for a large fraction of medical tests that "most positive findings will be false and may result in unnecessary further testing or worry". So why pick these five?

Kim Øyhus (2012-04-12 22:43:05)

Here we go again. Seth: You mean here we go again with more self-serving definitions of evidence?

Jim Breed (2012-04-13 09:04:07)

"Do you know what a randomized trial is?" I read that and now I am wiping tea off of my keyboard.

## Morning Faces Therapy Improvements (2012-04-13 05:00)

A friend with bipolar disorder writes:

I began the morning faces therapy in April, 1997. I can think of only two significant changes over the years in my use of the therapy: 1) I use a mirror instead of videotapes, and 2) I accept that once or twice a week I'm too tired to start as early as I'd like (so I get more sleep instead). To elaborate:

1) When I restarted the treatment in 2006 after having been hospitalized, I was too depressed to deal with videotaping. In fact, I was too depressed to get out of bed so early. The mirror solved both problems, because I could easily prop it on my mattress top. After a few days I was able to get up, allowing me to listen to music, use bright lights, etc., during the treatment.

2) Whether for lack of discipline or the proper genes, I simply can't go to sleep early enough so that I can get up early every morning. (Granted, I haven't tried everything, but for the sake of the argument, let it stand.) This shortcoming used to bother me a great deal. Then on October 6th, 2011, I read in this blog about someone else who didn't always start the treatment early, because he was "too tired to get up early". Well! It didn't seem so bad if someone else had the same problem. Over the years I've found that starting 30-60 minutes late once or twice a week doesn't seem to perturb my mood enough to cause great concern.

---

BlueMorrissey (2012-04-13 11:42:32)

As a bipolar guy, I appreciate your story. I also struggle with the discipline of getting up early and always doing morning faces. I cannot for the life of me look at my face in the mirror. Fortunately I watch CNBC in the morning which has studio hosts that look into the camera and my tv is HD and large enough to keep them close to actual size faces. Music while walking on the treadmill helps too. Like you I just can't wake up in the morning and exercise late, which probably only keeps me up later. I am lucky to have a job that does not start until late in the afternoon so I am not in a rush in the morning. I honestly just feel better when I sleep late, even when I had a 7 am job for 10 years, I could never get my circadian clock in sync and always seemed to be lethargic, unless manic. Good luck getting that balance. I'm always experimenting as I'm sure you are too.

Donald (2012-04-13 14:48:31)

I've recently started morning faces therapy and I still don't know if it works but I do enjoy my routine - before I get out of bed (or after I come back to bed with a cup of tea) I open up my laptop and watch some interviews on bigthink.com for 30 minutes. I watch it full screen but I don't think the faces are life-size, if there's a way round that I'd be keen to know. For me the therapy isn't purely face therapy, people are talking about inspiring and motivating goals and achievements, often with rags to riches

overtones (and I remember reading that it is often goal-oriented events that trigger hypomania so this subject matter is far from neutral). There's lots of scope for tweaks to effectiveness but the positive side at the moment is that it doesn't take discipline.

Kim (2012-04-22 15:51:40)

I would like to subscribe to your blog. Where is the subscribe button? I too, do many self-experiments and have done iodine and coconut oil with success for foot and nail fungus. The jury is still out on the plantar's wart I have had since my teens and the wart that popped up on my hand after I had a 'deep cleaning' done to my teeth by the periodontist.

### **Coconut Oil/Foot Fungus Update (2012-04-15 11:09)**

A month ago [1]I wrote about Chuck Currie's discovery that coconut oil cured his foot fungus and seems to be curing his toenail fungus. He put coconut oil on his foot, put it in a plastic bag, and put a sock on it. Then he could walk around or whatever – vastly more convenient than the soaking remedies (e.g., soak your feet in vinegar) many people recommend (which I tried) and incomparably better than the foot fungus and toenail fungus remedies you find in a drugstore (which I tried many times).

For some strange reason I had foot fungus on one foot but not the other – for ten years. I have been doing Chuck's remedy for a month. Within a few days it was clear it worked. Now the "good" and "bad" foot are indistinguishable. I am writing this post because I discovered that the plastic bag is unnecessary, making it even more convenient. I put the coconut oil on my feet and then put on socks. It still works. Nothing bad happens to the socks, which I think are a cotton/polyester blend.

I've been using Whole Foods house brand ("365") food grade ('expeller pressed virgin organic') coconut oil. A 16-oz jar cost about \$8. Maybe it will last 4 months with daily application. (For toenail fungus. My foot fungus is completely gone.) All other commercial foot fungus remedies should quietly disappear...

1. <http://blog.sethroberts.net/2012/03/02/coconut-oil-cures-foot-fungus/>

---

Kirk (2012-04-15 11:22:59)

I tried applying cider vinegar in the morning and coconut oil in the evening. Within 3 weeks the fungus had started to creep down my toes and the numbness in my right foot increased. I abandoned the vinegar/coconut oil experiment and returned to my previous treatment, and am now trialing a modification. The fungus has receded and I have little numbness in my right foot. My current treatment: I apply Povidone Iodine to my toenails in the morning, and in the evening soak my feet in Epsom Salts and then apply Clotrimazole to the toenails. I admit to being surprised at how quickly I saw a change. I'm used to running long-term experiments.

gwern (2012-04-15 12:14:58)

> Nothing bad happens to the socks, which I think are a cotton/polyester blend. So this isn't a very thick layer of coconut oil then? Seth: Yes, a thin layer.

Philip Kilner (2012-04-15 12:47:49)

I'd had athlete's foot for years which kept flaring up again and again (as it does), and a couple of years ago I got a cut in my finger

and developed what I suspected was a fungal infection. The hand infection was much more distressing for me, and was also intermittently quite painful. My doctor made it clear that she would not test it and use something specific, but rather would prescribe ointments by trial and error, so I gave up on that route. When I read your post, I started using Extra Virgin Coconut Oil, as sold for cooking, on both hands and feet. The feet were clear within days, the hands quickly started to improve and are now almost clear. The oil is solid at room temperature, but liquid at skin temperature, so it's easy to handle as it's solid as it comes out of the jar and melts as it is rubbed in. I use a couple of bean sized lumps morning and evening, and I find that I can rub it into the skin so that it's not oily enough to be an issue - less so than the stuff from the pharmacy, anyway. Easier and much less unpleasant to handle than the creams and potions I'd used before, leaves me smelling faintly of coconut (which I like but which doesn't last for very long), but with one critical difference - so far, it actually works! I'm very happy - thanks for the pointer! (BTW, also lost four stone with SLD, so this site has made a huge difference to my life)

Chuck (2012-04-15 19:16:19)

The reason I haven't used the "sock only" method is because I don't often wear socks (I live in So CA a block from the beach). I'm glad it's working for you and you found a more convenient application. I believe I also mentioned to you that a dermatologist told me to soak my foot in a bucket of warm water with a cap-full of household bleach for twenty minutes once every week or two to kill any new fungus. I found this work well along with the coconut oil. Also, the fungus can survive in your shoes, slippers and even the straps of flip-flops (the non-rubber/plastic kind). So it's a good idea, once you start treatment to put anti-fungal powder in your shoes - I through out my sleepers and flip-flops (I replace my flip-flops regularly anyway). Happy Feet

Alex Chernavsky (2012-04-16 06:22:08)

Speaking of skin problems, I have had a long-standing problem with painful cracks developing on my hands during the colder months of the year. I've tried various remedies, including different skin lotions, A & D ointment, and skin crack sealers (the type that resemble nail polish). Nothing worked very well, until I discovered [1]O'Keeffe's Working Hands Cream. O'Keeffe's is truly amazing. I apply it just once a day, using a generous amount at bedtime (I keep a jar of it in my nightstand). The cracks are totally eliminated. I ran out once this winter and didn't replace it for about ten days, and the cracks returned quickly - so I'm pretty sure that it works.

1. <http://www.amazon.com/O'Keeffe's-Working-Hands-Cream-3-4/dp/B00121UVU0>

Tyler (2012-04-16 08:13:21)

Has anyone had any success with this regarding any face-related fungus? I've had a recurring itchy bump for as long as I can remember, and nothing's seemed to work, including nightly coconut oil. I am hesitant to go to a dermatologist and get pills, as I imagine that can't be too great for gut flora, but I'm reaching wit's end. :)

Stone Glasgow (2012-04-16 11:25:48)

Try acetylcysteine for your face. Find cream with it or make your own.

Scott Pierce (2012-04-17 12:10:13)

I've been using H2O2 on ring worm (fungus) that keeps showing up on my sternum and it works within days. If I stop, it will come back in a month or two. Maybe I'll try the coconut oil.

[...] Coconut oil: cure for foot fungus? [...]

PHIL G (2012-04-22 11:17:21)

I personally use tea tree oil as an anti-fungal agent. As a teen, I frequently had athletes foot infections but never nail fungus. At the first sign of redness, warmth or cracking between toes I now apply tea tree oil. Clears in days. When I travel; hotel showers, gyms and pools are notorious for spreading fungus (tinea pedis) so I preempt the infection by routinely using small amounts of tea tree oil. Seth: A friend of mine used tea tree oil to get rid of her toenail fungus. I tried it and found it worked for foot fungus but not for toenail fungus – maybe I wasn't diligent or careful enough. You write: "As a teen, I frequently had athletes foot infections but never nail fungus." Why is that, do you think?

Stephanie (2012-04-22 16:36:33)

I also successfully treated toenail fungus with coconut oil. After getting out of the shower each day, I put a drop of rubbing alcohol on the nail and allowed it to get completely dry, then I massaged in some coconut oil and went about the day as normal. Within a month, it was nearly gone and after a few more weeks, totally gone. It works!

chuck (2012-04-22 19:04:35)

@scott, Ringworm on sternum - Fought this for 5 years but a few times in the tanning booth killed it and have had no problem for 3 years now

Jscott (2012-04-22 20:07:40)

I've never had 'athlete's foot.' I find this odd. I wonder if that is more important than the cures for it...?

BigTex (2012-04-23 05:11:12)

Just pee on your feet in the shower. Uric acid is your friend.

Jay Valento (2012-04-23 05:46:37)

Trader Joes has coconut oil for 5.99

Brad (2012-04-23 06:08:44)

I'll add another ingredient to this story in that perhaps non-topical application of the Coconut Oil will even required achieve the effect. I recently (3 weeks) started a Paleo type diet including using Coconut Oil in my cooking, at least once a day for breakfast's eggs but often 2 or 3 times. I had developed a fungus like look to one of my big toes over the last two years and it had slowly been spreading, much to my sadness. As of today, however, all of the new growth on the nail is fungus free. Completely unexpected results.

Ronald (2012-04-23 11:10:22)

I too have foot fungus - left foot only - toe nails are "messed" up - since mid 60's - Grisovulfin until mid 70's - also had fungus on right hand - lost all finger nails on right hand only at least 4-5 times - was in a research program for about one year in the mid late 70's - completely cleared fungus on the nails and skin on hand only no impact on the foot - fungus never came back on the hand!! - right foot did not have fungus until 3 years ago - damaged big toe nail at the base - fungus spread very rapidly - the soles and edges on both feet are extremely dry - need to use pumas stone to remove callus build up and sometimes the skin will split causing a little bit of bleeding - thanks I will try the coconut oil Seth: I predict good results.

Kristen (2012-04-24 09:51:32)

Isn't foot fungus or nail fungus a symptom of a systemic yeast infection. I know if I lay off sugar it clears up. Anyone else find the problem is from the inside out?

Gruesome (2012-04-25 09:56:21)

I believe the surest long-term remedy for athlete's foot is going soapless. Your skin will take on Teflon-like qualities, repeling all manner of infections and rapidly healing when broken. This works not only for athlete's foot, but also acne, and festering wounds. It's amazing how little scarring is left if you're hurt, but take all your baths soapless – just running warm water over

your skin without rubbing, or soaking in a warm bath. Your hair also becomes shiny, smooth and full of body without being greasy. And your pits and bits actually smell less and better. Seth: I stopped using soap on my face many years ago. I agree, it's a good idea. I cut way down on soap on the rest of my body when Richard Nikoley recommended it. I think that's a good idea, too, but it did not get rid of foot fungus. I didn't have athlete's foot. Sometimes going soapless helps with acne, sometimes not.

Monica Kelly (2012-04-25 10:00:41)

My doctor had me mix a concoction of coconut oil with oregano oil (from the health food store). I was skeptical as I had fungus in toenails for decades. Completely cleared up with in 6 months!

## **The Feeding Tube Diet (2012-04-16 21:35)**

In The Shangri-La Diet I noted that hospital patients given intravenous feeding often lose a lot of weight without hunger. I said this supported my theory that the body fat set point is raised by the smell of food. Without smell, the set point goes down. When your set point goes down you lose weight without becoming hungry.

You should be able achieve the same effect by nose-clipping all your food.[1] A new diet, however, makes smell avoidance considerably more difficult and expensive.

The K-E diet, which boasts promises of shedding 20 pounds in 10 days, is an increasingly popular alternative to ordinary calorie-counting programs. The program has dieters inserting a feeding tube into their nose that runs to the stomach. They're fed a constant slow drip of protein and fat, mixed with water, which contains zero carbohydrates and totals 800 calories a day. Body fat is burned off through a process called ketosis, which leaves muscle intact, Dr. Oliver Di Pietro of Bay Harbor Islands, Fla., said.

It is a hunger-free, effective way of dieting," Di Pietro said. "Within a few hours and your hunger and appetite go away completely, so patients are actually not hungry at all for the whole 10 days. That's what is so amazing about this diet."

Di Pietro says patients are under a doctor's supervision, although they're not hospitalized during the dieting process. Instead, they carry the food solution with them, in a bag, like a purse, keeping the tube in their nose for 10 days straight. . . .

Schneider said she was never hungry throughout the 10 days she was on the K-E diet, but admits that it still wasn't easy. "It was emotionally difficult, the 10 days of not eating," Schneider said. . . . Although the K-E diet is new to the United States, it has been around for years in Europe. Dr. Di Pietro charges \$1,500 for the 10-day plan, and says the before-and-after pictures sell themselves.

I sympathize with the "emotionally difficult." When I lost 30 pounds in 3 months drinking sugar water, I ate maybe 50 % of my usual calorie intake. I was never hungry and that too was bad. The world seemed drab without hunger.

Thanks to Tom George.

---

Adam (2012-04-17 04:55:36)

You can lose a lot of weight quickly without a feeding tube if you cut out all carbs like they do in this diet. When you stop eating carbohydrates, your body will start burning Glycogen for energy. With every molecule of Glycogen you lose four molecules of water – depleting Glycogen stores can, by itself, add up to a 5 kg "weight loss" in which NO FAT AT ALL has been burned. Since the health effects of weight loss are mediated by fat loss and not water loss, this isn't a diet for people who are interested in health. As far as I've seen, they aren't marketing it as such either (which I admire them for), but rather market it toward people who just want the illusion of being slim and healthy, for example for a photo shoot or a wedding.

Jim (2012-04-17 06:03:08)

@Adam, I agree. Although, in general, I do think that losing "water weight" has greater than zero value. If a relatively obese person ends up losing 5 or 10 or 20 pounds of water weight (not necessarily with the above described diet), I think that could add to their quality of life, mobility, self esteem, and ability to be active and continue the process of becoming healthful. So, IMO, while losing fat would have greater benefits, losing water weight would have some health benefit as well (in addition to the aesthetic benefits that you point out).

Ed (2012-04-17 06:20:00)

Dr. Roberts- would you ever think of setting up a SLD Clinic? Basically a formal way to try to get into the habit? Or some sort of community App where people could start it with thier friends, virtual or real? Seth: Thanks for the suggestion. Yeah, I would consider setting up a SLD Clinic. I'll mull it over. As for "community app" [1]the Shangri-La Diet forums are sort of like that.

1. <http://boards.sethroberts.net/>

Kirk (2012-04-17 09:02:55)

@Adam, I disagree. The K-E solution could be changed to include 25 % carbs (and 15 % protein and 60 % fats) , and so long as the client perceived no flavor, it would be as effective for weight loss as is the current solution. If this does not make sense, read Seth's paper about the science of the Shangri-La Diet. @Seth, I wonder if the perceived "emotional difficulty" of flavorless dieting is due to the high quantity of "pleasure mental objects" we moderns have become accustomed to experiencing due to flavored foods. (I am using Cabanac's concepts as he argues in his Fifth Influence book.) If that quantity is removed, then either we feel deprived of pleasure, or we need to adjust our senses and behavior to obtain a replacement quantity of pleasurable mental objects from other sources.

gwern (2012-04-17 09:54:01)

Link missing? Seth: fixed. thanks!

Adam (2012-04-17 17:55:12)

@Kirk, I'm not 100 % convinced that the Shangri-La Diet works for the reasons Seth thinks it does. The only way to find out for sure would be to give it a go. I wonder if they trialed using other combinations of macronutrients... if so, why did they settle on the combo that they use if it isn't the most efficient? Also, 25 % of 800 calories would still be only 50 grams of carbohydrate, which would still be sufficient to put many people into ketosis. Where is the paper about the science of the Shangri-La Diet? Maybe I can convince myself. Thanks for your feedback. Seth: Here is the paper ("What makes food fattening? A Pavlovian theory of weight control") about the science of the Shangri-La Diet: <http://graphics8.nytimes.com/images/blogs/freakonomics/pdf/whatmakesfoodfattening.pdf>

David Johnston (2012-04-17 20:02:38)

I've seen papers that support and papers that refute the set point hypothesis. So I think the jury is still out. It seems fairly certain to me that the brain is in the loop on energy regulation in non-simple ways. So maybe this model (feeding people through a nasal tube) is a way to disentangle some of the variables. It cuts out of the major hard-to-control variables (the nasal and tongue receptors signaling things to the brain as you eat). It's a simple matter to vary the macronutrient ratios without the test subject being aware of what they're being fed. This makes control subjects better controls as well. It's hard to be a good control if you know you're a control. In electronics (I'm an EE) when you have a circuit loop that is misbehaving, the

way to understand it is to break the loop so you can observe the in-out behavior of the individual parts of the loop. Find the broken bit, reattach the loop and see if it works. In a system with multiple interacting feedback loops (as with human diet), understanding it by observing the dynamic behavior is a futile approach. So if there are methods like this that help break the loops, researchers should jump on them and do all sorts of experiments.

Kirk (2012-04-18 09:54:45)

@David, Can you provide links to some of the papers which argue against the set point? It has become a new hobby of mine to read about set points. I have seen some of the more knowledgeable bloggers in the Paleo Nutrition sphere argue against a ponderostat, but they never provide links to scientific papers, nor do they explain how scientists such as Cabanac designed incorrect experiments or misunderstood the results. Bonus points if the papers aren't hidden behind a paywall! Seth: Yeah. And those who don't believe in a set point or ponderostat have yet to discover new ways of losing weight. In contrast to Cabanac and me. A serious problem with their position that they don't seem to understand.

john (2012-04-18 18:54:27)

Seth, you might like the flavour of this abstract . I like *C. elegans* for a number of reasons. <http://www.ncbi.nlm.nih.gov/pubmed/22491324> Abstract Feeding behaviour is modulated by both environmental cues and internal physiological states. Appetite is commonly boosted by the pleasant smell (or appearance) of food and destroyed by a bad taste. In reality, animals sense multiple environmental cues at the same time and it is not clear how these sensory inputs are integrated and a decision is made to regulate feeding behaviour accordingly. Here we show that feeding behaviour in *Caenorhabditis elegans* can be either facilitated by attractive odours or suppressed by repellents. By identifying mutants that are defective for sensory-mediated feeding regulation, we dissected a central flip-flop circuit that integrates two contradictory sensory inputs and generates bistable hormone output to regulate feeding behaviour. As feeding regulation is fundamental to animal survival, we speculate that the basic organizational logic identified here in *C. elegans* is likely convergent throughout different phyla.

john (2012-04-18 18:57:41)

there are some neat abstracts to be found by entering food/smell into pubmed

David Johnston (2012-04-18 19:57:47)

Kirk, Hyperlipid first pointed me to some anti set point papers. I'll go and dig them up. I didn't keep records. This web site pointed me to the supporting papers I've seen. Personally I can see why SPT is convincing. My own personal experience is of set-point like behavior. 245Lbs by for years. High fat, Low carb got me down to 215, but no further. I've been at this weight for a year and now I can 'eat badly' and stay pretty much at 215. It sure looks like a set point. But stable feedback states can look like a set point when it is stable state is actually sensitive to other inputs that aren't being exercised. I'm about to give Shangri-La a go. My goals are more to do with my waistline than in doing science.

David Johnston (2012-04-18 20:18:10)

Kirk, I started here: <http://high-fat-nutrition.blogspot.com/2011/10/adipostat-ballon.html> . Which points here: <http://www.ncbi.nlm.nih.gov/pubmed/14500570> and here: <http://www.ncbi.nlm.nih.gov/pubmed/19190032> Peter's article argues that these two papers give evidence to argue against set point theory. I don't see it myself, but then I'm not nearly as smart as Peter. Stephan Guyenet wrote about Cabanac here <http://wholehealthsource.blogspot.com/2011/08/food-palatability-and-body-fatn-ess.html> and links to the original papers. There were at least two other papers I didn't find. I got them by searching pubmed. What I see is the antis saying the mechanisms aren't set point like and the pros saying but it looks like a set point when we try it. Mechanism vs Effect. Apples aren't being compared with apples. Seth: In his comment at the end, Stephen Guyenet says "this supports the hypothesis that there is a body weight setpoint." True. What Stephen doesn't say, and what is the essence of Cabanac's contribution, is that Cabanac showed you can use the setpoint idea to find powerful new experimental effects. The setpoint idea itself is ancient - from the 1950s. I took the setpoint idea even further: I used it to find new ways of losing weight that work in the real world. I think ideas are ultimately judged by what they can do for us, not by whether they are "true", whatever that means.

Kirk (2012-04-19 11:49:10)

@David, Thanks for the links. I have to admit, I don't understand much of anything written at Hyperlipid. My guess is that the author at Hyperlipid believes the cause of excess weight is malfunctioning mitochondria (which is almost a good enough phrase for a band name). As for the abstracts, the first abstract uses the word 'suggests' several times, which indicates to me that they wade deep in speculation. The second abstract proposes a model based upon a review of the literature; alas, models by definition are speculation. I find it interesting that the abstract says, 'Adiposity is known to be carefully regulated', given that regulation is exactly Cabanac's argument. My hunch is that the people who oppose the concept of a ponderostat do so because they have their own favorite hunch as to THE Cause of Obesity and a ponderostat does not fit their theory.

joseph (2012-04-20 13:49:52)

I'm curious being on the seth diet I'll call it, is the nose clipping part of life for good? Or just for the few months it takes to lose weight?

Nancy Lebovitz (2012-04-20 22:44:37)

What are the aftereffects of the K-E diet? Is the weight loss stable?

TomGinTX (2012-04-21 15:41:27)

Seth wrote: > ... Yeah, I would consider setting up a SLD Clinic. ... I can imagine: "Welcome to the Shangri-La Clinic! Please sit here for an hour." (Hour passes.) "Now pinch your nose shut and drink this oil.... Good! Now sit here for another hour." (Hour passes.) "That's great! You can go home now. Come back tomorrow!" 8-)

Erik (2012-04-22 04:31:16)

Why stop at a feeding tube? Why not walk around with an IV? Maybe hook up electrodes to your head to shock your brain whenever you think of food? Hey, self lipo-surgery sounds good too. Seems what people really need is a little discipline and common sense.

nk (2012-04-22 13:27:53)

what's the ideal ratio of water and sugar for drinking sugar water? I purchased the book but it didn't cover much on the sugar water method so I'd appreciate it if someone can clarify for me! Thanks.

## **Cod Liver Oil Best Taken in Morning? (2012-04-18 05:00)**

Is it better to take cod liver oil in the morning than at other times of day? Kim Øyhus's experience suggests that:

Each mid winter and summer I tend to lose my feeling of when it is day or night, especially if I am in the northern parts of Norway, or if the weather is dark clouds for a long time, which often happens. So sorry, no statistics, just my sense of being unhinged from the diurnal cycle.

Taking 1-2 spoons of cod liver oil in the morning got me back to this rhythm in about 3-5 hours. It even works for fixing my diurnal rhythm after partying to sunrise, but only after a day's rest.

I have [1]posted many times about the value of taking Vitamin D3 in the morning.

1. <http://blog.sethroberts.net/category/sleep/vitamin-d3-and-sleep/>

## Do Sonograms Cause Autism? A New Study (2012-04-19 05:00)

[1]A new paper ("Are Prenatal Ultrasound Scans Associated with the Autism Phenotype? Follow-up of a Randomised Controlled Trial" by Yonit K. Stoch, Cori J. Williams, Joanna Granich, Anna M. Hunt, Lou I. Landau, John P. Newnham and Andrew J. O. Whitehouse) takes another look at the results of a randomized trial started in 1989. Half the mothers were given one ultrasound during their pregnancy, the rest got five. This study gave a questionnaire sensitive to autism-like traits to the now-grown-up children. This is potentially more sensitive than binary (yes/no) assessment because the questionnaire has about 50 questions.

Here is the entire abstract:

An existing randomised controlled trial was used to investigate whether multiple ultrasound scans may be associated with the autism phenotype. From 2,834 single pregnancies, 1,415 were selected at random to receive ultrasound imaging and continuous wave Doppler flow studies at five points throughout pregnancy (Intensive) and 1,419 to receive a single imaging scan at 18 weeks (Regular), with further scans only as indicated on clinical grounds. There was no significant difference in the rate of Autism Spectrum Disorder between the Regular (9/1,125, 0.8 %) and Intensive (7/1,167, 0.6 %) groups, nor a difference between groups in the level of autistic-like traits in early adulthood. There is no clear link between the frequency and timing of prenatal ultrasound scans and the autism phenotype.

[2]Parrish Hirasaki pointed out to me that when the study was done the intensity of ultrasounds was eight-fold less than now. Here's what the paper says about this:

Technological advancements over the past two decades have led to considerable improvements in ultrasonographic capabilities, with corresponding increases in acoustic output.

Did you read that and realize the intensities have increased by a factor of eight? Neither did I. Such a big difference in intensity means the results are not serious evidence – contrary to what the abstract implies – against the idea that sonograms are now causing autism.

More Asked about the failure to make clear the difference in intensity, the corresponding author, Andrew Whitehouse, replied:

The parameters of the ultrasound scans were reported clearly in the Methods section, and we refer to several other articles that include a description of the USS administered in this cohort. We are also very clear in the Discussion when we state that "the current study was not designed to investigate the use of [modern] instruments".

I disagree. So what if the parameters of the ultrasound scans were reported clearly in the Methods section? That's not the issue. The issue is failure to make clear the huge intensity difference between the ultrasounds they studied and modern ultrasounds. Saying that "the current study was not designed to investigate the use of [modern] instruments" does not make clear at all (much less "very clear") how much modern ultrasounds differ from the ultrasounds actually studied. Any study can put caveats like that at the end. Yet few studies are as irrelevant as this one to the question they claim (in the title, abstract and introduction) to help answer.

2. <http://blog.sethroberts.net/2012/04/06/do-sonograms-cause-autism-new-evidence/>

---

JRM (2012-04-19 07:50:29)

Could someone make a graph of sonogram intensity vs. autism rate?

WB (2012-04-19 09:16:07)

Seth, the manner in which "Dr." Whitehouse responded to your inquiry seems very suspicious to me, suggesting a dishonest answer. Maybe I'm being overly cynical, but his comments to you make me suspect serious conflicts of interest on the part of the investigators; probably difficult to prove of course. Makes me wonder, however, if the journal that published this, or any of the listed investigators, receive \$ \$ from the major manufacturers of ultrasound devices such as GE, Siemens and SonoSite. BTW, I note his basic background is as a speech pathologist who later acquired a PhD in psychology, according to his profile on the website of his employer, the Telethon Institute for Child Health Research based in Perth, Australia. Makes me wonder if any of the investigators were MDs. Seth: My guess is that the article is so misleading because to make clear its shortcomings - its lack of relevance - would have made it harder to publish. But that's just a guess.

Roger Sweeny (2012-04-19 09:53:53)

The study is misleading but not useless. It is evidence that old intensity ultrasounds don't cause autism. It leads to the inevitable question: did the recent surge in autism diagnoses began when old intensity ultrasounds were done or did it wait until modern eight-times intensity? If the former, there is evidence that ultrasounds are not responsible. If the latter, there is evidence that they are.

Tom (2012-04-19 12:18:28)

It seems that it would be very easy to test this in mice. At least whether prenatal ultrasound radiation affected socialization or ability to learn. Seth: It has been tested in mice. Realistic durations and intensities of ultrasound changed (i.e., damaged) the brains of fetuses.

Tomas (2012-04-20 07:51:33)

Seth, are you aware that there is also a very strong correlation between Pitocin (oxytocin) administration and autism? I think that both make strong case, though no studies have been conducted yet.

Nancy Evans (2012-04-20 15:07:32)

This is not a graph but some interesting numbers on Caroline Rodgers' blog <http://carolinerodgers.wordpress.com/2012/04/02/parallels-between-autism-prenatal-ultrasound-increases/> Her presentation at the Interagency Autism Coordinating Committee (IAAC) of U.S Department of Health & Human Services also offers more evidence on this issue.

Nancy Lebovitz (2012-04-20 19:40:27)

Have you read *\_The Brain that Changes Itself\_*? IIRC, that's where I ran into the theory that exposure to white (unstructured) noise before age two could lead to autism because the brain is trying to make sense of sounds where there is no sense.

## Why We Touch Our Mouths So Much: Evidence From Ants (2012-04-20 05:00)

In [1] a recent post I proposed that [2] we touch our mouths so much to transfer germs from our hands to our immune system. It's an early warning system. The full sequence is: 1. Hands. 2. Skin around mouth. 3. Tongue (lick lips). 4. Tonsils (immune system). Forewarned is forearmed: exposure to a tiny amount of Germ X makes you much more likely to survive exposure to a large amount of Germ X.

Ants have a similar early-warning system, says [3] a new study described [4] here.

Cremer and her colleagues began by investigating how nestmates encountering an infected ant acted. They infected *Lasius neglectus* ants with *Metarhizium anisopliae*, a fungus that sticks to the insects' outer cuticles and causes infection only after it has worked its way into the body, which takes a day or more. The researchers then placed infected or non-infected ants in a box with five nestmates, and watched what happened. . . . Ants without the spores were groomed at a constant rate over 5 days, while Cremer saw a spike in grooming of the fungus-infected ants in the first day or two of infection, suggesting that the pathogen was prompting a behavior change in the nestmates.

The grooming was protective:

But even though they'd been exposed, only 2 percent of nestmates died from fungal infections, even though half of the initially infected ants, which had been dipped in solvent with *M. anisopliae* spores, died within 5 days. When ants were exposed to a dose of fungus expected to cause a 2 percent death rate, Cremer's group saw an increase in antifungal activity, suggesting that this low level of infection was indeed enough to stimulate a protective immune response.

Earlier studies had shown what is called "social immunization" ("a protection of naive individuals of a colony after social contact to exposed individuals") among insects. This study was about how social immunization happens.

After I thought of this explanation of mouth touching, I became much less concerned about contact with sick people. I hadn't known about social immunization.

Ahrand (2012-04-20 07:07:11)

Maybe eye rubbing close to bedtime is similar ? Maybe even nail biting is similar ? (combined with precious nutrient recycling in that case)

charlie (2012-04-20 07:57:46)

What I noticed in law school, where you really don't want to get called upon and then ritually humiliated for an hour, that if you didn't touch your face it looked as if you understood the material – and were less likely to be the victim of the day. Did not work when the prof used an alphabetical chart.

### **Merck's Vioxx and the American Death Rate (2012-04-23 05:00)**

[1]Ron Unz makes a very good point – that just one awful drug (Vioxx) sold by just one awful drug company (Merck) appear to have caused hundreds of thousands of deaths:

The headline of the short article that ran in the April 19, 2005 edition of USA Today was typical: "USA Records Largest Drop in Annual Deaths in at Least 60 Years." During that one year, American deaths had fallen by 50,000 despite the growth in both the size and the age of the nation's population. Government health experts were quoted as being greatly "surprised" and "scratching [their] heads" over this strange anomaly, which was led by a sharp drop in fatal heart attacks. . . .

On April 24, 2005, the New York Times ran another of its long stories about the continuing Vioxx controversy, disclosing that Merck officials had knowingly concealed evidence that their drug greatly increased the risk of heart-related fatalities. . . .

A cursory examination of the most recent 15 years worth of national mortality data provided on the Centers for Disease Control and Prevention website offers some intriguing clues to this mystery. We find the largest rise in American mortality rates occurred in 1999, the year Vioxx was introduced, while the largest drop occurred in 2004, the year it was withdrawn. Vioxx was almost entirely marketed to the elderly, and these substantial changes in national death-rate were completely concentrated within the 65-plus population. The FDA studies had proven that use of Vioxx led to deaths from cardiovascular diseases such as heart attacks and strokes, and these were exactly the factors driving the changes in national mortality rates.

The impact of these shifts was not small. After a decade of remaining roughly constant, the overall American death rate began a substantial decline in 2004, soon falling by approximately 5 percent, despite the continued aging of the population. This drop corresponds to roughly 100,000 fewer deaths per year. The age-adjusted decline in death rates was considerably greater.

This illustrates how Merck company executives got away with mass murder on a scale that the Khmer Rouge would be proud of. It also illustrates why I find "evidence-based medicine" as currently practiced so awful. Evidence-based medicine tells doctors to be evidence snobs. As I showed in[2] my Boing Boing article about tonsillectomies, it causes them to ignore evidence of harm – such as heart attacks and strokes caused by Vioxx – because the first evidence of harm does not come from randomized controlled studies, the only evidence they accept. It delays the detection of monumental tragedies like this one.

1. <http://www.theamericanconservative.com/blog/chinese-melamine-and-american-vioxx-a-comparison/>
2. <http://boingboing.net/2012/01/10/tonsillectomy-confidential-do.html>

WB (2012-04-23 08:45:04)

In addition to the issue you rightfully raise about so-called evidence-based medicine, the Vioxx experience presents glaring "evidence" that the profit motive in medicine is a terrible component of what passes for a health care system. In my view, this is especially true with regard to publicly held companies such as Merck, Pfizer, the medical device unit of Johnson & Johnson, ..... and the list goes on and on. So what we end up with is an egregious combination of bad science and bad policy concerning public health.

bjk (2012-04-23 17:25:19)

"The FDA studies had proven that use of Vioxx led to deaths from cardiovascular diseases such as heart attacks and strokes, and these were exactly the factors driving the changes in national mortality rates. The impact of these shifts was not small. After a decade of remaining roughly constant, the overall American death rate began a substantial decline in 2004" To show that Vioxx was responsible for the decline, we would look at the rate of deaths from cardiovascular diseases and heart attacks

and strokes, not the overall death rate. I don't know what the numbers are, but looking at the overall death rate in 1999 and 2004 is taking evidence anti-snobbery too far.

Alex Chernavsky (2012-04-25 04:38:49)

Evidence that antidepressants lead to premature death: <http://www.sciencedaily.com/releases/2012/04/120424120450.htm>

Nancy Lebovitz (2012-04-28 12:56:42)

What's the lag effect for deaths from Vioxx?

Peter Schaeffer (2012-05-13 12:55:10)

The TAC needs to do some fact checking before publishing something like this. If Vioxx actually resulted in 500,000 premature deaths it would have shown up in the overall death rate. It didn't. See "National Vital Statistics Reports" ([http://www.cdc.gov/nchs/data/nvsr/nvsr60/nvsr60\\_04.pdf](http://www.cdc.gov/nchs/data/nvsr/nvsr60/nvsr60_04.pdf)). The overall and age-adjusted death rates fell from 1999 to 2005. Indeed, the age-adjusted death rate fell faster after 1999 than it did before. If the 500,000 statistic was correct, there should have been at least 100,000 incremental deaths in the peak year from Vioxx. That's 33 per 100,000 for the entire U.S. See any blips in the data of the magnitude? They don't stand out... Of course, the incremental deaths should really show up in the CVD (cardiovascular disease) mortality statistics. They don't. See "US Death Rates 1975-2009" ([http://seer.cancer.gov/csr/1975\\_2009\\_pops09/results\\_merged/topic\\_graph\\_heartdis\\_cancer.pdf](http://seer.cancer.gov/csr/1975_2009_pops09/results_merged/topic_graph_heartdis_cancer.pdf)). Also see some Arizona specific data ("Trends in Age-Adjusted Mortality Rates of Deaths due to Cardiovascular Disease, Arizona and US, 1980-2004" - <http://www.azdhs.gov/azcvd/documents/pdf/az-burden-of-cardiovascular-disease.pdf>). The Arizona data is not by itself particularly important (state level death rate variations are huge). However, the Arizona data exactly tracks the U.S. overall data. Is it possible that Vioxx resulted in 50,000 deaths over the period in question? Sure. I don't have anything approaching the background to evaluate such a claim. I wouldn't be surprised either way as to the truth. For the record, I do have opinions on topics like this. I spent years deflating Thiomersal / autism claims... However, there is a larger issue here. NSAIDs (Celebrex, Vioxx, Bextra, etc.) are all associated with incremental mortality. Indeed, even Naproxen (also a COX-2 NSAID) has been linked to higher death rates. However, these drugs are simply too valuable to give up. Ask the people who take them, if anyone has any doubts. For many, NSAIDs are the difference between a normal life and ongoing, severe pain. This is why the FDA panel voted 31-1 to keep Celebrex on the market. The same panel also voted 17-15 to keep Vioxx for sale. Even excluding panelists with industry ties, the vote was 8-14 (losing) to approve Vioxx. If Vioxx was really as bad as some allege, why did 8 panelists (with no industry ties) favor its continued sale? Why was the vote in favor of Celebrex (which is also linked to CVD) almost unanimous? See "10 on FDA Vioxx panel had ties to companies" (<http://www.msnbc.msn.com/id/7031927/ns/health-arthritis/t/fda-vioxx-panel-had-ties-companies/#.T6lukFJpe18>) Thank you Peter Schaeffer P.S. I have no ties to the drug industry (other than as a customer). I was once prescribed Naproxen many years ago. It was astonishingly helpful even though I only took it for a week or two. I have taken Aleve (OTC Naproxen) from time to time.

Peter Schaeffer (2012-05-13 12:55:47)

A few more notes. 1. If Vioxx had anything approaching the impact TAC (The American Conservative) is suggesting, it would have shown up in the CVD death statistics first and foremost. It doesn't. 2. Vioxx was withdrawn on September 30th, 2004. Many folks probably continued to take their pills for a few weeks longer. If Vioxx was really so deadly that removing it from the market for the last 3 months of 2004 had a material effect, then much larger increased in death rates should have shown up sooner. Indeed, since it was still on the market for most of 2004, the largest impact on death rates should have been from 2004 to 2005. In fact, the crude death rate rose from 2004 to 2005. Evidently, removing Vioxx raised death rates. 3. The age-adjusted death rates tell a more useful story. The age-adjusted (AA) death rate plunged from 2003 (832.7) to 2004 (800.8). From 2004 (800.8) to 2005 (798.5) it was almost flat. Removing Vioxx from the market stopped (for a while) progress in reducing death rates. 4. The introduction of Vioxx provides even stronger evidence. Vioxx was introduced on May 20th of 1999. However, sales were slow at first. Only 4.845 million prescriptions were written in 1999. The number of prescriptions rose to 20.630 million in 2000 and 25.406 million in 2001 (the peak year). The crude death rate rose from 847.3 in 1998 to 857.0 in 1999. However, it fell to 854.0 in 2000, and 848.5. Evidently an extra 15 million Vioxx prescriptions in 2000 reduced the death rate as did another 5 million in 2001. 5. The AA death rates tell an even better story. The AA death rate rose from 870.6 in 1998 to 875.6 in 1999. However, the

extra 15 million Vioxx prescriptions reduced it to 869.0 in 2000 and another 5 million Vioxx prescriptions reduced it to 854.5 in 2001. As mentioned above, the AA death rate falls from 832.7 in 2003 to 800.8 in 2004 (with Vioxx still on the market for most of the year). It then essentially flat lines in 2005 (798.8). 6. The use of crude death rates is ultimately misleading. The American population is obviously aging. AA death rates make considerably more sense. In a few years, the baby boomers will start dying off in large numbers. The crude death might even rise. What does that demonstrate other than the pig coming out the other end of the Python? 7. Obviously everyone will die eventually and that 500,000 is an estimate of premature deaths. Premature by how much? A year? A month? One second? If the reduction is material it should show up in death rates (AA and crude). It doesn't. 8. Death rates rise and fall for reasons clearly unrelated to Vioxx. The crude death rate rose from 1994 (866.1) to 1995 (868.3) and from 816.5 in 2004 to 825.9 in 2005. 9. See Table 8 [http://www.cdc.gov/nchs/data/nvsr/nvsr49/nvsr49\\_08.pdf](http://www.cdc.gov/nchs/data/nvsr/nvsr49/nvsr49_08.pdf) for a comparison of 1998 versus 1999 death rates. The overall death rate fell in the 65-74 cohort while rising 75-84 cohort and the 85+ cohort. CVD fell in both the 65-74 cohort and the 75-84 cohort from 1998 to 1999. The CVD death rate rose for the 85+ cohort from 1998 to 1999. See also Table 9 in [http://www.cdc.gov/nchs/data/nvsr/nvsr50/nvsr50\\_15.pdf](http://www.cdc.gov/nchs/data/nvsr/nvsr50/nvsr50_15.pdf) for a 1999 to 2000 comparison. As Vioxx prescriptions soared (quadrupling to 20 million) all 65+ death rates fell. The CVD 65+ death rate also fell. 10. In the last pre-Vioxx year the overall death rate was 847.3. In 2003 with Vioxx going strong, it was 841.9. In 2004 (14 million Vioxx prescriptions) it was 816.5. Of course, the age-adjusted data show that Vioxx "saved" even more lives. The 1998 AA rate was 870.6. The 2003 rate 832.7. The 2004 rate was 800.8. 11. The crude death rate was essentially flat from 2004 to 2005 when it should have fallen the most. The 65+ data is more dramatic. Table 9 of [http://www.cdc.gov/nchs/data/nvsr/nvsr59/nvsr59\\_10.pdf](http://www.cdc.gov/nchs/data/nvsr/nvsr59/nvsr59_10.pdf) shows 65+ mortality rates fell every year from 1999 to 2008. So did the CVD death rates. 12. Any alleged linkage between Vioxx going off the market in 2004 and mortality statistics suffer from a basic flaw. Vioxx was recalled on September 30. September 30th isn't Jan 1. Thank you Peter Schaeffer P.S. I am not claiming that Vioxx was harmless. NSAIDs are (apparently) intrinsically dangerous. However, the incremental deaths were too few to show up in the overall mortality statistics and more decisively, too few to show up in the CVD mortality statistics.

Peter Schaeffer (2012-05-13 12:56:20)

A few more notes 1. There were rumors that Vioxx was dangerous before the recall. Indeed the claims predate FDA approval (clearly another story). However, rumors aren't numbers. There were 19.959 million Vioxx prescriptions in 2003 versus 13.994 million in 2004. That's a fall of 5.965 million. However, the fall from 2004 to 2005 was 13.994 million. Yet, somehow raw (but not AA) death rates fell from 2003 to 2004 and rose from 2004 to 2005. 2004 Vioxx prescriptions were 70.11 % of 2003. That's only slightly below the 75 % we would expect from the withdrawal date. In other words, physician avoidance (pre-recall) was quite modest at best. 2. Total COX-2 sales did not plummet in 2004. The IMS data shows that they were flat or down slightly. Let me quote from "IMS Health, National Sales PerspectivesTM, 2/2005" "Despite the negative publicity and the voluntary withdrawal of Vioxx®, the COX-2 inhibitor class was flat for 2004 with sales of over \$5.3 billion. Celebrex® remained the largest product with sales of \$2.7 billion and Vioxx® achieved sales of \$1.8 billion in the first nine months of the year before being withdrawn on September 29." The link is [http://www.imshealth.com/portal/site/ims-health/menuitem.a46c6d4df3db4b3d88f61\\_1019418c22a/?vgnnextoid=003a1d3be7a29110VgnVCM10000071812ca2RCRD&vgnnextfmt=default](http://www.imshealth.com/portal/site/ims-health/menuitem.a46c6d4df3db4b3d88f61_1019418c22a/?vgnnextoid=003a1d3be7a29110VgnVCM10000071812ca2RCRD&vgnnextfmt=default) Other sources show Celebrex and Bextra sales peaking in 2004. Another report from IMS makes this point and suggests a decline in total COX-2 sales. See "Biotech Remains Industry Growth Engine, With 17 Percent Sales Growth". The key quotes are "Merck's surprise, voluntary withdrawal of Vioxx® in September and potential safety concerns associated with other pain relief medications resulted in doctors switching patients away from Vioxx or starting them on other COX-2 products. Patient volume for the remaining COX-2s initially increased by more than 25 percent following the withdrawal, driven by a 15 percent increase in new therapy starts and a two-thirds share of all Vioxx switches. "Over time, COX-2 usage has declined to below pre-Vioxx withdrawal levels, due in part to further safety concerns about this class of drugs," said Lisa Morris, global director, IMS longitudinal services. "By year-end, the prescription COX-2 and NSAID market saw a 9 percent decline in total patients." The link is [http://www.imshealth.com/portal/site/imshealth/menuitem.a46c6d4df3db4b3d88f61\\_1019418c22a/?vgnnextoid=933a1d3be7a29110VgnVCM10000071812ca2RCRD&vgnnextchannel=41a67900b55a5110VgnVCM10000071812ca2RCRD&vgnnextfmt=default](http://www.imshealth.com/portal/site/imshealth/menuitem.a46c6d4df3db4b3d88f61_1019418c22a/?vgnnextoid=933a1d3be7a29110VgnVCM10000071812ca2RCRD&vgnnextchannel=41a67900b55a5110VgnVCM10000071812ca2RCRD&vgnnextfmt=default). The 9 % decline may have been versus the third quarter of 2004 which means that total COX-2 prescriptions could have easily equaled 2003 (which appears to be the case). See also "Sales rise for Celebrex and Bextra after Vioxx withdrawal" ([http://www.usatoday.com/news/health/2004-11-30-painkillers\\_x.htm](http://www.usatoday.com/news/health/2004-11-30-painkillers_x.htm)) "Pfizer's Celebrex gained a majority of sales for new-generation painkillers in the month after Merck & Co. yanked Vioxx due to safety concerns, according

to IMS Health, a pharmaceutical information company.” 3. 2005 was a very different story. Vioxx sales were zero of course. Bextra went off the market on April 7th, 2005. Bextra did generate substantial revenues in the first quarter of 2005. However, the retail data (not the entire story) show Bextra growing from 2003 to 2004 (to over \$250 million per quarter) and then falling to \$148.370 million for all of 2005. Once again this is retail only data. Even though Celebrex stayed on the market with FDA approval, sales crashed in 2005. See “Sales plummet as cox-2 miasma vexes consumers” ([http://findarticles.com/p/articles/mi\\_m3374/is\\_10\\_27/ai\\_n15341417/](http://findarticles.com/p/articles/mi_m3374/is_10_27/ai_n15341417/)). Quote “According to IMS Health, sales of cox-2 inhibitors have plummeted 65 percent for the first five months of 2005, representing \$1.5 billion in lost sales of Bextra, Celebrex and Vioxx. Of those three drugs, only Celebrex remains on the market. And now, two other cox-2 inhibitors that were in the drug development pipeline at the time of the Vioxx withdrawal are not expected to make it to market any time soon—if at all.” Another source gives a 48 % fall in Celebrex sales in 2005. See “Pfizer to resume airing ads for Celebrex” ([http://www.usatoday.com/money/industries/health/drugs/2007-04-01-celebrex-usat\\_N.htm](http://www.usatoday.com/money/industries/health/drugs/2007-04-01-celebrex-usat_N.htm)). Quote “The return of Celebrex to TV follows its financial comeback. Celebrex sales hit \$3.3 billion in 2004 then dropped 48 % in the year after Vioxx’s withdrawal. Last year, Celebrex sales were \$2 billion. Still, it ranks behind ibuprofen and naproxen in arthritis prescriptions, according to market tracker Verispan. Before the Vioxx recall, Celebrex was ahead of naproxen but behind ibuprofen.” Let’s recap for a moment. COX-2 volumes were flat from 2003 to 2004 and death rates fell. COX-2 volumes crashed in 2005 and death rates rose. This is not the correlation the TAC is suggesting. 4. Drug companies do give away samples that could impact total consumption in 1999. However, volumes appear to be low compared to prescriptions. In 2007, drug companies spent \$8.4 billion giving out samples. See “Pharma scales back drug samples to physician offices” (<http://www.ama-assn.org/amednews/2012/03/26/prl20326.htm>). Total prescription sales were \$286.5 billion (IMS Health). The notion that Vioxx early adopters were more at risk is conceivable, but lacking in any substantiation. Why would doctors single out patients with the greatest CVD risk, as the first users of Vioxx? To make such a claim, the TAC needs facts or at least a mechanism (in my opinion). If Vioxx had been the first COX-2 drug on the market this would be a stronger thesis. A person could argue that the sickest patients (in general), with the most pain, were the first users. However, Celebrex was approved on December 31, 1998. 5. TAC’s use of overall and 65+ death rates suffers from several large problems. The biggest problem is that Vioxx apparently caused heart problems (all of Vioxx’s critics agree on this point). However, there is nothing in the heart disease data to support the TAC thesis. Online data shows that the CVD death rate fell from 1998 to 1999. To be precise the CDC has two sets of data from 1998. The standard data shows a fall for all age groups except for the 85+ group. Overall the rate falls from 268.2 to 265.9. Row 44 (the modified data) shows a slight rise overall (from 264.4 to 265.9) and big falls for the 65-75 group and the 75-84 group. The 85+ group rises as well. Any hint of a spike is absent. The 1999 versus 2000 CVD data show CVD death rates falling for everyone (as Vioxx sales quadrupled). Let’s look at this another way. An incremental 100,00 deaths per year is roughly 33 per hundred thousand for the entire population. No shifts of that magnitude show up in the CVD data. The NVSS (National Vital Statistics System) data makes the same point. The Major cardiovascular death rate fell from 1998 to 1999 (and kept falling in 2000) for all groups except for the 85+ cohort as Vioxx sales soared. Even the 85+ cohort is below 1998 levels in 2000. There is a big fall from 2003 to 2004. However, that should have occurred in 2005. The data has other big falls as well (1988 to 1989, 1989 to 1990, 2000 to 2001, and 2005 to 2006). The subcategories (Heart disease, Heart attack, Chronic ischemic heart disease, Atherosclerotic cardiovascular disease, Heart failure, and Stroke) show the same pattern. Most fall from 1998 to 1999 and 2000. Heart failure and Stroke rise slightly. If Vioxx was nearly deadly as TAC’s asserts, it would show up in the NVSS CVD data. It doesn’t. As a check, I graphed CVD mortality from 1998 to 2007. The Vioxx effect is not apparent. The expected spike from 1999 to 2000 and crash from 2004 to 2005 are clearly absent. Thank you Peter Schaeffer P.S. David Graham estimates that Vioxx might have caused 88,000 to 139,000 additional heart attacks / strokes with a 30-40 % mortality rate. That’s certainly plausible and not contradicted by the CVD data. Of course, total COX-2 mortality must have been higher because of the side effects of Bextra / Celebrex. As everyone knows, Celebrex remains on the market.

Ron Unz (2012-05-15 16:00:16)

Thanks for the interest in my discussion of the Vioxx mortality statistics. Among other matters, my latest column responds to some of the critique above: <http://www.ronunz.org/?p=3637>

## What Motivates Scientists? Evidence From Cancer Research (2012-04-23 05:00)

A friend of mine who worked in a biology lab said the grad students and post-docs joked about the clinical-relevance statements included at the end of papers and grant proposals: how the research would help cure cancer, retard aging, and so on. It was nonsense, they knew, but had to be included to help funding agencies justify their spending.

Principal investigators never say such things. Are they wiser than grad students and post-docs? Fortunately for the rest of us, actions speak louder than words. An action – actually, a lack of action – that suggests that P.I.'s know their research has little connection to curing cancer, etc., is 50 years of widespread indifference by cancer researchers to the possibility that their research uses a mislabeled cell line. For example, you think you are studying breast cancer cells but you are actually studying melanoma cells.[1] A recent WSJ article says that the problem was brought to the attention of cancer researchers in 1966 but they have been "slow" to do anything about it:

University of Washington scientist Stanley Gartler warned about the practice [of using mislabelled cells] in 1966. He had developed a pioneering technique using genetic markers that would distinguish one person's cells from another. Using the process, he tested 20 of the most widely used cancer cell lines of the era. He found 18 of the lines weren't unique: They were Ms. Lacks' cervical cancer. . . . A decade after publication of his findings Gartler attended a conference and introduced himself to a scientist. Dr. Gartler recalled the man told him, "I heard your talk on contamination. I didn't believe what you said then and I don't believe what you said now." "

What he meant was: I ignored what you said. Yet it costs only \$200 to check your cell line. Fifty-plus years later, mis-labeled cell lines remain a big problem. "Cell repositories in the U.S., U.K., Germany and Japan have estimated that 18 % to 36 % of cancer cell lines are incorrectly identified," says the article. This indicates considerable indifference to the possibility of mislabeling.

If you truly wanted to cure breast cancer, would you spend \$200 (out of a grant that might be \$100,000/year) to make sure you were using a relevant cell line? Of course. If you were trying to cure your daughter's breast cancer or your mother's melanoma, would you make absolutely sure you were using the most relevant cell line? Of course. I conclude that a large fraction of cancer researchers care little about the practical value of their research.

I believe that one reason [2]my personal science found new solutions to common problems (obesity, insomnia, etc.) is that my overwhelming goal was to find something of practical value. I wasn't trying to publish papers, impress my colleagues, renew a grant, win awards, and so on. No doubt many cancer researchers want to cure cancer. But this 50-year-and-not-over chapter in the history of their field suggests that many of them have other more powerful motivations that conflict with curing cancer.

Thanks to Hal Pashler. Hal's work on "[3]voodoo neuroscience" is another instance where the guilty parties, I believe, knew they might be doing something wrong but didn't care.

Alex Chernavsky (2012-04-23 08:00:52)

That *Wall Street Journal* article was really one of the most astounding things I've read in recent memory. Here's another quote that stood out for me:

"Screaming and shouting, it doesn't do any good. No one takes any notice for reasons I don't understand," said John Masters, a professor of experimental pathology at University College London, UCL. "The whole ethos of science is to strive for the truth and produce a balanced argument about the evidence. Yet, all this crap is being produced."

Seth: A curious quote. I don't think it's controversial that scientists have motivations other than "truth". To say "the whole ethos of science is to strive for truth" is to ignore those other motivations: status, job security, attention, community, and so on.

Tom (2012-04-23 09:46:23)

It will change when Fox News demands gigantic cutbacks in research spending because it's all based on fraud like this. A little drum-banging, some Limbaugh mocking, a Bill O'Reilly rant or two, and the grants will be suspended across the board as the GSA tries to clear its name by launching the biggest fraud investigation in recent memory. These can't-be-bothered researchers will start screaming like they're being burned alive. They don't seem to realize that they are standing on the precipice.

Tom (2012-04-23 14:48:54)

More misleading research, this time supporting the use of drugs to treat repetitive behaviors in autism: [pediatrics.aappublications.org/content/early/2012/04/17/peds.2011-3285.abstract](http://pediatrics.aappublications.org/content/early/2012/04/17/peds.2011-3285.abstract)

Nathan (2012-04-24 13:22:43)

[http://www.carolinajournal.com/exclusives/display\\_exclusive.html?id=8992](http://www.carolinajournal.com/exclusives/display_exclusive.html?id=8992) Seth, interesting article: "State Threatens to Shut Down Nutrition Blogger." By North Carolina's reasoning, your blog should probably be shut down.

Re: the NC blogger, I finally figured out how to explain this to software people. The AMA is the MPAA of medicine.

Alex Chernavsky (2012-04-26 10:28:43)

See also this article about "practicing engineering without a license", which is apparently a misdemeanor: <http://www.newsobserver.com/2011/02/03/964781/citizen-activist-grates-on-state.html> By the way, what is it about North Carolina?

Leila (2012-04-27 10:56:09)

NC is also the place where corporal punishment is still legal. [http://www.mattmetzgar.com/matt\\_metzgar/2012/04/corporal-punishment-ii-y-our-mind-is-playing-tricks-on-you.html](http://www.mattmetzgar.com/matt_metzgar/2012/04/corporal-punishment-ii-y-our-mind-is-playing-tricks-on-you.html)

Jm Purdy (2012-04-29 08:04:24)

When I attended Duke University in the early 1960s, I was appalled at how much racism and ignorance there was in North Carolina. At that time, I was told (perhaps erroneously) that there were no black undergraduate students at Duke. The racism began to lessen in North Carolina in the 1960s, but ignorance apparently is still endemic. Some things never change.

### Assorted Links (2012-04-27 13:04)

- [1]The corruption of science by research grants. This reminds me of a BBC documentary called something like Science Under Attack. It was hosted by a Nobel Prize winner (Biology) named Paul Nurse. Part of it was about "climate change denialism". If you don't believe that humans are dangerously warming the planet, Nurse implied, you are somehow attacking science. When people who win Nobel Prizes cannot see that AGW is a crock, something curious has happened.
- [2]Edward Jay Epstein interviews DSK. ""Thank you so much for your interest in this case," he says."
- [3]Researcher discovers new treatment for her own vertigo. "A University of Colorado School of Medicine researcher who suffers from benign paroxysmal positional vertigo (BPPV) and had to "fix it" before she could go to work one day was using a maneuver to treat herself [the usual treatment] that only made her sicker. "So I sat down and thought about it and figured out an alternate way to do it. Then I fixed myself and went in to work" and [thereby] discovered a new treatment for this type of vertigo."

peter (2012-04-27 15:02:25)

use of co-enzyme Q10, ( the Ubiquinol form not the ubiquinone form) has alleviated vertigo.

Volksverhetzer (2012-05-02 16:06:16)

Almost everybody has Vertigo, if you get high enough. It is easy to study construction workers, where they start out not that different than the rest of the population, but end up virtually losing it, after having worked for months on a scaffold or on a roof. I have noticed myself, for instance when I have not worked in a ladder for a long time, that you need some getting used to, before you stop getting Vertigo from looking down. So the simple way to treat Vertigo, is just to spend hours in an altitude where you get dizzy looking down, and sooner or later it stops, and then you can go higher. That construction workers stop having vertigo is also dangerous, as many die from falling down, after behaving like they were working just a couple of meters above ground, when they in reality are perhaps 10 meters or higher.

## **Effect of Vitamin D3 on My Sleep (2012-04-28 05:00)**

I have [1]blogged many times about [2] biohacker Tara Grant's discovery that she slept much better if she took Vitamin D3 in the morning rather than later. Many people reported similar experiences, with a few exceptions. [3] Lots of professional research has studied Vitamin D3 but the researchers appear to have no idea of this effect. They don't control the time of day that subjects take D3 and don't measure sleep. If the time of day of Vitamin D3 makes a big difference, measuring Vitamin D3 status via blood levels makes no sense. Quite likely other benefits of Vitamin D3 require taking it at the right time of day. Taking Vitamin D3 at a bad time of day could easily produce the same blood level as taking it at a good time of day.

I too had no idea of the effect that Grant discovered. I had taken Vitamin D3 several times – never in the morning – but after noticing no change stopped. I tested Grant's discovery by taking Vitamin D3 at 8 or 9 am. First, taking it at 8 am, I gradually increased the dose from 2000 IU to 8000 IU. Then I shifted the time to 9 am. The experiment ended earlier than I would have liked because I had to fly to San Francisco.

When I woke up in the morning I rated how rested I felt on a 0-100 scale, where 0 = not rested at all and 100 = completely rested. I'd been using this scale for years. Here are the results (means and standard errors):

[4]

Vitamin D3 had a clear effect, but the necessary dose was more than 2000 IU. If Vitamin D3 acts like sunlight, you might think that taking it in the morning would make me wake up earlier. Here are the results for the time I woke up:

[5]

There was no clear effect of dosage on when I got up. Shifting the time from 8 am to 9 am may have had an effect (I wish I had 3 more days at 9 am).

Many people have reported that taking Vitamin D3 in the morning gave them more energy during the day. I usually take a nap in the early afternoon so I measured its effect on the length of those naps:

[6]

Maybe my naps were shorter with 6000 and 8000 IU at 8 am. It's interesting that 4000 IU seemed to be enough to improve how rested how I felt but not enough to shorten my naps.

What do these results add to what we already know? First, the large-enough dose was more than 2000 IU. ([7]A \$22 million study of Vitamin D3 is using a dose of 2000 IU.) The dose needed to get more afternoon energy may be more than 4000 IU. Second, careful experimentation and records helped, even though many people found the effect so large it was easy to notice without doing anything special. For example, these results suggest the minimum dose you need to get the effect. Three, these support the value of supplements. Many people say it is better to get necessary nutrients from food rather than supplements. However, supplements allow much better control of dosage and timing and these results suggest that small changes in both can matter. I cannot imagine this effect being discovered with Vitamin D3 in food.

Stone Glasgow (2012-04-28 05:17:56)

You need to control your sun exposure; the body generates huge amounts of D3 in sunlight. Seth: Well, these results were helpful without doing that.

Paleophil (2012-04-28 07:37:01)

Hi Seth, I love your blog and have a couple questions. If taking vitamin D supplements in the morning is beneficial, then does that suggest that eating vitamin-D-rich animal/sea foods in the morning might also be beneficial? Seth: No I don't think it suggests that...I think there is too little Vitamin D3 in them. What do you think of the report by Mira and Jason Calton, authors of Naked Calories, that they traveled around the world to observe over a hundred traditional peoples in what they called The Calton Project (<http://caltonnutrition.com/calton-project.aspx>) and found that traditional peoples tend to eat a meal in the morning (<http://www.fatburningman.com/best-seller-naked-calories-mira-calton-jayson-calton-interview>)? Seth: That's very interesting. I'll try to find out more about it.

Chuck (2012-04-28 08:28:31)

Dave Asprey of Bulletproof Executive mention that the body can store D3 for up to a week. This was in reference to going on a trip and not wanting to take along a bottle of D3. You can take a weeks worth (25-50K IU) at one time and be good to go - if you're going to Hawaii and laying on the beach all day, you're doubly good to go. There doesn't seem to be an upper limit on D3 supplementation. However, tanning could be argued that it is a self regulating limiting factor (the tanner you are the more sun you need to produce the same amount of D3). I've read that the optimal dose is 1000 IU per 25 lbs of body weight - I'm around 130 and take 5000 IU/day - as soon as I get up - plus I spend as much time in the sun without sun screen as possible because I also heard or read that the type of D3 produced from the sun is slightly different from the supplements (and I just like being out in the sun). When it comes to sleep quality, and testing some protocol, I think it would be interesting to hook yourself up to a sleep monitor and compare the results from the monitor to how you feel when you wake up and how you perceived your nights sleep - restless, calm, don't remember a thing, etc. I would test it for some period of time where I didn't see the results from the monitor until the end of the test. I think that would give you a clearer picture of what your mind was doing compared to how you perceived your sleep. Anyway, the sun is out, so I gotta go. Cheers

Tom (2012-04-28 13:54:46)

Seth, if you have an iPhone, there is an app called "sleep cycle" that will track your restlessness during sleep. It uses the phone's accelerometer as a proxy for soundness of sleep. (While the app is designed to wake people up at the best point in their sleep cycle- thus maximizing their feeling of being rested - it also has a "no alarm" mode that would allow you to use it just for its sleep statistics display.)

by (2012-04-28 23:18:57)

I'm interested in the best way to track one's sleep quality. I know Dr. Roberts and others use "sleep-wanted" rating first thing in the morning, but when trying this plus an end-of-day rating for average fatigue, I felt sleep-wanted was sometimes wildly off. However, in some ways it's easier to jot down a number first thing in the morning than review the whole day's energy level at the end of the day. Anyone have any other tips for "pen-and-paper" sleep quality measuring?

Jazi zilber (2012-04-29 02:52:50)

I would not expect naps to be affected. Their function is to refresh after half a day. Which should not correlate much with night sleep. Interesting it is.

Antonio Pedro (2012-04-29 03:33:54)

I am also doing some experiments with it, which I will report soon. I have a question though: what is the maximum recommended dose for D3? Taking over 4000 IU for long periods of time, say years, seems a very large dose to me: I was wondering how safe it is. Cheers, Seth: Different places recommend different dosages. Some people say 2000 IU/day is dangerous. Some people have taken 10000 IU/day for a long time with no problem. Given the time of day effect and the huge importance of good sleep for good health, all previous studies (which did not control for this) are suspect. For example, maybe 2000 IU is only dangerous if you take it at night.

Vic (2012-04-29 10:03:09)

Seth, are you still taking the tablets or have you switched to gel-caps? Supposedly there is a big difference in absorption

between them... Seth: this study was done with tablets. Now I use gelpcaps...what is the difference in absorption?

Paleophil (2012-04-29 12:38:12)

It was an interesting podcast, so I listened to it again and my memory was a bit off. The Calton's visited over 100 countries (with peoples of all types), rather than over 100 traditional peoples. Here is what Jayson said about morning meals: 36:36 "When we traveled around the world, this is what we found: people basically ate in the morning, they would kind of snack on something small in the afternoon and then they'd eat again at night." [http://www.fatburningman.com/best-seller-naked-calories-mira-calton-jayson-ca lton-interview](http://www.fatburningman.com/best-seller-naked-calories-mira-calton-jayson-ca-lton-interview) This and other reports cause me to question whether Stone Age peoples really did mostly skip "breakfast." I suspect that if they had food in the morning before going out to hunt/gather, they would eat some of it (not knowing about any theories about better sleep from skipping breakfast), and if they didn't have any food, they didn't. Also, I doubt they would pass up choice berries, honey or other preferred available foods they came across just because it was morning. This doesn't mean that eating "breakfast" is necessarily optimal in today's world, of course, and some food would probably be gathered and brought back to camp for the main feast in the evening and the foods closest to camp would be used up first, forcing longer-distance foraging and later meal times. Seth: I wonder what they ate in the morning and when, relative to when they got up. I found that eating within about 3 hours of getting up was a bad idea. So an early breakfast would be bad but brunch is okay.

Paleophil (2012-04-29 16:01:11)

Yes, I wondered about that too and did some searching and found some indication that centuries ago people tended to eat breakfast around 9-10 am (<http://www.foodtimeline.org/foodfaq7.html>), rather than earlier. On the other hand, my understanding is that hunters and fishers tend to rise early. If true, then if I were a hunter, I'm thinking I would want to grab a quick bite of leftovers upon rising, so I wouldn't have to carry much or any food while hunting/fishing. Maybe meats and fish are less of a problem when consumed early in the morning than agricultural foods (there is some evidence for this - <http://www.gnolls.org/2181/the-breakfast-myth-part-2-the-art-and-science-of-not-eating-breakfast>)? Then again, going back further in time, in pre-weapon and pre-fire days I doubt hominids would have left much food uneaten in their camps overnight, so as not to attract predators. Perhaps there hasn't been enough time to adapt to morning meals? Seth: I listened to part of the podcast and heard that these indigenous people did not store food but ate it soon after they gathered it. That would rule out eating soon after you wake up. To get food they must have had to walk a considerable distance.

Vic (2012-04-29 22:50:54)

Dr. Davis heartscanblog claims that some people fail to absorb the vitamin D from tablets as well as the vitamin D from gelpcaps. This is based on his clinical experience tracking the response of serum vitamin D in response to supplementation. Seth: Thanks, that's good to know. I found that tablets worked.

Antonio Pedro (2012-04-29 23:58:02)

Hi Seth, thanks for your reply. I understand and agreed with your point regarding previous studies. Yet, "Some people have taken 10000 IU/day for a long time with no problem" is still a little too uninformative (though I see there can't be more precision as of now). My follow up questions is this: can we be tested in any way, such as take a blood test, to detect overdosages? I find it curious that apparently nobody is much worried high intake. Cheers, Seth: "Nobody is much worried high intake"? I am. I use the minimum dose that produces the sleep improvement.

Paleophil (2012-04-30 04:04:38)

Good point. That would fit better with a late morning brunch.

Guv (2012-04-30 19:58:06)

<http://blog.vitamindecouncil.org/2011/11/08/does-it-matter-how-you-take-vitamin-d/> "Does it matter how you take vitamin D" Summary: "The fact is that the studies are so conflicting, and the 25(OH)D measurement techniques are so variable, that it simply does not matter if you take vitamin D in oil or as a powder, it does not matter if you take food with your vitamin D, or on an empty stomach. What matter is that you take enough so that you obtain vitamin D levels of 50 -60 ng/ml"

Jenny (2012-05-01 02:46:34)

I have found over the last 5 months that there is an interaction between D3 (in the morning) and food intake in the evening. I need 3-4000IU D3 (gel caps) to enable me to sleep all night. However, a late (post 8pm) evening meal will disturb this, especially when carbohydrates - as in a pudding - are involved. Then I will wake again, and will not easily return to sleep. This suggests that the Leptin system is involved, (see Jack Kruse's work) and presumably overrides the D3 effect. However, without the D3 to enable me to sleep most of the time, I would not have noticed the effect of the late evening meal. Anyone else have similar observations? Seth: I don't understand the connection with leptin. I think your results suggest that D3 and late meals push in opposite directions. D3 pushes you toward sleeping through the night, late meals push you in the other direction. As for "without the D3 to enable me to sleep..." look up floor and ceiling effects.

gwern (2012-05-02 07:08:12)

As it happens, I finished my own experiment & analysis on Saturday, and as far as my data is comparable to Roberts's, I found the same thing - no effect on anything but restedness/'Morning Feel': <http://www.gwern.net/Zeo> #vitamin-d-at-morn-helps Isn't that strange? You'd expect the mood improvement to be mediated by sleeping better on one of the other metrics - sleeping more, waking less, etc. - but apparently not. Are there any neurobiologists or circadian specialists around?

Nick Winter (2012-05-05 05:51:45)

Seth, what's going on with the "Rested (percent)" x-axis? Are you really measuring significant difference in restedness feelings only around 98.9 % - 99.5 % on a scale of 0-100 %? Or is there some mistake with the labeling? Seth: The label is correct. If you think those differences are too small to tell apart, subtract them from 100. The implication that I wake up each morning feeling very rested is true. A psychologist named S. S. Stevens spent his whole career showing that people were quite good at attaching numbers to "sizes" (he used the word "magnitude") of internal states, such as loudness. Here I am attaching a number to how tired I feel when I wake up.

Anne (2012-05-16 10:26:04)

Hi Seth I just found this blog and it is very interesting. I am amazed about this topic. I have struggle with sleep problems for over 10 years and have tried almost everything. But this is complete new to me. I take 2000 D3 in the morning since some years back and it have worked wonders with the mood in the winter. May I ask to have some advice on how much I should take in the morning, and do I need to take something more. As I usually take Magnesium and calcium in the evening. Or is it posted in more detail earlier that I have missed Seth: I found that 2000 IU had no effect on me but 4000 IU and higher doses did have an effect. Now I take 5000 IU D3. Try different times in the morning: 7 am, 7:30 am, 8 am, etc. Figure out which works the best.

Anne (2012-05-16 23:55:16)

Thank you Seth ! I have taken 6000 this morning, as I have earlier irregular been taken 4000 and have not notice any diffence.

Guv (2012-05-17 20:26:45)

Just come across a few articles by Stasha Gominak, M.D. She writes that ideally the D25OH blood level should stay between 60 and 80 ng/ml to sleep perfectly. She also writes that "sleep (is) just as abnormal when it goes over 80, as it does when it's under 50." <http://drgominak.com/vitamin-d> <http://drgominak.com/sleep> Some food for thought there, something to keep an eye on if/when your 25ohD gets above 80 ng/ml Seth: Dr. Gominak's emphasis on blood levels - although conventional - doesn't make sense given the enormous importance of time of day. Maybe a blood level of X (e.g., 60) is good if you take your D3 at the right time of day and bad if you take it at the wrong time of day.

Anne (2012-05-18 13:01:34)

@ Gav Thank you so very much for the link on May 17th on D3- Ot was very useful and interesting. Now it really make sence too my and I undertand a lot of my doughther al well

Guv (2012-05-18 22:08:05)

I have also found the time of day to be important. & I have tested the theory that taking D3 in the evening before bed may disrupt sleep. In one experiment i took 2000 IU before bed & it felt like i was awake all night....I will not be repeating that experiment. I wonder if Dr. Gominak's upper limit of 80 ng/ml may also have some validity; ie. if ones serum 25ohD was slowly rising from the morning supplementation over time (months) until it finally got over 80 ng/ml, then sleep may become disrupted again, even with the morning D3 supplementation. That said, i would presume that most peoples serum 25ohD is nowhere near 80 ng/ml. That reminds me, i must get mine tested again, as we head in to Winter here in the southern hemisphere.

Anne (2012-05-20 01:11:38)

@ Gav I have read the Gominak links once more, they are really good and gives a lot of answers. I need to find a place to have my level checked to.

### **Interview with a Shangri-La Dieter (2012-04-29 05:00)**

A few days ago I asked Mark Qualls, a 59-year-old truck driver who lives in Longmont, Colorado, about his success with the Shangri-La Diet, which [1]he posted about.

How did you learn about it?

Freakonomics. When I read about you in that book, it made sense to me. The whole idea of a setpoint. I used to be an accountant. I weighed 290 pounds. I'm 6' 2". I lost 25 pounds when I started driving a truck. I've been there for almost 12 years. Around 260. I get a lot of exercise delivering groceries. I can eat anything I want but the idea of going on a diet makes me hungry. My doctor said lose a bit of weight but I just couldn't do it.

How do you do the diet?

I use canola oil. I tried flax seed oil but it has a horrible taste. I have no problem taking the oil. I feel like I could do the oil for the rest of my life. At least 4 tablespoons per day. I don't measure it. I have a jar by a sink at home, another in my truck. I take a sip, what seems about a tablespoon. I figure I'm getting at least 4 tablespoons per day. Some days I may get only 3 tablespoons.

What effect has it had?

I feel like I'm in control. I stopped drinking sweet tea, used to drink tons of it. For 20 years. I've been able to stop. I couldn't stand drinking water. Now that's all I drink. That's all I've had for two months. The most bizarre thing to me in the world. I deliver to convenience stores. All they have is soda pop and doughnuts and all that kind of stuff. I'd stop and have a doughnut and chocolate milk. Now I can go without it. I still think about it but now I can say no.

What about weight loss?

I'm down from 255 to 229 – a little over 2 months. I don't really try that hard. I pretty much eat what I want. On two days per week I try to eat hardly anything. Unless I almost eat nothing, I stay at the same weight. It's not hard to do it – to eat almost nothing. Almost any time of day or night I think "I could eat something". But then it's okay not to. It gives you willpower – that's how I explain it to people. Find the book and read the whole thing, I tell them. They need to understand the whole concept before they start taking oil.

Any downsides?

Eating is enjoyable to me. My mom is a great cook. My wife is a great cook. I like to eat. It's emotionally satisfying thing to eat stuff. But when I take the oil I can not eat. Now I eat slower. To try to enjoy the little bit of food you do it. You're not going to eat 3 more times today. I tell myself, I'm going to enjoy every bite of this cottage cheese. Because that's all I'm going to eat today. The social part I miss. It's a social part of your life that you don't have any more. Most of the time I've gone to eat with people since I started, I go ahead and eat something because I don't want to be a jerk about it. I still lose weight. That will be a day where I don't lose weight when I go out to eat. To lose weight I have to have a day when I don't eat anything. Today is a day where I told myself I want to lose 1 more pound. I ate breakfast with a friend,. There's nobody who expects me to eat with them. My wife's away.

How do other people react?

My wife's a skeptic about the whole thing. She doesn't think I can't keep the weight off. One lady at church, she got the book right away. She'd lost 50 pounds eating 1000 calories per day. She started the oil. She's gung ho about it. We see each other Sunday: how much did you lose this week? we ask.

dearieme (2012-05-01 05:41:55)

i) Mango: I don't know the African variety but can vouch for the Pakistani ones - delicious. ii) Yog: I buy Total and when I want a bit of fruitiness stir in some of my wife's wild bramble jam. Delicious too.

gwern (2012-05-01 08:09:35)

Agree on yogurt. I don't know if there are health benefits (no-fat versions seem to be most common), but plain slightly tart strained yogurt certainly does taste great when you mix in some jam or jelly.

sm (2012-05-01 13:41:27)

Mangoes—university where mangoes are a major export (Benin) publishes a study showing that mangoes cause weight loss. Please don't judge me, but I'm a little skeptical. Seth: I am more than a little skeptical.

Bob (2012-05-01 17:14:42)

Close tag to make Umami item appear. Seth: perceptive of you to figure out it was about Umami.

aelephant (2012-05-02 06:14:51)

Full free text of the mango study is here: <http://www.ncbi.nlm.nih.gov/pubmed/19254366>

Carol (2012-05-03 10:20:03)

Wow, the lowering of the CRP is dramatic. 50 % over the course of the study. This older study also concluded that IG (and another product together) worked <http://www.lipidworld.com/content/7/1/12>

## **Overtreatment in US Health Care (2012-05-01 22:31)**

In April there was a conference in Cambridge, Massachusetts, about how to reduce overtreatment in American health care. [1]Attendees were told:

The first randomised study of coronary artery bypass surgery was not carried out until 16 years after the procedure was first developed, a conference on overtreatment in US healthcare was told last week. When the results were published, they "provided no comfort for those doing the surgery," as it showed no mortality benefit from surgery for stable coronary patients.

One participant said that overtreatment cost one-third of US health care spending. As far as I can tell, no one said that "evidence-based medicine" underestimates – [2]in the case of tonsillectomies, almost completely ignores – bad effects of treatments. This failure to anticipate and accurately measure bad effects of treatments makes the overall picture worse. Maybe much worse.

1. <http://www.bmj.com/content/344/bmj.e3144?etoc=>
2. <http://boingboing.net/2012/01/10/tonsillectomy-confidential-do.html>

---

WB (2012-05-03 17:00:07)

Seth, thanks for providing this info. It is extremely important and I'm surprised no one else has commented yet. To my way of thinking, the story of medical overtreatment should have exploded into a major scandal years ago; and I don't understand why the main stream media hasn't been all over it. Must be the "anechoic" effect at work; Dr. Roy Poses at Healthcare Renewal has been talking about that for a very long time. Thanks again for your blog and the interesting topics you bring to us. Regards, WB

### **Morning Faces Therapy for Bipolar Disorder: What One User Has Learned (2012-05-03 05:00)**

A friend of mine has been using [1]morning faces therapy to improve his mood – he suffers from bipolar disorder – for 15 years. He is the first person I told about it. I recently asked him how his use of it has changed over the years. He replied:

I began the morning faces therapy in April, 1997. I can think of only two significant changes over the years in my use of the therapy: 1) I use a mirror instead of videotapes, and 2) I accept that once or twice a week I'm too tired to start as early as I'd like (so I get more sleep instead). To elaborate:

1) When I restarted the treatment in 2006 after having been hospitalized, I was too depressed to deal with videotaping. In fact, I was too depressed to get out of bed so early. The mirror solved both problems, because I could easily prop it on my mattress top. After a few days I was able to get up, allowing me to listen to music, use bright lights, etc., during the treatment.

2) Whether for lack of discipline or the proper genes, I simply can't go to sleep early enough so that I can get up early every morning. (Granted, I haven't tried everything, but for the sake of the argument, let it stand.) This shortcoming used to bother me a great deal. Then on October 6th, 2011, I read in this blog about someone else who didn't always start the treatment early, because he was "too tired to get up early". Well! It didn't seem so bad if someone else had the same problem. Over the years I've found that starting 30-60 minutes late once or twice a week doesn't seem to perturb my mood enough to cause great concern.

I asked how the therapy has helped him. He replied:

The benefits of the morning faces therapy have been both 1) quantitative and 2) qualitative.

1) I have had bipolar disorder for 27 years. With the therapy, I've been medication-free for 6 years, and I was on much reduced doses of medication for about 7 years. So it's fair to say the therapy has reduced the severity of the illness by around one half. Also, the lithium that I took in part caused kidney disease, whereas, obviously, there are no side effects from looking at faces in the morning.

2) The qualitative difference seems far more important to me. I am basically content with life; I am

comfortable in my own skin. I've never felt like this before, and life without this is empty.

Note to skeptics: you might think, well, bipolar disorder is known to go in remission, and maturity often brings contentment. But this fails to explain why stopping the treatment brings back both the illness and the essential sadness.

### Three Days in May: Sex, Surveillance, and DSK (2012-05-03 05:00)

Nicholas Sarkozy must be kicking himself. Sometimes a bird in the bush is worth more than a bird in the hand. If only I'd waited... He struck too soon. If only he'd waited until Dominique Strauss-Kahn (DSK) became his main opponent and then created a DSK scandal. The opposition would not have had time to regroup. DSK was careless, creating opportunities for his opponents. Edward Jay Epstein's new book, [1]Three Days in May: Sex, Surveillance, and DSK, makes clear that DSK was being monitored, presumably via his cell phones. A first-rate intelligence organization, says Epstein, can turn on your cell phone and listen to you. At one point a French journalist is given a transcript of a call that DSK made. How was this possible? the journalist asked. The answer given is that by freakish coincidence "DSK's speaker phone was accidentally left on while his line was somehow connected to a French phone that was legally under surveillance." Why the speaker phone should matter is not explained.

Such means of surveillance – available to those in power, but not to the rest of us – make those in power more powerful, harder to unseat. However, Epstein's book also shows the effect of lower-tech new recording devices, especially CCTV recordings, cell phone records, and key-entry logs. They make it harder to lie. DSK's accuser, Nafissatou Diallo, was lying, no doubt. The district attorney's office got to "Version 3" of her story before giving up. The discrepancies between what she said happened and the key-entry records reveal her lies beyond doubt. The new recording devices also pull two people into the story who otherwise might have remained out of it: a security guard and the head engineer at the hotel, who went into a private loading-dock area and did a kind of victory dance shortly after 911 was called. The 911 call made the matter public, which effectively destroyed DSK's chance of elective office. They claim to not remember what they were celebrating. If it had nothing to do with the 911 call, it is exceedingly strange – another freakish coincidence – that it happened at exactly the same time.

Three Days in May is a new kind of investigative journalism in the sense that it is based on detailed electronic records (such as CCTV tapes and key-entry records) that weren't available until recent years. Stories and movies are often set in remote locations or times to give the story a kind of freshness. Here freshness derives from the information being used. Epstein assembles hundreds or thousands of facts from these records into his story. I was interested to see a kind of power-law distribution of information value,[2] the same thing I see in my self-experimentation: almost all of the facts tell us just a little, a very tiny fraction of them tell us a lot. Although electronic surveillance is usually considered a government tool ("Big Brother is Watching") Epstein's book makes a more subtle point. These records make false accusations more difficult to sustain and conspiracies more difficult to carry out without detection – and who does that help? In any case, Three Days in May is a fascinating true crime story – and the criminal is not DSK.

---

Paul (2012-05-03 07:44:11)

DSK was a key threat to the austerity regime currently ruling (and decimating) Europe. I suspect the order to take him out came from higher up than Sarkozy.

Tom (2012-05-03 08:14:20)

Every couple of months, there's a story about how police pulled over a car for a burned-out taillight and "happened" to find millions in drugs in the car. I've always assumed those are actually illegal cellphone wiretap/warrantless search cases. BTW, look for many more of these cases shortly, as the FAA is about to be forced to give all police depts the right to fly quiet, unmanned surveillance drones everywhere, 24/7, without a warrant. Yep, only a few days before your local Chief Billy Bob has his own swarm of the things. [nytimes.com/2012/02/18/technology/drones-with-an-eye-on-the-public-cleared-to-fly.html?pagewanted=all](http://nytimes.com/2012/02/18/technology/drones-with-an-eye-on-the-public-cleared-to-fly.html?pagewanted=all)

Toli (2012-05-03 11:11:40)

At yesterday's debate between the French Presidential contenders, Sarkozy was trying to squeeze as much out from the DSK situation for political advantage... From the Times' liveblog: But that high-minded discussion quickly descended into crosstalk and a return to accusations of guilt-by-association that marked the debate's beginning. "No lessons from the political party that united behind Dominique Strauss-Kahn," Mr. Sarkozy said. Mr. Hollande responded by observing that Mr. Sarkozy had appointed Mr. Strauss-Kahn to the International Monetary Fund. All the best to set you up, my dear...

LemmusLemmus (2012-05-03 12:22:24)

Unless you have strong evidence from the book or elsewhere that Sarkozy's people were surveilling DSK, the first few sentences appear quite careless. I have not read the book, but I am pretty sure no such evidence is presented in it, having read an in-depth interview with Epstein on the occasion of its publication. Seth: A transcript of a phone call is not evidence of surveillance?

LemmusLemmus (2012-05-03 23:26:42)

Seth, was the transcript found in Sarkozy's pockets? His home? His office? Seth: Feel free to ignore my Sarkozy speculation.

Phil (2012-05-10 21:26:57)

This thread seems long dead but I just read the blog entry. You say 'At one point a French journalist is given a transcript of a call that DSK made. How was this possible?' the journalist asked. The answer given is that by freakish coincidence "DSK's speaker phone was accidentally left on while his line was somehow connected to a French phone that was legally under surveillance." Why the speaker phone should matter is not explained.' Maybe I'm missing something but the possible explanation that jumps immediately to mind is that DSK left his speakerphone on, connected to a phone under surveillance, while he made a call on his cell phone or on another phone. This would of course let the surveillers (if that's a word) hear DSK's end of the conversation, or, if his other phone was also on speaker, would let them hear the whole thing. That part seems easy enough and quite plausible; for instance, I use my office phone for some calls and my cell phone for others (even when I'm in my office) so if I somehow were to leave my speakerphone on, this could happen to me. Or at least, it could happen to me if my speakerphone were connected to another phone that was under surveillance. But that's the part that seems wildly improbable. For this to have happened, DSK \_and\_ the party on the other line would have to have \_both\_ failed to hang up. Or at least I think that's the case. Maybe it isn't; maybe if the person on the other end hung up, but DSK didn't the connection would still exist? If so then this is at least plausible: if DSK fails to hang up his phone 1 % of the time, and the person on the other end is the same, then this is the difference between a 1 % chance and a 0.01 % chance.

## Drug Companies Release More Data From Drug Trials (2012-05-05 05:00)

Drug companies, in a few cases, have<sup>[1]</sup> recently started to release much more data from drug trials. Unsurprisingly, analysis of the new data by outsiders – people who have nothing to gain from positive results – has often contradicted the drug company analysis of the same data.

One example involves the flu drug Tamiflu. The new analysis suggested that "Tamiflu falls short of claims—not just that it ameliorates flu complications, but also that the drug reduces the transmission of influenza." Another example involved Prozac. The new analysis "ended up bucking much of the published literature on antidepressants. . . . [It]found no link between Prozac and suicide risk among children and young adults . . . Prozac appeared to be more effective in youth, and antidepressants far less efficacious in the elderly, than previously thought."

Another reason to believe in the value of this new data is the work of Lisa Bero at UCSF. She looked at the efficacy of nine drugs using unpublished FDA data. "Nineteen of the redone analyses showed a drug to be more efficacious, while 19 found a drug to be less efficacious. The one harm analysis that was reanalyzed showed more harm from the drug than had been reported."

I hope that the FDA will eventually require that all raw data from drug trials be publicly available as a condition of approval. (The same should also be true of journal articles, as a condition of publication.) It is abundantly clear that drug company analyses are often misleading – which harms the public.

## How to Beat the Heat: Wet T-Shirt Edition (2012-05-05 13:52)

It has gotten hot in Beijing. Two days ago it was 90 degrees. Yesterday it was 84. For my (2 or 3) Beijing readers: I discovered an incredibly easy way to cool off. Take a T-shirt, get it as wet as desired, put it on. Instant cool. No need for noisy fan or air conditioner. Surely this is widely known, but I didn't know it.

---

aelephant (2012-05-05 15:22:21)  
Extra points if you are an attractive co-ed.

Elizabeth Molin (2012-05-06 07:44:00)  
A friend told me years ago that in the pre-airconditioned South, on hot nights one went to bed in a wet bathing suit, the thicker the better, in order to be able to sleep.

Greg (2012-05-06 11:24:44)  
I visited Mexico in the summer and stayed in a hotel with nothing but cold brackish water on tap. I discovered that cold showers are wonderful in the heat and can keep you comfortable for a few hours.

me (2012-05-06 11:43:34)

Wouldn't this only work in dry environments? Seth: Well, Beijing is dry.

dearieme (2012-05-07 07:43:05)

But you must have known that standing in wet clothes on a cold day gets you very cold indeed? Seth: That has never happened to me. But, as you say, I could have passed a multiple-choice test about it.

## **The Umami Hypothesis: We Need to Eat Microbes (2012-05-05 22:38)**

I believe we need to eat plenty of microbes to be healthy, an idea I call the umami hypothesis. I have blogged about it [1]many times. Here is an overview of those posts.

1. Psychological. We like foods with sour, umami, and complex tastes/flavors. My evolutionary explanation: these preferences increased microbe intake, which increased health. Fermentation, which increases microbes, easily produces all three of these characteristics. They [2]are not easily produced otherwise (in the absence of lemon trees). As a result, until recently these three characteristics were correlated with the microbe content of food. For example, until recently, the more sour a food, the more microbes. Seeking out sourness caused us to eat foods with more microbes. It's easy to see this correlation today. As milk becomes yogurt, it becomes more sour and more microbe-rich at the same time. As juice becomes vinegar, same thing. [3]The Chinese character for sour connects it with fermentation. As meat ages, it gets a stronger umami flavor and becomes more microbe-rich. For example, [4]umami in dry-cured hams increases with time. Umami flavor is produced by glutamate molecules. They increase in concentration when proteins break down into components. Nowadays meat is aged because it tastes better aged than fresh. The flavor improvement with age presumably caused our ancestors to age their meat. Microbes add complexity to flavor because they produce many byproducts. Many experiments support the idea that our food preferences are a guide to what we should eat. [5]When children chose their own food, they turned out very healthy.

2. Food traditions. Fermented foods are found in huge variety in a wide range of culinary traditions. [6]Sour fish soup. [7]Aged cookie dough. This suggests they taste good for genetic reasons. [8]Animals appear to like fermented foods – more evidence that this preference has an ancient genetic basis rather than a recent cultural one. [9]Fermented oat husks. [10]Eskimos eat "rotten" fish.

3. Benefits of probiotics (experimental evidence). Many experiments have found that children or adults given probiotics fare better than a control group. [11]Irritable bowel syndrome (IBS). [12]Competitive cyclists – men benefited but women didn't. [13]Probiotics help Italian children with IBS. [14]Probiotics reduce ventilator-associated pneumonia. [15]Probiotics help preterm infants ward off necrotizing enterocolitis – reducing the death rate by more than half. [16]Cheese with added bacteria stimulated the immune system of elderly subjects. [17]A probiotic reduces sick days among employees of a large company. [18]Probiotics reduce diarrhea and C. difficile infection among hospital patients. [19]Probiotics prevented colds in children. [20]Probiotics reduce/prevent diarrhea caused by antibiotics.

4. Benefits of fermented food (experimental evidence). [21]An experiment found a big protective effect of Vitamin K2, which is found in much larger amounts in fermented foods than other foods. [22]An experiment found that fermented bean paste is more protective against cancer when it is fermented longer. [23]A review article about the anti-allergic effects of fermented foods. [24]A book about the benefits of fermented foods cites hundreds of experimental studies. [25]Fermented noni juice fights cancer in rats, apparently because it stimulated the immune system. [26]Benefits of natto.

5. Hormesis. Small amounts of many "poisons" – chemicals or radiation in large amounts will kill you – pro-

duce big health improvements, especially less cancer. The usual explanation is that the small amounts of poison activate repair systems. The benefits of probiotics are easy to understand if the microbes in fermented foods activate the immune system. [27]Introduction to radiation hormesis. [28]Small amounts of radiation activate DNA repair. [29]Moderate radon exposure associated with less lung cancer. [30]Mortality of atomic bomb survivors in Hiroshima and Nagasaki. [31]The Baltimore shipyard study. [32]The implausibility of hormesis and more examples. [33]Reviews of the vast evidence.

6. Bad effects of antibiotics. Fermented foods add microbes inside the body, antibiotics reduce them. [34]Antibiotic use associated with higher risk of later infection. [35]Mosquitos made microbe-free via antibiotics are more susceptible to infection than untreated mosquitos.

7. The Hygiene Hypothesis. The hygiene hypothesis is that exposure to dirt in childhood reduces childhood asthma and allergies. The author's original idea was that the dirt caused infections. That didn't seem to be true but many studies have found that living on a farm and similar experiences reduce childhood asthma and allergies. This supports the general idea that exposure to microbes improves immune function. [36]Asthma and farm life. [37]Maternal exposure to farms helps babies. [38]Less allergic disorders among children in a polluted German city than in a clean one. [39]Benefits from biodiversity around the house where you grow up. [40]Review of the hygiene hypothesis. [41]What was wrong with the original proposal.

8. Epidemiology. Many studies have found that people who eat specific fermented foods are healthier.[42] Benefits of moderate drinking. [43]Yogurt consumption associated with less allergies in Japanese schoolchildren. [44]The later in life your family gets a refrigerator, the lower your chances of getting Crohn's disease. Refrigeration reduces microbial growth.

9. N=1. Cases in which fermented foods improved one person's health. [45]Kombucha. [46]Do fermented foods shorten colds? [47]High-dose probiotic, but not several fermented foods, eliminated exercise-induced asthma. [48]Kombucha eliminated heartburn. [49]Probiotics cure extreme coughing fits in a young girl. [50]Kefir improves digestion disrupted by antibiotics. [51]Yogurt apparently reduces how long colds last. [52]Yogurt reduces seasonal allergies. [53]A four-year-old gets sick less often after she starts eating more yogurt. [54]After eating lots of yogurt and acidophilus pearls, sinus congestion greatly reduced. [55]Soon after a big increase in fermented food and probiotic consumption, sinus congestion went down 90 %. [56]Kombucha improves bee health. [57]Acid reflux cured by kombucha. [58]Stonyfield yogurt employee gets sick less often, maybe because she is eating much more yogurt. [59]Professor of immunology starts taking probiotic and yogurt, stops needing asthma inhaler.

10. Unusual remedies. Several unusual remedies produce effects inside the body similar or identical to the effects of fermented foods. [60]Bee stings. [61]Hookworm infection (also [62]here). [63]After parasites greatly reduced on a remote island, allergies greatly increase.

11. The importance of gut bacteria. They must come from outside – our bodies do not make them. [64]They protect us against disease. [65]Japanese but not Americans have gut bacteria that digest seaweed. [66]Babies with diaper rash had less diverse fecal bacteria than babies without diaper rash. William Parker, a professor of medicine, has proposed that [67]the evolutionary reason for our appendix is that to allows quick repopulation of gut bacteria when they are lost due to diarrhea.

12. Miscellaneous. [68]High fermented-food consumption in Japan, the healthiest country in the world. [69]Japanese men who smoke have considerably less lung cancer than American men who smoke the same amount. [70]Filthy socks smell like kimchi, in spite of vastly different bacteria, suggesting the existence of a detection system that lumps different bacteria together. [71]Benefits of bacteria found in soil. [72]The value of readiness in another domain (military). [73]The health benefits of smoking. [74]Bacteria-free mice have malfunctioning immune systems. [75]Irradiated food (irradiated enough to kill microbes) makes cats sick. [76]Wild mice with more parasites have

better functioning immune systems. Analogy with pagophagia (ice chewing).

Disagreement with my view includes the following. To prevent asthma you should avoid all triggers, [77]says one group. [78]Health claims for probiotics were dismissed by scientists at the European Food Safety Agency. A UCLA professor of medicine who specializes in infectious disease [79]says we "will have to" produce more antibiotics to reduce infectious disease. [80]According to one writer, all "modern sane eating guidelines" say "fresh is better".

Seth's Blog » Blog Archive » Does Bedtime Honey Improve Sleep? Nine Reasons to Think So (2013-11-25 07:03:01)

[...] wondering why we like sour, umami and complex flavors was the first thing to suggest to me that we need to eat plenty of fermented food to be healthy. Many facts later, I'm sure this is true. Finally, evolutionary reasoning has helped me find [...]

## Climate Science Humor: What if Your Model Predicts Wrongly (2012-05-06 05:00)

After noting that James Hansen's 1988 climate model predicted too much warming in the subsequent 22 years, [1]someone [2]at Skeptical Science concluded:

The main reason Hansen's 1988 warming projections were too high is that he used a climate model with a high climate sensitivity, and his results are actually evidence that the true climate sensitivity parameter is within the range accepted by the IPCC.

There is no consideration of the possibilities that (a) one or more other parameters were wrong or (b) the model – aside from parameter values – is wrong (e.g., it oversimplifies). Surely you are joking, Mr. Skeptical Science.

Thanks to Phil Price.

1. <http://www.skepticalscience.com/Hansen-1988-prediction.htm>

2. <http://www.skepticalscience.com/Hansen-1988-prediction.htm>

---

Tom Fid (2012-05-07 13:34:27)

Climate sensitivity is sometimes a parameter in simple energy balance models, like the Schneider-Thompson model later used by Nordhaus. But in GCMs, as used in Hansen's work, climate sensitivity is an emergent property of other structure and parameters. So, stating that the model's sensitivity was too high (as I recall, by about 1/3) subsumes both (a) and (b). Seth: Interesting. Not so much "subsumes" but "is an example of" both (a) and (b). Then I would ask: what about other examples? Why are they not considered as possible explanations for the wrong predictions?

Phil (2012-05-09 07:01:30)

I can't comment on the technical content of the Skeptical Science post — I haven't even looked at Hansen's model — but I have to say that you are mis-characterizing the post. The post says "Unfortunately, Dr. Christy decided not to investigate why the NASA climate model was too sensitive, or what that tells us. There are two main reasons for Hansen's warming overestimates..." Obviously implicit in this statement is "Dr. Christy decided not to investigate...but I did." You may be right that the guy didn't consider that there are other possibilities, but you certainly can't conclude that from what he says here! Seth: I also read the other answers (intermediate and advanced levels) to the question/objection. When a complex model with many assumptions predicts incorrectly, it is close to impossible to figure out why because there are so many possibilities. The Skeptical Science author says nothing about the difficulty. The reasoning seems to be: if we adjust Parameter X, the prediction becomes accurate, therefore the reason the model predicted incorrectly was that Parameter X was given the wrong value. If we could estimate Parameter X entirely independently, this would make sense but nothing is said about that and that too is very hard. To me it looks like there are two possibilities: (a) although the Skeptical Science writer wants to impress readers with the quality of climate science, an enormous and enormously careful and highly unusual and very important effort by climate scientists – figuring out why Hansen's model was wrong – goes unmentioned or (b) the writer is overstating what is known.

Phil (2012-05-09 14:42:43)

Seth, I think you're missing Tom Fid's point. The climate sensitivity is not an input parameter to the model; it's an outcome that is determined from the model. Seth: When you put it like that, the Skeptical Scientist answer sounds circular. "Why is the room too hot?" "Because it got too warm." "Why was the predicted warming too much?" "Because a measure of output closely correlated with amount of predicted warming was too low." I do not disagree with you, however.

Phil (2012-05-09 23:24:26)

It's not circular. Suppose we agree that Hansen predicted more warming than actually occurred. There are three ways that could happen: 1. Emissions were higher than predicted, but climate sensitivity to those emissions was much lower than predicted. 2. Emissions were about the same as predicted, but climate sensitivity was lower than predicted. 3. Emissions were lower than predicted, but climate sensitivity was about right or was slightly higher than predicted. Of course you could make finer distinctions — "much much lower," "very slightly higher," etc. — but these are the coarse ones. Any of those three possibilities would lead to less warming than predicted. Global warming skeptics assume the answer is 1 or 2. The Skeptical Science guy is claiming to have looked into it and found the answer is 3. It's not circular.

Phil (2012-05-09 23:25:01)

Note that I have not looked into it and \_I\_ am not making any claims here. I'm just explaining that you have mischaracterized the Skeptical Science blog post.

## How Common Are Medical Errors? A Horror Story (2012-05-07 05:00)

[1]In this post a contract artist who calls himself Wolverine gives a long list of life-threatening medical errors that happened to him. I hope that he will eventually add dates so that the rate of error becomes clearer [more: all the errors happened within a 14-month period] but even without them the stories suggest that life-threatening errors are common. (As does the effectiveness of surgical checklists.) Medicine is a job where if you make a mistake only the customer suffers not you. Surely this is why the error rate is so high. Wolverine was operated on by a surgeon who, because of a fatal error, had lost his license to practice in California. He changed states, was hired again, and made the same error on Wolverine.

I learned about this from [2]Tucker Goodrich, who has been corresponding with the author and told me something remarkable:

He's eating a paleo with raw milk diet. The other transplant patients he knows are all eating the modern American diet and dying of infections; he's been infection-free for two years.

1. <http://roarofwolverine.com/archives/3019>

2. <http://yelling-stop.blogspot.com/>

---

BlueMorrissey (2012-05-07 07:55:46)

I had a surgeon who lost his license in one state for stealing drugs from the hospital and taking them himself. He moved to my state and performed surgery on me. It was botched, and a few weeks later he was arrested for writing prescriptions to friends and taking the drugs himself. His license was suspended for a short time and he is still in this state practicing. I had to have another surgery. The problem was then fixed. I would say the medical doctor lobby is strong.

WeeMike (2012-05-07 08:14:45)

I'd say that drinking raw milk may well have saved his life several times. The natural good bacteria in raw milk is vastly underrated when it comes to its health giving properties to us humans. I can add that having consumed it for several years now I have yet to have any kind of cold/flu or infection from cuts etc. Before that I would have a yearly or twice yearly bout of cold/flu, and yes this is the only thing that has changed in my diet.

Mitra (2012-05-07 16:26:04)

Hi Seth, I was wondering whether I can ask you an unrelated question! I know you said that eating breakfast sometimes causes early awakening as it did in your case. Would this apply to a cup of tea with a handful of nuts - like if I take that some time after waking but skip any other food till lunch? I am trying to experiment with this (following your method!), but would be glad to know your opinion/experience. Seth: I think early awakening can be caused by any calorie source. That includes nuts but not tea if you have it without cream or sugar.

Buffet Infantil Brinque Abrace (2012-05-08 14:22:13)

Apparently the problem is global, because in Brazil the same or worse. Announced this week on TV Globo, a fake doctor who did care within a hospital, but before his arrest held several consultations as a doctor, an absurdity, and medical error is not uncommon these days.

Lisa Wainer (2012-05-09 07:53:09)

The story above is really a horror story. I always joke that I have been nearly killed three times by medical professionals. These incidences were similar in nature (but not scope). The first time was when a doctor I had never seen before tried to discharge me ( I had already been given pain medication so was a bit out of it) before I had an xray that subsequently showed a bowel obstruction. Second time was a nurse who tried to give the incorrect dose of steroid medication. Had to fight to get the correct dosage. Third time was when a consultant wanted to do a camera endoscopy on me, despite my insistence that I had a history of obstructive disease and narrowing of the intestine and that this investigation was contraindicated in my condition (confirmed later by his superior). I refused to have the investigation. It is exhausting trying to get the appropriate care - but if you have to interact with the medical profession, it is wise, as the author says, to have someone there to advocate for you. Thankfully I was in a position to fight for myself, but only because I understood what I was being treated for and had educated myself about my condition both through my own research and constantly pestering the doctors for information. Curiosity did not kill this cat.

alphagruis (2012-05-14 11:30:49)

I agree heartedly with the above comment. It is of utmost importance to make every necessary effort to understand your condition and constantly pestering the doctors for reliable information. There are some nice outstanding doctors. Take the time to find them. I had parathyroid disease and for those who have similar condition here is a team of surgeons who did revolutionize the cure of it and do really the best job in the interest of their patients. <http://www.parathyroid.com>

## **Beijing Quantified Self? (2012-05-07 13:58)**

I recently had lunch with Richard Sprague, an engineer at Microsoft Beijing. He raised the possibility of starting a Quantified Self Meetup group in Beijing. The meetings could be held in one of Microsoft's two brand new buildings, which are in the exact center of Zhongguancun. If you might attend, please let me know (e.g., by commenting on this post).

---

Li Jie (2012-05-12 01:41:39)

I'm up for it! Will be in Beijing over the next week or two and will be interested in finding out more!

Xiaoyu (2012-05-13 21:59:11)

I hope this isn't too late. I would be interested in attending.

## **What Koreans Know About China That Many Chinese Don't Know (2012-05-08 05:00)**

Everyone knows that Chinese media is heavily censored. I recently learned from my Chinese tutor, who is from Korea, that the South Korean media delights in spreading China-is-scary-and-weird stories, which tend to be censored in China. Here are examples:

1. A frozen dumpling made in China contained part of a cigarette. Someone took a picture and posted it. Someone from Korea noticed before it was censored. News of this spread all over South Korea.
2. Someone in China took a picture of the Yangtze River in Jiangsu Province full of pill containers (e.g., blue/green capsules) floating on the surface. Censored in China, the picture was publicized widely in South Korea. I saw it on my teacher's cell phone.

Along similar lines, on May 2, a Korean journalist reported that she secretly entered a factory where medical pills were being made and found that among the ingredients were human baby parts. It sounds impossible, yes, but that is what was reported. (I wrote this several days ago, [1]I should have posted it sooner.)

"I never take Chinese medicines," said my teacher. I asked her why the Korean media like these stories so much. "They show that something impossible is happening in China," she said.

1. <http://www.dailymail.co.uk/news/article-2140702/South-Korea-customs-officials-thousands-pills-filled-powdered-human-baby-flesh.html>

---

peter (2012-05-08 16:56:50)

whatever the credibility problems of China, the South Koreans seem to have a penchant for lying to make themselves look good. From Wiki "Hwang Woo-suk (Korean: 황우석, born January 29, 1953)[1] is a South Korean veterinarian and researcher. He was a professor of theriogenology and biotechnology at Seoul National University (dismissed on March 20, 2006) who became infamous for fabricating a series of experiments, which appeared in high-profile journals, in the field of stem cell research." In addition, as i recall they were sore losers at the Olympics. the story about human baby parts sounds like pure bullsh\*t. The other 2 examples are plausible. Seth: I don't think the "baby pill" story makes South Koreans – in particular the journalists who reported it – look good. Rather, it makes Chinese look bad.

Txomin (2012-05-08 17:09:34)

Now, now, Peter, individuals like that can be found in any country.

peter (2012-05-08 17:44:40)

although, [http://www.dailymail.co.uk/news/article-2140702/South-Korea-customs-officials -thousands-pills-filled-powdered-human-baby-flesh.html](http://www.dailymail.co.uk/news/article-2140702/South-Korea-customs-officials--thousands-pills-filled-powdered-human-baby-flesh.html) #ixzz1uDZvdZaW reports baby flesh pill reported by a UK paper. Txomin: i agree

Sam Reeves (2012-05-09 04:28:23)

I'm not sure if the following article is the one you are referring to or not, but it's pretty similar. Although it's not the Yangtze river. <http://www.chinasmack.com/2012/pictures/rainbow-river-unused-medicine-capsules-dumped-in-henan-ditch.html> But this story is available for viewing in China, having said that it's not in Chinese, but was translated from the original story that was in Chinese. Seth: Thanks. I was told the story was censored in China...that doesn't mean it was entirely censored, but what you link to raises the possibility that it wasn't censored at all.

Alex Chernavsky (2012-05-10 11:09:22)

I'm puzzled by these stories of Chinese "medicines" being made from ground-up fetuses, or rhino horns, or bear bile, or some such crazy thing. Why don't the manufacturers just use fake ingredients? Who would ever know? Plus, it's a lot cheaper. God only knows how much real rhino horns cost these days.

Allen K. (2012-05-10 08:51:43)

"On measuring the males, they found that the testicles of the yogurt consumers were about 5 percent heavier than those of mice fed typical diets alone and around 15 percent heavier than those of junk-eating males." That last adjective is ill-chosen.

Alrenous (2012-05-10 20:10:35)

Well, I was definitely wrong about priming, thanks. Even if Bargh's counter-arguments are sound, I didn't think about it enough. All those criticisms are ones I could have made, but didn't. Moreover, Bargh seems to care more about being responsible for new tech than getting the right answer, presumably for the status benefits. Which means that odds are favour of Doyen and Pashler. Especially Pashler, who actually founded a desperately needed resource in his psychfiledrawer.com site. Standard journals seem to aggressively avoid replications, which means someone needs to even more aggressively pursue them for our culture to even pretend to have a working scientific tradition.

jazi Zilber (2012-05-26 11:59:18)

That priming studies are extremely sensitive is evident to anyone following this literature. It is still about drawing attention and making a really efficient but unnoticed manipulation. Thus, replications that have not done it "all right" are a priori expected to fail. Researchers that do not believe in the effect, are naturally expected to be the most careful to optimize priming effect. The main focus of the media (the "failed replication" of old walking slowly) is a priori faulty. Using 30 out of 30 words for priming is not only a "no go" for priming, but shows that the researchers had poor knowledge of how priming works. Making us expect less than perfect design in other uncontested aspects. True, Bargh's response was not wise in many ways. But at the moment the PLoS paper is no "failed replication".

jazi Zilber (2012-05-26 13:21:41)

typos. second sentence should read: researchers that do not believe in the effect, are naturally not expected to be the most careful to optimize priming effect.

## **A Beijing Bystander Inaction Story (2012-05-10 05:00)**

Long after the famous [1] Kitty Genovese story – supposedly many people watched her being murdered without doing anything – doubt was cast on its accuracy. In the meantime, John Darley and Bibb Latane, two professors of psychology, it as the starting point for a series of experiments on what they called [2] the bystander effect – the more bystanders, the less likely that each one will help. They concluded there was "diffusion of responsibility" – the more people that witness something, the less each witness feels responsible for doing something.

In China the problem is much worse. A few years ago a woman was hit by a car. A second car stopped to help her. The woman told the police that the second driver had hit her. The second driver was furious, gave many interviews, and eventually a witness was found who said it was the driver, not the injured woman, who was telling the truth. Someone I spoke to attributed her behavior to the need to pay hospital bills. The driver who hit her would never be caught, she reasoned. Maybe the second driver could be forced to pay.

My Chinese tutor, who is Korean, told me a story that illustrates the depth of Chinese bystander inaction and suggests another reason for it. A friend of hers was visiting from Korea. When this friend was in Wangjing (in the Chaoyang district of Beijing), she saw a person lying on a busy street, bleeding but still alive. Apparently the bleeding person had been hit by a car. Three hours later, the friend returned – and the accident victim was still there! Now dead. So, with difficulty – she doesn't speak Chinese – she called the police.

The police treated her as a suspect. She was forced to come to the police station five times, for hours each time.

What a deterrent to calling the police! I cannot believe the police were so stupid as to consider a Korean tourist

on foot who calls the police a serious suspect in the death of someone lying in the middle of traffic. I believe that by causing her a lot of trouble, they wanted to send a message: Leave us alone. The fewer calls they get, the less work they have to do. No wonder everyone ignored the bleeding victim.

"I am afraid I am scaring you," said my Chinese teacher. "You are," I said.

Tom (2012-05-10 09:38:18)

I'd be scared to post from inside China.

Bryan (2012-05-10 10:20:48)

I forwarded this to a friend who knows someone living in China. She said he told her "literally dozens of stories like this."

Patti (2012-05-11 05:38:53)

That is very disturbing information, but on an intuitive level makes sense. When a population is that large with economic/social growing pains it seems right that caring about your fellow citizen would be a low priority.

### **"How Ignorant Doctors Kill Patients" (2012-05-11 05:00)**

I have already linked to [1]this 2004 article ("How Ignorant Doctors Kill Patients") by [2]Russell Blaylock, a neurosurgeon, but after rereading think it deserves a second link and extended quotation.

I recently spoke to a large group concerning the harmful effects of glutamate, explaining it is now known that glutamate, as added to foods, significantly accelerates the growth and spread of cancers. I [rhetorically] asked the crowd when was the last time an oncologist told his or her patient to avoid MSG or foods high in glutamate. The answer, I said, was never.

After the talk, a crowd gathered to ask more questions. Suddenly I was interrupted by a young woman who identified herself as a radiation oncologist. She angrily stated, "I really took offense to your comment about oncologists not telling their patients about glutamate."

I turned to her and asked, "Well, do you tell your patients to avoid glutamate?" She looked puzzled and said, "No one told us to." I asked her who this person or persons were whose job it was to provide her with this information. I then reminded her that I obtained this information from her oncology journals. Did she not read her own journals?

Yet, this is the attitude of the modern doctor. An elitist group is in charge of disseminating all the information physicians are to know. If they do not tell them, then, in their way of thinking, the information was of no value.

The incentive structure of modern medicine in action. If you do harm, you are not punished – thus [3]the high error rate. If you do good, you are not rewarded – so why bother to think ("no one told us")? The similarity to pre-1980 Chinese communism, where it didn't matter if you were a good farmer or a bad farmer, is obvious. It is a big step forward that the rest of us can now search the medical literature and see the evidence for ourselves.

---

Alex Chernavsky (2012-05-11 06:33:22)

How does the evidence against glutamate compare with the evidence against all the other myriad foods / substances / lifestyle choices that have been implicated as risk factors in cancer?

JPB (2012-05-11 06:52:49)

Wow! Exactly why I avoid doctors as much as possible. I think the medical establishment contributed to my father's death last August. He was also a physician and blindly trusted his doctors advice! We also experienced the stone walling, lack of coordination of care and following of protocols without thinking.

Sam (2012-05-11 12:54:05)

I absolutely agree that modern medicine needs to change, and I'm a huge fan of your blog. Fermented food has made me healthier, and flaxseed oil has helped my gums. However, I have to point out that Dr. Blaylock is a member of the Association of American Physicians and Surgeons, a primarily political organization that publishes "peer-reviewed" research claiming HIV doesn't cause AIDS and Obama is a hypnotist (seriously). Their journal barely contains any scientific articles, just essays about how Obamacare is a communist menace, and what to do when the FBI raids your practice (again, seriously). They also published that study you posted a couple years ago showing that autism rates were falling due to the removal of mercury from vaccines, which relied on questionable data and some eyebrow-raising outliers. And of course we know that autism rates have not fallen - they continue to rise: <http://articles.latimes.com/2012/mar/30/local/la-me-0330-autism-rates-20120330> And just for fun, here's "A Doctors' Wives' Survival Guide, or What To Do When the FBI Knocks at the Door" <http://www.jpands.org/vol16no3/orient.pdf>

KenF (2012-05-12 06:59:56)

If "glutamate, as added to foods, significantly accelerates the growth and spread of cancers" Japanese people would be dropping like flies.

- [1]Probiotics reduce/prevent diarrhea caused by antibiotics. [2]News article. The abstract says "The pooled evidence suggests that probiotics are associated with a reduction in AAD [antibiotic associated diarrhea]." It should say that the evidence suggests – very strongly, in fact – that probiotics cause a reduction in AAD (because

there is no plausible alternative explanation of the association). This mistake is so elementary it is like saying  $2 + 2 = 3$ . And JAMA is one of the world's most prestigious medical journals.

- [3]Living without money. The author was much healthier than when he lived with money. Among the many possible explanations is that dumpster food, old enough to allow microbes to grow on it, is healthier than fresher and therefore more sterile food.
- [4]Not just farms. Children who grow up on farms have fewer allergies and less asthma than children who grow up in cities – important support for a modified version of the hygiene hypothesis (and [5]my umami hypothesis). This study finds that living near other sorts of biodiversity provides similar benefits.

Tim Beneke (2012-05-12 10:07:49)

A naive question: I understand that consuming a lot of dairy is associated with constipation. Mostly, there was a reliance on lactobacillus in the studies that were covered here. What is the connection between the constipation associated with dairy, the reduced diarrhea, and the lactobacillus – if any? Seth: Lactobacillus reduce diarrhea because they push out the bad diarrhea-causing bacteria. I suppose they do a better job digesting your food. I don't know why dairy causes constipation.

Alex Chernavsky (2012-05-12 11:14:26)

With regard to living without money – see also this excellent essay by Lars Eighner, a writer who spent several years being homeless: "[1]On Dumpster Diving"

Jenny (2012-05-14 16:00:54)

Probiotics also prevent diarrhea in coeliacs, caused by gluten. I, a coeliac, always take probiotics, my daughter - also coeliac - usually forgets to. We have, on occasion been 'glutenated' at the same events, and I always react 'better', ie am less affected than her. The gluten doesn't just cause food poisoning symptoms - more seriously it causes brain fog or concentration problems. The probiotics protect me from the brain fog too. (I use lactobacillus and saccharomyces boulardii.) I believe other coeliacs find this too.

## Umami Hypothesis Page (2012-05-13 05:00)

[1]Here is a summary/directory of my posts about what I call the umami hypothesis – the idea that we must ingest plenty of microbes to be healthy. My [2]Watts Towers. The easiest way to ingest plenty of microbes is to eat fermented foods.

## Vitamin K2 Deficiency Linked To Parkinson's Disease (2012-05-14 05:00)

Parkinson's disease often runs in families and [1]some of the genes responsible have been identified. One is called PINK1. [2]A new fruit fly model uses fruit flies with a similar genetic defect.

Patrik Verstreken and his team used fruitflies with a genetic defect in PINK1 or Parkin that is similar to the one associated with Parkinson's. They found that the flies with a PINK1 or Parkin mutation lost their ability to fly.

Upon closer examination, they discovered that the mitochondria in these flies were defective, just as in Parkinson's patients. Because of this they generated less intracellular energy – energy the insects needed to fly. When the flies were given vitamin K2, the energy production in their mitochondria was restored and the insects' ability to fly improved. The researchers were also able to determine that the energy production was restored because the vitamin K2 had improved electron transport in the mitochondria. This in turn led to improved energy production.

The obvious conclusion is that some Parkinson's patients may benefit from eating more Vitamin K2. Less obvious and less certain is that our diets contained more K2 in the past (so that the various genes that now cause Parkinson's were rendered harmless). Warren Buffet [3]famously said about risk exposure: "It's only when the tide goes out that you learn who's been swimming naked". Likewise, changes in diet (such as reduction in K2 intake) expose disease-causing genes. I have made this point [4]several times. It is counter-intuitive that disease-gene linkages suggest bad environmental changes.

Tom Passin (2012-05-14 06:03:36)

And the same for (other) essential nutrients that we don't make for ourselves, like Vitamin C, I think. If our bodies can't make it, our ancestors must have been able to get enough of it routinely.

Nancy Lebovitz (2012-05-14 18:33:19)

Have you looked into [1]Terry Wahls' recommendations? She's a doctor with MS who did her own research, developed a mitochondria-supporting diet (at least, that's the theory), and restored her health. I'm bringing this up because vitamin K2 is present in cabbage and such, and Wahls' diet is heavy on veggies, specifically including cruciferous vegetables. Seth: I've heard about her findings, yes. But hadn't made the connection with K2.

Darrin Thompson (2012-05-16 06:05:09)

Anyone know \_which \_ plants contain inositol hexaphosphate? And also, a little googling pulled up this: [http://en.wikipedia.org/wiki/Phytic\\_acid](http://en.wikipedia.org/wiki/Phytic_acid) Is IP(6) closely related to phytic acid? Phytic acid is supposedly one of the big problem chemicals in grains. My brane asplode.

Tomas (2012-05-16 06:18:33)

Well, it IS phytic acid. I guess the effect on cancer are due to its iron chelating capabilities. It also binds other minerals. Why not just avoid iron then, which makes more sense. The supposed cancer-fighting capabilities are the main argument of the proponents of whole grains - I think this article puts the whole topic into perspective <http://anthonycolpo.com/?p=852>

Nancy Lebovitz (2012-05-16 09:13:53)

[1]Mirepoix is a surprisingly high umami food- it's just two parts onion, 1 part carrot, 1 part celery, chopped up and pan-fried at a low to moderate heat. It's much more savory than its components.

## Surprising Predictions From Self-Measurement (2012-05-17 03:50)

Patrick Tucker, an editor at The Futurist,[1] posted a request on the Quantified Self Forums for "astounding" predictions based on self-quantification. He is writing a book about using data to make predictions.

Here are examples from my self-measurement:

1. Drinking sugar water causes weight loss. The self-quantification was measuring my weight. It began when I found a new way to lose weight, which pushed me to try to explain why it worked. The explanation I came up with – a new theory of weight control – made two predictions that via self-experimentation I found to be true. That gave me faith in the theory. Then the theory suggested a really surprising conclusion, that loss of appetite during a trip to Paris was due to the sugar-sweetened soft drinks I had been drinking. If so, drinking sugar water should cause weight loss. (The nearly-universal belief is that sugar causes weight gain, of course.) [2]I tested this prediction and it was true. [3]More.
2. Seeing faces in the morning improves mood the next day (but not the same day). This is so surprising I'll spell it out: Seeing faces Monday morning improves my mood on Tuesday but not Monday. For years I measured my sleep trying to reduce early awakening. Finally I figured out that [4]not eating breakfast helped. There was no breakfast during the Stone Age; this led me to take seriously the idea that other non-Stone-Age aspects of my life were also hurting my sleep. That was one reason I decided to watch a certain TV show one morning. It had no immediate effect. However, the next morning I woke up feeling great. Via self-measurement of mood, I determined it was the faces on TV that produced the effect, confirmed the effect many times, and learned what details of the situation (e.g., face size) controlled the effect. [5]More.
3. One-legged standing improves sleep. Via self-measurement I determined that [6]how much I stood during a day controlled how well I slept. If I stood a long time, I slept better. Ten years later I woke one day after having slept much better than usual. The previous day had been unusual in many ways. One of them was so tiny that at first I overlooked it: I had stood on one leg a few times. Just for a few minutes. Yet [7]it turned out that it was the one-legged standing that had improved my sleep. Without the previous work on ordinary standing I would have ignored the one-legged standing – it seemed trivial.
4. Butter is healthy. I found that [8]butter improved how fast I can do arithmetic problems. No doubt it improves brain function measured in other ways. Because the optimum nutrition for the brain will be close to the optimum nutrition for the rest of the body – at least, this is what I believe – I predict that butter will turn out to be healthy for my whole body, not just my brain.
5. Mainstream Vitamin D research is all messed up. Via self-measurement I confirmed Tara Grant's conclusion that taking Vitamin D3 in the morning (rather than later) improved her sleep. [9]It improved my sleep, too. When I had taken it at other times of day I had noticed nothing. Apparently the timing of Vitamin D – the time of day that you take it – matters enormously. Take it at the right time in the morning: obvious good effect. Take it late in the evening: obvious bad effect. Vitamin D researchers haven't realized this. They have neither controlled when Vitamin D is taken (in experiments) nor measured when it is taken (in surveys). Because timing matters so much it is as if they have done their research failing to control or measure dose. If you fail to control/measure dose, whatever conclusion you reach (good/no effect/bad) depends entirely on what dose your subjects happened to take. And you have no idea what dose that is.

SpiceGuy (2012-05-20 18:07:58)

Its nice to know that ginger has effective anti-cancer benefits. How do I make use of it? How does obtain or consume 100mg/kg body weight of whole ginger extract from a ginger root I bought at the grocery store?

## The Next Time a Top Economist Predicts Disaster... (2012-05-19 05:00)

Shortly before Obama took office, [1]many American banks, including the largest ones, were given a huge amount of money by the Federal government ("bailed out"). Why? Because Secretary of the Treasury Henry Paulson, Chairman of the Federal Reserve Ben Bernanke and other economists (not necessarily independent of Paulson and Bernanke) predicted a second Great Depression if they weren't. I didn't believe Paulson et al. – their track records of prediction were terrible. They hadn't foreseen the crisis. Why should I think they knew how to fix it? I believed their predictions of disaster were too confident.

At the time I didn't know [2]this bit of history:

The blood-curdling threats [now] being issued by Eurocrats should sound familiar to British readers. We went through precisely the same experience 20 years ago, when we were stuck with an over-valued exchange rate in the Exchange Rate Mechanism.

As in Greece, our leaders – all the main parties, the CBI, the TUC, the Bank of England – assured us that leaving the ERM would be disastrous. On September 11, 1992, John Major solemnly told us that withdrawal was 'the soft option, the inflationary option, the devaluer's option, a betrayal of our country's future'.

Four days later, we left the system, and our recovery began immediately. Inflation, interest rates and unemployment started falling, and we enjoyed 15 years of unbroken growth

Those who don't know the past are doomed to over-trust experts.

1. [http://en.wikipedia.org/wiki/Emergency\\_Economic\\_Stabilization\\_Act\\_of\\_2008](http://en.wikipedia.org/wiki/Emergency_Economic_Stabilization_Act_of_2008)

2. <http://www.dailymail.co.uk/news/article-2145139/Cameron-calls-eurozone-action-experts-warn-Britain-faces-depression-lasting-DECADE.html>

---

Anand Srivastava (2012-05-20 04:19:08)

Actually if they did not bail out the banks very rich people would have lost a lot of money. Yeah the middle class gets the shaft either way. But this way they lose more than they would have lost without the bail. The largest banks would have crashed, wouldn't that cause a depression. Bailing them out just postponed the problem. The USG is spending too much, and they have been spending a lot for a long time. China has been supporting their spending by mopping up all that excess USDs. Now that China is going into deficit, ie not mopping excess USDs anymore, how will USG pay for its deficit. Will some other entity mop up the excess? Or will the excess USDs be flooding the local market trying to prop up USG's lifestyle. Where will those excess USDs go? Will they cause inflation? If you look at the US's Trade Deficit, if it cannot be reduced very soon, it's a ticking bomb. It will explode and it will take down USD with it. Will USG reduce its expenditure? The interesting thing is that currently the Trade Deficit is completely due to the Budget Deficit, ie created by USG. When Inflation arrives, USG will print more money to continue to have the same budget in real terms, devaluing USDs further. It's not for fun that BRICS countries are making agreements for using local currencies for trade. And China and Russia are doing it with as many countries as possible. The end of the IMF system is near, you can choose to ignore it.

Lothario (2012-06-05 11:26:52)

You should research Austrian Economics from the likes of Ludwig Von Mises, Henry Hazlitt, and Murray Rothbard. The school of economic thought has an incredible track record of prediction, and explanation of all economic events based on praxeology - the study of human action. It was supplanted by the current and quite opposite Keynesian Economic method of thinking without ever being disproved for one very specific reason - Austrian Economics posits that the key to society wide wealth creation is savings, which means everything the government does from taxation to bailouts is extremely deleterious to the wealth of a nation and in direct conflict to the Austrian School of thinking. The Keynesian School of thinking teaches that spending is the key to generating society wide wealth creation, and with this thinking, the government is given the green light to tax, spend, bailout, or whatever else they can do to increase private or public spending. For this reason, the curriculum of government schools have adopted the Keynesian method of thinking. The only problem is that the Keynesian School of thought has failed miserably, over and over again, both in predictions and results, and yet the government maintains the tagline, "well we stopped it from getting even worse," and no one is the wiser because no one is taught Austrian Economics. An essay written by Murray Rothbard in the 60's I believe, titled 'Depressions, Their Cause and Cure,' explains exactly why our current 2008 recession occurred, and why not only did the government's not actually fix any of the underlying problems, but in fact has set the stage for a cataclysmic depression that must result now to purge the system of the endless malinvestment that resulted from manipulated, non-market established interest rates, etc. Brace yourself ^^

### **Usual Drug Trial Analyses Insensitive to Rare Improvement (2012-05-20 05:00)**

In [1]a comment on an article in The Scientist, someone tells a story with profound implications:

I participated in 1992 NCI SWOG 9005 Phase 3 [clinical trial of] Mifepristone for recurrent meningioma. The drug put my tumor in remission when it regrew post surgery. However, other more despairing patients had already been grossly weakened by multiple brain surgeries and prior standard brain radiation therapy which had failed them before they joined the trial. They were really not as young, healthy and strong as I was when I decided to volunteer for a "state of the art" drug therapy upon my first recurrence. . . . I could not get the names of the anonymous members of the Data and Safety Monitoring committee who closed the trial as "no more effective than placebo". I had flunked the placebo the first year and my tumor did not grow for the next three years I was allowed to take the real drug. I finally managed to get FDA approval to take the drug again in Feb 2005 and my condition has remained stable ever since according to my MRIS.

Apparently the drug did not work for most participants in the trial - leading to the conclusion "no more effective than placebo" - but it did work for him.

The statistical tests used to decide if a drug works are not sensitive to this sort of thing - most patients not helped, a few patients helped. (Existing tests, such as the t test, work best with normality of both groups, treatment and placebo, whereas this outcome produces non-normality of the treatment group, which reduces test sensitivity.) It is quite possible to construct analyses that would be more sensitive to this than existing tests, but this has not been done. It is quite possible to run a study that produces for each patient a p value for the null hypothesis of no effect (a number that helps you decide if that particular patient has been helped) but this too has not been done.

Since these new analyses would benefit drug companies, their absence is curious.

1. [http://the-scientist.com/2012/05/01/data-diving/#disqus\\_thread](http://the-scientist.com/2012/05/01/data-diving/#disqus_thread)

---

Thomas Wunderlin (2012-05-20 06:52:50)

Negative individual outcomes in clinical trials with generally positive results are, of course, the other side of the coin.

Alex Chernavsky (2012-05-20 07:45:10)

I have to say that I find statistics to be very confusing, both in the abstract and the concrete. I'm currently reading, *The Theory That Would Not Die: How Bayes' Rule Cracked the Enigma Code, Hunted Down Russian Submarines, and Emerged Triumphant from Two Centuries of Controversy*, and I can't make sense of why, exactly, there was so much controversy over Bayes' Rule. I feel like I'm missing something, which is how I often feel when I try to understand statistics. So, likewise, I don't know why drug companies would neglect to apply a statistical test that would likely work in their favor. Seth: Thanks for the book recommendation. The test I am talking about would need to be invented/developed. That is one reason it has not yet been applied. I suppose a drug company executive would say: Innovations in this area would not help us get drugs approved. There is a certain evaluation system. We need to follow it.

LemmusLemmus (2012-05-20 10:18:28)

"It is quite possible to run a study that produces for each patient a p value for the null hypothesis of no effect (a number that helps you decide if that particular patient has been helped) but this too has not been done. Since these new analyses would benefit drug companies, their absence is curious." I don't know what kind of test in particular you are thinking of (matching?), but if you can causally link an individual patient's health improvements to the drug, that means you can also link an individual patient's health deterioration to the drug. Enter lawsuits?

dearieme (2012-05-21 03:00:44)

Alex: try Gerd Gigerenzer's book on Risk. It's excellent, easy enough even for medics to follow, and very mind-clearing. <http://www.amazon.co.uk/Reckoning-Risk-Learning-Live-Uncertainty/dp/0140297863>

## Assorted Links (2012-05-21 05:00)

- [1]A good example of how misleading drug-company-sponsored analyses of drug trials can be. Independent reanalysis by Daniel Coyne, a professor of medicine at Washington University in St. Louis, reached opposite conclusions. Good work, Coyne.
- [2]Coke contains a carcinogen.
- [3]"I used sunflower seeds to lose weight." Someone else used them to reduce addictions. The link between the Shangri-La Diet and reduction of non-food addictions (smoking, coffee) fascinates me. People start SLD to lose weight and say they become less addicted to smoking, coffee drinking, and so on. One possibility is that by reducing hunger, SLD reduces discomfort. Addictions gain strength from discomfort, often resemble self-medication.
- [4]Steve McIntyre replies to Gavin Schmidt's claim that McIntyre's beliefs resemble "classic conspiracy theory". I used to watch a lot of football – when the 49ers won most of their games. (I am a classic fairweather fan.) I get a similar pleasure reading Steve McIntyre's posts as I did from watching 49er games.
- [5]Congratulations, UCLA press office! A study that measured the effect of omega-3 by comparing two groups of rats – one gets omega-3, the other doesn't – is called a study about the evils of fructose (both groups got a high-fructose diet). I am surprised the scientists involved didn't object to this misrepresentation. The study

supposedly shows – according to the press office – that fructose is bad because performance went down when the rats were switched from standard lab chow to a high-fructose diet. Let's say you start with a diet (standard lab chow) that has a barely adequate amount of omega-3. You feed both groups lab chow for several months. Then you do an experiment in which both groups get 60 % of their calories from the lab chow and 40 % of their calories from a diet that contains no omega-3. Performance is likely to decline due to insufficient omega-3 no matter what the new diet contains.

Thanks to Tim Beneke.

Mitra (2012-05-21 06:21:26)

Hi Seth, I have another question on an issue related to sleep. (thanks a ton for your response last time!). Sorry to bother you with this, but I thought you might find my experience interesting given your research on circadian rhythms...so here goes! Generally I used to go to bed anytime between 4 AM and 6 AM every day and wake up 7-8 hours later- it was a pretty weird routine, but it worked for me, I slept well and continuously, woke up well rested and never had any trouble with sleep. (I am an academic mostly working from home, not a shift worker). Suddenly I started having trouble sleeping - couldn't fall asleep on my usual time on quite a few occasions which left me puzzled - since there was nothing new in my life that would cause stress/anxiety etc. I later understood (my inference) that the way I practised intermittent fasting probably screwed up my sleep/wake cycle.(I was also taking Vitamin D at night while starting to eat more healthy and roughly following a Paleo style diet). In an attempt to loose weight, I would eat only one major meal in 24 hours and I would take that meal before I go to bed - that means at 2 AM or 3 AM. (taking only light snacks through the day). I read a Harvard study that suggested that if an animal takes food after a 16 hour fast, then its body starts treating the time when it takes food as "morning". According to Paul Jaminet, food intake dominates light in the setting of circadian rhythm, given the role the liver can play in the setting of the biological clock (particularly true in an environment of food scarcity created through the fasting). <http://www.wisebread.com/how-to-naturally-reset-your-sleep-cycle-overnight> To fix my routine, I have now started (a month back) going to bed at around 12- 1 AM after having dinner at normal time at 8 PM, but I observe two problems. First, I have occasional trouble falling asleep which is quite unusual for me. Second, I wake up after sleeping 5-6 hours every day and can't go to sleep after that, which is very unusual for me as well. I don't typically feel very tired throughout the day, so it is not a big problem I guess, but I don't feel nearly as well rested as I did before and I know 7-8 hours sleep is healthier, so I want to fix this if I can. I found your blog while investigating these issues - I have been trying out some of your ideas - skipping breakfast, morning sun, morning faces, Vitamin D and animal fat. They have helped, but haven't completely resolved the issue. (I am still continuing to experiment with your ideas, however). I was wondering whether you think .....a) Taking a time release melatonin tablet one hour before bedtime will help in more firmly re-establishing circadian rhythm - does melatonin have a role in this? b) Any other ideas? (Now I eat at 12 at noon and 8 PM at night, so only lunch and dinner, two meals in a day with only a small snack in between). Thanks a lot for your time if you have read up to this (don't blame you if you didn't) and hope you find my problem interesting! Best p.s: One clue - I have more trouble sleeping on those nights when I have more social contact in the evening. Seth: How much Vitamin D3 are you taking and when are you taking it? How much sun exposure in the morning are you getting and when? I've never tested melatonin. How much butter are you eating and when?

Glen Raphael (2012-05-21 06:53:08)

The link to McIntyre/ClimateAudit is broken. Seth: Fixed.

ddd (2012-05-21 10:57:37)

it's always better if a link to mcIntyre/climateaudit is broken.

dearieme (2012-05-21 14:06:26)

"I am surprised the scientists involved didn't object to this misrepresentation." I am surprised that you are surprised.

BlueMorrissey (2012-05-21 16:04:52)

Too add to the SLD. I have done varying degrees of it and lost weight with fish oil and bland foods since Christmas. I have not done nose-clipping or ELOO in a long time since my weight not far from where i'd like it to be. I recently began taking MCT oil for it's health benefits. It has no taste and I have noticed my appetite is substantially down. I'm losing more weight even though i'm really trying to right now. Just wanted people to know it's worked for me.

Mitra (2012-05-21 16:59:10)

Hi Seth, Thanks a lot for your response. Here are the answers to your questions. a) I am taking a little more than one table spoon of butter every day. I also eat meat and eggs fairly regularly - though it is often difficult to get fatty cuts of meat due to the low fat craze! I am eating the butter during the evening - around 8 PM. Should I eat more butter/animal fat? b) I used to take 1000 IU of Vitamin D every night. For the past two weeks, I switched to morning (after reading discussion of this in your blog) - then I upped my doze to 2000 IU in the morning - now for the last 2 days I have again upped my doze to 3000 IU in the morning around 9 AM. Should I try increasing my dose again? c) I have a lawn and the sun falls on it directly every morning. (I live in Brisbane which is often sunny on most months). So I stand (standing desk) and work on my computer in front of the lawn every morning starting around 9 AM. I would get more morning sun if I take a walk outside (it is a lawn rather than a back porch, so the roof is covered), but I don't do this until later in the day. I wake up around 7.30 every day, but I lie on my bed till 9 every morning trying to get back to sleep, so my day begins at 9 AM. Thanks again for your help. If I do try melatonin, are you aware of any negative side effects of melatonin? (I didn't find much in the literature, except that people ask you not to take it regularly, because then your body stops making enough of it once it senses it in the blood). Seth: Sorry, don't know about melatonin. I suggest you increase your butter intake to 4 T/day. And take 10000 IU of Vitamin D at 7 am. Continue the morning sun exposure. That should help a lot. After you are sleeping better you can reduce the Vitamin D and/or butter until your sleep gets worse, if you dislike those amounts. I don't know your weight but you have been taking dosages that are quite far from what data posted on this blog suggests are best.

Mitra (2012-05-21 18:30:21)

Thanks a lot. Seth. I will do this....I need to be go to bed a little early to wake up at 7 A.M and take the Vitamin D then. You are right about the dosages, I saw now that you recommend 60 grams of butter. ( I also probably shouldn't lie on bed so long after waking up so that I get morning sun sooner rather than only after 9 AM). I am 5 feet 9 inches (age 37) and my weight is now 170 pounds (male). I lost 14 pounds over the last three months (a Paleo style diet and 1600 calories a day approx), so I am not too overweight now, but I still have some abdominal fat and I also have impaired glucose tolerance or pre-diabetes and want to get my weight in the optimal range. (particularly given that I am South Asian and at a high risk for diabetes). Thanks a lot again for generously sharing your advice and all the great info on your fantabulous blog!

Anne (2012-05-21 23:00:22)

Hi Seth I will start to thank a lot for this goldmine of information you share on the blog and all the help with answer you give to everyone. That is so amazing rare in this age, and have put you on to my favorite to find the best information. I have read in to all the posts for days now and tried out all the tips for sleeping, except not enough one leg standing. When I saw this questions and your answers about sleep from Mitra. I almost get all the needed answers to many of my questions. As I have wondered when the best time for D3 was in the morning and if I should take the high amount of butter to. My experience so far is that I wake up earlier and earlier now in this test. I have started to take 7.200 iu of D3 some were between 6.30 am

to 7.30 am and around 5 to six tsp of butter a day to my meals. Yesterday I even tried to take 2 tsp of flaxseed oil at 11 pm, after reading a post about that. But today I woke up even earlier than ever at 4.30 am and was not able to get back to sleep, as I was extremely hungry. I am always very hungry in the morning and are not able to skip breakfast yet. I have order the Shangri-La diet book and hope to have it any day now. But I don't now how much answers there is on sleep in the book. I saw your answers to Mitra , so I have increased the D3 to 9600 today and also understand the right time to take it, as I have wondered about that to. But I still have some questions ( I live in Sweden and I am 5,5 inch tall and 150 pounds.) Does it matter when you have the butter to promote longer and better sleep To skip breakfast,how long has it to be before eating after wake up Does it matter what to eat and how long before bed, you eat dinner Does early sun exposure get me to sleep longer Do you take Omega 3 fish oil as well and If when in the day Do you take Flaxseed as well as butter or only one of them Kindly Anne

Mitra (2012-05-22 17:27:20)

Hi Anne, I will try to answer your questions BASED on the information that is already provided on Seth's blog and Seth's response to my questions. First, I think you can take butter anytime through the day, but Seth found taking fat (animal fat?) in the evening helped his sleep, so I plan on taking 60 % of my butter in the evening. To skip breakfast, it should ideally be 3 hours after waking up - like if you WANT to wake up at 7 AM, don't eat earlier than 10 A.M. Usually, it is recommended that people eat dinner 2-3 hours before they go to bed. Early sun exposure (along with Vitamin D3 in the morning) should strengthen your circadian rhythm and help with sleep. I don't know about omega 3 fish oil or flaxseed oil - I mean I don't know whether they can be taken together with butter or only butter is enough. You can experiment with all combinations. (Seth also says that more social contact in the morning and less social interaction in the evening can help - I found this to be true). Also, remember lot of standing in a day or one-legged standing enough number of times. You will find more info on these things in Seth's blog if you look at the topic "sleep" here. (Personally I felt less hungry when I started eating a fat heavy low carbohydrate diet). I take my dietary advice from Seth and from another book called "Perfect Health Diet" by Paul Jaminet. I plan to experiment with these remedies using Seth's advice. If these don't work for me, and given my specific problem, I also plan to take time release melatonin tablet one hour before bedtime for a week and see if it helps. It is annoying because I had perfectly fine sleep before I screwed it up by trying to do intermittent fasting in a wrong way.

Anne (2012-05-23 12:35:28)

Hi Mitra Thank you for taking the time to answer me on all the questions. I thought that I had read all the posts on sleep. Anyway after increase the dose to 9600 yesterday the sleep was better. If you have had a good deep and it went away whit a diet, it seems to me that what you eat really matters to sleep. All this years I have struggled, I have been told that I need to relax more and it is only happens to me, because I am stressed :-). Now it is summer and light in the morning, and very easy to get sun in the morning. But half the year it is dark when you go to and from work. I am thinking maybe to bay sun light box. I have one of the earlier and it did nor work that well, but the are very developed today. I got the Shangri La book yesterday so I hade read a lot yesterday. I tried to take oil capsule between breakfast and lunch as I was on the move, when I usually are starving. It worked very well and I could wait for a late lunch. But between lunch and dinner I used some flaxseed oil and it did nor work so well, I was starving after some time. But I am new so it will take some practice with try and error until it works as designed Kindly Anne

Mitra (2012-05-23 16:53:46)

Thanks - if you read my post carefully, my sleep problem didn't happen because of what I ate, it was more of a timing issue. Flaxseed oil has a strong flavour, so you have to drink it with your nose clipped for it to work. Anxiety about sleep (or more typically about other things) can also have an impact- so I think we have to strike a balance between doing absolutely nothing about this problem and being overly concerned about it. Best of luck!

### Assorted Links (2012-05-23 05:00)

- [1]Correlation between fat intake and brain-test scores. "Those women who reported the highest saturated fat intake also had, on average, the worst scores on reasoning and memory tests."

- How many iPads does it take to change a textbook market? [2]A perfectly good physics textbook is now available for free download (pdf). The author of the post, a physics professor at William and Mary named Marc Sher, does not understand what's going on when he refers to "the textbook publishers' price-gouging monopoly" and their "outrageous practices". Textbooks cost so much because students can be forced to pay that much. This has nothing to do with publishers, I submit, and everything to do with the power professors have over students. Sher would reply: All the textbooks are expensive. And I say: So what? If students could choose not to buy \$200 textbooks, none would be sold. Zero. And future years would see no more \$200 textbooks.

Thanks to Jonathan Graehl.

---

D (2012-05-23 08:06:59)

I imagine the people w/ high saturated fat intake weren't eating a paleo or low carb diet but were instead people who ate a lot of Mcdonald's and other fast foods. In other words, the group, having more of the obese and dumb, probably had more people on the left side of the bell curve to begin with. Contrast this with the kind of people who use olive oil, eat avocado, etc., who are middle to upper class people who are somewhat informed and follow trendy health advice, so they would be more likely to have more on the right side of the bell curve to begin with. Seth: I agree. This is common in epidemiology: People who do the "good" (= approved) thing are in better health than people who do the "bad" (disapproved) thing. But not because the "good" thing (such as avoiding saturated fat) is actually good, but because of other ways the two groups differ.

Patti (2012-05-23 08:07:06)

Seth - I am not a scientist and I am curious to know what you think of this study as it correlates to your consumption of butter. Thank you, Patti

G (2012-05-23 09:27:30)

Ugh, I hope D is right. I've been Shangri-La-ing with butter and coconut oil. I am also curious about Seth's opinion.

Jay Cobal (2012-05-23 09:51:09)

Seth, this is taken right from many of your posts, the new urban "Datasexual" <http://bigthink.com/endless-innovation/meet-the-urban-datasexual>

Hank the plant (2012-05-23 10:16:48)

The Kanazawa Hypothesis would predict the saturated fat result. Still, I second Patti, this is a good change to challenge my bias that quality animal fat is good. Personally, I feel much sharper when running on animal and coconut fat.

John Lusheski (2012-05-23 10:40:57)

The fat correlation must simply be due to confounders. Those kinds of conclusions fail to take into account basic inherent properties of the different fats. Long term controlled interventions show less lipofuscin, less collagen crosslinking, higher energy expenditure, less peroxidation, lower liver triglycerides, less body fat, etc with \*saturated\* fats. Also, there are similar results when compared to glucose, but you have to search deep, as it is hard to find a useful study in that regard (ie, not comparing corn starch to sucrose+lard+corn oil). There is one study in rats that uses a "cereal-based" diet, a "high polyunsaturated fat"

diet, and a "meat and milk based" diet. The last comes out best.

David Johnston (2012-05-23 10:46:34)

In the article, the researcher appeared to make a claim of efficacy for an intervention based on the results observational study with likely confounders and no clear causation argument. The journalist went right along and published it. This is typical but doesn't reflect well on either the journalist or the researcher. Seth: I disagree. The article explicitly stated the limitations ("this one can't prove..."). And the researcher is correct when he says "Our analysis suggests if you substitute out 5 percent of your saturated fat calories with 5 percent monounsaturated fats, you could have a 50 percent lower risk." It does "suggest" that conclusion in the sense of "make more plausible" that conclusion. I believe the correlation is due to confounders but I am not absolutely 100 % sure of that.

dearieme (2012-05-24 01:29:13)

Is there a good review anywhere showing how often results from correlative studies are supported or disproved by randomised controlled trials? Seth: I haven't seen such a review.

somebro (2012-05-24 19:12:48)

Dearieme: I believe John Ioannidis published something about this. His conclusion was that non-interventional studies should be given more credit.

john lushefski (2012-05-25 07:00:49)

dearieme, Why compare unrelated studies just because they are observational-turned-controlled? What makes you think their methods and/or results would provide any insight to a brand new observational result? But just for kicks, Harvard's Walter Willet and his team have been wrong with many [all?] of their conclusions from observatories. somebro, A blanket statement like that is completely useless though, as different studies vary significantly. These correlation studies with unsaturated fats go against the basic properties of fats, saturated being theoretically superior. Except, we don't even need to say "theoretically" because the work has been done already! We don't have the clear results in humans because they live too long to do well-controlled interventions that look at aging or aging indicators. Short term mice/rat studies, which are inconsistent anyway, that use industrial lard and/or sucrose tell us near-nothing about diet. They are useful for studying the physiology of obesity, but any diet advice given based on them is a set-up, or the authors [of the paper] are stupid.

## **Vitamin D3 in Morning: Moving D3 to Morning Improves Sleep (Story 23) (2012-05-24 05:00)**

Jim Breed has been taking large amounts of Vitamin D3 (5000-10000 IU/day) since 2008. Yet when he switched to taking it in the morning, his sleep quickly improved. Here's what happened:

I'm a married man, 230-240 pounds over the past 4 years, born in 1957, and I work as an engineer for the Department of Energy in an office. I try to do cardio for thirty minutes four times a week.

In 2008, I began taking 5-10000 IU Vitamin D3 daily. My blood tests:

October 2009 50 ng/ml

August 2010 65 ng/ml

May 2012 84 ng/ml

My doctor said to reduce my intake from 10000 IU to 5000 IU when it hit 84, as he prefers levels under 80.

Prior to beginning the morning D, I took one 5000 IU gel cap two times during the day. I usually took my supplements at breakfast, lunch, and dinner. I might take 5000 at lunch and 5000 at dinner. Since I started taking Vitamin D in 2008, I have not missed a day of work due to illness. This is unusual. Throughout grade school, high school, college, and my work for the Federal Government, I have never had a complete year where I wasn't sidelined by some cold, flu, what have you for an unscheduled absence due to sickness.

In November 2011, I started reading posts on your blog about morning D affecting sleep. I tried taking my Vitamin D in the morning – upon awakening, which is usually 6:30 am. Definitely by 8:30 am. Within a week, I noticed two things:

1. I started sleeping all night without waking in the middle of the night. For years, I have had trouble sleeping throughout the night. I usually slept with earphones so I could listen to the radio around 2 am for an hour until I fell asleep again. Once I woke up, it took a lot to get back to sleep. Now, I may stir for a few minutes or get up to use the toilet, but I fall back to sleep very quickly.
2. My bed times became more consistent and earlier. I married my wife in 2005. It had been a consistent source of tension between us that she liked to go to bed earlier than me (10:30 pm for her 11:30 for me). I wasn't tired. Midnight would have been better for me. Since the morning D, I have consistently beaten my wife to bed. I am just done for the day and ready to go to sleep by 10:30. This is truly a change for the better.

I did not expect these results. I reasoned that since my blood levels were so high, when I took D would not matter. I was surprised to be wrong.

I also found that an unexpected reduction in my dosage screwed up my sleep. This was really exciting. My wife and I traveled to Livermore, CA from our home in KS. She gave me some travel supplement packs that she makes up and it did not have our usual brand of D. Here is how the trip went.

1. Friday-fly to CA 10,000 iu at waking; great sleep in hotel room
2. Saturday-travel D; great sleep in hotel room
3. Sunday-travel D; great sleep in hotel room
4. Monday-travel D; great sleep in hotel room
5. Tues-travel D; restless sleep in hotel room. I heard the A/C unit. The bed was uncomfortable. I fell asleep during a meeting with the lights down at work
6. Wed-travel D; terrible sleep in hotel room. In a meeting at the lab I make a mental note to ask my wife what the travel dosage is.

It turns out that the travel dosage was 1000 IU. I thought it was just a different brand. Definitely, 1000 IU was not enough. I immediately went to Walgreens and got some 5000 IU gelcaps and began taking the 10000 IU upon waking. It took about a week to re-establish my previous restful sleep.

Reducing my dosage from 10000 IU to 5000 IU did not disturb my restful sleep patterns- When my doctor had me cut back to 5000 IU at the beginning of May, I didn't notice any decrease in restful sleep. If anything, it seems to be better than when I was taking 10000 IU.

---

Anne (2012-05-26 12:51:45)

Thank you Jim for sharing, I found it very valued and interesting to understand more. If I understand your story right, it actually take you many years to reach the right levels on D3, even as you took 10.000 IU daily. That could explain the reason why I after only one week does not yet have reached the good sleep. The travel part was also very good to know, how important the right levels are.

Thomas Johnson (2012-05-27 17:34:03)

Hi Seth, Do you have any results from personal experiments or anecdotal reports on using D3 to support an off-hours sleep schedule? I need to work 2 out of every 3 weeks on a 1am-1pm schedule, which requires going to bed around 5pm when it's quite light out and waking up around 12am. Do you know anyone who's tried D3 on waking to adjust their biological clock for an off-hours schedule, or perhaps for jet lag? Thank you for all of your research and for publishing these reports on D3 and other supplements! Seth: No I don't. I will soon fly from Beijing to San Francisco and I will use D3 to combat jet lag.

Anne (2012-05-27 21:32:29)

@Thomas I have a daughter 28 years old with severe disrupted sleep pattern developed over several years, meaning being up all night and stay up for two days and then go to bed at 4 pm and things like that. When she later wanted a more normal sleep. She had problem and never know if she would fall asleep at 6 pm or 6 am. She also never know if she would sleep to 3 am or 4 pm and she has really tried to have it working for over a year now with out any success. After reading this amazing blog I gave her a bottle of D3 for about 10 days ago, the first days 8000 IU and after reading more on the blog 10.000. She gets help most of the day that someone calls at 11 -12 am and she take the D3 up on awaking. The amazing results is that she has not have one single day that she has fell asleep at 6 pm and she also have more energies. Seth: Thanks for posting this story.

## **Medieval Metallurgy, the Evolution of Decoration, and the Shangri-La Diet (2012-05-25 05:00)**

[1]A new BBC series Metalworks! is about the history of British metal working. [2]My theory of human evolution says that decoration – more precisely, our enjoyment of it – evolved because it helped the most skilled craftsmen make a living. Long ago, technology evolved via massive amounts of trial and error, which required subsidy since payoff (discovery with practical value) was so infrequent. It was much easier to discover/learn how to make something that looked better than something that worked better, but the two sorts of discoveries were correlated: trial and error produces both.

The episode on ironwork (The Blacksmith's Tale) makes explicit how desire for decoration made it easier for the most skilled iron workers to make a living:

[Expert, at 16:50:] "I think decoration entirely depends on the amount of money the patron wanted to spend on that particular object." [Narrator:] By the end of the 15th Century, wealthy patrons, such as the Church and monarchy, were hand-picking known craftsmen at the top of their game to match a commission's requirements. When King Edward IV commissioned the Cornish smith John Tresillion to make these Gothic gates at Windsor in 1497, he did so with good reason. . . . [Expert:] "No blacksmith, ordinary blacksmith who was used to making horseshoes, could dream of working to this standard of perfection."

Quality of decoration is easy to see. It doesn't matter but it correlates with something that does matter – amount of trial and error (more trial and error, more innovation). We reward decoration to increase innovation.

The Shangri-La Diet derives from [3]a theory of weight control that emphasizes smell-calorie learning. Smell-calorie learning evolved for the same logical reason. Smells don't actually matter for health. But they are easy to notice and

they correlate with things that do matter for health, such as calories. Via smell-calorie learning we learn the correlations. After that the foods that smell best are the ones that contain more calories.

Tom (2012-05-25 11:46:52)

*Smells don't actually matter for health.* Smells don't matter for health? It seems to me that detecting rot, rancidity or the presence/absence of certain chemicals might be as useful as calorie detection. I also wonder how well caloric density typically correlates with smell. Seth: Yes, the analogy breaks down here, I agree. Some smells are unconditionally repulsive. Smell-calorie associations are learned so the smell becomes a very accurate predictor of caloric density.

bjk (2012-05-26 09:08:44)

A number of your themes touched on in this article. The National Institutes of Health (NIH) spent \$830 million funding obesity studies in fiscal year 2011. Between 2008 and 2011, NIH spent over \$3.3 billion on obesity research. Spending on obesity research also overshadows many other areas of research funded by NIH, including research on Alzheimer's disease, heart disease and breast cancer, which received \$448 million, \$437 million and \$715 million in 2011, respectively. Read more: <http://dailycaller.com/2012/05/24/government-spends-billions-on-obesity-studies/#ixzz1vzbNiu5J>

Alex Berg (2012-05-30 13:40:40)

Hi Seth, Regarding your evolutionary theory of Connoisseurs. I'm going a bit out on a limb here because I haven't read the full article you posted. I did read the section about Connoisseurs, and this post is mostly a comment to previous post about evolutionary theory of Connoisseurs. I believe the theory of evolution says that for a trait to prosper, it must be carried by a collection of genes which prosper. And genes prosper (by definition) if the individuals carrying the genes get more babies in each generation. Therefore, for the Connoisseurship gene to prosper, it must be good for the Connoisseurs themselves. It is irrelevant that its good for producers, as they are not necessarily carrying the gene. And in fact if the only good thing about Connoisseurship is that its good for the producers, then its bad for the Connoisseur-gene, because it means the Connoisseurs have less money/resources for other life-preserving options. I think that a theory for Connoisseurs which might fit with the evolutionary theory is that Connoisseur gene might prosper, because people who have access to both good and bad food should develop taste for the good food because it good for the body. But people who do not have access to good food, should accept the bad food and be happy. This is just an example of how the theory should be built. In particular this theory could be used on the Willat Effect. I'm a computer scientist, not evolutionary scientist. I read the book Robert Wrights 'The Moral Animal' (great book), and a bit of Less Wrong, and found that the right way to look at evolutionary theories is by looking at the proliferation of the genes. So I'm no expert in this, I just could not hold my tongue anymore. Seth: You write: "Therefore, for the Connoisseurship gene to prosper, it must be good for the Connoisseurs themselves. It is irrelevant that its good for producers, as they are not necessarily carrying the gene." People who live together tend to have more genes in common than people who live far apart. And people who live together have "shared fate" – they tend to live and die together. The effect of these two correlations is that if you help someone nearby, you are helping your own genes even if the action produces no immediate benefit to you. A large number of evolutionary biologists have been getting this wrong for a long time – making arguments like yours, which ignore correlations. This is now being recognized – e.g., E. O. Wilson.

## How Difficult is Chinese? A Tsinghua Professor Complains (2012-05-28 05:00)

Recently there was a competition for Tsinghua civil engineering majors. Whose structure can support the most weight? And so on. At the end of the competition, a professor handed out prizes to the winners. After the awards ceremony, the professor who had handed out the awards said to a colleague, "I don't like this job." His colleague was surprised: What was so bad about handing out awards? The professor explained that the students' names sometimes included characters so obscure that he didn't know them. Which was embarrassing.

---

garymar (2012-05-29 00:03:25)

Ditto for Japanese, with bells on! There are plenty of *common, ordinary* Chinese characters that take on strange readings when used as names in Japanese that even well-educated native speakers will shake their heads in puzzlement. That's why they print the pronunciation along the side with *furigana*.

M (2012-06-01 20:23:48)

After I came to China, I acquired a Chinese name. It turns out that one of the characters (suggested by a Taiwanese friend) is fairly obscure. Some native speakers have trouble with it – and I sometimes don't tell them if they make a mistake with the pronunciation, not wanting them to feel uncomfortable.

Adam (2012-05-29 17:59:17)

Re: superfoods They recommend Elk Antler Velvet because it boosts IGF-1 & 2. While it might make you beefy, it might also give you Cancer. A quick PubMed search for IGF-1 & Cancer turns up about 6254 results, and they aren't talking about prevention.

## **Personal Science is to Professional Science as Professional Science is to Engineering (2012-05-29 05:00)**

A few days ago I gave [1]a talk at Microsoft Beijing titled "The Rise of Personal Science: Discoveries about Acne, Blood Sugar, Mood, Weight Loss, Sleep, and Brain Function." (Thanks to Richard Sprague, who invited me.) The audience was engineers.

In response to a question, I said that the relationship between personal science and professional science resembled the relationship between professional science and engineering. Cause-effect statements (X causes Y) vary in their degree of plausibility anywhere from zero (can't possibly be true) to one (absolute certainty). Engineers, professional scientists, and personal scientists tend to work at different places along this scale:

Engineers work with cause-effect relationships at the top of the scale, that are well-established. (For example, Newton's Laws.) Relationships in which we have total confidence.

Professional scientists like to study cause-effect relationships that are in the middle of the scale of degree of belief: true and false are equally plausible. When both true and false are plausible, you can publish the results no matter what you find. If everyone already agrees that X causes Y, further evidence isn't publishable – too obvious. If it is highly implausible that X causes Y, professional scientists cannot study the question because a test of whether X causes Y is too unlikely to pay off. If you find that X does cause Y you can publish it but that's too unlikely. Finding that X does not cause Y is unpublishable ("we already knew that").

Personal scientists can easily test ideas with low plausibility. First, because personal science is cheap. Many tests cost nothing. Second, because what other people think is irrelevant. (A professional scientist who takes seriously an idea that "everyone knows is nonsense" risks loss of reputation.) Third, because there is no pressure to produce a steady stream of publications. An example of a personal scientist testing an idea with low plausibility is when I tested the idea that standing causes weight loss. I thought it was unlikely (and, indeed, I didn't lose weight when I stood much more than usual). But I could easily test it. It led me to discover that [2]standing a lot improves my sleep.

Plainly we need all three (engineers, professional scientists, personal scientists). Has anyone reading this heard someone besides me make this point?

I have been shocked – I sort of continue to be shocked – how much I have been able to discover via personal science. But a high rate of discovery makes sense if personal science supplies a necessary ingredient – ability to test low-plausibility ideas – that has been missing.

Patti (2012-05-29 07:11:52)

Maybe because you actually have an educational background in statistics and psychology I think you have a slight advantage at personal science. I also think you might have a more innate ability for observation. Some people are able analysis their behavior but are unable to be successful. The question then is why is Seth Roberts so successful at personal science/low plausibility ideas while others fail? For instance, I tried an extremely low-salt diet (low-flavor) and was able to lose 10 pounds. Then I could not stand the lack of flavor and started to eat salt again thus gaining back all the weight. I have been doing personal science all my life with abysmal outcomes. I can't think of any idea I have ever come up after careful observation has changed my life in a significant way. Seth: My weight loss ideas derived from a combination of unexpected observation and new theory. But a lot of other things I have found that worked came from long-term monitoring (e.g., sleep) that turned up a sudden change. That's what led me to study one-legged standing and butter, for example. I think long-term monitoring is something many people can do.

Jenny (2012-05-29 11:19:44)

Not quite, but nearly on the same track - I have been reading the beginning of Good Disruptive Change (<http://gooddisruptivechange.com/start-here/>) where Susan Alexander talks about the importance of measurement for keeping track of change. This seems to me as personal science in action - even if it is only for the benefit of the originator.

Alrenous (2012-05-29 11:49:56)

Why is it important to make sure a medical ultrasound is properly calibrated and maintained? "Ultrasound is used in labs normally for lysing cells, for ripping them open and getting out the DNA," So, how many ways can medical ultrasound go wrong and create the same effect? Can it accidentally get lensed or echo?

## **How I Will Teach Next Semester: Human Evolution and College Teaching (2012-05-31 05:00)**

I have wondered for a long time how to apply my ideas about human evolution to teaching. [1]My theory of human evolution says that specialization and trading are central to human evolution and includes a mechanism that increases diversity of expertise. The more diverse the expertise of you and your trading partners, the more you gain from trading. If I make knives and you make knives, we will gain less from trading than if I make knives and you make baskets.

I also discovered - independently - that the more choice I gave my Berkeley students (junior and senior psychology majors) about what to learn, the more they learned. It was as if they had an internal drive to learn all sorts of different things and the more I allowed that motivation to push and guide them, the more they learned. To see big effects it wasn't enough to merely give them a wide choice of term paper topics (as many college teachers do). I pushed them out into the "real" (off-campus) world (they couldn't do a library project) and said learn whatever you want. In this situation they learned an enormous amount. The connection with my theory of evolution was obvious: something inside of them was pushing them to be diverse in what they learned. What they learn = what they will become expert in. What they become expert in = what they will have to trade.

The more I allowed the underlying diversity of my students to be expressed, the more they learned. Yet almost all college classes treat all of the students in the class the same: same material, same assignments, same tests. The diversity of the students - especially the ways they differ from the professor - is a nuisance. So my theory suggests that standard college teaching is greatly at odds with human nature. It assumes one size fits all when that could hardly be more wrong. It should be possible to greatly increase how much is learned by doing a better job of recognizing human nature. My experience so far supports this prediction.

Recently I thought of a new way to deal with diversity among my students. Next semester I will try it. One of the courses I am teaching (at Tsinghua University) is Frontiers of Psychology, with about 25 students. It's required of freshman psychology majors. Here's what I'll do. For the first four or five class periods (one class per week), I'll cover a wide range of psychological topics, ideas, and methods. There will be reading assignments (e.g., choose one paper out of 30 and do a class presentation) but no grading. Then every student will draw up a list of "learning goals" for the rest of the semester. The goals can be whatever they want (related to psychology). They can read a book, read some articles, collect some data, give a talk to a high school class, whatever. Each goal will have a deadline. The assessment will be binary: goal completed/not completed. Their final grade will depend on how many goals they completed. The goals will be ordered. The further down their list they get, the higher their grade, with each level of completion assigned a grade at the beginning. They will make class presentations throughout the semester about their progress: what they are doing, what they have learned.

For the students, the benefits (compared to conventional teaching) are that (a) they get to learn exactly what they want yet (b) the grading criteria are very clear and (c) they are still motivated to work. For me, the benefits are that it should be a lot easier to judge if a goal has been completed than to grade homework essays, which is what I've done recently. Nor will I have to worry about what happens in class each week.

Any comments?

---

ChristianKI (2012-05-31 06:18:47)

This incentives students to set easy goals. Whether that's a good thing depends on your students. If they are perfectionist that need to learn to set goal that they can actually achieve it's good. If they on the other hand are people who try to game the system to get the highest grades with the least amount of effort it's bad. Seth: In my experience, college students want to learn stuff quite apart from grades. I will assign grades to the various achievements so if the most difficult goal isn't very hard that student will have ensured they don't get a very good grade. But I agree with your basic point: it isn't obvious it will work.

Darrin Thompson (2012-05-31 07:03:16)

I have a reservation much like ChristianKI. What about a well defined skill, like computer programming? Mark Guzdial's research shows that most colleges don't teach computer programming and computer science well. At Georgia Tech all students had to take an intro to computer science and for business majors it was known as a "three-peat" until the department figured out more effective teaching methods. (I follow Mark's writing to this day. I tried to teach a group of high school aged home schoolers to do programming a couple of times. I considered my efforts a failure because I only ever selected the students likely to succeed if they practiced on their own. Mark's work shows there is a better way, much like you are attempting here.) However, coding and computational thinking are a hard skill, in the dual sense that you either have the skill or don't, and that it is difficult for many people to acquire. "Learn what you want" seems too open to allow teaching difficult skills. <http://xkcd.com/863/> Once you have the prerequisite skills there's tremendous benefit to go and "build what you want using your newly minted skills. You have two weeks." Or two days even. We did a three day project here where I work. Anyone in R & D could work on anything they wanted for two (and a half) days and then there were dozens of presentations as we explained what we built. It was successful at generating a lot of innovative ideas, which are otherwise very tough to come by in our environment.

Andrea (2012-05-31 07:17:43)

Cool!

Elizabeth Molin (2012-05-31 09:52:14)

When I was teaching World Lit (1st semester: the Bible through Milton; 2nd semester: Rousseau through Richard Wright), I had no discretion as to the material to be covered. For the midterm and final exams, my students were required to choose three of the (many) exam questions and wrote a one-hour essay on each—but I had the students set the exams: each could suggest as many questions as they liked, and I put all their questions as choices on the exam. The idea was to let them dig deeper into whatever interested them and write their essays on that, even if this meant an essay on Mme Bovary, an essay on Hedda Gabler, and an essay comparing Mme Bovary and Hedda Gabler.

Kirk (2012-05-31 09:53:04)

To satisfy the 'easy goals' concerns, after a student makes a presentation, you could ask the class whether the goals were sufficiently difficult to merit a passing grade. Peers can always identify slackers. As for drawing up one list of goals at the top of the semester . . . the companies I worked for always required yearly goal-setting, and then the manager and I would review the goals and progress every quarter. During most Q1, Q2, or Q3 review sessions at least one goal would be revised. Now that I am out on my own, I set personal goals every year and review them at least every 3 months, and I typically modify at least one goal. Either I exceeded or underachieved the target metric, or I changed life direction such that one enthusiasm has replaced an earlier one. In summary, you may be spending less time grading essays and more time consulting one-on-one with your students. (Sounds like a good trade-off to me.) I don't know if it applies; your approach reminds me of Lee Sheldon's teaching method where he has students accumulate experience points (XP).

Jill (2012-06-01 07:23:22)

Will you help the students who need greater direction/structure to develop their goals? I think for some freshman, a "sky's the limit" approach could be scary.

Aaron Blaisdell (2012-06-01 10:43:07)

Very interesting, Seth. I've been trying to revamp some of my courses to better meet the diversity of student interests and tap into a more natural way to learn. This quarter, I'm teaching a large course (188 students) on the Principles of Learning (Pavlovian and Instrumental conditioning, mostly), so I followed the traditional lecture and test format out of necessity. But, I did have three students from the class taking the course for honors, which entails conducting their own research of the primary literature (with some exceptions) to more deeply explore a particular topic or theme. Instead of the typical APA format paper to turn in at the end of the quarter, I had the students publish a weekly blog, each blog post focusing on one or two papers. At the end (next week) they are to write a wrap-up blog post to put what they've covered into perspective along with their own analysis and bigger question, future direction type stuff. They and I have thoroughly enjoyed the process so I'll replicate this again! One of the blogs even covered the Shangri-la diet (which I also covered in class lecture as an example of using our knowledge of Pavlovian conditioning principles to manage our own eating behavior in the real world). The blogs, if anyone is interested, are here: <https://willyoublogwithme.wordpress.com/> <http://royakarakian.blogspot.com/> <http://behavioraltreatmentsfor substanceabuse.blogspot.com/>

Roger Sweeny (2012-06-03 08:03:23)

*The more I allowed the underlying diversity of my students to be expressed, the more they learned.* Well, yes, but ... Perhaps the major justification for school (certainly elementary and high school) is that everyone should know some minimum set of things. In other words, the major justification for school is that students *don't* get to pick what they learn. Seth: Fair point. I agree that it is important to teach everyone how to read, basic math, basic science, and a few other things. As you say this happens in elementary school and high school. I don't think it has been explored enough how to allow students to learn these basic skills in many different ways but I agree every student should learn them.

Sweet Nina (2012-06-05 10:54:53)

I agree that it is important to teach everyone how to read, basic math, basic science, and a few other things.

Tom (2012-06-01 22:42:24)

Off-topic, Seth, but you may find these n=1 observations on vinegar and weight loss interesting: [itsthewooo.blogspot.com/2012/06/things-i-used-to-do-that-help-wt-loss.html](http://itsthewooo.blogspot.com/2012/06/things-i-used-to-do-that-help-wt-loss.html)

### Academic Politics, Alan Turing and Stanford (2012-06-02 05:00)

[1]This series of posts about a proposed Alan Turing conference at Stanford left me wondering about the best academic novels I had read. Pnin is good, but not very academic. Gone by Renata Adler is fantastic but about office politics. I didn't like Changing Places nor Lucky Jim. I doubt a novel could be better than this:

A couple of days later we received a note from Lester Earnest to say he was withdrawing from the committee. Since Les was underwriting the event this was a blow; we had lost our funding.

I wrote to Les asking him what had happened, knowing that the exchange with [Jennifer] Widom [chair of the Stanford CS department] over the December holiday was surely sufficient to deter and depress anyone.

A few hours later Ed Feigenbaum wrote to the committee saying that he had not spoken to Les but that he would withdraw from the committee himself. This puzzled both me and Les because Les had just told me that Ed had talked him out of supporting the conference.

Is there a blog about academic politics?

1. <http://challengingturing.org/>

---

Darrin Thompson (2012-06-02 06:01:57)  
Gripping.

Allen K. (2012-06-02 08:34:06)  
"Changing Places", you mean. I didn't like it either. Seth: Thanks for the correction.

Jonathan (2012-06-02 14:54:04)  
Richard Russo's "Straight Man" is the funniest novel I've ever read.

Nancy Lebovitz (2012-06-03 04:21:49)  
Pamela Dean's "Tam Lin" is just the thing if you have any fondness for small liberal arts colleges. Something rotten in the classics department. Donna Tartt's "The Secret History" is a gripping story about a less attractive small liberal arts college. Also has something rotten in the classics department. The only thing I remember from "Publish and Perish", aside from that it's a horror novel is a scene of going berzerk in a boring meeting. I like to think the scene was developed over the course of many boring meeting.

dearieme (2012-06-03 04:50:36)  
"I didn't like ... Lucky Jim": then it's as well I don't read you for your sense of humour.

Alex Chernavsky (2012-06-03 05:08:34)  
[1]*Cantor's Dilemma: A Novel*, by Carl Djerassi, is an academic novel. I read it years ago, when it first came out. It was decent but not great. (Djerassi is the inventor of the Pill. He is emeritus professor of chemistry at Stanford University.)

1. <http://www.amazon.com/Cantors-Dilemma-Novel-Carl-Djerassi/dp/0140143599>

## How Much Vitamin D Should I Take? (2012-06-03 10:00)

[1]A new study of a quarter million Copenhagen residents found that those with Vitamin D blood levels of 40-70 nmol/L [16-28 ng/ml] had the lowest death rate. People with lower and higher amounts had higher death rates, in other words. The death rate versus blood level function has a reverse-J shape, i.e., too little is worse than too much. About 1 % of the sample had levels above 140 nmol/L [56 ng/ml], for practical purposes a "high" level.

Because [2]Vitamin D3 seems to have a big time-of-day-dependent effect on sleep (Vitamin D in the morning improves sleep, Vitamin D in the evening makes sleep worse) it is plausible that people with high Vitamin D levels were more likely to take it in the evening than those with moderate levels and this is why they had higher mortality. Likewise, it is plausible that those with moderate levels were more likely to take Vitamin D in the morning than those with low levels and better sleep explains the lower mortality. Although epidemiologists adjust for smoking in studies like this, they don't yet adjust for sleep quality. It is also plausible that people who were more sick took more Vitamin D – hoping it would improve their health.

I think I have a better way to decide how much Vitamin D3 to take: choose the minimum amount that produces

the best sleep. Sleep is so strongly connected with health that I wouldn't want to choose worse sleep over better sleep simply because of epidemiology. [3]At the same time that I greatly improved my sleep, I stopped getting easy-to-notice colds. Apparently my immune system was doing a better job of fighting them off.

There is evidence that [4]Vitamin D improves immune function independently of its effect on sleep. [5]A 2009 survey found that "those with less than 10 nanograms of vitamin D per milliliter [25 nmol/L] of blood, considered low, were nearly 40 percent more likely to have had a respiratory infection [over what period of time?] than those with vitamin D levels of 30 ng/ml [75 nmol/L] or higher."

So those three studies (epidemiology, lab, epidemiology) taken together make a good case that my Vitamin D levels should be at least 25 ng/ml. I will have my Vitamin D level measured soon and it will be interesting to see how much an approach based purely on self-measurement (find the minimum amount of Vitamin D that optimizes sleep) agrees with this.

Thanks to Chase Saunders.

More. In an earlier version of this post I confused ng/ml with nmol/L.

Joe (2012-06-03 11:33:51)

Looking forward to your vitamin D3 test results! Mine is 90 ng/ml, and I generally sleep like a baby.

Caleb Coop (2012-06-03 13:25:21)

That's a good point Seth; based on how people take pills it's likely many with the high levels were taking a 5000 w/ breakfast and a 5000 w/ dinner. So it's still an open and very interesting question what the long term effects high levels obtained differently might be. Since the body tops out around 10,000 when producing from the skin, I tend to think supplementing under that would be safe. It's finally warm enough to make Vitamin D naturally where I live, and I believe there are additional hormeosis benefits from moderate solar radiation damage below the sunburn level. So I've stopped taking my D in the morning because of worry about unnaturally high levels. Seth, would you still take your 6000-7000ish dose in the morning if you were going to be getting enough sun exposure later in the day to top out skin production? My default is to be conservative in exceeding what would have happened in nature. Though I do believe some bio-hacks could surpass the benefits of simple ancestral reenactment, and really respect those like you who try them out on themselves. We're all richer for you sharing your results. Seth: I take 5000 IU, not 6000-7000 IU, in the morning. Yeah, I'd still take it even if I were going to the beach. Which is purely hypothetical!

P. Winter (2012-06-03 16:10:53)

Have you read THE MIRACULOUS RESULTS OF EXTREMELY HIGH DOSES OF THE SUNSHINE HORMONE VITAMIN D3 MY EXPERIMENT WITH HUGE DOSES OF D3 FROM 25,000 to 50,000 to 100,000 IU A Day OVER A 1 YEAR PERIOD [Kindle Edition \$1.99 } written by Jeff Bowles?

Guv (2012-06-03 17:19:59)

Hi Seth, looks like you have a couple of typos..... The two nmol references should read nmol/liter (not nmol/milliliter). For those people not familiar with the nmol/L measurement, divide by 2.498 (or 2.5) for ng/ml. eg. 40-70 nmol/L = 16-25 ng/ml This range is a lot lower than all the various recommendations i have seen around the web; which generally quote the optimal range anywhere between 40 ng/ml (100 nmol/L) on the bottom end to 80 ng/ml (200 nmol/L) on the top end, depending on where you look. I have seen higher ranges recommended to treat illnesses, ie. the Mercola web site suggests 70-100 ng/ml (175-250 nmol/L) to treat Cancer & Heart Disease. Seth: I have fixed the mistakes, thanks. If Vitamin D has a strong of time-of-day effect - i.e., it matters a lot what time of day you take it - then I believe all recommendations will need to be reconsidered in the light of new evidence that measures or controls time of day.

Guv (2012-06-03 17:48:39)

thx Seth, i too will be interested to hear what your Vit D level is measured at. ( & how you interpret the result). I actually had mine tested last week, tho i have not been back to get the results yet.

Chuck (2012-06-03 20:47:26)

I just had mine checked - 84 nmol/L. I take 5000 IU each morning (I recently switched from capsules to liquid on Robb Wolf's advise - capsules maybe less effective) and get plenty of sun (7 - 15 hrs/wk). So I'm not sure if it's the sun or supplements, or both. I began supplementing 3 years ago and haven't had one cold in that time - usually got one cold / flu per year. Seth: That's very interesting. When you started the supplements 3 years ago, did you also increase how much sunlight you got? Or did amount of sunlight stay more or less constant?

P.Bear (2012-06-03 22:02:02)

Please read: Vitamin D and host resistance to infection? Putting the cart in front of the horse <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3138330/> I recommend that only a very few of my patients take vitamin D, only those whose levels are below 14ng/ml. Higher levels of 25-D above (about 40ng/ml) are associated with increased all cause mortality. P.Bear Seth: Thanks for the link. That paper references an experiment measuring whether 2000 IU/day Vitamin D reduced colds. It found no effect. This may be because the experiment used too low a dose and did not control the time of day that the subjects took Vitamin D - that is, Vitamin D in the morning may help but not at other times of day.

Sara (2012-06-04 02:41:11)

Seth, I wonder if you are aware of the link between early D3 deficiency and Type I diabetes? The research is pointing toward D3 having a modulating effect on the immune system (Type I diabetes is an autoimmune disorder). There is probably a factor of genetic vulnerability due to a polymorphism of the VDR gene which combined with an early (even in utero) lack of D3 is linked fairly conclusively with development of Type I diabetes. I found it veeeeery interesting that high intake of D3 seems protective against a hyperimmune response. I can link you up to some papers if you are interested. Obviously each paper has its issues (for example, you can't really induce a deficiency or leave one untreated in order to observe the effect) but the body of evidence taken together is quite convincing. Seth: I was not aware of the link, thanks for pointing it out. Please post another comment with links to the papers, if that's possible.

David (2012-06-04 05:47:20)

What did the study that you cited mean by "lower" death rate? Lower by some material amount? After watching this TedX video, I have a renewed appreciation for asking about the significance of most scientific studies. <http://www.youtube.com/watch?v=TDB6iBOhuq0> &feature=share Seth: The highest and lowest death rates differed by a factor of 2.

Pete (2012-06-04 06:57:58)

As vitamin d as taken is inert the time of day is unlikely to matter. It is then converted to 25(OH)D which is inert. It is only converted to an active compound when needed, so when it is taken is very unlikely to matter. Your body is used to getting it at midday but I doubt it cares. Please do not take sustained daily doses above 20,000IU a day without being told to do so by a

doctor it is dangerous. If you can take those high doses without getting ill it is because your parathyroid has failed. Seth: Since the time of day obviously matters, at least some of the time – see the 20-odd examples I have collected – something is wrong with your theory.

Pete (2012-06-04 08:45:05)

20 examples is not many so it could easily be a fluke. However, it is more likely one of the other ingredients. The oil could give you reflux and that could be affecting you sleep. Do you get the same effect from sun light? Do you get the same effect if the vitamin d is applied to the skin rather than taken orally? Seth: "Easily be a fluke"? Do you know of a case where someone collected twenty examples of something that turned out to be a fluke? I found that Vitamin D in the morning improved my sleep. I found the same effect with gencaps (with oil) and tablets (without oil). So it's not the oil. I have found that sunlight in the morning improves my sleep. I have not tried applying Vitamin D to my skin.

Dave (2012-06-04 11:56:19)

In the study claiming higher blood levels were correlated with a higher death rate, did they try to correct for the possible effect of people with poor health being more likely to supplement with vitamins, or that sort of thing? Seth: No they didn't. That's what I meant by "It is also plausible that people who were more sick took more Vitamin D — hoping it would improve their health."

P.Bear (2012-06-04 12:33:55)

This video may interest some of you artificial seco-steroid "Vitamin D" takers: [https://www.youtube.com/watch?v=E\\_SwHX5K\\_nE](https://www.youtube.com/watch?v=E_SwHX5K_nE) One might also read this interesting blog: <http://www.newswithviews.com/Ellison/shane158.htm> This article in Townsend Letter is of interest, but I would not follow any medical advice from non health care professional MP cult members. <http://www.townsendletter.com/Jan2009/vitaminD0109.htm> for health, P.Bear

Carol (2012-06-04 13:26:49)

For years I've had bad sleep, and once I was in peri-menopause, it got worse. I had trouble going to sleep, and if I had a hotflash during the night, I would wake up, and be unable to go back to sleep again. I was the walking dead some days. I worked in a windowless office 5 days a week, for 9+ hours a day for the last 13 years. I also live in the PNW, so sunshine is a fleeting thing most of the time. I had been taking Vitamin D (low dosage) in the evening, but then I switched to the morning, and was taking 10,000 a day for about 2 months. The sleeping got progressively better, and I'm now to the point that I fall asleep easily, and even a hot flash only wakens me a bit, and I can go back to sleep. This is HUGE for me. I had my levels tested, and it is 63.4 ng/ml, which is in range (30-100). I've switched to 5,000 iu a day now, since I get almost no sun exposure opportunities. I also took both dry and oil based capsules. I didn't notice a difference.

Antonio Pedro (2012-06-04 16:05:26)

Hi all, Have you guys heard about this? [http://www.amazon.com/MIRACULOUS-EXTREMELY-SUNSHINE-EXPERIMENT-ebook/dp/B005FCKN2S/ref=sr\\_1\\_1?s=books&ie=UTF8&qid=1338666649&sr=1-1](http://www.amazon.com/MIRACULOUS-EXTREMELY-SUNSHINE-EXPERIMENT-ebook/dp/B005FCKN2S/ref=sr_1_1?s=books&ie=UTF8&qid=1338666649&sr=1-1) It is not quite the same as what has been discussed here but it is surely related. Cheers, Antonio Pedro

Chuck (2012-06-05 06:31:44)

A qualified yes to the increase of sunlight. I've always gotten some sun exposure during the summer - more some years than others - but it wasn't until last year ( 16 mos ago) that I really put an effort into getting daily sun. Living in So CA you have opportunities for sun exposure - you can have a warm sunny day any month of the year - but you still have to have ability to go outside and take your shirt off. Last year my ability became open ended. I started with 15 minute sessions - front and back, shirt off, pants on, no sunscreen (this is important) and I do wear a baseball cap most days (it makes it easier to read) - when the sun was at it's highest point. You'd be surprised at what 15 minutes of sun on white skin will do. I would do this on every sunny day, extending the time a little each week or 5 straight days of sun exposure. I can now spend two hours in the sun with no sign of burning. If I start feeling any burning sensation, I cover up or get in the shade. Most days I'll just sit out facing the sun with my shirt off for an hour or so. Sometimes I'll split the time between front and back. As it gets hotter, I actually spend less time in the sun, unless it's before noon or after 3 PM, or I'm on the beach close to the water. I've found, if you listen to

what your body is telling you, you won't get burnt or sun stroke. Like most other things in life, the poison is in the dose.

Guv (2012-06-13 16:48:38)

it looks a new study on Vitamin D levels has been released since the Copenhagen study (discussed in the article above). This is some blurb from the Vitamin D Council. "While a study out of Denmark reports, in an observational study, that both high and low vitamin D levels are associated with an increase in mortality, a study published just last week out of Israel reports that only low vitamin D levels are associated with increased risk of mortality. Published in the Journal of Endocrinology and Metabolism, lead investigator Dr Walid Saliba of the Carmel Medical Center found that in an analysis of 182,152 subjects, vitamin D levels above 20 ng/ml were better than levels below 20 ng/ml." <http://blog.vitamindcouncil.org/2012/06/12/the-research-continues-low-vitamin-d-increases-mortality/> That is all the info i have on it, to find out more a login is required, which i do not have.

Leszek (2012-06-14 15:15:06)

Long story, but interesting. Once I get better, I'll be brief :) Yesterday, I took D3 in the morning (just 800 IU) and for the first time in several months, if not years, I slept soundly all night. Too early to proclaim a victory but I have no explanation for this other than early morning D3 dosing. Need some advice. Need to tell my story. I experimented with D3 before, with mixed results. I have Hashimoto Thyroiditis and have had cognitive, mood, and sleep problems for about 15 years. Thyroid medication, which I have been taking last two years (an equivalent of about 120 mcg levothyroxine, which is a fairly typical dose) has not worked well, until about a year ago, when I briefly experimented with D3 supplementation. I am not sure how much I took then, I think about 8000 IU, twice a day, 4000 in the morning and 4000 with dinner. Ten days into D3 supplementation, I had my levels measured and I was low (25 ng/mL). Two weeks into supplementation, I started feeling normal, confident, clear-headed, energetic, just like what I had prayed for for years. I am not sure how well I slept at that time. This improvement did not last. One month later I felt thirsty all the time, got up at night every half an hour, my normally very slow heart rate increased uncomfortably and I was in a worse shape than ever. It had felt like an excess thyroid supplementation (except for thirst which seemed odd to my doctors), but it was not. I discontinued D3 and went back to my pre-D3 normal. I resumed supplementation, and that again caused restless nights, thirst, frequent urination, etc. I discontinued D3 for about six months. I thought for good. Last six months I nearly lost all hope: sluggish, sleepy, confused, getting lost in familiar places, avoiding people, stiff and achy all over, particularly in calves and achilles tendons, in a word: your standard low-thyroid mess. Last month, I spent some time in Utah and felt a touch better. I don't have much sun here (Seattle) so I thought perhaps it is a matter of D3 after all. This time (a week ago) I took 2000 IU (half in the morning, half at night) and excessive thirst and fast heart rate, particularly at night, had returned immediately, within just 24 hours. After just 2000 IU of D3! This is really not that much for someone with just D3 at 35 ng/ML (as of two months ago). So I bought 400 IU tablets and yesterday decided to take two (800 IU), in the morning (I am not sure why in the morning, pure accident). The effect on sleep was so good and so dramatic that I started looking for empirical evidence that perhaps all I need to get over this nightmare is to take D3 in the morning. I think 800 might not be enough to improve my other problems. I want to take 2000 early in the morning for a week and see what happens. What do others think? Keep your fingers crossed for me.

Leszek (2012-06-14 15:44:39)

Let me just add that thyroid problems are highly correlated with D3 and, in women, with iron deficiency. Furthermore, I was briefly on a too high dose of levothyroxine (my TSH was 0.08) and it felt very much like what I was experiencing during night-time D3 dosing, except for excessive thirst. I have no proof but it seems to me that D3 is making thyroid hormones more effective, perhaps via increased t4 to t3 conversion.

## **What to Do About Antibiotic Resistance? Improve Immune Function (2012-06-05 05:00)**

I recently got a flyer from my HMO. "Feel better soon . . . without antibiotics!" said the front page. "Antibiotics do not kill viruses" said the second page. Apparently the point of the flyer is to reduce antibiotic usage. I am surprised that doctors need protection from patients asking for antibiotics for viral diseases.

Antibiotic resistance is a problem, yes, but the bigger problem is how those who run our health care system ignore the immune system. Here are examples:

1. The historical solution to the problem of antibiotic resistance has been to develop new antibiotics. The problem has not stimulated research into how to strengthen the immune system. Here is [1]a 1992 editorial in *Science*: "Mechanisms such as antibiotic control programs, better hygiene [= more handwashing], and synthesis of agents with improved antimicrobial activity need to be adopted in order to limit bacterial resistance." Nothing about improving immune function. [2]A 2012 World Health Organization report about the problem does not contain the word immune.

2. [3]The idiocy of tonsillectomies. Forty years after researchers figured out that tonsils are part of the immune system, tonsillectomies remain common. Removing tonsils because of too many infections makes as much sense as removing part of the brain because of memory loss. I have never encountered a doctor who appears to understand this.

3. Epidemiologists have yet to systematically study what makes the immune system more or less powerful. For example, [4]this epidemiology textbook does not contain the word immune. Nor does [5]this review of 25 epidemiology textbooks.

4. A respected professor of pharmacology at the University College London named [6]David Colquhoun left [7]the following comment on this blog: "Talking of made up theories, the corniest of all has to be "stimulating the immune system". There is [not], and never has been, any evidence that it happens – it is the eternal mantra of every quack who is trying to sell you their own brand of implausible therapy." [8]Here is an example of the evidence he says doesn't exist. Professor Colquhoun is a Fellow of the Royal Society.

5. I know very little about the immune system. I barely know what a T cell is. My job (psychology professor) has nothing to do with it. Yet I have come up with three ideas related to it: 1. Tonsillectomies are idiotic. 2. [9]We need regular intake of microbes to be healthy – in part to stimulate the immune system. 3. [10]We need exposure in small

amounts to the germs around us for our immune systems to best protect us. (So it's not obvious that outside of hospitals more handwashing is a good thing.) Only because these ideas are obvious ( #1 and #3) or semi-obvious ( #2) was someone as ignorant as me able to think of them. That one ignorant outsider thought of three of these things before the hundreds of thousands of health researchers did suggests how little they think about the immune system.

Someday the people in charge of our health care – or the rest of us, ignoring them – will figure out how to make our immune systems work much better. We will sleep much better, eat much more fermented foods, take enough Vitamin D at the right time of day, and so on. Perhaps we will wash our hands less and kiss more. Antibiotic usage will go way down, selection for resistant microbes will become much less intense, and antibiotic-resistant microbes will become much less common. The problem will disappear.

---

Mike (2012-06-05 05:18:17)

A while back I went to a doctor because I had a persistent sore throat and some other symptoms and he did a bunch of other tests first. Me: "What about my sore throat." Doc: "I'm not concerned. It just looks like a virus." Me: "OK, but it's been sore for over a month now." Doc: "I can prescribe you an antibiotic." Me: "Antibiotics don't do anything to viruses." Doc: "Correct." Me: "...". Doc: "...". Me: "...". Doc: "We could do an allergy panel." Me: "No thanks."

Koanic (2012-06-05 05:33:23)

The Antiseptic Baby and the Prophylactic [1] Pup Were playing in the garden when the Bunny gamboled up; They looked upon the Creature with a loathing undisguised; — It wasn't Disinfected and it wasn't Sterilized. They said it was a Microbe and a Hotbed of Disease; They steamed it in a vapor of a thousand-odd degrees; They froze it in a freezer that was cold as Banished Hope And washed it in permanganate [2] with carbolated soap [3]. In sulphurated hydrogen [4] they steeped its wiggly ears; They trimmed its frisky whiskers with a pair of hard-boiled shears; They donned their rubber mittens and they took it by the hand And 'lected [5] it a member of the Fumigated Band. There's not a Micrococcus [6] in the garden where they play; They bathe in pure iodoform [7] a dozen times a day; And each imbibes his rations from a Hygienic Cup – The Bunny and the Baby and the Prophylactic Pup. - by Arthur Guiterman

Nancy Lebovitz (2012-06-05 06:29:48)

One way that the medical profession doesn't respect the immune system– hospitals tend to be bad about interrupting patients' sleep. Seth: yes, very good point.

Tuck (2012-06-05 07:36:34)

"Someday the people in charge of our health care — or the rest of us, ignoring them..." I'll go with the latter scenario. We recently had a bit of a battle with our pediatrician over how to handle a fever. She just had no clue that fever is a first line of

defense against infection... If you read the literature, which I did, you can pretty quickly ascertain that "treating" a fever leads to worse outcomes, while letting it run leads to better outcomes (survival is better, in my book). I even found an amusing study, basically a letter to the pediatric profession, noting that parents were alarmed by fever in direct relation to their time spent with a medical professional. The letter concluded that pediatricians ought to do a better job of conveying correct information to their patients. Obviously our doctor hadn't gotten the memo. And I think she's a good doctor, she's just hobbled by a bad education (Harvard Med, as I recall...). After chastising us for not treating the fever with Motrin (I refused) she sent us an alarmed text telling us \*not\* to use Motrin, as the illness likely had a hemorrhagic component, which the Motrin would make worse. The kid recovered nicely with essentially no treatment whatsoever, but a healthy paleo diet and lots of sunshine... (Interestingly, I had her sit out in the sun for a bit to generate some Vit. D, and her fever promptly skyrocketed. Cause and effect?)

Rich (2012-06-05 09:38:45)

It's funny, I was watching The Brady Bunch with my 9 yr old yesterday where Mrs. Brady and Cindy both get their tonsils out because they were getting periodic sore throats and the sniffles.

peter (2012-06-05 10:16:41)

<http://www.lowdosenaltrexone.org/> since i've been taking low dose naltrexone (about 3-4 years) i've had one cold.

Walter (2012-06-05 16:24:46)

Seth, Given I have no tonsils would you add anything to your list of suggestions? Thanks, Walter Seth: Sue the doctor who removed them.

Patti (2012-06-05 17:01:47)

Tuck you are very lucky your child was okay. Yes although fever is the first line of defense it is also the first sign the body is out of homeostasis. Fevers in children can be very dangerous due to their unpredictability. Nancy Lebovitz. I agree with you 100 %.

Introsphere Roundup: All the news that's fit to ponder – June 5 | Koanic Soul (2012-06-05 19:01:16)

[...] best guys in the game, Ive deduced game down to one thing., – I am alpha Seth Roberts – What to Do About Antibiotic Resistance? Improve Immune Function Sovereign Man – These popular services won't keep your information private! Unamused [...]

chris (2012-06-05 21:09:10)

Hey Seth, A few problems with your post. I'll organize them by point. 1. Researchers would love to stimulate the immune system, however, that is not a reason to forgo antibiotics. Antibiotics save lives, and even in non-fatal diseases can greatly increase quality of life. The immune system is incredibly complex and difficult to try to regulate from the outside, so progress is very slow on that front. Also, increasing your immune system (whatever that means exactly? More T cells, B cells, cytokines, better complement response, etc? You would need to specify what you mean by that first and foremost) response has nothing to do with bacterial resistance to antibiotics, so it is not surprising that it wasn't included in the editorial you link to. Bacterial resistance is a competition between bacteria and antibiotics, not our immune system. Sure, a better (still too vague) immune system would help resistance to any disease, but we don't have good data on exactly how to do that yet (from what I currently understand). 2. Tonsillectomies. You are absolutely right than an abuse of tonsillectomies would be idiotic. However, the current guidelines (seen here from the Mayo clinic <http://www.mayoclinic.com/health/tonsillectomy/MY00132/DSECTION=why-its-done>) only call for the procedure in the case of severe recurrent infections and other complications (basically if your tonsil keeps getting infected, the immune system there isn't doing its job and the risks are outweighing the benefits of keeping that tonsil). Seth: Sounds tautological ("if the risks are outweighing the benefits"). 3. Before that question could even start to be addressed you would have to explain what exactly constitutes a "more powerful" immune system. Otherwise what do you study? Give a phone survey asking how powerful someone thinks their immune system is? Seth: The more powerful your immune system, the fewer colds you get and the shorter time they last. That's one way to measure immune function. 4. What I think the professor was referring to is the incredible overuse of the term "stimulating the immune system" by quacks who simply use it as a way to claim that all modern medicine is a waste of time.

That is very different than the article you linked to that gives a specific mechanism, specifically showing how a vitamin D deficiency could limit immune system function. 5. Conventional medicine does not ignore healthy habits that also support your immune system such as getting enough sleep, eating healthy, not being deficient in nutrients, etc. Also, your second and third points in point number 5 are based on conjecture, not hard evidence. I would recommend that you do a little more research into exactly what medical researchers and immunologists are doing before you assume you've come up with something that completely overturns a field. For example, if I thought I came up with a simple thought experiment that overturned special relativity, I would go educate myself more on the topic, maybe email an expert or two and ask their opinion before I posted my opinion on a blog saying I was smarter than a bunch of Ph.D. physicists. It is much more likely that I just don't understand relativity than that I've disproved it. Seth: "I would recommend that you do a little more research into exactly what medical researchers and immunologist are doing." You seem to be saying I have overlooked something that contradicts what I say here. What is it? Contrary to what you say, my second and third points in point number 5 are based on hard evidence, which you can find via the linked page and posts. I have posted twice about hard evidence for the third point (existence of an early warning system) and dozens of times about hard evidence for the second point (microbes in our food stimulate our immune system). The fact that you think "thought experiments" are involved supports my view that these ideas are remarkably obvious.

Jaroslav (2012-06-06 01:39:49)

[1]Early Exposure to Microbes Reduces Inflammation Related to Chronic Disease Later In my country (Czech Republic) we have a saying - or rather, used to have, as the hygienic and neurotic approach to raising children has caught up with us - that every child should eat a cart of dirt and cart of manure during childhood to be healthy.

Adam (2012-06-06 05:00:18)

Chris said: "1. Researchers would love to stimulate the immune system, however, that is not a reason to forgo antibiotics. Antibiotics save lives, and even in non-fatal diseases can greatly increase quality of life. The immune system is incredibly complex and difficult to try to regulate from the outside, so progress is very slow on that front. Also, increasing your immune system (whatever that means exactly? More T cells, B cells, cytokines, better complement response, etc? You would need to specify what you mean by that first and foremost) response has nothing to do with bacterial resistance to antibiotics, so it is not surprising that it wasn't included in the editorial you link to. Bacterial resistance is a competition between bacteria and antibiotics, not our immune system. Sure, a better (still too vague) immune system would help resistance to any disease, but we don't have good data on exactly how to do that yet (from what I currently understand)." Seth's point wasn't that people that need antibiotics should forgo them, so you are attacking a Straw Man in the first part here. He also never said that antibiotics don't save lives or that no one needs them. What I think he is trying to say is that the specialists are looking at a small part of a bigger picture, which is limiting the potential solutions they could come up with. The body isn't a sterile environment where bacteria and antibiotics are interacting with each other alone. In many cases, people will recover even from bacterial illnesses all on their own, even without antibiotics. In some illnesses, antibiotics merely shorten the duration or intensity of the disease. In this sense, you can think of antibiotics as an aid to the immune system, not as a replacement for it and not separate from it. Your last point, that we don't have a good idea about what boosts the immune system might be true for you specifically, but that doesn't mean that information isn't out there. There are several examples in this thread already. To add to them, there is some good data out there that zinc boosts the immune system. I recently read a study where they gave zinc to severely ill pediatrics and reduced the rate of antibiotic treatment failure by about 50 %. Search PubMed for "2012 Lancet zinc" and I'm sure it'll come up.

Chris (2012-06-06 11:55:52)

Hello Seth and Adam, Thank you for your responses. I will try to clarify what I may have left too vague while trying to be brief. Seth, I don't understand your tautological argument. All I am saying is that there are still situations today where tonsillectomies are a good procedure. Sometimes, the damage that can be done by leaving a tonsil outweighs the potential benefits of keeping that tonsil (cancer, severe recurrent painful infection, etc) I apologize for the tongue in cheek response about an immune survey. You can indeed measure components of the immune system in response to certain therapies. Maybe looking at cold rates would be beneficial for some studies, but not antibiotic resistance because the common cold is

typically caused by rhinoviruses, not bacteria. Also, the amount of confounding variables (including differential exposure to germs) in an epidemiological study would make it very difficult to justify creating an entirely new immune boosting treatment without a more controlled trial. About the field as a whole (and this should help to answer your questions too Adam), you are conflating infectious disease/microbiology with immunology. Yes, both components (the infecting microbe and the host immunity) are important, but they are so complex that two different fields currently deal with them. Antibiotic resistance is fundamentally a bacteria vs. antibiotic problem, our immune system is not really a part of it, outside of being part of the environment that the bacteria are trying to inhabit in your body. Yes, the antibiotic aids our immune system, but that is by killing off some of the bacterial population, not by "working together" in some way. The only difference between antibiotic resistant bacteria and susceptible bacteria is that one will not be killed by an antibiotic while it is infecting you. Your immune system does not influence bacteria susceptibility to that antibiotic, nor does the antibiotic boost your immunity. Therefore, to accuse infectious disease people about not studying the immune system is to accuse them of not doing someone else's job. Immunologists are working on that, try searching for nature reviews of microbiology in Pubmed. You can find articles like this one (<http://www.ncbi.nlm.nih.gov/pubmed/22113499>) that involve immunologists looking at things like dietary components and their influence in innate immunity. However, the field is still in its infancy and nowhere near making good enough treatments to negate further antibiotic production. Still, contrary to your post, scientists are researching how to improve immunity. Immunologists are not all a bunch of dense scientists completely ignoring entire avenues of potential therapies.

Chris (2012-06-06 15:02:10)

Adam, To clarify what appears to be a strawman: Seth asserts and implies in his post that research into antibiotics is unnecessary and that simply following his guidelines will make antibiotics obsolete. That to me implies that he thinks we should stop researching antibiotics. "Antibiotic usage will go way down, selection for resistant microbes will become much less intense, and antibiotic-resistant microbes will become much less common. The problem will disappear." "Antibiotic resistance is a problem, yes, but the bigger problem is how those who run our health care system ignore the immune system. " -not necessarily true... There are diseases out there that will still infect you no matter how strong your immune system is (MRSA, B. anthracis, tuberculosis, the list goes on) and that is what we need antibiotics for (and of course antivirals for the major viral diseases) I found what I think is your article in the Lancet (<http://www.ncbi.nlm.nih.gov/pubmed/22656335>). Some points: deficiency in many vitamins/minerals is known to affect your immune system, and the researchers didn't measure pre-treatment zinc status. It could have been that all the subjects were zinc deficient, and that increasing their zinc levels brought their immune function back to normal (rather than boosting it). Also, what was considered a failed outcome of the study (death, intensive care, or a need to change antibiotics rapidly) has very little to do with antibiotic resistance (that is, the zinc supplementation does not change whether or not the infection was caused by a resistant microbe, which actually makes me wonder as to why they included that 3rd failed outcome). Finally, as the authors clearly state: zinc is an adjunct treatment, NOT a potential substitute for antibiotics. Please tell me if anything above is unclear, it is difficult to discuss studies in a medium as limited as blog comments.

Chris (2012-06-06 15:41:23)

And in one more obnoxiously long blog comment, I will try to address your posts you link to in points 2 and 3 under point number 5: Your evidence for "we need to eat microbes" is weak overall and misleading in places. What can seem painfully obvious is often wrong in experiment. I will go through each of your points Point 1: We like umami, sour, complex flavors, etc. Another interesting theory is that we like spices in our foods because many extracts of spices contain antimicrobial compounds (allicin in garlic, this study on traditional Indian foods and Vibrio cholera <http://www.ncbi.nlm.nih.gov/pubmed/21415500>, onions, turmeric, etc, the list goes on and on). This would imply that it was better for us evolutionarily to ingest less microbes. Two competing thought experiments, no hard evidence either way. You need more than just that conjecture to prove that all microbe exposure is good for you. Seth: My theory is not "all microbe exposure is good for you." It is that the microbe exposure we get from eating microbe-rich foods (e.g., fermented foods) is good for us. There's a big difference. Why you keep talking about "thought experiments" puzzles me. That's not where my data are from. Point 2: Food traditions. People fermented their food first and foremost to make it last longer, not for health benefits. There may be some benefit to eating fermented foods, no doubt, but claiming "genetic preference" for fermented foods is a stretch. Back in the day, you ate what was available, and if that was only fermented stored food, you would probably develop a taste for it. Seth: "People fermented their food first

and foremost to make it last longer.” And you know this because . . . ? Point 3: Probiotics. I agree with probiotic use and definitely appreciate their therapeutic potential. That said, only certain species of microbes are beneficial in our guts (variants of *E. coli*, *Lactobacillus*, *Bacteroidetes* and *Firmicutes* families, etc). Probiotic benefits do not imply that you should just throw every microbe into your system that you can. If you throw the organism I do research on, *Salmonella enterica*, in your gut in the name of probiotics, you will be one very unhappy person for 7-14 days. Point 4: Fermented foods. See point 3. Certain microbes are great for you, certain microbial products are great for you, but NOT all of them. The details absolutely matter. *Staph aureus*’s toxin is also a microbial byproduct, just as much as lactic acid or propionic acid (propionic acid is what gives Swiss cheese its flavor). Seth: What does *Staph aureus* have to do with fermented food? Point 5: hormesis. None of your cited evidence has anything to do with bacteria or infectious microbes. The mechanisms by which radiation and other stressors may cause hormesis are very different from your immune system. Seth: Radiation hormesis involves intracellular repair systems. The immune system is another sort of repair system. Point 6: Bad effects of antibiotics. Are caused by a decrease in normal microbiota. Which would imply improvement by reintroducing the normal microbiota, NOT just any microbe randomly. Not just eating microbes. Still. Seth: I suggest that many (or all?) of the bacteria we need in our gut are found on the food we eat. When we eat food with lots of microbes, we are inevitably eating food with lots of bacteria specialized for that food. Not “random” microbes. Point 7: Hygiene hypothesis. Very interesting area of active research. Not a reason to just flood yourself with any microbe though. In case it is hidden behind a paywall, here is the conclusion of a recent review (on pubmed here <http://www.ncbi.nlm.nih.gov/pubmed/22257145>): “While it is clear that the microbiota significantly influences host immune maturation and immune activity, the molecular basis for these immunomodulatory mechanisms is only beginning to be elucidated. The presence of certain bacterial species or strains seems to be important, potentially because of direct interactions with the host (e.g., via PRR activation) or via their metabolic activity in vivo (e.g., SCFAs generation). Thus, care should be exercised in the selection of immunoregulatory microbes for administration in human studies as it is likely that not all microbes are equally effective and dietary factors may significantly influence the production of immunoregulatory metabolites. In addition, significant effort needs to be focused on the elucidation of the microbiota-associated molecular pathways that are impacted by dietary factors so that rationale prevention and treatment strategies can be formulated, which will include matching essential microbes and dietary components. Specific projects mining the microbiota for metabolites and ligands that modulate host immune function will likely lead to a new class of immunotherapeutic agents with relevance to a variety of inflammatory states, including allergy and asthma. Lastly, the hygiene hypothesis should now be updated to include dietary factors and the interaction of dietary factors with the microbiota.” Points 8-12 can all be explained with information above that discusses why fermented foods and certain probiotics can be good for you, so I will end here. In conclusion, I find no hard evidence for your point number two, at least in terms of the “just eat plenty of dirt and/or microbes and you’re set”. There is evidence that specific microbes at specific times can have great benefits to patients, but what you advocate is a huge overgeneralization and could potentially lead some of your readers to put themselves at more risk of disease than they should be.

Adam (2012-06-06 17:18:40)

Chris, it sounds like you are a microbiologist? If so, you must be aware that there are both Bacteriocidal and Bacteriostatic antibiotics. As the name suggests, some of these drugs KILL bacteria and some just prevent them from multiplying. If there is not an interaction between the immune system, the bacteria and the antibiotic, how is it that Bacteriostatic antibiotics are effective in treating bacterial infections? It seems to me that Bacteriostatic agents slow the bacteria down enough that the immune system itself can eliminate the bacteria successfully. I don’t really get your distinction between bringing an impaired immune system back up to normal function and boosting the immune system. It seems like you think the immune system is always running at 100 %, except in rare cases. Do we even have a good definition of what 100 % is? How do we quantify it? To me, it seems much more likely that most people’s immune systems are somewhere between 0 and 100 % of their potential, maybe on a sort of Bell Curve. It isn’t hard to imagine that there are a variety of interventions that could move one toward the right (toward 100 %).

Cliff Clayton (2012-06-06 18:11:00)

As a fellow non immunologist, I refer everyone to the Jamniet’s Perfect Health Diet. They recommend Potassium Iodide. This may not be an example of immune boosting but I will take it. I have suffered from chronic sinus infections most all my life (58 I am). I have slowly worked my dosage up to 8 mg/day over the course of 4 months. I now have free breathing through both

nostrils most of the time instead of seldom if ever. I sleep better. No sinus pressure/headache. This must be how most people breath. Amazing.

Chris (2012-06-06 20:41:59)

Hey Adam, Yes, as you stated, bacteriostatic antibiotics do exist, and their mechanism of action is to prevent bacterial growth without killing them (although the line is a bit blurry, because many bacteriostatic compounds become bactericidal at a higher concentration). So yes, they would ideally hold the bacterial population in stasis while your immune system acted to kill them off. However, the key distinction is that the antibiotic is still not interacting with your immune system, it is just slowing bacterial growth giving your immune system time to respond. The same immune response would happen without the antibiotic, but the bacteria would have had more time to multiply and cause a more severe disease without the antibiotic. A stronger immune system won't make the bacteria more or less susceptible to the drug, and is therefore not an acceptable answer for the problem of bacterial antibiotic resistance. It will help you clear any infection more quickly (if it is an infection that your body is able to handle, for those it can't you'd better hope you have some antibiotics available), so it may make the drug APPEAR more effective, but it is still a completely separate entity. I think I may be coming off a little unclear on my overall point, so let me clarify. A stronger immune system is a great thing, there are whole branches of immunology focused on defining exactly what a strong immune system is and figuring out how we can make our immune systems better. That said, it is an extremely complex process that on this blog is erroneously depicted as being extremely simple and withheld from the public because all immunologists are supposedly a bunch of morons. That's what I have an issue with, because it is simply not true. The medical establishment is not ignoring the fact that our immune system is an incredibly important tool and many researchers are actively trying to improve it. The author of the blog is falsely depicting himself as smarter than an entire field of medicine, while acknowledging that he barely knows a T cell from a B cell. That just ain't right. Seth: You write: "it is an extremely complex process that on this blog is erroneously depicted as being extremely simple and withheld from the public because all immunologists are supposedly a bunch of morons." That is far from what I wrote. One of my points is that there are simple helpful things that can be said about the immune system (e.g., the existence of an early warning system) that have not been said by insiders. That is not the same as saying the immune system is "extremely simple" or "all immunologists are . . . a bunch of morons". You have ignored my broad point that the problem of antibiotic resistance can likely be solved by improving immune function. Another simple idea I haven't heard from insiders.

Yoshie Gilb (2012-06-07 01:49:16)

I enjoy you because of all your labor on this web page. My mom really likes working on internet research and it is easy to see why. We learn all about the lively way you present sensible secrets on this web site and as well as inspire participation from other ones on this subject matter plus my princess is certainly discovering a lot of things. Have fun with the rest of the year. Your carrying out a glorious job.

andrew (2012-06-07 10:34:23)

He isn't saying he is smarter only that the incentive structure of doctors and researchers is not aligned with patients very well. The point is pay attention to your daily routine and make small changes is a good strategy for staying healthy.

Jill (2012-06-07 11:04:29)

@Chris, my take on what Seth was saying re: antibiotic-resistant bacteria and stronger immune system is this: If people generally had stronger immune systems, antibiotic use would probably decrease, thereby reducing the process by which bacteria become antibiotic-resistant (and out-compete the nonresistant strains). I don't think he was trying to say that a stronger immune system will modify the response of resistant bacteria to the antibiotics they are resistant to. Seth: That's right, thanks.

Chris (2012-06-08 21:37:15)

Tried to respond to respond to Andrew and Jill a few days ago but the internet was eating my comments. I'll just skip that for now and go back to Seth's. " It is that the microbe exposure we get from eating microbe-rich foods (e.g., fermented foods) is good for us." First of all, thank you for clarifying that you only think certain microbes are good for frequent ingestion. I apologize

for writing so much that attacked the idea that any microbe exposure is good for you (the impression I got reading many of your posts discussing spending time around sick people and dumpster dive for food with microbes on it etc). Seth: I have proposed two ideas. 1. Regular intake of food-associated microbes (in large amounts – e.g., fermented foods) is good for us. 2. Exposure to all microbes in small amounts – amounts large enough to stimulate the immune system but small enough so that the immune system gets rid of them quickly – is good for us and we do various things to expose ourselves (early warning system). If you disagree with #2 – apparently you do – I would like to know why. Yes, many microbes in fermented foods can be good for us. And this idea came from medical researchers, not you, like back in 1986 <http://www.ncbi.nlm.nih.gov/pubmed/2666378> Seth: That paper barely mentions fermented foods. It says yogurt is good for people with lactose intolerance. My claim – and my evidence – are much broader. Nor does that paper say that humans need regular intake of food-associated microbes, which is the whole point. If some nutritionist or health organization or anybody associated with health care has said we need regular intake of food-associated microbes to be healthy, please provide an example (e.g., a link). Look at any mainstream book about nutrition and you will see that what I am saying is novel. What part of your hypothesis, which you have now clarified to be almost exactly in line with medical research, was ignored by the medical establishment again? Seth: My ideas #1 and #2. And my claim that tonsillectomies are idiotic. Again, it should be easy to show I'm wrong. Just provide a link. "Seth: Radiation hormesis involves intracellular repair systems. The immune system is another sort of repair system." Yes. A COMPLETELY DIFFERENT SORT OF REPAIR SYSTEM. Seriously, are you saying that the INTRAcellular machinery (think little proteins in a single cell that cut and paste DNA) that repairs DNA damage (like strand breaks, indels, base analogues, etc) is the same as an EXTRAcellular immune system made up of T cells, B cells, macrophages, neutrophils, antibodies, complement etc? Please tell me you're not. Seth: "The same as"? Of course not. Two things can have similarities without being "the same as" each other. In this case the similarity between intra-cellular repair systems and the immune system is generalized benefit from stimulation. Stimulation by X provides protection against Y. "You have ignored my broad point that the problem of antibiotic resistance can likely be solved by improving immune function. Another simple idea I haven't heard from insiders." I have not. A quote from me above "There are diseases out there that will still infect you no matter how strong your immune system is (MRSA, B. anthracis, tuberculosis, the list goes on) and that is what we need antibiotics for (and of course antivirals for the major viral diseases)" To elaborate: you haven't heard it from insiders because insiders know that there is no reason to believe an improved immune system will protect you from all disease. People will always get sick, and we will always need antibiotics. Seth: Just because "people will always get sick" doesn't mean antibiotic resistance will always be a problem. Your main claim ("There are diseases out there that will still infect you no matter how strong your immune system is (MRSA, B. anthracis, tuberculosis, the list goes on)") is unsupported by any evidence I can find. Here are examples of articles that argue that a better immune system helps fight off MRSA: <http://suite101.com/article/new-treatment-for-mrsa-may-include-boosting-the-immune-system-a287293> <http://www.ncbi.nlm.nih.gov/pubmed/22665379> <http://www.ncbi.nlm.nih.gov/pubmed/22164166> Re tuberculosis: Huh? Surely you've heard of TB vaccines? The fact that you, who identify yourself as an insider, appear unaware of TB vaccines supports my point about insiders ignoring the immune system. Including simple obvious stuff about it. If the bacteria are resistant to the antibiotics we use, we need new antibiotics. Bacteria have co-evolved with us for millions of years, and with antibiotics more extensively for the last century. They have intricate cellular machinery to attack us that is just as complex and profound as the immune system is. Upping our immune "power" will not protect from all pathogens. We need all the tools in the toolbox to defend ourselves, particularly vaccines and antibiotics. quick aside to Andrew: where in the post did Seth mention medical research's incentive system? Jill: see my response to Seth above.

Eugene Woodbury (2012-06-09 15:31:31)

The consumption of microbes is enjoying a fast food revival in Japan. *Aspergillus oryzae* even has its own cute mascot: <http://blog.japantimes.co.jp/japan-pulse/moldy-mos-burger-confirms-koji-boom/>

Adam (2012-06-09 18:40:59)

Another cool non-antibiotic cure for bacterial disease: fecal transplant. [http://en.wikipedia.org/wiki/Fecal\\_bacteriotherapy](http://en.wikipedia.org/wiki/Fecal_bacteriotherapy) "Benefits of FMT include the restoration of the colonic microbiota to its natural state by replacing missing Bacteroidetes and Firmicutes species, eradication of *C. difficile*, and resolution of clinical symptoms such as diarrhea, cramping and urgency. Antibiotic resistance in CDI is an uncommon event- rather CDI relapses due to the presence of *C. difficile* spores[19]. Although once considered to be 'last resort therapy' by some medical professionals due to its unusual nature and 'invasiveness' compared with antibiotics; perceived potential risk of infection transmission; and lack of Medicare coverage for donor stool, the recent po-

sition statement by specialists in infectious diseases and other societies[1] is moving away from FMT as a last-resort treatment and toward acceptance of FMT as standard therapy for relapsing CDI and also Medicare coverage in the United States. Indeed the Editor-In-Chief of the Journal of Clinical Gastroenterology, Dr Martin Floch, announced in a recent editorial that "FMT using donor stool has arrived as a successful therapy"[20]. Given that antibiotics are the original cause of CDI through their damage of the normal human flora and removal of protective Bacteroidetes and Firmicutes species, further antibiotic therapy should be avoided. It has now been recommended that endoscopic Fecal Microbiota Transplantation be elevated to first-line treatment for patients with clinical deterioration and severe relapsing C. difficile infection[5]. The earlier the infusion is initiated, the less likely the patient's condition will deteriorate, thereby preventing the higher mortality rate associated with severely affected patients. Fecal Microbiota Transplantation is being increasingly used in clinical practice and since complications of FMT are so rare its use is likely to increase exponentially in the coming years." Seth: Very interesting, especially the low complication rate.

Chris (2012-06-09 20:56:03)

Still the tonsillectomies thing?? Did you not read the Mayo clinic guidelines are posted? Tonsils are no longer removed for flippant reasons like a one-time infection. They are removed for things like cancer of the tonsils, and extremely painful recurrent infections that hamper quality of life. Seth: I read the Mayo Clinic guidelines long ago. Unlike you, apparently, I don't believe everything I read on the Mayo Clinic website. Only a small fraction of tonsillectomies involve cancer of the tonsils. For "recurrent infections", tonsillectomies are ineffective – see the latest Cochrane Review. "Seth: "The same as"? Of course not. Two things can have similarities without being "the same as" each other. In this case the similarity between intra-cellular repair systems and the immune system is generalized benefit from stimulation. Stimulation by X provides protection against Y." Except when it doesn't. Please provide any evidence that exposure to a nonpathogenic bacterium throughout the lifespan (not just in development, which is discussed in the hygiene hypothesis) increases immune response to a different microbe, via either increased innate or adaptive immunity. Seth: See studies of how probiotics reduce colds and other infections. I provided links to them on my umami hypothesis page. Also, thanks for doing my research for me. You just cited two studies from Pubmed that cite real medical researchers doing research on...wait for it... the immune system!! What happened to this? "those who run our health care system ignore the immune system" Seth: I didn't say it was completely ignored. Of course not. Also, if you actually read the paper, Seth: Which paper? they do not do what you say they do. No immune system is "improved" through our intervention (although I applaud you for finally deciding to search pubmed instead of just claiming you know things). In the PVL paper, the PVL cytotoxin SECRETED BY THE BACTERIA increases the immune response. This was not a treatment that boosted the immune system, it was a finding that this specific type of bacteria is going to be associated with better outcomes because your immune system recognizes it better (this is a simplistic explanation, but captures the idea). The staph aureus paper, if you read beyond the "immune enhancement" title, actually involves injecting P4 along with a pathogen specific antibody. This is a form of chemotherapy, it just doesn't happen to involve antibiotics. It is still a drug however, and it doesn't just magically "boost" the immune system. You add antibodies that are specific to the bacteria into the blood, they coat the pathogen, your body recognizes them like any other antibody and engulfs the bacterium. It is just another tool to use against tough to treat diseases. No one is throwing out antibiotics because of these tools, because bacteria will become resistant to things like pathogen-specific antibodies via mutations just like they would become resistant to antibiotics. All of these forms of research are useful and will hopefully give us enough options to treat future disease, but none is perfect on their own. Seth: I fail to see how all this supports your claim that "There are diseases out there that will still infect you no matter how strong your immune system is (MRSA, B. anthracis, tuberculosis, the list goes on)" – as if, when it comes to these diseases, strength of immune function didn't matter. "Re tuberculosis: Huh? Surely you've heard of TB vaccines? The fact that you, who identify yourself as an insider, appear unaware of TB vaccines supports my point about insiders ignoring the immune system. Including simple obvious stuff about it." And if you had in-depth knowledge about TB vaccines instead of knowledge from Google University, you would know that the TB (aka BCG) vaccine is one of the least effective vaccines we have (approximately a 50 % success rate) <http://www.ncbi.nlm.nih.gov/pubmed/8309034> and that active research to make a better one is underway. If we had a good vaccine, TB wouldn't be such a massive worldwide problem <http://www.ncbi.nlm.nih.gov/pubmed/22608339>. Currently MDR-TB (multi drug resistant TB) is one of the most devastating global pathogens. New antibiotics developed to treat TB (the second line antibiotics) have saved countless lives, but now TB is resistant to those as well, and we are looking for more. Seth: I don't see how any of this makes your claim that TB "will still infect you no matter how strong your immune system is" less wrong. As shown by the (partial) effectiveness of TB vaccines, the immune response to TB matters a lot. Stronger immune

system -> less need for anti-TB antibiotics -> less concern with multi-drug resistant TB. I am unable to figure out what part of this reasoning you disagree with, and why. "Seth: I have proposed two ideas. 1. Regular intake of food-associated microbes (in large amounts — e.g., fermented foods) is good for us. 2. Exposure to all microbes in small amounts — amounts large enough to stimulate the immune system but small enough so that the immune system gets rid of them quickly — is good for us and we do various things to expose ourselves (early warning system). If you disagree with #2 — apparently you do — I would like to know why." Sigh. Okay, I'm done trying to assume what you are trying to say, because you keep re-clarifying your statements (moving goalposts). Please provide peer-reviewed research, ideally with a plausible mechanism, that explains your points 2 and 3. Also, explain how point 3 is different from the widely researched hygiene hypothesis. For point 2, explain how it is different from probiotics. I didn't cite that paper as a specific example of a paper that said fermented food was good for you, I cited it as an example that probiotics had been in the literature for 30 years. Seth: The notion that yogurt is good for us is more than 100 years old. There is a big literature on probiotics, of course. If you think the idea that yogurt and probiotics are good is the same as my umami hypothesis (yogurt and probiotics do not taste of umami), fine, let's move on. How my point 2 (early warning system) is different from the hygiene hypothesis: I am saying all of us (not just children) actively do things to expose ourselves in tiny amounts to the microbes around us. We actively self-vaccinate. The hygiene hypothesis says nothing about self-vaccination. Finally, please don't just self-cite your old posts again. I read them, and magazine articles that talk about elephants liking beer don't count as scientific evidence. Please show me the relevant literature that spells out a plausible mechanism that explains exactly your statement "Regular intake of food-associated microbes (in large amounts — e.g., fermented foods) is good for us." -Specifically why the intake must be regular, and why the microbes must be food associated. Otherwise you are just talking probiotics and normal flora, which is nothing new. Also explain this "Exposure to all microbes in small amounts — amounts large enough to stimulate the immune system but small enough so that the immune system gets rid of them quickly — is good for us and we do various things to expose ourselves (early warning system)." -specifically how the immune system is stimulated by these microbes, and what changes in the immune system we can expect from this exposure. Give solid evidence why things like touching our mouths means we are sampling bacteria and not just itching. As I side above, clearly explain why this is not just the hygiene hypothesis. Seth: I cited two kinds of evidence (both peer-reviewed) for the early warning system idea: 1. people frequently touch themselves near their mouth. (Your "itching" explanation: read about the differences between "proximate" and "evolutionary" explanations. Both may be true.) 2. "group immunity" data with insects. I could have added (peer-reviewed) data about 3. Placement and function of tonsils. 4. Effect of loss of tonsils (very bad long-term). These 4 lines of evidence have never been proposed to support the hygiene hypothesis. Enough hiding behind old posts and vague explanations. If you really know your stuff, I want coherent, testable hypotheses that are proven true by scientific experiments. Seth: My post put forth an obvious idea: If our immune systems were much stronger, we would need to use antibiotics much less. If we used antibiotics much less, antibiotic resistance would be much less of a problem. Are you still saying this is WRONG?

Vas (2012-06-10 00:07:45)

Hi Seth, I was referred to your excellent blog by Allen. I know very little about medicine, but I can tell you that when I go to Ukraine I find a different approach. Antiviral medicine is freely available and affordable (from personal experience it works - though that could be a placebo effect). There are also sprays that are said to stimulate the immune system (prescribed by doctors.. may have been a hormone, I could find the name if you were interested). Vasiliy Seth: By Allen you mean Allen Neuringer? Yes, I am interested in the name of these sprays that are said to stimulate the immune system. I have not heard of them.

Vas (2012-06-10 21:02:40)

Yep, Allen Neuringer. Interferon is what my sister was prescribed by a doctor for her kids to do something like boost their immune system if they were to be in an environment where they were likely to get sick (e.g., around other sick kids). The wikipedia page seems to suggest that interferons do indeed have something to do with the immune system. For less medical things, there are echinacea sprays that are said to boost the immune system (apparently there have been some scientific trials that suggest echinacea decreases the duration of a cold). Seth: That's interesting, thanks. I didn't know about echinacea sprays.

Patrik (2012-06-10 21:58:06)

*Removing tonsils because of too many infections makes as much sense as removing part of the brain because of memory loss.*  
What? Are you implying that physicians actually treat the cause, and not the symptom? HOW DARE YOU? ;P

Vas (2012-06-11 14:04:49)

Of course echinacea sprays/teas are not prescribed by M.D.s, but I've had positive experiences with them.

Chris (2012-06-12 21:14:00)

Hi Seth, Been without internet for a few days, saw you had a new post on this topic, so I will put more emphasis on responding to that, but in brief I will address your closing comment: "Seth: My post put forth an obvious idea: If our immune systems were much stronger, we would need to use antibiotics much less. If we used antibiotics much less, antibiotic resistance would be much less of a problem. Are you still saying this is WRONG?" Yes. Probably not the part that you think though. If we used antibiotics much less, there would be less antibiotic resistance, yes. However, you have no evidence that if our immune systems were much stronger, we would need to use antibiotics much less. First of all, you still cannot clearly define what a stronger immune system consists of. Secondly, you have not shown data shown that "XYZ" indicator of improved immune function was shown to be protective against "ABC" disease. Finally, you haven't taken into account the fact that oftentimes, people get sick not because their immune system is deficient, but because the microbe simply has better mechanism of attack than your body has of defense. Even if the body's current immune mechanisms were improved (whatever that means), if a microbe has bypassed the immune system, it won't matter (e.g. staph aureus had a protein A on its surface that binds antibodies in reverse, preventing normal immune response, a higher titer of antibodies would not necessarily then lead to a better disease outcome. There are thousands of other examples of similar mechanisms bacteria use to defeat the immune system (phagosome survival, altered membrane charge, etc) Just because something seems "obvious" doesn't mean it is right. @ Patrick And when you cannot treat the underlying cause, treating the symptoms is better than nothing, no? Painkillers do not treat the underlying cause of migraines, but they can sure help. @ Vas N=1, placebo effect (that actually describes a lot on this blog) Seth: You write "you have no evidence that if our immune systems were much stronger, we would need to use antibiotics much less." When I started to sleep much better, I got colds much less than previously and much less than most Americans. This suggests that most Americans would get sick less if their immune function was improved. The most interesting part of your answer is "oftentimes, people get sick not because their immune system is deficient, but because the microbe simply has better mechanism of attack than your body has of defense." This view implies that "oftentimes" variations in immune function have no effect on probability of getting sick. What is your evidence that it has EVER happened that strength of immune function made no difference? I believe there is none.

Vas (2012-06-14 21:22:27)

Chris, I make no claims about the efficacy of echinacea (in terms of improving immune function), and perhaps it has been a placebo effect in my case, but I can say that N is substantially greater than 1. Here are just some of the studies: <http://www.umm.edu/altmed/articles/echinacea-000239.htm>

## **Attention The New Yorker Subscribers! (2012-06-08 16:24)**

My New Yorker subscription runs out in July. In February I got a letter from the magazine that said "We Need Your Instructions At Once". Renewal price: \$49.99 (1 year) or \$79.99 (2 years). In May I got a similar letter that said "Renewal Confirmation". Renewal price: \$29.99 (1 year) or \$49.99 (2 years).

dearieme (2012-06-08 23:08:29)

30 bucks? Worth it for the cartoons alone, I'd have thought. That's assuming it lasts a year.

BlueMorrissey (2012-06-09 08:08:19)

My dad got a price that was about double for a wall street journal subscription than the asking price I received. Have no idea why, but of course he used my mailing to renew his subscription. Thought maybe at first mine was for just half a year, but it was for just as long. He gets the paper and I use the online edition from the same subscription. Not much difference in cost to add the internet version.

Nancy Lebovitz (2012-06-09 08:33:55)

I've heard about websites tweaking prices in an effort to get the most revenue.

Tom (2012-06-09 15:22:14)

Standard practice in the magazine business for decades. If you want the cheapest price, let your subscription lapse, then resubscribe with one of the "blow-in" cards from a newsstand copy. Make sure you keep a xerox of the offer; when the bill arrives it will invariably be for far more than the contracted price, (just as with any long distance phone plan you ever signed up for.) Yes, systematic fraud on a grand scale. Never prosecuted, AFAIK.

Jack (2012-06-09 18:47:59)

What do you think happens to psychology students who don't become professors? They become marketers and invent tests to subject their professors to. Just another rat in a maze. In general, in marketing, you offer your best prices to your worst customers.

P.Granja (2012-06-09 19:39:07)

Regarding an older post/link - Amish farm kids have fewer allergies than Swiss farm kids. You suggested that something else besides growing up on a farm could be responsible for reducing allergies: drinking microbe-rich raw milk. I don't know if you already thought of it, but how about the lack of electric light and a better sleep/12hour fasting? «"People who work at night have a 150 percent higher rate of metabolic disease," and "If you overlay the CDC diabetes map with the NASA nighttime satellite map, there's an almost perfect match," says Satchin Panda, regulatory biology specialist at the Salk Institute. The more light in a region at night, the higher the incidence of diabetes. According to Panda, this is because your liver needs sleep. Actually, it's not the sleep per se that your liver needs, but a defined period of fasting each day, which throughout humanity's evolutionary history was the hours of darkness when you couldn't really do much but snooze» <http://www.bakadesuyo.com/should-we-blame-the-diabetes-epidemic-on-light>

Dennis (2012-06-28 15:33:52)

Hi, Can you publish the promo code for the renewal rate or site that was in your letter? The people of the CS won't let me renew my sub for that price if i don't have a promo code... Thanks! Seth: Sorry, I don't have it any more.

### More Examples of Mainstream Health Care Ignoring the Immune System (2012-06-11 05:00)

In [1] a recent post I made an obvious point. If our immune systems were stronger, we would need antibiotics less often and antibiotic resistance would become less of a problem. I hadn't heard this point made (for example, [2] this WHO report fails to say it). This was one example, I said, of how mainstream health care ignores the immune system. Perfectly obvious things, such as this idea about antibiotic resistance, fail to be noticed. I gave five more examples. Since then I have come across even more examples:

1. Hospitals do little to help patients sleep and often interrupt sleep, [3] Nancy Lebovitz pointed out (better sleep → better immune function). [4] This article describes the problem. One way to improve hospital sleep – beyond don't wake patients up – would be to provide exposure to strong sunlight-like light in the morning and prevent exposure to sunlight-like light after dark. [5] I found that an hour of sunlight or similar light from fluorescent lamps in the morning improved my sleep. Most fluorescent light resembles sunlight (both have strong bluish components), incandescent light (reddish) does not. Until they install dual lighting systems (bluish light during the day, reddish light at night), hospitals can provide blue-blocker glasses to wear after dark.

2. The book [6] *Immortal Bird* (sent me by the publisher) tells how Damon Weber, born with a defective heart, had a heart transplant when he was a teenager. After the transplant, problems arose. The doctors involved (at [7] New York-Presbyterian Hospital/Columbia University Medical Center) took the problems to be signs of transplant rejection. In fact they were due to infection. Drugs given to deal with the mistakenly-assumed rejection suppressed Damon's immune system. They reduced his ability to fight off the infection and he died. The author of the book, Damon's father, sued the doctors and hospital for malpractice. The doctors did not exactly "ignore" the immune system, but they apparently failed to fully grasp the danger of immune suppression, even though the infection that killed Damon is common in transplant cases. (Although Columbia Presbyterian charged half a million dollars for the transplant, [8] "three years into the lawsuit the [hospital's] medical director claimed Damon's post-op records couldn't be located.")

3. I asked a UCSF medical student what she'd been taught about the immune system. "We cover it!" she said. In a section called "Infectious Disease, Immunology, and Inflammation". What makes the immune system work better or worse? I asked. "If you're stressed out, it doesn't work well," she said. If you're malnourished, like in Bangladesh. You need "nutrients and vitamins". (A booklet I got telling me to take less antibiotics told me to "eat healthy".) She also said the students get entire lectures on how to treat diseases so rare they might never be encountered. There is a whole section on genetics. Sure, they cover it. So superficially that they don't remember the most basic idea: Better sleep → better immune function. I said our health care system is built around first, let them get sick. That's right, she said. Ignoring the immune system is an excellent way to allow people to get sick.

4. [9] Melissa McEwen pointed out that proton pump inhibitors, such as Nexium, reduce the body's ability to fight

infection. They are prescribed for acid reflux and reduce how much acid the stomach makes. Because stomach acid kills bacteria, there should have been far more concern about their safety. "Proton pump inhibitors (PPIs) are among the most widely prescribed medications worldwide [billions of prescriptions]. . . . The collective body of information overwhelmingly suggests an increased risk of infectious complications," says [10]this article. Because the drugs are so common, the damage is great and, because of more infection, not restricted to those who take them. It could have been avoided by research into treatments that do not harm the immune system.

Rachel (2012-06-11 07:02:04)

Also getting your feet cold and wet decreases immune resistance: [http://www.ctv.ca/CTVNews/Health/20051114/cold\\_warm\\_nose\\_051114/](http://www.ctv.ca/CTVNews/Health/20051114/cold_warm_nose_051114/) Seth: A very interesting study, thanks. It deserved a lot more publicity than it got. I had guessed people get more sick during the winter because their sleep is worse.

Chuck (2012-06-11 08:53:59)

I think there are too many confounding factors in the cold wet feet study to give it much credence. Number one on the list is exposure to the virus - past or present - dormant or active. A better test, but by no means conclusive, would be to set up the test as they did and then expose everyone to the virus. Then see who comes down with a cold and who doesn't. Still too many confounders though.

Chuck (2012-06-11 08:58:16)

I commented on your last post on vitamin D how I haven't had any colds since I've been taking 5k IUs and getting plenty of sun exposure. I also stopped taking Prilosec (a proton pump inhibitor) at about the same time. Interesting.

Patti (2012-06-11 12:54:12)

Let's be clear, there is no such thing as an Immune System in the human body. There are eleven systems in the body and not one of them is called the Immune System. The body has the Lymphatic System which includes organs that develop cells devoted to immunity. Geez I learned this the first week of Anatomy and Physiology, you would think a doctor would know better.

Kirk (2012-06-11 16:24:31)

@Patti, Thank you so much for educating us. While you are at it, you should send a blistering letter off to the Mayo Clinic, because they have a web page titled, 'Your Immune System.' Also send a nasty snarky letter of correction to WebMD, because they have a web page with the subtitle, 'Using Your Immune System to Stay Well'. And be sure to lecture the Cleveland Clinic, given that they have a web page saying, 'The human body has a highly efficient immune system, providing multiple defenses

to ward off invaders such as bacteria, viruses and harmful chemicals.'

Patti (2012-06-11 19:30:18)

Kirk, Yes those are all great websites for the general public. My point was directed at a medical professional not you, but since you have responded I shall make this comment just for you. There is no such thing as an Immune System. Cells/tissues of the Lymphatic System make up immunity. If you look at an actual college level Anatomy and Physiology textbook you will be able to read that there is no such thing as an Immune System. There are eleven systems in the body, not twelve. Maybe someday they will subdivide the Lymphatic System into two systems, but that is not how it is today. Suggestion for you - maybe you should consider getting your information from actual fact based text books instead of web pages? Just saying... Patti

Tom Moertel (2012-06-11 20:24:49)

The human body doesn't actually have "systems." Believing that it does is to mistake a model of the thing for the thing itself.

Nancy Lebovitz (2012-06-11 21:27:20)

For what it's worth, it seems to me that people are more likely to get sick when the weather does wide daily swings- mostly in the spring where I've lived (Delaware and Philadelphia).

Chuck (2012-06-12 07:56:54)

"...fact based text books..." Now there's a laugh.

Greg (2012-06-12 09:35:49)

Seth, here's an example of the widespread belief that suppressing the immune system is harmless. The immune system is involved in the local inflammatory response post-injury. One might imagine that this has something to do with the healing process (though I have no idea what the medical textbooks say about this). It has been known for many years that non-steroidal anti-inflammatory drugs, which suppress inflammation, may also impair healing, particularly of bone and cartilage (see e.g. <http://www.ncbi.nlm.nih.gov/pubmed/15177303> from 8 years ago). Many years later, human data on this subject is still lacking (see <http://www.ncbi.nlm.nih.gov/pubmed/20487623>), while perscription of NSAIDs apparently remains standard of care for orthopedic injuries. My friend was recently perscribed one for a sprain, and I asked a doctor I knew why. He agreed that they could slow the healing process, and that they were only perscribed for pain relief (my friend had no pain, and was not given this information by the perscribing doctor).

Kirk (2012-06-12 10:30:21)

@Patti, First, my apologies for the tone of my previous reply. I still do not understand why using 'immune system' is inappropriate. A search of PubMed for titles which include 'immune system yields 6815 titles. I briefly browsed several papers to learn the authors worked in departments such as Medicine and Immunology. (The search string at PubMed is: immune system[Title] )

Kirk (2012-06-12 11:33:37)

Seth, it would be interesting if you could use your contacts to find a competent Traditional Chinese Medicine physician to interview about whether that system considers it important to improve the immune system. Seth: Good idea. I think a lot of Traditional Chinese Medicine herbs do just that - stimulate the immune system. But what about prevention?

susan (2012-06-12 20:58:05)

It seems to me that our problem is not a weakened immune system, but rather an overactive immune system. there is an epidemic of autoimmune diseases happening, whether it is type 1 diabetes, multiple sclerosis, eczema or lupus. my recent experiences demonstrate this. my daughter was recently diagnosed with type 1 diabetes mellitus (T1DM). T1DM is a disease in which the body's immune system attacks the insulin-producing cells in the pancreas. the endocrinologist who diagnosed my daughter said that there is a big increase in T1DM, especially in the northern latitudes. He posited that it may be due to lack of sunlight, much like MS. I suffer from eczema, which is also on the increase and is also an autoimmune disorder. Just some observations. Thank you-Susan

Chris (2012-06-12 21:36:00)

Oh boy... 1. Yes better sleep does seem to lead to better immune function. Good thing no one in the medical community studies that. Oh wait, <http://www.ncbi.nlm.nih.gov/pubmed/21835655> Also, hospitals don't wake patients up solely to disturb their sleep, usually it is to get rounding/pre-rounding out of the way so the doctors can see and treat more patients. If you ran a hospital where you could never disturb the patients, you would get very little done. 2. That is a tragic story. However, if it was transplant rejection, and immunosuppressive therapy wasn't initiated there would have been a guaranteed organ rejection and death. That's the thing about medicine, you actually have to make hard choices with real consequences. Transplant rejection and an infection can manifest very similarly, and the life of your patient hangs in the balance. Then you have to own up to your mistakes. Very much unlike watching from the stands and having 20/20 hindsight as you criticize from a blog. Its not like they gave immunosuppressive therapy for no reason. They knew it had risks. 3. Thanks for that anecdote from talking to one medical student. Did you by chance ask her if sleep deprivation effected the immune system, or just listen to her list variables from a course she took and see if she missed your favorite variable sleep? I would bet that if you directly asked her about sleep deprivation, she would have told you it was not good for the immune system. Either way, one medical student at one medical school is hardly damning evidence. My friend, who will be a medical student next year, knew that before taking a course on the immune system. Of course her evil medical education will probably beat that knowledge out of her and teach her how to give advice that makes people sicker (/sarcasm). 4. Please, less citing of blogs and more citing of studies. Oh and btw, the study you did cite said this "PPIs have REVOLUTIONIZED the management and complications of acid-related disorders with a HIGH MARGIN OF SAFETY; however, with the data available, efforts to reduce the dosing of or discontinue the use of PPIs must be reassessed frequently." (emphasis mine) It does not call for the end of PPIs, only that they be used responsibly in the treatment of acid related disorders with this new data in mind. But hey, you do a great job of quoting out of context. Oh would you look at that, evidence based medicine changing practices to improve patient care! But I thought the doctors didn't care about making people better! Seth: What does "HIGH MARGIN OF SAFETY" mean? I have no idea. "High margin" compared to what?

Chris (2012-06-12 21:39:49)

@ Kirk It would be even more interesting if the TCM practitioners actually had data showing their treatments could increase immune function. Also, competent TCM Doctor is a bit of an oxymoron when there is no evidence supporting TCM being, oh I don't know, effective against disease. Seth: You appear unaware of evidence that the immune system is effective against disease ("you have no evidence that if our immune systems were much stronger, we would need to use antibiotics much less").

Adam (2012-06-13 08:45:49)

To feed the troll (though I know I shouldn't): "A 2011 Cochrane review documented that acupuncture is effective in the treatment of migraines, neck disorders, tension headaches, and some types of osteoarthritis ..." There's also a little drug called  (Artemisinin) from TCM that is the most effective known medicine for treatment of Malaria and the worldwide standard. The discoverer is being considered for a Nobel prize.

Kirk (2012-06-13 11:05:06)

By 'competent TCM physician' I mean the following: ask for a referral from a trusted colleague. Seth works/lives in both the Bay Area and Beijing. He knows intelligent and skeptical colleagues who have had various medical issues. I think it possible that one or more of them would have received useful treatment from a TCM physician, most likely after failing to find relief from allopathic medicine.

Kirk (2012-06-13 11:36:15)

If you ask a TCM physician about prevention steps to improve the immune system, I suspect you will hear about food therapy, supplements, Qigong, acupuncture, and meditation. You may also hear about unfamiliar concepts such as Yin or Yang deficiency (and many more). I am slogging through a book about Chinese healing, but the concepts are so foreign that not much is making sense. I have never been to a TCM physician so I have no idea what you might hear. I have an economic perspective on whether TCM is valid, in that those medical technologies which do not succeed at treating problems eventually fade away due to lack of customers. TCM appears to be practiced in the Bay Area and is thriving in China.

Bryan (2012-06-13 13:29:36)

"She also said the students get entire lectures on how to treat diseases so rare they might never be encountered." Sort of like how we get entire lectures in law school on esoteric legal issues we will probably never encounter.

### **The Glacially-Slow Conquest of Scurvy And Its Relevance to Modern Life (2012-06-12 05:00)**

Scurvy is a disease of civilization because you need civilization to make long ocean voyages. It is the first disease of civilization to be understood and eliminated. In [1] a paper called "Innovation and Evaluation" (gated), Frederick Mosteller, a professor of statistics at Harvard, noted how long it took. In 1601, James Lancaster, a sea captain, did an experiment involving four ships on a long voyage. Men on one ship got lemon juice, men on the other three ships did not. The men given lemon juice were far less likely to get scurvy. In 1747, James Lind, a doctor, compared six purported cures for scurvy. Lemons and oranges (one cure) were much better than the other five (as Lind expected). In 1795 the British Navy started using citrus juice regularly and wiped out scurvy on their ships. In 1865, the British Board of Trade recommended citrus juice for commercial ships. It took more than 200 years for a simple and effective remedy – discovered before Lancaster – to spread widely.

The sailors at risk of scurvy did not control what they ate. The people who controlled what they ate never got scurvy. Sure, the people who controlled what sailors ate did not want them to get scurvy (high rates of scurvy were a big problem) but they also had other concerns. The lesson I draw from this story is do not let anyone else (doctor, expert, etc.) solve your health problems for you. Sure, other people, as part of their job, will sell you something, provide advice, write a prescription, provide therapy, do surgery, whatever. It might work. They want to help you – the more they help you, the better they look, the more business they attract. But it is entirely possible, this bit of history teaches, that they are slow on the uptake or have conflicts of interest and a much better solution is available.

Thanks to Steve Hansen.

---

Darrin Thompson (2012-06-12 06:28:42)

If you dig around the internet long enough you can find an article describing how the cure to scurvy was found and then lost for a long time.

Andrea (2012-06-12 06:51:38)

Sorry, Seth, I'm having trouble understanding what you mean about the sailors: "The sailors at risk of scurvy did not control what they ate. The people who controlled what they ate never got scurvy." Do you mean that the cooks on the ship always made sure that they ate lemon juice, but they didn't build it into the menu for the rest of their shipmates? How do you know this? Seth: What the sailors ate was determined by the food they took on board at the beginning of their trip. This was not determined by the cooks, as far as I can tell from the books I have read about this. It was determined by higher authorities.

Nancy Lebovitz (2012-06-12 07:57:41)

I'm pretty sure Seth means that the people who made decisions for the Royal Navy weren't getting scurvy.

gwern (2012-06-12 09:17:23)

Darrin: you mean [http://idlewords.com/2010/03/scott\\_and\\_scurvy.htm](http://idlewords.com/2010/03/scott_and_scurvy.htm) ?

dearieme (2012-06-12 10:51:05)

I suppose the likes of Pepys were in charge of provisioning. Does he say much about it?

Introsphere roundup – Week thru June 12 | The Second Estate (2012-06-13 04:21:49)

[...] Roberts – The Glacially-Slow Conquest of Scurvy And Its Relevance to Modern Life, – More Examples of Mainstream Health Care Ignoring the Immune System, – What to Do [...]

Tuck (2012-06-13 14:15:42)

@gwern: If that's not what Darrin was referring to, it's a fine account.

Phil (2012-06-16 17:01:52)

gwern - that is the best article on health i have read. the lessons to be drawn, the parallels, and the sheer magnitude of the story are awesome.

Douglas Knight (2012-06-21 19:19:19)

[1]An alternative link for the Frederick Mosteller paper The paper Darrin and Gwern cite suggests that it isn't so simple as saying "lemons cure scurvy." What happened between Lancaster and Lind? It is not hard to imagine that people did experiments, and rejected citrus. It does seem, though, that they should have done enough to get the right answer. Seth: I think the paper they cite says that people forgot that lemons cure scurvy. Or were confused. Not that any experiment rejected citrus.

1. <http://www.sciencemag.org/content/211/4485/881.short>

Douglas Knight (2012-06-22 09:43:37)

There was no controlled experiment, but it wasn't a matter of people forgetting. You can say they were confused, but Lancaster and Lind were just as confused. Several arctic expeditions got scurvy, despite lime juice. This wasn't an experiment, but it was very good evidence. Actually, there was even better evidence: there was no difference between people on the ship, with more juice, and those off. The simple claim "citrus cures scurvy" is just not true. The biochemical situation is simple, but the food consequences are complicated. What if the British Navy had listened to Lind? They would have put lemon juice in his copper vats and found no effect on scurvy. Would we today know they had tried? We remember Lancaster and Lind because their experiments matched the slogan "citrus cures scurvy," not because they were the only experiments, let alone the only claims of data.

Matt (2012-06-13 11:09:33)

It's not true that you can't learn anything from the low numbers. You can get a sense that hospital costs were very low relative to late 20th century costs, and you can get a sense of when hospital costs started climbing rapidly. The effect on the reader – especially one who might not appreciate he is looking at a log plot (which for NEJM readers would be quite a lot I would imagine) wouldn't be as large with a log plot. So it depends on what the presenter of the graph wants to accomplish. If he wants the reader to see a rise in hospital costs in the 1870s then a fall in the 1910s then a log plot is best. If he just wants to point out the large and dramatic climb of healthcare costs in the late 20th century, I think an unlogged plot is best. Seth: "You can get a sense that hospital costs were very low relative to late 20th century costs, and you can get a sense of when hospital costs started climbing rapidly." You may get the wrong sense. With no correction for inflation who knows what the hospital costs in 1910 were relative to late 20th century costs. Nor do you know when hospital costs started climbing rapidly. Perhaps hidden in those tiny values are large percentage increases. Perhaps the sharp rise apparent on the graph is an artifact of changes in the inflation rate.

Matt (2012-06-13 23:31:27)

The cost is in 2010 dollars. Seth: Good to know. Then I would just say that the graph makes it hard to see anything interesting apart from the date when costs first started to rise quickly.

max (2012-06-15 05:45:24)

To me the interesting thing (purely visual estimate) is to see that for an (on average) 2 times decrease of the mortality rate a modern (post-1965) hospital required a 7-fold cost increase.

### **Variation in Abbott Blood Sugar Test Strips: A Warning (2012-06-14 05:00)**

I've measured my fasting blood sugar (= blood sugar before breakfast) for about four years. I began out of curiosity but became alarmed when the values approached "pre-diabetic" (> 100 mg/dl, diabetic is 126 mg/dl or so). Eventually I learned that walking an hour/day put them in the 80's consistently. Perhaps 84 is optimal, who knows.

I have used Abbott test meters and strips. They need so little blood that testing is painless. Recently (January 2012?) Abbott introduced new "butterfly" test strips that "wick" the blood. The meters stayed exactly the same. The new test strips are certainly better. I started to use them. I started using them after a gap (a month?). All of a sudden my scores were about 5 mg/dl better – for example, 84 instead of 89. I assumed this was due to lifestyle changes on my part. I was walking more, I was more muscular, whatever. These were plausible explanations. Surely Abbott had not corrected a huge mistake (given the size of the business, the importance of diabetes, and the need for accurate test strips, to be consistently off by 5 mg/dl would be a huge mistake).

Now I wonder. I recently found some old-style test strips, barely expired (2012/04). I have compared them to the new-style strips (expiration 2013/06). Here are my results:

Morning 1. New: 81, 84. Old: 99, 91, 100.

Morning 2. New: 80. Old: 96, 94, 95.

Morning 3. New: 84. Old: 104, 97, 105.

Morning 4. New: 86. Old: 101, 100, 100.

These results involve three different meters. The old strips come from three separate vials. It is clear that the old strips produce readings much higher (about 15 mg/dl higher) than the new strips.

The old strips are expired but I doubt they got 15 mg/dl worse in 1-2 months. I expect they are accurate when they leave the factory and slowly get worse. Now I have some idea of how much worse (and in what direction). Apparently there is a big increase in bias with little increase in variability. I've gone from batch to batch before and never noticed a difference. Only when comparing the new strips with the old has a difference been clear. The earlier comparison, with a 5 mg/dl difference, compared unexpired old strips with the new strips.

I conclude that with the old strips, deterioration with age is worse than I expected and I should pay more attention to test strip age.

---

Darrin Thompson (2012-06-14 06:58:05)

Cool. Now you are a connoisseur of test strips.

dearieme (2012-06-14 07:23:34)

It's one of the Miracles of Modern Medicine that no test reading ever comes with a plus-or-minus interval attached. To ask them also to record potential bias is therefore a hopeless cause. Seth: I don't mind the absence of a plus-or-minus interval. I can figure that out myself by doing repeat tests. I cannot figure out bias and 15 points is really bad.

Carol (2012-06-14 08:50:21)

I am using a Reli On meter that uses strips by Abbott that take a larger amount of blood, and they too suffer from this effect - and it starts happening before they expire. These strips are individually wrapped. I originally noticed this problem with my original meter (that came from Target) that used strips in a bottle, so I switched to a meter that used individually wrapped strips. It still happens, just more slowly. By the end of the pre-expiration period, they are 10-15 points higher.

Alex Chernavsky (2012-06-14 09:30:55)

I bought a digital fever thermometer a few years ago. The first time I had to use it, I measured my temperature about five or six times in a row. I was appalled by the variability in the readings - they differed by as much as a degree. I'd prefer to use one of those old-fashioned mercury thermometers, but I think that they're not available anymore. Maybe I could get a used one from eBay.

Christopher Burd (2012-06-14 12:28:16)

I believe consistency is a big problem with glucose test strips, second only to price (alleged markups 1000 %+ over production costs).

Govert (2012-06-17 03:27:21)

You might find this post about Diabetes Technology (and how little has changed) quite interesting:  
<http://www.hanselman.com/blog/TheSadStateOfDiabetesTechnologyIn2012.aspx>

Jazi zilber (2012-06-17 09:13:10)

Tim ferriss compared sugar strips of various makers, finding large differences (i faintl think 10-20) I think it is reported in four hour body

## How Useful is Personal Genomics? A Case Study (2012-06-15 09:42)

How much can you help yourself by getting your genome sequenced? A lot, a little, not at all? Scenario 1 (big help): You discover you have a greatly elevated risk of Disease X. You do various things to reduce that risk that actually reduce it. Scenario 2: (a little help): You discover you have a greatly elevated risk of Rare Disease X. You do various things to reduce that risk but they don't help. At least, when Disease X starts, you will be less upset. Scenario 3 (no help): You discover that you have a greatly elevated risk for a common easily-noticed disease (such as obesity). You already watched your weight, this changes nothing. Scenario 4 (harm): You discover that you have a greatly elevated risk of Scary Disease X (e.g., bipolar disorder). It is depressing news. Later studies show that the gene/disease association was a mistake. (Many gene/disease associations have failed to replicate.)

[1]A recent Wired article tries to answer this question for one person: Raymond McCauley, a bioinformatics scientist who had his genome sequenced four years ago and learned he was "four or five times more likely than most people to develop age-related macular degeneration (AMD)". The article says "of all the ailments described in the 23andme profile, AMD has one of the strongest genetic associations". If I found this in my genetic profile, I would want to know the confidence interval of the increased risk. Is it a factor of 4.5 plus or minus 1? Or 4.5 plus or minus 8? This isn't easy to figure out. In addition to the question of variability, there can easily be bias (= estimate is too high). Let's say I do 100 gene/disease association studies. Then I scan these studies to pick the one with the strongest gene/disease association. It should be obvious that this particular association is likely to be too high and, depending on the details, could plausibly be pure chance (i.e., true association is zero). I have been unable to find out how replicable the gene/AMD association is. According to [2]Wikipedia, "the lifetime risk of developing late-stage macular degeneration is 50 % for people that have a relative with macular degeneration, versus 12 % for people that do not have relatives with macular degeneration." (Until it was eliminated via better diet, pellagra also ran in families.) The Wired article does not say whether any of McCauley's relatives have/had AMD – a huge omission, given the uncertainty of gene/disease associations.

It wasn't obvious what McCauley should do, according to the article:

McCauley read that there were a few preventative measures he could take to reduce the chances of AMD one day rendering him blind: don't smoke and avoid ultraviolet light, for instance. Also, it seemed, he could try taking a special combination of vitamins, including B12 and lutein. But when he consulted the research, he could find little evidence to support the effectiveness of the regime, based on his genotype.

The article says nothing about quitting smoking but he does wear glasses that reduce ultraviolet light and takes certain vitamins. It is very hard for him to determine whether they help.

[3]Here is a study that found greater omega-3 consumption associated with lower risk of AMD. [4]Here is a study that found AMD associated with inflammation (too little omega-3 increases inflammation). [5]Here is a study that

found no association between vitamin and mineral intake and AMD. Based on this, if 23andme told me I had an increased risk of AMD, I would make sure to optimize my intake of flaxseed oil (or other omega-3 source) using some sort of brain test.[6] I have documented in other posts that brain function is sensitive to omega-3 intake and (probably) most people don't get enough. Of course, just as it is foolish to smoke (a lot) regardless of whether you have genetic risk of AMD, it is foolish to not optimize one's omega-3 intake, whether or not you have genetic risk of AMD. In other words: everyone should optimize their omega-3 intake. If the 23andme results cause McCauley to do something wise like this that he would otherwise not have done, they have helped him.

The omega-3 study appeared after the Wired article so I don't know how McCauley reacted to it. A puzzle about the story is that it isn't even clear that the gene/AMD associations are true. Consider McCauley's older relatives: parents, grandparents. Did/do any of them have AMD? If not, it is more plausible that all of them were at 12 % risk of the disease than at 50 % risk. Suppose all of them had, according to 23andme, the same increased risk as McCauley (at least some of them have the risk-bearing genes). Now it becomes more plausible that something is wrong with the 23andme risk estimate. If some of McCauley's older relatives do have AMD, it is not clear why the 23andme results would make much difference. He should have already have known he was at increased risk of AMD.

The upshot is that in this particular case, I cannot even rule out Scenario 4 (does harm). All four scenarios strike me as plausible. Based on this article, we are a long way from learning the value of personal genomics.

Previously I used [7]the example of Aaron Blaisdell to make the possibly counter-intuitive point that if you have a genetic disease something is wrong with your environment. Well, I do not have any obvious genetic disease. But I discovered, via self-experimentation, that my environment was terrible – meaning it could be improved in all sorts of ways: stop eating breakfast, drink flaxseed oil, eat butter, look at faces in the morning, take Vitamin D in the morning, and so on, not to mention eat fermented foods (which I figured out via psychology, not self-experimentation). My findings about what is optimal are so different than the way anyone now lives (except people who read this blog) that I believe everyone's environment can be vastly improved. If so, the value of discovering you have a genetically elevated risk of this or that is not obvious – you should already be trying to improve your environment. At least that is what my data has taught me. On the other hand, maybe genetic info (even wrong genetic info!) will give you a kick in the pants. Maybe that has happened with McCauley.

gwern (2012-06-15 10:21:09)

> The upshot is that in this particular case, I cannot even rule out Scenario 4 (does harm). All four scenarios strike me as plausible. Based on this article, we are a long way from learning the value of personal genomics. The ultimate value could be as propaganda - fake information - like the evopsych theory of placebos. The value of information for a recommendation like 'quitting smoking is 1 % better for you than the average person' is exactly 0: you should already be doing it! But the impressive circumstances - whoo \*genomics\* - may be more likely to make one do it. As far as paying voodoo priests to impress you with

theatricality, \$1-1000 isn't that expensive.

Greg (2012-06-15 12:00:19)

I have found 23andMe to be a very big help. It told me three years ago that I have elevated risk for Celiac Disease. I had never heard of it before. When I read about the symptoms, they described my health situation at the time. I had been suffering for years. Additional testing confirmed that I should not consume gluten. My symptoms resolved with a gluten free diet and I continue to be symptom free today.

Tom (2012-06-15 12:35:42)

Off-topic, but any idea why women are feel cold when most males are comfortable? I'm sitting in a Starbucks in a short-sleeved shirt and the AC just switched on, and as a result I'm finally getting comfortable. Yet I noticed that every woman near me has just put on a sweater. It doesn't make sense to me that the genders have always been this way. Any idea what might have changed in the modern environment to create this discrepancy? Seth: As a way of defending body fat. It is clearly more difficult for women to lose weight than for men to lose weight. Perhaps the evolutionary reason is to give women a greater chance of surviving a famine.

Sheila Buff (2012-06-15 15:35:49)

Hi Seth, Risk factors for AMD are indeed well established from epidemiological studies, but for the personal component you would have to know family history, and not everyone does. If McCauley's parents died young, for example, their genetic tendency for AMD wouldn't have been expressed and he wouldn't know he's at risk. In such circumstances, having the genome info would be helpful, since some preventive measures, such as not smoking, can prevent or slow AMD. Solid research shows that the main candidate gene for AMD is HF1. Assuming that 23andme tested accurately for SNPs of HF1, McCauley's increased risk is highly likely. In addition to not smoking, he should consider taking ocular supplements. The AREDS study showed that taking high levels of antioxidant vitamins (C, E, beta carotene) and zinc could reduce the risk of progression to advanced AMD by about 25 %. The AREDS II study, which is expected to end in 2013, adds fish oil, lutein, and zeaxanthin to the formula. Seth: You write: "Assuming that 23andme tested accurately for SNPs of HF1, McCauley's increased risk is highly likely." I'm less sure. In the genome-wide association studies that found the association that 23andme relies on, a huge number of tests were done, looking for gene/disease associations. I have yet to read anything that convinces me that the researchers involved understand how to correct for the number of tests done. That leaves replication as the only test of accuracy and these gene/disease associations often don't replicate. I believe the 23andme statement about increased risk could easily be wrong.

Tom (2012-06-15 17:55:00)

*Seth: As a way of defending body fat. It is clearly more difficult for women to lose weight than for men to lose weight. Perhaps the evolutionary reason is to give women a greater chance of surviving a famine.* Interesting, and makes sense. I understand that, compared to men, women store a higher percentage of Omega 3 fatty acids (vis a vis Omega 6 fats), enabling them to continue to supply the developing fetal brain should food supplies falter during pregnancy.

Nancy Lebovitz (2012-06-15 21:24:18)

Off topic: I've [1]raised the question of whether there's any evidence about the health effects of organically raised vs. conventional food, and turned up practically nothing. One anecdote about someone who ended their celiac problems by switching to organic food, and no experiments on multi-cellular animals. It occurred to me that folks here might be doing some self-experimentation on the subject, or know about institutional research.

1. <http://nancylebov.livejournal.com/548256.html?view=3677856#t3677856>

Kirk (2012-06-16 10:13:24)

@Tom, In the past few years I talked with two women (at separate times) who each said she wanted to move to a colder climate. Each woman was overweight, comfortable with her size, and was eating high-carbohydrate foods during the conversation. In terms of my own experience, I have felt excessively cold during several periods in the past ten years. The first was when I was trialing a low-carb way of eating. The second was when I attempted 16-hour true fasts. Based upon my experience, my con-

clusion is that the women you noticed were in the midst of a restricted-calorie, low-carbohydrate, or intermittent-fasting regime.

LemmusLemmus (2012-06-16 15:12:17)

Nancy: I believe the British government published a report on that some months ago, finding essentially no health effect. There may have been a link to that study from the Marginal Revolution blog. Hope this helps somewhat.

Kirk (2012-06-16 16:10:48)

@Nancy, I definitely noticed a huge difference between non-organic coffee and organic coffee. Regular coffee generates muscle knots in my upper back. Usually I buy organic apples, potatoes, and sweet potatoes, based upon the recommendations of several smart bloggers in the paleo field, but I have not noticed any difference.

Evolutionarily (2012-06-27 23:03:34)

This appears relevant to the discussion: <http://www.fooledbyrandomness.com/NEJM.pdf> NEJM Whole-Genome Analysis In their article on a whole genome scan looking for SNPs associated with sporadic ALS, Dunckley et al. (NEJM August 3 2007 issue) 1 consider finding ten SNPs that replicate over three studies unusual, based on unadjusted p-values of <0.05 in each study. We question the non-randomness of the result as presented, as it recalls the following "mysterious letter" effect 2 . In study one with 766,995 SNPs, one expects 38,350 SNPs to meet the criterion by chance; 5 % of that gives 1,917 SNPs; 5 % of that gives 95 SNP expected to replicate over the three studies; the authors report ten. A major assertion is a Bonferroni adjusted p-value for marker FLJ10986 less than 0.05 in the first study. Computation of a Bonferroni p-value is the simple multiplication of the unadjusted pvalue,  $1.8 \times 10^{-5}$ , by the number of tests under consideration, 766,995, which, being greater than 1, is taken to be not significant. We are skeptical that any of the claims (See Figure 1) would replicate and the biological conclusions could be ex-post explanations to what appear to be random data Seth: Yes, this is what I mean when I say the scientists involved seem to have no idea how to handle the false positive problem produced by doing so many tests.

J Q Simon (2012-07-14 08:22:13)

Re: Macular degeneration - both my parents had it, which puts me at high risk. I started taking lutein every day and increased my intake of purple and orange foods (zeaxanthin and beta-carotene). I am over 50, which also increases the risk. After one year I had to change my eyeglass and contact lens prescription to a lower one - my vision has improved.

J Q Simon (2012-07-14 08:31:36)

Re: Women feeling colder than men. I was always the one (woman) wearing a sweater when everyone else was in T shirts. It turns out I was hypo thyroid. The standard medication, Synthroid, did nothing to change this, or the other symptoms. I finally found a doctor who would listen to me instead of just taking a TSH test, and I started taking compounded T3 only. Every symptom improved, including temperature. Many people, especially women, are subclinical hypothyroid. TSH test alone does not find this. (Subclinical really means TSH alone does not find hypothyroidism) The doctor should also test Total T4, Free T4, Total T3 and Free T3.

### MIT Professor Reenacts the Movie Groundhog Day (2012-06-16 04:49)

A friend of mine went to college at MIT. "One of my professors repeated himself," she said. "Every lecture was the same."

The class was introductory physics. "You mean he gave the same lecture year after year?" I said.

"No. Every lecture." Hard to believe, but yes, every lecture was the same. The professor was replaced in the middle of the term.

---

dearieme (2012-06-16 06:11:35)

I had a lecturer in freshman physics who launched himself into a repeat of his previous lecture. We persuaded him to desist by throwing things at him.

Evelyn M. (2012-06-17 17:22:43)

They must be pretty slow at MIT if it takes them half a semester before taking any action.

### Assorted Links (2012-06-17 05:00)

- [1]New study shows that a Yakult probiotic drink helps people with lactose intolerance and the benefits persist 3 months after one month of drinking it. Yakult is common in Chinese and Japanese supermarkets but rare in American ones. Until I read this article, I didn't realize that people drink it because of lactose intolerance, which is much more common in Asia than America. Via [2]Cooling Inflammation.
- [3]news from the Human Microbiome Project. "To the scientists' surprise, they also found genetic signatures of disease-causing bacteria lurking in everyone's microbiome. But instead of making people ill, or even infectious, these disease-causing microbes simply live peacefully among their neighbors." You may recall that a Nobel Prize was given for the discovery that ulcers are caused by a certain species of bacteria. However, almost everyone with the "disease-causing" bacteria does not get ulcers. Apparently the "surprise[d]" scientists studying the human microbiome did not know that. If it were better known that you don't need to kill bacteria to make them harmless, antibiotic usage would be less attractive.

Bacterium (2012-06-17 11:32:01)

It's "a bacterium". (Sorry, pet peeve) Seth: Thanks for the correction. I have fixed it.

dearieme (2012-06-17 14:19:58)

Yakult is widely available and widely advertised in Britain. Seth: Any idea why? For instance, who buys it? Why do they buy it? I haven't seen it for sale anywhere in Berkeley, including Whole Foods, which has about 8 brands of kombucha. I have never seen it advertised. It is for sale in Asian markets near Berkeley

dearieme (2012-06-17 17:21:01)

No idea, it's just a commonplace supermarket product. For example: [http://www.mysupermarket.co.uk/#/tesco-price-comparison/yogurt\\_and\\_milk\\_drinks/yakult\\_original\\_fermented\\_milk\\_drink\\_7x65ml.html](http://www.mysupermarket.co.uk/#/tesco-price-comparison/yogurt_and_milk_drinks/yakult_original_fermented_milk_drink_7x65ml.html)

dearieme (2012-06-17 17:26:08)

P.S. That link shows that it's stocked at ASDA, the British branch of Walmart. Maybe our supermarkets just stock a wider range of stuff than yours or, at least, a different range. I remember a few years ago an American blog speculating on the identity of an exotic fruit photographed at a store in Latin America somewhere. It was a lychee, which we wouldn't consider unusual at all.

dearieme (2012-06-17 17:34:39)

Come to think of it I remember being in a till queue in Sainsbury's a couple of years ago and an American behind me being astonished that I was buying goats milk. He seemed to think that v exotic, but our big supermarkets stock goats milk (full fat, skimmed, semi-skimmed) goats butter, yoghurt.... [http://www.mysupermarket.co.uk/#/grocery-categories/goats\\_milk\\_in\\_tesco.html](http://www.mysupermarket.co.uk/#/grocery-categories/goats_milk_in_tesco.html) Tesco is our biggest supermarket chain: you might care to google to see whether they stock stuff that interests you. Their delivery service is very good, though perhaps not to Beijing.

dearieme (2012-06-17 18:42:17)

Since you don't like Lucky Jim, I had better explain that that last sentence is a joke of sorts. :)

max (2012-06-18 00:16:31)

Seth, a recent review (<http://v.gd/yCy0FS>) has found that: "The available trials showed no benefit of omega-3 PUFA supplementation on cognitive function in cognitively healthy older people. Omega-3 PUFA supplementation is generally well tolerated with the most commonly reported side-effect being mild gastrointestinal problems." Seth: Thanks for the link. I think time will eventually show that the cognitive tests used were insensitive.

How to manifest whatever you want | Koanic Soul (2012-06-27 17:28:32)

[...] to the Melonhead, and flicked open my RSS reader while deciding what to do next. Up popped an article by Seth Roberts mentioning the GI healing properties of Yakult, a fermented yoghurt drink common in Asia. [...]

## Double Interview on the Benefits of Probiotics (2012-06-18 05:00)

[1]This curious 2006 article has an interview with one researcher in one column and an interview with another researcher in another column. Their results differed.

Pro probiotic. "Children with [infectious acute diarrhea] who took Lactobacillus [various strains and species, in nutritional supplement form, not in yogurt form] had a shorter duration of diarrhea (on average 0.7 days shorter) than those who took placebo. Also, they had fewer episodes of diarrhea, i.e. fewer stools, on the second day of treatment than those in the placebo group. Interestingly, the children who took higher doses of Lactobacillus had shorter duration of diarrhea, and it seems that a daily dose of at least 10 billion viable bacteria is necessary to have a beneficial effect."

Anti probiotic. "I published a big study looking at Lactobacillus GG in kids with Crohn's disease who were already doing fairly well on medication. We put them on the probiotic or a placebo for two years. We followed them for two

years and looked for whether the probiotic group had a lower rate of relapse and whether there were any differences between the two groups. We didn't find any differences."

1. <http://www.npr.org/2006/07/20/5568701/q-a-pros-and-cons-of-probiotics>

---

Tom (2012-06-18 08:19:35)

Seth, you may have already seen it, but Art Ayers' most recent post also talks about probiotics: [coolinginflammation.blogspot.com/2012/06/dr-oz-on-gut-flora-repair.html](http://coolinginflammation.blogspot.com/2012/06/dr-oz-on-gut-flora-repair.html)

john (2012-06-18 10:11:07)

Okay, I don't know how much of a difference is the "supplement factor" [vs natural food], but to me, the idea of beneficial effects of certain diverse bacterium is beyond the need for a trial like this. It simply makes sense according to all the physiological evidence we have, and these large-scale trials are too easily corrupted to tease out much useful information. Seth: My guess is that there are lots of things that can go wrong – lots of ways taking probiotics that don't work. You need the right dose, you need enough diversity, maybe the bacteria can die. Or don't work optimally. For example, is taking two probiotics better than taking one? Until you can measure the benefits you can't answer questions like that.

### **Who Watches the Watchdogs? The Myths of Journalism (2012-06-19 16:00)**

In [1] a great essay, Edward Jay Epstein points out, at least by implication, that the Pulitzer Prize committee is not terribly interested in the truth of things:

A sustaining myth of journalism holds that every great government scandal is revealed through the work of enterprising reporters who by one means or another pierce the official veil of secrecy. . . This view of journalistic revelation is propagated by the press even in cases where journalists have had palpably little to do with the discovery of corruption. Pulitzer Prizes were thus awarded this year to the Wall Street Journal for "revealing" the scandal which forced Vice President Agnew to resign and to the Washington Star/News for "revealing" the campaign contribution that led to the indictments of former cabinet officers Maurice Stans and John N. Mitchell, although reporters at neither newspaper in actual fact had anything to do with uncovering the scandals. . . . Yet to perpetuate the myth that the members of the press were the prime movers in such great events as the conviction of a Vice President and the indictment of two former cabinet officers, the Pulitzer Prize committee simply chose the news stories nearest to these events and awarded them its honors.

The Nobel Prize in Biology committee operates the same way, except with the disadvantage that there is not one important (= useful in a big way) biology discovery per year. There are far fewer than that. So almost every year the Nobel Prize in Biology goes to discoveries with little practical importance that are described as having great practical importance. The profession (in this case, biology) is credited with much more power than it actually has.

Why does this happen? One possible reason is that no one points it out. (Epstein's essay, still relevant today, was published in 1974.) When a powerful journalistic institution does bad things, it is incredibly dangerous (to your career) to point this out. This is why the Murdoch scandal is so big – it went on so long. Spy magazine had a column called Review of Reviewers. It was hilarious because the misdeeds were great. Unlike almost anything else in Spy, the

author was anonymous. Brilliant writing that the author did not take credit for because it was dangerous to criticize the watchdogs. Likewise, hardly anyone except Epstein criticizes the prize committees (who resemble watchdogs) so they can be profoundly inaccurate.

---

dearieme (2012-06-20 11:33:48)

None of the greatest scientists - the real top drawer chaps - has won a Nobel, except for Einstein. The reason is that the others worked, and died, too early. It almost makes you wonder whether the institution of the Nobel was part of social changes that led to a reduction in the standard of science. (P.S. Am I too hard on Planck, Rutherford, Mme Curie?)

### **The Difficulty of Finding a Good Experiment to Do (2012-06-20 05:00)**

My self-experimentation began because of one tiny thing – [1]an article I noticed in the Brown University Science Library about teaching mathematics to college students. "The best way to learn is to do," it started. Which made sense. To learn how to do experiments – one of my goals as a graduate student – I started doing self-experiments. Let's imagine I had never seen that article, which is entirely possible. In this parallel universe, I become a psychology professor and then one day notice that someone else has done the personal science I have actually done. Has written "[2]Self-experimentation as a source of new ideas," The Shangri-La Diet, and so on, including the experiments I've described on this blog. How would I react?

Many things about it would not impress me. You devised an arithmetic test to measure your brain function – so what? You measured yourself for a long time – big deal. You did an experiment – yawn. I might be slightly impressed by the experimental designs, which are simple and effective. Most experimental psychology uses more complex designs. What would baffle me would be the discovery of safe powerful beneficial treatments. How did this guy find these treatments? For example, the first experiment in "Self-experimentation as a source of new ideas" is about the effect of breakfast on early awakening. Eliminating breakfast reduced the fraction of days with early awakening from about 50 % to 10 %. Not eating breakfast is easy and perfectly safe. I don't know of anything like this in all sleep research.

To a psychology professor, doing an experiment on one's sleep is nothing. Finding something naturalistic (= not a drug) and sustainable that caused a big improvement, however, would be . . . unprecedented? Seemingly impossible? Psychology professors study everyday topics of great interest, such as memory and problem-solving and happiness, quite often. They would love to find easy safe sustainable non-drug ways of improving these things by large amounts. But I can't think of a single example.

I thought about how hard it is to find big beneficial experimental effects (it's easy to make things worse) when I read [3]this post by the economist Yanis Varoufakis. He is excited about working for an online game company (Valve) because the nature of their game will allow experimental study of economics.

Econometrics is a travesty! . . . Econometrics purports to test economic theories by statistical means. And yet what it ends up testing is whether some 'reduced form', an equation (or system of equations),

that is consistent with one's theory, is also consistent with the data. The problem of course is that the 'reduced form' under test can be shown to be consistent with an infinity of competing theories. Thus, econometrics can only pretend to discriminate between mutually contradictory theories. All it does is to discover empirical regularities lacking any causal meaning. [Why is he sure they lack any causal meaning? – Seth]. . . The reason for this unavoidable failure? None other than our inability to run experiments on a macroeconomy such as rewinding time to, say, 1932, in order to see whether the US would have rebounded without the New Deal (or to 2009 to see what would have happened to the US economy without Ben Bernanke's Quantitative Easing). Even at the level of the microeconomy, keeping faith with the ceteris paribus assumption (i.e. keeping all other things equal in order to measure, e.g., the relationship between the price of and the demand for milk) is impossible (as opposed to just hard).

In sharp contrast to our incapacity to perform truly scientific tests in 'normal' economic settings, Valve's digital economies are a marvelous test-bed for meaningful experimentation. . . . We can change the economy's underlying values, rules and settings, and then sit back to observe how the community responds, how relative prices change, the new behavioural patterns that evolve. An economist's paradise indeed...

I find this baffling. It's like thinking: Now I can write. Soon I will be writing stuff that the world wants to read! Okay, now he can do experiments. Good. After a few of them, I suppose, he will learn what every experimental scientist knows and confronts every working day: it is incredibly hard to do interesting experiments. The "sharp contrast" between the new setting and the old one has yet to be demonstrated.

Okay, how did I find a bunch of big beneficial safe sustainable effects? I am now finishing a paper in which I try to answer this question. To be brief: 1. [4]As I've said, I believe that the distribution of surprise/observation follows a power-law-like distribution. Almost all observations, very little surprise, a tiny fraction of observations, great surprise. Which is pretty obvious. 2. The "slope" (parameter) of the distribution depends on subject-matter knowledge (more knowledge = more favorable slope, i.e., "chance favors the prepared mind"), scientific skill (more skill = more favorable slope), and novelty (more novelty = more favorable slope). I was in good shape on all three. For example, when I studied sleep, I knew a lot about sleep. Novelty is enormously important. In my personal science I could easily study treatments (e.g., not eating breakfast) and dimensions (e.g., how rested I felt when I awoke) that had rarely if ever been studied before. I could do this again and again, keeping novelty high and thus keeping the slope very favorable. (Varoufakis will get a burst of novelty when he begins experimentation (the situation is new) but forced to use that situation for all his experiments the novelty will run down, making the slope of the distribution less favorable.) 3. My cost/observation was very low and the benefit/observation remarkably high (I was improving my own health). So I was very motivated to make observations. My answer in the paper is a little more complicated but that's most of it.

gwern (2012-06-20 07:47:05)

> Psychology professors study everyday topics of great interest, such as memory and problem-solving and happiness, quite often. They would love to find easy safe sustainable non-drug ways of improving these things by large amounts. But I can't

think of a single example. Spaced repetition comes to mind for memory.

Alex Chernavsky (2012-06-20 09:30:17)

Gretchen Rubin wrote a book about using self-experimentation to increase her happiness. The book is called, [1]*The Happiness Project*.

1. <http://www.amazon.com/The-Happiness-Project-Aristotle-Generally/dp/006158326X/>

Cliff Styles (2012-06-20 11:03:07)

I read this excellent post, and one thought that came was that science fiction writers need to do more self-experimentation. Or perhaps any fiction writers: Nabokov's comment that he saw his writing as working in his laboratory seems apt?

ChristianKI (2012-06-20 12:02:54)

@gwern: Spaced repetition didn't get discovered by a professor but by a student who did self experiments. Piotr Wozniak was a student in molecular biology at first and afterwards a student of computer science. Hermann Ebbinghaus became professor after doing his work on memory.

gwern (2012-06-22 09:21:19)

Christian: Ebbinghaus was already a PhD when he began his memory experiments... And nothing about the context in Roberts's post says he \*had\* to be a professor: Roberts said he couldn't think of an example of a safe non-drug-related procedure which has large benefits on memory. I provided one.

## **No Mention of Fermented Foods in Article about Importance of Bacteria (2012-06-21 05:00)**

[1]A new article in the New York Times by Carl Zimmer is about the importance of the bacteria inside of us. Several studies are described. Then it comes to the practical use of the knowledge. Here's what we can do to improve our inner bacterial ecology:

To ward off dangerous skin pathogens like *Staphylococcus aureus*, for instance, Dr. Segre envisions applying a cream infused with nutrients [Treatment 1] for harmless skin bacteria to feed on. . . . Adding the bacteria directly may also help. Unfortunately, the science of so-called probiotics [Treatment 2] lags far behind their growth in sales. In 2011, people bought \$28 billion of probiotic foods and supplements. . . . A growing number of doctors are treating *C. difficile* with fecal transplants [Treatment 3]: Stool from a healthy donor is delivered like a suppository to an infected patient. The idea is that the good bacteria in the stool establish themselves in the gut and begin to compete with *C. difficile*. This year, researchers at the University of Alberta [2]reviewed 124 fecal transplants and concluded that the procedure is safe and effective.

No mention of fermented foods. The obvious difference between fermented foods and Treatments 1-3, besides pleasure (fermented foods more pleasurable), is that Treatments 1-3 can be sold for high prices. Fermented foods cannot. (Except wine.) The omission is curious. Just because the people that Zimmer interviews have tunnel vision doesn't mean that Zimmer must.

1. <http://www.nytimes.com/2012/06/19/science/studies-of-human-microbiome-yield-new-insights.html?pagewanted=2&r=1&smid=pl-share&pagewanted=all>

dearieme (2012-06-21 07:52:39)

In the days when we made our own wine we found that the yeast was so mobile that it could even start a fermentation in a jar of pickled gherkins in the fridge. In the era when people made their own bread and beer, yeast must have got everywhere.

minderbender (2012-06-21 13:03:54)

dearime, that may be true of wine yeast, but I am skeptical. I am a homebrewer (beer), and I also make bread from time to time, and I have never noticed anything like this.

dearieme (2012-06-21 15:29:06)

"skeptical"? The bloody stuff was bubbling.

minderbender (2012-06-22 12:48:01)

So, something got in it. What leads you to believe it was wine yeast?

### **Effect of Niacin on Restless Legs Syndrome: The Importance of Dosage (2012-06-22 05:00)**

K. Thomas Packard, who works in the healthcare industry, recently studied the effect of niacin on his Restless Legs Syndrome. He had read how a megadose [1]helped Dennis Mangan's mother. He gave [2]a talk about his results and [3]posted at Genomera.

The niacin didn't help him. However, the highest dose he tried was 500 mg/day. Mangan's mom, who surely weighs less than Packard, took 1000 mg/day. He doesn't explain why he thought a much lower dose would work. Perhaps he weighs twice as much as Mangan's mom, so 500 mg/day, in terms of body weight, may have been only 25 % of the dose that worked for her. It's too bad he went to all that trouble and used a maximum dose that could easily have been too low.

Part of the study "hypothesis" (= idea to be tested?) was

The "medium" dose may generally be more effective, than both the "low" and "high" doses, in eliminating symptoms of RLS and avoiding side effects of niacin.

Why this might be true isn't explained.

After Week 3, Packard wrote "The niacin was not working, so I abandoned the experiment on Wednesday. I went back to my original medication and am doing OK." He says nothing about side effects.

Packard later found that his ferritin was low, apparently a side effect of this study. If his RLS persists after he improves his ferritin level, I hope he tries niacin again at better dosages.

1. <http://www.boingboing.net/2010/05/17/restless-legs-syndro.html>
2. <http://www.genomedad.com/self-tracking-presentation-at-quantified-self>
3. <http://genomera.com/studies/effects-of-niacin-on-restless-leg-syndrome>

---

Tomas (2012-06-22 05:43:50)

I think that niacinamide is generally safer, because it doesn't have the "niacin flush" effect. Niacinamide lowers stress hormones by lowering free fatty acids; I usually take 500mg once or twice a day and it makes me feel calmer. I guess it might work for RLS as well.

JRM (2012-06-22 13:22:57)

"The "medium" dose may generally be more effective, than both the "low" and "high" doses, in eliminating symptoms of RLS and avoiding side effects of niacin. Why this might be true isn't explained." Paul Jaminet in his book, Perfect Health Diet, talks about the concept of plateau ranges for nutrients. For zero up to a certain level, a nutrient is of increasing benefit. Then there is a plateau range of maximum benefit for a nutrient. Then intake over that amount causes a decrease in benefit and finally, excessive nutrient intake is harmful. In my own case, I find carb intake is best between 50-75 grams of carbs a day. Less than that, I get jittery from being in ketosis. More than that, I get acne.

Tom (2012-06-23 00:31:08)

*I find carb intake is best between 50-75 grams of carbs a day. Less than that, I get jittery from being in ketosis* You might test supplementing with inositol: [itsthewooo.blogspot.com/2012/05/dont-cold-turkey-inositol.html](http://itsthewooo.blogspot.com/2012/05/dont-cold-turkey-inositol.html)

Edward J. Edmonds (2012-06-23 11:46:26)

I never see this get mentioned but 0.5-1 tsp of salt dissolved in 250mL of warm water works whenever I have RLS like symptoms.

David (2012-06-26 01:10:46)

Seth I had RLS for many years. I discovered through time that inflammation was the primary cause of my discomfort. A new study was published in the January 14, 2012 issue of "Sleep Medicine Review Journal" that supports my theory: [http://www.rlcure.com/rls\\_study.pdf](http://www.rlcure.com/rls_study.pdf) The following website has evidence based on scientific studies that the vitamins/supplements that people have claimed has made their RLS less irritating all have anti-inflammatory qualities, including niacin. <http://www.rlcure.com/studiesr.html> A blog for RLS sufferers with helpful tips can be found here: <http://therestlesslegsblog.wordpress.com> David

Laura (2012-06-26 09:35:55)

Some research suggests that low ferritin levels are a secondary cause of RLS. When I read this, and was aware of my own low ferritin levels, I upped by Iron supplementation...no more RLS! <http://www.aafp.org/afp/2000/0701/p108.html>

## **The Art of Fermentation by Sandor Katz (2012-06-23 05:00)**

The Art of Fermentation by Sandor Katz was published two weeks and I got a copy from the publisher. It has a few conceptual chapters ("fermentation as a coevolutionary force", health benefits, small business) but most of it is DIY, how to ferment X, Y, and Z. Unlike a set of recipes, he includes background with each food so the result is a cross between an encyclopedia and a cookbook. There are also several pages of color photographs, cute marginal drawings, and excellent lists of references and sources. It covers lots of stuff I rarely see. For example, there is one page on fermenting eggs. When I'm in China, I eat lots of fermented eggs. The book doesn't mention the controversy in China about heavy metals in the fermented eggs.

The author's enthusiasm is contagious and I'm sure the book will encourage me to ferment more stuff. Nowadays I just make yogurt, kefir, and kombucha – not even sauerkraut. I once got a book called something like The Book of Yogurt that consisted of 30 different yogurt recipes – which differed from each other by only about 5 %. Page after page the same with only minor differences. Talk about [1]cut and paste! I got rid of it ("this is useless!") but now I wish I had saved it because it was so funny.

Which is only to say that food writing is either incredibly difficult or incredibly awful. I used to subscribe to Saveur. Some of their recipes were very good. The writing was awful, however – like something from a tourist guide. Please, don't tell me how beautiful the country, how friendly the cook, or how tasty the food! Katz does better than that, especially when he is describing what he has actually done. But about half of the book reminds me of my first piece of extended writing – a "state report" about Maine that I did when I was in fifth grade. I went to several encyclopedias and copied the interesting stuff. Katz has gone to quite a few books and copied the interesting stuff.

In at least one case, he has copied too much. I have made yogurt hundreds of times. Only in the beginning did I do something like what practically everyone in America, including Katz, advocates: heat the milk up, let it cool, put in the culture. Now I just take the milk from the refrigerator, put in a tiny amount of culture, surround the milk with hot water (using a Chinese yogurt-making machine that keeps the water warm), and wait. So much easier. The final product is better (smoother, thicker) than the old hard way, especially when I learned that tiny amounts of culture work better than large amounts. "In my experience, cultures from commercial yogurts never maintain their viability beyond a few generations," Katz writes. My experience is different: I've never had a problem using them.

In contrast to Harold McGee's *On Food and Cooking*, *The Art of Fermentation* is more personal, more hands-on, and less scientific, all of which are improvements, in my opinion. It is also more opinionated, which since the opinions are commonplace, is bad. "I too love the beer they are usually thinking of . . . However I define beer more broadly than the famous 1516 Bavarian beer purity law . . . I define beer as a fermented alcoholic beverage in which . . . " At another point, to my surprise, he mentions Jane Jacobs and her theory that agriculture began in cities. "If Jacobs's theory is correct, then fermentation practices must also have had urban roots," writes Katz. This is not interesting. The small business chapter is interesting whenever Katz is telling the story of a small business and uninteresting the rest of the time ("Consistency is not necessarily important to the home experimentalist").

Oh well. I am glad to have a book that will encourage me to ferment more stuff and from which I can learn a lot about fermentation. The book is obviously a labor of love and there are not many of those.

1. [jonah-lehrer-plagiarism-new-yorker-examples-pile-up.html](#)

---

Chuck Currie (2012-06-23 07:40:41)

I'm going to get the book because I've become very fascinated with fermentation - made yogurt a few years ago using a heating pad for a constant heat source. The first pad was new, however it would automatically shut off to keep from burning the user - obviously that didn't work. Got an old style pad from a neighbor who had two - it worked great, yogurt turned out great, burnt out the heating pad on the second batch - haven't made yogurt since. I like sauerkraut (Bubbe's), but get a little bored with it - my 93 yr old, Swiss heritage, Kansas farm girl mom says it tastes just like her mom's. They kept it in a crock in the cellar. Found Sonoma Brinery barrel fermented Kosher pickles at WF - really good (most Koshers have too much garlic for my taste - not these - they even have little red chillies floating in the container with them). Really like kombucha (would really like to know how to pronounce that correctly) - but find it sometimes gives me stomach problems - a little heartburn - could be the carbonation - any ideas? I only drink the "original" flavor, so it's not any added ingredients. Have you posted your fermentation

recipes? If not, would you? Cheers Seth: I too like Sonoma Brinery products, the kosher pickles and the "raw sauerkraut".

Char (2012-06-23 20:46:36)

How long do you let your yogurt ferment? Seth: 24 hours.

Andrea (2012-06-24 17:41:42)

Would you give us your recipes for kombucha and yogurt? It sounds as though you have figured out lots of shortcuts.

Chuck Currie (2012-06-25 07:55:18)

Sonoma Brinery Outrageous Bread and Butter pickles are Outrageous too. My daughter has a friend who is a chef and says they're the best pickles he's ever eaten. Do pickles in vinegar count as fermented food? Seth: that's good to know about the Bread and Butter pickles, which I haven't tried. I like to think that sour pickles count as fermented food. They're aged at room temperature.

minderbender (2012-06-26 10:23:40)

I think Chuck's point is probably that you can imagine different ways for something to get sour: (A) It is sour because it contains bacteria that are producing some kind of acid (lactic, acetic). (B) It is sour because it contains a product that itself contains/contained bacteria that produced some kind of acid (e.g. vinegar, yogurt). (C) It is sour because someone simply added a bunch of acid (lactic, acetic, citric). (A) obviously counts as a fermented food. (B) depends a little on why fermented food is healthy, but it could be considered a fermented food to the extent it contains the relevant stuff. Some vinegar is distilled, some isn't. Maybe non-distilled vinegar has good stuff from the aceto bugs. (C) probably doesn't count as fermented food. And distilled white vinegar is basically (C), it is hard to imagine that it contains any bacteria cells or even bacteria by-products (other than the acetic acid itself). So if you make pickles by soaking cucumbers in room-temperature distilled white vinegar, you may not be getting any real benefit beyond flavor. I suppose there are probably a few bacteria in there, but it's hard to imagine they are numerous/active enough to provide real benefit.

minderbender (2012-06-26 10:32:05)

Incidentally, if you are going to try to home-brew beer, I suggest starting with an actual homebrewing guide, not a chapter of a larger book on fermentation. Brewers are doing lots of interesting stuff, e.g. this: [http://www.themadfermentationist.com/2012/06/100-lactobacillus-berliner-weiss e.html](http://www.themadfermentationist.com/2012/06/100-lactobacillus-berliner-weiss-e.html) In general there is a large, thriving community experimenting with beer (and mead and wine), and people who are operating outside that community tend not to be up-to-date and to make a lot of rookie mistakes. E.g.: <http://www.themadfermentationist.com/2011/10/booze-for-free-book-review.html> Many homebrewers, myself included, think that John Palmer's *How to Brew* is the best starting place: <http://www.howtobrew.com/> (The website is free, the book is more extensive and is probably worth buying.)

Jay (2012-06-25 07:59:18)

The climate model paper is interesting. I'm an ex-physicist in the life sciences. It's humbling to see how little we know about complex systems – and even more humbling to come face to face with the general intractability of complex systems. I recently came across an excellent paper that compares condensed matter physics to biology (evolution in particular). It shows just how difficult it is to find appropriate models for complex systems. The same applies for climate science. Paper here: <http://arxiv.org/pdf/1011.4125v1.pdf> Non-free version here: <http://www.annualreviews.org/doi/abs/10.1146/annurev-conmatphys-062910-140509> Conclusion from paper below:

In the natural development of the sciences, issues of complexity are sensibly postponed until they can no longer be avoided. Physics was able to delay serious consideration of collective effects for nearly three hundred years, and only in the last thirty years or so has it confronted complex collective phenomena involving multiple scales of space and time, unpredictable dynamics and large fluctuations. Its track record of success is mixed. Biology was not so lucky: at its outset, complex phenomena were encountered, but tools were lacking to cope with the difficulty. Rather than abiding by ignorance, a language-culture was developed to explain away the conceptual difficulties using guesswork solutions such as “natural selection”. As Schrodinger wrote, “Instead of filling a gap by guesswork, genuine science prefers to put up with it; and this, not so much from conscientious scruples about telling lies, as from the consideration that, however irksome the gap may be, its obliteration by a fake removes the urge to seek after a tenable answer.”—E. Schrödinger, *Nature and the Greeks*, pp7-8.[202] Today, with the “urge” removed, the development of sophisticated technology has allowed biology to take refuge in single-molecule biophysics, genomics and molecular biology. But the stultifying language-culture still remains. This sanctuary is an illusionary respite: the core problems of biology remain irksome to some, and are inextricably interwoven with evolution. Indeed, the very existence of biological phenomena is an expression of physical laws that represent a new asymptotic realm in nonequilibrium statistical physics. Ulam famously quipped[203] “Ask not what physics can do for biology; ask what biology can do for physics.” Our answer is clear.

dearieme (2012-06-25 08:37:27)

The link to the UC Davis Inquisition didn't work for me. Seth: Thanks, I have fixed it. It may be gated.

Alex Chernavsky (2012-06-25 11:06:12)

The *BMJ* link still isn't working. The correct link is here: <http://www.bmj.com/content/344/bmj.e4150> Seth: thanks, I fixed it . . . again.

## **Make Yourself Healthy Article by Me at Boing Boing (2012-06-25 10:16)**

[1]An article by me about how a woman figured out she had gluten intolerance is on Boing Boing today. I first learned about the story through a comment this blog. Thanks, Ginna!

If you know of a case where someone (such as you) improved their health through science (= looking at data, experimentation, collecting data – the opposite of trusting experts) please let me know. In the gluten intolerance story, the experimentation and data collection were as simple as trying a gluten-free diet and learning its effect on (a) how

you feel and (b) a kidney function score.

Alex Chernavsky (2012-06-25 11:24:32)

There's a problem with the link in the post. This link should work: <http://boingboing.net/2012/06/25/make-yourself-healthy-daughte.html> Seth: Thanks, I fixed it.

Jim Purdy (2012-06-25 14:19:35)

This isn't exactly a self-experimentation story with an ending, not yet anyway. Instead, it's more like the beginning, or just a question that may lead me to a self-experiment that would be different from medical advice. I often have swelling in my legs (lymphedema), and sometimes the skin starts to break down, and clear fluid (lymph) drains out. In the past, I have worn tight over-the-calf socks to provide some compression, and I try to restrict salt, elevate my feet, moisturize the skin on my legs, and walk more. But one solution from doctors bothers me a bit: they treat the fluid loss as the problem (instead of just a symptom of something else), and they try to stop the draining with compresses soaked with a Domeboro solution. The Domeboro does seem to slow and stop the drainage, but I'm not sure that's the best approach. From what I've read, the lymph carries some healing substances, including tPa, or Tissue Plasminogen Activator. As a survivor of two mild strokes, I'm familiar with tPa, which is used in emergency rooms to break up clots after a stroke. It seems to me that there may be some good evolutionary reason why the body is sending clot-busting tPa to an open wound, instead of the usual clot-forming substances in blood. After all, a small skin wound usually is closed off in seconds or minutes with a blood clot. So why is the body trying to keep the wound open and draining? I can think of 3 possible answers: 1. Maybe the wound is being kept open to release fluid and reduce the swelling. A clot, on the other hand, might trap the lymph, and perhaps interfere with normal blood flow. 2. Or maybe the clot-busting tPa is keeping dangerous clots from forming in the legs, which could travel to the heart or lungs and form fatal blockages. In either of the cases above, the tPa may be beneficial, and stopping the lymph could cause worse problems. 3. Of course, on the other hand, the oozing lymph may just indicate a failure of normal functioning, in which case the doctors might be right to try to stop it. I don't know the answer, but I'm reluctant to fight against something that the body seems to be trying very hard to do. I have several medical appointments in the next few days, and I see some possible arguments in my future. In previous arguments with doctors, they wanted to amputate a leg and do quadruple coronary bypasses. In both those cases, without surgeries, the leg and heart conditions got better. Those would have been dangerous and life-changing surgeries, so I don't blindly follow "doctors' orders," and I'm not sure I want to follow their orders now. I'll let you know what happens. I may just end up ditching my atheism, and becoming a Christian Scientist, since they don't trust doctors either. Seth: No one could forget your amputation story.

Ginna (2012-06-25 15:16:49)

No problem!

Jim Purdy (2012-06-25 20:15:00)

Seth, your BoingBoing article was fascinating. And I loved the doctor's arrogance in dismissing a patient's comment as "trendy." Doctors ... who needs them? Oh, I remember who needs doctors: the drug and medical device companies.

Wally Vanzile (2012-06-26 17:48:15)

My dad asked me one time "How far can a dog run into the woods?" There is an accurate answer.

Roger Sweeny (2012-06-28 10:38:34)

Last year, I read *How Doctors Think* by Jerome E. Groopman (Mar 12, 2008). Groopman is an honored establishment doctor.

Just about the first story in the book concerned a woman who almost died from gluten intolerance because her doctors weren't looking for it. Seth: I didn't know that. I will get the book.

## Disappointing Visit to Apple Store (2012-06-26 05:00)

One of my friends loves her Ipad so I decided to get one. On the same day I started looking at options Microsoft announced their tablet, the Surface. It sounded good. I decided to do more research.

I went to the Apple Store in Palo Alto. The main things I will do with my Ipad are read books and magazines and watch movies. I asked to see a movie on "the new Ipad". No movies were available, so I watched a trailer for Brave. It was not a good experience. Lots of glare. How much worse could the Surface be? I wondered.

I was curious about the new naming policy. No "Ipad 3", just "the new Ipad". "Why isn't this called the Ipad 3?" I asked an employee. "Company policy," he said. "What's the reason for the policy?" I asked. "They don't tell us that," he said.

I left the store thinking I would wait for the Surface. Later that day I had lunch with a friend, [1]Steve Omohundro, who (with colleagues) long ago predicted the tablet computer and won a design competition (possibly sponsored by Apple) for doing so. He and his colleagues gave a talk about it and Steve Jobs was in the audience. I forgot to ask him what he thinks of the Ipad and the Surface.

1. <http://steveomohundro.com/>

---

Allen K. (2012-06-26 05:53:52)

Did he predict it before the movie 2001? <http://www.youtube.com/watch?v=JQ8pQVDyaLo>

Damon (2012-06-26 08:39:11)

Totally random post! In other news, Google is announcing its tablet tomorrow. Seems there's a multitude of tablets to choose from now...but I must say the Surface does look compelling.

Jim Breed (2012-06-26 10:29:49)

I love my new iPad (iPad 3 to me). 1. The retina display is really easy on the eyes. I like reading it on the elliptical much better than physical books. 2. It makes it very easy to keep up with email. 3. The Wall Street Journal app was the deal sealer; when I tried it on my daughter's iPad, I knew my android tablet was history. 4. A few, 10 %, of my business students would pull up the powerpoints in class. I predict this use will only grow. I use the iPad more than my phone or computer. It is at the sweet spot of usefulness and portability.

Shawn (2012-06-26 13:04:35)

I hate glare too. It give's me killer migraines. Most people don't get migraines quite like I do from glare but I guess my eyes are extra sensitive to reflected light. However, a sizable # of people are sensitive to it and a website was created to petition Apple to offer a non-glare laptop option, which they ended up giving in to. I really dislike the fact that a lot of the new laptops and flat screen computer monitors have reflective surfaces and essentially look like a mirror. I prefer the old TFT LCD screens which do not have me headaches. If it was not for self experimentation it would have been very tough to discover the trigger (it took

me many years before starting to self-experiment, and not long afterwards I figured it out).

Kim Øyhus (2012-06-26 20:54:42)

There are several anti-glare films available for all pads.

Alex Chernavsky (2012-06-27 08:09:15)

I have an iPad 2. I don't use it very much. I far prefer to sit at a regular desktop computer (the iPad's on-screen keyboard is very awkward to use). When I *do* use the iPad, my main use is reading articles that I had previously save in my InstaPaper account. The glare doesn't bother me (I never even noticed it, to tell you the truth). Frankly, I'm a little puzzled by all the hoopla surrounding tablet computers and smart phones. Using either type of device is an exercise in frustration, in my opinion. I can see how they might be useful, though, if you don't have easy access to a regular desktop PC. Luckily, though, I am almost always in close proximity to either my work computer or my home computer, and I rarely travel.

## **The Power of Blog (Fermented Foods Division) (2012-06-28 05:00)**

A few weeks ago I posted [1]a short note about Yakult, a probiotic dairy drink popular in Asia. Yesterday, I came across [2]someone who had read that note. He wrote about it in a post categorized as Learning Koanic Soul.

To test whether I did indeed now possess Melonhead powers, I attempted to manifest the thing I wanted most, and had been striving to attain the longest: a cure for the adverse side effects of the Accutane I'd taken 8 years ago.

Here's a brief list of the side effects I suffered:

- chronic diarrhea
- chronic fatigue
- inability to eat almost every food, including pills
- insomnia
- additional symptoms, increasing exponentially when I eat forbidden foods or miss sleep

Over the last 8 years I'd painstakingly developed a coping regimen that worked in theory, as long as I did it perfectly. But it was so strict that holding down a job or traveling were almost impractical. And any error meant days if not weeks of down time. I rarely achieved better than than 50 % functionality. And my diet was so limited that I ate only one meal continuously – lean steamed meat with rice, scallops and shrimp.

All attempts at a cure had failed, and not only failed, but proven that I couldn't even digest the pills that might make me better. Instead, the difficulty of digesting the pills induced a failure cascade, a reinforcing feedback loop of insomnia, stress, fatigue and diarrhea. After years of fighting this illness, I had learned a great deal but was running out of things to try.

So, for my first manifestation attempt, I decided to demand an INSTANT cure.

Not a regimen for coping with symptoms... Actual, immediate, damage reversal. . . .The experiment began as I wrapped up a Skype conversation with a Melonhead. He'd just finished describing his "powers" to me. I got the idea for the experiment, and told him what I'd try to manifest. Immediately I experienced a boost in energy – I'd been feeling sick. I was shocked – it appeared to be already working.

I finished talking to the Melonhead, and flicked open my RSS reader while deciding what to do next. Up popped an article by Seth Roberts mentioning the GI healing properties of Yakult, a fermented yoghurt drink common in Asia. Accompanied with link to scientific paper and news report.

This startled me, because I'd been planning to try fermenting my own yoghurt next, although I had low expectations for success. I was planning on getting a yoghurt making machine, yada yada. I began reading with interest. Could this be the sign I'd requested?

As I finished reading, my girlfriend arrived home. I told her I wanted to buy some of this "Yakult" stuff tomorrow, figuring the grocery stores were closed tonight. She replied that she had some in the refrigerator.

This got my attention. I'd requested an instant cure... and the cure, if it was one, had been sitting IN MY REFRIGERATOR before I requested it.

The main problem was the massive sugar content of Yakult. I knew that I had sugar malabsorption issues – I can't eat fruit. There was an excellent chance that if I tried the Yakult, I would become sick for at least 3 days, and endure excruciating pain. For the record, torture by several consecutive days of gut cramps is one of the few things I am afraid of, being a subset of torture in general. Nevertheless, I elected to drink two (disgustingly sweet) Yakult bottles that night.

Over the next couple of days I continued to ramp up my Yakult dosage. My body rebelled some at the radical change, but it also showed signs of improvement. The expected disaster failed to materialize.

Day two was the worst. I felt as if I might be becoming genuinely sick. Given the amount I'd drunk, this meant a solid three days of agony were kicking off. That night I endured some physical pain, but I was also strangely energized, so that I had the mental reserves to face it out. Normally the illness saps all capacity for resistance.

That night I received a "message" (or had a thought, whichever you prefer) that "it would take three days." Sure enough, on day 3 I knew was better, significantly so, instead of worse. There could be no further doubt that it was working. For me, something had finally changed.

Note that I would expect a full gut healing to take place over 3-6 months. It's not simply a matter of fixing diet or finding the right pill, but 1. rebuilding bacterial colonies and 2. regrowing and healing intestinal lining damaged or eaten away by inflammation and acidity. While these results are not instant, they are screamingly fast in GI terms.

Impressed by this initial success, over the next few days I began to let manifestation guide my behavior intuitively, rather than using logic to determine my actions. An image of a key supplement appeared in my head – I went and bought it at the precise store I remembered seeing it. When I arrived I discovered it was on sale: 2 for 1.

At the grocery store, I simply wandered, letting manifestation dictate my purchases. I grew disgusted with the excessive sweetness of Yakult: lo and behold, I found a bulk yoghurt with a lower sugar content. I tested a few key supplements I had lying around, and found I could now digest pills. So I started taking everything I'd stored up but been unable to use. This resulted in a major improvement. At the same time, I gradually began eating a more diverse collection of foods, letting intuition guide me. No disaster ensued.

Once it was clear that I was cured, I wanted to know my new limits. And I didn't intend to wait 6 months to find out. Among other things, I've tested a half block of cheese (lactose and fat intolerance), modest amounts of fruit (fructose and insoluble fiber intolerance), and the finisher, a greasy-spoon

restaurant meal.

None of these could induce a return of the diarrhea that has plagued me for the last 8 years. However, the first and third did make me tired and give me gas for a couple of days. So I'm not invincible. The former was probably a matter of trying too much fat too soon (I have liver damage impairing fat digestion), and the latter was simply unfit for human consumption.

All this took about two weeks to transpire, from June 15 to June 28 [2012], and brings us to the present. I am eating a varied and delicious diet, and enjoying good energy and good health. My 8 year torment is at an end.

Conclusion: His girlfriend is Asian, he isn't. More seriously, it really does show the power of fermented foods, in this case Yakult and yogurt.

1. <http://blog.sethroberts.net/2012/06/17/assorted-links-184/>

2. <http://www.koanicsoul.com/blog/2012/06/27/how-to-manifest-whatever-you-want/>

---

Koanic (2012-06-28 06:23:05)

Hah, didn't know you were a reader. I do know how to embarrass myself, don't I? By the by, I fit the success of yoghurt, versus the failure of other fermented foods I tried such as kombucha and apple cider vinegar, under the Neanderthal cave herder hypothesis, that they fermented milk and cheese in the cool backs of their caves. Seth: It's interesting that Yakult worked where kombucha and apple cider vinegar failed. Not easy to predict that.

Tom (2012-06-28 11:06:27)

Such a moving post. You have a wonderful impact on the world, Seth.

dearieme (2012-06-28 11:45:23)

OK, so why is the stuff on the shelves of every British supermarket but hard to get hold of in Berkeley? Seth: Good question. Better choice of distributor in Britain?

## **How Low Blood Sugar is Too Low? New Evidence (2012-06-29 05:00)**

Some people avoid all carbs (that is, all bread, pasta, rice, etc.). Others advocate "safe starches". No doubt wheat can be dangerous – witness celiac disease (associated with a genetic difference). But I have noticed clear improvements in brain function (measured by arithmetic speed or something similar) after eating something sweet, such as pudding. None of this, unfortunately, helps answer the question: how low blood sugar is too low?

[1]A new study makes more plausible the idea that really low levels of carbs may be bad for you:

A nested case-control study data set was generated from the cohort-study data set ( $n = 4140$  type 2 diabetic outpatients) by sampling controls from the risk sets. Cases ( $n = 427$ ) were compared with an equal number of controls chosen from those members of the cohort who were at risk for the same follow-up time of the case, matched for age ( $\pm 3$  years), sex, body mass index (BMI) ( $\pm 2 \text{ kg m}^{-2}$ ), duration of diabetes ( $\pm 5$  years), and Charlson's Comorbidity Score (CCS) ( $\pm 1$ ). The main predefined analysis was the comparison of cases and controls for proportion of patients with each HbA1c class ( $<6.5\%$ ,  $6.5\text{--}7.4\%$ ,  $7.5\text{--}8.4\%$  and  $\geq 8.5\%$ ). During a mean follow-up of  $5.7 \pm 3.5$  years, 427 deaths were recorded. The lowest risk of death was observed in the HbA1c  $6.5\text{--}7.4\%$  category; a lower HbA1c was associated with a non-significant trend towards a higher risk. The risk associated with a low ( $<6.5\%$ ) HbA1c was significantly greater in patients who were insulin-treated than in the rest of the sample.

The study is saying that diabetic patients in the HbA1c  $6.5\text{--}7.4\%$  category do not improve their health when given insulin that lowers their blood sugar even more. Their health may get worse.

1. <http://www.ncbi.nlm.nih.gov/pubmed/22633797>

---

dearieme (2012-06-29 05:29:12)

As I understand it, HbA1c is a weighted average reading of blood sugar over the preceding few months. But what if not only the level matters, but also how variable it is? Wouldn't that be lost in correlating HbA1c versus this-and-that?

anand srivastava (2012-06-29 05:32:38)

They probably did not include diabetics who were controlling it based on diet alone. That is diabetics only on drugs were considered. Its very obvious that the body will not be able to control bg if you supply any external way of reducing bg. The external factors and the internal factors will be in conflict. So the chances of death due to hypoglycemia will get higher as you keep the blood control below a certain level, and the death due to hyperglycemia will become more prominent as the bg level goes to another extreme. I guess the  $6.5\text{--}7.4\%$  is the happy medium, in the insane world of drug based glycemic control.

dearieme (2012-06-29 05:33:03)

It looks to me as if they should have separated the  $<6.5\%$  people into two groups: (a) the insulin-treated, and (b) the others. Then they could tell whether there is any higher risk for group (b) and whether group (a)'s higher risk is significant.

Chris Masterjohn (2012-06-29 05:47:08)

Hi Seth, This might represent too low blood sugar, or too much insulin treatment, or it might not. The problem is HbA1c is not a specific marker for blood sugar exposure. A lower HbA1c could indicate higher red blood cell turnover. Or, it could reflect a greater activity of fructosamine 3-kinase, which "detoxifies" the fructosamine residues of HbA1c to a product that, if it is not quickly taken care of itself, will degenerate to form 3-deoxyglucosone. Second only to methylglyoxal, 3-deoxyglucosone is one of the most major sources of advanced glycation endproducts (AGEs) in diabetes. The problem is that the formation of HbA1c probably does not mediate much of the disease process in diabetes, whereas the formation of 3-deoxyglucosone probably mediates a major part of the disease process. I wonder if they discuss this issue in the full text. Unless they looked into it specifically, it could just mean that HbA1c is not a very useful marker of the pathological process of diabetes. Chris Seth: Those are good points, thanks.

Tuck (2012-06-29 06:36:39)

It's well-established that "tight" control of blood sugar via medication increases mortality. This is the finding of the ACCORD Diabetes trial. However I don't know that you can read that result, or the result in this trial, to infer that a low-carbohydrate diet would also have ill effects. The difference, of course, is that a low-carb diet allows the body to produce the appropriate amount of glucose to fuel the body, and also results in a low insulin level. Hyperinsulinemia has its own dangers, which may be the cause of the increased mortality seen in this study. "ADA: ACCORD Diabetes Trial a Complete Bust" <http://www.medpagetoday.com/MeetingCoverage/ADA/9739>

Ann (2012-06-29 08:16:01)

Funny thing is... I would swear to an increase in my math abilities, as well as all other non-critical brain function, when in ketosis - just the opposite of what you've said. I find myself thinking much more clearly, and, using my judgment in stressful situations as a marker, much more effectively and quickly, when I HAVEN'T eaten carbs. I suppose there may be something to be said of the type of carbs one eats, and the relative fat content of said foods. Something to blunt the "sugar rush" that I always feel when eating simple carbs. And I'm not even diabetic!

James Babcock (2012-06-29 09:34:42)

This result does not generalize to non-diabetics. The most likely relevant difference is the number of hypoglycemia events (both reported and unreported), which is much higher in the intensive-control group but which is caused exclusively by mistakes in use of insulin. Also conspicuously missing from the study: any thiamine or thiamine analogs. Thiamine deficiency is extremely common among diabetics (because of increased excretion), and a major risk factor for heart disease.

Mark (2012-06-29 09:35:38)

I agree with Ann, I also focus better when in ketosis.

vgm (2012-06-29 09:54:29)

Seth: the brain uses a lot of the body's glucose intake for energy. Is this a possible explanation for your improvement after eating something sweet? Furthermore, pudding strikes me as somewhat fatty. Given the buttermind results, perhaps you could test the hypothesis by trying sweet; sweet + fat; and fat. Seth: Yes, that is a plausible explanation. I am unclear about how your proposed experiment tests that explanation.

Jonathan (2012-06-29 11:52:09)

I think you're framing the question wrong. I would bet that the insulin itself is causing more damage than the level of blood sugar. This would be consistent with the study's result, and also consistent with the possibility that people who do not inject insulin have better health when they eat in a way that causes less cumulative pancreatic insulin release. Seth: Yes, that is a fair comment. As a way to decide how much "starch" to eat, this is crummy evidence. It is also better than nothing. Alternative explanations like yours point the way to better evidence - studying non-diabetics, for example.

Robbo (2012-06-30 04:54:11)

"But I have noticed clear improvements in brain function (measured by arithmetic speed or something similar) after eating something sweet, such as pudding." Interesting. The guy who holds all the Swedish memory records eats very low carb during competitions because he says it helps him sustain his concentration.

Jazi zilber (2012-07-01 18:49:09)

Extremely low blood sugar is dangerous. I mean really low (maybe 60 and down or something) Now, having diabetes means sugar fluctuates, especially when using insulin. Thus, having lower A1c means that sometimes sugar went really low. Which is dangerous. I think that without diabetes, H1c is best at about 5 or a tiny bit more. Indicating blood sugar of <100.

WB (2012-07-02 17:06:23)

In my view Anand and Tuck are onto something important that deserves much more discussion; and is typically overlooked in

the context of Type 2 diabetes. It seems to me that using artificial methods of adding (synthetic) insulin to the body to control blood glucose in the T2 diabetic is a wrong-headed way to deal with the problem. It seems almost too obvious to have to say that T2 diabetes is a "disease" of too much glucose in the bloodstream. If this is a true statement (and I don't know who could reasonably argue with it), then it follows that a T2 sufferer should take steps to restrict (not completely eliminate) the intake of foods (sugars and other carbs) that turn into too much sugar in the blood, thereby burdening (i.e., overworking) the pancreas day in and day out; ultimately to the point of exhaustion. It's well known that constantly high level of insulin production (caused by the pancreas having to overwork itself to knock down the constant flow of excess glucose from ingested sugars and other excess carbs - together with whatever synthetic insulin is added artificially in the case of the T2 diabetic) causes and/or adds to inflammation in the body (particularly of the pancreas and other major organs). This alone could, and likely does, explain the higher mortality rate.

Robbo (2012-07-04 01:38:44)

@WB "T2 sufferer should take steps to restrict (not completely eliminate) the intake of foods (sugars and other carbs) that turn into too much sugar in the blood" I'm curious why you specifically say 'not completely eliminate' rather than 'or completely eliminate'.

Adam (2012-07-04 04:13:48)

Seth, you said: "I have noticed clear improvements in brain function (measured by arithmetic speed or something similar) after eating something sweet, such as pudding." They have also measured increases in willpower following consumption of sweet things. What occurred to me is that this might be more like a tradeoff than a net benefit. What I mean by that is that yes, you might gain a brief moment of improvement in brain function or willpower, but what happens after it? There is a medical term called "reactive hypoglycemia" or "postprandial hypoglycemia" that describes low-blood sugar in non-diabetics after consumption of high amounts of carbohydrates. If temporarily elevated blood glucose increases brain function, I wonder what happens when blood sugar is depressed... People who do not eat carbs don't have problems with low blood sugar as far as I know and they certainly aren't going to have reactive hypoglycemia. Average fasting glucose level for patients on a low-carb diet in one trial I looked at recently was 92.6 mg/dL. Seth: I get the improvement after eating what most people would consider small amounts of sweet things (e.g., a small package of pudding). There is no reactive hypoglycemia afterwards.

WB (2012-07-04 16:06:34)

@Robbo: Hi Robbo, you ask a valid question. I've been restricting carbs for the last 5- plus years and have greatly benefited from it. I will never go back to the so-called standard "balanced" USDA approved diet. When I first decided to commence carb restriction I was probably on the edge of becoming a T2, but fortunately succeeded in avoiding or circumventing it by being very strict for a long time. And even now, most of the time my carb intake is still very low (probably no more than 10-15 grams of carb per day). But nowadays I do allow myself to indulge in carbs to some extent; e.g., dark chocolate or some cheesecake or, strawberries with cream. I completely understand the "no carb" frame of mind because I've been there, and in fact most of the time I'm still doing essentially that. It's just that now I feel I can loosen up from time to time. I firmly believe, from my experience, that T2 can be cured with carb restriction (while avoiding all meds), and for many individuals something close to complete elimination, especially in the early days of recovery, is definitely a good thing. Regards, WB

Adam (2012-07-04 22:16:05)

Seth, you said: "I get the improvement after eating what most people would consider small amounts of sweet things (e.g., a small package of pudding). There is no reactive hypoglycemia afterwards. From JELL-O's website a 100g package of pudding has 92g of carbohydrate and 72g of sugar. The medical standard for an oral glucose tolerance test is 75g and oral glucose tolerance tests are no longer used to diagnose reactive hypoglycemia because they were found to CAUSE it. I'm not saying that you're wrong and you do get reactive hypoglycemia, rather I'm trying to say that it is highly plausible that a sugary snack could cause it in people in general. Even if it doesn't cause clinical reactive hypoglycemia, it could still cause lowering of the blood sugar after it has peaked, which would presumably have the opposite effects of increased blood sugar on cognition and willpower. Seth: I ate much less than 100 g of pudding. Maybe 30 g.

Jim Purdy (2012-06-30 05:26:24)

Seth, the chewing gum study will have huge ramifications, including: – Presidential debates with all the candidates chewing gum. No more "oops" moments. – Chess competitions with grandmasters chewing gum. – The collapse of the SAT/ACT test prep industry. Why would anybody spend money and time studying, if they could just chew gum instead? – The collapse of business for psychiatrists and antidepressants. Why pay for that when you can just chew gum? – Parents will start their infants on chewing gum at a very early age. – A whole new industry of "smart gum" products – A new government revenue source, taxing gum as a luxury item. – But, alas, all this will be short-live, because government regulators and organizations will ban gum chewing as performance-enhancing "doping." (All above was said with tongue, I mean gum,in cheek.)

Jim Purdy (2012-06-30 16:45:42)

Is that Jaminet story about one baseball team's bone injuries just a case of cherry-picking their data? By contrast, I did a Google search for diets of the highly successful marathon runners from Kenya and Ethiopia, and it looks like their diets tend to be low-fat, with lots of items from corn and cereal grains. And I would suggest that running marathons requires stronger bones than standing around in a ball park. Of course, there could be confounding factors. but we all know that US baseball players have never used performance-enhancing substances that might have harmful health effects. No, uh-huh. Seth: Implicit in Jaminet's post is the idea that (a) the Boston Red Sox could easily be given better food (according to what Jaminet believes) and (b) you could measure the effect of the change in diet – for example, team batting average, number of broken bones.

D (2012-06-30 17:23:18)

"...jacked up his IQ by 40 points." That's enough make me set my default to "ignore" whenever this man makes claims.

Jim Purdy (2012-06-30 19:03:17)

D, do you really mean that you're not going to order Dave Asprey's \$69 whey protein powder and his other products that he spent \$ 250,000 to develop? <http://www.bulletproofexec.com/products/> I guess I'll just have to settle for cheaper things like

the gallon of Organic Valley Whole Milk that I bought today at Whole Foods Market. But then I don't claim to be as smart as Dave.

Adam (2012-07-01 17:35:27)

Re: chewing gum My understanding is that the effects are short-lived, maybe lasting only about 15 minutes or so. With that said, I think it makes a lot of sense to bring a stick of gum with you into a test, even if it is a temporary boost. Re: Dave Asprey I'm also incredibly skeptical of this guy.

### DIY Medicine: Sinus Infections Caused by Wheat Gluten (2012-07-02 05:00)

Five years ago programmer and author [1]David Kadavy suffered from constant sinus infections. The doctors he had seen about it hadn't helped: "They tended to test me for environmental allergies, stick a camera up my nose, and ultimately prescribe some bullshit allergy medication that didn't work." What did work:

One day I was reading an old book on holistic medicine. Of course, the first thing I wanted to know was how could I prevent being constantly congested. The book said that foods such as wheat, meat, and dairy often contributed to excess mucous production – and thus, sinusitis. I was miserable, and clearly willing to try [2]anything, so I cut out all three of those things the very next day.

Within two days, the difference was incredible. My head had cleared up, I had boundless energy, and other problems – such as a patch of eczema that I had on my eyelid for years – all cleared up. . . . Through a bit of experimentation I was able to place the blame for my sinus woes (and that eczema thing) on wheat. . . . Not only did the experience have me looking at food differently, it also had me looking at medicine differently. How could I see so many GPs, allergy specialists, ENT [ear nose and throat] specialists, and dermatologists without a single one of them saying "you know, you should look at your diet?"

Yes, how could that be? And, to paraphrase [3]Alex Tabarrok, what else are they missing?

Thanks to [4]Melissa McEwen.

Joe levy (2012-07-02 05:11:50)

What else is missing? How about a control group? Seth: You think it's plausible that his health improvement might not be due to the dietary change? Why?

dearieme (2012-07-02 05:43:45)

My sinus problems ameliorated when I gave up citrus fruit, and improved again when our cats died. So pelt your cats with oranges, chaps!

Joe (2012-07-02 10:44:07)

I wonder how he's doing today. Any idea?

David Kadavy (2012-07-02 11:41:28)

I'm doing well, Joe. I still avoid gluten, and don't get sinus infections (or colds, really, for that matter) anymore. I do even better if I avoid lectins as well (Paleo diet), but I'm not as strict with that.

Evolutionarily (2012-07-02 21:05:36)

A similar but milder incidence happened to me upon removing Wheat from my diet when first trying "Paleo". I used to wake up every morning with a mildly runny nose that would always need a good blowout in my morning shower. It was about a week into the diet experiment when I noticed that for the first time for as long as I could remember I was no longer doing this and my nose was noticeably clearer.

Fatcat (2012-07-03 06:42:08)

I have noticed the same thing since going gluten free 2 years ago for my fibromyalgia/chronic fatigue. In addition to the fibro and the fatigue, I got rid of my sinus problems and my daily headache and my skin cleared up. I'm not even tempted to eat wheat now.

Robert McMaster (2012-07-03 10:24:07)

Joe Levy needs to be introduced to the 'scientific method'. When wheat containing substances are removed from the diet chronic sinus infections abate. When wheat is re-introduced, the symptoms re-emerge. Repeat this experiment. Do it again. Once more. If the evidence squares up, decide under which regime you wish to live and act accordingly. Are not the controls clear enough? There's 'evidence based medicine' and 'outcomes based medicine'. Can Waldo spot the racket? Seth: Yeah. Science is about learning from evidence, yet many people who learn terms like "control group", "placebo", "double-blind", and "randomized" use them to avoid learning from evidence. They use them to belittle evidence. There should be a name for this paradox. Evidence-based medicine may be better than what it replaced but it has a strong strain of this belittlement, as you say.

Robert McMaster (2012-07-03 14:42:33)

ahh... 'evidence based medicine'. What kind of '[\*.\*] based medicine' were they practising so long before that? Have the charlatans of that time - what, 15 years ago - been turned out, dismissed, fined, jailed? By what (objective) measures are health outcomes better or different under this new regime than the one nameless one it has replaced? Headline of today: GSK fined \$3b for casually lying about everything while the evidence based physicians lined their pockets and smacked their lips. plus ca change, plus c'est la meme chose

Sam (2012-07-31 16:35:20)

I used to have extremely bad congestion in my sinus cavities. I heard from Jerry Pournelle, who I respect, that a machine called the SinuPulse cleared up his sinuses. I bought one and had good results. Even better results happened after using it for a year. It

seems that I now no longer get sinus build up as easily as I used to. I go months without using it and have no problems. I wonder if sinus problems come from some bacteria or other creature that builds up and washing it away cures the irritation of the sinuses?

### **Where to Buy Miso in Tokyo (2012-07-03 05:00)**

In Tokyo I went to a shop that specialized in miso. It sold about thirty varieties, several of which I liked very much. There is a choice of packaging: hard or soft. The hard packages could be used for gifts. The phone number of the shop is 03(3841)7116, which you can use to google it. It is in the Hanakawado district, between Kototoi Dori and Edo Dori, near the Senso-ji Temple and the Amuse Museum. It is open 9 am to 6 pm. Maybe closed Sunday.

Address: 2 - 8 2-chome, Taito-ku, Tokyo Hanakawado ☞ 111-0033, which 0.23 km from the Asakusa Station.

Incidentally, nowadays I tend to eat miso with a poached egg. Boil 0.8 cup water, add egg, cook until poached, add the miso which has been mixed with 0.1 cup water.

---

JC (2012-07-03 06:19:17)

Interesting. How much miso? Seth: Start with 1.5 tablespoons. Strangely enough this is the part of the recipe I am least sure of.

Nancy Lebovitz (2012-07-03 10:29:27)

What types of miso do you prefer? Seth: Dark rich. Older. More pungent. In Tokyo you can smell the miso before buying it and some miso smells more complex.

garymar (2012-07-03 15:06:09)

Definitely closed Sundays. I've been back there several times, still picking up the Hatcho Miso which is pure non-GMO soybean fermented for a minimum of 3 years.

mk (2012-07-04 12:44:57)

what about radiation? Fukushima Daichi nuclear melt-down of four reactors is contaminating everything.

JC (2012-07-09 04:42:41)

Wow, 1.5 tablespoons mixed with 0.9 cup of water makes for a very miso-y concoction. Will give it a go though, thanks

### **Magic Dots: Quasi-Reinforcement Helps Get Things Done (2012-07-04 05:00)**

[1]

This photo illustrates a method I have used for many years to get work done, usually writing. Every six minutes of work, I make a dot or line. One hour = 10 marks = a box (counting method from Exploratory Data Analysis). I use a stopwatch. I make a mark when I am more than halfway to the goal. If I glance at the clock and it says 4 minutes (more than halfway to 6 minutes), I make a mark. If I glance at the clock and it says 10 minutes (more than halfway to 12 minutes from 6 minutes), I make a mark. I only zero the clock when I take a break. I use one piece of paper per day.

I devised this. It is based on an effect discovered by [2]Allen Neuringer and Shin-Ho Chung called quasi-reinforcement. Neuringer and Chung studied pigeons. They found that if you give a pigeon food every 500 times it pecks a key, it will peck the key slowly (say, 2 pecks/minute). If you give the pigeon a brief flash of light every 20 pecks – a marker that shows it is doing the right thing to get food – it will peck much faster (say, 4 pecks/minute). The flashes of light are quasi-reinforcement, said Neuringer and Chung – they have some but not all of the properties of ordinary reinforcement, such as food. By themselves, the flashes of light don't interest the pigeon. It won't peck a key to get them. The amazing thing about this effect is that it doubles how hard the pigeon works without raising its salary.

I noticed improvement – it was easier to write – within about 20 minutes the first time I tried this. I chose six minutes as the unit because shorter times were more distracting and longer times less effective.

I told [3]Gary Wolf about the dots method two years ago and he's been using it ever since. He says it is good for getting started on something he needs to write. After he gets going, he stops doing it. He uses it as an example of the value of self-tracking. I too find that after I get going on something, I need it less. If I stop, however, I drift backwards toward doing less productive stuff or nothing.

Gary asked me about this a month ago and I started doing it again (instead of [4]percentile feedback). I noticed something I had never noticed before, which was that the system lifted my whole energy level and gave me a "can't wait to get started" feeling in the morning. This too made it easier to get stuff done. It reminded me of some rat research I'd done. Put a rat in a Skinner box and it will explore for a while. If it doesn't get any food, after a while (10 minutes?) it will stop exploring and curl up in the middle of the box. However, if I give the rat a pellet of food at random times (at the rate of one pellet/minute), it will keep exploring the box indefinitely. Learning psychologists have emphasized that when you reward an action, you make it more likely. The rat experiment I just described suggests a second effect: when you give reward – at least, when reward is rare – you make all actions more likely. You increase exploration, not just the rewarded response. When I was a young professor I went to a two-week neuroscience program at Dartmouth. It was all lectures. The other attendees were graduate students. I had little in common with them. There was little to do in the town, besides eat Ben & Jerry's. The next town was 8 miles away. I couldn't find anything I enjoyed doing. After a week, I had trouble getting out of bed, like the rat curled up in the middle of the Skinner box. A psychiatrist might have said I had major depression. I flew home and was fine.

---

MikeW (2012-07-04 07:31:41)

A couple years ago I came up with a similar timer-based strategy to handle household chores. I wrote a simple Windows app that, every 9 minutes, grabs a random item from my long to-do list, displays it, and beeps loudly (in case I'm not in the same room as the computer). I settled on 9 minutes because that was usually enough time to do the kind of task on my list (start a load of laundry, wash dishes, pay bills, order vitamins, brainstorm ways to improve my diet, etc.). I find it to be a very effective motivator - it makes even the most tedious tasks almost enjoyable when I know in 9 minutes I can drop it. The randomness is important, too. If I did things in the order I'd prefer to do them, the cat's litter box would never get changed. I noticed the higher energy effect, too. But I always thought it was physiological, not psychological. Most of my tasks involve getting up and physically doing something, so I assumed the energy came from deeper breathing and getting some light exercise.

dearieme (2012-07-04 08:13:20)

I don't see how these methods let you benefit from procrastination. (I was due to move office. I delayed (ill health). Finally I've been told they've found another solution and I needn't move at all. Result!) Don't do today what can be put off beyond tomorrow.

by (2012-07-04 12:50:00)

I guess both systems are good. (the box, and percentile feedback) Your mind just became inured to the percentile feedback system and so it is not having the same exciting effect on your productivity. Maybe in a few months you will switch back to percentile feedback. Do you think? I notice the same thing with hobbies. No matter how much I love something, after I've done a lot of it it gets stale. This is too bad. I could create a menu of hobbies for myself and rotate among them to keep my excitement high every day, but it's difficult to make progress at something when one must drop it and pick it back up frequently. Not to mention finding enough things that I actually really enjoy. Seth: Percentile reinforcement becomes hard for me when for whatever reason productivity goes down. It is hard to look at low scores all day.

by (2012-07-04 16:32:30)

Dr. Roberts, How many days after starting up the dots method again, was it before you first had the can't wait to get started feeling? Seth: about 2.

by (2012-07-04 16:39:53)

MikeW, so you've been using the 9 minute random timer for a couple of years now, and it's still as useful as when you started?

MikeW (2012-07-04 18:16:43)

by: yes, I'd say the random task timer is just as useful as ever, but I've never used it on a regular schedule. It goes in spurts. Lately I've had it running daily because I felt I wasn't making enough headway on my to-do list.

by (2012-07-04 22:41:00)  
Thanks!

Andrea (2012-07-05 06:37:08)  
MikeW, is the app available? On iTunes, by any chance?

MikeW (2012-07-05 07:20:53)

Andrea: I've seen a similar app available for Android and iPhone, called Job Jar. It has the random selection I want, but not the cracking-the-whip-every-9-minutes functionality. I suppose you could download that, then use a stopwatch app (or a real stopwatch) in conjunction with it. I'm a programmer, so I often cook up apps for my own use with no desire to distribute them commercially. I've thought about rewriting this Windows app to work on my Android phone, but haven't put that on my to-do list yet, ha-ha. It would take more than 9 minutes!

Darrin Thompson (2012-07-05 12:40:12)

Been trying this today on a bunch of un-fun work I have to do. This is a life changer. Thanks for posting it. Seth: You're welcome. What happened?

Aaron Blaisdell (2012-07-05 15:01:09)

Seth, I've been using this type of secondary reinforcement for some of my pigeon and rat studies, too. It's very useful when the subject must complete a set of responses before receiving its primary reinforcement. I'd say the reason why the rats were exploring the box throughout the session when you gave them random food deliveries is that you kept activating the general search mode (exploration) of the food reward system. This idea ties into the behavioral systems theory work of Staddon & Simlehaug, Shettleworth, and Timberlake. I doubt that ANY activity would increase (in fact, you state that sleeping curled up in a ball decreased), but certainly feeding-related activities (which includes exploring for more food) would increase. Self grooming might be another activity that would decrease (cf. Sara Shettleworth's studies of hamsters in the 1970s).

by (2012-07-05 16:00:36)

I gave the dots a first try. They didn't motivate me enough that I could keep at the task for a full hour. There was confounding from the effects of coffee, though. I kept track of my motivation while using the dots, and it went down the whole time, but that was because caffeine was wearing off. I guess my point is the effect isn't stronger than caffeine, but I'll give it another go later. Seth: My first question is: do they motivate you at all? Meaning: do they make work easier?

by (2012-07-05 22:12:31)

This first experiment didn't give me any reason to think so. All I noticed was that I was looking at the clock to see if it were time to make another dot. I will try the system again tomorrow. The percentile feedback system I downloaded here though has increased my productivity about 20 % since I started using it three weeks ago. Seth: Glad to hear it about the percentile feedback. About the dots: Their obvious value is to get started and gain momentum on difficult stuff. I don't think you will notice any effect on stuff that isn't hard to do.

by (2012-07-06 09:34:09)

Ah, well won't be a problem finding a source of test opportunities for that!

by (2012-07-06 17:09:20)

I tried again, and this time my enthusiasm for the work increased over the hour while doing the dots. I think it was just due to getting into the task, but the dots did give me an extra push to keep going. The stream of ratings of my enthusiasm was (18 % before starting), 22 %, 14 %, 22 %, 19 %, 20 %, 26 %, 22 %, 33 %, 30 %, 26 %. Thanks for discussing this and the other productivity techniques. They're fun to try. Seth: That's a good idea, measuring enthusiasm on a numerical scale. I think I would use a 0-100 scale with 50 = neutral, >50 = want to do the task, < 50 = don't want to do the task. Maybe 60 = barely want to, 70 = somewhat want to, 75 = want to, 80 = quite want to, 90 = very much want to.

Vanner (2012-07-08 08:34:54)

Video game designers have been using this strategy for years now. I first noticed this playing the online multiplayer game "Call of Duty". Even if you ended up with the worst score at the end of the game, you always received an accolade of some kind. This positive feedback always had me playing the game well past a reasonable bed-time.

by (2012-07-08 12:41:45)

(re: Dr. Roberts' numerical rating system) I'm very glad to hear how you interpret percentages and their corresponding feelings. To me, this is the hardest part of self-experimentation, coming up with a rigorous, reproducible scale. The percentages I used were "what popped into my head from my gut" when asking myself, so, how enthusiastic do I feel right now? I am chronically sleep deprived, so I think that's why my numbers were so low. I see your system provides guideposts for keeping the ratings consistent.

### **Morning Faces Therapy: More Good Results (2012-07-06 07:37)**

Navanit Arakeri, who is 31 and lives in Bangalore, sent me [1]the following email about the effect of looking at faces in the morning:

Thank you, it's the most extraordinary thing. It's taken my average daily mood from 6/10 to about 8/10 [on a 1-10 scale where 1 = very, very bad mood, 5 = neutral, and 10 = amazingly good mood. 6/10 = just better than neutral and 8/10 = very good. Note: if 5 = neutral, then a 1-9 or 0-10 scale will work better than a 1-10 scale] It has made me officially "happy". And much more emotionally resilient to irritants and bad news.

I do it on waking at around 8:00 AM every day. I play "morning news" videos on mute on my iPad with no zoom (so it's much smaller than life-sized). [2]Example video

I do it for only 20-40 minutes, usually around 25 minutes. I've been doing it for about 45 days now.

I'm seeing a few interesting differences compared to your experience:

1. I don't get the evening irritability at all. In fact, sometimes I get a Big Mood Improvement (see #2) in the evening (around 8:00 PM). The evening effect doesn't happen every day, while the morning improvement is much more consistent.
2. Sometimes the mood improvement is so strong that I have an involuntary smile on my face. I can sit and stare into space feeling very happy. . . .

Sleep quality has been good throughout.

What led him to try it? "I wanted a simple self-experiment to test [3]my lifelogging iPhone app and this fit nicely. I had read [4]your original self-experimentation paper several years back, but never got around to trying it," he said.

How long before he could tell it was working? "It was very clear by the 3rd morning," he said.

He recorded the "involuntary smile" states, which lasted 30-60 minutes, on his iPhone. This graph shows how often they happened versus time of day over a 33-day period:

[5]

A value of 8, for example, means that there was roughly a one-quarter chance that during that time period he would be in the "involuntary smile" state. Before this the likelihood of involuntary smiles was zero.

---

by (2012-07-06 09:28:37)

Involuntary smiles is a nice idea of rating mood. Random querying is automatically part of the system. This post inspires me to look into trying morning faces again; the difficulty of finding the faces sources and the time investment put me off it. So many ideas to try.

Jim Purdy (2012-07-06 10:49:26)

Seth, when I read your blog, sometimes I think that I'm reading some amazing Nobel Prize-worthy science. But other times, I think I'm reading a hilarious spoof from The Onion. The problem is, I never know which is which. Seth: Navanit Akakeri is a real person.

dearieme (2012-07-06 14:21:24)

I don't know what the fuss is about: doesn't one automatically contemplate the ancestral portraits on the walls of one's breakfast room?

Pablo Stafforini (2012-07-07 02:31:44)

If I understand your correspondent's message correctly, he watches muted news videos for 20-40 minutes each day. Lacking any sound, such videos would be unbearably boring for nearly every person—however attractive the news reporter might be. Am I missing anything here? Seth: It's a good question how Navanit keeps from being bored. I've asked him. I listen to podcasts, lectures, audiobooks, etc., while looking at the faces.

BlueMorrissey (2012-07-07 09:32:53)

As i've stated before, I watch Squawk on the Street on MSNBC in the morning for 30-60 minutes for my morning faces. I don't know how people look at only faces or their own face. I need a little entertainment. I also watch Red Eye which I dvr the night before on Fox News. It has faces and some witty comedy which puts me in an even better mood.

Jim Purdy (2012-07-07 12:00:42)

The recent comments above by Pablo Stafforin, Seth, and BlueMorrissey are fascinating to me, because I feel just the opposite. I gave away all my TVs and radios back in 2005, and I thoroughly enjoy the peace and quiet – no faces, no noise, and my apartment is almost soundproof, so I seldom hear the neighbors. And I get really annoyed when I go to a website and it immediately starts automatically making some noise. Without radio, TV, or newspaper subscriptions, I get all my news from the internet, especially New York Times, CNN, MSNBC, Google News, and Yahoo News. For fiction, I watch all those shameless lying fake journalists on Rupert Murdoch's Fox "News."

Pablo Stafforini (2012-07-07 13:34:12)

Jim, my living conditions are very similar to yours—I also lack TVs and radios, and proudly so. (I don't get my "news" from anywhere, since I follow a [1]low information diet.) My point was simply that it would be very boring to do nothing but watch silent videos of faces for 20-40 minutes. I hope Seth's correspondent can elaborate on his strategies to avoid boredom.

1. <http://changethis.com/manifesto/show/34.04.LowInfo>

dearieme (2012-07-07 16:50:35)

To avoid boredom, wouldn't the obvious strategy be to watch Buster Keaton movies?

Navanit Arakeri (2012-07-08 00:03:27)

I do fidget a lot and glance at the clock every 5-6 minutes while looking at the videos. I tend to start day dreaming and need to consciously bring my attention back to the face. Having said that, I don't feel "bored" in the conventional sense while watching them. It never feels like a chore. I look forward to them every morning.

### **Notes on Navanit Arakeri's Morning Faces Experience (2012-07-07 09:57)**

[1]My last post described how [2]Navanit Arakeri found that looking at faces on his iPad in the morning improved his mood. Three things struck me about his experience.

1. Small faces worked ("much smaller than life-sized"). [3]I found that life-size faces produced the biggest effect. I never studied the effect of face size in detail (trying many different sizes). I first experienced the effect after watching Jay Leno do his monologue on a 20-inch TV – much smaller than a life-size face. Obviously we recognize faces when they are much smaller than life-size. For example, we recognize faces in newspaper photos. And we recognize people at a wide range of distances, meaning that the retinal image of a face can vary greatly in size without preventing recognition. Both facts suggest that the size of the face may not matter a lot for this effect.

2. He watched right after he got up. There is surely a window of effectiveness – a time period outside of which the faces do nothing – but when? And how long? I don't know. It surely depends on your exposure to sunlight, which is incredibly hard to measure. Navanit found a simple rule that worked ("watch right after you get up"). When I first experienced the effect I did the same thing that works for him – I watched TV a few minutes after I woke up.

3. He became less irritable ("much more emotionally resilient to irritants and bad news"). I noticed the same thing. A paradox of depression is that people become more irritable. Depression is a disease of passivity – you don't want to do anything – but irritability is over-reaction. I've heard it claimed that depression may be caused by not eating enough fruits and vegetables. Okay, lack of a vital nutrient might cause people to have less energy, but why would it make them more irritable? Not obvious. The fact that the morning-faces effect includes this component is part of why I think it sheds light on what causes depression. Perhaps anything that raises your mood will make you less irritable but I can only say it didn't feel that way – it felt like something special. Like everyone else I have my mood raised by ordinary events (e.g., good news, a joke) and these do not seem to produce a big increase in serenity.

---

Jeffie D (2012-07-07 13:29:03)

What's never been clear to me is how many faces are needed to have a favorable effect. Is watching one person performing a monologue for 30 minutes enough, or is a random sampling of faces flashed onto a screen for a few seconds apiece just as or more effective? Seth: One person is enough. Most of my research was done watching Booknotes on C-Span, which involves two persons.

Andrea (2012-07-07 14:17:05)

Does this technique apply mainly to single people? I am wondering if I could improve my mood if I took a good look at my husband's face in the morning instead of rushing around. Seth: You need 15-30 minutes to get a noticeable difference. A few minutes, no.

Navanit Arakeri (2012-07-08 00:06:41)

I now use a single 2:20 minutes video looped to play again and again on the iPad. When I first started I used a variety of different faces. For me there's no difference between the two in terms of impact on mood. I save a lot of searching and tapping with the current method though.

Nancy Lebovitz (2012-07-08 01:20:06)

I'm convinced that irritability is a thing in itself. Serenity might also be a thing. For a while, I'd get irritable whenever I had a hot flash, and that seemed reasonable because I generally don't like being overheated. Then I had some no irritability hot flashes, and I concluded that there were some PMS symptoms involved in some hot flashes, but not all of them. (Note: hot flashes vary tremendously, and not just by intensity.) It wouldn't surprise me if some irritability is a nutritional issue. I'm pretty sure that not all depression has a large component of irritability.

Michael Bishop (2012-07-08 09:04:46)

"There is surely a window of effectiveness — a time period outside of which the faces do nothing — but when? And how long? I don't know. It surely depends on your exposure to sunlight, which is incredibly hard to measure." Why are you sure there is a window. Why are you sure exposure to sunlight interacts with it? Seth: I varied the time I saw the faces. The time made a big difference. Later in the day, such as noon, they had no effect at all. The window must be open and shut by another clock and sunlight is the only plausible driver of such a clock.

vs (2012-07-10 10:24:03)

On a somewhat related note, this is a very interesting article on a therapist dealing with her own mid-life crisis. In a way it illustrates the value of personal science, due to the futility of seeking help from a professional who is likely to be unsuccessfully dealing with their own issues: [http://www.themorningnews.org/article/therapist-know-thyself?utm\\_source=feedburner&utm\\_medium=feed&utm\\_campaign=Feed:+TheMorningNews/features+\(The+Morning+News\)](http://www.themorningnews.org/article/therapist-know-thyself?utm_source=feedburner&utm_medium=feed&utm_campaign=Feed:+TheMorningNews/features+(The+Morning+News)) Seth: yes, very interesting article and very good point about its relation to personal science.

Alex Chernavsky (2012-07-10 20:30:32)

Seth, just wondering if you have any experience with meditation. This method of looking intently at faces reminds me of some meditation techniques (I have not tried them myself).

dearieme (2012-07-09 14:29:45)

I've been following your blog for some time now and have at last made an observation on myself. I much prefer (= am made happy by) showering in daylight rather than artificial light. Perhaps everyone else knew this already, but I didn't. It will constrain me a bit in winter, but so be it. Seth: How long does the improvement (greater happiness due to showering in daylight) last?

Tom (2012-07-09 17:53:07)

A couple of stories that are up your alley: Doctor's "ignorance" leads him to the truth about what's making a child ill: [childrenshospital.org/dream/dream\\_fall06/fishing\\_for\\_the\\_right\\_solution.html](http://childrenshospital.org/dream/dream_fall06/fishing_for_the_right_solution.html) Germs from pets = healthier babies: [latimes.com/news/science/la-sci-dogs-cats-babies-health-20120709,0,6527217.st](http://latimes.com/news/science/la-sci-dogs-cats-babies-health-20120709,0,6527217.st) ory

dearieme (2012-07-10 02:02:44)

Seth, it seems to last for much of the rest of the day. Many hours, anyway. I'm wondering whether anyone makes one of those artificial sunlight lamps that would be suitable for our bathroom.

Misericorde (2012-07-10 08:23:41)

May we please have the correct link for the item on sewer work and immunity. Seth: Link fixed, thanks.

Sean Estey (2012-07-10 22:25:44)

I'm not seeing the cause and effect between having kids->better immune system. Couldn't a simpler explanation be that healthy people are more likely to have children than non-healthy people? They may have been healthier than the non-parents

even before their children were born. Unhealthy people are probably more likely to have lower fecundity.

Tom (2012-07-11 00:28:30)

The simplest explanation is that children, like dogs, track in a lot of germs.

Tom (2012-07-11 00:30:25)

(and, in case my implication wasn't clear, the immune system then develops a broader portfolio of antibodies.)

### **Prize Fight: The Race and Rivalry to be First in Science by Morton Meyers (2012-07-10 05:00)**

Prize Fight: The Race and Rivalry to be First in Science (2012) by Morton Meyers (copy sent me by publisher) is about battles/disagreements over credit, often within a lab. Jocelyn Bell noticed the first quasar – how much credit does she deserve relative to her advisor, Anthony Hewish, who built the structure within which she worked? (Not much, said Bell. "I believe it would demean Nobel Prizes if they were given to research students.") The structure and subtitle of the book make little sense – there is a chapter about how science resembles art and a chapter about data fabrication, for instance, and nothing about races or being first. The core of the book is two stories about credit: for the discovery of streptomycin, the first drug effective against tuberculosis, and for the invention of MRI (magnetic resonance imaging). Meyers is a radiology professor and a colleague of one of the inventors of MRI.

I liked both stories. I find it hard to learn anything unless there is emotion involved. Both stories are emotional – people got angry – which made it easy to learn the science. Streptomycin was found by screening dirt. It was already known that dirt kills microbes. The graduate student who made the discovery was indeed a cog in a machine but later he was mistreated and got angry and sued. The first MRI-like machine was built by a doctor named Raymond Damadian, who was not one of the recipients of the Nobel Prize given out for its invention. He had good cause to be furious. The otherwise good science writer Horace Freeland Judson wrote an op-ed piece about it ([1]"No Nobel Prize for Whining") that ended "His behavior stands in stark and elegant contrast to the noisy complaining of Raymond Damadian". To name-call ("whining", "noisy") in a New York Times op-ed is to suggest your case is weak.

I have had a related experience. When I was a graduate student, at Brown University, I did experiments about cross-modal use of an internal clock. Do rats use the same clock to measure the duration of sound and the duration of light? (Yes.) I got the idea from human experiments about cross-modal transfer. By the time [2]my paper ("Cross-Modal Use of an Internal Clock") appeared, I was an assistant professor. A few months after it was published, I went back to Brown to visit my advisor, Russell Church. On the day of my visit, he had just received a new issue of the main journal in our field (Journal of Experimental Psychology: Animal Behavior Processes – where my article appeared). It was in a brown wrapper on his desk. I opened it. The second article was [3]"Abstraction of Temporal Attributes" by Warren Meck and Russell Church. (Meck was a graduate student with Church.) I didn't know about it. It was based on my work. The first experiment was the same (except for trivial details) as the first experiment of my article. The introduction did not mention me. I leafed through it. Buried in the middle it said "This result replicates previous reports from our laboratory (Meck & Church, in press; Roberts, 1982)."

I was angry. Why did you do this? I asked Church. "To make it seem more important," he said. I consoled myself by thinking how bad it looked (on Church's record). I never visited him, and almost never spoke to him, again. Years later I was asked to speak at a conference session honoring him. I declined. What he did amounted to rich (well-established) stealing from poor (not established) and jeopardized my career. When my article appeared, I didn't have tenure. It was far from certain I would get it. I hadn't written many papers. If you read both papers (Meck and Church, and mine), you could easily be confused: Who copied who? This confusion reduced the credit I got for my work and reduced my chance of getting tenure. Church surely knew this. Failure to get tenure could have ended my career.

---

Nancy Lebovitz (2012-07-10 05:47:20)

Is anything known about how internal clocks work? I'm not sure if I can still do it, but when I watched tv, I had a very accurate idea of what an hour and a half hour were. Seth: My research implied that the internal clock of rats – the one used to measure minutes and seconds – resembled a stopwatch in several ways.

Darius Bacon (2012-07-10 15:24:17)

[http://en.wikipedia.org/wiki/Jocelyn\\_Bell\\_Burnell](http://en.wikipedia.org/wiki/Jocelyn_Bell_Burnell) #Nobel\_Prize gives quite a different impression about the credit over pulsars. It does list a bunch of other awards she received.

dearieme (2012-07-10 16:01:47)

It wasn't until I read his WKPD entry some time ago that I learnt that the attribution of the transistor to Shockley was somewhat polluted. Much more was made of the point that "Shockley's field effect principle had been anticipated and devices based on it patented in 1930 by Julius Lilienfeld, who filed his MESFET-like patent in Canada on October 22, 1925" than is made in the current WKPD entry.

Bryan (2012-07-11 21:29:57)

Just came across this in my Twitter feed: <http://www.guardian.co.uk/books/2012/jun/29/experiment-eleven-tuberculosis-pe-ter-pringle-review> Seth: Yes, this book is another view of the streptomycin discovery.

dearieme (2012-07-12 06:47:48)

WKPD: "Originally, the discovery of streptomycin was credited only to Schatz's supervisor, Selman Waksman, who would later receive a Nobel Prize in 1952 for this work. Schatz, however, strongly contested the crediting and in 1950 brought litigation against Waksman, requesting recognition as streptomycin's co-discoverer and a portion of streptomycin royalties. Schatz's requests were eventually granted in an out-of-court settlement." So why didn't the Nobel Committee then aware a prize to Schatz? (i) Cowardice? (ii) Vested interest of professors not happy with recognising research students as contenders for the prize? Seth: the Nobel Prize was given for work that "led to the discovery of streptomycin" not for the discovery itself.

## **"I Hate Dreamhost!" Beware, Potential Dreamhost Customers (2012-07-11 05:00)**

I recently got the following email:

I googled "dreamhost sucks" and found your blog. I really hate this company. I have a small business and they somehow managed to create a second account for my company in spite of the fact that we never requested one. Then they emailed us that we owed more money on our account and shut off our access

and emails due to the amount overdue. After months of various DH staffers replying to my emails (we hadn't ever selected phone support so they would only correspond via email) the problems were finally passed to a "supervisor". The supervisor promptly cancelled the duplicate account and reset our live and fully paid account so that we could use it again. This took months of frustration and provision of the same information to the different DH staffers. There is obviously no communications within their staff there. Very frustrating.

Today, they sent an email to me requesting an additional albeit minor sum of \$9.95 for a temporary account that was created when nobody at my company could access our account. They insist we created it and pay for it or they'll suspend our live account. I complained and asked for the same supervisor that resolved DH's past errors, and the staffer, Jay H, promptly cancelled our fully paid, live account, and told me we still had to pay for this temporary account created by a DH staffer when we didn't even have access to our site and emails due to DH's original errors!!

So frustrating. I'm now looking for a new domain and web host company, with excellent customer service and professionalism. DH doesn't take responsibility for their own errors and seems to dream up ways to charge clients extra money for stuff they never requested. Outside of the online world, this would be called extortion.

Feel free to post. I hate Dreamhost!

As do I. I wish I had left the second I discovered they hadn't backed up my site, after saying they had. (They had backed up only a small fraction of it.) After that, my sites kept getting hacked. First, we moved this blog and [www.sethroberts.net](http://www.sethroberts.net) off Dreamhost. They stopped getting hacked. Then the Shangri-La Diet forums got hacked. We moved them off Dreamhost. No more hacking. The cost of even one incident of hacking is far more than you will ever save from their low rates.

[1]Dreamhost hacked – and see the comments.

1. <http://techcrunch.com/2012/01/20/dreamhost-hacked-password-changes-made-mandatory/>

---

Alex Chernavsky (2012-07-11 08:04:04)

For what it's worth, I've hosted all my sites on DreamHost for the last five years. I have not had any significant amount of trouble with the company.

Darrin Thompson (2012-07-11 08:36:07)

Use Rackspace Cloud. It's not expensive. My pathetic affiliate link: <http://www.rackspacelcloud.com/550.html> I've used them for a few years now. I've needed their support people on a few occasions and they are always available, super helpful, and know what they are doing. One time I thought some service I was using might down over an account issue. The support person's response? We never do that.

James A Donald (2012-07-11 16:16:12)

I am on the extremely cheap and competent cyberultra, have never had a problem with them. They don't do backups, or indeed anything, other than simply work.

James A Donald (2012-07-11 16:19:52)

Going through my logs, it looks as if someone has been attempting to guess my passwords, making tens of thousands of failed guesses, and Cyberultra made no attempt to filter them out. However, since my passwords are unguessable, this was no problem for me. The usual attack is to socially engineer password recovery services. If anyone has been trying that on cyber

ultra, they have failed. <http://www.000webhost.com/directory/reviews/cyberultra.net>

SB (2012-07-24 04:35:31)

A recommendation for A2Hosting: [http://calnewport.com/blog/2012/04/29/walking-in-merlin-manns-footsteps-and-a-book-you-should-know-about/?utm\\_source=feedburner&utm\\_medium=feed&utm\\_campaign=Feed %3A+StudyHacks+%28Study+Hacks %29 &utm\\_content=Google+Reader](http://calnewport.com/blog/2012/04/29/walking-in-merlin-manns-footsteps-and-a-book-you-should-know-about/?utm_source=feedburner&utm_medium=feed&utm_campaign=Feed%3A+StudyHacks+%28Study+Hacks%29&utm_content=Google+Reader) "When I first started blogging in 2007, I needed web hosting. I noticed that Merlin Mann had a note on 43 Folders about his happiness working with a company named A2 Hosting. That was good enough for me: I signed up for their introductory package. That was five years ago and I've been nothing but happy with their service ever since."

### **American Dietetics Association Tries to Outlaw Competition: More (2012-07-11 17:27)**

Michael Ellsberg has written [1]another fascinating article about how the American Dietetics Association is trying to make it illegal to compete with their members – that is, make it illegal to give nutritional advice without board certification. ([2]His earlier article.) State boards have threatened several bloggers with jail if they continue to provide nutritional advice.

Thanks to [3]Dr. B G.

by (2012-07-12 11:19:25)

The TED talk reminds me of the creativity blogs I see around. I've never been able to get up the motivation to read them. A productivity blog, which is sort of how I classify this one, I see the benefit. I need to clean my house. I need to get my work done. I would like to sleep better and be in a better mood. I love reading Dr. Roberts's and others' ideas on these. But creativity? Will it really help my life out much?

Txomin (2012-07-12 18:00:10)

Indeed. I've met family therapists whose personal life is a complete train wreck and professionally are no more reliable than fortune cookies.

shtove (2012-07-14 06:02:29)

Spotted this from the Atlantic: Lies, Damned Lies, and Medical Science <http://m.theatlantic.com/magazine/archive/2010/11/lies-damned-lies-and-medical-science/8269/>

## More About Pork Fat and Sleep (2012-07-14 13:56)

One day in 2009, I ate a large amount of pork belly (very high in fat – pork belly is the cut used to make bacon). That night I slept an unusually long time. The next day I had more energy than usual. This led me to do an experiment in which I ate a pork belly meal (with lots of pork belly, about 250 g) on some days but not others. I compared my sleep after the two sorts of days. I kept constant the number of one-legged stands I did each day because [1]that has an effect. During the first half of the experiment I kept this constant at 4; during the second half, at 2. I [2]originally posted the results only from the first half.

Now I've analyzed the results from both halves. Here are ratings of how rested I felt when I woke up, on a scale where 0 = 0 % = not rested at all and 100 = 100 % = completely rested.

[3]

The two halves were essentially the same: pork belly produced a big improvement. Here are the results for sleep duration.

[4]

No clear effect of pork belly in either half of the experiment.

The main thing I learned was that pork fat really helps. The effect is remarkably clear. With micronutrients, such as Vitamin C, the body has considerable storage. It may take months without the nutrient to become noticeably deficient. With omega-3, which is between a micronutrient and a macronutrient, my experiments found that it takes about two days to start to see deficiency. With pork fat there seems to be no storage at all. I needed to eat lots of pork fat every day to get the best sleep. That repletion and depletion are fast made this experiment easy. How curious we are so often told animal fat is bad when an easy experiment shows it is good, at least for me.

2. <http://blog.sethroberts.net/2009/10/31/effect-of-animal-fat-on-sleep-more/>
3. <http://blog.sethroberts.net/wp-content/uploads/2012/07/2012-07-15-effect-of-pork-fat-on-rested-ratings.jpg>
4. <http://blog.sethroberts.net/wp-content/uploads/2012/07/2012-07-15-effect-of-pork-fat-on-sleep-duration1.jpg>

---

curiousguy (2012-07-14 14:21:24)

Do you feel bad about killing intelligent creatures like pigs?

jeffk8900 (2012-07-14 15:31:02)

I think it is easy for others to scapegoat pork do to religious hang ups. How often does that bias creep in?

Adam (2012-07-14 16:56:51)

@curiousguy He didn't kill the pig, he just ate part of it.

Sky King (2012-07-15 05:24:43)

@ curiousguy: Here's an editorial written in the NY Times that you might find interesting: <http://www.nytimes.com/2011/03/15/science/15food.html?pagewanted=all> Here's another: [http://www.bbspot.com/news/2003/08/plant\\_pain.html](http://www.bbspot.com/news/2003/08/plant_pain.html) So I guess it should be considered to be unethical to eat plants, too! Hopefully, you'll be able to sustain on eating cardboard and styrofoam for the rest of your life. Good luck!

Alrenous (2012-07-15 06:04:25)

Intelligence is not consciousness. You can tell pigs don't have human-style consciousness, because a similar argument about a pig killing me would have no effect on the pig. Even assuming we can speak pigese, the pig would just kill me anyway, regardless of any rational, legal, or moral persuasion.

RAD (2012-07-15 07:20:57)

Seth, your premise about pork fat impacting your sleep is based on your Rested Rating values and those values seem incomprehensible to me. For myself, I think my subjective "Rested Rate" varies much more than your 94 %-100 % range and I can't imagine subjectively distinguishing between 97 % and 98 %, never mind having three values at 97.5 %. Did you really have a night (Oct 24th?) with less than 3 hours sleep that you rated as 99 % Rested? I feel only about 80 % rested this morning so maybe I'm missing something obvious :) Seth: Perhaps my values are higher than yours because I did several things to increase them - e.g., one-legged standing - that you aren't doing. Years ago they were much lower. If you can distinguish between 2 and 3 you can distinguish between 97 % and 98 % - they are equally different from 100 %. And I have had years of practice making these ratings. The values for Oct 24 are correct, I checked. Strange, huh?

Mitra (2012-07-15 07:38:20)

Alrenous Isn't it a disingenuous argument? I mean the pig can still feel pain and wants to avoid it all costs - in that respect the nervous system of the pig and the human operates similarly. Whether the pig can reflect on the pain or the universality of suffering (!) or whether it can compose a poem/essay on the pig condition is besides the point. All beings seek security and wish to avoid pain. Is it right for me to kill a pig? Whether pigs have human style consciousness does not help me answer that question.

peter (2012-07-15 08:30:24)

<http://perfecthealthdiet.com/2012/02/pork-did-leviticus-117-have-it-right/> Pork consumption has a strong epidemiological association with cirrhosis of the liver. Startlingly, pork may be even more strongly associated with alcoholic cirrhosis than alcohol itself! The evidence was summarized by Francis Bridges in a recent (2009) paper [1], building on earlier work by Nanji

and French [2]. A relation between pork consumption and cirrhosis of the liver is apparent across countries and has been consistently maintained for at least 40 years. We would expect that if pork can cause liver cirrhosis it will also promote liver cancer, since injured and inflamed tissues are more likely to become cancerous. Indeed, there is an association between pork consumption and the primary liver cancer, hepatocellular carcinoma. Nanji and French [3] write: The authors investigated the possibility that dietary fat, meat, beef, and pork consumption might be factors that would, in addition to alcohol, correlate with mortality from hepatocellular carcinoma (HCC) in different countries.... The correlation between HCC and alcohol was 0.40 ( $p < 0.05$ ); that with pork consumption was also 0.40 ( $p < 0.05$ ). There was no correlation with total fat meat, beef, and cigarette and tobacco consumption. Seth: That's good to know, I didn't know that. When I started eating lots of butter, I stopped eating lots of pork fat.

Wayne (2012-07-15 10:57:27)

Interesting, Seth. A couple of questions related to your original post, and then a question for peter on the risks of pork. 1. Can you quantify what kinds of pork belly quantities you're talking about here? 2. How are you consuming it? In other words, what kinds of foods are you eating (I'm assuming you're not just tucking into some lard with a spoon, but rather are eating other foods with a lot of pork belly in them). Then, to the animal rights activist, we are designed/evolved to be omnivores. That means we are supposed to be meat eaters. Peter: the article you reference regarding the risk of eating pork. Do you know if there is a distinction made in that work between CAFO pork and pastured, organic pork? Thanks! Seth: The pork belly weighed on the order of 250 g. I ate it in soup with vegetables, such as onion, carrot, and mushrooms, and spices. No potatoes.

curiousguy (2012-07-15 13:10:36)

My problem with eating pigs has nothing to do with religion. @ Adam, "He didn't kill the pig, he just ate part of it." That's like saying I didn't whip the slave, I just bought the cotton. @ Sky King: I wouldn't be surprised if plants are much more intelligent than they seem - that doesn't mean they're as intelligent as mammals, or that killing intelligent animals is ok. @ Alrenous A similar argument wouldn't work on a 3 year old either, and it wouldn't work on millions of mentally handicapped humans out there, but I'm pretty sure they have "human style consciousness", and I doubt you'd be ok with killing children. Pigs generally don't kill people, and even if they did that doesn't mean it's ok to kill them. Psychotic people sometimes kill other humans, but we don't kill them - we just make sure they don't hurt anyone else. Seth: I have no trouble with your avoidance of meat (for example, I can't imagine arguing that it's not "ok" to avoid meat), yet you seem to dislike the fact that I do eat meat. The asymmetry of tolerance is interesting, can you explain it?

curiousguy (2012-07-15 14:45:14)

@Seth, if you replace 'meat' with 'slavery', I think you'll see where I'm coming from. That said, I'm not trying to come down on anyone for eating meat. Rather, I'm sure that someone as open minded as you are has thought about the rightness of killing intelligent animals for food; you don't seem to have a problem with it, so I was curious about how you justify it. Seth: I have watched many nature documentaries - most recently, Frozen Planet. We are surrounded by animals killing animals.

Alex Chernavsky (2012-07-15 14:46:25)

Wayne wrote, "...we are designed/evolved to be omnivores. That means we are supposed to be meat eaters." You're deriving "ought" from "is". Some evolutionary psychologists claim that we evolved to be rapists. That doesn't mean that we are *supposed* to rape. Presumably, we can rise above our evolutionary tendencies. It's perfectly possible to be healthy on a vegan diet. See, for example, the story of Scott Jurek, who is a vegan ultramarathoner: <http://minnesota.publicradio.org/display/web/2012/06/19/books/scott-jurek-veg-an-ultramathon/> @Sky King: Your first link was unconvincing, and the second link was a joke. In any case, even if plants are sentient (which is *highly* unlikely), you'd still be better-off being a vegan, because animal agriculture is inefficient - you have to feed a lot of plant material to an animal in order to produce a small amount of meat.

peter (2012-07-15 15:01:13)

Wayne, if you've read the article, you know as much as i do.

Adam (2012-07-15 16:42:29)

@curiousguy: "That's like saying I didn't whip the slave, I just bought the cotton." What is your point? Buying cotton is not an immoral act, but whipping a slave is. Killing a pig isn't widely considered to be an immoral act, and buying pork most certainly is not.

Alrenous (2012-07-16 07:28:03)

Mitra, Nerves are not consciousness. Wasps avoid pain. There's this one wasp you can trap in a behavioural loop until it starves to death. It blocks its den with a rock, and it checks the immediate environs whenever it opens the 'door.' If you replace the rock, it will check again. Whether pigs have proper consciousness is the whole of the question. And since you argued that they do, not against the idea they cannot act differently than they do, I must conclude you agree that the argument works if the consciousness point is sound. curiousguy, >A similar argument wouldn't work on a 3 year old either, Yes it would. I'm insulted that you'd think I'd believe this nonsense. As such, I will not reply again. >and it wouldn't work on millions of mentally handicapped humans out there I'm thinking of a girl who had a severe head injury after a car accident. I saw her caretaker using these arguments and it worked on her too. You're claiming that someone with handicapped consciousness has full consciousness. No, by definition, they don't. I still argue against killing them, because in the case of humans the thing is never certain. >Pigs generally don't kill people, and even if they did that doesn't mean it's ok to kill them. Irrelevant. The point is that pigs cannot be meaningfully distinguished from squishy machines. Psychotics can easily be distinguished - they only kill when they think they can get away with it. There's a thing called a high-functioning psychotic who act well-adjusted, because they understand it is in their best interest. Rational arguments work on them.

curiousguy (2012-07-16 13:37:47)

@Seth: We're surrounded by both animals and humans doing all sorts of things, that doesn't mean we ought to do the same things. Seth: That's awfully vague ("all sorts of things"). I already knew you disagreed with me so I am not sure what this adds.

Sky King (2012-07-17 04:46:26)

@Alex: Alex, I'd be more than happy to debate you on the merits of meat-eating vs. vegetarianism, but first I was wondering if you could answer for me a few questions. I clicked on your name which brought me to your website. I saw your pics and most had you with a dog or a cat in those pics. It also appears that you work at, or own, a pet store. So it's pretty obvious that you love pets, as do I, but my question is: since your pets are carnivores, what are you feeding them?

Alex Chernavsky (2012-07-17 13:40:45)

Sun King: I work at a large animal shelter. When I was first hired, I worked as a farm hand. After interacting closely face-to-face with the cows, pigs, and chickens, I decided that farm animals are just as worthy of our compassion as are dogs and cats. I then gave up eating all animal products (eggs and dairy are actually worse, in some ways, than meat). I also don't wear fur, leather, or wool. Animals have an inherent interest in living out their lives, just as human beings do. My wife and I share our home with cats. We considered converting our cats to a vegan diet, but there is evidence that cats develop health problems when fed currently available vegan cat foods. The vegan foods are also expensive and reportedly unpalatable to cats. (Dogs do much better on vegan diets, but we don't have any dogs.) Our cats eat conventional commercial cat foods. If someone develops a healthy and palatable vegan cat food, then our cats will likely be switched to that diet.

curiousguy (2012-07-17 18:35:02)

@Seth: Why is it relevant that we are surrounded by animals killing animals? We are also surrounded by animals raping animals, humans killing/raping humans, etc. Seth: Many enormously useful insights - e.g., about the immune system - have come from studying animals. That's why I think animal behavior is relevant.

ds (2012-07-18 02:18:26)

Not everyone can be healthy on a vegan diet. I tried and nearly killed myself. People need to be less myopic. N=1 is great, but does not mean n=every1.

Sky King (2012-07-21 11:33:28)

@Alexia You need to stop being ignorant and start educating yourself concerning the biology and the evolutionary development of humans (and carnivores) so you'll be in a position to better understand nutrition that will enable you, and your pets, to long and healthy life. If you need links to sites and/or books that will help you to understand how vegetarianism is slowly, but surely, killing you and your pets then I'll be more than happy to provide you with some links. Let me know.

Alex Chernavsky (2012-07-22 09:46:57)

@Sky - thanks for your concern, but I'm good. (And please note that there is a [1]substantial difference between vegetarianism and veganism.)

dearieme (2012-07-16 10:47:34)

"...now the minimum that cancer patients deserve." I always stop reading when I reach an unjustified "deserve".

### Is Crohn's Disease Really "Incurable"? (2012-07-16 14:11)

I recently came across two different people who, diagnosed with Crohn's disease, repeated [1]the standard line that it "has no known cure". Really? Never? The people who said this were just repeating what they had been told. Unlike twenty or thirty years ago, however, it is easy to do one's own research. The people who said this gave no indication they had done any research. Because Crohn's is so unpleasant, their passivity was curious.

I knew that calling Crohn's disease "incurable" was an overstatement because [2]I had written about Reid Kimball,

who had found a way to eliminate via diet essentially all the symptoms. For practical purposes, he was cured. (Reid objects to the word "cure".) I knew he was hardly the only one. But what if I started from ignorance? How hard would it be to challenge the conventional "incurable" line?

Not hard at all. I googled "Crohn's success" (without quotation marks in the search query). [3]The top search result (titled "Crohn's Disease: Success with Diet and Probiotics") included this:

I learned of a pediatric gastroenterologist, Dr. J. Rainer Poley, who had conducted extensive studies on the effect of certain sugars and starches on people with intestinal diseases. My husband and I decided to take our daughter to see this doctor for another opinion. When we asked him if there was any other treatment she could try besides medications, he explained that at a recent medical conference in Europe, he had learned of success medical doctors were having with probiotics. He instructed our daughter to eat plain yogurt every day and to take a specific probiotic capsule called Culturelle® containing Lactobacillus GG [Gorbach and Goldin] twice daily. Based on Dr. Poley's research, he wanted her to limit the consumption of concentrated sugars (specifically table sugar, technically known as sucrose). The intent of the sucrose-restricted diet was to starve the harmful bacteria by taking away their major food source. The yogurt and Lactobacillus GG would help replenish the "good" bacteria. Since it has been well documented that an overgrowth of bacteria is prevalently seen in people with Crohn's disease, this treatment sounded like a plausible solution.

Our daughter, feeling drained from the effects of Crohn's disease, felt motivated to try the doctor's recommendations. . . . After about two weeks, she began to feel better in general. At the follow-up doctor's appointment three months later, she had gained six pounds and her lab work was ALL NORMAL! . . . She continues to remain well [over 7 years later] with normal lab work and without clinical symptoms.

I asked Ms. Kalichman how others had fared with this treatment. She replied:

Periodically, I hear from others who have tried the treatment that my daughter does, and it seems that many have been helped a lot. Unfortunately they don't always continue to keep in touch, so I don't have any idea how many are totally well. Our daughter continues to be well as she has been for almost 9 years now...no meds and no clinical symptoms.

That took about 5 minutes, including emailing Kalichman. She referred me to [4]a video about it.

Jim Purdy (2012-07-16 21:21:08)

I often have digestive problems, sometimes including constipation, bloating, gas, and even a generalized discomfort all through my chest and abdomen. I don't know what my medical diagnosis might be (celiac? IBS? Crohn's? gluten sensitivity?), because I've never mentioned these problems to any doctors. Their solution to everything seems to be a bunch of drugs, and I can't imagine how assaulting my gut bacteria with a lot of chemicals can possibly be a good idea. Instead of drugs, I've been eating a lot of bowls of high-fiber cereal-like concoctions of nuts, seeds, raisins, plain Greek yogurt, ground flax seed, powdered cinnamon, Sweetleaf Stevia with inulin, and whole milk. I get most of the ingredients from my local Whole Foods Market. I say "cereal-like," because it tastes like a bowl of cold cereal, but there are no cereal grains involved. The mixture is delicious, and it seems to be really helping my digestive problems.

Sarit (2012-07-17 01:37:54)

I can't figure out how to sign up for updates :( Seth: Thanks for the suggestion. I'll look into adding email updates.

Mike (2012-07-17 06:44:31)

I have a niece with diabetes type 1. The parents, also, take the view that "it has no known cure" in spite of the fact that the internet has many, many cases of kids who have cured their diabetes with a change in diet (namely Dr. Natasha McBride's GAPS protocol and even Robb Wolf's Paleo Diet). I've sent many references to them - the latest response is that it's just too hard to make these kinds of changes with a 12 year old! So, my niece will have to live with diabetes until she's old enough to do something about it herself.

Alex Chernavsky (2012-07-17 08:14:37)

My wife doesn't have Crohn's disease, but she has a history of idiopathic digestive problems - possibly irritable bowel syndrome. In any case, she's been drinking kombucha daily for the past few years and has experienced considerable relief (though some problems remain). Prior to starting the kombucha, she tried various prescription drugs that either had no effect or actually made matters worse. She's also tried other fermented foods (such as soy yogurt and miso) as well as several different probiotic supplements, but none of those had any effect. Seth: That's very interesting that kombucha was more effective than other fermented foods. It's hard to measure their general potency.

Bob (2012-07-17 11:41:32)

I was diagnosed with Crohn's about 4 years ago. My doctor prescribed Asacol which reduced the symptoms for about 6 months. However they then returned with a vengeance. I wasn't thrilled with what came next on the treatment regimen so I did a lot of research, part of which first brought me to this blog, and stumbled across a YouTube video advocating the use of low doses of Naltrexone for the treatment of MS and other autoimmune conditions. Curiosity piqued, I found that it was also used successfully to treat Crohn's. I decided to self-experiment and ordered some Naltrexone from an online pharmacy. Within a couple of weeks my symptoms were noticeably better and after several months I started to reduce my Asacol dosage ending up at roughly half the prescribed dosage. I am not ready to call myself cured but I have been without symptoms for at least a year and a half and have not had to be subjected to the escalation in treatment.

I have Crohn's (2012-07-17 20:00:05)

This is more of the "blame the victim" bs that is rampant in our culture. It's a huge part of the Tyranny of Positive Thinking that blames the patient and not the disease. It's great that some people can remove their symptoms. However, all the diet changes and meditation and prayer and exercise and all of that did not change my symptoms one bit. Why? Because it's an auto-immune disease. My body is wacky, not my attitude and not the way I take care of myself.

ds (2012-07-18 02:07:39)

Above commenter is right. Crohns and other forms of ibs ibd are highly individual. Some approaches work for some ppl, some don't. Degree of intensity is also highly variable as are co-diseases.

James Babcock (2012-07-18 08:57:45)

> "This is more of the "blame the victim" bs that is rampant in our culture. It's a huge part of the Tyranny of Positive Thinking that blames the patient and not the disease." Er, what? No one's suggesting that people with Crohn's disease are to blame. What this article is saying, is that a few specific foods and supplements might help. That's qualitatively the same sort of thing as saying that particular drugs might help, and I don't think blame enters into the discussion, nor should it. Seth: Maybe he or she means I am "blaming the victim" because I note how easy it was to find Crohn's success stories. Which the two people I refer to did not do. Let's call it "educating the victim".

## Is Crohn's Disease Really "Incurable"? (continued) (2012-07-18 05:00)

The official line on Crohn's disease is that there is "no known cure." In [1]my previous post I described how easily I found contrary evidence – in that case, a girl who with the help of her mom made dietary changes that got rid of her Crohn's symptoms in weeks. She has been symptom-free for more than seven years. An existence proof.

There are many other examples. I asked Reid Kimball for links. Here they are:

A website that collects success stories: [2]<http://scdlifestyle.com/category/specific-carbohydrate-diet-success-stories/page/4/>

Facebook groups: SCD - [3]<https://www.facebook.com/groups/2215406763/> GAPS - [4]<https://www.facebook.com/groups/thegapsdiet/>

Reid's website [5]<http://crohnsend.com>, Jay "CrohnsBoy" Baluk [6]<http://crohnsboy.com/> and Jini Patel Thompson [7]<http://listentoyourgut.com/> are more examples.

The official website of the SCD has a testimonials section: [8]<http://btvc.webfactional.com/book-reviews/listing/>

Melissa (2012-07-18 09:26:33)

Are these people cured or are they simply controlling their illness better by eating a strict diet? Seth: I agree, it's a grey area. After I come down with scurvy, I am careful to eat a diet that contains enough Vitamin C and never get scurvy again. Is that controlling my illness by eating a strict diet? People usually say that Vitamin C cures scurvy. I suppose I should ask people who say Crohn's has "no known cure" what they mean.

Sara (2012-07-18 18:47:56)

I was told that my osteo-arthritis was incurable and that I was heading for an early hip replacement (I was 37 at the time). Now, four years later, I'd say it's 'cured' and my method was a gut healing diet (GAPS diet, actually). That was very restrictive for about 4 months and now I just try to stay away from certain foods and I'm ok. I tend to think of these things more as hypersensitivities which require long-term management - it's probably a combination of genetic profile + metabolic damage caused by long term consumption of foods you are not genetically designed to eat so much of. A sort of low-level allergy. As a 'side-effect' my depression disappeared and has never recurred to the same level - I just don't have the level of 'low' that used to exist in my brain. Seth: This supports my belief that the foods that make your brain work best will turn out to make the rest of your body work best and vice versa.

ds (2012-07-21 01:14:51)

Scurvy is not a chronic autoimmune disease. Scurvy IS vitamin c deficiency. Generally "curing" an ai is actually putting symptoms in remission and keeping them there. Seth: I was under the impression that scurvy was caused by Vitamin C deficiency. If taking a drug once/month puts your symptoms in remission, but as soon as you stop the drug your symptoms come back, are you cured? I believe people would say no.

CJ (2012-07-22 19:55:50)

Please don't use the word "cure" in association with dietary management of Crohn's; it's no more of a cure than is a gluten-free diet for celiacs. You don't fix the root problem. That said, for >4-1/2 years, I have been on an SCD-type diet, and found complete relief after tweaking it in. Specifically, I lean towards a meat-heavy, grain-free diet with plenty of Gottschall-type yogurt. Carbohydrate restriction helps more than anything; I find I do best with lots of fatty beef, but (of course) the diarrhea needs to stop first. After about a year on the SCD, I found the works of Dr. Wolfgang Lutz, who found a low-carb diet worked wonders for Crohn's. I combined the two, and have found complete relief. The only times I have problems are when I stray from the diet, either by accident (usually when testing new food products), or during experiments. My weight is normal, I have had \*no\* diarrhea for more than 4 years now, no bleeding, and have a labor-intensive job that requires my lifting almost 150 % of my own body weight. But the disease is still there, and if I eat the wrong thing, it comes to the surface promptly. But since I don't eat the wrong things except on rare occasions, my blood values are normal, my fecal calprotectin is normal- I'm waiting to get another colonoscopy done, but I am confident the results will be very good. The root of the disease is in grains, and secondarily to sugars. Complicating this is a massive imbalance in the intestinal flora- which is why probiotics help, and fecal "transplants" cause marked relief in many. Too many antibiotics, not enough fermented foods, too many sugars, WAY too much starch- and not enough vitamin D. For the love of all things holy, PLEASE take your vitamin D if you have Crohn's, even if you get sunlight. Take 2,000 to 5,000 IU vitamin D every day.

Peter (2012-07-24 14:25:20)

Our friend's daughter's gastroenterologist says 1) there's no scientific proof that the SCD diet relieves symptoms and 2) online testimonials are self-selected to cover only positive outcomes. This doctor practices at the #1 rated children's hospital in the world. He may merely be callous and intellectually uncurious but he is the patient-facing representative for an evil system. That he is paid a vast amount of money and the recipient of much professional adulation is maddening.

Sara Lake (2012-07-28 03:06:15)

I guess the definition of 'cured' is quite broad. I mean, what is it really? No symptoms, no matter what you do? No symptoms when you do what most people do? I consider my arthritis (and my depression) cured, even though I'm pretty sure they will recur if I decided to eat like my sister does for any length of time. Her way is not healthy, although for the moment she 'seems' to be getting away with it. Find the cause and deal with it, then you are cured. Maybe it's a psychological thing - people don't want to feel different, and if they have to live differently to others, they still feel 'sick' or 'faulty'. @Peter, testing special diets is, unfortunately, never going to be a well-funded area. There is no big, expensive drug to market at the end of it, and if you implicate a big part of the food industry (e.g. grains), they will bite back with quite a bit of well-funded force.

## Trust Me I'm Lying: Confessions of a Media Manipulator by Ryan Holiday (2012-07-19 05:00)

When Clinton was President, Ryan Holiday writes in Trust Me I'm Lying (copy sent me by publisher, Ryan is a friend),

[Matt] Drudge accused prominent journalist and Clinton adviser Sidney Blumenthal of a shocking history of spousal abuse – and one covered up by the White House, no less. Except that none of it was true. . . . An anonymous Republican source had whispered into Drudge's ear to settle a political score against Blumenthal. . . . [Drudge] refused to apologize for the pain caused by his recklessness.

In spite of knowing this, I still read Matt Drudge. I don't have to. There are a zillion other things to read. That may or may not make me a horrible person but it illustrates the depth of the problem that Ryan writes about: Spreading lies pays.

A more mundane example is press releases. Bloggers love press releases, Ryan says (speaking from experience working at American Apparel). All the work is done for them. So what if press releases are profoundly dishonest in the way they present a half truth (positive stuff about the product) as if it is a whole truth? It's an easy way to get a few thousand clicks. "I recall sending e-mails to Gawker and Jezebel on several occasions over matters of factual errors and not receiving a response," writes Ryan. "My anonymous tips seem to arrive in their inboxes just fine – it's the signed corrections that run into issues." A car site published a rumor that turned out to be false. A friend of Ryan's complained that the headline wasn't fixed:

[Ryan's friend:] Why keep the headline up since we now know it's not true?  
[Car site:] You guys are so funny.

Taking the headline down would generate fewer clicks than leaving it up. Shameless.

"That way lies madness," I told a friend who worried about how much traffic his blog attracted. Bloggers who will do anything for a click do so, of course, because their salary depends on it, whereas my friend did not get significant income from his blog. Sure, paying bloggers by the click pushes them to write stuff that people want to read – which sounds good, aren't snobs bad? – except what if people don't care that much about the truth?

I think of science. Who do professional scientists more closely resemble? 1. Bloggers who will do anything for a click. 2. Disinterested seekers of truth. Well, it's a job, not a hobby. Science and job are not a good fit ([1]as I've written), just as factory food and health are not a good fit. We can see the consequences of the bad fit between factory food and health in the obesity epidemic (which I believe is caused by eating calorie-dense quickly-digested food that tastes exactly the same each time – factory food is much more standardized than food you make yourself) and the epidemic of digestive problems (caused by too-sterile food – factory food is more sterile than food you make yourself). We can see the consequences of the bad fit between science and job in the failure to find solutions to one growing problem after another (obesity, Crohn's disease, autism, depression, poor sleep, etc.). Trust Me I'm Lying is about the consequences of the poor fit between being paid by the click and caring about the truth of what you write.

## The Non-Obvious Value of Self-Tracking (2012-07-20 05:00)

A New York doctor named Jay Parkinson [1] is skeptical about the appeal of self-measurement:

There is a very, very small subset of people who want to document their life according to their health—the quantified selfers. But this group is tiny because it's just data geeks who are obsessed with data. They are people who truly believe data changes behavior.

As caricatures go, this is fair. The audience and speakers at Quantified Self meetups do appear to be "data geeks who are obsessed with data" and, yes, this is a tiny subset of people. I don't put myself in that category. I have zero interest in "documenting" my life. I record a tiny amount of stuff and only stuff I think will make a difference. For example, I stopped measuring my blood pressure after it became clear it was low enough.

Parkinson continues:

Data gets old after a while. After about a month, for those who are not obsessed, it becomes meaningless. That is, unless you have an obsession with data. . . . Good luck trying to build a viable business around that group.

Yes, and "there is a world market for about five computers", as [2] the president of IBM supposedly said in the 1940s. I have measured myself for so long (decades) not because I am obsessed with data but because I reaped huge benefits. In the beginning, self-measurement showed me how to reduce my acne considerably more than my dermatologist's advice alone. Later it led to all sorts of improvements: better sleep, better mood, lower weight, fewer colds, healthier gums, better balance, better brain function. Life-changing benefits. The fraction of adults who would like to sleep better, be in a better mood, lose weight, get fewer colds, and so on is very large – perhaps 99 %. Is Starbucks a "viable business"? It is built around people needing stimulants (caffeine). An enormous number of products and services are about losing weight. One of the world's most "viable business" is illicit drugs. I believe a large fraction of illicit drug use is self-medication for depression. (More: The day I posted this, I came across [3] this: "She said heroin helped her fight depression.")

There is nothing obvious about how I managed to improve my sleep, mood, weight and so on. [4] The solutions I discovered via self-measurement were exceedingly surprising, at least to me. So there is nothing obvious about how to use self-measurement to improve one's sleep, etc. Self-measurement is needed, yes, but it's not the only thing that's needed. I needed: 1. Wise choice of what to measure (e.g., measure the problem, not the solution – I don't have a FitBit for example.) 2. Wise choice of what to change. (To improve my sleep, for example, I needed a good understanding of sleep research. "Common sense" was not enough.) 3. Experimental design skill. 4. Data analysis skill. To say data is boring (to most people) is like saying tires are boring (to most people). By themselves, tires have little use, just as data alone has little use. But they are part of something very useful.

Consider literacy. For a long time, the notion that "everyone would benefit from literacy" seemed ridiculous. Books were too expensive! There were so few of them. Only a tiny fraction of people (e.g., monks) knew how to read. It was hard to learn to read. Good luck basing a business on literacy! But eventually everything changed. Right now, few quantified selfers, as far as I can tell, seem to know how to learn something useful from their measurements. (When

I had been doing it for a short time, I didn't know either.) For example, Stephen Wolfram appears to have learned nothing of use from [5] a huge amount of self-measurement. New measurement devices, like FitBit and so on, are like books – it is as if few people know how to read. But that can change.

Andrea (2012-07-20 09:00:18)

So where did you get the idea that standing might improve sleep? Was this from your research on sleep? Seth: It was an accident. I tried standing a lot to see if I would lose weight. I noticed my sleep improved – it helped that I was recording it.

Dena Shunra (2012-07-20 09:43:15)

Self-measurement (which is a subset of self-awareness, a virtue lauded as "an unexamined life is not worth living") is not new for individuals. It's not new for business ventures (there's a whole profession dedicated to that, accounting. It helps with counting and paying taxes, but also with figuring out which parts of a business work, who is worth credit and who is not, etc.) Not engaging in self-measurement implies hurtling through the world willy-nilly, willfully ignoring indicators of trouble until the loudest indicator of all, collapse, is noted. Anyone who would belittle self-inspection and self-examination does not have the best interest of his readers at heart.

by (2012-07-20 12:17:39)

Yes, I think data is just the method of life improvement that works very well for you. I'm sure there are people out there who can improve their life simply by wishing it, for years, and then one morning they wake up and pounce upon a discovery and their problem is solved. But data works for me too.

dearieme (2012-07-20 14:16:59)

Some people are self-obsessed, some are not.

Txomin (2012-07-20 16:43:06)

Everyone tracks their habits one way or another in order to manage their health.

## **Fear of Food: "The Hubris of Experts" (2012-07-21 05:00)**

At the end of Fear of Food: A History of Why We Worry about What We Eat by Harvey Levenstein (2012), an historian at McMaster University, the author summarizes what he has learned:

During the course of writing this book, I have often been asked what lessons I personally draw from it. . . . The hubris of experts confidently telling us what to eat has often been well-nigh extraordinary. In 1921, for example, the consensus among the nation's nutritional scientists was that they knew 90 % of what there was to know about food and health.

Yeah. Two questions for an expert giving advice, especially apocalyptic advice ("You'll die if you don't . . ."): 1. What fraction of what there is to be known on your subject do you know? 2. May I quote you?

When I was a freshman in college, I went to hear a talk (off campus) about the chance of life elsewhere in the universe (or was it the galaxy?). The speaker multiplied a bunch of numbers together and came up with an estimate. "What's the error in that estimate?" I asked. The speaker had no answer. He didn't know. It's essentially the same thing.

---

dearieme (2012-07-21 06:24:55)

"In February 2010, the press reported on a meta-analysis of 21 lengthy studies, comprising 347,747 subjects, that concluded that there was no association between saturated fat consumption and the risk of heart disease." A reference to the source would have been useful, but still the point is made.

mike (2012-07-21 12:40:34)

Point of the scientific process is it gets it right over time. In the short term are there mistakes... sure. Over time experiments are rerun, repeated and the answers are revised. 1900's science was wrong and right about a large number of things, and improvements are made and the process continues. The point is these reviews of literature take place, and improvements are made. The process is self correcting.

Txomin (2012-07-22 06:47:42)

How many times I've heard "I don't know what to believe"? How many times I've answered "You don't have to believe anything. Search for information to learn not for instructions to follow"? Alas, it is quite common to come across people that can't comprehend the difference between knowledge and belief. Seth: That's an interesting reply ("You don't have to believe anything"). What do people say after you say that?

Txomin (2012-07-22 22:57:34)

They become confused. The usual claim is, essentially, that the veracity of a statement supersedes its understanding... as if, you know, the first could be established independently of the second. Some people get it when I ask them whether they know or they believe the earth is round. Seth: Thanks for explaining that.

sadeyedlady (2012-08-04 12:46:16)

this is precisely why i turn my back when the paleo community aggressively markets its diet. i try very hard (and frequently fail) at staying meat- and leather- free. one time i contributed to a discussion on the New York Times website discussing veganism, and the entire discussion was shouted out by about 5 paleos who were being sarcastic and aggressive vs. the vegans. i think that most paleo eaters are romanticizing early human life and, based on their romantic notions, are making sweeping health generalities about the benefits of the paleo diet. i see great value in eating as many whole foods as possible and limiting grains. but i do NOT believe that invariably means that humans function optimally as carnivores. anyhow, i follow your site and thought i would chime in with my opinions on this issue. p.s. i have brewed kombucha for many years and enjoy it. one can readily find scobys from reputable local dealers via google and the like. not sure whether that is also the case in PRC. Seth: Thanks, very interesting. By the way you don't need a scoby, you can use a few tablespoons of store-bought kombucha.

Alex Chernavsky (2012-07-22 09:02:29)

I'm not the least surprised about the allegations against Stephen Jay Gould. Look at the vicious smear campaign he waged against his Harvard colleague, E. O. Wilson. About the best thing that can be said about Gould is that he occasionally wrote interesting essays for *Natural History* magazine.

dearieme (2012-07-22 16:22:01)

Over the years I became increasingly aware of a problem with a particular line of interdisciplinary work. It often seemed, I guessed, to be refereed by people who were capable of spotting weaknesses in the part of the work they understood best but were prepared to give the benefit of the doubt to the parts they didn't. This, I suspect, led to ropey work being published, ropey workers being promoted, ropey grants being awarded. I've no reason to suppose that what was going on was crooked - not angels, perhaps, a few friendships and connections relied upon, maybe, but nothing (so far as I know or suspect) more. Whether this sort of thing does as much damage as fraud I have no way of knowing.

garymar (2012-07-22 17:15:36)

dearieme, Interesting word, 'ropey'. I looked it up on the OED and it's listed as 'British informal'. In a similar vein, I remember reading a philosopher's critique of Toynbee's idea of the rise and fall of civilizations. In my rough memory, the philosopher noted that, for example, the Egyptologists would say, "Toynbee's view of Egyptian civilization is utter nonsense, but the rest of the book is admirable"; or the students of Eastern European history would say, "his ideas on Russia betray an utter lack of knowledge on the subject, but we were fascinated by his descriptions of other cultures". Etcetera, etcetera. So if you lined up all the criticisms of those versed in their respective fields, you'd find very little left of his original thesis.

by (2012-07-22 21:36:39)

Recently I was scheduling some recurring appointments to visit my relatives. For no real reason I could decide, I decided to visit my male relative in odd months and female in even. It was funny to see this link :)

Maria (2012-07-25 12:39:29)

I'm sorry, I know you've answered this before, but I was unable to find it. What software do you recommend for self analysis. I have about 20 variables that I've been tracking manually, and it's just too many to do manually. Your recommendation would be very helpful. Seth: I recommend R. It's free and it's good. That's what I use.

### What to Do in Beijing: My Suggestions (2012-07-24 05:00)

Because Tyler Cowen is going to Beijing, I made a list of suggestions:

1. Don't go to the Great Wall. It's a long drive. I preferred to see it on the Today Show. The only interesting bit was a guy who sat in a chair on the path to the wall and charged 30 cents to go further. We paid the 30 cents but in retrospect I wish we hadn't.

2. Visit some of the many "markets" that consist of a building full of tiny booths. There are markets devoted to cameras, jewelry, clothes, electronics, furniture, etc. There can be more choice of furniture in one building (say, 100

manufacturers) than exists in the entire Bay Area. Along similar lines there is a whole neighborhood full of tea sellers – if you like tea.

3. Peking duck is a good dish but I cannot tell the difference between the better restaurants serving it. So don't go out of your way to go to an especially good place. I usually go to [1]Quanjude which has a branch very near my school (Tsinghua).

4.[2] Middle 8 is a very good restaurant (in Haidian and Chao Yang).

5. [3]Din Tai Fung is a very good dumpling restaurant. It is a big international Taiwanese chain. So it isn't even mainland Chinese food exactly.

6. There are grilled chicken wing restaurants near the west gates of both Peking University and Tsinghua University. I don't know their names but they are very good. Popular with students.

7. I have never found a nice place in Beijing to walk. Even in parks there is a lack of shade.

8. In my neighborhood (Wudaokou) there are excellent Korean restaurants.

Feel free to leave your suggestions in the comments.

1. <http://en.wikipedia.org/wiki/Quanjude>

2. [http://www.tripadvisor.com/Restaurant\\_Review-g294212-d1204537-Reviews-Middle\\_8th-Beijing.html](http://www.tripadvisor.com/Restaurant_Review-g294212-d1204537-Reviews-Middle_8th-Beijing.html)

3. [http://en.wikipedia.org/wiki/Din\\_Tai\\_Fung](http://en.wikipedia.org/wiki/Din_Tai_Fung)

---

Jim (2012-07-24 06:38:42)

You must visit the Hutongs! Especially long confusing walks in the hutongs that end up at Ho Hai. Once you are finished with Old Beijing (the Hutongs), go to modern Beijing (shopping malls, of course). I recommend Raffles. Take a 1-2 day trip to Chuandixia (to the West of Beijing). This is one of my favorite spots in China! If you do want to go to the Great Wall, stay overnight at Shaan Ba (in English- Mountain Bar). I agree that visiting the wall can be annoying, but for most people it will be a must see.

Tom (2012-07-24 07:47:07)

One of the (authentic) branches of Din Tai Fung is in Arcadia, California: Din Tai Fung Dumpling House [www.dintaifungusa.com](http://www.dintaifungusa.com)  
1108 S Baldwin Avenue, Arcadia, CA 91007-7508 Phone: (626) 574-7068

Andy (2012-07-24 07:49:21)

Din Tai Fung is awesome!! The two in Tokyo are terrible, but I've been to the original in Taipei and few other branches in China/Taiwan and they are much better. So juicy. Best dumplings I have had.

Eric (2012-07-24 14:09:22)

This is a nice walking route: <http://goo.gl/maps/pYscW> Start from the Lama Temple subway exit C, walk down Guozijian St (going into the Confucius Temple or the Guozijian if you want) and then making an arbitrary turn at the end of that st and getting lost in the hutongs.

garymar (2012-07-24 22:41:41)

I ate at Quanjude – it was great! I still have the card giving the number of my duck. It was like 80 million or something. Japan has 12 Dintaifung restaurants, with 7 in the Tokyo area. I'll try it out. Two of them in Shinjuku alone. Are they all bad? Probably because it's "Chinese adapted to Japanese tastes" Chinese food, unlike "Chinese adapted to American tastes" in LA.

garymar (2012-07-24 22:44:46)

Actually the website has the Shinjuku restaurant listed twice, so only one in Shinjuku. [http://www.dintaifung.com.tw/jp/area\\_a\\_list.asp?AreaCountryNO=20](http://www.dintaifung.com.tw/jp/area_a_list.asp?AreaCountryNO=20)

Adam (2012-07-25 05:15:39)

I can attest to the fact that the Shanghai Din Tai Fung is delicious.

Richard Sprague (2012-07-25 13:37:40)

Don't forget to pack a VPN of some kind if you want to access the entire internet while in China. I use Witopia (for my apartment) and 12VPN on my iPhone.

## **You Don't Need a "Mother" to Make Kombucha (2012-07-25 05:00)**

You make kombucha by brewing tea, adding sugar, and adding a starter of some sort. Usually the starter is part of the "mother" (SCOBY) from a previous batch of kombucha but I have just found that adding a little bit of store-bought kombucha also works. I added two tablespoons of GT's kombucha and two tablespoons of Revive kombucha to sugared tea. Two weeks later there was a perfectly good mother on top of the tea. This is useful to know even if you have a mother if you want to make kombucha slowly. In The Art of Fermentation, Sandor Katz advocates adding a bottle of kombucha into your sugared tea if you don't have a mother.

---

Alex Chernavsky (2012-07-25 07:01:39)

I've been making kombucha for over two years now, and what's interesting to me is the large amount of variability from batch to batch. I use the same mother, same recipe, same fermentation jars, etc. – and yet, the results are quite variable. Sometimes the kombucha is fizzy right out of the fermentation jar; sometimes it's flat. Sometimes it has a pleasant yeasty taste to it (almost like beer), sometimes it's bland. I wonder why that is. I like to do a second fermentation inside sealed, glass bottles. I pour about two or three ounces of apple juice (or other type of juice) into an empty bottle that originally held GT Dave's-brand kombucha. Then I top it off with my own kombucha (that's been fermented for 8 - 10 days), seal the bottle tightly, and let it ferment for two or three days. The result is a nicely carbonated beverage. You have to be careful to use juice that's free of preservatives – otherwise, there is no fermentation.

Robin (2012-07-25 07:48:47)

Thanks for that Alex. I've had very variable results and figured I was somehow messing something up. I'm going to try your apple juice hack with my next harvest.

LP Johnson (2012-07-25 08:33:50)

I tried using store bought kombucha to ferment a jug of tea, and I got mold only a couple days in. I threw it out, but would it have been ok? Just skim off the mold like with kraut? Some possible factors: temperature was staying around 90 F, I drank directly out of the bottle of kombucha before using it, lastly I was unsure how much sugar to use and used only about 1/4 cup to a gallon tea. Seth: That's not enough sugar. See my answer to another comment for a reasonable amount.

Chuck Curre (2012-07-25 10:15:50)

More details please: How much tea - a quart, a pint, a gallon? How much sugar? Where do you put it to ferment - on the counter, in a cupboard? What did you do with the "mother"? Not through her from a train, hopefully. Thanks... Seth: Here are the quantities I use: 1.8 L water, 180 g white sugar, 10 g high quality black tea. I put the jar on the counter. I put spare mothers in the refrigerator.

Bryan (2012-07-25 14:25:44)

Twice I tried creating my own mother this way and it didn't work. I brewed some tea, added sugar, and then added a bottle of GT's. I then waited 3 weeks - nothing. Maybe there was too much/not enough sugar? Seth: Maybe the problem was the GTs. You might try Revive or another brand. Or try 2 T each of several brands. I think there is wide latitude on the sugar.

Alex Chernavsky (2012-07-25 14:51:10)

I use a third of a cup of white table sugar per quart of water (well, *tea* actually).

Elizabeth Molin (2012-07-26 06:51:04)

On the general subject of fermented foods: <http://jezebel.com/5928541/cheese-may-lower-diabetes-risk-will-also-make-you-very-happy>

Jim Breed (2012-07-26 10:58:45)

I have had better luck with bottled water than tap. I believe that not having chlorine from the water treatment inhibits fermentation. Sandor Katz mentions this in his book.

Sam (2012-07-31 16:08:10)

Nice trick. Ascorbic acid, vitamin C, can be used to take the chlorine out of tap water. Only takes a very very small amount. <http://www.iuhoakland.com/Chloramine.pdf>

sadeyedlady (2012-08-05 10:29:14)

i've been brewing kombucha for about 10 years now. i imagine kombucha as a bacteria bath. if you are lucky, the right bacteria congregate and take over. i have had many batches that didn't work out well-where mold or another unhealthy life form dominated over the brew. initially, a few T of kombucha will work to ferment a batch of sweet tea into kombucha, but i do not think that the batch can be used to create new batches of kombucha, if only because of the variability of the bacteria that the brew will come into contact with. there are so many bad bacteria that can thrive in an acidic environment, that i would be afraid of creating a self-sustaining kombucha brew without a scoby. perhaps you weren't referring to a self-sustaining batch of kombucha in your post. if so, then carry on! just my personal hunches here.

Tom (2012-07-27 14:54:40)

*Jim: maybe you should rearrange your furniture and get the best of both worlds Shh! Don't tell him. :-)*

## **Fermented Dairy Intake Negatively Associated with Diabetes (2012-07-28 05:00)**

[1]A new epidemiological study followed about 16,000 people in Europe for about 12 years and focused on their dairy intake. Did the ones who came down with diabetes eat differently from those who didn't?

The paper begins:

Current dietary guidelines for prevention of diabetes aim at substituting SFAs [saturated fatty acids] with unsaturated fatty acids. However, conventionally held notions that all SFAs, including those from dairy products, are detrimental to health have recently been challenged.

The shift of evidence (dairy less bad than previously believed) supports my view that what's good for the brain (I found butter was good for my brain) is likely to be good for the rest of the body. The paper's main conclusion is the possible protective value of cheese and yogurt:

This large prospective study found no association between total dairy product intake and diabetes risk. An inverse association of cheese intake and combined fermented dairy product [= cheese, yogurt, and "thick fermented milk"] intake with diabetes is suggested.

The combined fermented dairy association was not large in size (a risk reduction of 12 %) but was significant (barely). When your main finding is barely significant you have no hope of using your data to explain it so the new information essentially stops there. The results support my view that fermented foods are unusually healthy.

In response to these findings, the director of research at Diabetes UK [2] said, "This study gives us no reason to believe that people should change their dairy intake in an attempt to avoid [diabetes]." Wow. It is as if a prominent physicist said the earth was flat.

Thanks to Elizabeth Molin.

wobbly (2012-07-28 06:16:21)

That Telegraph URL needs a quick trim of its last six characters. Seth: I fixed it, thanks.

Alex Chernavsky (2012-07-28 06:57:00)

Seth, did you see this other article from the *Telegraph*? "[1] Doctor diagnosed with terminal cancer survives after injecting himself with disused drug"

1. <http://www.telegraph.co.uk/health/healthnews/9420980/Doctor-diagnosed-with-terminal-cancer-survives-after-injecting-himself-with-disused-drug.html>

Shawn (2012-07-28 12:43:23)

I'm not sure if my earlier comment got through so I will repeat the gist of it: dairy causes acne for some people.

dearieme (2012-07-28 13:45:39)

Seth, you mentioned Yakult yoghurt a few weeks ago. Do you know anything about how it compares with Actimel? <http://en.wikipedia.org/wiki/Actimel> Seth: No I don't. Probably little difference.

Adam (2012-07-28 18:05:12)

According to Dr. John Ioannidis (yo-NEE-dees), a renowned expert in evaluating medical studies, as many as 80 % of the conclusions drawn from non-randomized trials are false; as many as 25 % from randomized trials; and as many as 10 % from the "platinum standard" \*large\* randomized trials. Old article, but well worth reading if you missed it: <http://www.theatlantic.com/magazine/archive/2010/11/lies-damned-lies-and-medical-science/8269/> With that in mind, I DO believe that fermented foods probably ARE good for you, but this study by itself is not very good evidence for that idea. Out of curiosity, does anyone know why they say Saturated fat causes Diabetes? What do they usually reference when they make that claim? Seth: "this study by itself is not very good evidence for that idea"? Since when is evidence one-dimensional? If you think about the many dimensions of evidence, I hope that you will realize that this study is very good on some of them (e.g., the dimension of realism, the dimension of practicality). I don't agree with Ioannidis's black and white view of research (it is either right or wrong), either. Imagine if someone said "80 % of people are bad".

Adam (2012-07-28 18:09:50)

I think I answered my own question. Saturated fat doesn't cause Diabetes. <http://www.diabetes.org/food-and-fitness/food/what-can-i-eat/fat-and-diabetes.html> "Why should you eat less saturated fat? Because saturated fat raises blood cholesterol levels. High blood cholesterol is a risk factor for heart disease. People with diabetes are at high risk for heart

disease and limiting your saturated fat can help lower your risk of having a heart attack or stroke.” Does it? The Framingham study is often quoted as “proving” that eating Fat increases Serum cholesterol, so what did the researchers conclude?: “The failure to turn up any positive association between food intake and serum cholesterol level in the Framingham Diet Study led to the exploration of a large number of variant analyses. These were uniformly unsuccessful in finding expected relationships.” Hmmmm...

Adam (2012-07-29 17:46:58)

Seth, you said: “Since when is evidence one-dimensional? If you think about the many dimensions of evidence, I hope that you will realize that this study is very good on some of them (e.g., the dimension of realism, the dimension of practicality). I don’t agree with Ionnidis’s black and white view of research (it is either right or wrong), either. Imagine if someone said “80 % of people are bad”. Maybe it’d help if I clarify what I meant by “bad”. I mean, the conclusion reached based on the evidence gathered has a high probability of being wrong. That doesn’t mean it IS wrong, but it means that the evidence isn’t very valuable to someone who values high quality evidence. With that said, it is absolutely hypocritical for the director of Diabetes research to dismiss it, since nearly ALL of the recommendations they DO support are based on Epidemiological evidence to begin with. It gives the impression that they are just picking & choosing willy-nilly which data to accept & which data to reject. Seth: “bad” evidence is inconclusive. it is evidence that doesn’t help much. When the evidence for an idea is “bad” it doesn’t imply that the hypothesis under consideration “has a high probability of being wrong”. I agree, Diabetes UK is just picking the evidence they like.

Paul N (2012-07-30 12:10:32)

Slightly off topic, there is also some evidence, both historical and from studies, that probiotics are beneficial to dental health. Certain lactobacilli species compete for adhesion sites with the nasties that form dental caries. Some lead to increased saliva production, which also benefits teeth (and digestion). Some googling of umami and dental health turns up some interesting, though occasionally conflicting, studies. I think this is further support for the umami hypothesis. I suspect that populations that traditionally ate lots of dairy (i.e. fermented) got good dental health as much from the probiotics as from the dairy itself. Of course, modern highly sweetened dairy products, fermented or otherwise, completely defeat the purpose... Seth: Interesting point, thanks. Hadn’t heard that before.

---

Rashad (2012-07-29 06:39:51)

The Yale item is so disappointing. My wife does research on study abroad, and one of her key findings/points of emphasis is that program design plays a huge role in how much "immersion" students get during the study abroad process. It sounds like they just expected the students to automatically immerse themselves, whereas studies have shown that without tons of incentives, and effort on the part of the study abroad program, students will often self-segregate and mostly hang out with other foreigners. Seth: Interesting. In this case, it goes beyond what you say. Not only did the Yale students in Beijing not learn Chinese from being in Beijing, apparently the time they spent in Chinese class – in Beijing – was less helpful than the same time in Chinese class in New Haven.

Seth Roberts (2012-07-29 14:25:43)

posted for Ethesis: NPR, yesterday morning, had people on the Peoples Pharmacy (whatever that is) in the last 15 minutes of the show talking about how to teach people to self track and how it improved compliance and effort with diabetics. Neat stuff, especially as it supports many things you've said. BTW: [www.blogger.com/comment.g?blogID=2192186541955038172&postID=7651199277746247337](http://www.blogger.com/comment.g?blogID=2192186541955038172&postID=7651199277746247337) The article that got me thinking about all of this was about a Japanese anesthesiologist who was caught having simply made up the data in 172 papers published in scientific journals. If you can have made up your data 172 times before anyone notices and, according to the journals, it had no impact because no one paid attention to those articles anyway - how much talent do you really have?

Alex Chernavsky (2012-07-30 19:23:38)

Google apparently has a database with 20 million scanned books. You'd think that someone at Google could write a script to search for instances of plagiarism. I suppose it might be difficult to distinguish true plagiarism from cases where an author is quoting another source. Seth: Good idea. It shouldn't be hard to separate quotations from non-quotations with very high accuracy. I think the problem is that this doesn't support anyone's research agenda.

Txomin (2012-07-30 21:28:52)

Thank you for continuing to post on academic fraud.

garymar (2012-07-30 22:55:08)

That Penkowa case is hard to figure out. She looks like someone with real talent *who also* cuts corners and considers academic research a contact sport.

## Mark Bittman Glimpses a Big Truth: Avoidance of the Obvious by Doctors (2012-07-31 06:23)

Mark Bittman writes about food for the New York Times. If he covered health instead of food, would he have dared to write [1]this?

When I was growing up, drinking milk at every meal, I had a chronic upset stomach. . . . In adolescence, this became chronic heartburn, trendily known as GERD or acid reflux, and that led to . . . an adult dependence on Prevacid, a proton-pump inhibitor. Which, my gastroenterologist assured me, is benign. ([2]Wrong.)

Fortunately my long-term general practitioner, Sidney M. Baker, author of "[3]Detoxification and Healing," insisted that I make every attempt to break the Prevacid addiction. Thus followed a seven-year period of trials of various "cures," including licorice pills, lemon juice, antibiotics, famotidine (Pepcid) and almost anything else that might give my poor, sore esophagus some relief. At some point, Dr. Baker suggested that despite my omnivorous diet I consider a "vacation" from various foods.

So, three months ago, I decided to give up dairy products as a test. Twenty-four hours later, my heartburn was gone. Never, it seems, to return.

His gastroenterologist (and probably several other doctors) failed to tell him that his digestive problem might be due to eating the wrong foods. It is as if an astronomer fails to understand – or at least tell his students – that the earth is round.

It is equally interesting that someone smart enough to write for the New York Times fails to figure this out for himself. How strange that a food writer would not connect food and health – someone else had to draw his attention to the possibility. Although Bittman praises Dr. Baker, you are not going to figure out what foods are bad by adding things, such as licorice pills, to your diet. Dr. Baker failed to understand this obvious point, which Bittman still fails to see, apparently. Bittman should be utterly astonished by this mountain of avoiding the obvious, including his own.

In [4]a later column he feels "frustration" and begins to notice how big the problem – self-serving avoidance of the obvious by doctors and the rest of mainstream health care – is:

Experiences like mine with dairy . . . are more common than unusual [huh?], at least according to the roughly 1,300 comments and e-mails we received since then. In them, people outlined their experiences with dairy and health problems as varied as heartburn, migraines, irritable bowel syndrome, colitis, eczema, acne, hives, asthma ("When I gave up dairy, my asthma went away completely"), gall bladder issues, body aches, ear infections, colic, "seasonal allergies," rhinitis, chronic sinus infections and more. (One writer mentioned an absence of canker sores after cutting dairy; I realized I hadn't had a canker sore — which I've gotten an average of once a month my whole life — in four months. Something else to think about.)

Although lactose intolerance and its generalized digestive tract problems [5]are well documented, and [6]milk allergies are thought to affect perhaps 1 percent of the American population, the links between milk (or dairy) and such a broad range of ailments has [have] not been well studied, at least by the medical establishment.

Yet [wrong word] if you speak with people who've had these kinds of reactive problems, it would appear that the medical establishment is among the last places you'd want to turn for advice. Nearly everyone who complained of heartburn, for example, later resolved by eliminating dairy, had a story of a doctor (usually a gastroenterologist) prescribing a [7]proton pump inhibitor, or P.P.I., a drug (among the most prescribed in the United States) that blocks the production of acid in the stomach.

Finally he turns to emotion:

There is anger as well as surprise, because you'd think that with a grapevine's worth of anecdotal stories and at least some studies linking dairy to physical problems, few people began this kind of self-testing at the suggestion of their doctor — unless, that is, their doctor was in the "alternative" camp. [he is so angry he gets confused?]

So I got mail saying things like, "When I think back to all the things I've missed because I had a migraine, it makes me a little angry that the solution for me was so simple." When a lifetime of suffering, medical visits and prescription drugs can be resolved with a not especially challenging dietary change — one that, when it works, has rewards well worth the sacrifice — a certain amount of retroactive frustration seems justifiable.

The big trip begins with the small step. Maybe Bittman will begin to wonder at the dystopic miracle of a healthcare system in which respected gastroenterologists fail to grasp that digestive problems are often caused by food. No one

else in prestige media has managed to notice this, as far as I can tell.

Thanks to Lisa Wiland.

charlie (2012-07-31 06:56:27)

The big truth is these are sub clinical problems, and most doctors don't have time to deal with them. My father is a GI. He had a patient die on him last week during a procedure. When the next patient comes in complaining of an upset tummy – and he is fat, out of shape, and prone to eating a lot of polish sausage, what do you expect any doctor to say? Doctors have real problems to face – not these subclinical ones. Yes, after 40 you have to be your own physician. But are these subclinical problems something you can blame the medical establishment for. Take two aspirin and call me in the morning....

Sean S (2012-07-31 07:41:50)

It's true that the high and mighty doctors don't have 2 minutes to explain how to fix these "sub-clinical" problems, but how much more time each day would the doctors have to deal with the "real" problems if they quickly disposed of these easy ones? I suspect this is less of an example of doctors having more important stuff to do than it is a case of their ignorance. They learn very little about nutrition in medical school, and we know one thing, doctors NEVER admit their ignorance. For a doctor to take a patient's money, whether the problem is "sub-clinical" or not, he should have a duty to provide decent care and help that patient. If he's too busy to do a thorough job, then he should not schedule as many patients and take a hit in income.

Brian (2012-07-31 09:06:26)

I suffered from GERD my entire life, until I went on the Atkins diet. Over the years, I was prescribed various antihistamines to stop my "allergies", which largely consisted of post-nasal drip (caused by GERD). Eventually, I was prescribed a proton pump inhibitor. By this point, I had developed esophageal ulcers from the frequent vomiting that came with the GERD\*. Fortunately, with medical treatment, the ulcers healed. After stumbling on a dietary cure for the GERD, the post-nasal drip and the vomiting also went away. I don't care if the problems were subclinical, they caused me lots of trouble. (\*The ulcers probably developed while I was on another medication that caused nausea.)

Tom (2012-07-31 09:25:56)

The idea that people should expect doctors to ignore "subclinical" problems is one of the most moronic things I've ever heard. As if anyone – including doctors – know what is "subclinical" without investigation! The New York Times had two articles in the past two weeks about a 12-year-old boy who went from complete health to dead within two days because of a scraped knee. The doctors missed all the signs of sepsis, no doubt out of their conviction that it was a "subclinical" problem unworthy of their time. Back on the topic of Gerd, when I was diagnosed, I didn't hear a single thing about diet from my gastroenterologist, supposedly one of the best in my state. Just take two Aciphex (proton pump inhibitor) daily, and elevate the head of my bed. I got the idea that he thought diet had nothing to do with it.

Javeux (2012-07-31 09:52:57)

I was prescribed PPIs once, but I couldn't understand how they'd provide a cure or justify their side-effects, so I didn't end up filling the prescription. I suggested to the doctor that my long-standing joint pains could perhaps be related to my long-standing GI complaints, but he didn't 'see how that would work.' Luckily, this was an NHS doctor. If I had a snarky GI taking half a day's pay off me to waste my time with unscientific anti-treatments, I wouldn't be so complacent. I got relief from GERD when eating a low-carb diet, but it just seems to be a crutch, rather than a real solution, like for diabetes and other things people use them for. It wouldn't surprise me if some of the people posting in Bittman's comments had underlying problems that dairy was taking the wrap for, e.g. oestrogen can inhibit lactase enzymes <http://pmid.us/21080139> Antibiotic use probably wouldn't help support the bacteria that help digest lactose either.

SB (2012-07-31 11:59:49)

Maybe doctor's would spend time if they were labelled pre-clinical, you know, like pre-hypertension and pre-diabetic and pre-cancerous and pre-obese and other excuses for making patients out of healthy people.

Txomin (2012-07-31 17:28:48)

First, systematic academic/scientific fraud. Then, systematic medical malpractice. The only thing missing now is addressing the systematic miscarriage of justice.

Adam (2012-07-31 17:41:53)

To me the whole premise & approach to GERD is backwards. The stomach is SUPPOSED to be Acidic & if you make it less Acidic, OF COURSE you are going to cause problems (C. difficile associated diarrhea, Pneumonia, Fractures, B12 deficiency, Hypomagnesemia, etc.). It seems like such a simple concept, I refuse to believe that intelligent people in Medicine can't grasp this. As far as GERD being sub-clinical, it is until it isn't. GERD can progress to Barrett's esophagus, which can in turn progress to Cancer.

Tomas (2012-08-01 06:18:49)

I pretty much agree with Javeux, low-carb or avoidance of certain type/class of food can work, but it's only a band aid. And unlike Seth, I am not surprised that doctors and food writers often fail to see the food - gut connection and are not aware of these "easy" fixes. Overall, the Time article looks like a manifestation of the Dunning-Kruger effect - which is when you only know little about something, you easily overestimate your skills or amount of knowledge you possess. Overall, nutrition is in its dark ages compared to other disciplines, e.s. physics

Patrik (2012-08-02 23:18:24)

A couple fundamental problems with medicine today. 1) Western medicine, in most cases, is embarrassingly similar to shamanism. Most of the time, doctors have little or no idea as what they're doing, even though they have great power and prescribe substances with great ceremony with great confidence. We like to laugh at the ignorance of physicians of the 18th century; my guess is that those of the 23rd century will laugh at us. Notable exceptions being where cause and effect are visibly obvious. For example, if I get by a car and my bones are broken and I am bleeding severely. In cases, like these, by all means, take me to a emergency room and fix me up with the latest and greatest in medical technology STAT! 2) Doctors are trained to fix the symptom, not the cause. They are also largely the puppets of Big Pharma. I suffered migraines my whole life until my 30s. I am prescribed meds to help me manage the pain. These meds are better than nothing. Then I quit eating grain-based products, no migraines ever. (Interesting to note is that I don't \*know\* if it is gluten or some other concomitant substance to which I am sensitive.)

Chuck Curre (2012-08-07 12:45:19)

I believe that food is the cause and the cure - Let food be your medicine and medicine be your food. I suffered from GERD for many years, was a Prilosec addict, then discovered Paleo/Primal/etc. Eliminating grains in effect eliminated the dairy - I didn't drink milk ala carte and drank my coffee and tea black. No more GERD no more Prilosec. I was able, after several months, to add back grass fed cream and butter with no obvious consequences, however, plain milk and yogurt still caused a little

heartburn. A few weeks ago I decided to try raw milk and so far all is good. And, the pleasure of a cold glass of milk is under appreciated. I have also noticed a small positive change in body comp - lost some stubborn lower (below the navel) belly fat. So, when it comes to milk, pasteurization and homogenization, could be the problem - not the milk per se. It would be interesting to see if Mark Bittman would be willing to challenge his biases and give raw milk a try. FYI - I am 65 yrs old and probably genetically tolerant of milk (real milk) due to Swiss ancestry.

## 7.8 August

### My Dental Exam: Good Gums (2012-08-01 05:00)

A week ago I had my teeth cleaned. So dirty! said the dental hygienist. This wasn't surprising. Because I am in China a lot, I get my teeth cleaned only twice per year. Long ago they got dirty so fast my dentist insisted on four cleanings per year. "But aren't my gums okay?" I asked the hygienist. They felt okay. Not tender. They didn't bleed when I flossed (which wasn't often). No, she said. You have pockets of 5 (= 5 mm depth). There is bleeding. Indeed, when I washed out my mouth with water at the end, there was some blood.

Yesterday I had my teeth examined. The hygienist was wrong. Almost all my pockets were 2's, with a few 3s. That's very good and a vast improvement from the 4s and 5s I had before I became a big fan of flaxseed oil. My gums improved exactly when I started drinking flaxseed oil, no doubt because the omega-3 in flaxseed oil reduces inflammation. My gums were fine in spite of all the plaque - which is supposed to make gums bad. Apparently the hygienist was so devoted to her theory (lots of plaque = bad gums) that she failed to see an exception she stared at for 30 minutes.

There is a well-established correlation between gum disease and heart disease (more gum disease, more heart disease), probably because both are caused by inflammation. So good gums is very good news - it shows I am doing a good job of reducing inflammation throughout my body. These results also support two of my pet theories:

1. Studying what foods make the brain work best is a good way to improve overall health. I started studying flaxseed oil, and how much to take, because I discovered by accident that it improved my balance. Experiments (what is the effect of flaxseed oil on my balance?) soon showed the optimum amount/day was more than flaxseed oil makers recommended! Before I started eating lots of butter, the optimum for me was about 3 tablespoons/day. After I started eating lots of butter, the optimum seems to have gone down to 2 tablespoons/day. Gum improvement seems to be easy to notice at about 1 tablespoon/day.

2. Our health care system fails to get the simplest things right. Omega-3 is not a mysterious nutrient. It has been shown to improve health in thousands of studies. It is well-known that it is anti-inflammatory. It is also well-known that too much inflammation is a major problem. Even so, our health care system has failed to grasp that a large fraction of the population eats too little omega-3 and this has an easy fix. Other examples of failure to get the simplest things right include [1]gastroenterologists not realizing that digestive problems may be caused by food, [2]dermatologists not realizing that acne may be caused by food, and everyone not realizing that [3]cutting off part of the immune system (tonsillectomies) is a terrible idea.

What other simple things does our health care system get wrong?

1. <http://blog.sethroberts.net/2012/07/31/mark-bittman-glimpses-a-big-truth/>

2. <http://www.freakonomics.com/2005/09/15/seth-roberts-on-acne-guest-blog-pt-iv/>

---

Tomas (2012-08-01 06:38:37)

The case of omega3 is not that easy. Yes, it's been confirmed that they can help - but only short-term. Long-term, the good results vanish or even are negative. The mechanism behind may work like this - initially, O3 displace O6, which means less inflammation. But gradually, PUFAs build up in the body and cause trouble (read: oxidation). O3s are even more "fragile" than O6s because of the position of the double bond - one more reason to think that loading on them may not be a good idea. What works for me is cut PUFAs in general and get enough fat-soluble vitamins. The result is basically same as yours - some plague, no carries, ok gums - with less flossing and brushing than before. Seth: The improvement produced by omega-3 is "only short-term"? The improvement in my gums has lasted six years.

Jon (2012-08-01 07:16:10)

How do you consume your butter? I usually only like it with bread products but I've heard some opine that animal fat and wheat are toxic for the body. I don't know if that is true or not but I've found that cutting down on wheat does help me to maintain my weight better, along with your sugar water treatment. Seth: I eat my butter with small thin pieces of roast beef. If animal fat is toxic for the body, why does butter taste so good?

John (2012-08-01 07:35:19)

As Tomas sort of says, omega-3s can help short term because they block arachidonic acid metabolism. High amounts may be a long term problem, but the long chain 3s still seem okay for the brain. It seems safer to just consume low amounts of each though.

Tuck (2012-08-01 08:01:01)

The basic thing that doctors get wrong is that they think their patients are non-compliant or idiots. Sure that's true in some cases, but as someone who now eats in opposition to the standard advice, I can tell you: it's hard. EVERYONE else is eating high-carb, low-fat, as they've been advised to by the government. The medical profession seems to think that the fact that their advice is not producing the result they desire (a low fat diet is not reducing fat) is because their patients are non-compliant liars... They (speaking broadly) don't consider the other possibility, that their advice doesn't produce the desired result. It's much easier to think that your patients are liars. One regularly sees this in the literature: "dietary interventions don't work..." No, dietary interventions work really well, as the paleo and low-carb studies show; what doesn't work is the standard advice. Also, on the omega-3/omega-6 front: "As Tomas sort of says, omega-3s can help short term because they block arachidonic acid metabolism." This is not correct. "As arachidonic acid was not provided by the diet, it can be concluded that alpha-linolenic acid does not inhibit chain elongation and desaturation of linoleic acid to arachidonic acid in man." <http://www.jlr.org/content/27/4/421.short> I suspect that if Seth is seeing improvement in his dental condition because of eating flax oil, it's because the flax oil is altering the ecosystem in his mouth to a more beneficial one, or because the cells of his mouth are able to use it directly, and in place of a carbohydrate-based ecosystem/substrate. I've experienced the same improvement without short-chain n-3 consumption, through eating a low-carb/high-fat diet, but I don't eat much short-chain n-3 fats.

dearieme (2012-08-01 13:55:46)

"How do you consume your butter?" Betwixt toast and marmalade. Between oatcakes and cheese. On boiled potatoes. On steamed vegetables. (Who eats peas without butter on them; or broccoli?) As garlic butter on steaks. In most sauces that my wife makes in her cooking, and in her soups. In sandwiches.

Antonio Pedro (2012-08-01 15:29:26)

"If animal fat is toxic for the body, why does butter taste so good?" I don't really follow that logic. Lot's of people love trash

food. But maybe I am missing something. Cheers, Seth: The logic is that evolution would have not caused us to want to eat something that is toxic.

dearieme (2012-08-01 17:47:22)

"How do you consume your butter? " Another possibility is as ghee, with Indian food. Seth may know whether it's healthy.

Alex Chernavsky (2012-08-01 18:10:50)

I've been taking approx. 3 tablespoons of flaxseed oil daily for about three years. I noticed that I have considerably less staining on my teeth. But, sadly, my pockets have not decreased in size. They're still pretty deep. The last time I visited the dentist, my hygienist said that she'll have to do a deep-cleaning soon. Not sure if that procedure works or not, but I scheduled an appointment for September.

Antonio Pedro (2012-08-01 20:39:47)

So what would explain trash food or bad eating habits more generally? I am now living in US (Los Angeles) and I am surprise that many actually \*prefer\* trash food. Best, Seth: A great deal of time and energy has gone into learning how to fool people into eating food that is bad for them but profitable for the seller. For example, we like all fats – evolution's way of getting us to eat animal fat (good). But our liking for fat also makes us like food made with plant fats (some of which are bad).

Tomas (2012-08-02 02:50:58)

Tuck, for PUFA metabolism I consult Chris Masterjohn's articles. He clearly states that Too much LA, ALA and EPA (twenty-carbon omega-3 eicosapentaenoic acid) can interfere with the body's production and utilization of AA and DHA. Seth: I didn't say that, I don't know what you are doing. I was just speculating why our health care system supposedly fails to see the problem.

Ashish (2012-08-02 17:16:47)

My gums have seen a similar reduction in problems (from 3s and 4s and 5s to 2s) over the past couple of years. I've been taking Omega 3 pills for longer than that, so as far as I can tell, the improvement is due to oil pulling - in my case with sesame oil. What amazes and infuriates me about this is that my dentist and hygienist, who have been managing my oral care for years, are so completely uninterested in what has changed to cause the improvement. I've tried to tell them about oil pulling, but if it's not in their manual, it doesn't exist. (And their other patients won't be hearing about it.)

Morris (2012-08-02 19:39:44)

I have suffered from periodontal gum disease for many years despite following dentists' instructions. Things slowly got worse until 3 years ago when I got a bad flare and lost 3 tooth implannts. I decided to look into the causes myself and found that this is a systemic microbial disease which also affects connective tissue and the heart. I changed my diet, rest and exercise regime. Now 2 years later my gums have (and continue) improved greatly, tartar deposition rates have decreased so much that 6 month cleaning is now the norm (not 2). I see like improvements in my joints. My diet includes ample w-3 fats from seafood.

David (2012-08-02 23:57:26)

I have used a tooth powder (named "Ecodent", made in Wisconsin) for a number of years, and it has resulted in great gum health. The key is to brush within five minutes of eating, always, at least initially. Google "Nara" for background.

shtove (2012-08-06 16:06:53)

My gums are fine. Last checkup didn't need a clean, contrary to previous monthly check ups. The gap between last check up and this was 9 months, in which period I brushed with coconut oil twice a day, one of these with sodium bicarb added. Also on low inflammatory diet a la paleo. Don't take industrial seed oil, like flaxseed - just ghee, coconut oil, animal fat (including beef drippings) olive oil and tinned sardines/anchovies/salmon fillets. Is it the case that the effect of these O3 oils will wear off?

Tuck (2012-08-02 07:01:15)

The cessation of psoriasis was probably a function of ceasing to eat wheat, rather than of losing weight... "[1]Psoriasis in a nationwide cohort study of patients with celiac disease." "[2]Serologic markers of celiac disease in psoriatic patients." Lots of mystery skin ailments seem to be caused by wheat consumption, not just dermatitis herpetiformis. What's interesting is the excema, they're now finding, is caused by a breakdown in the tight junctions of the skin. Celiac's hallmark is the breakdown of tight junctions in the intestine, but obviously it can also affect the skin, since dermatitis herpetiformis = celiac disease. It will be interesting to see what the mechanisms turn out to be for non-celiac gluten sensitivity...

2. <http://www.ncbi.nlm.nih.gov/pubmed/18384553>

Darius Bacon (2012-08-02 12:37:28)

I've seen psoriasis apparently cured by a vitamin-D/K combo. Sunlight by itself helped but did not tame it. (Self-diagnosis, never went to a doctor about it. Using the Thorne Research D/K2 droplets and I'm curious if anyone else has seen this effect. Vitamin D by itself didn't do it either.) This jibes with the article where he attributes it to green veggies, which tend to have K.

garymar (2012-08-06 00:58:57)

The fake Bagel Company was interesting. The vast majority of "likes" came from Egypt, Indonesia, and the Philippines. Maybe Facebook is so new for these people that they click the Like button to indicate "I have read it". Probably a lot of it is simply, "It was written in English but I understood it!" Notice that he got almost no response from English-speaking countries.

## Whose Side is the FDA On? (2012-08-03 05:00)

The FDA is supposed to protect Americans against unsafe drugs – drugs with bad side effects, for example. According to [1]this interview with Ronald Kavanaugh, a former FDA employee who worked there 10 years, that is not what actually happens. Here are excerpts from the interview:

I think most people would be shocked at how malleable safety data is. Human studies are usually too short and the number of subjects in them too small to adequately characterize [= detect] the most dangerous risks.

Human clinical pharmacology trials are typically done in Europe, yet clinical pharmacology reviewers at FDA have been barred from analyzing this information prior to studies being conducted in the US.

If reviewers say things that companies don't like, they will complain about the reviewer or they will call upper management and have the reviewer removed or overruled.

When you do raise potential safety issues, the refrain that I heard repeatedly from upper management was, "where are the dead bodies in the street?" Which I took to mean that we only do something if the press is making an issue of it.

FDA's response to most expected risks is to deny them and wait until there is irrefutable evidence post-marketing, and then simply add a watered down warning in the labeling.

Which is why bad side effects are sometimes discovered after FDA approval.

Thanks to Anne Weiss.

Tuck (2012-08-03 08:24:14)

Yeah, it's known as "regulatory capture". It's one of the primary criticisms of government regulatory efforts: "Alternatively, it may be better to not create a given agency at all lest the agency become victim, in which case it may serve its regulated subjects rather than those whom the agency was designed to protect. A captured regulatory agency is often worse than no regulation, because it wields the authority of government. However, increased transparency of the agency may mitigate the effects of capture." [http://en.wikipedia.org/wiki/Regulatory\\_capture](http://en.wikipedia.org/wiki/Regulatory_capture) I did a post about this a while ago. One of the reasons the FDA was created was to prevent adulterants like sawdust (primarily composed of cellulose) from being added to foods. Now, the FDA actively promotes adding cellulose to foods, at the prompting of industry. The FDA's not on the consumer's side any more. And it resists all efforts at transparency. "[1]Sawdust and Ice Cream"

1. <http://yelling-stop.blogspot.com/2011/05/sawdust-and-ice-cream.html>

dearieme (2012-08-03 09:26:35)

I have long wondered at the odd but common assumption on blogs that only American trials count - it hadn't occurred to me that it carried the force of law. It would be far more sensible for the US to combine European data with US data taken on blacks and mestizos (spelling?) - that way you'd have a better chance of getting studies with enough of those two racial groups to give them some reasonable assurance of safety. In fact, you could argue that the present US system carries needless risk for those two groups in particular.

dearieme (2012-08-03 09:27:22)

And come to think of it, perhaps Asian racial groups too.

Elizabeth Molin (2012-08-03 12:09:38)

And women? Except in the case of something like a birth-control pill, studies are often done only on male subjects.

dearieme (2012-08-03 14:30:31)

Elizabeth: really? How extraordinary.

Ed Terry (2012-08-17 12:41:07)

The few scientists at the FDA who have the courage and conviction to report questionable practices in their agency now have their email monitoring. The whistle-blower act, which is supposed to protect government employees against reprisal for reporting illegal and dangerous practices at any agency is ineffective. Management and supervisors manipulate the system against whistle blowers, often leading to job loss. I suppose these federal employees ought to resort to the US Postal Service to deliver their concerns to members of congress.

## **Fibromyalgia Improved by No Longer Eating Fruits and Vegetables (2012-08-05 05:00)**

A British doctor in her 40s [1]suffered from a range of problems that all started around the same time:

My legs ached and tingled, I felt tired and my mood was flat. I slept badly — I suffered from restless legs and my muscles kept twitching — and couldn't concentrate during the day. . . I stopped enjoying going out and couldn't get enthused about seeing friends. . . . In December 2010, I had great trouble climbing into the loft to get the Christmas tree, having neither the strength nor the enthusiasm for it. . . . I longed to retire early, so I could stay in bed all day.

She diagnosed herself as having fibromyalgia, a disease usually said to have "unknown cause". Treatments for fibromyalgia

include "painkillers, antidepressants, anti-epilepsy drugs, and cognitive behavioural therapy," wrote the doctor.

She noticed her symptoms varied with what she ate:

The muscle pains were worse after eating carrots, potatoes and parsnips. My son's girlfriend made a delicious parsnip soup for a dinner party last year, and I enjoyed a big bowlful. The following day my legs were aching worse than ever, and I felt terrible. . . . [Using a food diary, I learned] I was also badly affected by potatoes, green beans, carrots, almonds and tomatoes. I searched the internet and found that, among many different theories, some suggested a link between fibromyalgia and dietary oxalate, though this isn't recognised by the medical profession.

Many vegetables contain a lot of oxalate, which acts as a pesticide.

I tried a low oxalate diet, cutting out virtually all 'healthy' food — I avoided most fruits and vegetables, salads, beans, nuts, wheatgerm, soya — as well as tea, coffee and chocolate. I could eat meat, fish, dairy, cheese, white rice, white pasta and only low-oxalate fruit and vegetables, such as bananas, peas, mushrooms, onions and cauliflower. Within a few days the symptoms were totally gone; I could walk without

pain and sleep normally. My motivation came back — in the eight months since starting the diet I've painted the house, landscaped the garden and booked a holiday. Having suffered from the need to pass water frequently, my nocturnal trips to the bathroom have ceased. And, bizarrely, my teeth have felt clean all day long. . . . I've found eating any high-oxalate food results in tingling legs and muscle pains within a matter of hours. I've become so adept at noticing the signs I can tell what foods and drinks have oxalates in a short time after ingesting them.

Would her discovery help others? She suggested the diet to five women in her practice.

They had all presented with at least four of the following [eight] symptoms: muscle pain, tingly legs, fatigue, irritable mood, bladder irritation, poor concentration, restless legs and poor sleep. I asked them to score the severity of these symptoms before and after changing to a low oxalate diet. . . . Out with bran-based cereals, nuts, spinach and smoothies, and in with Rice Krispies, sausages, shortbread and cola! . . . All the patients improved significantly — on average their symptom score halved after three weeks of the 'unhealthy' diet.

This surprises me. I would have thought that a condition as vaguely defined as fibromyalgia would have more than one cause.

In any case, this is extraordinary progress – published in The Daily Mail. Surely more important than any of the 7000 peer-reviewed articles on fibromyalgia I found via PubMed. A PubMed search for "fibromyalgia oxalate" turned up nothing.

[2]More about a low oxalate diet. Thanks to Dave Lull.

---

dearieme (2012-08-05 05:32:41)

"Apparently she is the first person to make the connection." I suppose that rules her out for the Nobel in medicine/physiology, then? Seth: Since I wrote that I am no longer sure she is the first. A low-oxalate diet is promoted for various disorders, I learned, although apparently never in the PubMed literature. But, yeah, it's been a long time since anyone resembling an ordinary doctor, which she is, has won a Nobel Prize in medicine/physiology.

Jim Purdy (2012-08-05 06:52:55)

Just a little bit of amateur web searching turned up articles about *Oxalobacter formigenes*, which is a beneficial oxalate-degrading bacterium commonly found in the human gut. However, it can be destroyed by antibiotics, and perhaps indirectly by small intestinal bacterial overgrowth as a result of protein pump inhibitors. So, quit the antibiotics, quit the PPIs, take some yogurt and other probiotics, and keep eating lots of fruits and veggies that provide fiber for your good gut bacteria, But I ain't no doctor. I'm just a cranky old patient. So I don't give (or take) medical advice.

Adam (2012-08-05 18:00:47)

Some common foods high in Oxalate are "SCRT": Spinach Chocolate Rhubarb Tea I believe Fibromyalgia is more common in women & there is at least an old wives' tale that women eat more chocolate than men. Maybe I'm grasping at straws here.

Anyway, rather than cutting out ALL vegetables, maybe a 1st approach would be to cut out these big 4 and see if there is improvement? If so, then one might consider further reducing other sources.

dearieme (2012-08-06 03:03:02)

Perhaps the important lesson is that wittering about "healthy eating" is pointless if the advisee doesn't know what is healthy for her. (It's easier for men, who know that sausages are healthy for them.)

Jenny (2012-08-06 04:19:24)

One of the main antibiotics that destroys *Oxalobacter formigenes* in the gut is Augmentin - commonly prescribed with a PPI to enable you to 'tolerate' it. No wonder you can end up with oxalate overload afterwards. The Paleo diet is 'half-way' to the low-oxalate diet, which probably explains why many people get improvements but not quite full health on the paleo. As a gluten-abstaining coeliac, who still has fibromyalgia, I will definitely try modifying my diet to see if I can remove the fibromyalgia. I would like to get fit without severe pain all the time!

Jenny (2012-08-06 04:29:05)

The same doctor mentioned in the article above also said 'It may also be that certain bacteria in the bowel normally break down the oxalate, but that these bacteria may disappear, perhaps after a course of antibiotics. There must be genetic factors, too, as fibromyalgia is more common among families of those affected.' Yesterday, I came across an article stating that gut bacteria are altered during pregnancy (apparently to increase insulin resistance so that the baby gets more glucose) and this alteration is retained. This might explain why more women end up with fibromyalgia - and why more women can never shed their 'baby' weight.

### **Vitamin D3 Timing and Sleep: More from Tara Grant (2012-08-06 18:53)**

It is [1]from Tara Grant, a California journalist whom I met at the 2011 Ancestral Health Symposium, that I got the idea that the time of day you take Vitamin D3 matters (morning good, evening bad). She recently wrote more about her experience:

I had never had a sleep problem growing up, or during my 20s or early 30s. I kept a regular sleep cycle, woke up rested, preformed well in school and never needed to have naps. However, when I was in my mid-to-late 30s, the sleep problems started. [She woke up many times per night.] This was around the same time I went Primal and adopted several changes in my diet and lifestyle, including taking supplements. One of those supplements was Vitamin D3 [10,000 IU/day], something I had never taken before.

The sleep problems persisted for a couple of years. When I changed the time of day I took my Vitamin D [making sure to take it in the morning, never in the evening], they resolved. I didn't change anything else, as I didn't need to.

My experience has been that Vitamin D3 in the morning improved my sleep and that the dose needed to get this improvement was more than 2000 IU. Doses of 4000 IU and more were effective. [2]More than 20 people have had similar experiences. A few people have found that Vitamin D3 in the morning did not improve their sleep.

1. <http://blog.sethroberts.net/2012/01/19/vitamin-d3-and-sleep-more-good-news-from-primal-girl/>

2. <http://blog.sethroberts.net/category/sleep/vitamin-d3-and-sleep/>

---

Tom Passin (2012-08-06 20:05:54)

I have slept very badly for many years. It is hard to get to sleep and then I wake up often. I also have sleep apnea, for which I use a CPAP machine while sleeping, which doesn't help because if the pressurizing mask slips it may leak, which tends to wake me up. I've been taking 4000 units/day of D3 in the morning after reading about it here. It does help, but only modestly. But what I do notice is that I tend to get very sleepy about 12 - 13 hours after taking the D3. I don't necessarily fall asleep easily or sleep better if I go to bed at this time, though sometimes I get so sleepy I can't do much else besides lie down. This period of sleepiness seems to last for a few hours. If I get through it, I wake up enough to function all right until I go to bed. If I have gotten through the sleepy period in the evening, I will generally sleep about as well as if I had gone to bed earlier during the sleepy time. The effect will last for one or two more days if I omit taking the D3. Sometimes I adjust the time I take the D3 according to what I may be doing in the evening, such as being at a concert or driving home, to try to avoid getting to sleepy at the wrong time. That's only partly successful. Seth: You might want to try a range of morning times to find what works best. I noticed that taking Vitamin D3 at 7 am had a much better effect than taking it at 8 am.

ChristianKI (2012-08-07 01:37:44)

I think it would be interesting whether "in the morning" mean the same thing for everyone. There are people who get up at 5 o' clock and there are people who get up at 11 o' clock. Maybe the 11 o'clock people don't get the full benefits of taking vitamin D3 after awakening? Seth: I agree. My experience has been that I needed to try a range of different morning times (from about 6 am to 9 am) to find the time that worked best.

Tom Passin (2012-08-07 08:52:53)

I have tried various morning times. So far, I haven't noticed any convincing results except for the 12-hour sleepiness one. I could try again, now that I'm more familiar with the normal effects that I get.

Terry Elliott (2012-08-08 16:04:52)

My wife has had recent good luck with D3, but I have had much better sleep with one ibuprofen. For some reason I am sleeping 30-60 minutes longer and having way more dreams. Anybody else have similar experiences?

Bruce McCullough (2012-08-09 14:44:58)

I found that 5000 IU in the morning eliminates my restless sleep and makes falling asleep much easier. Originally I was at 7000 IU, and dropped it to 4000. I went to a conference and took only 2000 IU every morning. What a mistake. restless sleep came right back. Got home and increased back to 5000. Time of morning appears to be somewhat irrelevant to me. Sometimes I take it at 6am, usually between 7 and 8, sometimes as late as 9am. 9am may well be associated with decreased sleep quality, but 6-8am are not.

### **The Cost of Hope by Amanda Bennett (2012-08-07 05:00)**

I came away from *The Cost of Hope* by Amanda Bennett (copy sent me by publisher) full of admiration for two people the book barely mentions: Bennett's parents. How did they raise her to be such a competent and resourceful person? The book isn't about her. It is mainly about her husband's fatal illness and their marriage. She never brags, but glimpses of staggering competence slip through. In 2006,

I am the only editor of a major newspaper in the United States [the *Philadelphia Inquirer*] to run the Danish cartoon of Mohammed wearing a bomb on his head instead of a turban—the cartoon that causes

riots in Europe. By the following Monday, protesters are in front of our building carrying signs with my face and the face of Hitler. Joe Natoli, my publisher, and I plunge into the crowd, shaking hands, talking to families, listening to their stories. The crowd turns friendly. I emerge with several copies of the Koran.

She tells this story because her husband is proud of her, which means a lot to her:

The pride I see on Terence's face . . . keeps me going, even when I am scared.

However, she was courageous before she met him. In 1983, she took a job in Beijing as a correspondent for the Wall Street Journal, which is where she met her husband. Their first encounters, she says, were a series of fights.

Most of the book is about what happened when her husband came down with a rare form of kidney cancer – especially how much the treatments cost. For \$600,000 – paid mostly by insurance – they bought a few more years of life together. It was worth it, says Bennett, adding but did it have to cost so much? Her best insight comes when she notices the wildly different prices paid for exactly the same treatment (CAT scans) – exactly the same treatment, same machine, same operator. The "retail" rate is, let's say, \$20,000. One insurer pays \$5,000, another pays \$1,000. She wonders why. Her moment of insight comes when she is back in Beijing at a fakes market with her 10-year-old daughter. At such markets, tourists are told prices wildly above what the seller will accept. In one case a fake Chanel purse is offered for 2000 yuan ( \$300). A woman who pays 200 yuan walks away happy. "I got it for 200!" she tells her friends. Bennett's (adopted Chinese) daughter pays 20 yuan. (Apparently Bennett has her parents's parenting skills.) Wildly inflated retail prices for health care – so much more than what sellers will accept that they are almost meaningless – exist to take advantage of poor negotiators, Bennett realizes.

The Cost of Hope was a pleasure to read and, as I've said, Bennett is an astonishing person, but it omits an important point. Bennett, like most people who write about the high cost of American health care, fails to point out its central tenet: [1]First, let them get sick. Bennett's husband died young (early 60s). He was significantly overweight, how much we aren't told. Apparently he had diabetes – again, few details are given. Obesity and diabetes are preventable. One of the first treatments her husband receives for his cancer is IL-2, meant to boost the immune system. What about boosting his immune system before he got sick? For example, by improving his sleep. This [2]neglected approach might have prevented or delayed her husband's cancer and extended his life much more cheaply and painlessly than what happened. The biggest flaw of her book is her failure to ask – literally ask, such as ask the head of the National Institutes of Health – why prevention, especially cheap prevention, is ignored.

1. <http://blog.sethroberts.net/2011/09/18/first-let-them-get-sick/>

2. <http://blog.sethroberts.net/2012/06/11/more-examples-of-mainstream-health-care-ignoring-the-immune-system/>

Robin (2012-08-07 08:03:20)

I'm curious - why do you think her character is the result of how her parents raised her? The people I know who are the most resourceful have been those who, essentially, raised themselves without much parental involvement (not that my experience is in any way representative of the wider population). But even if we were to credit the parents, was it their genes or upbringing? Sorry to trot out this old question but I do find it odd that you left with, above all things, admiration for her parents.

Seth Roberts (2012-08-07 13:49:32)

Why do I admire her parents? There is a famous poem by Philip Larkin that begins "They fuck you up, your mum and dad. They don't mean to but they do..." He wasn't joking. I am utterly sure there are many ways to raise children that omit important things (which might include periods of independence and stress) and cause those children to be less effective and happy adults than they otherwise would have been. Anybody who thinks that genetics ever acts by itself – in the absence of the right environment – understands very little about development. Parents control the environment. A study that suggests "parents don't matter" may simply be showing that parents don't know what the right environment is.

Robin (2012-08-07 21:22:32)

Yes that opening line resonates! I think it is my own bias to attribute people's successes to their own efforts (and fortuitous circumstances) whereas I'm more likely to think "bad parents" when they are, for want of a better term, fucked up. In my own family, we have one set of parents but wildly WILDY different outcomes for the siblings... from prison to medicine and investment banking. It is hard to not be overly influenced by such data points when they are so close to home.

Robbo (2012-08-08 08:36:46)

Hmm "“They fuck you up, your mum and dad. They don't mean to but they do...” He wasn't joking.” He wasn't a scientist either, argument from poetry isn't one of the classic fallacies but it ought to be. Hmm "Parents control the environment." Not really, sure they are an important influence, reducing as children grow up, but school, TV and the peer group are also important influences so that 'control' is not the word. "...parents don't know what the right environment is." For sure, but who does ? Maybe different children thrive best with different parenting.

Alex Chernavsky (2012-08-08 10:44:49)

Seth, are you then skeptical of the arguments that Steven Pinker presents in his book, *The Blank Slate*? (He argues that your parents have surprisingly little influence on your character [aside from supplying your genes].) See also: "[1]Do Parents Matter?", by Malcolm Gladwell. Seth: Yes, I am skeptical of both books – Pinker and Gladwell (or rather the woman, Judith Harris, that Gladwell writes about).

1. [http://www.gladwell.com/1998/1998\\_08\\_17\\_a\\_harris.htm](http://www.gladwell.com/1998/1998_08_17_a_harris.htm)

AM (2012-08-08 23:00:40)

I don't know Amanda Bennett or her parents, but I'd hate to think that someone would give MY parents the slightest bit of credit for anything I happen to accomplish in life. I'm sure I'm not alone.

eshetti.co.za (2012-08-09 02:50:30)

Seth, are you skeptical of arguments that Steven Pinker presents in the book, *The Blank Slate*? Seth: You mean arguments about how parents don't matter? Yes.

## **What Was Mark Bittman Thinking? (2012-08-07 08:24)**

[1]Stephen Dubner has drawn my attention to a recent comment by Mark Bittman, the main food writer at the New York Times (the most prestigious and influential newspaper in the world), [2]on his NY Times blog:

[3]Sysco is the latest food giant . . . to come out against gestation crate confinement of pigs. . . .

Speaking of pigs, the VP of PR for Chick-fil-A dropped dead of a heart attack the week after the chain's latest homophobia/anti-gay marriage scandal.

As Dubner says, my first reaction is: Was the Times website hacked? Apparently not. My second reaction: Is Bittman in good health? If so, I hope he will explain why he thought it was a good idea to call a person a pig. That the person

in question recently died and his family is grieving makes this even stranger. Dubner emailed Bittman about it but got an automated reply.

More. Bittman removed the comparison and [4]apologized.

1. <http://www.freakonomics.com/2012/08/07/speaking-ill-of-the-dead-apparently-okay-if-the-dead-worked-for-chick-fil-a/>
2. <http://bittman.blogs.nytimes.com/2012/08/03/team-u-s-a-links/>
3. <http://lists.hsus.org/t/6323269/24870703/5379/3/>
4. <http://bittman.blogs.nytimes.com/2012/08/07/a-note-to-my-readers/?gwh=7A55B30C28FF8EA88F3544B6ADC1C9E4>

---

Mike C (2012-08-07 10:41:37)

The apparent joke/gibe was inappropriate and insensitive. Ethically, it's maybe questionable, depending mainly on whether the spokesman's family is likely to happen upon this comment. The behavior of Cathy and Chick-fil-A is simply appalling. Ethically, it's utterly out of bounds. It's important to call things out, but also to note the relative perspective.

Adam (2012-08-07 16:48:45)

What is wrong with calling a person a pig? Just because someone died doesn't mean we have to pretend they were fabulous. Maybe the guy was cruel & evil. Maybe his family isn't grieving, but celebrating. I'm not saying it is likely, but it is possible. Seth: Bittman called him a pig because of the company he worked for, not because of his personal traits. Why is calling a person a pig a bad idea? Because I believe it usually does more harm than good. Leaders, of course, love conflict – it empowers them. For them, from a purely selfish point of view, treating other people as dirt really works. But the conflict (e.g., war) they cause by this behavior – which their followers imitate – is usually a terrible thing for everyone else (e.g., lots of people die). Most people aren't leaders. Bittman, for example, gains nothing by calling anyone a pig. He merely looks bad. The simplest answer to the question "why is calling a person a pig a bad thing" is: It makes you look bad.

Tom (2012-08-07 16:50:14)

Yes – a man's early death is only a **relative** tragedy, which must be carefully weighed against the fact that his boss's religious belief **miffs** you. Because the dead person is obviously a baddie. No way he might just be a decent African American executive nearing retirement after decades of just doing his job & providing a better life for his kids than he'd had. Read this and see if you're still as delighted by his death: [uga.edu/gm/ee/index.php?/single/2012/06/1573/](http://uga.edu/gm/ee/index.php?/single/2012/06/1573/) Oh, BTW, what specific part of Cathy's personal behavior was out of bounds or appalling, and why? And what specific corporate behaviors are you referring to? Has the corporation even expressed an opinion? Or are you just offended that they're not open on Sundays? A whole lotta conflation/sloppy thinking/bigotry on this issue. And it's kind of amazing how quickly a sense of entitlement has grown around gay marriage. It might be better to make sure Obama wins before you demonize people for expressing their religious belief....in an interview with a Baptist magazine, no less. (Pardon the relativism.) If Obama loses, gay marriage might not be as inevitable as some are thinking. (Hell, Obama only went all-in because Biden forced his hand by not being able to shut up!) How inspiring!

David Johnston (2012-08-07 18:59:46)

Either he didn't write what you said he wrote or more likely, he has changed it.

Tony (2012-08-07 21:40:46)

He changed it. I read it earlier today.

Adam (2012-08-08 03:08:23)

Tom wrote: "No way he might just be a decent African American executive nearing retirement after decades of just doing his job & providing a better life for his kids than he'd had." He might be, I don't know. Maybe Bittman can clarify what makes Don Perry a pig in his eyes.

JC (2012-08-08 03:48:05)

Bittman has apologised: <http://bittman.blogs.nytimes.com/2012/08/07/a-note-to-my-readers/>

Dapko (2012-08-08 06:29:04)

Yes, "demonizing people for religious belief" those poor poor victims who hide behind religion to justify hatred and discrimination. As the Westboro Baptist Church has shown, there is no limit to the depths that people will sink to justify these hatreds in the name of religion. Women shouldn't have access to birth control? Religion! Two consenting adults shouldn't marry? Religion! Evolution didn't happen? Religion! There is really no end to what a certain sector of society will be satisfied with when hiding their baser beliefs behind their "religion". Certain members of our congress actually felt emboldened to say that insurance companies should be able to refuse coverage for any procedure, pharmaceutical etc that they didn't believe in. Sorry Aunt Millie, no cancer treatment for you, it's against my religion! I don't think Bittman picked the best way to express his opinion on Dan Cathy and his restaurant, but I do think it's time for people to stop cowering in front of clearly discriminatory and hurtful beliefs just because they're done in the name of religion.

Tom (2012-08-08 07:54:01)

Again with the sloppy thinking. I guess being right means never having to reason anything through. *it's time for people to stop cowering in front of clearly discriminatory and hurtful beliefs* Wow, this is insane: "clearly discriminatory and hurtful beliefs" BELIEFS? You contend you deserve dominion over what they BELIEVE? Good luck with that. I'm sure it'll be an effective use of your time on Earth. Or does "people" not mean you, but merely gay and/or vegan columnists you agree with? In which case an end-zone dance on the occasion of another person's heart attack – an EMPLOYEE tasked with cleaning up his boss's mess – is hunky-dory? Please tell us: how many degrees of separation from the guilty party are required before death becomes too harsh a penalty? And what does "stop cowering" actually mean, since it makes no literal sense? Does "stop cowering" mean deface their outlets with 10 foot high graffiti? Because that is a literal crime, but inside the jurisdiction of your skull is merely the cessation of "cowering"? Or does "stop cowering" mean a closeted CFO from an unrelated company interfering with another company's business, harassing its helpless minimum-wage employee from the safety of his Lexus, then posting video of her on the web without her consent? While loudly and defensively asserting his heterosexuality? My hero! Way to not-cower! Back on Earth, what you think of as "not cowering" actually looks like boneheaded, vicious, tone-deaf narcissism.

Dapko (2012-08-08 11:28:46)

For someone who talks about reason, your post is certainly devoid of any. Sheesh, what a big pot of word soup teeming with hyperbole. Ten foot high graffiti? Harassing helpless employees? That's like accusing every pro-lifer of approving the gunning down abortion providers. I already stated that I don't think Bittman picked the best way to express his opinion about Dan Cathy, but why pay attention to anything I've stated when you can off on an outraged rant? I never stated that I wanted dominion over anyone's beliefs, I stated I wanted the right to question those beliefs without being told they are off bounds because they are religious beliefs. If someone doesn't believe in two consenting adults having the right to get married, let them make a coherent argument for why instead of hiding behind "my priest/pastor/religious text told me so". I really don't care what anyone believes until those beliefs start affecting other peoples lives that don't share those beliefs. Believe in heaven? Fine. Believe Jesus rose from the dead? Fine. Believe gays shouldn't marry? Why? Believe woman shouldn't have access to legal reproductive health care? Why? What gives you the right to have your religious beliefs negatively affect the lives of others? No one is forcing you to get an abortion or marry a same sex partner if you don't believe in those things. The same respect should be afforded to others who don't hold the same views.

BlueMorrissey (2012-08-08 14:53:39)

Seth, thanks for calling a spade a spade. As a Christian I believe what Christ says, which mentions nothing about hate, but

love. Some who are hateful are not true Christians, but want to belittle others to make themselves feel self-righteous. As a single man, i'm not zealous about the subject, but many parents do not want to live in a culture that promotes ideals that go against our beliefs and have their children believe what is not taught by our faith. The best solution would be to have the government get out of the business of sanctioning marriage. It is not biblical to put politics in the Christianity forefront. Christ said as much. God is love, that means everyone. I do not expect for one second for unbelievers to accept my ideals, or should anyone else who knows scripture. I do have difficulty understanding why those who are not religious to believe marriage to a same sex partner is necessary for happiness. Sorry, that so many on my side have come across as intolerant, but the same can be said for the other side. Also, where is the outrage against Muslims who put to death and are truly hate mongers of homosexuals. We ALL have done wrong and should not judge or expect others to believe as we do. If you do not believe as I do, then there is no reason to accept my view, but calling us all a hate group is not a good reason to condemn us for our beliefs. Tolerance. I hope we can all express our views without so much anger and hostility, but with open and honest discourse.

Margaret (2012-08-08 20:46:34)

BlueMorrissey: Thanks for most of that! (Mostly) quite reasonable. However, I would say: "where is the outrage against Muslims who put to death and are truly hate mongers of homosexuals" Well, they're not doing that in my town, or state, so I guess that's why we don't get as upset. What people do wrong here in America is more upsetting than what people do on the opposite side of the planet. It's just human nature to care more about things closer to oneself. And this? "I do have difficulty understanding why those who are not religious to believe marriage to a same sex partner is necessary for happiness." Well, why would one believe that marriage to an opposite sex partner is necessary for happiness? Or perhaps, since you're a single person, you'd rather not answer that. Anyway, what's the difference? Presumably many people, gay or not, wish to be married. Is that so odd?

BlueMorrissey (2012-08-08 21:04:59)

I understand we do not get outraged at Muslims because we do not interact with them much in this country. As a matter of fact I do not know any. By the way, they treat Christians in the same matter as homosexuals, so we can both agree that intolerance is wrong in every sense. You have a point about heterosexuals wanting to be married for happiness. I guess my own personal bias is that marriage is a religious ceremony and those who are not religious want marriage instead of a civil union. It's not odd I suppose. It doesn't affect me or Christians in the grand scheme of things. We believe Christ is God and all the other matters are societal and not a big concern of mine. I pray for Christians and non Christians all the same. We are all the same in some sense, but we just have different worldviews and should respect our differences. I just believe we can express our beliefs without being called a hate group just like gay people do not like being told God hates them, which is totally false. I do not have hate in my heart for anyone and I am sure many of those with different views feel the same. There are radicals on both sides. I do live in a bit of a cocoon, but have gay friends and relatives who I care very much for. I think the majority of true Christians feel the same way. Thanks for you reasonable response.

## **How Patrick Vlaskovits Discovered His Migraines Were Due to Wheat (2012-08-08 05:00)**

My personal science taught me that (a) there are useful things health experts don't know (b) that the rest of us can discover. I am curious how these discoveries are made. When [1]Patrick Vlaskovits [2]commented

I suffered migraines my whole life until my 30s. I am prescribed meds to help me manage the pain. These meds are better than nothing. Then I quit eating grain-based products, no migraines ever.

I asked him how he discovered the connection. He replied:

This was in years pre-Paleo – I played with Atkins and one day my wife said to me: "You haven't had a migraine for at least a month now." And it hit me, holy shit, I hadn't.

Until then, my whole life even as a small child, I would get insane mind-melting-migraines seemingly at random — and when they hit, my face would twitch and aside from the pain, I would experience hyper-light-and-sound-sensitivity. My response would be to sit the shower in the dark for hours on end and then crawl into bed to fall asleep and hopefully wake up sans headache. This was from grade-school through post-grad-school.

What no one had seen until then was the lag time between my digesting some wheat product and onset of migraine – usually about a day. Nowadays, I tend to eat wheat-free (and disallow it from my toddler's diet) but I will indulge in a NYC pizza or something similar if traveling – I reckon that about 10 % of those cheat instances I am hit with an earthshattering migraine.

BTW I mentioned this a few years ago to Ryan Holiday, and he mentioned it to his girlfriend – a few weeks ago I saw both of them in NYC, and she has a virtually identical story. Crazy.

He added later:

[After avoiding wheat] my nighttime tooth grinding also stopped as did my insomnia ["being tired but unable to fall asleep, would go to bed at 11pm, my mind would race for hours on end in a state of neither sleep nor being awake, I would finally fall asleep around 5 am, and have to get up at 730 am to go work, and be exhausted all day — this went on for years"] – generally, I feel 1000x better not eating wheat –

I have been tested with a skin-prick test and was told that that my results came back normal, not sensitive to anything.

I am unsure of what it is in wheat that I react to - an obvious culprit could be gluten in modern wheat, could also be mycotoxins (per Dave Asprey's thinking), could perhaps be pesticide residue; I simply don't know. – however, at the end of the day, it doesn't matter. A simple risk less change resulted in orders of magnitude change for the better.

Last thing, another family friend has a 10 year old who has migraines, I recounted my story to them and early evidence looks like health improvement via avoidance of wheat.

How well-known is this connection? A few articles mention it: [3]this one, for example. Here is [4]a whole paper – in 1979 – about how food causes migraines:

The commonest foods causing [migraines] were wheat (78 %), orange (65 %), eggs (45 %), tea and coffee (40 % each), chocolate and milk (37 % each), beef (35 %), and corn, cane sugar, and yeast (33 % each).

Thirty years later, this extremely useful information has yet to reach most migraine doctors, apparently. [5]An even older article (1976) said:

The 10 chief offenders among food allergens are cow's milk, chocolate and cola (the kola nut family), corn, eggs, the pea family (chiefly peanut, which is not a nut), citrus fruits, tomato, wheat and other small grains, cinnamon and artificial food colors. Food allergy results in a remarkable variety of clinical syndromes.

The Mayo Clinic website says that [6]migraines are sometimes caused by food but [7]fails to say that if you suffer from migraines you should try an elimination diet to look for possible causes.

Josh (2012-08-08 05:59:47)

Thanks for sharing Seth. I'll have to give this a try the next time my cluster headaches arrive.

dearieme (2012-08-08 07:32:34)

My blocked sinuses are made worse by citrus fruit. Dreadful shame - I love freshly squeezed orange juice, but there you are. But I'm not so sensitive that I've had to give up G & T. In my fifties I became intolerant to Brazil nuts and (I now suspect) hazels. Fortunately almonds are OK.

Aaron Blaisdell (2012-08-08 07:58:39)

"My whole life even as a small child" Hahahaha! I can't picture Patrick ever having been a "small" child! Seriously though, Brent Pottenger also banished the migraines that plagued him most of his adolescent and early adult life by giving up grains, especially wheat.

Kris (2012-08-08 11:25:25)

Same with me. I have been wheat free for over two years. I recently realized, I have not had a migraine in a long time, probably two years. I used to get them every month or so. Now it is a great excuse for not eating all the wheat I am offered, instead of an amorphous claim of trying to eat better. I tell them my doctor told me to do it and it has stopped my migraines. Also, since I stopped the wheat: Pre-diabetic symptoms - gone. Seasonal allergies- almost completely gone. Sinus infections- very rare, used to be regular. Stomach aches, heartburn- very rare, used to be common. Soreness after working out is drastically reduced. I could list things all day that are better.

How Patrick Vlaskovitz Discovered His Migraines Were Due to Wheat | Allergy to Wheat - Symptoms Treatment (2012-08-08 16:00:08)

[...] article: How Patrick Vlaskovitz Discovered His Migraines Were Due to Wheat This entry was posted in Uncategorized and tagged almost-completely, doctor, doctor-told, [...]

Tracy Caraker (2012-08-08 17:20:29)

I've noticed that my teeth grinding has stopped since going Paleo/wheat free. I haven't woken my husband in a LONG time! I'd been doing it so long, my canine teeth are flat!

Lori (2012-08-08 18:09:23)

Seth, Great post! I used to wake up every morning unrested and exhausted due to sinus inflammation. I thought the cause of the inflammation was due to environmental factors like dust, pollen, etc. This was not the cause! Ive been wheat free for three weeks now and I wake up every morning rested and not struggling to breath. Amazing that the source of my sinus inflammation

was from wheat.

Joe (2012-08-08 21:50:31)

I'm not an "anti-doctor" or "corporations are evil" type, but I really feel like the entire industry has been co-opted by the pharmaceutical companies. It seems like any time you go to a doctor, the first and only option they even consider is some kind of drug. Food, lifestyle, and vitamins don't even enter the discussion, and if you bring it up, they practically laugh it off. I research canker sores and the whole reason I do so is because I've had them my whole life and pretty much the most information I got from a doctor or dentist was, "Yeah, that happens to some people." I've had great success with Vitamin B12, and when I mention that to doctors, I usually just get a smirk and they pass it off as placebo. A placebo that doesn't work with any of the other supplements I've taken for some reason. It's a shame that this side of healthcare gets so ignored.

Sally (2012-08-09 06:39:46)

I had a similar experience. I suffered from migraines, frequent sinus infections, anxiety, heartburn and IBS symptoms my entire life. I guess I always thought this was the normal state, because my mother had the same problems. In February of this year, I did a 30 day Paleo challenge and eliminated all grains. Within a week, my chronic sinus congestion had disappeared, my digestive symptoms were gone, and I have not had an anxiety attack or a migraine in the past six months since continuing to avoid gluten.

### **Tyler Cowen's Unusual Final Exam (2012-08-09 05:00)**

In a discussion of college education – I believe there should be [1]more allowance for human diversity – sparked by [2]this post, Alex Tabarrok told the following story:

Tyler [Cowen] once walked into class the day of the final exam and said, "Here is the exam. Write your own questions. Write your own answers. Harder questions and better answers get more points." Then he walked out. The funniest thing was when a student came in late and I had to explain to him what the exam was and he didn't believe me!

I was impressed. This approach, unlike most exams but like actual economies, rewards rather than punishes specialization. I asked Tyler what happened. He replied:

I would say that the variance of the test scores probably increased!

I don't recall if I ever did that again for a whole exam but most of my exams do that for at least one question. It's the question where you learn the most about the student.

2. <http://marginalrevolution.com/marginalrevolution/2012/08/a-spontaneous-order-firm.html>

---

q (2012-08-09 05:43:53)

it's a good idea. my only recommendation would be to do this for an exam near the beginning of the class, just so you can act on the information you get while class is going on.

threepipeproblem (2012-08-09 05:52:30)

This is awesome. It's also awesome when bloggers one has independently elected to follow post about one another.

Wonks Anonymous (2012-08-09 13:52:52)

Your link goes to a post about Valve Software, not a final exam. Seth: The post about Valve Software led to the discussion.

Assorted links (2012-08-12 15:11:01)

[...] 2. Tyler Cowen's unusual final exam. [...]

Lonely Libertarian (2012-08-12 17:20:45)

One principle that I learned over my time doing consumer insights work is that we always tend to underestimate population variance - it is a LOT larger than we measure - Tyler's class is one more data point in support of that theory...

Joseph Ward (2012-08-12 20:29:15)

this is the best idea i've heard of in education. i totally agree with cowen that it might not be feasible for an entire exam, but this is great.

Matt (2012-08-12 21:35:59)

I sat an International Political Economy exam (set by the excellent Alex Coram) in which the final question was "Write a question you wish had been in this exam, and answer it". As I recall some students didn't appreciate that opportunity as much as I did. I think the approach is useful in that it rewards understanding rather than regurgitation, and that it contains a meta-question that is something like: which are the important topics in this course?

Josef (2012-08-12 23:26:40)

This is a good idea except that the question should be more specific and random if this tactic is used repeatedly. e.g. "Write your own question and answer it using cost-benefit analysis" "Write your own question pertaining to business cycles and answer it" This way students won't be tempted to spend large amounts of time designing their own exams beforehand.

Simon K (2012-08-13 04:46:20)

This is a similar approach to something I frequently do when interviewing candidates for jobs. The last question I'll usually ask each one is, "Is there anything else you wish I'd asked you?"

Jill (2012-08-13 04:49:14)

Just personally, if I were given an exam like that, I would want a list of keywords or something for guidance. I can imagine some students panicking and completely blanking on what topics the class covered.

Richard Bruns (2012-08-13 05:41:46)

I was an Economics TA for a few years. The last question on my (ten-question) final exams was always "List and discuss four things you have learned in this class that were not asked about on this exam." I generally got positive responses to that; people were eager to show off things that they had studied.

Chris MacDonald (2012-08-13 07:17:41)

One result of this strategy is that every student will be correct in their prediction of what will be on the exam. Regardless of which material is actually most important, if a student believes X, Y, and Z will be on the exam, she will study X, Y, and Z. Faced with an open-ended exam, she will write on what she has studied, namely X, Y, and Z. Or, in principle, another thing that might happen is that a student might write and answer a bunch of suitably difficult questions all rooted in materials from the last half of the course. That would lead to a high grade, despite ignoring (and perhaps being ignorant of) half the material. So, yes, additional constraints would be wise.

tt (2012-08-13 09:09:36)

my hypothesis: he didn't have an exam ready to give

ragbatz (2012-08-13 13:00:23)

In the 1960's a Harvard chemistry professor posed a question on a chemistry final examination along these lines: 10 % Extra Credit. Write a question to be used as an extra credit question on a final examination in chemistry. The ideal extra credit question should be worth about 10 % of the grade on the examination as a whole, and test facility with the material covered during the course. My friend Tom Hervey received full credit with the following answer: 10 % Extra Credit. Write a question to be used as an extra credit question on a final examination in chemistry. The ideal extra credit question should be worth about 10 % of the grade on the examination as a whole, and test facility with the material covered during the course.

John (2012-08-14 06:46:49)

I like the idea - how will the answers/questions be objectively assessed?

Boabdil (2012-08-14 15:31:45)

I once taught an upper division course. At the beginning of the course I handed out 100 questions. I told the students we will cover the answers to all 100 questions in the course. Further, each student will have 10 questions randomly chosen from the list of 100 questions on his Final Exam. I did not grade on a curve and I told them they could all get A's or everyone could Fail. Surprisingly, the grade distribution was not different from the other courses.

Eric H (2012-08-14 18:23:21)

tt - you evidently have no idea how fast Tyler reads and can generate content.

Swetha (2012-08-15 06:09:04)

What is "Hard" ? Aren't such things relative? So, evaluation would be based on the difficulty as perceived by the student or the teacher?

Sven (2012-08-17 08:28:53)

Seth, it amazes me that on this great blog full of great ideas you continually venerate a great big zero like Tyler Cowen. Thorstein Veblen, Jane Jacobs, Renata Adler, and ... Cowen? One of these things is not like the others... Seth: What's wrong with this post?

Dr. Mike Reddy (2012-08-22 03:10:45)

A few years ago, i was all over the UK papers (some positive, most negative) and had a 2 page spread in THE after doing this; in a more structured way though. Look up "lecturer lets students set own exam" on Google for the media coverage. It worked well as a pedagogic exercise/experiment in assessment for learning. As a PR disaster for my institution, it wasn't quite so good; the first act of the newly appointed VC was to make a statement supporting me on academic grounds, which I'm sure he wasn't pleased about. I even had a poison pen letter from a Daily Mail reader, and lost out at a subsequent job interview when it was raised :-( Oh well... Seth: for example [1]<http://www.dailymail.co.uk/news/article-393053/Write-exam-lecturer-tells-students.html>

Jeff Poitevint (2012-09-01 16:07:18)

I think it's a very good idea. You completely eliminate the possibility of cheating and get to evaluate one's understanding of the class. The smartest students would have evaluated the instructors positions on subjects and formed their exam based on what the professor believed.

## **How Martha Rotter Cured Her Acne By Self-Experimentation (2012-08-10 05:00)**

Several months ago I posted about [1]how Martha Rotter figured out that her acne was caused by cow dairy products. Now [2]a longer version of her story (by me) is on Boing Boing. There is a ton of useful information in the comments. Some examples:

"[3]Dairy is what caused my acne." Someone [4]replied: "Same here, specifically milk. I switched to soy milk in high school and my moderately-bad acne went away very suddenly. . . . If I eat a lot of cheese at once, like having pizza more than a couple days a week, my backne gets worse and I get acne inside my ears." [5]Someone else misunderstands genetics: "I do have tumor-forming disease (fortunately stable, and partially corrected with surgery) so I do have some sympathy when it comes to this sort of thing, but my condition is so well established as genetic I never even saw hope in trying to control it with diet." [6]Aaron Blaisdell had a well-established genetic condition (porphyria) that went away when he changed his diet.

[7]Someone else found that dairy mattered:

I had terrible acne as a teenager and I drank almost a carton of milk every day. . . . When I moved out on my own, I no longer had milk delivered at the door and I fell out of the habit of drinking it altogether, switching to tea and water instead. My face cleared within weeks. . . . Whenever I indulged in cheese, the break-outs returned.

[8]Someone else discovered multiple causes:

I have had strikingly similar experiences with a very particular form of acne, for years. Multiple doctors with no results until I got frustrated with it. I heard that the four most common causes of skin reactions can be wheat, milk, peanut butter and eggs - so I took all of them out \*and\* meat.

And watched my skin slowly return to normal.

After playing with my food by putting one thing in, seeing what happened, and then taking that out and trying something else, I found that wheat in particular is the trigger for me with dairy as a close second.

[9]Someone else: "I took wheat from my diet, and my skin cleared up. If I allow wheat back in for one day, the next day I have acne."

[10]Not all solutions were dietary:

My wife and I found the only thing that worked reliably—even including a couple of different kinds of antibiotics—was "the regimen" as described on acne.org. Basically you use a low-strength (2.5 %) benzoyl peroxide every day and moisturise like mad afterwards.

These are just examples. There are many more helpful comments.

MikeW (2012-08-10 08:29:52)

As one commenter says, "I suspect there isn't a one-size-fits-all solution to acne anyway." That seems a very sensible, obvious point. Walk around any American city and you'll see a huge variety in people's faces: skin/hair color, the shapes of their eyes, noses, mouths. I don't see any reason why that wide individual variability wouldn't also extend to food sensitivities. Nobody mentions food combinations. Personally, I don't have noticeable breakouts with wheat or dairy on their own, but eaten together (pizza, buttered waffles) they almost always give me trouble. My theory is that the butter makes my skin oilier, while the wheat has some inflammatory effects that obstruct the oil secretion pathways.

AM (2012-08-10 12:00:16)

I recently took the expensive ALCAT food "intolerance" test. So did a friend. We were each given a list of foods to avoid - completely different lists - and both of us have found some relief from our symptoms. Each of us is complex and unique, and only individualized testing (whether self-testing or a commercial battery of tests) can help us figure out the optimal path for ourselves. For one person it's drinking pork fat and avoiding milk - for another, it could be the opposite. Can we generalize at all? Smoking, mercury, and beefy running shoes: suboptimal.

Javeux (2012-08-10 12:33:23)

People use diet to overcome some of their ailments, but give up on dairy intolerance? I mentioned oestrogen inhibiting lactase in a previous comment, and it seems progesterone can do the opposite. Bacteria in the small intestine are also very efficient at inhibiting lactase. I'm sure there are many other factors than these three. Dr. Ayers talks about the importance of bacteria with lactose-digesting gene clusters, and some of his readers have overcome dairy intolerance by carefully consuming kefir and other LAB-containing foods. Those Peat-arians don't seem to have too much trouble overcoming it when they try either. I'm starting to translate "taking dairy out improved my acne" to "my diet sucks and my GI tract looks as good as my face during a breakout." I'm sure I could be wrong, but it definitely doesn't seem clear cut, and pizza was mentioned more than once in those comments. I don't think it's a case for demonising dairy.

## Edward Jay Epstein Reviewed Movies For Vladimir Nabokov (2012-08-11 05:00)

[1]Edward Jay Epstein attended college at Cornell. When he was a freshman, he took Vladimir Nabokov's [2]lecture course about European and Russian literature. Nabokov told his students that a great writer creates pictures in readers' heads. One of the exam questions, about Anna Karenina, was Describe the train station where Anna met Vronsky.

Epstein hadn't read the book. However, he had seen the movie, so he described in great detail the train station in the movie. After the exam, Nabokov asked to meet him. Epstein told him he hadn't read the book. Nabokov said it didn't matter, and gave him an A. He offered Epstein a job. Ithaca had four movie theaters. Movies were released on Wednesday, so every Wednesday each theater would have a new movie. Nabokov loved movies. He went on Friday. He wanted to know which movie to choose. Epstein's job, for which he was paid, was to watch all four movies and report back.

Epstein did this conscientiously but in retrospect, he said, one of his comments was a mistake. [3]The Queen of Spades (from Pushkin's story) was one of the movies. Epstein told Nabokov it reminded him of Dead Souls. (They were reading Dead Souls in class.) This interested Nabokov. He looked at Vera, his wife, who was sitting at his desk facing him. He asked Epstein why The Queen of Spades reminded him of Dead Souls.

"They're both Russian," said Epstein.

More: [4]Epstein tells the story himself.

B (2012-08-11 11:38:02)

What's the source for this story? Seth: Epstein is the source. He told me.

minderbender (2012-08-13 17:24:26)

I thought Anna and Vronsky met on a train, not at a train station. I have a vivid memory of snow swirling onto the train while it rushes back - from Moscow to St. Petersburg? - but Vronsky is only on that train because he has already fallen for Anna. They met, if I remember correctly, on the train going the other direction. Anyway, best book I've ever read.

## Eliminating Nocturnal Urination (2012-08-12 05:00)

A male reader who wishes to be anonymous writes:

I am 53. When I was in my late 40s I started having to wake up to urinate in the middle of the night. Sometimes more than once. I complained to the physician. He said, "That's BPH [= benign prostatic hyperplasia = enlarged prostate]. It's what happens in middle age. Live with it."

A couple years later on an airplane, I read an article about [1]pygeum [a herbal remedy] as a cure for BPH. I started taking some. It helped, but not a lot. Reading about pygeum I stumbled across saw palmetto. I started taking a supplement that contained both of them. Now I was much improved, but there was still room for improvement.

A friend told me about magnesium supplementation. I started taking magnesium in addition, and I was cured. It's like I'm in my 30s again. I only have to urinate in the middle of the night if I drink a lot of fluid right before bed.

Sleep is so important, this is really important. At a talk Thursday at the Ancestral Health Symposium, Robb Wolf quoted someone as saying, "If someone sleeps well, you can't kill them; if they sleep badly, you can't keep them alive."

1. [http://en.wikipedia.org/wiki/Pygeum\\_%28herbal\\_remedy%29](http://en.wikipedia.org/wiki/Pygeum_%28herbal_remedy%29)

---

Nick (2012-08-12 06:11:07)

Same thing happened to me. I was peeing every night at 4:00 am. Started taking one ZMA before bed, and it went away.

Javeux (2012-08-12 07:00:10)

I found more salt helped. I think a lot of people on wholefoods diets end up eating too little. I'm sure a good balance of all the electrolytes would be most effective, as well as avoiding drinking when you're not thirsty to meet some sort of arbitrary "healthy" H2O quota.

RyanE (2012-08-12 11:36:49)

I was starting with this problem until I found out I had sleep apnea. Since starting on the CPAP, I haven't gotten up in the night, and apparently this is fairly common.

AM (2012-08-13 08:43:51)

Google turns up quite a few studies looking at the effects of magnesium on vasopressin - a hormone very important for our sleep and for not-peeing.

Jim (2012-08-13 13:42:53)

I saw the link on the Happy Healthy Long Life Facebook page: there was a study that linked male waist size with urinary problems and sexual dysfunction. It may be of interest <http://www.newswise.com/articles/view/592070/?sc=sphn>

Brandon (2012-08-13 13:51:12)

Hi Seth, Can you ask your mystery male reader how much of each of the supplements he takes (and/brands he takes etc.)? Thanks, BW

by (2012-08-14 15:40:31)

Silent acid reflux is an inhibitor of good sleep and sadly there does not seem to be any way to know it's disrupting your sleep without seeing a doctor for a scoping.

shane (2012-08-14 17:31:13)

well seth, i just ordered some NOW Foods Pygeum and Saw Palmetto + Pumpkin Seed Oil and Doctor's Best High Absorption Magnesium. i'll give it a shot. thanks for posting.

by (2012-08-15 07:03:51)

Anyone, recommendations on good books on sleep? I read The Promise of Sleep by William Dement already, which was okay, but I feel there must be better out there.

mystery male reader (2012-08-17 12:07:12)

Brandon, I take Vitamin Shoppe vitamins. Magnesium Citrate Complex 160 mg magnesium as magnesium citrate, oxide 3x daily  
Saw Palmetto Plus saw palmetto extract 160mg pumpkin seed oil 40mg pygeum africanum 10mg 3x daily

Brandon (2012-08-20 10:59:49)

MMR, thanks for the follow up. On my way to purchase the above today. I appreciate it. Brandon

Jared (2012-08-20 11:56:59)

Thanks for the info, took extra magnesium chelate at night and now I dont have to get up many times in the night Before reading your blog i actually thought getting up in the night to go to the bathroom was normal!

Alex Chernavsky (2012-08-13 06:50:17)

Here's another article that I found to be interesting: [1]A very modern trauma It's a blog post about some new studies about post-traumatic stress disorder (PTSD). The studies suggest that this is a modern disease (soldiers from the American Civil War didn't seem to get it, for example).

1. <http://mindhacks.com/2012/08/11/a-very-modern-trauma/>

John Lawrence Aspden (2012-08-13 08:58:37)

Seth, can't imagine how you found my little blog. Sorry if you took any diss from it. You must admit your diet sounds like a (genius) hoax from a standing start! But the combination of actually feeling it working and reading your clear explanations and justifications of the theory have brought me round as far as 'A good idea, not proven'. I'd seriously like it to be true though. Not just for me (I'm usually slightly overweight) but for all the poor fat people in the world who are made extra miserable by idiots telling them it's their fault. The weak spot in the theory to me looks like 'set point adjusting to lack of flavours'. I can't imagine why it would work that way. I can imagine some poor caveman starving to death because last Tuesday he couldn't finish his plate of mammoth and now it's gone off! Surely he'd be well advised to eat everything he can get his hands on in mid-winter. Evolution does seem to come up with some spectacularly crap mechanisms, but control of appetite must be very ancient, and you'd think it properly debugged by now. Also, I get the impression that your diet just doesn't work for some people, so there must be some pieces of the puzzle still to put in, even if the theory's basically right. Why the hell has there not been any large-scale independent controlled experiment on this? The effect seems obvious, large, testable and Nobel-prize worthy. Seth: "The weak spot in the theory to me looks like 'set point adjusting to lack of flavours'. I can't imagine why it would work that way". My explanation: The weight control system uses the strength of smell-calorie associations to judge the abundance of food. When food is abundant, we eat food that tastes better (= stronger smell-calorie association) than when food is scarce. Zero smell-calorie association is treated as close to weak smell-calorie association. When food is scarce is when your set point should go down, just as when you are unemployed is when you should spend money in your bank account.

John Lawrence Aspden (2012-08-13 09:01:07)

Actually our caveman might get more benefit from sharing the spare food. Prediction: This only works in social species.

Jan (2012-08-15 02:40:38)

Sauerkraut: I will never ever cease to be amazed how some countries treat some foods like WMDs (or worse). This reminds me to go to our local market where a local sells home-made sauerkraut from a vat almost the way it was sold for hundreds of years [http://static.etrend.sk/uploads/tx\\_media/2007/01/22\\_Rac03.jpg](http://static.etrend.sk/uploads/tx_media/2007/01/22_Rac03.jpg). And then stop by a farmer to grab a bottle of raw milk to have a healthy sip! Jan

John Lawrence Aspden (2012-09-03 10:42:10)

Seth, second month of this didn't go so well, details here: <http://johnlawrenceaspden.blogspot.co.uk/2012/09/shangri-la-diet-fail-but-interestingly.html> I think I'm using the wrong types of oil. Do you have any specific recommendations for a particular brand that I'd be able to get hold of in England? I'd be quite happy to order it from America if necessary. This is interesting. Any other advice/tips also much appreciated.

## **"How We Stopped SOPA": Talk by Aaron Swartz in New York (2012-08-13 19:15)**

Aaron Swartz was a key figure in the successful fight against SOPA (Stop Online Piracy Act). On Thursday (August 16) he will tell how a tiny number of online activists managed to defeat a bill pushed by the entertainment industry, which had spent hundreds of millions of dollars per year trying to get it passed and believed its survival was threatened if it wasn't passed. [1]Aaron will speak at 7 pm at ThoughtWorks, 99 Madison Avenue, 15th floor, New York NY.

1. <http://www.thoughtworks.com/events/thoughtworks-new-york-and-aaron-swartz>

### Acne: Reality is Not a Morality Tale (2012-08-14 05:00)

Someone named Red Fury made an interesting comment on [1]my Boing Boing article about acne:

I had acne on/off for years. . . . In my mid-thirties, I tried the Retin-A at night, antibiotic gel for day regimen for about 2 years - no effect. . . . Then, I was talking to a co-worker whose daughter was taking 'modeling classes' to become a teen model. She casually mentioned her acned daughter had to give up rice, potato chips, and bread, all of which are high-glycemic index foods. My quack-radar went off, and I looked around for something scientific behind that advice. [2]<http://www.ajcn.org/content/86...>

Huh. I guess those nutrition-bashing dermatologists actually did a study and published the scientific results in a peer-reviewed journal. . . . My acne disappeared completely as soon as I eliminated rice and potatoes.

He finds a study that supports the casual advice, he follows the advice, his acne disappears. By convincing him to follow the advice, the scientific study helped him get rid of his acne. Which is impressive.

The interesting twist is that [3]the study was published twice, clearly breaking the rules. Bad scientists! Who did something really good.

Tuck (2012-08-14 06:48:22)

Wow, that approach sounds... scientific!

TMS71 (2012-08-14 10:46:25)

Doctors are reflexively dismissive of any claim that people can solve their own health problems. The case for a dietary cause of acne in Loren Cordains 'A Dietary Cure for Acne' was completely overwhelming, even elucidating the mechanisms. Docs are arrogant and ignorant and this is just more evidence that they don't deserve to be held in anywhere near the esteem that they are.

Adam (2012-08-14 16:47:24)

TMS71: I don't think Seth appreciates name calling & it doesn't seem productive to me here either. SOME doctors are arrogant & SOME doctors are ignorant. Don't hold these ones in esteem, but don't lump ALL doctors into one category. Some black people commit crimes, but how would it come off if I said "Black people are criminals"?

Evolutionarily (2012-08-14 22:33:27)

Adam it is a common human bias to make that error. If people hear that all terrorists are Muslim (not true), many people will mistakenly infer that all Muslims are terrorists. That mistake seems elementary, but I think we are all capable of making it in certain applications. Perhaps it is even the default... Does anybody know the formal name of this logical error?

nathan (2012-08-15 10:36:15)

Yep, I just found out that inadequate cleanliness is not the cause for acne outbreaks.

TMS71 (2012-08-15 10:47:09)

Dude, this story is a cliché. Most Docs are reflexively dismissive of any alternative approaches. Its infuriating and they deserve the name calling. As for those Docs who are open-minded, I'm sure they weren't offended. If the shoe fits - wear it.

Juha (2012-08-18 02:21:09)

I've learned that many foods high in carbohydrates cause me acne and heartburn. Three years ago I cut pretty much all sorts of candy and the like from my diet and a few weeks later I also dropped rice, potatoes, bread and pasta. I did this because I believed that the carbs in my diet aren't good for me (increase the risk for diabetes even if I'm not overweight). Over time I realized that my acne and heartburn symptoms have gotten better, too. Initially I wasn't sure if there's a connection but today it seems pretty obvious to me. If I eat any of those high-carb foods on lunch I often have some heartburn and acne in the evening. I don't like to eat those foods often but I don't always have a choice if I want to get enough calories so I unwillingly experiment with this several times a month. So far the evidence seems pretty convincing to me. What's curious is that lentils don't worsen my symptoms. They're high in carbs, too. I'm not sure but it could be that they also have quite a bit of protein and their glycemic index is roughly half what the GI is for rice, potatoes, bread and pasta. I find it interesting that several paleo bloggers suggest to avoid lentils because of their high phytate and lectin content. Rice may be okay since it's a "safe starch". At least for me it's the other way around.

Red Fury (2012-08-30 23:51:22)

Well, if you're interested in self-experimentation after consulting medical journals, I have decades of my own data! The most unusual experiment is discovering that my paternal family's centuries-long history of dying of massive heart attacks around the age of 60 is due to 'Familial Defective Apolipoprotein B-100', and it has inspired me to be the first one to Fight the Future through diet and exercise. BTW, I am female and a long-time Men's Health reader.

Dave Newman (2012-09-03 09:33:34)

Good Post! Other foods you may consider eliminating from your diet to cut down on breakouts are milk, sugar and most processed foods. Drink lots of water and eat a good diet of fruits and veggies.

Tom (2012-08-15 07:55:11)

Epstein's idea that Zakaria did not plagiarize is a bit of a stretch. If anything, what Zakaria did was even more cynical, since what he did was a widely known Internet method called "spinning". In spinning, individual words are swapped with their synonyms to proactively foil Google searches (which only detect identical text strings): [newsbusters.org/blogs/tim-graham/2012/08/10/talk-about-concealed-carry-fareed-zakaria-plagiarized-paragraph-history](http://newsbusters.org/blogs/tim-graham/2012/08/10/talk-about-concealed-carry-fareed-zakaria-plagiarized-paragraph-history) - In other words, Zakarias is not just copying, he's consciously attempting to destroy the evidence at the same time. It's pretty cynical, and when you compare the passages (which Epstein *doesn't* show, making it harder for readers to check his own work, ironically making his own article disingenuous for similar reasons), undeniable. Also, it's a little unfair to suggest Zakaria did it to improve Lepore's "banal" writing. "Banal" writing is not improved by spinning, as the sequence and structure of ideas (and, in fact, the ideas themselves) remain identical. He didn't do it to improve her work. He did it to steal it. Seth: I'm not saying Zakaria improved anything. I don't think Zakaria tried to "destroy evidence" - I think he thought it hardly mattered how the basic facts, which he properly credited, were laid out. You can't "steal" something that is worthless, which I think is a reasonably close description of how much Lepore added to what her source said (i.e., she added almost nothing). Yes, Epstein should have shown the two passages. But I agree with his big point. Zakaria is being punished for changing an insufficient number of words. Like Epstein, I disagree that this deserves the punishment that Zakaria is getting. Let's say I write "saturated fat is bad for you". Sure, I copied this from someone else. Should I be punished for not giving a source? I don't think so. It's a banality. The mainstream media commit major crimes every day - the way they trust self-interested experts who grossly distort the truth. To ignore those major crimes and focus on this trivial crime is yet another sign of how poorly the media police themselves.

q (2012-08-17 15:21:38)

i have a hearing disorder that can lead to hyperacusis and misophonia in some people. i have it as the result of some ear damage, probably from a virus. somw sounds appear distorted to me - for instance the S sound is louder than it "should" be. sometimes i find it unsettling and i feel anxiety because of that. sometimes i feel disoriented because it's harder for me to understand what's going on around me. if i weren't careful, it could become an anxiety type disorder.

Alex Chernavsky (2012-08-18 04:53:33)

Progressive's behavior is perhaps not quite as outrageous as it might seem at first glance. The *New York Times* covered the story here: [http://www.nytimes.com/2012/08/18/your-money/progressives-side-of-the-insuran ce-case-that-blew-up-on-the-internet.html](http://www.nytimes.com/2012/08/18/your-money/progressives-side-of-the-insuran-ce-case-that-blew-up-on-the-internet.html)

## **B. F. Skinner: Brilliant Engineer, Brilliant Self-Promoter, Mediocre Scientist (2012-08-16 05:00)**

I majored in psychology at Reed College. At the time, the whole major centered on Skinnerian psychology – the importance of reward in controlling behavior. The introductory course used a Skinnerian textbook (e.g., we learned the correct meaning of "negative reinforcement" – it does not mean punishment). Other courses also had a Skinnerian emphasis. They never convinced me. I always thought it was an exceedingly narrow way to study behavior.

When I was a graduate student, I visited Harvard and heard Skinner give a talk, titled "Why I am not a cognitive psychologist". During the question period I asked if he was familiar with the work of Saul Sternberg – perhaps the most influential cognitive psychologist. No, said Skinner. I thought it was foolish to criticize an area of research you know little about.

After I became a professor, I went back to Reed to give a talk. After the talk, I went out to dinner with several psychology professors. I told them I thought Skinner was a brilliant engineer – the Skinner box is really useful – but a mediocre scientist. He was unable to discover anything, he just repeated the same result (rewarding something increases how often it is done) countless times. They had no reply.

In the last two days, strangely enough, Skinner has come up in two different conversations. In the first, a friend said that Skinner's views about language were ridiculous. I agreed. Why write such nonsense? my friend asked/complained. I said maybe Skinner's productivity system worked too well. It caused him to write when he had nothing to say. In the second, a different friend brought up [1]David Freedman's recent Atlantic article called "The Perfected Self", which argues that Skinnerian techniques really work when you implement them as smartphone apps – techniques to lose weight, for example. "B. F. Skinner's notorious theory of behavior modification was denounced by critics 50 years ago as a fascist, manipulative vehicle for government control," writes Freedman (or an editor), but actually that theory is really good.

My area of academic psychology (animal learning) is the same as Skinner's. Within this field, I have never heard anyone complain that Skinner's work was "fascist" or "manipulative" or a "vehicle for government control." It never became popular – it was always a minority point of view – probably because it was boring (the same thing over and over) and perhaps because it was anti-intellectual. Skinner wrote a well-known paper about why theories are unnecessary. He didn't understand the role of theories in science and didn't bother to find out. Sure, the psychology theories of the time (1950) were awful. Psychology theories are still mostly awful. But there are plenty of good theories in other areas of science.

For a long time, Skinnerian ideas, nearly dead in academia, lived on in the treatment of autism. The people applying these ideas called themselves "behavior analysts" and the whole field of applied Skinnerian psychology was called "behavior analysis". What caused this persistence was that the techniques worked. Using the techniques (carefully rewarding this or that behavior) improved the lives of autistic children and their parents. Which was a real contribution. I could make a long list of famous psychologists who have done less to improve human well-being.

The success of Skinnerian ideas in improving the lives of autistic children should not be confused with figuring out what causes autism. To figure out the cause of autism is to figure out the environmental cause(s) – to which people with certain genes are more sensitive – and how autism can be avoided entirely, not meliorated. I have blogged about possible causes of autism [2]many times, in particular the possibility that [3]sonograms cause autism. I have no idea if behavior analysts understand the difference between melioration and figuring out the cause. Maybe Skinner would claim there is no difference – he was full of bizarre statements like that. If your child is autistic, you are in crisis. You have zero interest in questions about "cause" – you simply want help. In any form. Behavior analysts, while helping autistic children and their parents, contribute nothing that helps us find the cause of autism. Which, if you are planning on having children, you care about enormously. So you can avoid having autistic children.

So Skinner's legacy is mixed. The Skinner box is terrific. I happily used them in my research for years, even though I hardly believed a single word Skinner said. As an engineer – an applier of stuff discovered by others – Skinner made a lasting contribution. As a self-promoter, he was incredibly successful – he was on the cover of Time, for example. As a scientist, he was a zero. He discovered nothing that matters. As a thinker (e.g., the book Beyond Freedom and Dignity) he was less than zero. He was a charlatan, claiming over and over that he understood puzzling things (e.g., language) that he did not understand. An unusual mix. Few great engineers are charlatans.

Darrin Thompson (2012-08-16 06:17:06)

"If your child is autistic, you are in crisis." Yes. "You have zero interest in questions about "cause" — you simply want help." Well, sort of. You figure out really quickly that not many people can help much. But if I had good theories about cause I could use those to design interventions on my own. Somehow I've missed on behavior analysis for autism. I will have to look at it. We've got some behaviors at home that need, shall we say, meliorated. :-) Thanks for posting on that.

Jeremy (2012-08-16 15:46:00)

While I agree with many of your criticisms of Skinner I think your characterization of him as a charlatan is too harsh. Skinner did make real contributions to psychology, he framed operant behavior in a useful way and he provided an important critique of punishment that helped to reduce the use of punishment in schools and in the treatment of people with mental illness. Many techniques derived from operant approaches remain useful in education and therapy Although flawed I think Beyond Freedom and Dignity and Walden II are fascinating challenging books well worth reading. Seth: I agree that Skinner made real contributions to psychology: the Skinner box and cases where behavior analysis works, such as autism. I call that engineering. My graduate school advisor, Russ Church, who did a great deal of research about punishment, told me that Skinner ignored data about punishment that did not fit his beliefs. And continued to espouse those beliefs.

Txomin (2012-08-16 18:53:28)

I must say "Bravo!". For reasons unknown (or at least unsaid), it requires an uncommon degree of insight and honesty to voice this sort of criticism. Could you please do the same with Chomsky? He is even more deserving if possible as his tour de force has been far, far more duplicitous, devastating, fallacious, opportunistic, and, ultimately, inane. Seth: Thanks. Yeah, I feel the same about Chomsky as I do about Skinner, minus the brilliant engineer aspect. But I am not a linguistics professor and know far less about him. So I am not very qualified to comment.

David Johnston (2012-08-16 20:37:30)

Chomsky's work on the formal treatment of grammar had a heck of a lot of influence on the path of compiler development in computer science. Regardless of any relevance (or lack of) to human linguistics, Chomsky did good in the world elsewhere.

Angus Stocking (2012-08-17 06:43:19)

It's Freedman, not Friedman. Thanks for the link. Seth: Thanks for the correction.

Jeremy (2012-08-17 08:16:02)

"Skinner ignored data about punishment" This is undoubtedly true, Skinner's theory of punishment did not hold up. However, his work did inspire people to re-examine the use of punishment and to try to avoid it when possible. For a good examination of Skinner's work see the text book: Introduction to Learning and Behavior [Russell A. Powell, Diane G. Symbaluk, P. Lynne Honey]

Txomin (2012-08-18 15:01:04)  
@David. Compiler linguistics. Funny.

Aub (2012-08-21 06:39:07)  
Txomin, I'd love to hear you elaborate on your criticisms of Chomsky.

Hi Seth. The last link is broken - it should be: [www.economist.com/node/21560523](http://www.economist.com/node/21560523) Seth: thanks, fixed.

jimpurdy1943@yahoo.com (2012-08-19 11:39:48)  
The article about the human microbiome is interesting. If more people – and especially doctors – understood the importance of the bacteria that have co-evolved with humans and other mammals, there would be much less use of drugs that disrupt our gut microflora. Two examples: 1. ANTIBIOTICS devastate our good intestinal bacteria, and thus often create opportunities for drug-resistant pathogenic bacteria to colonize (colon-ize) our bowels. 2. ANTACIDS AND PROTON PUMP INHIBITORS (Nexium, for example) reduce the stomach acids which begin the digestive process and kill harmful bacteria. The result is that bad bacteria and undigested food get to the intestines, causing chaos. Doctors, who needs them? Well, maybe the millions of people who doctors have gotten addicted to painkillers.

garymar (2012-08-19 16:55:24)  
I read Ramachandran's *Phantoms in the Brain* book: absolutely fascinating but the technical portions were very heavy going. The comments in the psychiatrist's blog point to a likely reason for his not thinking of using the mirror technique: if he tries it and it doesn't work, then he's labelled 'altie woo-type', the patient might complain about his unorthodoxy, etc. Malpractice suits hang over every doctor.

Adam (2012-08-19 17:33:34)  
Great post there by the Psychiatrist. "Without ducking responsibility, what's wrong with medicine today is that it is predicated on providing treatment, not on reducing suffering. Not on solving problems. The reason it never occurred to me to use

the mirror is because the mirror is not something doctors do. Never mind it is fairly safe. What we do is offer treatments. Medications. Procedures. Not \*maneuvers\*."

Alex (2012-09-17 08:27:33)

The same passage Adam quoted above in the psychiatrist's article stood out in blinking neon for me as well. This is precisely why I have found personal science such an important component of tackling my kids' autism. Reading you, Seth, opened my eyes to the possibilities. Life is one big experiment now. Thank you, Seth!

### **More Dairy Fat, Less Heart Disease (2012-08-20 05:09)**

I found that [1]butter made me faster at arithmetic. This contradicted the usual view that butter is unhealthy. However, there is plenty of evidence that the usual view is wrong. The latest issue of the American Journal of Clinical Nutrition contains another example. [2]An epidemiological article titled "Dietary intake of saturated fat by food source and incident cardiovascular disease: the Multi-Ethnic Study of Atherosclerosis" found a negative correlation between dairy fat and heart disease:

Although dietary recommendations have focused on restricting saturated fat (SF) consumption to reduce cardiovascular disease (CVD) risk, evidence from prospective studies has not supported a strong link between total SF intake and CVD events. . . . After adjustment for demographics, lifestyle, and dietary confounders, a higher intake of dairy SF was associated with lower CVD risk [HR (95 % CI) for +5 g/d and +5 % of energy from dairy SF: 0.79 (0.68, 0.92) and 0.62 (0.47, 0.82), respectively].

However, saturated fat from meat was associated with more heart disease:

In contrast, a higher intake of meat SF was associated with greater CVD risk [HR (95 % CI) for +5 g/d and a +5 % of energy from meat SF: 1.26 (1.02, 1.54) and 1.48 (0.98, 2.23), respectively].

It isn't obvious how to explain the interaction (the direction of association of saturated fat depends on whether it is in dairy or meat). The authors conclude:

Associations of SF with health may depend on food-specific fatty acids or other nutrient constituents in foods that contain SF, in addition to SF

[3]This recent article also questions the idea that dairy fat causes heart disease. One more reason to question conventional nutritional advice.

1. <http://blog.sethroberts.net/2011/11/25/butter-and-arithmetic-how-much-butter/>

2. <http://www.ajcn.org/content/96/2/397.abstract>

3. <http://intl-advances.nutrition.org/content/3/3/266.abstract>

---

dearieme (2012-08-20 05:14:45)

'conventional nutritional advice is less certain than its proponents say': how true. It's like the global warmongers - the lack of intellectual humility is appalling.

Txomin (2012-08-20 05:53:57)

Indeed. The ineluctable foregone conclusion of certainty... smoke, anyone? It is as if anything less than absolute unquestionability in a number of matters implies some sort of treason.

Jim Purdy (2012-08-20 07:22:06)

The "official" advice about cholesterol and saturated fat is very inconsistent. For example, the website of the National Institutes of Health has links to many research studies that seem to show benefits from both saturated fat and cholesterol. And, by the way, the NIH website and the FDA website contradict each other on many issues, especially involving drug safety (the FDA never met a BigPharma drug it didn't like, while the NIH links to many studies about the damage done by drugs.). I tend to trust the NIH much more than the FDA, largely because of the FDA's horrible record of financial conflicts of interest. Recently, based on my reading of information on the NIH website, I began eating a diet of up to a dozen or more hard-boiled eggs daily, with great results. My weight is the lowest in years, my blood sugar is dropping, and my blood pressure is also much lower. On my little blog (<http://nihsearchengine.blogspot.com/>), I have an unofficial search engine of the NIH website, as well as links to NIH information about topics like "Saturated fat and heart disease" and "Eggs and dietary cholesterol." I better finish this comment now, before all these whole eggs kill me.

Links « Rhymes With Cars & Girls (2012-08-21 06:05:52)

[...] Roberts, More Dairy Fat, Less Heart Disease. My first thought here was, don't Indians get heart disease? Presumably whatever effect there [...]

worthwords (2012-08-21 08:54:12)

»I found that butter made me faster at arithmetic. This contradicted the usual view that butter is unhealthy. What do you mean by this? I think the usual view is that TOO much butter means a diet high in saturated fats which is seen as a risk factor for coronary heart disease. How on earth does your one man unblinded experiment contradict that? There's a lot of unknowns about interactions between food and health which is why lots of studies such as the one you referred to are conducted. 'Usual' Dietary advice evolves with evidence (assuming food industry lobbyist are tamed). The problem with dietary advice is that it's almost impossible to run trials and identify co-founders so you resort to theory testing. If some epidemiological study of sufficient power shows that those eating more butter are more likely to develop CHD, then it's reasonable to suggest there may be a link - however you cannot imply causation from such studies - food, people, genetics, diets are too complex. Butter eating may just be a confounder for another factors. That's how we end up with very broad classifications of healthy diets such as "Mediterranean diet/lifestyle". Consuming cholesterol from eggs is not the same as having high blood cholesterol. Eggs are generally do not need to be restricted. Seth: My butter results contradict the usual view because they suggest that butter improves brain function, which is part of health..

Jim Purdy (2012-08-21 11:33:02)

Seth, does butter really make you better at arithmetic? I suspect that a better explanation is the old cliché, "Practice makes perfect," which would mean that butter would give you the illusion of making you better at anything you do often, whether arithmetic, or chess, or public speaking, or weight lifting. In that case, it would be the repetition, not the butter. Seth: Butter made me suddenly better, after a long time when I didn't improve. There is also other evidence for my explanation, including that when I reduced how much butter I ate I got worse.

Adam (2012-08-21 17:19:31)

While it is true some data suggest Fat intake is associated with CVD, there's also data that suggest Fat intake is associated with increase length of lifespan. Here's data from the 7 country study, which is often used to try to convince people NOT to eat Fat: [http://rawfoodsos.files.wordpress.com/2011/12/fat\\_life\\_expectancy\\_men\\_1950.jpg?w=408&h=363](http://rawfoodsos.files.wordpress.com/2011/12/fat_life_expectancy_men_1950.jpg?w=408&h=363) Since this recent study showed DECREASED risk for CVD, maybe Dairy is the ultimate source for getting that life-saving Fat; decrease your risk for CVD \*AND\* increase the length of your life! Sounds like a win-win to me.

## **Lessons of SOPA: How a Slam Dunk Bill was Stopped (2012-08-21 08:00)**

Passage of SOPA (Stop Online Piracy Act) seemed inevitable. It was introduced with 40 Senate co-sponsors, including plenty of both Republicans and Democrats. (At the time it was called PIPA – Protect IP Act.) Senate passage requires 51 votes; to override a filibuster you need more. The entertainment industry (Hollywood) had spent hundreds of millions of dollars per year to pass such a bill; the people behind the lobbying felt the survival of their industry was at stake. Senator Patrick Leahy, whose office wrote the bill, is in the new Batman movie.

Yet SOPA was defeated.

The story, as I was told it, begins on a Sunday. The bill was scheduled for a vote on Wednesday, three days later. [1]Peter Eckersley, who works at the Electronic Freedom Foundation in San Francisco, called [2]Aaron Swartz, who lives in New York, to ask, "How are we going to defeat this?" At that point, Aaron hadn't heard of it. [3]Aaron's talk about this.

It is a stunning example of David defeating Goliath. I asked Aaron what he learned from it. He told me three lessons:

1. Popular support matters. It can overcome large amounts of money. The anti-SOPA forces spent little money but got many people to tell their Congressman or Senator that they opposed the bill. The domain registrar GoDaddy [4]reversed its position on the bill. Aaron worked with lobbyists for Google. The lobbyists believed, at least at first, that the bill could not be stopped, only weakened.
2. A little-known issue can be made a well-known issue. When SOPA was introduced, shortly before the scheduled vote, no one had heard of it. At MSNBC, and presumably other news organizations, employees were told not to cover it. When people at Google were approached to support the opposition, at first they said the bill couldn't possibly be that bad or they would have heard of it. Without coverage by MSNBC etc., eventually everyone heard of it.
3. People will act if they can be convinced they are responsible. People at Wikipedia and Google, not to mention the originator of the GoDaddy boycott, were convinced to act, says Aaron, because they were convinced that they bore responsibility for the outcome, whatever it was. (I would put it differently. I would say they were convinced they could help determine the outcome.)

What interests me most about this story is how wrong the lobbyists were. They're the experts in how to change/defeat legislation. They were utterly wrong. They understood the forces within their system but had no understanding of what was possible outside their system. I think healthcare experts will turn out to be equally wrong.

The entertainment industry (Hollywood) had spent hundreds of millions of dollars per year to pass such a bill; the people behind the lobbying felt the survival of their industry was at stake. Senator Patrick Leahy, whose office wrote the bill, is in the new Batman movie." This is incorrect. SOPA (Stop Online Piracy Act) was introduced by Lamar Smith to the House of Representatives. PIPA (PROTECT IP Act) was introduced to the Senate by Patrick Leahy. Two completely different bills, both introduced at nearly the same time and both attempting to accomplish the same thing. Pretty much the rest is correct though, it had bi-partisan support (SOPA introduced by a Republican and PIPA by a Democrat). [http://en.wikipedia.org/wiki/PROTECT\\_IP\\_Act](http://en.wikipedia.org/wiki/PROTECT_IP_Act) [http://en.wikipedia.org/wiki/Stop\\_Online\\_Piracy\\_Act](http://en.wikipedia.org/wiki/Stop_Online_Piracy_Act)

James A Donald (2012-08-21 18:22:30)

Lobbyists are always in favor of a bigger, more intrusive, more activist, and more interventionist state, since that is more money in their pockets, even though it is often less money in the pockets of their clients. Lobbyists are excessively cozy with the state. Let us suppose you are a big business that employs a team of lobbyists. Chances are Senator big shot will call up your lobbyists, and ask "what most terrifies your biggest paying customers. What could plausibly pass, and create the most horrifying ruin and destruction for them. They will tell him. He will then introduce the bill, in order to get paid off for it not passing. Seth: In this particular case, you could say the lobbyists believed that only tweaking was possible because that is the main thing lobbyists are paid for.

## **Why Self-Track? The Possibility of Hard-to-Explain Change (2012-08-22 05:00)**

My personal science introduced me to a research method I have never seen used in research articles or described in discussions of scientific method. It might be called wait and see. You measure something repeatedly, day after day, with the hope that at some point it will change dramatically and you will be able to determine why. In other words: 1. Measure something repeatedly, day after day. 2. When you notice an outlier, test possible explanations. In most science, random (= unplanned) variation is bad. In an experiment, for example, it makes the effects of the treatment harder to see. Here it is good.

Here are examples where wait and see paid off for me:

1. Acne and benzoyl peroxide. When I was a graduate student, I started counting the number of pimples on my face every morning. One day the count improved. It was two days after I started using benzoyl peroxide more regularly. Until then, I did not think benzoyl peroxide worked well – I started using it more regularly because I had run out of tetracycline (which turned out not to work).
2. Sleep and breakfast. [1]I changed my breakfast from oatmeal to fruit because a student told me he had lost weight eating foods with high water content (such as fruit). I did not lose weight but my sleep suddenly got worse. I started waking up early every morning instead of half the time. From this I figured out that any breakfast, if eaten early, disturbed my sleep.

3. Sleep and standing (twice). [2]I started to stand a lot to see if it would cause weight loss. It didn't, but I started to sleep better. Later, I discovered by accident that [3]standing on one leg to exhaustion made me sleep better.

4. Brain function and butter. For years I measured how fast I did arithmetic. [4]One day I was a lot faster than usual. It turned out to be due to butter.

5.[5] Brain function and dental amalgam. My brain function, measured by an arithmetic test, improved over several months. I eventually decided that removal of two mercury-containing fillings was the likely cause.

6. Blood sugar and walking. My fasting blood sugar used to be higher than I would like – in the 90s. (Optimal is low 80s.) Even worse, it seemed to be increasing. (Above 100 is "pre-diabetic.") [6]One day I discovered it was much lower than expected (in the 80s). The previous day I had walked for an hour, which was unusual. I determined it was indeed cause and effect. If I walked an hour per day, my fasting blood sugar was much better.

This method and examples emphasize the point that different scientific methods are good at different things and we need all of them (in contrast to evidence-based medicine advocates who say some types of evidence are "better" than other types – implying one-dimensional evaluation). One thing we want to do is test cause-effect ideas (X causes Y). This method doesn't do that at all. Experiments do that well, surveys are better than nothing. Another thing we want to do is assess the generality of our cause-effect ideas. This method doesn't do that at all. Surveys do that well (it is much easier to survey a wide range of people than do an experiment with a wide range of people), multi-person experiments are better than nothing. A third thing we want to do is come up with cause-effect ideas worth testing. Most experiments are a poor way to do this, surveys are better than nothing. This method is especially good for that.

The possibility of such discoveries is a good reason to self-track. Professional scientists almost never use this method. But you can.

---

Jim Purdy (2012-08-22 05:58:53)

Getting taken seriously when I do any self-tracking is an uphill battle when I'm dealing with arrogant jerks in long white coats (a.k.a. MDs). They dismiss my experiences as anecdotal, and if I don't slavishly follow their "doctor's orders," they call me noncompliant, nonadherent, crazy, and suicidal. At that point, I have a name for them. I call them my ex-doctors. An arrogant jerk is still an arrogant jerk, even if the jerk wears a long white coat.

Lisa Wiland (2012-08-22 07:21:10)

I'm interested in self-tracking, but I haven't figured out HOW to do it (without it being too cumbersome / time consuming / inconvenient). Is there something you've written (or someone else has written) that gives tips to a beginner? I imagine you've learned a lot over years of doing this about what makes it easy enough to stick to. When you suggest that one measure something daily, then wait and see ... well, I'm trying to think about what sorts of things are likely to be worth measuring. I guess that depends on the individual, and what issues/problems they'd like to improve. Sleep and mood are clearly useful

ones. Weight too.... But I'm curious - what do YOU measure daily? And - about how much time does your self-tracking take (not analyzing / making connections, just the stuff you record each day)?

Seth Roberts (2012-08-22 09:08:57)

I measure daily: 1. weight. 2. fasting blood sugar. 3. sleep. 4. brain function. It takes about 7 minutes.

Jim Purdy (2012-08-22 11:59:59)

Seth, Im sorry, but I'm still a skeptic about your butter-arithmetic hypothesis, and your assertion that consuming butter makes you feel better. In one of the Public Library of Science blogs, "Obesity Panacea," a recent post called "Does thinking hard impact your heart?" made this statement: "The results of this study suggest that an experimental mental work condition consisting of a 45-min period of reading and writing a summary, as other types of mental work (such as arithmetic) utilized in the laboratory, can modulate cardiovascular responses in healthy young adults through a reduction in cardiac parasympathetic activity." In other words, perhaps it is the mental work (arithmetic), not the butter, which makes you feel good. (But my long-ago calculus class at Duke in 1961-62 sure didn't make me feel good. And the grade I got really made me feel bad.) <http://blogs.plos.org/obesitypanacea/2012/08/09/does-thinking-hard-impact-your-heart/> Seth: I believe butter makes me faster at arithmetic. From your comment I am unable to figure out why you question this. I have not studied mood effects of butter.

Nancy Lebovitz (2012-08-23 04:07:50)

I've heard about that sort of neutral accumulation of data in studying nature- there are projects that keep track of bird-watching results. I've heard of another project of that sort done by scientists- I'll post if I remember any more details. The Longevity Project is probably another one. Seth: Many scientific projects collect data over long periods of time (years). In psychology this is called longitudinal research. In psychology at least, the people who do these studies don't try to learn the cause of sudden changes (if any). In what I've seen, they ignore them.

Nancy Lebovitz (2012-08-23 04:08:31)

I agree that data accumulation is a rare way to do science, and there should be more of it. Seth: Data accumulation is common. Outlier investigation is rare.

Shawn (2012-08-23 04:13:34)

Thanks for this post. Ever consider posting some of the templates you use for self-tracking? Regarding one-legged standing, I've been doing it for a few days now and am getting restorative sleep that I have rarely had since childhood, where I was on my feet for a large chunk of the day playing. I wonder why I didn't think of doing something so simple on my own; clearly it would have helped to have used a journal.

Adam (2012-08-23 05:58:58)

Seth, you wrote: "I measure daily: 1. weight. 2. fasting blood sugar. 3. sleep. 4. brain function. It takes about 7 minutes." 1. is obvious. 2. I'm interested in, but a Glucometer is expensive. Are you testing only once a day? When do you test? Seth: I test once/day at 8 am. 3. I've heard you describe before. You record your subjective feeling of restedness on a scale from 0 to 100, including decimals (ie 97.5). 4. You test with solving arithmetic in some program. Any chance you could share the details if not the program itself? Seth: I will soon announce a way that a small number of people can use the test I now use. I no longer use an arithmetic test.

Web comic for a future Assorted Links page: <http://xkcd.com/1096/>

dearieme (2012-08-23 09:26:10)

I dare say that a Nobel prize goes, from time to time, to what used to be known as an "operator". Since learned societies presumably increasingly fill up with "operators" (consider the state of the Royal Society), what is to be done? Surely few Real McCoy scientists would want to spend their energy and time on crusades to put things right?

BenSix (2012-08-23 10:26:06)

I wonder if people who collect one thing obsessively sneer at the fanatical collectors of another. "Spending all my money on King George coffee mugs is one thing but wasting thousands of vintage striptease costumes? That's *weird*."

minderbender (2012-08-23 16:23:21)

BenSix, I think that can be answered with another recent XKCD: <http://xkcd.com/1095/>

dearieme (2012-08-25 14:02:21)

@Seth, have you any views on these remarks about rice? <http://chiefio.wordpress.com/2012/08/24/you-are-what-you-eat/#comment-39476> Seth: It reminds me of what a friend said: "If rice were so bad for us, the Japanese wouldn't be the healthiest people in the world."

Vic (2012-08-25 21:10:12)

Japanese aren't the healthiest people in the world. They have extremely high incidence of hemorrhagic stroke, one of the most terrible conditions imaginable, and very high incidence of digestive cancers. Japanese male life expectancy is lower than

male life expectancy in Switzerland, Iceland, and Israel. Seth: Thanks for the correction – if it is true that the Japanese (male and female together) do not have the longest life expectancy in the world.

Frank (2012-08-26 12:59:47)

Hey there. Why did you shut down the discussion about Canker Sores. I wanted to see if Heidi from Canada found her cure. I have had Canker Sores for a decade, 2-3 large ones at a time. Then I went vegan and suddenly POOF they were gone for 2 months. But now they are back. Smaller and less frequent. I did accidentally have Walnuts and Flaxseed oil in my diet. Maybe I need to increase them. What is confusing is some sites say Walnuts cause canker sores. Maybe it is just an allergic reaction some people might have.

### **Want to Track Your Brain Function? (2012-08-28 07:28)**

I am looking for people who want to try a mental test I have developed to track brain function. You do it on your laptop, once or more per day. One test session takes three minutes. For five years, I've been using various tests to track my

brain function – first, balance, then, for a long time, arithmetic speed. The new test is better than these earlier tests, at least for me, because I find it enjoyable, which makes it easy to do several times/day. Via brain tracking, I have found that flaxseed oil and butter make my brain work considerably better. I was also able to find the best dosages. I believe that learning what foods (and dosages) make your brain work best is a good way to figure out what foods (and dosages) are best for the rest of your body. For example, after I figured out what amount of flaxseed oil was best for my brain, my gums became much healthier (less inflammation). The new test, which I do more often than the older tests, has made clear that there are all sorts of reliable yet mysterious ups and down in my brain function. I was unaware of this.

I want to find out what happens when other people use the new test. I am looking for a small number of people to do the test at least daily and send me their data at least weekly for at least 3 months. The test requires a computer running Windows 7. The test is written in R (free), but you don't need to know R to use it. The installation requires details that I will need to handle by talking with you.

To find people to do this, I will use a bidding system. (Giving a program to those who ask for it is a waste of time, I have found.) The questions below ask for two bids: non-refundable and refundable. If you use it as promised – you set the details of how much you will use it – you get back the refundable amount.

If this interests you, please apply by sending an email to [try.brain.tracking \(at\) gmail.com](mailto:try.brain.tracking@gmail.com) with answers to the following questions (as email text, not attachment):

1. Name, age, sex, location, job.
2. Computer you will use it on (e.g., Thinkpad 520), age of computer, operating system.
3. Phone number (and Skype id, if any). I need to talk to you to set it up.
4. Website or blog (if any).
5. Any relevant expertise or experience? (e.g., work with computers, researcher, other self-tracking)
6. Non-refundable amount. How much (U.S. dollars) are you willing to pay (via PayPal) to get this test?
7. Over 3 months, on what fraction of days will you commit to doing the test at least once? at least twice?
8. Refundable amount. This money will be refunded if you meet the goals you set in Question 7 and send me the data at least 6 times (spaced at least one week apart).
9. Anything you want to add?

You will get an automated reply. After that, I will contact you only if I want more information or if yours is one of the winning bids.

Clyde Adams III (2012-08-28 09:39:04)

"...send me the data at least 6 weeks." It looks as if there is a word or phrase missing here. Perhaps you meant: "...send me the data [for] at least 6 weeks."

AM (2012-09-11 09:20:39)

I must not be the only one of your readers who has (only) a Mac. Seth: The brain tracking program uses an R program only available for Windows. There is no easy way around this, I have found.

"During this past century, there have been few, if any, studies reporting on the energy value of a whole food within a mixed diet that could confirm the accuracy of Atwater's coefficients." If you allowed bad language here, I might call that a fucking disgrace.

David Johnston (2012-08-29 15:39:15)

The almonds calorie link is sent through [proxy.michaelhartog.com/](http://proxy.michaelhartog.com/). This is blocked by many company filters. All you need is the latter part. I.E. <http://www.ajcn.org/content/96/2/296.full>

### 50 Years of Knuckle Cracking Did Not Produce Arthritis (2012-08-30 05:00)

Warned by relatives that knuckle cracking causes arthritis, Donald Unger decided to crack only the knuckles of his left hand. For 50 years he frequently cracked his left hand, never his right. Finally he wrote [1]a letter to a scientific

journal (in which he calls himself "the author") pointing out that he did not have arthritis in either hand, supporting the conclusion of another study which studied a much smaller amount of knuckle cracking.

Thanks to Bryan Castañeda via [2]Now I Know.

1. <http://blog.sethroberts.net/wp-content/uploads/2012/08/knuckle-cracking-for-50-years.pdf>
2. <http://nowiknow.com/>

---

gwern (2012-08-30 07:57:56)

And in gratitude for his decades of work, he received... an Ignoble Prize.

Jim Purdy (2012-08-30 09:12:09)

The National Institute of Health website has links to many published studies which show little or no harm from long-term knuckle cracking. However, according to a 1990 report (<http://www.ncbi.nlm.nih.gov/pmc/articles/PMC1004074/>): "Habitual knuckle cracking was associated with manual labour, biting of the nails, smoking, and drinking alcohol." Just wondering: Does Donald Unger drink, smoke, bite his nails, or do manual labor? Seth: Unger's study was better controlled than any of the NIH studies, in the sense that the hands being compared were identical in terms of diet and genetics.

Bob (2012-08-30 11:58:23)

He's an internist in Thousand Oaks. BTW, the reply to Unger's letter is funny & worth reading.

Roger Sweeny (2012-08-30 13:24:35)

This whole thing is, of course, a joke. It is one of the recipients of the 2009 Ig-Nobel Prizes. Seth: Calling someone's 50-year project "a joke" is not terribly nice. What do you mean by "a joke" and how do you know it is "a joke"?

garymar (2012-08-30 18:03:16)

Unger's letter is light-hearted and whimsical ("spinach-eating"!) and the authors of the previous study answered in kind. So in a way it is a joke, on both their parts. More like a case study so of course it's statistically 'underpowered'. Seth: "Joke" usually means "didn't actually happen" ("I was joking!"). I see nothing to suggest that what Unger described didn't actually happen. In fact, I believe Unger – like most of us – is not creative enough to make such stuff up.

Roger Sweeny (2012-08-31 08:16:15)

Seth, You're right. I don't know whether the 50-year "self-controlled study" actually happened or not. It's certainly not impossible but fifty years of one-sided knuckle cracking seemed unlikely to me. The letter and response read like satire to me. The response is certainly satire, especially the "statistical analysis" of Dr. John Adams, e.g., "Typically, sample sizes of roughly twice the available research budget are required for valid inference." (Not seeing a journal name at the top or bottom of either page also made me suspicious.) If I had access to a medical library, I would see if the cited 1973 article actually exists (I'm so ignorant I don't even know if there was a Western Journal of Medicine in 1973). If I was a hot shot Berkeley Psychology Professor, I'd call Dr. Unger and ask him personally whether the letter described something that had actually happened or was "a joke." It is funny.

Roger Sweeny (2012-08-31 08:25:38)

As a very ordinary person, with access to the extraordinary Internet, I could google "Donald L. Unger." There I would find a couple of stories that indicate the project was indeed real and not a joke. Probably should have done that before I commented :)

Tom (2012-08-31 15:09:36)  
Or you could call him. office Phone: (805) 494-4505

### **Textbook Buying Tip (2012-08-30 12:22)**

I met a Berkeley student who paid \$17 (including shipping) for Statistics (4th edition = latest edition) by Friedman, Pisani and Purves at abebooks.com. She got an edition meant for India, but the text is the same. [1]The current lowest price at abebooks is \$37 (including shipping). Amazon charges \$108 (including shipping). More Dave Lull points out it is even less ( \$25) [2]elsewhere.

1. <http://www.abebooks.com/servlet/SearchResults?bi=0&bx=off&ds=30&isbn=0393929728&recentlyadded=all&sortby=17&sts=t&x=45&y=13>
2. <http://www.bookfinder.com/search/?keywords=0393929728&st=sh&ac=qr&submit=>

dearieme (2012-09-01 05:59:17)

On what evidence could a jury think that Macdonald's guilt was beyond reasonable doubt? In Britain there are, from time to time, cases where the prosecution's case is so weak that the judge throws it out without any need for a jury decision. Do any of the US states allow that?

Matt (2012-09-01 13:31:57)

I wonder if ice cream is supplying me with a nutrient I am deficient in...

garymar (2012-09-01 17:45:46)

Fantastic scenes of cities in China uninhabited years after construction, with a goatherd tending his goats past immaculate, empty government buildings. I especially like the "Dinosaur" city of Erenhot. I saw an awful lot of high-rise apartments in Shenzhen that were all filled, with laundry hanging out, TV antennas and dishes, etc. But that was 4 years ago.

Bryan (2012-09-01 23:55:41)

dearieme: First, the vast majority of cases – be they civil or criminal – never reach trial. The great majority of civil cases are settled and criminal trials are plea bargained. In civil cases, a defendant can move for summary judgment, which essentially challenges the sufficiency of the plaintiff's case. This is a pre-trial motion that, if granted by the judge, ends the case. In criminal cases, there is no such mechanism. Thus, trial is the only way to test the sufficiency of the prosecution's case/evidence.

Practically, if the prosecution has a very weak case, it won't go through the time or expense of trial. But, if the case is high-profile like the McDonald murders (or the prosecutor is overzealous), the pressure will be great to take it to a jury. There's not much the judge can do stop it.

dearieme (2012-09-02 02:30:04)

Bryan, in British criminal trials the judge has the power to listen to the prosecution case and, if he thinks it lame enough, stop the trial, discharge the jury and deliver a verdict of not guilty himself, without hearing the defence case. I don't suppose it's done often, but you see it in the papers from time to time. I imagine that it leads to peppy debate in the Prosecutor's office. I imagine that it's intended to.

Michael (2012-09-02 23:21:30)

I'm not a lawyer, so I'm not sure on the details, but in America, at least at the Federal criminal level, a judge can simply enter an acquittal without sending the trial to jury, or disregard a jury's guilty verdict and enter an acquittal (called "judgement notwithstanding verdict"). The judge cannot throw out a not-guilty verdict and enter a guilty verdict however, as that would violate the sixth amendment right to a trial by jury. How often this comes up, whether it's the same at state level, or how it works in civil cases, I don't know. At the Federal criminal level, it's in the Federal Rules of Criminal Procedure section 29.

AM (2012-09-11 09:32:54)

Mmmm ... Marmite ...

### Assorted Links (2012-09-03 05:00)

- [1]Five quantified-self stories
- [2]False Alzheimer's diagnosis. "Alzheimer's symptoms such as confusion, memory loss and personality changes also can be side effects from medication—even commonly used drugs. For example, the entire class of anti-cholinergic drugs, which includes many antihistamines, antianxiety drugs, muscle relaxants and sleeping pills . . . Cholesterol-reducing statins have also been linked to brain fog in some people. In many cases, the cognitive symptoms vanish when medication is stopped. "I have had people referred to me with a clear history of dementia and when I started to peel back the medications, they were much better," says Gary Kennedy, chief of geriatric psychiatry at Montefiore Medical Center in the Bronx, N.Y."
- [3]Ancestral Health Symposium 2012 (Boston) recaps. I thought Robb Wolf's talk was excellent. Jay Stanton had original ideas about weight control. Most of the other talks, not so much.

Tarkan (2012-09-03 14:47:54)

Could you write more about vitamin d please? I'm interested to know more about sitocalciferol / alfacalcidol, the new synthetic version of vitamin d. Thank you.

## Two Recent Health Care Experiences (2012-09-04 05:00)

A friend and his pregnant wife, who live in Los Angeles and are not poor, recently had an ultrasound. (Probability of the ultrasound machine not operating properly and producing more than the stated amounts of energy: unknown, but [1]a recent Stockholm survey found one-third of the machines malfunctioned.) Part of the office visit was a post-ultrasound visit with a genetic counselor. The genetic counselor walked them through illnesses in their family tree and assessed their coming baby with very low risk for Trisomy 21 (Down syndrome), Trisomy 13 and Trisomy 18.

At the end of their session, they were offered other services they might opt to buy to better know their chances of knowing about any fetal problems: [2]Chorionic villus sampling and [3]amniocentesis as well as a maternal blood test. None were really necessary.

My friend was irked that the CVS and the amniocentesis were called "low risk". Maybe you know that a large fraction of doctors claim to practice "evidence-based medicine". You might think this means they pay attention to all evidence. In fact, evidence-based medicine practitioners subscribe to a method of ranking evidence and [4]ignore evidence that is not highly ranked. Most evidence of harm is not highly ranked, so evidence-based medicine practitioners ignore it. This makes every treatment appear less dangerous – misleadingly so. When a doctor says "low risk," the truth, because the practice of ignoring evidence of harm is widespread (and drug companies routinely underestimate risk), is closer to "unknown risk". The combination of (a) understating risk, (b) selling unnecessary stuff of which you have understated the risk, and (c) doing this with pregnant women, whose fetuses are especially vulnerable, is highly unattractive.

Also recently, the friend's toddler had some sort of infection. The toddler had a bit of a fever, but was generally in good spirits, and played with his toys (i.e., was not bed-ridden or in severe distress). After a few days, his wife took the child to their pediatrician to make sure everything was fine.

"Don't just accept the antibiotics," my friend told his wife. "Push back a little. See what happens."

The pediatrician did prescribe antibiotics. When my friend's wife said she preferred not to give the child antibiotics if it were not really necessary, the doctor (female) said, "You're right. I actually don't know if the infection is bacterial or viral."

Both stories – which obviously reflect common practice – illustrate how the healthcare system is biased toward treatment, including treatments that are unnecessary and dangerous. The good news is that this bias is clearer than ever before.

Richard A. (2012-09-04 06:00:07)

Did Neil Armstrong really need that bypass surgery?

Ruth (2012-09-04 07:03:10)

My friend taught me a brilliant system for what to do when the kids were sick. First of all, don't run to the doctor after the first sniffle or cough. When it's more serious, go for a checkup. The doctor usually prescribes antibiotics. Ask if they are warranted. If they are, go home with the prescription but don't fill it. If by next morning the kid is on the mend, you never need to fill the prescription. 90 % of the time, this is what happened. I rarely ended up filling the prescription. I felt good that at least a health professional had seen my kid to rule out something serious - wouldn't want to just never go to the doctor to avoid meds.

Alex Chernavsky (2012-09-04 07:27:41)

"Push back a little. See what happens." This is generally good practice when dealing with experts. About twelve years ago, I had undertaken some complicated financial transactions, so I hired an accountant to prepare my tax return. When he showed me a draft of the return, I was stunned at my unexpectedly high tax liability. I found an area of the return that looked suspicious to me. The account *insisted* that there was no mistake. But he called me a couple of hours later and admitted that he had inadvertently double-counted some income. Experts are to be treated with deep suspicion.

Mark (2012-09-04 07:45:08)

Agreed... all experts should be treated with deep suspicion. Anybody can have an opinion, but experts dangerously base theirs on inductive reasoning, i.e., "what I saw over the past must remain true today."

Richard A. (2012-09-04 07:45:38)

While I do disagree with Dr McDougall's low fat approach- Heart Surgeons Kill First Man on the Moon: Neil Armstrong [http://www.drmcDougall.com/misc/2012nl/a ug/armstrong.htm](http://www.drmcDougall.com/misc/2012nl/a%20ug/armstrong.htm)

## **New Walking-Catalyzes-Learning Results (2012-09-05 05:00)**

[1]Two years ago, I discovered that if I walked on a treadmill while studying Chinese flash cards, it became much easier. Without walking, I could barely study 10 minutes without getting exhausted and stopping. If I walked at the same time, however, I could study much longer - say, 60 minutes. Huge difference. Walking on a treadmill made studying Chinese pleasant. This was stunning because walking on a treadmill by itself was boring and studying Chinese (or any other dry knowledge) is supposed to be boring. I concluded that walking created a thirst for dry knowledge, which studying Chinese satisfied. My evolutionary explanation was that this linkage evolved to push us to explore our surroundings. [2]My posts about this.

In [3]an April 2012 QS talk, Jeremy Howard reported the same thing.

I discovered that if I am walking on a treadmill at 1.2 miles per hour at a 1 degree incline I have an error rate of about 5 %. Whereas if I don't [walk on a treadmill] it's about 8 %. I also know that I can do that for an hour. Whereas normally if I'm just sitting down I can just do it 20 minutes. . . . And at the end of that hour I was ready to do something else. Whereas at the end of 20 minutes, normally I'd [audience member: "Take a nap"] Yeah, I'd be totally ready for a rest . . . I also discovered I was 40 % faster [at learning].

He added, "I love my Chinese every day." More recently, someone named Adam [4]posted on the QS forums that he'd had a similar experience:

As Jeremy Howard mentioned in his talk, SRSing (is that a word?) is exhausting. Like him, after a period of about 20 minutes, I often reach a level of fatigue that makes it difficult to continue studying. I first read

about the "treadmill method" on Seth Roberts's blog & found it highly effective. Like Mr. Howard, I could study for hours without become bored . . . The only problem here is that I don't have easy access to a treadmill. My gym is quite far & it is impractical to go there every day, while I desire to SRS every day.

That two other people noticed such a big effect is good reason to think that it will be true for most people.

---

dearieme (2012-09-05 05:12:46)

When I was a fresher I was asked to leave a library because my habit of walking around was distracting other readers. My habit was to sit and read for some minutes and then stride about, running the stuff through my mind, looking at it this way and that. Sometimes I'd carry some notes to look at. It worked.

Allen K. (2012-09-05 06:01:14)

For the last couple of years, I've napped 1/2 hour almost every day, but pretty much stopped once I started my treadmill desk ( \$50 treadmill off craigslist). Having a standing desk wasn't enough.

Adam (2012-09-05 07:21:38)

@Seth: That Adam is me! We actually met a while back when you came to Shanghai for a visit. I'm the Anki/SRS obsessed gentleman who was present at the Korean BBQ. @Allen K.: I suppose I could study flashcards on my cellphone while walking on nearly any kind of treadmill, but I'm curious what kind you bought. Did you modify it yourself to turn it into a treadmill desk? Does that mean that you use your laptop on it? If you could share some of your methods and/or pictures, I'd really appreciate it.

Chuck (2012-09-05 09:04:46)

I like to listen to podcasts while I walk, usually with my dog, and easily walk for an hour, or more, while listening. However, if I try to listen to a podcast while sitting, I go about ten minutes, then realize I can't remember a thing the person(s) said, and give up. Not that I can remember everything said in an hour long podcast, but I think if I listened to it daily over a period of time, like studying the same flashcards over and over again, I could remember the whole thing. Or, I could become bored with the parts I do remember and subconsciously stop listening. Video casts are not as hard to get through, and I think it's because what you see on the video usually changes from moment to moment - kind of like flash cards - and there's more of a visual interaction. Probably the influence of television - audio/visual/sedentary conditioning. Ha! Talk radio is another medium I cannot listen to unless I'm driving or walking. I find it all very interesting. Seth: Very interesting. Would online education be better if it were designed to be consumed while walking, instead of looking at a screen?

Bryan (2012-09-05 11:05:13)

When I memorizing stuff for the California bar exam, most of the time I was on my feet. I'd either pace around the room reading my notes aloud or walk around campus reading my notecards to myself. Seth: yes, I will change the title of this post. It's obviously walking, not necessarily treadmill walking.

Joanna (2012-09-05 13:26:45)

But treadmill walking and reading is safer than regular walking if you're looking down at written material - kind of like walking and texting, which is not really very safe. Regular walking outdoors would certainly work for podcasts - I will have to try that

one. And merely glancing at notes while pacing around indoors wouldn't seem to be too dangerous. Other than that I think I would stick with treadmills. Seth: Yes, I quickly stopped walking around my neighborhood studying flashcards – it was too tricky.

Matt (2012-09-06 04:28:18)

I find that I can easily retain information that I hear during a podcast while I'm walking OR driving, but if I'm sitting I do not retain nearly as much. Perhaps it is the motion rather than the walking, specifically.

Adam (2012-09-06 06:50:08)

Bryan's comment reminded me, I used the "Walking Effect" when studying for my licensing exam as well. That was before I had a smartphone or knew what Anki was. I made hundreds of paper flashcards with brand and generic drug names on them, then walked for hours around the track at a local high school. The track works pretty well as long as it isn't too crowded.

Alex Berg (2012-09-06 14:22:38)

Anat Baniel also believes motion improves learning and thinking. She has some interesting ideas, and her movement exercises has been a revelation for me regarding headaches due to desk work

Derek Ramsey (2012-09-06 17:36:50)

To quote "<http://autism.com/pdf/families/adviceforparents.pdf>": "There are several ways to help autistic children learn to talk, including....Vestibular stimulation, such as swinging on a swing, while teaching speech"

## **Bic For Her and Personal Science (2012-09-06 05:00)**

Bic's new line of pens ([1]Bic for Her) was greeted with scorn by Amazon reviewers. [2]David Vinjamuri, experienced in brand marketing, guessed that the reason for the debacle was that the persons who approved the product were quite different than the persons expected to buy it.

Brand companies are not good at assigning authentic consumers [= consumers of their brands] to work on their brands. They [wrongly] assume that [their] lack of personal experience with the product can be made up [for] by lots of analysis. It is very, very hard to imagine that the people who made the decision to launch "Bic for Her" were the same [people] expected to buy them. And that's why the huge majority of consumer brand launches fail. There are lots of ways to make an awful mistake, but some of the worst could be avoided if consumer companies were staffed by actual consumers.

Health care has the same problem. In health care, the persons who devise a new treatment (a new treatment for acne, asthma, arthritis, diabetes, whatever) are usually 100 % distinct from the persons expected to use that treatment. For example, roughly 0 % of acne researchers have acne.

If Vinjamuri is right – and I think he is – this explains a lot about the awfulness of modern health care – [3]the terrible side effects of Accutane, for example. And it explains why personal science works so much better. When [4]personal scientists search for a solution to a health problem (e.g. [5]acne), they are 100 % the same as the people who will use the solution. No wonder the solutions they find are so much better than what a doctor would prescribe.

dearieme (2012-09-06 10:06:06)

When my GP was recommending a colonoscopy, he was lightning quick to point out that he'd had one. (We have aged together, he and I.)

Robbo (2012-09-06 13:20:37)

Roger Altounyan, who discovered / invented the asthma drug Intal was asthmatic himself and experimented on himself in making the discovery. That was not very unusual in the past, now I believe it is strongly discouraged.

### **Marginal Revolution University: A Hidden Advantage (2012-09-07 05:00)**

Tyler Cowen and Alex Tabarrok have started [1]Marginal Revolution University, intended to be a set of online classes that will "communicate [their] personal vision of economics". One selling point is the content will be designed for online delivery, rather than being recordings of lectures.

They don't mention another advantage. Before I was hired at Berkeley, I went there for a series of interviews. One was with a group of graduate students. One of them asked, "Which do you like better, teaching or research?" "I like research better," I said. The graduate students smiled. You're supposed to say you like them equally.

At Berkeley I met plenty of professors who liked teaching small classes. I never met a single professor who liked teaching large classes. (That included me – I didn't like teaching them.) [2]Berkeley has recently joined Harvard and MIT to form EdX, a nonprofit company that will offer online classes. "We are deeply committed to public education," said Berkeley's chancellor. Well, that might sound good or it might sound pro forma, but either way few of Berkeley's professors want to teach the classes that EdX would offer, such as Introductory Psychology. Unless a class with 100,000 students is more personal than a class with 500 students. Whereas Tyler and Alex must want to do what they're doing. No one is pushing them to do it.

-

Jonathan Shewchuk (2012-09-07 18:53:36)

For what it's worth, I'm a Berkeley CS prof who likes teaching large classes. I like them because (1) I thrive better (go into the zone more easily) in front of a large audience and (2) my department is wise enough to award more teaching credit for large classes. Perhaps it's ironic that I'm not really tempted to do an EdX courses because I don't think I lecture well in a studio. I need the live audience. Some of my colleagues in the department seem really excited about their large-scale online courses. Granted, those are usually upper-division courses like software engineering, and it's only the full-time lecturers who seem excited about large-scale lower-division courses.

JeffE (2012-09-07 20:11:19)

I also like teaching large classes. (I'm a CS prof at Illinois.) Administering large classes, on the other hand....

gwern (2012-09-08 09:13:59)

> How current reward structures have distorted British science. I wonder if the author, an Oxford professor of psychology, understands how earlier reward structures distorted science. Interestingly, just yesterday I ran into a link showing one way in which British science seems to be superior to American science: less inflation and claims of positive results > Concerns that

the growing competition for funding and citations might distort science are frequently discussed, but have not been verified directly. Of the hypothesized problems, perhaps the most worrying is a worsening of positive-outcome bias. A system that disfavors negative results not only distorts the scientific literature directly, but might also discourage high-risk projects and pressure scientists to fabricate and falsify their data. This study analysed over 4,600 papers published in all disciplines between 1990 and 2007, measuring the frequency of papers that, having declared to have “tested” a hypothesis, reported a positive support for it. The overall frequency of positive supports has grown by over 22 % between 1990 and 2007, with significant differences between disciplines and countries. The increase was stronger in the social and some biomedical disciplines. The United States had published, over the years, significantly fewer positive results than Asian countries (and particularly Japan) but more than European countries (and in particular the United Kingdom). Methodological artefacts cannot explain away these patterns, which support the hypotheses that research is becoming less pioneering and/or that the objectivity with which results are produced and published is decreasing. <http://mres.gmu.edu/pmwiki/uploads/Main/Fanelli2011.pdf> “Negative results are disappearing from most disciplines and countries”, Fanelli 2011; seen on <http://hardsci.wordpress.com/2012/03/10/secular-trends-in-publication-bias/>

Adam (2012-09-10 06:49:26)

One thing that occurred to me is that Yoni’s study only looked at acute effects. Intermittent fasting has a variety of long-term beneficial effects on health, and health has beneficial effects on cognition. It seems plausible to me that if we took 2 people and had one intermittently fast for several months & one eat normally, we might find that the baseline level of cognition was higher in the intermittent faster. Then we could take both & show that, yes, an intermittent faster would have a short-term “boost” in cognition due to elevated blood sugar after a meal, but it could still be the case that his average cognitive level was higher than the control subject. Be aware that I’m aware I’m totally speculating here, but I do think there are still a myriad of reasons to advocate intermittent fasting. I’m also curious of the magnitude of the negative effects Yoni recorded. It is hard to pull that kind of data out of charts shown in a flash in a video clip. Has he a blog or other site where he’s shared them?

Adam (2012-09-10 16:21:21)

“Even blood glucose levels in the range of high normal appear to be associated with brain atrophy, a new study shows. In a sample of randomly selected older middle-aged people, high normal levels of fasting plasma glucose were significantly associated with hippocampal and amygdalar atrophy over 4 years.” <http://www.medscape.com/viewarticle/770353> Elevating blood glucose for a cognitive boost seems to be a good short-term strategy but a bad long-term one. Seth: I found that walking an hour per day reduced my fasting blood glucose from high normal to low normal. Maybe the hippocampal and amygdalar atrophy are due to not walking much. The hippocampus is often called a mental map, sensitive to travel.

## **Independent Discovery That Walking Catalyzes Learning (2012-09-09 05:00)**

Two years ago I discovered that if [1]I walked while studying Chinese flashcards (using [2]Anki), both activities – walking and studying – became easier. I could walk much longer on my treadmill and I could study much longer. Walking made studying more pleasant and vice-versa. Around the same time, [3]Jeremy Howard, the president of [4]Kaggle, made the same discovery independently. In an email to me, he writes:

I came up with the idea accidentally a couple of years ago – I needed to go to the gym every day, and that included 30 minutes on a cross-trainer (but I only managed to do 15 min most days). I needed something to do to keep me amused, so I brought along my PC and started doing my Anki whilst on the cross-trainer. I discovered I could do my cross-trainer for at least twice as long, and my Anki results were better too. Later I added treadmill walking to my Anki study too.

He says more about it, including how much it helped him, [5]in a QS talk.

As Nabokov says [6]in Pale Fire,

If on some nameless island Captain Schmidt  
Sees a new animal and captures it,  
And if, a little later, Captain Smith  
Brings back a skin, that island is no myth.

Learning methods that use this effect are going to have a big advantage over learning methods that don't.

Ilya (2012-09-10 07:58:58)

Seth, I am thinking about making a treadmill desk. Have you paid attention to your ability to do more creative work while walking? When I say creative work, I mean things like programming, any kind of design, writing. Thanks in advance, Ilya. Seth: I think treadmill walking makes it harder to do creative work, such as writing. I prefer sitting down for that. It puts me in an outer-directed frame of mind (paying more attention to the outside world), while creative work requires introspection.

Zay (2012-10-03 17:07:32)

I find I come up with my most creative ideas when I am moving through space. This used to be walking in the woods but I can no longer go for those hikes because of health reasons. I do notice that while I'm driving in the car, my mind becomes creative. (This is at times other than rush hour.) I am fascinated with the fact that my mind becomes creative the moment I move. When I stop at stop lights my ideas are put on hold. So I prefer to drive in the open country where they can flow freely.

Darrin Thompson (2012-09-11 06:05:16)

That cooling apparatus is really interesting. Will sports governing bodies ban it? Is it really as amazing as the authors say? Is there (dun dun dun) danger? The part at the end where the authors disclose their financial interest really dampened the magic for me. :-) Seth: I saw it as putting your money where your mouth is.

dearieme (2012-09-11 06:11:04)

Cooling hands isn't new: my father taught me it in the 50s. I was to put my hands, palm upwards, under the cold water tap so that the water ran down from my wrists across my palms. It worked a treat.

dearieme (2012-09-11 06:13:22)

I should add that however hot I was, and however hot the day was, the cold water came from high moorland and was always cool.

John Speno (2012-09-11 06:49:08)

When I read about the NZ twins, I assumed they meant they had FH (Familial hypercholesterolemia). Seth: Yes, maybe so.

Sade (2012-09-11 08:34:50)

You do know that inherited high cholesterol is a thing, right? <http://ghr.nlm.nih.gov/condition/hypercholesterolemia>

garymar (2012-09-11 16:49:57)

Seth, this blog is a goldmine of aggregated blog links. I clicked thru and read 3 out of 4 items.

garymar (2012-09-11 16:55:48)

Make that 4 out of 4.

Elizabeth Molin (2012-09-13 08:53:41)

Re home energy use, here is the kind of thing I obsess about: you can line a baking sheet with foil before use, and it won't need washing. But then the foil is dirty and can't be recycled. Washing the baking sheet requires (heated) water and soap. Which is more energy-efficient? Which is more environmentally sound? Which is cheaper? (Sometimes you can slip the dirty baking sheet into a "full" dishwasher, which you have to run anyway. And dishwashers are more energy-efficient and cost-effective than washing by hand. I think.) I have never seen any comparisons of this kind of thing and wish someone would do one; I can't, as I don't have the expertise. How much does it cost to produce, package, ship, and advertise a foot and a half of foil? How do you figure this out?

Alexey (2012-09-13 13:05:53)

>How much does it cost to produce, package, ship, and advertise a foot and a half of foil? How do you figure this out? 75 sq.ft of AL foil is about \$2.50 in a grocery store. 1.5 sq.ft are 5 cents. That of course includes all the costs to produce, package, ship and advertise. Washing the baking sheet in the dishwasher = free if washed with other stuff. Does not happen that often. Washing the baking sheet manually = cost of water and detergent + time spend. Water is \$1.5/1000 gallons -> negligible,

detergent = 1 cent, time = about a minute of vigorous scrubbing. So if you're getting paid more than \$3/hour or getting more than \$3/hour worth of entertainment by not doing the washing, then washing the baking sheet manually may not make sense. ;)

Elizabeth Molin (2012-09-14 13:06:25)

Thanks, Alexey! One less thing to obsess about. I do feel kind of DUH now that I see how simple it is...

### **The Terry Deacon Affair (2012-09-12 05:00)**

Terrence Deacon is a professor of anthropology at the University of California Berkeley – at the moment, chair of the anthropology department. (Deacon, [1]like me, is interested in the evolution of language.) How unfortunate for the department, especially his graduate students, that he has [2]recently been accused of using vast amounts of another person's work without giving her credit. It isn't easy to see the overlap, maybe because Deacon is a terrible writer ("by far the most unreadable book I have ever encountered" [3]said a reviewer of one of his books), but there appears to be no doubt of the similarity and Deacon's exposure to the work he is accused of not citing. Deacon says he doesn't remember it.

When I brought [4]unquestionable examples of plagiarism by Leslie Iversen, an Oxford professor, to the attention of Julie Maxton, the Registrar of Oxford University, [5]she dismissed them ("honest error" – appearing to say that Iversen didn't know that word-by-word copying is wrong). In this case there is no word-by-word copying but the failure to cite is far more upsetting to the persons not cited. What may have been copied is more abstract ("deeper", you could say) and therefore more important.

At first, the complaint was dismissed. "I have concluded that the information available to me does not warrant appointment of an Investigative Officer under our campus faculty disciplinary procedures. The conduct you have alleged would not constitute a violation of the University of California's Faculty Code of Conduct," wrote Janet Broughton, Vice Provost, on May 27, 2011.

Later (December 12, 2011), Robert Price, Associate Vice Chancellor for Research, responded, "The fact that certain concepts or phrases used by Dr. Deacon in the article you provided are the same or similar to concepts that appear in chapters from your book is not evidence of plagiarism, as these concepts may not be unique to your work. Perhaps the way you use these concepts is unique, which then would constitute plagiarism." This understates the evidence, which is a long series of similarities.

Finally, the fact that outsiders find the claims (of failure to give credit) credible appears to have convinced Price that something must be done. "The continuing public dispute that your claims have generated lead me to believe that such an investigation [of the claims] is necessary in order to "clear the air"", [6]wrote Price. After being successfully pressured to investigate, Price, a political science professor, in a September 3, 2012 letter reveals a lack of understanding of social pressure:

I wish to make crystal clear to you, your associates, and to all those to whom you are communicating that the University of California, Berkeley has not found that Professor Deacon has engaged in any form of research misconduct. The sole reason for undertaking an investigation are the claims made by you and your associates. [Contradicting what he said earlier – that the "continuing public dispute" led to the investigation.] . . . The idea that you would use my communications with you ["use" in the sense of posting on a website] and the ongoing examination of your allegations by UC Berkeley as part of what increasing strikes me as a vendetta against Professor Deacon is reprehensible.

My letter to Alicia Juarrero [who complained] ends with this paragraph: "Our University policy on research misconduct, as well as the federal regulation on which it is based, require that all stages in the research misconduct investigation procedure are treated as strictly confidential. (UCB "Research Misconduct: Policies, Definitions and Procedures," item IC and Federal Regulation 45CFR93.108). I expect that you will adhere to this requirement." Rather than adhere to the stated requirement of confidentiality, Dr. Juarrero shared the letter with you and you, in turn, posted it on your website. What purpose is being served other than to make it appear that Deacon is guilty of something before even a single one of your claims has been validated? This sort of tactic will be familiar to those who remember the history of Joe McCarthy.

"What purpose is being served"? Uh, making the accusations harder to ignore? As for McCarthy, he made accusations [7]without supplying evidence ("In this envelope [which he didn't open] I have the names of 80 Communists in the State Department"). That is not happening here.

[8]Why Alicia Juarrero Got Mad at Terry Deacon. [9]New Terry Deacon Website.

Chuck (2012-09-12 09:38:58)

There are those who believe in openness and transparency; and, there are those who do not in order to protect their position and power. I would expect very little openness and transparency from a political science professor from UC Berkley. Developing something new is hard work. Expecting those raised in T-Ball America where no one keeps score and everyone gets a trophy to work hard is no longer the norm. Disciplining a professor for unethical behavior could damage his delicate self esteem. And besides, who's to judge what is, or isn't, unethical? Everyone gets a trophy. Everyone's self esteem is intact.

Txomin (2012-09-12 18:37:43)

Evil hateth the light.

Michael Lissack (2012-09-13 02:19:51)

For the record, Prof. Price directly supplied me with a copy of the letter announcing the investigation and did so WITHOUT making any request of confidentiality. His accusation that Alicia Juarrerro did something wrong is thus completely disingenuous. He supplied the letter. He made no confidentiality request. She DID NOT supply the letter and has not "broken" a request for confidentiality which she never agreed to in the first place. At the Institute for the Study of Coherence and Emergence (<http://isce.edu>) our position on this matter is very clear: Terry Deacon is a serial plagiarist and UC Berkeley has no interest in dealing with that ugly truth. Seth: And Professor Price has a poor memory.

Bryan (2012-09-13 22:31:15)

Seth, I heard two interviews tonight that made me think of your writing on this issue: [http://thestory.org/archive/the\\_story\\_091312.mp3/view](http://thestory.org/archive/the_story_091312.mp3/view)

### Early Immune Warning System: A Bit of Evidence (2012-09-13 05:00)

[1]I have proposed that three things – a tendency to touch each other (e.g., shake hands), a tendency to touch near our mouths, and our tonsils – together form an early warning system for our immune system. The early warning system helps the immune system get tiny exposure to microbes circulating in the community. It performs self-vaccination. Like ordinary vaccination, exposure to tiny amounts of Microbe X protects against exposure to a large amount of Microbe X.

In Daniel Everett's anthropological study of the [2]Pirahã people (Don't Sleep, There are Snakes: Life and Language in the Amazonian Jungle, 2009) he says the Pirahã "all touch one another frequently" (p. 85). "They loved to touch me too." He has never seen kissing but "there is a word for it, so they must do it." This supports the idea that a tendency to touch others is widespread.

If this theory is true, reducing microbe exposure to zero (e.g., sterile food) is a seriously bad thing. It's been proposed that the polio epidemics of the first half of the 1900s were caused by cities becoming too clean.

[3]Evidence from ants.

---

lef (2012-09-13 08:39:19)

in a previous post (what to do about antibiotic resistance?improve immune function) you mentioned this idea( listed as 3 there). You said there "So it's not obvious that outside of hospitals more hand washing is a good thing". I find it interesting because frequently I see that even people who criticize some aspects of cleanliness when it comes to washing hands they are mainstream.If you can make it more precise I think it will be even more interesting.for example what do you mean by more, 1)more than conventional guidelines suggest, 2)more than someone who doesn't wash them even after using a public toilet,your meaning of more, is closer to 1 or closer to 2? Seth: Closer to 1. But, actually, it isn't clear at all to me what level of hand-washing is best.

gwern (2012-09-13 09:19:26)

Counter-example: Japan.

joseph (2012-09-13 13:50:41)

hi there is a NY Times article about autism its a OpEd, and the theory is that its a Immune Disorder <http://www.nytimes.com/2012/08/26/opinion/sunday/immune-disorders-and-autism.html?pagewanted=all>

william (2012-09-14 19:57:05)

A book you might find interesting is The Epidemic of Absence by Moises Valasquez-Manoff.

Adam (2012-09-15 09:48:11)

Then again, Japan has the crazy mutant forms of Gonorrhea resistant to \*everything\*, so they must be sharing germs somehow!

Carlos Urzúa (2012-09-21 13:52:22)

Perhaps sneezing is also a sharing mechanism, not because of vaccination effect, because of the capacity to spread the disease in a not so virulent form. If the microorganism can infect the most quantity of hosts without a very aggressive strategy it will be stable and not evolve to increase virulence. If killing hosts is what infects the most hosts it will be selected to do so. Maybe the body developed this sneeze reflex as a prophylactic measure. Facilitating the spread of non-lethal diseases and in doing so preventing them from being seduced by the lethal option which is a very juicy alternative. I once saw a talk which described how when a country with cholera controlled the sewage in a way that corpse & dying patient contaminated water was prevented from reaching the public supply, forced the bacterium to be less virulent, keeping people alive more as the fittest way to survive. The strategy didn't eradicate, but attenuated the disease. Better to have seasonal flu than SARS. Seth: Good points.

### **Unaccountable by Marty Makary (2012-09-14 05:00)**

The not-yet-released book [1]Unaccountable: What Hospitals Won't Tell You and How Transparency Can Revolutionize Health Care by Marty Makary, a professor of surgery at Johns Hopkins, may or may not make good arguments – I haven't read it – but it certainly begins with a good story:

Harvard surgeon Dr. Luctan Leape at a national surgeon's conference . . . opened the gathering's keynote speech by looking out over the audience of thousands and asking the doctors to "raise your hand if you know of a physician that you work with who should not be practicing because he or she is dangerous."

Every hand went up.

The author, Marty Makary, asked the same question at his talks and got the same response. Both of them – Leape and Makary – should have started asking "What fraction of the surgeons you work with are unfit to practice?"

I wonder how the rest of us can identify those unfit-to-practice surgeons. [2]My experience has taught me not to trust a surgeon who says I need surgery.

## **Does Too Little Vitamin K2 Cause Prostate Cancer? (2012-09-15 05:00)**

People with unusual genomes often resemble canaries in a coal mine: More sensitive than the rest of us to bad environments. This is illustrated by [1]a new study of prostate cancer/genome associations.

Repeating earlier work in Europeans, they compared the genetic profiles of Japanese groups of prostate cancer sufferers with non-sufferers. . . . The joint numbers included 7,141 prostate cancer sufferers and 11,804 non-sufferers. The most recently identified loci are on chromosomes 11, 10, 3 and 2. . . .The locus on chromosome 2 is linked with GGCX, a vitamin K-dependent [actually, vitamin K2] enzyme that regulates blood clotting [Vitamin K2 does not regulate blood clotting], bone formation and cancer biology. Japanese foods such as natto and seaweeds are rich in vitamin K, which is thought to protect against cancer. Interestingly, the association of this SNP with prostate cancer was significant in all populations except for the Japanese in the USA, indicating that environmental factors, such as diet, are involved.

[2]Here is the paper. Why would the correlation not show up for Japanese in the USA? Maybe because Japanese in the USA all get too little Vitamin K2.

Neither the press release nor the article make clear what I am saying: These results make it a lot more plausible that Vitamin K2 protects against prostate cancer. A lot of mainstream nutritional advice is based on epidemiology. The K2/prostate cancer connection is especially interesting because it does not suffer from the usual problems of epidemiology: difficulty measuring intake (do you have any idea how much K2 you consume?) and vast confounding (Vitamin K2 intake is probably correlated with many other things).

---

Alex Chernavsky (2012-09-15 08:43:16)

Denise Minger says that she experienced a lot problems with tooth decay (i.e., getting cavities) before she started taking K2 supplements. The commenting system won't allow me to post a hot link, so I've had to obfuscate the URL [rawfoodsos.com/for-vegans/](http://rawfoodsos.com/for-vegans/)

Adam (2012-09-15 09:50:47)

I can't recall if I found this link here or not, but it is worth posting again if anyone missed it:  
<http://www.metafilter.com/117835/Vitamin-K2> "... [R]ecent studies have shown that poor Vitamin K2 status is associated with a number of other health issues, including increased risk of coronary artery disease and fracture. By directing calcium

from soft tissues into your bones, K2 reduces soft-tissue calcification, including hardening of the arteries (atherosclerosis), and increases bone density. Studies also suggest that Vitamin K2 improves insulin resistance in older men, can be beneficial for patients with leukemia, and may even help patients with Parkinson's by improving electron transport within mitochondria."

Miki Ben Dor (2012-09-17 00:20:01)

"Vitamin K2 does not regulate blood clotting". Do you happen to have a reference for that? A doctor would not allow a friend of mine to supplement K2 due to some pro clotting genetic defect. Seth: There is a difference between Vitamin K (blood-clotting) and Vitamin K-2 (other). Apparently that doctor didn't understand this.

shortdude (2012-09-20 21:41:58)

A couple of Israeli doctors have published a series of interesting papers where they suggest that BPH and prostate cancer are caused by incompetent valves in the testicular veins. This prevents normal drainage of blood from the testicles, and necessitates pathological flow of blood from the testicles to the prostate. The prostate is thus exposed to enormous levels of testosterone from the testicles, which causes hypertrophy and eventually cancer. (and also increases the conversion of testosterone to DHT, think male pattern baldness) This vitamin K2 study is interesting. I feel like there's some obvious connection here between the venous pathology and clotting function that I'm missing.

Guv (2012-09-20 00:26:37)

where are my manners, should have said Hi Seth first.....Hi Seth, off topic i know, just interested to know if you are still taking 2 tablespoons (approx 30ml/just under 30 grams) of flax oil a day? Seth: Yes. When I am in China I eat about 60 g of ground flaxseed instead. Can't get good flaxseed oil in China.

dearieme (2012-09-20 04:01:47)

Aha, flaxseed (aka linseed). I accidentally sprouted a flaxseed recently. Have you any experience with eating flax shoots? Are they as tasty as bean shoots? (I didn't try eating mine since it had sprouted in a compost bin.)

### **Last Weekend's Quantified Self Conference (2012-09-21 10:09)**

Last Saturday and Sunday there was an international Quantified Self Conference at Stanford. I attended. In Gary Wolf's introductory talk, he said there are 70 Quantified Self chapters (New York, London, etc.) and 10,000 members. I was especially impressed because I recently counted about 50 chapters. One new chapter is Quantified Self Beijing. It has its first meeting – in the form of a [1]day-long conference – in nine hours and I haven't quite finished my talk ("Brain Tracking: Why and How"). Please indulge me while I procrastinate by writing about the Stanford conference.

Here are some things that impressed me:

Office hours. A new type of participation this year was "office hour", meaning you sit at a table for an hour. My office hour, during which two people showed up, was the most pleasant and informative hour of the whole conference for me. I thank Janet Chang for suggesting I do this.

[2]

Robin Barooah used a measure of how much he meditated, which he collected via an app he made, to measure his depression. When he was depressed, he didn't meditate. Depression is half low mood, half inaction. It is very rare that the inactive side of it is measured. It is so much easier to ask subjects to rate their mood, but this has obvious problems. Robin inadvertently found a way to measure level of activity over long periods of time. He also found that participation in an experiment that tested a PTSD drug caused long-lasting improvement, another idea about depression I'd never heard before. At dinner, Robin told me that his partner, when they're at a restaurant, has sometimes said "God bless Seth Roberts" for allowing her to eat butter without guilt.

Steve Jonas, from QS Portland, told me that he spent a long time (many weeks) doing some sort of mental test. During one of those weeks, he consumed butter a la Dave Asprey, in coffee. Much later he analyzed the results, computing an average for every week, and noticed that during the week with butter his performance was distinctly better than performance on other weeks. I hope to learn more about this. Steve also gave a talk about learning stuff using spaced repetition. He noticed that learning new stuff increased his curiosity. After he used spaced repetition to learn stuff about Mali, for example, he became more interested in reading news stories about Mali. I think this is an important conclusion about education, the way rote learning and encouragement of curiosity are not opposites but go together, that I have never heard before.

[3]Larry Smarr, a computer science professor at UC San Diego, gave a talk called "Frontiers of Self-Tracking" centered on his Crohn's disease. I was struck by what was missing from his talk. He began self-tracking before the Crohn's diagnosis and clearly the self-tracking helped establish the diagnosis. However, you don't need to self-track to figure out you have Crohn's disease, roughly everyone who has gotten this diagnosis did not self-track. I couldn't figure

out how much the self-tracking helped. Crohn's is generally associated with frequent diarrhea, which is exactly the opposite of hard to notice. Larry said nothing about this. Later he talked about massive amounts of personalized genetic data that he was getting. I couldn't see how this data could possibly help him. Isn't self-tracking supposed to be helpful? If I had a serious disease, I would want it to be helpful. At the same time, judging from his talk, he seemed to be ignoring the many cases where people have figured out how to better live with their Crohn's disease. I would have liked to ask Larry about these gaps at his office hour but I had an eye problem that caused me to miss it.

I asked Nick Winter, cofounder of [4]Skritter, what he thought of the recent Ancestral Health Symposium at Harvard (August 2012), which we both attended. He didn't like it much, he said, but it more than justified itself because Chris Kresser's talk about iron led him to get his iron checked. It turned out be off-the-charts high. Partly because oysters, partly because of red meat. I think he said he has since donated blood and it came down. I hadn't previously heard of this danger of eating red meat. Again I discussed with Nick why he found that butter had a bad effect on his cognitive performance, the opposite of what I found. One possibility is that the butter slowed digestion of his lunch, thus reducing glucose in his blood at the time of the cognitive tests. But this does not explain why a certain drug eliminated the effect of butter.

In his talk, Paul Abramson, a quant-friendly San Francisco doctor, said that mainstream medicine is "riddled with undisclosed conflicts of interest". I hope to learn more about this.

Jon Cousins contributed a neat booklet about what he had learned and not learned from starting [5]Moodscope. What he hadn't learned was how to make a sustainable business out of it. I suggested to him that he might be able find professors who would apply for grants with him that would use Moodscope as a research tool. The grants would pay Jon a salary and might include money for software development. Mood disorders are a huge health problem – depression is sometimes considered the most costly health problem of all, worldwide – and Moodscope is a new way to do research about them. Paying Jon a salary for a few years would cost much less than assembling a similar-sized sample (Moodscope has thousands of users) from scratch. I wonder how professors who do research on mood disorders will see it.

Jim Purdy (2012-09-23 11:13:25)

That doctor performance story was enlightening. And scary.

dearieme (2012-09-23 16:53:39)

"The average length of the procedures increased by 50 %": good, bad, unknowable?

Tom (2012-09-23 23:33:03)

They took more care and identified more polyps, I imagine. For a given level of reimbursement, their examination might be more cursory – unless they knew their performance was being monitored.

peter (2012-09-24 13:31:35)

how is hydrogen therapy administered?

dearieme (2012-09-24 16:56:10)

"They took more care and identified more polyps, I imagine": I'd be very suspicious of using time as a proxy for taking care.

## Drug Companies Hide Unfavorable Evidence (2012-09-24 05:00)

Ben Goldacre, a British epidemiologist and newspaper columnist ("Bad Science"), who used to attack homeopathy (trivial), has now written about something important: [1]drug companies hide vast amounts of unfavorable evidence. I already knew this but many details were new to me.

I liked some of the comments:

We live in France and used a traditional GP for five years. Every time one of us went [to see him] he or she would come back with prescriptions for three or four medicines. Over that time he prescribed our family of five an estimated 60-80 medicines. We only ever took one, and everyone always got better without using these medicines. . . . This same GP also would refer us to thoroughly incompetent specialists. A few years ago I had a frozen shoulder. I went to see a 'specialist' who yanked my arm and shoulder about, clearly having no idea how an arm actually moves, and he then suggested operating. . . . Instead I looked on the Internet for info and found some exercises I could do and also underwent some Bowen technique treatment. A year later I was fine.

As a business consultant, I was approached many many years ago by a company who wanted help to set up an independent research institute evaluating farm pesticides. They'd found the doses prescribed for actual application were many times the amount actually needed (for obvious profit reasons), sometimes efficacy was in doubt, and loads of hideous ecological side effects were buried.

Speaking of "many times the amount actually needed", I attended a talk about lighting standards in office buildings in which the speaker said the standards were too high (e.g., desks were better lit than necessary). His explanation was that the more lighting there is, the more air conditioning you need. The more air conditioning, the more cost, and architects are paid a fixed percentage of the cost. One of his slides showed that someone in the industry wrote down this rationale.

My GP often says the pharmaceutical industry wants to see everybody on prescription. He does prescribe tests, a lot of them, but drugs very rarely, and most of his recommendations are targeted at patients' lifestyle: diet, exercise, work, relationships. When he does prescribe drugs, if it is an antibiotic or an anti-fungal, you have to come back after 1 week so that he can see if the treatment has worked/is working. If you need longer term treatment, for example physiotherapy and painkillers for back pains, or if you have a long term condition such as diabetes, he insists on seeing every month, to check that you are treatment compliant. . . . I have to thank him for a lot. Until fairly recently, I was stuck in a really unhealthy work environment, and could not find another job. I had done a Psychology course which had nothing but praise about antidepressants, so I asked him if he would prescribe me one of the newest tricyclic ones. He was extremely angry, told me I needed a new job, not tablets, and that if I ever got that drug elsewhere and he found out, he did not want to see me again (he would probably have found a blood test to check up I was 'clean'). So I did not go down the tablet route, and he was right: all I needed was to change job.

Two or three years ago, I was working in Germany and went to see a German doctor. He looked at the list of daily medications my British doctor had prescribed (5 different drugs), ostensibly to help me survive middle age. He looked shocked, and told me that the British medical profession is dominated by the pharmaceutical industry, and he advised I stop taking three of the drugs prescribed. Now, having come back to the UK, every time I visit my GP, I am bullied once again to take this or that. If I try to resist, I receive very patronizing lectures about this or that risk.

Thirty years of bi-polar disorder taking virtually every possible anti-depressant over time, and at times when hospitalized, forced to take them under the duress of threatened sectioning under the Mental Health Act. Throughout those years I told the psychiatrists that the drugs didn't work beyond an initial "placebo effect" lasting about 2 weeks, and that the side effects were often awful. Now it seems I may have been right all along. . . . Big Pharma, [you] made a difficult life a lot worse.

Maybe Goldacre will someday grasp that "evidence-based medicine", which he often praises, also [2]hides a vast amount of unfavorable evidence.

Jim Purdy (2012-09-26 05:08:49)

Seth, you said: "Clayton Christensen's latest book (about universities) is not good, judging by this review. Christensen has had a stroke, which might explain it." I'm not sure that surviving a stroke explains much of anything. I know lots of fellow stroke survivors, and everything depends upon which part of the brain was affected. In my case, I've had two fairly mild left-brain ischemic strokes, and the most frustrating problems that they caused me were that they messed up the use of my right hand for handwriting and typing. Dadgummit, I can no longer print small enough to fill in the blanks in the books containing the most challenging New York Times crossword puzzles. But if you'll accept a stroke as an excuse for my rambling comments, I'll take that.

Jscott (2012-09-26 15:45:14)

Genome sequence work-around for those that want anonymity <http://www.fourhourworkweek.com/blog/wp-content/uploads/2011/01/Becoming-Brad-Pitt-Uses-and-Abuses-of-DNA.pdf> (Bonus chapter that did not make it into The Four Hour Body by Tim Ferriss)

## Secrets of a Long Life: Butter, Pork Belly, No Medicine (2012-09-26 05:00)

The New York Times recently ran [1]a story about a 107-year-old woman named Juliana Koo, who lives in New York City. Her longevity secrets are remarkably close to what I say on this blog:

“Somebody asked her the secret of long life,” said Ying-Ying Yuan, a step-granddaughter of Mrs. Koo. “She said, ‘No exercise, [2]eat as much butter as you like and never look backwards.’”

Shirley Young said her mother also [3]likes pork bellies, “especially the hot part, but she doesn’t overdo anything.”

“And [4]she doesn’t take any medicine,” she said. “When doctors give her medicine, she usually hides it, or when she takes something, she takes half a pill. People keep on giving her Chinese herbs, things like that. She never takes them.”

Jim Purdy (2012-09-26 05:22:32)

“And she doesn’t take any medicine.” That’s immensely important. I know way too many old folks who are taking astonishing amounts of prescription painkillers, antidepressants, proton pump inhibitors, statins, diuretics, blood pressure pills, diabetes medications, muscle relaxants, allergy drugs, and much more. All those drugs do very bizarre things to their bodies and minds. And of course the doctors are eager to prescribe even more BigPharma junk to treat all the problems created by the drugs. I’m amazed every time I read about somebody who goes into hospice care, and then they get better when all their drugs are stopped. Seth: “I’m amazed every time I read about somebody who goes into hospice care, and then they get better when all their drugs are stopped.” That’s exactly what happened to the mother of a friend of mine, whose drugs were stopped accidentally. The next time you read about this, please send me the link.

Chuck (2012-09-26 07:10:40)

I’m going on record and officially inviting you to my 107th birthday party in 2053. However, due to the upcoming worldwide shortage of pigs, I may have to become a hog farmer like my great-grandfather in order to assure myself of enough pork belly. Cheers

Wilson (2012-09-26 11:17:39)

You never hear these oldsters mention the real reason for their longevity: pure chance. In graduate school I lived in a house owned by a 96 year old woman. No lie, every Saturday night she would drink one can of beer and smoke one Marlboro cigarette. She claimed that’s what kept her going. Was it hormesis, or just blind luck? Seth: If pure chance is the real reason, the similarities I point out here must also be pure chance. Yet there are three. If someone forced me to guess the effect of one cigarette per week, I’d guess it was beneficial. The trouble with living in badly-polluted Beijing is I don’t know how many cigarettes per week it equals.

KenF (2012-09-26 13:06:16)

107 year olds don't take medicine because they have had good health their whole lives. That is why they are still around at 107.  
Seth: I'm pretty sure she has gotten sick, was offered medicine for her sickness, but didn't take it.

Gary Conway (2012-09-26 13:22:08)

What's the catch? ;-) Just discovered your blog today after seeing your ahs presentation. Very interesting & looking forward to reading more!

Jim Purdy (2012-09-26 13:49:34)

I once was driving a car with a passenger who had an active case of tuberculosis. He asked me if it was okay for him to smoke a cigarette in the car. Normally, I would say no, because cigarette smoke really bothers me. But in his case, I silently did some instant risk assessment, considering two options: 1. If he smoked, would the smoke particles carry the TB pathogens my way? 2. Or would the smoke kill the TB critters? I decided that the second option was preferable, and I told him to go ahead and smoke. Looking back, I probably made the wrong decision, and I got both evils at once. It amazes me every time I see a cigarette being smoked by someone with TB or cancer or COPD. What are they thinking?

Matt (2012-09-26 17:01:18)

They are thinking that they want a cigarette.

Nancy Lebovitz (2012-09-26 18:47:24)

It's interesting that she doesn't trust Chinese medicine, either. I do think there's an element of chance/genetics to unusual healthy longevity.

Txomin (2012-09-26 18:57:55)

Interesting but anecdotal.

Bryan (2012-09-26 22:08:57)

Txomin: I take it you just started reading this blog?

Evolutionarily (2012-09-27 02:28:23)

As we know Jeanne Calment the longest lived human being ever recorded at 122, smoked for almost 100 years. For some strange reason doctors though it would be a good idea for her to give it up, at the age of 116! Some speculate it was actually what killed her, ha! Did it have anything to do with her longevity? If he had not smoked would she have lived longer or shorter? Of course we will never know... According to the Strategies for Engineered Negligible Senescence (SENS) there are seven main causes of ageing (like cell loss, intracellular junk, extracellular junk, mutations, and a few others) so according to pure probability we will have humans born with constitutions robust to some or all of these factors. Perhaps Jeanne Calment was simply a 1 in 6 billion occurrence and she could have done practically anything and made it easily to 120 years old. I don't put much stock in what centenarians credit as being responsible for their longevity because I view it as a bit of a lottery, I see them as equivalent to the market traders Nassim Taleb chronicles in Fooled By Randomness who backwards rationalise their success to certain identifiable factors when in reality much of their success was pure chance/luck. Juliana Koo might credit butter, but perhaps were she brought up in Italy she would be crediting Olive Oil instead.

dearieme (2012-09-27 02:47:53)

My mother smoked heavily all her life. In her mid seventies her doctor persuaded her to stop. This immediately led to more severe coughing fits than before, during one of which she had a heart attack and died. I have no idea what to make of this.  
Seth: I have recently had trouble with my contact lenses. They hurt a little bit. After I take them out (they are designed to be worn continuously for a month), my eyes hurt much more and I can barely keep them open. They take a day or so to stop hurting. If coughing resembles blinking, there is a similarity.

lisa truitt (2012-09-27 12:24:58)

It seems to me that many variables could greatly influence a persons longevity. There is an interesting study in the book Outliers. This community of Italians immigrated to America. They had much lower generative disease than the Americans they lived amongst. Researchers at first assumed they must be eating differently. When it was discovered that this was not the case they were very intrigued. It turned out it was because of their tight knit old world village where everyone knows and is friends with everyone type of social structure. Sure, genetics is one factor, but not the only or even necessarily the strongest factor. People try to blame their diseases on genetics too, but the above study shows that there are powerful environmental factors that determine whether the genes involved in particular diseases are expressed or not. Seth: I agree.

dearieme (2012-09-27 14:42:19)

Or an isolated social structure might protect you from infections that are as-yet-unrecognised causes of many diseases.

Ravi (2012-09-28 07:37:39)

This is silly Seth. At best you can say, Butter, Pork Belly and not taking medicine can be termed as not having an effect on mortality, not the cause of longevity.

### **The Complex Flavor of Fermented Foods (2012-09-27 05:00)**

One of the main reasons I think we need to eat fermented foods to be healthy is that their flavors correspond neatly to the flavors we like. Fermentation of fruits and other sweet foods changes sugars to acids, making the food taste sour – and we like sour food. Fermentation of proteins produces glutamate, which produces an umami flavor – and we like umami-flavored food. With many foods, their fermentation produces many microbial byproducts, giving the food a complex flavor – and we like complex flavors.

The connection between fermentation and complex flavor is well-put in [1]a Saveur article about fermented foods:

[As a child] I only knew Claussen and other vinegar-cured pickles, the kind you buy in jars off the supermarket shelf, and I liked them just fine. But when I finally tasted a real pickle—the kind made the old-fashioned way, fermented with nothing more than salt, water, and time—I realized what I had been missing. A vinegary pickle plows through your palate with its tartness (often in a most pleasing way), but a live-cultured, salt-cured, fermented one tells a more multifaceted story. It is sour, to be sure, but it tastes of something more, something elusive: It's the flavor of Middle Europe captured in one bite. When I started cooking for a living, I realized that the complexity I'd tasted in that pickle is the hallmark of well-made fermented foods, which include some of my very favorite things to eat and drink: not just pickles, but aged cheeses, tangy sourdough breads, blistering kimchis, tart yogurts, winy salamis, and of course, wine itself.

1. <http://www.saveur.com/article/Techniques/Preserving-Plenty>

---

Alex Chernavsky (2012-09-27 06:33:45)

But I wonder why many fermented foods seem to be an acquired taste (i.e., they often don't taste good the first few times you try them). I still find that to be the case myself. I recently made a fermented hot pepper sauce (well, more of a *paste*, actually) out of habaneros, carrots, onions, garlic, and salt. The stuff has a pungent odor, and I didn't actually enjoy it much until I ate it a few times. Now I find myself craving it, and I'm disappointed that the jar is almost empty.

threepipeproblem (2012-09-27 07:05:09)

Have you seen Dave Asprey's stuff. He is saying (and supposedly cites sources, although I have not investigated) that many ferments are now unsafe, because they produce histamine, tyramine, and other -amines. He says that this has changed as a result of humans applying fungicide to so many soils, which kill 98 % of the natural fungi and leave nasty ones behind. He says that well produced ferments where they are testing the bacteria are ok but that home ferments are not. I'd love to hear your take on this stuff. Seth: I haven't seen those comments nor was I able to find them via Google.

threepipeproblem (2012-09-27 15:16:32)

He covered this in a video. I'm not entirely sure because I have watched 2 or 3 by him. This might be the one where he made the specific point about fungicide – <http://vimeo.com/44715668> – but he tends to cover the amine stuff in all of them. Interesting watch, anyways.

Paleophil (2012-09-27 16:19:22)

"Fermentation of fruits and other sweet foods changes sugars to acids, making the food taste sour" Some fermented foods taste sour to me (especially vinegars), but meads, wines, liquors, raw fermented honey and raw fermented custard apple have never tasted sour to me (some wines have tasted bitter, but not particularly sour). I find that the best sweet fermented foods are less strongly sweet than fresh domesticated fruits and honeys—a more full-bodied, pleasant sweetness that is not "sickeningly sweet."

Ryan (2012-10-03 19:14:28)

Fermented foods are a great way to change the profile of a food. It took me years (as a child) to figure out pickles = cucumbers. I think it adds a whole new layer to our food and drink opportunities.

### **Writer For Rookie Paints Too Pretty a Picture of Her Treatment For Bipolar Disorder (2012-09-28 05:00)**

It was generous of Sady Doyle, a New York writer in her thirties, to use her real name when writing [1]about her bipolar disorder for Rookie, the website for teenage girls. ("Because of this article, you'll always be able to Google me and find out that I have this sickness.") It is what I expect from Rookie to post this sort of thing – I was a big fan of Sassy, an earlier magazine for teenage girls that tried hard to be truthful. But I was surprised to see this:

Here's the part of the story that matters: once I got the diagnosis, got the pills, and got in touch with a therapist I really liked, I woke up in the morning. And I was happy, genuinely happy, for the first time in a very long time. That's what matters about my nervous breakdown—or yours, or anyone's. When I got the help I needed, I was able to recover.

Okay, that's what happened, as Brave New Worldish as it may sound. But is it true "that's what matters" – meaning that's all that matters? No, I don't think so. I think it also matters (a lot) that Doyle has been told she must take pills (such as lithium) for the rest of her life and those pills usually have bad side effects (lithium causes weight gain, for example). It is seriously misleading for Doyle to fail to make these points. Doyle vaguely implies she has been told she will need to take pills for "a long time", which is an understatement, and says nothing about side effects. Maybe she omitted this stuff because she didn't want her readers "to be afraid to seek treatment" (as she might put it). That is the opposite of truth telling.

Here's something about current treatments for bipolar disorder (a comment left on [2]an article about drug company deception) that is as true now as when I quoted it three days ago:

Thirty years of bipolar disorder taking virtually every possible anti-depressant over time, and at times when hospitalized, forced to take them under the duress of threatened sectioning under the Mental Health Act. Throughout those years I told the psychiatrists that the drugs didn't work beyond an initial "placebo effect" lasting about 2 weeks, and that the side effects were often awful.

I am not saying bipolar disorder drugs are worthless. I am saying they have bad side effects so often that any description of what it's like to have bipolar disorder that makes claims of universality ("That's what matters about my nervous breakdown—or yours, or anyone's") should point this out.

1. <http://rookiemag.com/2012/09/on-falling-apart/>

2. <http://www.guardian.co.uk/business/2012/sep/21/drugs-industry-scandal-ben-goldacre?commentpage=all#start-of-comments>

---

Jill (2012-09-28 06:14:13)

How long has she (Sady) been on a regimen that works? Perhaps she is in a sort of "honeymoon" period, during which the relief is so great that to her, right now, that's all that matters. As a journalist, she owes her audience something a bit less short-sighted, but it's not necessarily "the opposite of truth telling." Seth: Yes, an update after a year would be a good idea.

Alex Chernavsky (2012-09-28 07:05:33)

Sady Doyle should read Robert Whitaker's book, [1]*Anatomy of an Epidemic: Magic Bullets, Psychiatric Drugs, and the Astonishing Rise of Mental Illness in America*, particularly Chapter 9 ("The Bipolar Boom"). Here's a paragraph that I was able to extract from the preview on Amazon (I removed the superscripts that reference footnotes):

The remarkable decline in the functional outcomes of bipolar patients is easy to document. In the pre-lithium era, 85 percent of mania patients would return to work or to their "pre-morbid" social role (as a housewife, for example). As Winokur wrote in 1969, most patients had "no difficulty resuming their usual occupations." But then bipolar patients began cycling through emergency rooms more frequently, employment rates began to decline, and soon investigators were reporting that fewer than half of all bipolar patients were employed or otherwise "functionally recovered." In 1995, Michael Gitlin at UCLA reported that only 28 percent of his bipolar patients had a "good occupational outcome" at the end of five years. Three years later, psychiatrists at the University of Cincinnati announced that only 24 percent of their bipolar patients were "functionally recovered" at the end of one year. David Kupfer at the University of Pittsburgh School of Medicine, in a study of 2,839 bipolar patients, discovered that even though 60 percent had attended college and 30 percent had graduated, two-thirds were unemployed. "In summary," wrote Ross Baldessarini in a 2007 review article, "functional status is far more impaired in type I bipolar patients than previously believed, [and] remarkably, there is some evidence that functional outcome in type II bipolar patients may be even worse than in type I."

1. <http://www.amazon.com/Anatomy-Epidemic-Bullets-Psychiatric-Astonishing/dp/0307452425/>

Jim Purdy (2012-09-28 15:08:32)

I think medical students must be taught nonsense like this: Bipolar disorder is caused by a lithium deficiency. Diabetes is caused by a metformin deficiency. High LDL is caused by a statin deficiency. Obesity is caused by a xenical deficiency. Pain is caused by an oxycodone deficiency. Upset stomach is caused by a proton pump inhibitor deficiency. Geez. How has modern "medical science" (Now there's an oxymoron!) gotten so loony? Seth: I think they are taught that depression, etc., are "biochemical" disorders. Which means nothing but supports the use of drugs. A Berkeley psychology major who worked in a job where she encountered lots of people with mental disorders found they were quite different than she had been taught. Diagnosis was less clear, for one thing.

---

dearieme (2012-09-29 08:20:51)

Nice juxtaposition, there.

Jim Purdy (2012-09-29 12:42:46)

Arsenic is only one of many toxic substances in our environment and our food. Instead of obsessing over each toxin separately, maybe it would make more sense to take broader actions that would protect against multiple hazards. For example: 1. Eat more organic foods, containing lower levels of pathogens. And don't argue about whether a food meets some government standard for safety. The fewer toxins the better. Period. 2. Take very good care of your gut bacteria. Your intestinal microbiome is very important to your health, by keeping bad stuff from crossing from the intestines into the bloodstream. Do all you can to support your gut bacteria. 2a. PREBIOTIC FIBER: Your good gut bacteria love fiber! I take a Jarrow brand of high-fiber prebiotic supplements with FOS and insulin (that is inulin, not insulin). I also eat a lot of high-fiber fresh produce. 2b. PROBIOTIC GERMS I also take a high-dosage probiotic called VLS #3. And I also eat plain yogurt with live cultures. I prefer plain Greek yogurt. Interestingly, the same toxins that hurt our bodies also harm our gut bacteria, so reducing toxins will give us a double benefit by strengthening our microflora. So eat your yogurt, but not the "fruit-flavored" junk yogurt. Have some plain Greek yogurt, with real fruit like apple slices and red grapes and banana slices. And sprinkle on some inulin powder, or a stevia brand that contains inulin. I'll see you at the Whole Foods Market. I'm the old bearded guy checking out the yogurt.

Tom (2012-09-29 19:48:51)

Reading Taleb's comment got me reading the other books he's raved about. This one might be up your alley: [http://www.amazon.com/review/R1YDOM1Y5TR6FA/ref=cm\\_cr\\_rdp\\_perm](http://www.amazon.com/review/R1YDOM1Y5TR6FA/ref=cm_cr_rdp_perm)

Paul N (2012-09-30 12:37:12)

I agree with Jim Purdy here that obsessing over individual toxins often misses the larger problem, which is the industrial production of food, and the wrong types of food, at that. In the case of rice, the plant has a greater affinity to take up arsenic than other grains, and especially in wet (irrigated) conditions. The arsenic is mainly in the husk, another reason to

avoid brown rice. As for the yoghurt, I'd suggest go a step further and use kefir instead - it has a far better mix of probiotics than any yoghurt. You can learn more than you ever thought possible at Dom's Kefir Site (google it). You can also make kefir, yourself, on your countertop, simply by mixing some store bought kefir with milk at about 10:1 ratio. Let it sit for 24 hours and then refrigerate and leave for another few days. I also use it for culturing mil to make my own cheese, culturing cream to make my own butter, and the whey for pickles and sourdoughs! Better still if you get kefir grains to do it the proper way... Unlike yoghurt, kefir works over a wide range of temperatures, and is best at room temperature - in other words - it's hard, very hard, to go wrong with it! So then you can just buy milk, save the money and reduce your support of the food processing industry. When you can buy a gallon of milk and make kefir for the less than the price of a quart tub of yoghurt, you are making much better use of your money, and supporting the \*production\* of food, not the \*processing\* of it.

Willy (2012-09-30 20:01:28)

Paul N, I bought the Kefir granules. I think I will try water but it does not look so easy.

Paul N (2012-10-01 09:22:59)

Willy, The kefir granules only work with full fat milk - they actually "digest" the milk fats in some way. For doing water (with sugar) you need "water kefir grains" (also called sugar kefir grains, or Tibicos). they are a different beast, good with sugar solutions, fruit juices, coconut water (but not coconut milk), etc. Dom's kefir site explains it all, and examples of different recipes are at [www.kefirgrains.info](http://www.kefirgrains.info) I have the water kefir grains and use them for making carbonated "coconut beer", ginger beer, and a few other things. Left in there long enough, they will make vinegar. ( I also have kombucha that can do that too...) Once you get into making stuff -fermented and otherwise - from just ingredients, it is amazing how much better it is, and how much cheaper too. Well worth an hour every few days. An easier to buy as many ingredients as possible (fruit, veg, eggs) from the producers directly - farmers markets and the like. As Joel Salatin says, the problem is not getting the really good (non-industrial produced) food into the supermarkets, the problem is to get people out of the supermarkets and buying direct from producers. Supermarkets, by their nature, encourage corporate food production. Try going for two weeks not buying anything from a supermarket. Not easy, but you will seek out sources of (fresh) food you never knew existed in your area.

## **The Growth of Personal Science: Implications For Statistics (2012-09-30 05:00)**

I have just submitted [1]a paper to Statistical Science called "The Growth of Personal Science: Implications For Statistics". The core of the paper is examples, mostly my work (on flaxseed oil, butter, standing, and so on). There is also a section on the broad lessons of the examples - what can be learned from them in addition to the subject-matter conclusions (e.g., butter makes me faster at arithmetic). The paper grew out of a talk I gave at the Joint Statistical Meetings a few years ago, as part of a session organized by Hadley Wickham, a professor of statistics at Rice University.

I call this stuff personal science (science done to help yourself), a new term, rather than self-experimentation, the old term, partly because a large amount of self-experimentation - until recently, almost all of it - is not personal science but professional science (science done as part of a job). Now and then, professional scientists or doctors or dentists have done their job using themselves as a subject. For example, a dentist tests a new type of anesthetic on himself. That's self-experimentation but not personal science. Moreover, plenty of personal science is not self-experimentation. An example is a mother reading the scientific literature [2]to decide if her son should get a tonsillectomy. It is personal science, not professional self-experimentation, whose importance has been underestimated.

An old term for personal science might be amateur science. In almost all areas of human endeavor, amateur work doesn't matter. Cars are invented, designed and built entirely by professionals. Household products are invented, designed and built entirely by professionals. The food I eat comes entirely from professionals. And so on. Adam Smith glorified this ("division of labor" - a better name is division of expertise). There are, however, two exceptions: books and science. I read a substantial number of books not by professional writers and my own personal science has had

a huge effect on my life. As a culture, we understand the importance of non-professional book writers. We have yet to grasp the importance of personal scientists.

Professional science is a big enterprise. Billions of dollars in research grants, hundreds of billions of dollars of infrastructure and equipment and libraries, perhaps a few hundred thousand people with full-time jobs, working year after year for hundreds of years. Presumably they are working hard, have been working hard, to expand what we know on countless topics, including sleep, weight control, nutrition, the immune system, and so on. Given all this, the fact that one person (me) could make ten or so discoveries that make a difference (in my life) is astonishing – or, at least, hard to explain. How could an amateur (me – my personal science, e.g., about sleep is outside my professional area of expertise) possibly find something that professional scientists, with their vastly greater resources and knowledge and experience, have missed? One discovery – maybe I was lucky. Two discoveries – maybe I was very very very lucky. Three or more discoveries – how can this possibly be?

Professional scientists have several advantages over personal scientists (funding, knowledge, infrastructure, etc.). On the other hand, personal scientists have several advantages over professional scientists. They have more freedom. A personal scientist can seriously study "crazy" ideas. A professional scientist cannot. Personal scientists also have a laser-sharp focus: They care only about self-improvement. Professional scientists no doubt want to make the world a better place, but they have other goals as well: getting a raise, keeping their job, earning and keeping the respect of their colleagues, winning awards, and so on. Personal scientists also have more time: They can study a problem for as long as it takes. Professional scientists, however, must produce a steady stream of papers. To spend ten years on one paper would be to kiss their career goodbye. The broad interest of my personal science is that my success suggests the advantages of personal science may in some cases outweigh the advantages of professional science. Which most people would consider impossible.

If this sounds interesting, I invite you to read my paper and comment. I am especially interested in suggestions for improvement. There is plenty of time to improve the final product – and no doubt plenty of room for improvement.

I'd love to read it. Sounds really interesting.

Devin Bean (2012-10-20 20:43:59)  
I'd love to read it as well. Thanks! Seth: You can download it via the link attached to "a paper" above.

## 7.10 October

### Two Dimensions of Economic Growth: GDP and Useful Knowledge (2012-10-01 05:00)

Ecologists understand the exploit/explore distinction. When an animal looks for food, it can either exploit (use previous knowledge of where food is) or explore (try to learn more about where food is). With ants, the difference is

visible. Trail of ants to a food source: exploit. Solitary wandering ant: explore. With other animals, the difference is more subtle. You might think that when a rat presses a bar for food, that is pure exploitation. However, [1]my colleagues and I found that when expectation of food was lower, there was more variation – more exploration – in how the rat pressed the bar. In a wide range of domains (genetics, business), less expectation of reward leads to more exploration. In business, this is a common observation. For example, yesterday I read [2]an article about the Washington Post that said its leaders failed to explore enough because they had a false sense of security provided by their Kaplan branch. "Thanks to Kaplan, the Post Company felt less pressure to make hard strategic choices—and less pressure to venture in new directions," wrote Sarah Ellison.

Striking the right balance between exploitation and exploration is crucial. If an animal exploits too much, it will starve when its supply of food runs out. If it explores too much, it will starve right away. Every instance of collapse in Jared Diamond's *Collapse: How Societies Choose to Fail or Succeed* was plausibly due to too much exploitation, too little exploration (which Diamond, even though he is a biologist, fails to say). I've posted several times about my discovery that [3]treadmill walking made studying Chinese more pleasant. I believe walking creates a thirst for dry knowledge. My evolutionary explanation is that this pushed prehistoric humans to explore more.

I have never heard an economist make this point: the need for proper balance between exploit and explore. It is relevant in a large fraction of discussions about how to spend money. For example, yesterday I listened to [4]the latest EconTalk podcast, a debate between Bob Frank and Russ Roberts about whether it would be a good idea for the American government to spend \$2 trillion on infrastructure projects (fix bridges, etc.). Frank said it would create jobs, and so on – the usual argument. Roberts said if fixing bridges was such a good idea, why hadn't this choice already been made? Roberts could have said, but didn't, that massive government shovel-ready expenditures, such as \$2 trillion spent on infrastructure repair, inevitably push the exploit/explore balance toward exploit, which is dangerous. This is an argument against all Keynesian stimulus-type spending. I have heard countless arguments about such spending. I have never heard it made. If you want examples of how the American economy suffers from a profound lack of useful new ideas, look at health care. As far as I know, there are no recorded instances of a society dying because of too much exploration. The problem is always too much exploitation. People at the top – with a tiny number of exceptions, such as the Basques – overestimate the stability of their position. At the end of *The Economy of Cities*, Jane Jacobs says that if a spaceship landed on Earth, she would want to know how their civilization avoided overexploitation. When societies exploit too much and explore too little, said Jacobs, problems (in our society, problems such as obesity, autism, autoimmune disease, etc.) stack up unsolved. Today is China's birthday. Due to overexploitation, I believe China is in even worse economic shape than America. Ron Unz, whom I respect, [5]misses this.

My broad point is that a lot of economic thinking, especially about growth and development, is one-dimensional (measuring primarily growth of previously existing goods and services – exploitation) when it should be two-dimensional (measuring both (a) growth of existing stuff and (b) creation of new goods and services). Exploration (successful exploration) is inevitably tiny compared to exploitation, but it is crucial there be enough of it. If there is a textbook that makes this point, I haven't seen it. An example of getting it right is Hugh Sinclair's excellent new book [6]*Confessions of a Microfinance Heretic* (copy sent me by publisher) that debunks microcredit. Leaving aside the very high interest rates, the use of microcredit loans to buy TVs, and so on, microcredit is still a bad idea because the money is, at best, used for a business that copies an existing business. (The higher the interest rate, the less risk a loan recipient dares take.) When a new business copies an already-existing business, you are taking an existing pie (e.g., demand for milk, if the loan has been used to buy a cow and sell its milk) and dividing it into one more piece. The pie does not get bigger. As Sinclair says, the notion that dividing existing pies into more pieces will "create a poverty-free world" is, uh, [7]not worthy of a Nobel Prize.

Sure, it's hard to measure growth of useful knowledge. (It is perfectly possible for a company to [8]waste its entire R & D budget.) However, I am quite sure that realism does better than make-believe – and the notion that growth of GDP is a satisfactory metric of economic growth is make-believe. If you've ever been sick, or gone to college, and have a sense of history, you will have noticed the profound stagnation in two unavoidable sectors (health care and

education) of our economy. That are growing really fast.

Nancy Lebovitz (2012-10-01 05:12:32)

To the extent that microcredit increases individual security, it increases the likelihood of exploration. Also, even a conventional business has room for some exploration, even if most don't use it. Seth: By its nature, taking on debt decreases security, if you must pay back the debt. And taking on debt at high interest – microcredit loans tend to have interest rates on the order of 70 %/year – decreases security even more. Less security, less risk-taking, as you say.

Chuck (2012-10-01 06:14:52)

I like it.

Bob (2012-10-01 07:20:55)

You probably already know this Seth, but the Austrian economists have been stressing the market as discovery procedure for a long time, particularly Hayek's "Competition as a Discovery Process" and Israel Kirzner's work on entrepreneurial discovery. Perhaps there is an Austrian textbook that covers exploration/exploitation, though I've not encountered it in exactly this form that I can recall.

Patrik (2012-10-01 22:42:28)

Just want to note, the exploration/exploitation continuum roughly maps to the The Innovation Spectrum spanning from Sustaining to Disruptive. Image here: <http://vlsvts.co/Ne04U1>

Bryan (2012-10-01 23:34:23)

»If you've ever been sick, or gone to college, and have a sense of history, you will have noticed the profound stagnation in two unavoidable sectors (health care and education) of our economy. That are growing really fast. Case in point: <http://www.theatlantic.com/entertainment/archive/2012/10/why-there-needs-to-be-a-real-grad-school-of-rock/262802/>

anand srivastava (2012-10-03 00:05:37)

Have you read FOFOA? He has a very interesting theory of the current crisis. He thinks that we will not move into Gold Standard after this Fiat crisis. We will instead move to something like Euro. Where Gold is the major reserve but it does not back the currency directly. Also all Paper claims to gold will disappear. The currency in gold standard is also a paper claim to gold. Which depresses the price of gold. It makes so much sense. FOFOA's dilemma: When a single medium is used as both store of value and medium of exchange it leads to a conflict between debtors and savers. FOFOA's dilemma holds true for both gold and fiat, the solution being Freegold, which incidentally also resolves Triffin's dilemma. <http://fofoa.blogspot.in/2011/05/return-to-honest-money.html>

shtove (2012-10-04 13:00:34)

Last place I thought I'd find gold-buggery! My view is we've run up against resource limitations, so tilting the balance toward exploration is vital. Even so I reckon we've seen the end of GDP growth - peak exploitation and peak-debt are already behind us, the age of making money off money is over. Perhaps we're moving into a steady state economy - not a disaster, but certainly far removed from the expectation that it's just a matter of time before we get back "on course". As usual, the hard-science bloggers provide the best insight on areas outside their disciplines because they can apply maths and stats - try this one for the steady-state hypothesis: <http://liminalhack.wordpress.com/> And anyone interested in the Chinese debt disaster has to follow Michael Pettis: <http://www.mpettis.com/>

Thomas Colthurst (2012-10-27 14:12:02)

Interesting post. I'm confused about one part, though: why do you think \$2 trillion of additional infrastructure spending would effect the explore/exploit balance? I don't believe any federal research budgets were being cut to fund the \$2 trillion, so explore would stay the same; almost all of the resources would either come from re-allocating things already in the "exploit sector" (such as private sector construction workers) or from unused resources (such as unemployed workers). In computer science, we often think about the explore/exploit distinction in the context of the "multi-armed bandit" model and we try to prove theorems like such-and-such algorithm does this good of a job of managing the trade-off in such-and-such situations. It isn't just useless theorizing, though: at Google (where I work), we use multi-armed bandits to optimize the ads and websites we show to our users. (See <http://support.google.com/analytics/bin/answer.py?hl=en&answer=2677320> for example). Seth: Why would \$2 trillion of infrastructure spending affect the exploit/explore balance? Because it would all go toward exploit, creating a large number of people (everyone who gets the money) whose interests lie in more exploit, less explore. Unemployed workers drift between explore and exploit - they will do what they are hired to do. Once they are hired, they start to become committed. An unemployed worker hired to exploit will want more exploit; an unemployed worker hired to explore (after working in exploit) will begin to see why the country needs more explore.

Paul N (2012-10-28 10:22:05)

Seth, That's a great explanation - in response to Thomas. I have seen in my community the results of "government stimulus" - the workers hired to exploit do indeed want more, and see that as the best way forward. Even worse, the community starts to buy into it as it seemed to work better than explore - in the short term anyway. I think of it as the economic equivalent of sugar/empty calories. It has a short term benefit of increased activity and usually little long term gain. Explore has an inherent risk component and no one - governments, corporations, people seems to want to take that on. Even universities and research institutions suffer this, as their funding mechanisms often seem to favour exploit. Can you give an example of someone hired to "explore"? Seth: Thanks! To answer your question, someone hired by an innovative small business. When something's new, there's a lot to learn about how to make it, sell it, improve it.

Why "follow your passion" is bad career advice. | Uncouth Reflections (2012-10-02 08:07:26)

[...] HT: Seth Roberts Share this:TwitterFacebookEmailPrintLike this:LikeBe the first to like this. [...]

Mike C (2012-10-02 08:59:33)

It would be very interesting to hear more details on what "a big mistake" really means. As a parent, I'm about to face these choices myself. As a kid, I didn't really have a choice, as there was really no way to afford anything but a state school (even though I likely could have gained an offer from MIT). Regrets? Sort of. But as a technologist, I regret not moving to the SF Bay Area in the 90s a lot more... Seth: It was a few years ago she told me this. I think "big mistake" meant fewer job opportunities and being looked down on a lot.

WB (2012-10-02 09:22:28)

Seth, re your piece on "Desirable College" and particularly your friend who attended the local law school: The cost of post secondary education has become a big problem and in many respects is outright scandalous. It is terrible public policy to require prospective college students and their parents to take on such enormous amounts of debt to get a decent education. The economy is of course part of the problem, but so is the way quite a few colleges and universities are administered. Many have become so "financialized" that they have lost sight of their essential mission. But it has now gotten so bad, maybe more people will finally begin to wake up about the issue and start communicating with their political representatives. And yes, your friend probably did make a big mistake, but not just because she attended the local law school, rather than a "top tier" school. See this link to a blog by a law professor (Paul Campos) who has been writing about this for awhile. It should be required reading for anyone who thinks they want to attend law school (and also their parents). <http://insidethelawschoolscam.blogspot.com/>

shortdude (2012-10-02 10:53:25)

There's a big difference between law school and college. Most people these days acknowledge that if you don't go to a top tier law school, then you face poor employment prospects for the foreseeable future. The market is over-saturated to the extreme. However, when it comes to college, choosing a school really depends on what you want to do. If you plan on medical school, for example, it doesn't matter much at all where you go. If business is your thing, then going to NYU or Penn can make a huge difference. On a side note, that girl sounds kind of spoiled and entitled - maybe her application just wasn't as great as she thought it was?

dearieme (2012-10-02 11:23:14)

Adam Smith wrote about how you must expect a surplus of lawyers, and of how a few would make a lot of money and many would make little. Shrewd chap, Professor Smith.

Tom (2012-10-02 19:59:21)

College is a loan-sharking racket now.

AM (2012-10-02 21:04:47)

Choosing a local law school (unless "local" means Cal or Stanford) over Harvard and Yale was such a horrible decision that I wonder how your friend got into those top schools in the first place. Yes, that sounds terribly snarky, but if she'd spent even five minutes investigating the legal job market (aka reading Above The Law) she'd have made a different choice. The law school market is very different than the college market.

John (2012-10-03 11:07:33)

dearieme, could you give us a citation or link for Adam Smith (and I assume you mean THE Adam Smith) on lawyers?

Bryan (2012-10-03 13:30:29)

I second John's request. I tried searching for it but came up empty.

Pat (2012-10-03 14:15:01)

interesting about your lawyer friend. She was right in that it should not matter, but we are living in a Veblen world.

dearieme (2012-10-03 16:18:42)

@John: my copy of The Wealth of Nations is from Penguin Classics, edited by Andrew Skinner, 1970: the relevant bit is on p 207 onwards. It's probably more useful to you to note that it's from Book I, chapter x "Of wages and Profit in the different Employments of Labour and Stock". It must be available free on the web. You could Google this bit about "your son": "... but send him to study the law, it is at least twenty to one if ever he makes such a proficiency as will enable him to live by the business."

dearieme (2012-10-03 16:20:52)

As predicted <http://www.econlib.org/library/Smith/smWN4.html>

dearieme (2012-10-03 16:34:49)

Here's some more Smithian wisdom, bearing on student loans don't you think? I.10.92 In professions in which there are no benefices, such as law and physic, if an equal proportion of people were educated at the public expence, the competition would soon be so great, as to sink very much their pecuniary reward. It might then not be worth any man's while to educate his son to either of those professions at his own expence. They would be entirely abandoned to such as had been educated by those public charities, whose numbers and necessities would oblige them in general to content themselves with a very miserable recompence, to the entire degradation of the now respectable professions of law and physic.

dearieme (2012-10-03 16:38:28)

Nobody can consider himself educated who has not read The Wealth of Nations, The Origin of Species, and Gibbon's Decline and Fall. Says me.

## **Extremely Disappointing Facts About Doctors (2012-10-03 05:00)**

The gist of Unaccountable: What Hospitals Won't Tell You – and How Transparency Can Revolutionize Health Care (copy sent me by publisher) by Mart Makary, a med school professor at Johns Hopkins, is that doctors have failed to regulate themselves. Nobody else regulates them, so they are unaccountable. In many ways, Makary shows, bad behavior (e.g., unnecessary treatment, [1]understating the risks of treatment) is common. Hospitals hide how bad things are. Makary mostly discusses surgeons – he's a surgeon – but gives plenty of reasons to think other specialties are no better.

The book is one horror story after another. At one point, Makary quit medical school. He was disgusted and appalled by seeing doctors – his teachers – push an old woman to consent to an operation she didn't want and didn't need. She refused, again and again, but the doctors kept pushing. Makary objected. He was ignored. Finally she

agreed. The operation killed her.

I know Peter Attia as a co-founder, with Gary Taubes, of the recently formed [2]Nutritional Science Initiative. Makary met him when Attia did a surgery residency at John Hopkins Hospital. Attia had seen a doctor about back pain and had been told he needed surgery. They operated on the wrong side, causing damage that prevents Attia, an excellent athlete, from playing most sports. Eventually Attia left medicine. He felt "modern medicine was too frequently dishonest with patients, at times understating risks and overtreating patients as a matter of reflex" – "as a matter of reflex" meaning "as a matter of course", i.e., usually. And Johns Hopkins Hospital is one of the better hospitals in America. "Almost everyone I talk to has a story about a friend or a family member who was hurt, disfigured, or killed by a medical mistake," writes Makary. He has six such stories, including his grandfather and his brother. His grandfather died from unnecessary surgery.

The "when-you're-a-hammer problem" says Makary, "plagues modern medicine at every level." He witnessed a case conference where a young otherwise-healthy patient had a small liver tumor. "The transplant surgeons [more than one] in the audience recommended a liver transplant. I was flabbergasted. Why on earth would any doctor recommend a transplant?" Makary asked around. He discovered there was nothing unusual about the transplant surgeons in the audience. He called a friend who was one of the few surgeons trained in both cancer treatment and transplants. His friend said "there was a battle for turf taking place nationwide between transplant surgeons and cancer surgeons. Both claim to be liver experts."

Makary tells about trying to obtain informed consent for a surgery when he was an intern. He didn't know much about the surgery. The patient didn't agree. "It was well-known among interns that if an attending senior surgeon found out that a patient refused surgery close to surgery date, duck for cover. Mine would surely be livid." Makary spoke to an upper resident. He couldn't get approval. They went to the chief resident. He got approval. Congratulations all around amongst the doctors, "glad that the wrath of the attending surgeon would be averted."

Supposedly state medical boards oversee doctors. Makary devotes part of a chapter to describing how they don't. He asked state medical boards why they don't search a national database before issuing a medical license. "My favorite excuse was that they could not afford the four-dollar-per-doctor fee."

In 1978, the Shah of Iran needed an operation. The United States government set him up with a Texan named Michael DeBakey, "considered by many to be the best surgeon in the world." During the surgery, DeBakey failed to take "a simple standard safety measure." Due to this failure, the Shah developed a serious complication, became very sick, and died. The Shah and the United States government had failed to realize – and, more important, none of the experts they consulted had told them (I assume) – is that DeBakey was a famous heart surgeon. The Shah's operation involved his spleen. DeBakey knew little about such operations and had done almost none – but (I assume) didn't point this out.

A survey done at many hospitals asks employees if they "feel comfortable speaking up when [they] sense a patient safety concern." At the median hospital, the percentage is about 70 %. In the Milgram experiment (where subjects are ordered to give painful shocks), when audiences were asked by Milgram to predict what they would do in that situation almost all said they wouldn't give the shocks. In fact, most people did give the shocks – indicating that people vastly overestimated their likelihood of resistance and speaking up. So 70 % is likely an overestimate. (A study of nurses found that about 95 % of them broke safety rules when ordered to do so. Roughly all of them had said they would never do such a thing.) Since talk is cheap, why is the median percentage as low as 70 %? No doubt many respondents had seen themselves fail to speak up.

These aren't the worst stories, these are average, I just opened the book here and there. There are dozens more. No previous book has spelled out so clearly the depth and width of doctor misbehavior, especially how common it is, and the failure of those supposedly responsible, such as hospital administrators and state boards, to do anything

about it.

Title from [3]12 extremely disappointing facts about popular music.

charlie (2012-10-03 05:37:25)

You've got to separate hospital from doctors. Two very different incentive structures.

Steve G. (2012-10-03 06:57:24)

Although much maligned and slandered, medical malpractice lawsuits seek to influence physician & hospital behavior, but it's a weak system. Meritorious cases often don't win; they are extremely expensive to pursue; and most doctors and hospitals will go to extreme lengths to avoid liability. For a good consideration of the topic, consult Tom Baker's The Medical Malpractice Myth. In the end, doctors more than lawyers need to address this issue. It's a much greater problem that most realize or (for those who should know), want to admit.

WB (2012-10-03 08:24:06)

1. Seth: There is a term for this that I first learned from reading one of Nassim Taleb's books; a term I'd never heard before: iatrogenic (from the Greek term iatros, physician + E -genic). Of course this ancient term refers to inadvertently induced harm. What the Makary book talks about obviously goes beyond that. 2. There is an important blog, <http://hcrenewal.blogspot.com>, that focuses on ethics problems in the medical care industry. The lead author is Roy Poses, MD who has been actively talking about it for a long time without getting much traction either within his profession or in main stream media. He refers to this as the "anechoic" effect. The blog describes its mission as "Addressing threats to health care's core values, especially those stemming from concentration and abuse of power. Advocating for accountability, integrity, transparency, honesty and ethics in leadership and governance of health care." 3. @ Steve G. The medical malpractice system is more than weak. It is part of the problem because of the way "malpractice" is defined and determined by our court systems. This system helped open the door to what is generally referred to as "defensive" medicine based on "protocols" for testing and treatment concocted by the medical care system and (as it turned out) designed mostly to protect physicians against malpractice claims. As long as the physician follows the applicable "protocol," legal claims are nearly impossible to pursue effectively. This is something that needs to be addressed by policy makers (e.g. legislators) rather than doctors or lawyers. The reason is that there are way too many conflicts of interest among the regular players in the existing medical system. And I agree with you that it is a greater problem than most of us realize - much greater.

LemmusLemmus (2012-10-03 10:23:48)

This somewhat related post may be of interest: <http://economiclogic.blogspot.de/2012/10/disclosing-hospital-quality-works.html> (I have not read the paper it refers to.)

JPB (2012-10-03 13:06:18)

Having lost several family members and friends to doctors pushing for surgery, etc., I have lost faith with the medical profession, despite coming from a family with 5 doctors, 7 nurses, and more. When is the medical "profession" going to come to it's senses? How many more people will have to die before doctors start questioning the protocols?

Alex Chernavsky (2012-10-03 16:38:48)

Unfortunately, you as a patient have to keep your wits about you and do your own homework. By remaining vigilant and skeptical in the face of "expert" medical opinions, I've saved myself a lot of grief on several occasions. God help you if you are, by nature, a trusting soul, or ignorant, or both.

anand srivastava (2012-10-04 00:27:41)

There is a concept called Super Organism. I read it first time on FOFOA's blog. Its not that only ants create superorganism (SO). Every organism will build one. And humans are no exceptions. The Medical establishment is also an SO. It has its own set of incentives, that define the SO. It is not that individual members of the SO are inherently evil, its just that they have to behave that way for the betterment of the SO. So the people who don't work for the SO's health are thrown out and the people who work in accordance are nurtured. Yes the only way to fix the problem would be to change the incentives. And yes criminal penalties for mistakes would make it better, as it will change some incentives.

dearieme (2012-10-04 05:33:52)

"you as a patient have to keep your wits about you and do your own homework": not always easy if you're feeling ill.

Nancy Lebovitz (2012-10-04 08:00:48)

You guys have been focusing on inappropriate care that given, and there's certainly plenty of that, but the other side is appropriate care that isn't given. Fat people (possibly especially fat women) are apt to have their actual symptoms ignored and just get told to lose weight. This can mean years of unaddressed illnesses, whether because the patient has to go through a number of doctors or gives up on trying to get help. I've only heard a little about it, but apparently unusually thin people are at risk of being told to just gain weight. What's more, if you've got a disease that's considered uncharacteristic of your weight (like type 2 diabetes in a person who isn't fat), it can take a long time to get a diagnosis. Pain medication is frequently withheld, partly because doctors have a rational fear of being accused of giving pain meds to addicts or resellers, and partly because of a less rational tendency to not take pain seriously. More generally, only getting paid enough for very short appointments means that doctors have much less time for diagnosis, and are less likely to hear all the relevant symptoms or have time to think about them.

WB (2012-10-04 12:27:19)

@ Nancy: You make valid points. But along a different line of thinking (such as becoming more aware of the things that we all could do to avoid many, all-to-common maladies in the first instance), there is the thing that is often never discussed by doctors: nutritional changes. Most physicians have no in-depth knowledge of this and, if they ever do advise life-style changes, it is usually along the lines of "eat less, exercise more" which is utterly useless advice. ( Our grandmothers can do better than that!) Beyond this, in the case of doctors, it's usually a matter of pulling out the Rx pad or administering tests. But this is not working for most of us, and it will only get worse unless and until we take charge of our own health and well being. We all need to acquire more self knowledge of what works and what doesn't, and it's mostly free. What does (and can) work is some degree of individual effort to set aside certain assumptions (such as, e.g., the "balanced diet" is best) to find out what kind of nutritional changes can actually help many of us eliminate (reverse) many common "diseases" and then implement those changes. Seth has talked about some of these on this blog. There is a lot of great information out there on the world wide Web, and even in "old fashioned" books. One just has to open the mind a little bit and start digging. It's not necessarily easy in the beginning, but is well worth it. In my view, that's a lot better approach (and cheaper to boot) than expecting doctors to be able to show us the way to health. There may be a few, but you won't find them in the main stream. Conventional "medicine" is fine for things such as repairing injuries and helping us overcome some infectious diseases. But if we're seeking long term, every-day health, medicine is a wrong-way street.

Nancy Lebovitz (2012-10-04 13:19:15)

WB, I'm in substantial agreement. Adjusting diets for individuals can make huge improvements. One of my friends has found that his digestive tract shuts down if he doesn't eat a good bit of wheat fairly often, and it's the same for a couple of his relatives. I wonder whether there are people with intractable ailments who just need to add the right food to their diets. Something else that was simple, cheap, safe, and effective- I cleared up a case of acid reflux by sleeping on my left side for a couple of nights. The suggestion was in wikipedia.

One reason that the tables of desirable BMI must be wrong is that they make no allowance for age or sex. Perhaps they ought ideally to allow for race too. Who knows?

Bryan (2012-10-05 07:14:34)

Gary Becker argues that patents should be minimal: <http://www.becker-posner-blog.com/2012/09/reforming-the-patent-system-toward-a-minimalist-system-becker.html>

## Five Most Important Rules of Nature Photography (2012-10-05 05:00)

A friend sent me some photos taken on a mountain hike. They seemed to derive from the following rules:

1. Carry a small camera in a big bag.
2. Always take a picture of a flower.
3. Change clothes from one picture to the next. (For example, wear pants in one picture and shorts in another picture, or a blue shirt in one picture and a white shirt in another picture.)
4. Make a funny face (for example, press finger into cheek).
5. Wear a funny shirt.

---

Tom (2012-10-05 08:25:34)

It's amazing the lengths people go to to convince their Facebook friends that their life really is awesome.

Jim Purdy (2012-10-05 19:37:54)

6. Don't bore everybody you know by showing them your pictures of flowers, shorts, shirts, and funny faces.

## When You're a Lawyer, Everything Looks Like an Opportunity to Argue (2012-10-06 16:29)

I [1]recently posted about Unaccountable by Mart Makary, a book about the bad behavior of doctors. One of his points is "The when-you're-a-hammer problem plagues modern medicine at every level." He illustrated this with a case where transplant surgeons said an otherwise-healthy person with a small liver tumor should get a liver transplant. Which struck Makary as ridiculous.

A lawyer who reads this blog sees the same thing in lawyers. He told me the following story:

One of the sixteen defendants we sued moved to transfer the venue of our case from [Southern California city] to [Northern California city]. Both plaintiffs, all of his doctors (over a dozen), all of the witnesses (again, about a dozen), and all of locations where the incident took place are in or near [N. California city]. When we got the motion I took it to my boss who said, "Huh. We should've filed it in [N. California city] to begin with. I don't know why we didn't." It would've been inconvenient for us, b/c we're in [S. California city], but we've filed cases up there before, so we could handle it.

So, did we stipulate with the defendant and just transfer the case up north? No. We filed a pathetic, perfunctory opposition. We had an argument, but it was very weak: one of the defendants was located in [S. California city]. That's basically all we had to hang our hat on.

We filed our opposition, defendant filed their reply. We all trekked down to court to argue our positions in front of the judge. The hearing should've taken 30 seconds – "Defendant's motion granted." – but the judge actually entertained oral argument. Finally, he granted the motion.

When I got back to the office, I noted to my secretary what a huge waste of time all of this was. The law was clear, virtually all of the facts were on opposing counsel's side, we should've filed up north to begin with, so why fight it? Why not save everyone – us, opposing counsel, the judge and his staff – time and just agree? "Well, you gotta take a shot," was her reply. Which is what I hear from attorneys all the time. "You gotta try, you gotta make the argument." In other words, we have hammers so the hammers must be used no matter what.

No, it isn't quite like a transplant surgeon who says a new liver is needed b/c of a small tumor – no one's life or health is at risk – but how much time and resources are wasted in the legal system on bullshit like this?

---

Steve G. (2012-10-07 02:22:04)

Seth, Don't fall for the anecdotal evidence trap. Yes, these motions get filed, although I'm surprised that a plaintiff's attorney filed it. As a practitioner, including medical malpractice claims, the waste-of-time stuff usually comes from the defense attorneys representing insurance carriers. Paid by the hour, and with virtually unlimited resources, insurance carriers (never the named the defendant but the ones who call the shots) do this sort of thing. Plaintiffs' attorneys, at least this one, realized that the more time that they put in on a case, the less the rate of return—if there is a return—since we work on a contingent fee basis. I wanted to get my case tried on the merits as quickly & efficiently as possible. You should know that most medical malpractice cases are unsuccessful, regardless of merit. Juries don't like to enter verdicts against the good doctor. Please also note the venue of the anecdote: California. Having practiced in Iowa and Illinois, I can tell you that legal cultures, including the amount of posturing and BS, vary greatly from place to place. Chicago was a very different practice than Champaign. In Chicago-area courts & legal practices, you find a great deal more posturing & tactical use of delays & uncertainties. (And I will not even contemplate corruption of judges, who are elected in Illinois, a hideous thing.) Iowa is more sedate. In a smaller jurisdiction, you can't afford to develop a reputation as a time-waster (think iterated prisoner's dilemma). Judges are busy enough. Also, judges are appointed and don't have to solicit campaign funds, although we do have retention elections, which, until recently, were non-partisan. So are we perfect? No. Do some attorneys waste time & BS? Yes. But on the whole, the courts and the legal culture, at least in Iowa, tend to minimize this nonsense. And I hate it, too!

Bryan (2012-10-07 08:16:50)

»Don't fall for the anecdotal evidence trap. I take it you're new to this blog?

AM (2012-10-07 17:12:29)

» Don't fall for the anecdotal evidence trap. > I take it you're new to this blog? Hah!

Steve G. (2012-10-08 21:42:09)

Ah, no, I've been here before. I think the world of anecdotes. In my professional world they're called cases. Indeed, consider the power of the anecdote, assuming for a moment its veracity (no small assumption, I understand). A single true event can negate contrary statistical suggestions of a virtually infinite data set, thereby pleasing Mr. Popper (of Vienna & London, not of the Penguins). I think that this is why the law is so very cautious about statistics, since we are most often concerned with the single incident. But when making public policy, anecdotes are poison. Case in point: the McDonald's coffee case (see the documentary "Hot Coffee" if you don't appreciate my reference), or other tales of lawyers gone wild. Here statistics should guide us in separating anomalies from trends. So, I'm sweet on both anecdotes & statistical generalizations.

shtove (2012-10-09 11:40:33)

In the UK this is managed through the threat of a wasted costs order - if a lawyer has been unreasonable he runs the risk of paying personally. I imagine many US jurisdictions have the same. We've all come across hammer-nail abuses, but systems do adapt in some degree.

charlie (2012-10-07 11:01:26)

Am I reading it correctly the Vitamin D study recieved 100,000 IU a month? At once? Seth: Yes. Here's a description: "Participants were randomly assigned to receive an initial dose of 200 000 IU oral vitamin D3, then 200 000 IU 1 month later, then 100 000 IU monthly (n = 161), or placebo administered in an identical dosing regimen (n = 161), for a total of 18 months."An experimental design that assumes that all that matters is the blood level of Vitamin D3< /strong>

Jake (2012-10-07 13:56:51)

This Vitamin D study was a poorly done should be ignored. They did not test for blood levels of Vitamin D which is essential as there is huge variation in people's ability to absorb Vitamin D. Here is a better study: A controlled study of severely Vitamin D deficient women over 50 from Harlem were randomly selected to be supplemented. One group was supplemented to bring them up to moderately deficient. They had a 60 % reduced risk of colds and influenza. Another group were supplemented to bring them up to optimum Vitamin D blood level and they had a 90 % reduction in risk.

Nancy Lebovitz (2012-10-07 17:34:30)

Jake, is that an actual study or how you think it should have been done?

dearieme (2012-10-07 17:37:41)

"someone agrees with me that "correlation does not equal causation" is not great wisdom": then you're both wrong. The advice is offered to freshers for good reason. Seth: Correlations are useful. They provide evidence relevant to causation. The saying I disparage says roughly the opposite. How is that helpful?

## **Kahneman Criticizes Social Psychologists For Replication Difficulties (2012-10-08 05:00)**

In [1]a letter linked to by Nature, Daniel Kahneman told social psychologists that they should worry about the repeatability of what are called "social priming effects". For example, after you see words associated with old age you walk more slowly. John Bargh of New York University is the most prominent researcher in the study of these effects. Many people first heard about them in Malcolm Gladwell's Blink.

Kahneman wrote:

Questions have been raised about the robustness of priming results. The storm of doubts is fed by several sources, including the recent exposure of fraudulent researchers [who studied priming], general concerns with replicability that affect many disciplines, multiple reported failures to replicate salient results in the priming literature, and the growing belief in the existence of a pervasive file drawer problem [= studies with inconvenient results are not published] that undermines two methodological pillars of your field: the preference for conceptual over literal replication and the use of meta-analysis.

He went on to propose a complicated scheme by which Lab B will see if a result from Lab A can be repeated, then Lab C will see if the result from Lab B can be repeated. And so on. A non-starter, too complex and too costly. What Kahneman proposes requires substantial graduate student labor and will not help the grad students involved get a job – in fact, "wasting" their time (how they will see it) makes it harder for them to get a job. I don't think anyone believes grad students should pay for the sins of established researchers.

I completely agree there is a problem. It isn't just social priming research. You've heard the saying: "1. Fast. 2. Cheap. 3. Good. Choose 2." When it comes to psychology research, "1.True. 2. Career. 3. Simple. Choose 2." Overwhelmingly researchers choose 2 and 3. There isn't anything wrong with choosing to have a career (= publish papers) so I put a lot of blame for the current state of affairs on journal policies, which put enormous pressure on researchers to choose "3. Simple". Hardly any journals in psychology publish (a) negative results, (b) exact replications, and (c) complex sets of results (e.g., where Study 1 finds X and apparently identical Study 2 does not find X). The percentage of psychology papers with even one of these characteristics is about 0.0 %. You could look at several thousand and not find a single instance. My proposed solution to the problem pointed out by Kahneman is new journal policies: 1. Publish negative results. 2. Publish (and encourage) exact replications. 3. Publish (and encourage) complexity.

Such papers exist. I [2]previously blogged about [3]a paper that emphasized the complexity of findings in "choice overload" research – the finding that too many choices can have bad effects. Basically it concluded the original result was wrong ("mean effect size of virtually zero"), except perhaps in special circumstances. Unless you read this blog – and have a good memory – you are unlikely to have heard of the revisionist paper. Yet I suspect almost everyone reading this has heard of [4]the original result. A friend of mine, who has a Ph.D. in psychology from Stanford, told me he considered Sheena Iyengar, the researcher most associated with the original result, the greatest psychologist of his generation. Iyengar wrote [5]a book ("The Art of Choosing") about the result. I found nothing in it about the

complexities and lack of repeatability.

Why is personal science important? Because personal scientists – people doing science to help themselves, e.g., sleep better – ignore 2. Career and 3. Simple.

Darrin Thompson (2012-10-08 05:50:59)

We should clarify the saying you are using. It's better stated this way: "a. Fast. b. Cheap. c. Good. Pick any 2." At least that's the software version of it. It expresses our frustrations with management who drive us to produce quickly and cheaply but are horrified to discover that when it's done it isn't any good. Or that we could build it cheaply and have it turn out well, but it's going to take longer. Or that we could build it well, and quickly, but it will cost a lot. And beat that system the answer is to invest some resources to improve our tooling or our processes. Seth: You mean my statement was confusing because I numbered the choices? I've heard the "pick 2" saying in regard to making movies and making physical stuff.

Vic (2012-10-08 12:21:45)

Seth - isn't this the time of year when you criticize the nobel prize in medicine? :) Seth: Any day now. :)

Tim Beneke (2012-10-08 12:51:28)

I liked your post a lot. The whole issue of the "sociology of knowledge and social psychology" (and psychology and science generally) and how the kind of "external-to-truth" factors influence what are considered to be findings in psychology needs to be understood much better than it is. There needs to be better access to all the research that more or less fails to replicate important claims. There needs to be systematic research on the research so the field can better clean up its act... It leaves me rather confused as one who is fascinated by findings in social psychology and tries, a little, to theorize them and integrate them into my daily existence. How seriously should we take important claims? I know one important Asian-American psychologist who has been very skeptical of Bargh as well as other highly publicized findings in psychology... Seth: There's a saying "everyone believes an experiment except the experimenter." Let me revise it to "everyone believes an experiment except other experimenters" – who understand how easily the results can be shaped to fit what the experimenter wants.

David Johnston (2012-10-08 20:49:45)

I strongly suspect that well organized retail companies have large data sets on the effect of choice size on purchasing habits and use that data to decide how many and what type of products to display. The difference is that they're not in the business of publishing their data in research journals and probably consider it proprietary business intelligence.

Tom (2012-10-08 21:43:19)

*The difference is that they're not in the business of publishing their data in research journals and probably consider it proprietary business intelligence.* I think it's more likely that nobody bothered to ask them. Occam's razor.

Duncan (2012-10-09 15:07:32)

Jim Manzi has a pretty good article about the Iyengar experiment: <http://www.nationalreview.com/corner/198579/non-paradox-choice/jim-manzi>

Jim Manzi (2012-10-14 14:25:28)

David, There have been many, many such well-structured RCTs by retail companies. They are generally termed "SKU rationalization" experiments. Duncan, Thanks. I go into this experiment and subsequent analyses in much greater detail in my book published in May. Best, Jim Manzi

## **Hidden Side Effects of Statins and How Easily You Can Uncover Them (2012-10-09 05:00)**

In 2009, a British rheumatologist named Andrew Banji wrote about the hidden side effects of statins [1] in the Daily Mail:

I discovered the link between statins and rheumatic side-effects quite by chance. My attack of tendon inflammation occurred at the front of my shin - a highly unusual place for tenosynovitis - so I decided to do some research into what could have triggered this. I was amazed to discover the only other related case was linked to a patient on statins.

Following a high cholesterol-reading of 9.2 a couple of months before, I'd been put on the drug. Intrigued by the connection, I decided to stop taking my statin to see what happened. Within a couple of weeks, the pain had gone.

I went back to my GP and, over successive months, tried various statins, including rosuvastatin which is one that is often prescribed.

Each form of the drug caused terrible problems, including night cramp, muscle pain, severe muscle disorders known as myopathy and general fatigue. In fact, I became so tired I couldn't lift anything when I was gardening or even walk the half-mile from my home to the center of town.

Yet whenever I halted the medication, my symptoms disappeared within a few weeks. . . .

I began to realize many of my patients with musculoskeletal conditions such as polymyalgia - pain, stiffness, and tenderness in the muscles - were on statins. When I advised them to stop taking their medication, their problems went away.\

By 2009, statins were perhaps [2] the most heavily prescribed drugs ever, making tens of billions of dollars for drug companies. Yet this story shows that at that point a doctor who was taking statins was not yet aware of major common side effects. How convenient for drug companies. The story also shows that patients with a variety of muscular problems had to be told by a doctor to stop taking their statins to find out if the statins were causing the problem. That should have been common sense. On a more positive note, this story shows how easily some health problems can be fixed ("when I advised them to stop taking their medication, their problems went away").

1. <http://www.dailymail.co.uk/health/article-1128333/Viewpoint-The-hidden-painful-cost-statins.html>

2. [http://money.cnn.com/magazines/fortune/fortune\\_archive/2003/01/20/335643](http://money.cnn.com/magazines/fortune/fortune_archive/2003/01/20/335643)

dearieme (2012-10-09 08:22:20)

One of the big studies of statins hid the side effects as follows. They gave the drug and the placebo to the two groups. In the first few weeks of the study many of the subjects suffered side effects so bad that they dropped out. These people were then obliterated from the statistics and the subsequent boasted-about results for benefits and side effects ignored their existence. In my little corner of science we'd have called that "lying". Seth: I didn't know about that. Because these drugs are so widely prescribed and so profitable and yet have so little apparent benefit – so little that the side effects could easily be worse than the benefits – "lying" is a rather weak term for the deception you describe.

Kim Øyhus (2012-10-10 00:12:59)

Patches in the body can have different genes, biochemistry, or something. They react differently from the rest of the body. The front of his shin could be such a patch. This should be useful for something.

Evelyn M. (2012-10-10 05:18:29)

So what did the good British rheumatologist named Andrew Banji do about his elevated cholesterol level of 9.2 mmol/l (355.76179 mg/dl)? It is unlikely that Cholesterol at this level can be brought down by dieting alone.

Adam (2012-10-10 08:05:32)

Evelyn M., total cholesterol is basically meaningless. We're even discovering that LDL cholesterol, while better, is not that useful as a predictor of heart disease.

Statin Enthusiast (2012-10-10 22:37:08)

These are not hidden side effects. These are pretty well known side-effects documented all over literature, especially the joint pain and muscle pain. Most of these happen when statins are over-prescribed, i.e. doctors give patients with very high cholesterol more Statin than the recommended dose (the dose that the original safety trials were done). Some people think CoQ10 supplementation could help but the reality is that no body to-date knows for certain the exact reason why statins cause these problems. Seth: You seem to be saying the author of this article made a fool of himself (and opened himself up to charges of incompetence) in Great Britain's most popular paper.

dearieme (2012-10-11 02:39:16)

A retired friend points out that a far higher proportion of his pals who are on statins report nasty side effects than is consistent with the literature. He's an epidemiologist by trade.

David Evans (2012-10-15 06:35:53)

I've compiled a list of over 140 scientific papers that document the adverse effects of statins [http://healthydietsandscience.blogspot.co.uk/search/label/Statins %20and %20Cancer](http://healthydietsandscience.blogspot.co.uk/search/label/Statins%20and%20Cancer)

## **Vitamin D3 Eliminated Colds and Improved Sleep When Taken in the Morning (Stories 24 and 25)** (2012-10-10 05:00)

A year and a half ago, the father of a friend of mine started taking Vitamin D3, 5000 IU/day at around 7 am – soon after getting up. That his regimen is exactly what I'd recommend ([1]good dose, good time of day) is a coincidence – he doesn't read this blog. He used to get 3 or 4 terrible colds every year, year after year. Since he started the Vitamin D3, he hasn't gotten any. "A huge lifestyle improvement," said my friend. His dad studied engineering at Caltech and is a considerable skeptic about new this and that.

Much more recently his mother changed the time of day she took her usual dose of Vitamin D3. For years she had been taking half in the morning (with a calcium supplement) and half at night. Two weeks ago she started taking the whole dose in the morning. Immediately – the first night – her sleep improved. She used to wake up every 2 hours.

Since taking the Vitamin D3 in the morning, she has been waking up only every 3-6 hours. A few days ago, my friend reports she had "her best sleep in years".

Sleep and immune function are linked in many ways beyond the fact that we sleep more when we're sick. A molecule that promotes sleep turned out to be very close to a molecule that produces fever, for example. I found that when I did two things to improve my sleep (more standing, more morning light) [2]I stopped getting colds. So it makes sense that a treatment that improves one (sleep or immune function) would also improve the other (immune function or sleep).

A few days ago [3]I posted a link about [4]a recent Vitamin D study that found no effect of Vitamin D on colds. The study completely neglected importance of time of day by giving one large injection of Vitamin D (100,000 IU) per month at unspecified time. I commented: "One more Vitamin D experiment that failed to have subjects take the Vitamin D early in the morning — the time it appears most likely to have a good effect." These two stories, which I learned about after that post, support my comment. What's interesting is that the researchers who do Vitamin D studies keep failing to take time of day into account and keep failing to find an effect and keep failing to figure out why. I have gathered [5]23 anecdotes that suggest that their studies are failing because they are failing to make sure their subjects take their Vitamin D early in the morning. Yet these researchers, if they resemble most medical researchers, disparage anecdotes. (Disparagement of anecdotes reaches its apotheosis in "evidence-based medicine".) The same anecdotes that, I believe, contain the information they need to do a successful Vitamin D clinical trial. Could there be a serious problem with how Vitamin D researchers are trained to do research? A better approach would be to study anecdotes to get ideas about causation and then test those ideas. This isn't complicated or hard to understand, but I haven't heard of it being taught. If you understand this method, you treasure anecdotes rather than dismiss them ("anecdotal evidence").

---

Paul N (2012-10-10 09:06:33)

Many great scientific advancements have come about because of "anecdotes" - some unusual "thing" that has been observed/reported. That is how penicillin was discovered, same for x-rays. It is a case of cause and effect, where sometime the cause is not apparent. Most scientists start with a cause and want to see an effect, they are mostly unwilling to take an (anecdotal) effect and identify the cause - what prestige/grants/papers are there in researching anecdotes? Yet that is exactly how (nobel prize winners) Warren and Marshall discovered that a bacteria - H. Pylori - not acid or spicy foods - was the cause of stomach ulcers. Evidence based medicine is getting very good at ignoring real world evidence in favour of lab mice evidence, and, in the process, is becoming less useful by the day.

charlie (2012-10-10 09:28:38)

You're drawing a false contrast here; it isn't evidence based medicine vs. anecdote. The Vitamin D study set out to study one thing : does an improved level of Vitamin D in the blood stop colds. The answer is no. You're asking whether taking Vitamin D in morning improves sleep, which then improves colds. Seth: Okay, maybe I should restate my point by turning it into a

question. Why do I find it easy to find anecdotes showing benefits of Vitamin D – in particular, the importance of taking it in the morning – when those who do clinical trials find it so hard to show benefit?

Nancy Lebovitz (2012-10-10 10:09:30)

Some anecdotes about organic food and health: <http://nancylebov.livejournal.com/556141.html> Following up about a study of GMO and rats <http://nancylebov.livejournal.com/556467.html>

gwern (2012-10-10 17:04:21)

> A few days ago I posted a link about a recent Vitamin D study that found no effect of Vitamin D on colds. The study completely neglected importance of time of day by giving one large injection of Vitamin D (100,000 IU) per month at unspecified time. I commented: “One more Vitamin D experiment that failed to have subjects take the Vitamin D early in the morning — the time it appears most likely to have a good effect.” Why does time matter if the injection is \*1\* day per month? If it affects that day's circadian rhythm, that's just 1 day out of 29-31 days and shouldn't affect the net results. If the disturbance lasts that many days (which there's no reason to think), then conversely, few of the anecdotes should be possible, and in particular neither of my RCTs should have found an effect because they were randomized on a much smaller-than-monthly basis. > Why do I find it easy to find anecdotes showing benefits of Vitamin D — in particular, the importance of taking it in the morning — when those who do clinical trials find it so hard to show benefit? Why indeed.

Adam (2012-10-10 18:53:23)

I take 4000 units of Vitamin D in drop form every morning right when I wake up and I still get colds. I can't say I noticed any improvement in my sleep from Vitamin D. There is plenty of evidence that Vitamin D levels should be in the range of 30-100 & that supplementation is often required to get it there. I'm still a bit skeptical about the sleep bit though.

Adam (2012-10-10 18:55:35)

P.S. Is there a plausible mechanism by which Vitamin D could effect sleep quality? Because it is so persistent in the body, I'm a bit puzzled about why there would be a temporal effect. Seth: There are countless examples where the brain detects change, not constancy. If you have no idea what I'm talking about, search "edge detectors". That could easily be true here. The brain is sensitive to changes in level of Vitamin D.

Jim Purdy (2012-10-11 03:51:53)

Seth, your self-experimentation is always fascinating, in the way you apply it to many diverse health issues, and you come up with many unexpected results. However, with all the data you have accumulated over the years, I wonder whether you are finding any pattern – connecting the dots, if you will – that leads you toward any new and broader hypotheses or theories. One of my favorite authors is the evolutionary psychologist Randolph Nesse, who has written extensively about evolutionary medicine. Nesse seems to start with a broad theoretical evolutionary approach, and he then delves into the details – kind of a top-down approach. On the other hand, your research seems to start with the details from your self-experimentation, and perhaps your data lead to a bottom-up approach toward a theoretical construct. I'm not sure if I'm explaining this well, but I wonder if you are familiar with Nesse's work, and if you see much common ground between his work and yours. Seth: My data has led me to three broad ideas. 1. Evolutionary thinking is a good way to generate ideas to test. 2. A theory of weight control (setpoint controlled by smell-calorie associations). 3. A theory of depression (mood/energy oscillator controlled by seeing faces). Or four broad ideas, if you count 4. There is a lot of useful stuff that medical researchers haven't figured out. I am familiar with Nesse's work. I agree with your description of how we're different. The common ground is both of us see value in evolutionary thinking.

gwern (2012-10-11 09:20:42)

Adam: check out <http://www.gwern.net/docs/2012-gominak.pdf>

Nancy Lebovitz (2012-10-11 10:07:16)

The earlier hypothesis here was that taking vitamin D in the evening disrupts sleep. It wasn't that vitamin D in the morning

would improve sleep in general. Seth: The two ideas – Vitamin D in the evening disrupts sleep and Vitamin D in the morning improves sleep – go together, but it's true that the former is far less interesting than the latter. In my self-experimentation, I tested the latter and found evidence supporting it.

dearieme (2012-10-11 18:13:05)

O/T: of any interest, Seth? <http://blogs.bmj.com/bmj/2012/10/10/richard-smith-a-successful-and-cheerful-whistleblower/>  
Seth: thanks very interesting. I will post about it in a few days.

Adam (2012-10-12 03:41:06)

Gwern: Thanks for the study, I found it very interesting. I think that you don't understand my question, however. I can see how Vitamin D could affect sleep, but I don't understand why it would be related to time of ingestion. If I take Zolpidem, for example, I will get sleepy when my blood level goes up, and the effects will wear off as my body metabolizes and eliminates the drug. With Vitamin D, on the other hand, I take the drug & my blood level goes up & stays up, basically forever (it has a half-life of 10-21 days, whereas Zolpidem has a half-life of about 3 hours).

Guv (2012-10-14 16:33:26)

Adam, My guess would be that Vitamin D probably does fluctuate throughout the day, like a lot of other hormones. But I guess the only way to know for sure is to test every few hours throughout a 24 hour period. I got a few hits googling, "vitamin d" diurnal, & "vitamin d" circadian. Here are 2 studies I had a quick look at, <http://www.ncbi.nlm.nih.gov/pubmed/11980618> (on postmenopausal women). <http://www.jcircadianrhythms.com/content/2/1/3> (I know it's on horses, but what the hay).

## **JAMA Jumps to Conclusions About Vitamin D (2012-10-11 05:00)**

[1]A recent experiment published in JAMA, one of the most prestigious medical journals in the world, found that giving people a very large dose of Vitamin D (100,000 IU) once/month did not prevent colds, even though it greatly increased blood levels of Vitamin D. This finding supports [2]my view that it is important to take Vitamin D in the morning. (Because a study in which this wasn't done found no effect.) My view implies that blood levels may not matter – you can get high levels of Vitamin D by taking it at what I consider the wrong times of day. The usual thinking about Vitamin D has been that blood level is all that matters.

The editors of JAMA considered the Vitamin D study so important that they asked someone ([3]Dr. Jeffrey Linder, associated with Harvard Medical School) to write a commentary – an associated editorial that puts the new finding in context.

[4]Linder's commentary (might be gated) is important because (a) it is a kind of random sample of how top research doctors think (he was selected to write it) and (b) he completely fails to grasp that the time of day Vitamin D is taken might matter. Colds, the immune system, sleep, time of day – it's not far-fetched. When you do an experiment to see if X causes Y, and find no effect, I believe that there are usually many possible reasons other than X never causes Y. Something was wrong with the equipment, something was wrong with your X (e.g., it was stale), something was wrong with your measurements (e.g., ceiling effect), and on and on. Linder did not see it this way.

The 2011 IOM report called for additional research to determine whether vitamin D therapy reduces the incidence of respiratory tract infections. The VIDARIS trial [= the new study] has rigorously addressed this question. Results suggest that vitamin D should join the therapies listed in the Cochrane reviews as being ineffective for preventing or treating upper respiratory tract infections in healthy adults.

He seriously thinks one null result proves something. Sure, the new study is "rigorous" in certain ways. But it was far from exhaustive. It did not explore the many ways Vitamin D may be given, for example. It did not consider the

possibility that blood levels don't matter. Linder's combination of (a) interest in rigor and (b) failure to understand the importance of exhaustive reminds me of a friend. When she was in 1st grade she had a pile of pennies. She knew how many she had – she had counted them. However, she did not know how to subtract. When she spent some of her pennies, to find out how many she had left she had to count them all over again.

My friend had half the skills an accountant needs. Linder's commentary reflects only half the skills a scientist needs. To the extent that he is representative of top research doctors, this is shocking. It is as if most accountants at Arthur Andersen didn't know how to subtract.

I have asked Dr. Linder if he has any response. If he does, I will post it.

---

LemmusLemmus (2012-10-11 05:37:25)

What reasons are there to believe that it might matter when you take vitamin D? Seth: I believe this because (a) I never noticed any effect of Vitamin D until I started taking it early in the morning and got the dose right (a weaker dose had no clear effect), (b) cases where people changed the time of day they took Vitamin D and noticed a big change in sleep (Tara Grant's original observation), (c) cases where people started taking Vitamin D in the evening and their sleep suddenly got worse, (d) cases where people started to take Vitamin D in the morning and their sleep suddenly got better, and (e) persistent failure of big Vitamin D studies that do not control time of day to find effects of Vitamin D. Five sorts of findings.

Glen Raphael (2012-10-11 06:48:18)

Lemmus: As I understand it, the reason people thought of taking D at all is that exposure to sunlight boosts Vitamin D. Humans mostly evolved before electricity and cars and artificial light so we're used to regularly getting a big pulse of Vitamin D at a specific time of day, every day, which then tapers off at night. That pulse (it is thought) helps set the rhythm of our body clock - when we feel tired, when we feel awake, how our mood and body temperature change through the day. So the initial idea behind taking Vitamin D was that if people who spend all day indoors and a lot of their time under artificial light get depressed or have trouble sleeping especially in the winter, they might be missing that daily pulse of sunlight. if you give them back a big pulse of Vitamin D \*as if\* they were getting lots of morning/midafternoon sun, they might get back on track. Like a pacemaker. Feel more awake in the morning, feel more tired around bedtime, sleep better through the night. Lots of anecdotal evidence (and a few studies) suggest this actually works - that people who take a daily dose of D early in the day sleep better and feel better and get fewer colds. But if it works, the expected mechanism is that the \*timing\* of the D improves your sleep quality and quantity, and we know that people who sleep well have a stronger immune system and get fewer colds or recover faster from the ones they get. One massive \*monthly\* dose of D does NOT simulate what the sun does to us, so it doesn't fit the pattern that is thought to improve sleep/mood/immune system response. Nor does D taken in the evening, or taken at random times.

Chuck (2012-10-11 06:56:07)

It seems to me that the Pharma/Medical industry want so badly to prove that non-pharmaceuticals are ineffective, they will design their trials to fail. They are not impartial or unbiased. We don't know if there were trials that indicated taking Vit D was effective. It could be the reverse of pharmaceutical trials where they hide the failures - in this case, they hide the successes. Bio-hacking, self experimentation, what ever you want to call it, may have some of the same biases (placebo effect), but not

as likely (you may think something worked, but not long after discover maybe not, and try something else). After all, it's your health you're tinkering with, not some abstract population. Cheers

Arthur (2012-10-11 06:59:20)

Does not seem a very good post to ask for a response. You probably should have talked about your evidence that the time of day matters, instead of just linking to other posts. He will probably not click the link, and respond to you like you were a nutjob, or simply not respond. Seth: My criticism is reasonable whether or not my idea that time of day matters is true or supported by evidence. It surprises me that a serious scientist would take one null result as seriously as Linder does, not recognizing that there are dozens of possible explanations of that result that do not assume Vitamin D is worthless.

Chuck (2012-10-11 07:30:07)

Ok, this is the part of the trial I find incredible: There were 322 participants and during the nine months of the trial, there were a total of 1,204 reported incidents of upper respiratory tract infection - 1,204 UTIs in 322 people in 9 months! I think I could walk down the street and randomly select 322 people who, over the next 9 months, would not have 1,204 incidents of UTI. That is just a crazy number. I think there were some not so healthy individuals in the trial who skewed the numbers in both groups. I wonder if the incident of UTI per individual participant is in the report? Not just the average per all participants. Did everyone contract 3 UTIs? Or, half contract 6, and the the other half none? Or, a third 9? I would also like to see the serum Vit D levels of each individual participant, so you could compare those who contracted a UTI versus those who didn't, those who contracted more than the average versus those who contracted less than the average. Averaging everything out skews the effect, one direction or the other. Think of all the people you know and work with, are they really sick more than 3 times a year? From any cause, let alone UTI? I'm not buying it. I can't remember the last time I had a UTI, let alone 3 or more in 9 months. I've been taking Vid D regularly for over 4 years, and haven't had a single cold, or the flu. This calls for Raspberries, instead of Cheers

MikeW (2012-10-11 07:46:19)

Dr. Linder's eagerness to close the book on D supplementation isn't shared by the study authors themselves. The last paragraph of the JAMA article makes it clear they realize the narrow scope of their findings: "In conclusion, we report that monthly administration of 100 000-IU doses of vitamin D3 did not reduce the incidence or severity of URTIs in healthy, predominantly European adults with near-normal vitamin D levels. Further research is required to clarify whether there is benefit from supplementation in other populations and with other dosing regimens." The authors acknowledge that in another recent randomized controlled trial, Mongolian schoolchildren lowered their RTI incidence by 50 % with only a 300 IU daily supplement. In that case, the D3 was added to milk served in school - whether that was first thing in the morning or later in the school day, I don't know.

Chuck (2012-10-11 07:47:01)

Well, I found it - 13 of 322 participants did NOT contract a UTI. 13 out of 322! What this tells me, is New Zealanders are not very healthy people, and must have very compromised immune systems. Or, do I just hang around a healthier bunch of people? This study proves nothing, one way or the other, to me. I'll keep taking my Vit D every morning. I use the Carlson's drops - might try putting it on my skin, in the crook of my elbow, instead of orally. Heard this might be more beneficial. I need to think about how to test this before I start though. Cheers

David Johnston (2012-10-11 08:51:49)

I've been on A, D3 & K2 at 7.30am for about half a year. It has without doubt improved my sleep. My family is currently in the middle of a shared cold with sneezing and stuffed sinuses, except for myself. I thought I might have mild symptoms two days ago, but it passed without incident. Before taking the morning vitamins, I would have expected to share in their joy. I was similarly immune when I used to travel internationally for work about once a month, to diverse places around the world. I did this continuously for about 4 years. After an initial breaking in period, I found I was broadly resistant to colds. My guess is that my immune systems was being exposed to a wider variety of bugs and so was better primed. The hell of permanent jet lag is not worth it though.

charlie (2012-10-12 09:42:12)  
@chuck; that is a pretty normal rate.

David (2012-10-12 10:44:54)

As far as offering useful guidance to the average person deciding if they should take vitamin D supplements, it is useless: 1. All subjects had normal vitamin D levels, not so for the average person 2. Monthly dose is exactly the opposite of how an average person would take vitamin D 3. As mentioned, it doesn't rule out benefits, seen in other studies, by not even attempting to follow previously used successful protocols

## **The 2012 Nobel Prize in Physiology or Medicine (2012-10-12 05:00)**

As usual, there is plenty of disease and disability in the world: depression, diabetes, heart disease, cancer, stroke, obesity, autoimmune disease, and so on. As usual, the Nobel Prize in Physiology or Medicine – supposed to be given for the most useful research – is given for research with no proven benefit to anyone (except career-wise). Once again implying that the world's best biomedical researchers – judging by who wins Nobel Prizes – either don't want to or don't know how to do useful research.

Once again [1]the press release tries to hide this. "From surprising discovery to medical use" reads one heading. If you read the text, however, you learn there is no actual "medical use". Here's what it says:

These discoveries have also provided new tools for scientists around the world and led to remarkable progress in many areas of medicine. iPS cells can also be prepared from human cells. For instance, skin cells can be obtained from patients with various diseases, reprogrammed, and examined in the laboratory to determine how they differ from cells of healthy individuals. Such cells constitute invaluable tools for understanding disease mechanisms and so provide new opportunities to develop medical therapies.

Apparently you can make "remarkable progress" in medicine without helping a single person, which says a lot about what passes for medical progress. Although iPS cells are supposedly "invaluable tools" for understanding disease mechanisms, we are not told a single disease that has thereby been understood or a single therapy that has been developed.

The Guardian printed [2]a roundup of responses to the award. I read it eagerly. Maybe one of the comments will explain how the prize-winning work actually helped someone (besides career-wise). After all, Yamanaka, one of the winners, had previously won the Finland Prize, given to research that "significantly improves the quality of human life today and for future generations". Paul Nurse says the prize-winning work did such-and-such, "paving the way for important developments in the diagnosis and treatment of disease" unfortunately not saying what those "important developments" are. Martin Evans says:

The practical outcome is that now we not only know that it might be theoretically possible to convert one cell type into another but it is also practically possible. These are very important foundation studies for future cellular therapies in medicine.

Emphasis added. Another comment: "These breakthroughs will ultimately lead to new and better treatments for conditions like Parkinson's and improve the lives of millions of people around the world." A bold prediction, given that they have not yet improved the life of even one person. Julian Savescu, an ethicist at Oxford, says "This is as significant as the discovery of antibiotics. Given the millions, or more lives, which could be saved, this is a truly momentous

award.”

Year after year, the Nobel Prize in Physiology or Medicine is given for research that, we are told by biologists with huge conflicts of interest, will – no doubt! – be incredibly valuable in the future. Indicating there was no research that might be honored that had already been useful. It is as if you have a baseball award for best hitter but all hitters all over the world strike out all the time so you end up giving the award to people who strike out best. They are the best hitters, you tell credulous sportswriters. They receive the prestigious award for best hitter at an elaborate ceremony, with toasts all around. Nobody says they cannot hit.

1. [http://www.nobelprize.org/nobel\\_prizes/medicine/laureates/2012/press.html](http://www.nobelprize.org/nobel_prizes/medicine/laureates/2012/press.html)

---

dearieme (2012-10-12 07:03:05)

I admit to my surprise some years ago when I glanced at the rules and saw that they required the work to have brought benefits, because it's quite obvious that the prizes are routinely awarded for work that might perhaps contribute to benefits at some time - perhaps distant - in the future. Perhaps it's just another example of the rule that Pure research always drives out Applied. Seth: I think Alfred Nobel included the "have benefits" requirement because he didn't want to have happen exactly what has happened: Scientists decide among themselves, with no regard for anyone else, what research is best. "I don't want this prize to make them rich while they continue to do exactly what they want to do," he thought.

Alex (2012-10-22 07:42:46)

Donnall Thomas just passed away. His 1990 Nobel for developing bone marrow transplants was definitely for results, not potential. Have you seen a trend away from that, or do you think it's always been a mix? <http://www.nytimes.com/2012/10/22/science/e-donnall-thomas-furthered-bone-marrow-transplants-dies.html?hpw&pagewanted=all>

L (2012-10-22 09:54:25)

nobel prizes are not important. stop trippin!! mother teresa of calcutta won and so did balack obama and all gore w his global warming bullshit!! how the hell dey win!! hindi ko alam!!! basta: BUISIT!!!

Tony Mach (2012-10-27 05:57:57)

I looked at the medicine Nobels something like two years ago and was puzzled how little positive impact on everyday medicine came from all this brouhaha. A lot of what I call "molecular masturbation", very fine research no doubt, but with a complete disconnect to finding the causes of the diseases that plague so many of us. Medicine as a whole seems "stuck" and in dire need of a paradigmatic shift (if not several). So many little and big barriers ("common knowledge" like sat-fat is bad, the many problems with the research and publishing process, or "big pharma") that hinder progress in the medical sciences. As more and more people are starting to gain personal experience about things that have a positive (or negative!) result on their very own health (personally I think especially the Paleo thing is going good), there will be some in the medical science that will go down the same path. I sometimes wonder when exactly personal experiments came out of fashion in the medical and biological sciences – your blog is surely an shining example that even as an individual one can make some change.

## New Product: Cascal Fermented Soda (2012-10-12 14:10)

This low-calorie soda (60 to 80 calories in a 12-ounce can) falls somewhere between kombucha and less-sweet sodas such as the aptly named GUS (Grown Up Soda). Its hook is the use of fermented juices as its base, resulting in a more complex flavor than sodas and sparkling waters based on plain juice.

[1] \$1.25 at Whole Foods. I'm in.

My interest in fermented foods partly derives from learning about a similar product. At a Fancy Food Show a few years ago, I learned about someone who wanted to develop a high-end non-alcoholic alternative to wine. He found he couldn't get enough complexity without fermentation. That emphasized to me how our food preferences – in this case, a desire for complexity – push us to eat fermented foods.

bjk (2012-10-12 20:01:18)

Is carbonation itself a substitute for fermentation? The tingle from kombucha feels a little bit like carbonation.

Paul N (2012-10-13 15:01:35)

That's because the tingle from Kombucha \*is\* carbonation. You also get the same carbonation from normal yeast ferments, using whey, and kefir-water grains. If you really want to answer your own question, try drinking some club soda and see what you think. Then shake some kombucha to make it go flat - but keep it cool, and try that. There is simply no comparison, and that is why so many "gourmet" foods, the world over, are fermented.

Peter (2012-10-13 18:03:23)

Ikea sells a fermented pear soda. The food department manager in the area store told me it's very popular and they have a hard time keeping it on the shelves. <http://www.nearof.com/?p=266>

## Assorted Links (2012-10-13 05:00)

- [1]Jane Jacobs vs. Robert Moses (excerpt from Ric Burn's documentary New York)
- [2]use of Adderall to treat kids without ADHD. Horrifying. I don't even know if ADHD is caused by bad nutrition or if it reflects too-rigid teaching – that is, teaching all kids the same way. Roughly 99 % of health care ignores the causes of things. I suppose that in a society, like ours, that pays little attention to finding out the causes of problems, the solutions to those problems will become, as the problem worsens, increasingly bizarre and dangerous.
- [3]health benefits of kefir

Jim Purdy (2012-10-13 20:25:34)

That New York Times story about the drugging of America's children is scary. Drug companies and doctors already have saturated the adult market and turned countless millions of adults into drug addicts dependent on painkillers, antidepressants, and other strange chemicals. So how can they keep growing their market? Expand the market by getting America's children addicted, thus creating new generations of drug-consuming zombies.

L (2012-10-14 06:55:30)

You don't need grades to be a billionaire in America.

David C (2012-10-14 08:58:37)

I'd be interested to see if kids diagnosed with ADHD are more likely to be the younger ones in their class. I.e. if you have a summer birthday, are you more likely to be considered ADHD?

David C (2012-10-14 09:00:56)

Should have googled first. Looks like it's been studied and is the case: <http://www.telegraph.co.uk/health/health-news/9123519/Youngest-in-school-year-more-likely-to-be-diagnosed-with-ADHD-research.html>

Jill (2012-10-15 06:21:16)

I also noticed a between-the-lines scare tactic used by the school admins: "Increase our funding, or your children are going to be medicated."

shtove (2012-10-16 11:47:53)

Hi Seth. Thanks for the blog. Keeps me learning. I like the links posts, but can you give a bit more description (Jacobs v Roberts?) + set up the links to open in separate windows? Easier to navigate your post while deciding whether to follow the link. Barry Ritholtz is a good example: <http://www.ritholtz.com/blog/2012/10/10-tuesday-am-reads-42/> Seth: Thanks, I didn't know about how to cause links to open in separate windows. Now I do.

Patrik (2012-10-16 21:04:14)

Horrrifying is the right word. This quote speaks volumes: "We've decided as a society that it's too expensive to modify the kid's environment. So we have to modify the kid." Seth: "As a society"? I wonder. Professors who can do research think it is higher-status to study high-tech stuff like drugs than low-tech stuff like food. (Curiously there is more money to study the high-status stuff, we're taught that rarity increases status.) Maybe this is human nature (as Veblen argued), maybe it is promoted by science journalists who never call them on this. Since Veblen found the same pattern (less useful = higher status) in many societies and cultures, it isn't clear it is a society's "decision".

## How Common is Dishonesty in Medical Research? (2012-10-14 05:00)

Richard Smith, former editor of the BMJ, [1]writes about Peter Wilmshurst, a British cardiologist, an unusually brave and honest man:

He was the coprincipal investigator on a trial funded by NMT, an American company, to see whether closing a hole in the heart of patients with migraine would cure their migraine. It didn't. He refused to agree to be an author on a paper published in the journal *Circulation* because the paper was misleading, and he gave an interview to a journalist in the US pointing out the problems in the study. NMT sued him for libel, not in the US, where proving libel is difficult, but in England, where the onus is on the defendant to prove his innocence. NMT probably assumed (rightly in the case of most people) that the financial risk would cause Wilmshurst to cave in. They were wrong, and the case collapsed when NMT went bust.

The interesting thing about the stories Smith tells about Wilmshurst is the high rate of misconduct they imply:

[In 1996] we invited him to come to the BMJ and give a talk—behind closed doors—to our staff and advisers and colleagues from the *Lancet*. He reeled off case after case of misconduct, many of them involving prominent people. The audience listened intently, but I was unsure of the reaction. Might somebody leap up and say “How dare you accuse x of misconduct. He is one of the great men of British medicine”? In fact in my memory the reaction was the opposite. People said things like “Actually, it's worse than you know...” . . .

Many of [Wilmshurst's stories] involve doctors who are guilty of misdemeanours but who sit in judgement on others. He told the story of Peter Richards who decided to bury the fact that Clive Handler, a doctor, at Northwick Park Hospital, [2] was found guilty of using NHS research funds to subsidise his private practice at a time when Richards was medical director of the hospital and chair of the professional conduct committee of the GMC. Previously he had been dean of St Mary's Medical School, prorector for medical education at Imperial College, and chair of the Council of Deans of UK Medical School and Faculties. When Handler eventually appeared before the GMC, the GMC's lawyers ask that Richards stand down from chairing the committee. As Wilmshurst said, it's as if a judge at the Old Bailey were to say “I'll have to excuse myself from hearing this case as I helped the accused bury the body.” After having to stand down from this committee Richards continued to chair other conduct committees. Wilmshurst told several stories of doctors who had been found guilty of research misconduct but [had] gone on to be deans and others in charge of researchers.

Smith does not point out what this means. Doctor X is found guilty of research misconduct. Everyone knows this. Doctor X is still appointed dean or whatever. Maybe the people who make these appointments don't care. Or maybe research misconduct is so common it cannot be a disqualification.

At the end of the article Smith points out his long friendship with Wilmshurst:

RS has known Wilmshurst for 16 years . . . the BMJ was sued for libel over an article by Wilmshurst that was published when RS was editor of the journal. The article has not been retracted but is not available on the BMJ website.

Presumably Smith was forced by BMJ lawyers to be this vague. I have not been able to locate the article. From [3] a talk by Wilmshurst. “Eventually Rubin got his report published in [*The New England Journal of Medicine*, under the editorship of Dr. Arnold Relman], because he threatened that unless his report was published he would go to the press and point out the collusion between the journal and Sterling-Winthrop.”

Wilmshurst's conclusion: “Dishonesty is common in medical research.”

Thanks to dearime.

Jim Purdy (2012-10-14 05:28:26)

Is anybody surprised? Seth: I was surprised that people were promoted to dean and similar posts after being found guilty of research misconduct. I was also surprised that Smith did not give a reference to the Wilmshurst paper in the BMJ mentioned at the end.

L (2012-10-14 07:05:34)

I'm not surprised. Dr Linder emailed me back! He's the guy Seth wrote about a few days ago. He emailed me right away

Nancy Lebovitz (2012-10-14 07:42:25)

[1]More about the poor quality of published science Publication bias, resistance to replication efforts, fraud. Also, descriptions of efforts to solve the problems.

1. <http://blogs.discovermagazine.com/notrocketscience/2012/10/10/science-has-been-a-very-naughty-boy/>

Tom (2012-10-14 14:02:54)

If Taubes' and Attia's NuSI can get some honest research done, it'll be revolutionary for that fact alone.

Nathan (2012-10-14 19:22:36)

I think a relevant question to consider is "how common is dishonesty in every field/endeavor?" I think that you provide good evidence about dishonesty in medicine, but do you think it is more common than in other places? Or perhaps you just think it's more damaging to lie when it affects physical health directly. Seth: I think you can do a lot more damage inside the body (drugs, surgery, medical devices) than outside the body (most goods and services). So dishonesty – e.g., hiding bad side effects – is much more damaging.

Txomin (2012-10-14 20:03:07)

I also am far from surprised. Dishonesty is ubiquitous in the academic world. I expect nothing different from scientific circles. It is an issue of human nature.

kxmoore (2012-10-14 23:41:53)

great ted presentation here on suppression of clinical trial publications. scary stuff. <http://blog.ted.com/page/5/>

Tuck (2012-10-15 07:43:38)

"...to see whether closing a hole in the heart of patients with migraine would cure their migraine. It didn't." That ironic. As it happens, I have such a hole in my heart: a "patent foramen ovale". When it was discovered, I spoke to a colleague of mine, who had the surgery to close it up. To his surprise, his life-long string of migraines ended, and he's not had one since. Turns out there's two types of patent foramen ovale: the one I have, which operates normally (no blood flow between chambers) and the one he had, which allows blood flow between the chambers, and hence creates micro-clots which can cause micro-strokes, which are thought to be one of the causes of migraines. I wonder if the failure of this experiment was simply checking the wrong variable? As to the topic of your quote, I wish it were surprising, but after a few years of research diet and the medical

profession, I've a: realized that my high esteem for doctors was a matter of faith, not reason, and b: I've lost that faith.

Ray Cathode (2012-10-17 12:42:21)

"Dishonesty is common in medical research." Thankfully, we know that this could not happen with climate change...

L (2012-10-22 03:37:00)

Hey dearime used to comment everyday. Where u at now babe?? Doctors are not ur friends!! We are not ur friends. Seth, stop trying to fight the system and do something more lucrative w ur life. No Nobel prize for people who hurt the prize givers! Cmon, u should do something more positive.

### **One Man's Interest in Fermented Foods (2012-10-15 05:00)**

Julie O'Brien and Richard Climenhage [1]run a small company in the Ballard neighborhood of Seattle called Firefly Kitchens, devoted to making fermented foods. The company was founded in 2010.

Climenhage, a former high-tech executive, became intrigued with fermented foods about 10 years ago after a nutritionist suggested he consume more fats and fermented food. It cured the chronic heart palpitations that he had endured for two years.

"Six weeks and two days after changing my eating the palpitations were gone, never to return," Climenhage said. "So I was sold. I started making my own sauerkraut and never looked back."

L (2012-10-17 05:03:45)

Dr Linder emailed me from harvard. He's the md gp at brigham womens/internist. I asked for an appointment w him to talk about seths discovery of timing n d. Linder wrote that he is not accepting new patients. Strange bc I didn't say I wntd to be a pt I stated I wanted to talk of seths ideas. Linder can't even figure that out in my email! I never want to be his patient!! I'll always get respiratory infections if he's my gp. Gp are lowest paid drs. Compared to cardiothoracic surgery or neurosurgery, both of which I'm considrg

Alex (2012-11-14 19:51:33)

Link is broken on the Schavan article. Seth: Fixed, thanks.

### The Reddit Protein Powder Tests (2012-10-17 05:00)

A few months ago, a Redditer with access to a protein measurement device [1] offered to measure the protein content of protein powders that readers sent him. He got about twenty samples, presumably from all over the United States. [2] Most of them turned out to have reasonable amounts of protein but four had much less than expected.

The tester interpreted the results [3] here. One of the tested brands, American Pure Whey, [4] clearly has problems. Call it a positive control. By confirming those problems, the rest of the measurements gain credence. One company whose protein powder scored low is Gaspari. Unfortunately I cannot read [5] their reply, which appears on my browser without text.

I look forward to more truth-in-advertising tests. It is really helpful that the data is public – in this case, via Google Docs. Jimmy Moore (of Livin' La Vida Low Carb) has measured the effect of several supposedly low-carb-friendly products on his blood sugar. His results are [6] here.

Thanks to [7] Eric Meltzer.

This post surprises me!! Grt jb Seth!! A Chinese friend says that unborn fetuses r thrown in Chns h2o. Via aborted girls nt wntd chns wnt boys. Says she's chns n wnt b chn goods. Doesn't trust Chinese stuff. They're strangely made. Tea w qustnbl crap in

them!! They club rats lrg as dogs. Eat w beer!!

Chuck (2012-10-17 08:19:55)

I found Reddit's last Edit/Comment to be the most enlightening - that his commenter's were more upset with his analysis than the fact that no third party is even analyzing these products is telling. Brand loyalty uber alles. Cheers

## **The Fallibility of Epidemiologists: Neglect of the Immune System (2012-10-18 05:00)**

Anne Weiss recently repointed me to [1]an interview with the epidemiologist Tom Jefferson about swine flu. Jefferson, let me stress, is a good epidemiologist. In the interview he makes a point I make on this blog, that research is heavily shaped by two questions: 1. what will make money? 2. what will be good for my career? (How curious that economists – with the exception of Veblen and Robin Hanson – spend so much more time on #1 than #2.) For example:

Interviewer Why aren't researchers interested in [other viruses]?

Jefferson: It's easy: They can't make money with [them]. With rhinoviruses, RSV and the majority of the other viruses, it's hard to make a lot of money or a career out of it. Against influenza, though, there are vaccines, and there are drugs you can sell. And that's where the big money from the pharmaceuticals industry is. It makes sure that research on influenza is published in the good journals. And that's why you have more attention being paid there, and the entire research field becomes interesting for ambitious scientists.

Because Jefferson is willing to tell the truth about virology, it is interesting what he doesn't say.

The big glaring gap is that in a discussion about how to avoid getting sick he says nothing about improving immune function. Not one word. He isn't a doctor. He doesn't work for a drug company. There is no obvious reason he fails to discuss this. He is reflecting the blindness of his whole field, I believe. It isn't a mystery how to improve immune function: Sleep better and eat more fermented food. I have blogged before ([2]here, [3]here, and [4]here, for example) about how widely this supremely important question – how to improve immune function – is ignored.

The other gap in the interview is more subtle. Jefferson recommends hand-washing as a great way to avoid getting sick. He says:

I wash my hands very often – and it's not all because of swine flu. That's probably the most effective precaution there is against all respiratory viruses, and the majority of gastrointestinal viruses and germs as well.

Later he says:

One study done in Pakistan has shown that hand washing can even save children's lives. Someone should get a Nobel Prize for that!

In contrast, I believe that touching other people (and thereby picking up their germs on your hands) is part of [5]a self-vaccination system whose goal is to protect us against the dangerous microbes nearby by exposing us to them in

small amounts. Part of the system is an enjoyment of touching others and being touched. Another part is whatever causes us to constantly touch ourselves around the mouth. A third part is the tonsils, perfectly placed to pick up a tiny fraction of the germs around our mouths.

This theory of mine, which is supported by several lines of evidence, suggests that hand washing has a serious downside: It interferes with the self-vaccination system. Jefferson says nothing about any downside of hand washing. I'm not saying that Jefferson should have known of this theory of mine, of course not. (For one thing, the interview was before I thought of it.) My point is that – for reasons having nothing to do with money or career – he is too certain about what he knows. Maybe hand washing is only helpful when persons have weak immune systems or in places with large amounts of germs, such as hospitals. With strong immune systems in normal places, maybe it does more harm than good.

I became aware of the big gap in research after [6]I improved my sleep and stopped getting colds. Before that, I had gotten the usual number of colds. No one had said that could happen – had said there was so much room for improvement in immune function. Anne Weiss became aware of the gap in research when she visited her doctor:

[More than 10] years ago I was seeing a family medicine doc who also taught epidemiology at [Famous Canadian University]. At one of my appointments I asked her how I could strengthen my immune system. She laughed in my face and told me that just was not possible.

Weiss says she was treated "as if I had asked about the existence of fairies or unicorns." (She added that attitudes seem to be changing and one Canadian hospital now uses probiotics to prevent and treat *C. difficile* infection.)

Epidemiologists could easily study environmental control of immune function. They could ask questions like how many colds do you get in a typical year?, when you get a cold, how long does it usually take before the symptoms disappear? and during the last year, how many days did your longest cold last? As far as I know, they haven't done so.

Jill (2012-10-18 05:45:51)

I honestly wouldn't be able to answer those questions very well without actually recording my colds for a year. I can say that I seem to get fewer/shorter colds in the last few years than I used to (I spent winters during my teens with a chronic respiratory infection) - maybe I'm doing better due to having children? I don't know, but sometimes I'm surprised to find myself without cold symptoms.

charlie (2012-10-18 06:00:38)

when all you have is a hammer... The hand-washing studies came out of what doctors should do. They are significantly more exposed than anybody else since they see sick people all day. Back in the real world, SR should mark this as "medical error." I am wonder in psychology practices, what percent of complaints are sub-clinical? 85? 95? 99 %

Rashad (2012-10-18 07:10:17)

Well, the other thing to take into account is potency of the disease vector. Obviously most of the time we are exposed to a cold, we don't get sick, so immune function plays a huge role there. However for a lot of the things that go via the fecal-oral route, I think there are much higher rates of infection, hence less variance due to the immune system. For example, with food poisoning, my anecdotal experience is that if you eat the thing that is poisoned, you will get sick, with several instances of shared sickness across multiple people. Similarly with things like cholera, salmonella, etc. But I could be wrong and immune function could have a big role there. Anyway, the potency of the fecal-oral route is I'm pretty sure the main reason for hand washing. Best practice in normal life is probably wash your hands after using the bathroom, but not that often otherwise, which is I suspect what most people do.

Rashad (2012-10-18 07:11:56)

Although one counter-example I just thought of is eating street food in a new developing country. Usually after the first illness or two the body adjusts, although when I lived in Egypt I knew several people that never did and just couldn't eat street food, so maybe they had weaker immune function?

jimrandomh (2012-10-18 08:15:27)

Rashad: I suspect that in most cases food poisoning is actually more about toxins than microbes - ie, it's the nasty chemicals the bacteria made before you ate them, not the bacteria themselves. It's also the case what we think of as food poisoning symptoms are actually immune responses, and if we want to measure immune system strength we should be looking at who's sick two days later. I also suspect that when people go to developing countries, their immune systems start having false positives: they fire in response to things that are actually harmless.

libfree (2012-10-18 09:25:43)

I whole heartily agree with much of what you have said here but I have to pick up on the evolutionary point that we haven't been prepared to live in cities of 1 million+. I think you might get better results from asking people how many days they missed work last year to illness. I get colds but I shrug them off so fast and they are so mild that I haven't missed a day of work to illness in 5 years. Seth: I agree, missed days of work is a good question. And you make a good point about cities of 1 million. In the past ten years I think all of my colds appear to have come from the combination of (a) poor sleep and (b) riding crowded public transit.

Evelyn M. (2012-10-18 13:59:45)

Quite a few travelers who normally are relatively free of colds develop bad colds or the flu following a long flight in economy class. Business class is considered less risky by those who travel frequently for that reason.

Nancy Lebovitz (2012-10-18 17:19:05)

The enough sleep issue is partly economic/political- there are people whose employers want unduly long work weeks from them.

Nancy Lebovitz (2012-10-18 18:58:55)

Off topic: Mathematical paper hoax. <http://www.lrb.co.uk/blog/2012/10/17/pau-l-taylor/stochastically-orthogonal/>

Nancy Lebovitz (2012-10-18 19:02:01)

More careful look at the math paper hoax: the nonsense article wasn't published because the hoaxer wasn't willing to pay the fee, but it did get polite reviews.

Nancy Lebovitz (2012-10-19 06:52:52)

<http://scholarlyoa.com/publishers/> Sorry, guys– the problem seems to be fake open-access journals rather than a fake paper.

Jenny (2012-10-19 14:09:18)

Some mentioned they hadn't counted their colds. I have. For the first 58 years of my life, I had one every 4-6 weeks. Then I found I had coeliac disease and stopped eating gluten. Also, my nutritionist put me onto high levels of probiotics for 3 months, and then a maintenance dose, which I take to this day. In the last 7 years, I have had only 4 illnesses! I attribute this to both the lack of gluten (no gut damage) and the probiotics. Fermented foods are a very effective way of getting probiotics, when you can work out how to make them/get them. These days I have Kefir, and want to experiment with others.

### **Doctor Logic: "Acne is Caused by Bacteria" (2012-10-19 05:00)**

Presumably Dr. Jenny Kim is a good dermatologist because the author of [1]this NPR piece chose to quote her:

UCLA dermatologist Dr. [2]Jenny Kim says many people don't realize it's bacteria that cause acne. "Some people say your face is dirty, you need to clean it more, scrub more, don't eat chocolate, things like that. But really, it's caused by bacteria and the oil inside the pore allows the bacteria to overpopulate," Kim says.

If I were to ask Dr. Kim how she knows that acne is "caused by bacteria" I think she'd say "because when you kill the bacteria [with antibiotics] the acne goes away." Suppose I then asked: "Is there evidence that the bacteria of people who get acne differ from the bacteria of people who don't get acne (before the acne)?" What I assume Dr. Kim would answer: "I don't know."

There is no such evidence, I'm sure. It is quite plausible that the bacteria of the two groups (with and without acne) are exactly the same, at least before acne. If it turned out, upon investigation, that the bacteria of people who get acne is the same as the bacteria of people who don't get acne, that would make it much harder to say that acne is caused by bacteria. As far as I can tell, Dr. Kim and apparently all influential dermatologists have not thought even this deeply about it. To do so would be seriously inconvenient, because if acne isn't caused by bacteria, it would be harder to justify prescribing antibiotics. Which dermatologists have been doing for decades.

It isn't just dermatologists. Many doctors believe that *H. pylori* causes ulcers – wasn't a Nobel Prize given for discovering that? The evidence for that assertion consisted of: 1. *H. pylori* found at ulcers. 2. Doctor swallowed billions of *H. pylori* and didn't get an ulcer. (Not a typo.) It was enough that he got indigestion or something. 3. Antibiotics cause ulcers to heal. That was enough for the two doctors who made the *H. pylori* case and the Nobel Prize committee they convinced. The doctors and the committee failed to know or understand that *H. pylori* infection is very common and almost no one who is infected gets an ulcer. Psychiatric causal reasoning has been even simpler and even more self-serving. We know that depression – a huge problem – is due to "a chemical imbalance", according to many psychiatrists, because (a) antidepressants work (not very well) and (b) antidepressants change brain chemistry.

Dr. Kim's false certainty matters because I'm sure most people with acne don't know what causes it. I didn't. Dr. Kim's false certainty and similar statements from other dermatologists make it harder for them to find out. I wrote about [3]a woman who figured out what caused her acne. It wasn't easy or obvious.

Thanks to Bryan Castañeda.

Alex Chernavsky (2012-10-19 06:53:40)

Seth, I've read your earlier posts about *H. pylori*, but I'm still unclear about what you think is going on, exactly, when ulcers form – and when they go away following antibiotic use. Can you elaborate? Seth: I don't know why most people with *H. pylori* infection don't get ulcers – in other words, the crucial difference between those who get ulcers and those who don't. Probably it's nutritional, although I'm not sure. I believe ulcers go away following antibiotic use because bacteria were somehow helping to maintain the ulcers.

Brian (2012-10-19 07:12:02)

When I had esophageal ulcers, the gastroenterologist checked to see if they were caused by bacteria, determined that they were not and then prescribed a proton pump inhibitor and something he called a liquid bandaid (I forget the technical name). After a few weeks, my ulcers were gone and I discontinued medical treatment.

Morris (2012-10-19 08:57:44)

Seth There is a view that holds that acne postules are caused by mucin blockage in lymph vessels. The mucin is a response to bacterial endotoxins. This accords with my experience. Healing periodontal gum disease (known to be microbial) has caused occasional postules to appear in the vicinity. I have experienced some other strange correlations to my acne which occurred decades ago.

charlie (2012-10-19 11:50:20)

Isn't *H. pylori* the gold standard for self-experimentation? So, if I parse down, antibiotics cure acne. A lot of people don't want to take anti-biotics and/or accutane. All the poor doctor is saying is don't take sandpaper to your face because that won't help. (Another thought – people with acne are in some way defective, and the acne is just a visual warning not to reproduce with them) Seth: "Poor doctor"? I doubt she is poor. Statements like hers, as I say, block helpful research.

Jenny (2012-10-19 13:58:41)

I've just read Chris Kresser's article on the link between gut bacteria imbalance and/or Sibo and acne. Much more plausible, and I am certainly one who 'lost' the acne the day I went gluten free. <http://chriskresser.com/the-gut-skin-connection-how-altered-gut-function-affects-the-skin>

Kitty (2012-10-19 15:11:40)

I had terrible skin my whole life and tried every cleanser and skin product ever invented (or so it seemed). My skin cleared up almost immediately when I stopped eating wheat, and it has stayed clear.

D (2012-10-20 18:23:05)

What about the role of androgens. Take steroids, get backne. I've also noticed that women who skew towards the masculine side of the spectrum tend to be more likely to have acne problems.

L (2012-10-22 03:42:21)

What the he'll are u doing at tsinghua?? Join me at harvard. Stop wasting ur time teaching chinx who don't know Spanglish!! What a waste!! They can't compare to us Americans in Boston!! MIT is nearby if u want to stop a little lower. But tsinghua?? Babe. What a joke!!

Tony Mach (2012-10-25 15:13:27)

It took me some awful while to figure out my personal connection between my acne and my diet – we need more pages like yours Seth! I can now say with certainty that for me acne is caused by dairy from pasteurized cow milk. Three to six hours after I eat dairy, I get an outbreak of acne. Though dairy is clearly the main cause for my acne, I sometimes get very very low level acne, which I haven't been able to track down: Traces of dairy in my food? Traces of cereal grains? Nuts? A reaction to beef? Bacterias acting up? I simply don't know (yet), this isn't so clear cut as dairy=>acne. And though I have \*not\* been able to trigger an acne out-break with cheese from raw milk, I remain suspicious that milk does more harm to my body than just acne. I had spurious "funky" symptoms after raw milk consumption. I had one low blood sugar episode and recently one swollen hard node (lymph node?), both after raw milk cheese consumption (again within the 3 to 6 hours timeframe).

Tony Mach (2012-10-27 11:06:26)

So Seth, here is the story how I found out my acne/dairy connection: In summer 2010 my health problems got noticeable worse (unrefreshing sleep, strange pains, strange sensations in the skin and other stuff I don't want to share here :-P ), and I had to do something. Furthermore I was gaining weight, I was suspecting something along the lines of Diabetes, or some other metabolic problem. As I was looking into dietary changes, I stumbled over Wolfgang Lutz's and Robert Atkins' work. Being engineer by training, I figured that if blood sugar might be the problem (which, as it turned out, wasn't the case for me), then reducing carbs might be a solution (stop fueling the problematic sub-system) – so both Lutz and Atkins appealed to me and I thought let's give it a try (I was a bit frightened about such an radical change of diet – you read all kind of BS – but hey, I felt like I was going to die anyway). Before the change, I ate a lots of white bread, some milk-chocolate and drank lots of milk. First I reduced carbs – like Lutz suggested, I tried to aim for 6 bread units – but within days I noticed that some problems (like the strange pain and skin sensations) diminished right away. The acne cleared up noticeable. So I thought why bother with low-carb, let's go full no-carb (like Atkins suggests for some month). And voila, with no-carb everything go better, and I started to feel healthy for the first time in my life. I lost over 30 pounds, all health problems either went away or were almost gone, and life started to become enjoyable. This was a period of about two months over with most problems went away, some fast, some slower. So for over half a year I was focused on the carbs=evil scheme, started eating cheese again (hey, no carbs!), when slowly some of the health problems returned, my weight started to rise again. At that point I panicked a bit and made a huge mistake: I thought I can figure this one out too, I have to do something right away. So I trusted what some doctors had written about an pathogen (which I tested for with borderline results), how to cure it (with over the counter medication like Vitamin D and NAC and other stuff) and I thought let's try this too! The things I took made me worse, but as it was supposed to be a "die off"/"herx" reaction, I wasn't too alarmed. Turned out that experiment cost me almost an year until I got better again. So for about a year I was not in the mood for big experiments and personal stuff like moving to another city kept me busy. But slowly I introduced "safe starches" into my diet (like plantains), because kept reading one should not go too much low-carb. I tried out self-made sourdough rye bread (makes me enormously hungry, so I stopped again) and at one point I thought: What the heck, I'm going to eat ice-cream today – 3 hours later I got slightly noticable pimples and local inflammation (I think they are called nodules), and after another roughly 3 hours the acne was prominent. After that, my suspicion was that milk might be bad for me, but maybe some properly "ripe" cheese like hard cheese (properly digested by bacteria) might be OK. So I waited for the acne inflammation to go back and tried again with an parmesan. Bingo, acne again, and again on the 3 to 6 hours timeframe. So I didn't touch milk or dairy again, but now I looked for raw milk cheese, as I read something about it being possibly better. After a while I found raw-milk-cheese, tried it – and got no acne. Tried again, after some time, with another brand – again no acne. Tried cheese from pasteurized milk – acne. As I still have health problems, I am still in the process of figuring out things. Next up for me is trying to get rid of beef for a week or two, to see if that might be a problem for me. In summary: - I was not very systematic in my experiments, and had some lucky moments. - All the macro-nutrient ratio paradigms are IMHO BS and not applicable for the majority (might make sense if someone has real/major metabolic problems like T1DM, etc.) - Having said that, in my view some carb foods come with baggage: e.g. cereal grains and (pasteurized) milk - A quickly reacting, non-dangerous, clearly visible (objective) surrogate health marker (in my case acne) is worth its weight in gold - With such a marker, one should completely eliminate suspicious foods (in my case \*ALL\* dairy) and then introduce it again (two or three challenges) - For me, pasteurized-milk-dairy=acne, raw-milk-dairy=no-acne - Milk-chocolate is dairy - Some surrogate health markers (e.g. weight) reacted "funky" for me: I changed my diet to no-carb, my weight went down, and without any big chances my weight started to climb again. - I still have some residual health problems - For most of the health problems

that went away, I don't know exactly what food (Cereal grains? Dairy? Vegetable oils? etc.) caused what problem - As I felt like I was going to die on my old diet, I am not particular keen on going back full scale to my old diet to see if after one or two month all my old symptoms return, to erode which food caused which symptom... - Medical science and several MDs helped me diddly squat - For me, Paleo blogs were much more helpful than the medical community - There are more tidbits I found out, but I lack the energy right now to write them down shortly - There is a lot I still don't know about my health problems In closing: In my view it is important to get ideas what may (or may not) be a problem, what experiments one can do safely (I had no problem with larger amounts of sat-fat, but two spoons of vegetable oil gave me a weird pressure in the temples...). The time delay between consumption and health effect is interesting to know too, some things act faster, some slower. While I think that I am not alone in that dairy causes acne, I think not everybody seems the same, and by now I wouldn't be surprised if for some people acne is caused by other things besides dairy. So much more to write, I guess ... P.S.: Some conditions are thought to cause acne (e.g. some adrenal issues) and I wonder if the medical science has the causation wrong, and in fact both the accompanying acne and the "primary" condition have both the same underlying cause (e.g. dairy).

### **More Fermented Foods, Less Runny Nose? (2012-10-20 05:00)**

As recently as four or five years ago, and for many years before that, I often had a runny nose. I went through boxes and boxes of Kleenex. I carried a handkerchief everywhere and often used it. Not because I had a cold—I almost never got colds. It was different than that. You might say I was mildly allergic to something in the air.

Because of reading an article I will discuss in a moment, I have just noticed that my runny nose has vanished, both in Berkeley (clean air) and Beijing (dirty air). So I don't think it's due to the dirty air in Beijing. There was no sharp change but as best I can remember it went away during the period when I started eating lots of fermented foods. Most days I eat about three types – yogurt and two other things, such as kimchi or kombucha. It is plausible that more exposure to bacteria caused my immune system to stop overreacting.

[1]The article, from The Scientist, describes research suggesting that not enough bacteria can cause disease – specifically, sinusitis. Sinusitis, just like ulcers, has been associated with a particular bacterium, but the researcher involved, Susan Lynch of UCSF, has a more sophisticated understanding of causality than those two bacteria-causes-ulcers scientists and the committee that gave them a Nobel Prize. Lynch points out, quite reasonably, that the bacteria associated with sinusitis "have also been detected in the sinuses of healthy individuals . . . "Just because you find these organisms, it does not mean they are driving disease." (The bacterium that supposedly caused ulcers, *C. pylori*, turned out to be very common. Almost everyone infected did not have ulcers.)

Lynch and her colleagues discovered

Samples from [sinusitis] patients tended to have less diversity of bacterial species than those of healthy controls. Furthermore the relative abundance of certain species differed between patients and controls. Sinusitis patients's noses were enriched with a skin bacteria called *Corynebacterium tuberculo*stearicum, for example, while samples from healthy controls were enriched with *Lactobacillus* bacteria, including *L. sakei*.

Which you could obviously get from fermented food. Following up this observation, the researchers did a mouse study that found that giving mice the bad bacteria caused sinusitis-like symptoms but giving mice both bad bacteria and good bacteria did not cause the symptoms. The good bacteria were protective.

---

Jim Purdy (2012-10-20 08:17:34)

Seth, your fermented probiotics may well have helped promote a healthier bacterial balance in your nasal microbiome, but could there also have been other factors? For example, had you been taking antibiotics earlier, and could the antibiotics have been killing off the "good" bacteria like lactobacilli and bifidobacteria? Seth: I had taken antibiotics 20 years earlier. I doubt their effect lasts so long. The first useful thing I learned from my self-experimentation was that antibiotics were not helping my acne, so I stopped taking them.

Jo (2012-10-20 10:48:52)

Interesting, my spouse has developed a sporadic runny nose for the first time in his life, he was hospitalized a year ago and had some antibiotics at that time but none since. (His immune system has actually been very good for the last year, no or only very mild colds/flu) We were blaming it on the fact he has had to take lots of new medications, but they are for the heart, and we saw no connection whatsoever with his nose. He does eat yogurt, but not on a daily basis. Oh, and we both take Vitamin D, but I'm the one who has had several colds! Seth: great observation! I mean about your spouse.

Paleophil (2012-10-20 14:40:32)

I used to carry handkerchiefs with me always too, and frequently use them, as did my father. After I adopted a Paleo diet, I found I no longer needed them.

Rafael Gray (2012-10-21 10:57:48)

Despite a Weston Price + fermented food products I still had AM congestion (Spring trees, dust mites) although better but became incidentally dramatically improved after markedly reducing wheat. Am not 100 % grain free by any means but must be some total load issue because doesn't worsen after eating a wheat product. And I've certainly done the gamut of various allergy reduction supplements and treatments etc. My Kleenex utilization index has dropped dramatically! Question: is there any rationale for a sinus mucus "transplant"? That's something I have yet to read anything about, a la fecal transplantation

L (2012-10-22 03:28:39)

Can't win, babe. Dirty air in Beijing, prob like smoking, Even worse. U may not need tissue. Later u can get a heart transplant to save u. Pollution might give brain tumor. U may know lots of stuff, but the chinx air will kill n=1!!

## Short-Term Effects of Fat, Protein and Carbohydrate on Cognition: Fat Best (2012-10-21 05:00)

[1]A German study published in 2001 measured the effect of starkly different breakfasts (all fat, all protein, or all carbohydrate) on cognition during the next hours. Participants (17 men in their 20s) ate the same packaged dinner at home and next morning came to the lab and ate different breakfasts. All of the breakfasts were "cream-like" and all contained 400 calories. The design was relatively sophisticated. Practice effects were reduced by giving considerable practice with the tests before the main measurements began. Brain tests included a simple reaction time task, a choice reaction time task, and a "combi-test" in which the subject does two things at once that provides six measures of performance. One set of tests took 15 minutes. The tests were done once/hour for 3 hours after the breakfast.

The simple reaction time test showed no difference between the breakfasts. The choice reaction time test and the combi-test did show differences: The all-fat breakfast was better. The improvement produced by the fat breakfast compared to the other two breakfasts was clearest about two hours after the breakfast.

EMG (brainwave) measurements showed no differences between the breakfasts.

These results agreed with previous work.

Cunliffe et al. (1997) reported that a pure fat meal did not increase reaction times in contrast to carbohydrate ingestion when measured hourly for 4 h after the meal. In our study, fat ingestion even improved reaction times compared with baseline. Our subjects scored best for all tasks of the combi-test after the fat meal. This finding is in line with the higher accuracy of a focused attention task after a high-fat meal compared with a low-fat meal reported by others (Smith et al. 1994).

The "fat" breakfast in this study was 25 % soybean oil (high in omega-6), 25 % [2]palm oil (high in saturated fats) and 50 % cream (high in saturated fats). I have not compared omega-6 to nothing but I suspect it would produce worse results, given that olive oil appears worse than nothing. So I suspect that the improvement due to fat was due to the palm oil and cream. I concluded, based on evidence that I and others collected, that butter (high in saturated fats) improves arithmetic speed. I usually ate 30 g (= 2 tablespoons = 270 calories) of butter twice/day. Close to the dosage of this experiment. The timing of the effects I saw (sharp improvement from one day to the next) is consistent with a change that happens within 2 hours.

These results, which I didn't know about until recently, support [3]my earlier conclusions about butter. My measurements cost almost nothing whereas this experiment must have cost thousands of dollars ( \$400/subject?) plus hundreds of hours of researcher time. Maybe I should compare cream and butter. Cream has advantages. Mark Frauenfelder suggested using cream to make yogurt. Superfood!

[4]A more recent study found saturated fat consumption correlated with cognitive decline. It was a survey, however, with many differences between the groups being compared. I trust experimental evidence much more than survey evidence.

---

Vic (2012-10-21 07:25:17)

Olive oil is only 10 % Omega-6, it's mostly mono-unsaturated fat.

Jim Purdy (2012-10-21 08:23:23)

I don't understand why doctors have so much fear of essential brain building blocks like fats and cholesterol, and why they promote statins that interfere with these brain functions. Seth: Might be the same reason that tonsillectomy surgeons ignore – or don't even know – that tonsils are part of the immune system.

Alex Chernavsky (2012-10-21 08:25:53)

Seth, can you speculate about why the simple reaction-time test was apparently less sensitive than the other two tests? And does this study change your view of the overall usefulness of the simple reaction-time test as a measure of cognitive function?

Seth: The simple RT test was less sensitive because it involves less mental processing. No, this study does not change my view of the value of simple RT as a measure of cognitive function. I have never believed it is a good measure of that.

MikeW (2012-10-21 08:37:47)

Interesting result, but I wish they had tested past that 3-hour window. Almost all of palm oil's saturated fats, and about 2/3rds of cream's, are the longer-chain c16:0 and c18:0. These don't peak in the bloodstream til about 5 hours after consumption. Short- and medium- chain fats (found in dairy and coconut/palm kernel oil) are metabolized more quickly, and peak in about 2 hours. So, to me, all the 3-hour test shows is that c14:0 and shorter saturated fat consumption can improve mental performance. It doesn't say anything about c16:0/c18:0, the predominant saturated fats in meat, eggs and nuts.

Matt (2012-10-21 08:49:13)

Another thing you could try is beef tallow versus butter. The fatty acid profiles are very similar with at least one notable difference: butter (and cream) have butyric acid, while tallow does not.

gwern (2012-10-21 09:19:52)

One of the downsides of yogurt is that the low-fat craze has gotten there, as well, and it's easy to remove all fat from yogurt. Like my grocery store - if I want Greek yogurt, I can take my choice of 3 delicious varieties... all zero fat.

Nick (2012-10-21 10:22:53)

Currently there are two routes to do science: 1. research institutions (the vast majority of the research) 2. the n=1 self-experimenter (a select minority; people like you, Seth) Yesterday I was struck with an idea: Why not crowd source science? Set up a website where people from across the globe can participate in worthwhile science projects. It could encompass all sorts of subjects, from psychology to nutrition to collaborative physics. People can join in experiments they feel to be promising and interesting. Just as Wikipedia overhauled the encyclopedia, this website could revolutionize science.

Nick (2012-10-21 10:24:51)

[http://en.wikipedia.org/wiki/Citizen\\_science](http://en.wikipedia.org/wiki/Citizen_science) Perfecting a model of citizen science is what I'm talking about.

Ed M. (2012-10-21 11:50:15)

I make my yogurt with heavy whipping cream exclusively. Tastes great. –Ed

David Johnston (2012-10-21 12:50:16)

Ed - Share your heavy cream yoghurt recipe!

Paul N (2012-10-21 22:19:47)

Not sure what Ed's recipe is, but I'm happy to share mine. Buy the best, and freshest, whipping cream you can get. Organic is best, and without any additives like carageenan gum. Buy some plain kefir (not yogurt) -you'll have to look for it- but it's worth it - and you only have to buy it once. Add kefir to the cream in a ratio of about 1:5, place in a glass jar/bottle and leave somewhere at room temp (countertop, cupboard above fridge, etc) for 24hrs. This is why you use kefir instead of yogurt - it works at room temp, not 35-40C like yogurt - and is a much stronger mix of probiotics. After 24hrs, put the cream back in the fridge and leave for three days. It is then ready to eat, is as thick as whipped cream, and has a slight tangy taste. you can flavour with vanilla, stevia, honey, coffee, brandy, etc You can also make cultured butter from it at this point. Just half fill a jar with your kefir-ed cream, leave out to warm to room temp (or sit in a warm water bath if you can't wait), and then just shake the jar end to end. Normally takes about three minutes for the cream to break, but longer if it is cold. You can then pour off the buttermilk, and use that for pancakes or other (gluten free) baking. Wash the butter with cold water until is clear and store. Salt it if you like. Not only will this be the best butter you ever tasted, it is probably the healthiest, and possibly cheapest too. The three minutes of shaking is worth it and makes an ideal pre-dinner mini workout, or to get the blood going in the morning!

Txomin (2012-10-21 22:37:22)

Thanks for the recipe, Paul.

L (2012-10-22 03:21:23)

Perhaps obese Americans should increase intake of saturated fats. It will surely decrease cancers, heart disease, stroke, etc!! Who's willing to do n=1 on this? Let me know! We can publish this together!!!!

dearieme (2012-10-22 03:39:54)

O/T, but I thought you might be amused by this from this morning's Telegraph, by the excellent James Le Fanu. Finally, a cautionary reminder of the confusion that can arise when medication causes the symptoms of the condition it is intended to treat. Here, a lady from Worcester writes to tell of the ever-more intrusive symptoms of her long-standing anxiety, where she would become fixated on the fine detail of things – dots on carpets, small stones, leaves, people's eyebrows, and so on. Her doctors and the community psychiatric nurse were sympathetic, but had no suggestions as to what to do. Then late last year, her anti-anxiety medication Stelazine became unobtainable in Britain – since when her fixation episodes have vanished, so far never to have returned.

L (2012-10-22 07:06:14)

why do stupid people take meds and get stupider????!

David Johnston (2012-10-23 16:58:09)

L: I'm certainly doing a n=1 study on increased saturated fat intake. It's improved my numbers, but so did a low fat diet and exercise in the Look Ahead study. When I die, I'll let you know.

RonBoyd (2012-10-23 17:22:25)

Seth, I don't know what this sentence means. Please explain. "I have not compared omega-6 to nothing but I suspect it would produce worse results, given that olive oil appears worse than nothing. " Seth: In Expt A I compared flaxseed oil to olive oil. In Expt B, I compared flaxseed oil to nothing. Expts A and B were very similar. Comparing olive oil in Expt A to nothing in Expt B, olive oil was worse than nothing.

David Johnston (2012-10-23 20:11:13)

So ELOO worked for weight loss in the Shangri La diet, but not for achieving fast speeds in cognitive speed tests. Is that a correct interpretation of your data? Seth: Yes.

L (2012-10-23 23:52:04)

thank u mr david johnston.

Evelyn M. (2012-10-25 10:26:37)

To make yogurt I use 3 1/2 cups whole milk, 1/2 cup heavy cream and four tablespoons of dried whole milk powder (which adds protein as well as cream). It works very well. If you want to make "Greek yogurt" - in Persian it is called mast-e-keesayee (or bagged yogurt) - just drain the yogurt through cheesecloth in the fridge until it becomes the texture you prefer.

L (2012-10-25 15:14:29)

@ Evelyn m : what do you do after all the milk and cream are put together? Do you always use a cheesecloth for all types of yogurt u make??

Evelyn M. (2012-10-27 14:00:35)

Hello, L. Thanks for reading my comment. I heat the milk and cream mixture to about 125 degrees F in a microwave and then put it in a yoghurt maker that keeps a very low, steady temperature. I usually leave it there for about 24 hours before moving it to the refrigerator. Most of the time I use the yogurt as is, I only make the strained version for special occasions, such as Persian New Year in March or Christmas. By the way, I wonder why sour cream hasn't been mentioned. Sour cream is a wonderful product, pretty well unique to the U.S. (at least I never found it for sale in England). One can easily find a brand that doesn't have any additives, such as Daisy, and it makes just about everything taste better.

- [1]You can major in Fermentation Science. No joke. When I was eight, I learned the concept of college major. I asked my mom, "What did you major in?" "Extracurricular activities," she said. I failed to get the joke. She later explained she had spent more time working on the school paper than on her classes.
- In a famous paper, the statistician Ronald Fisher accused Mendel of faking his data. Fisher wrote: "the data of most, if not all, of the experiments have been falsified so as to agree closely with Mendel's expectations." This is not terribly consistent with the fact that Mendel's highly improbable conclusions were correct. It's as if Fisher had said "Person X used false info to claim he is worth \$10 billion" and (b) in fact Person X is worth \$10 billion. You can see that (a) and (b) may both be literally correct but that the term "false info" (Fisher's "falsified") probably conveys the wrong impression. [2]This paper ("A Statistical Model to Explain the Mendel-Fisher Controversy") has a more plausible explanation of the pattern in the data that Fisher noticed.
- [3]Conflict of interest in the Nobel Prize in Literature. The conflicts of interest underlying the Nobel Prize in Physiology and Medicine – which are given out for "pure" science, thus justifying more funding – remain unnoticed by journalists.

Thanks to Bryan Castañeda.

Jim Purdy (2012-10-22 06:58:52)

Fermentation science majors are highly cultured folks.

Tom (2012-10-22 08:26:01)

Peter at hyperlipid talks about the Look Ahead study's being halted early because of a supposed lack of difference between the studies arms, pointing out that it's possible that the true reason the study was halted was that it was well on its way of proving that the standard of care kills people (all cause mortality In the intervention arm was higher than the other arm (and rising) when they cut off the study.) In other words, it's very likely that halting the study is a massive cover-up that will permit the standard of care from being corrected, resulting in the continued pointless deaths of thousands of people. [high-fat-nutrition.blogspot.com/2012/10/look-ahead-trial-stopped.html](http://high-fat-nutrition.blogspot.com/2012/10/look-ahead-trial-stopped.html) [www.cardiosource.org/News-Media/Publications/Cardiology-Magazine/2012/10/Look-AHEAD-Trial.aspx](http://www.cardiosource.org/News-Media/Publications/Cardiology-Magazine/2012/10/Look-AHEAD-Trial.aspx) They will do anything to keep from proving the unsurprising conclusion that feeding diabetics huge amounts of carbohydrate (the ADA diet) for years kills them.

L (2012-10-22 10:00:28)

how cute!! at 8! when i was 8, my mom taught me how to be financially independent. i read books and she taught me what to do!'. i love u mom!!! now i am hella rich!!! yowza!! dont need a man to take care of me!!

L (2012-10-22 12:02:56)

i shared ur ideas w harvard director. gave them ur url. medical school director shangri la diet world domination is starting NOW!! i told harvard director to drink olive oil. LOTS OF IT. i shared personal science etc. we'll get seth his well deserved nobel prize in his LIFETIME!!!!!!

Bryan (2012-10-23 00:47:51)

Jim, no offense, but you're going to hell for that.

L (2012-10-23 02:24:45)

ya jim: hellarious!!

## **Big Diet and Exercise Study Fails to Find Benefit (2012-10-23 05:00)**

Persons with Type 2 diabetes have an increased risk of heart disease and stroke. They are usually overweight. A study of about 5000 persons with Type 2 diabetes who were overweight or worse asked if eating less and exercise – causing weight loss – would reduce the risk. of heart disease and stroke. The difficult treatment caused a small amount of weight loss (5 %), which was enough to reduce risk factors. [1]The study ended earlier than planned because eating less and exercise didn't help: "11 years after the study began, researchers concluded it was futile to continue — the two groups had nearly identical rates of heart attacks, strokes and cardiovascular deaths."

Heart disease and stroke are major causes of death and disability. Failure of such an expensive study ( \$20 million?) to produce a clearly helpful result is an indication that mainstream health researchers don't understand what causes heart disease and stroke. Another indication is that the treatment being studied (eating less and exercise) was popular in the 1950s. Mainstream thinking about weight control is stuck in the 1950s. It is entirely possible that greater weight loss – which mainstream thinking is unable to achieve – would have reduced heart disease and stroke. If you understand what causes heart disease and stroke, your understanding may lead you to lines of reasoning less obvious than people with diabetes are overweight -> weight loss treatments).

One of the study organizers – Rena Wing, a Brown University professor who studies weight control – told a journalist "you do a study because you don't know the answer." She failed to add, I'm sure, that wise people do not give a super-expensive car to someone who can't drive. You should learn to drive with a cheap car. Allowing ignorant

researchers to do a super-expensive study was a mistake. To learn something, do the cheapest easiest study that will help. (As I have said many times.) You should not simply do "a study". This principle was the most helpful thing I learned during my first ten years as a scientist. In this particular case, I doubt that a \$20 million study was the cheapest easiest way to learn how to reduce heart disease and stroke.

I made [2]progress on weight control, sleep, and other things partly because studying myself allowed me to learn quickly and cheaply. If researchers understood what causes major health problems, they would be able to invent treatments with big benefits. That the Nobel Prize in Physiology or Medicine is given year after year [3]to work that makes no progress on major health problems is another sign of the lack of understanding reflected in the failure of this study. I have never seen this lack of understanding – which has great everyday consequences – pointed out by any science blogger or science columnist or science journalist, many of whom describe themselves as "skeptical" and complain about "bad science."

---

charlie (2012-10-23 05:33:36)

Given the population – old and very fat – I have a feeling no amount of weight loss would make a difference in mortality. There is plenty of evidence that modest weight loss+exercise can prevent/delay the onset on diabetes, but as a treatment once you get there it isn't going to help.

L (2012-10-23 05:51:00)

hi charlie! i agree w u and seth: its hard to reverse something like diabetes, hypertension....now, we cant eliminate cancers, it would put mds out of business!!! but... if one person can find a cure....and they dont have a special interest in keeping an oncology position.,,. a drug rep at purdue said: ya we want a cure for cancer. that means MONEY!!!! wow! i just thought of another research project. us personal scientists have to be healthy to live longer... i am going to put a bunch of snobby mds out of work!!! yeah!!!

Jim Purdy (2012-10-23 06:19:36)

Charlie and L: Both of you say that diabetes can't be reversed, but then how do you explain all the claims that weight loss surgery can cure type 2 diabetes? I would never consider having weight loss surgery, but I'm fascinated by all the claims that some weight loss surgeries reverse or cure diabetes. I'm not sure whether the "cure" could be due to bypassing an intestinal section that produces some hormones, or whether the surgery alters the gut microbiota and thus changes something. I think these issues need to be researched further. I think one of the sad stories of medical history is the timing of the discovery and commercial production of insulin in the early 1920s, for two reasons: 1. The discovery of insulin put a sudden end to some very promising research being done by Doctor Frederick Madison Allen, who had been treating diabetic patients with an extremely low-calorie "starvation cure." Allen's dietary approach was briefly hailed as a major breakthrough, but insulin gave people an alternative that let them avoid dieting. Dieting was, and still is, the better choice, and the focus should be on how to make diets more successful, maybe with some combination of low carb, high fiber, as well as prebiotics and probiotics. 2. The discovery of

insulin gave a tremendous boost to the BigPharma industry and the development of all the highly profitable bizarre drugs that have led researchers away from natural Darwinian medicine approaches that are based on sound evolutionary science. Seth: I say the same thing about the discovery of antibiotics. The cost of the discovery is rarely noticed. One big cost of that discovery was less attention to how to improve immune function. Another, as you say, was promotion of a drug=cure mentality, when other non-drug solutions are much better in the long run. Diabetes is an obvious example.

Mark (2012-10-23 06:25:07)

"Allowing ignorant researchers to do a super-expensive study was a mistake." Right on, Seth! Unfortunately, this is the name of the game in the publish or perish, grants as academic currency world.

Daytona (2012-10-23 06:38:58)

I have heard speculation that the reason why they cut the study short was not simply that it was obvious that the intervention group wasn't successful. Instead they stopped early because they were seeing worse outcomes in the intervention group and they didn't want to the last 2 years to highlight the trend. By stopping early, they can say "the outcomes between the intervention and control were the same" instead of finishing the trial and being forced to report that the intervention group (following the standard medical advice) did worse. Any thoughts on if there is any truth that rumor?

Tuck (2012-10-23 06:49:00)

The sad thing is: we know how to cure or dramatically improve outcomes in diabetes through changes in diet and exercise. We've known how for a few decades. It's really easy. And to Seth's point, the fellow who figured it out was a self-experimenter who had diabetes himself, figured out that the standard protocol (which hasn't changed) didn't work, and used a simple tool (now cheap and readily available) to solve the problem. But the diet is 100 % the reverse of the American Diabetes Association plan, so it's ignored. One is forced to come to the conclusion that the perceived status of the medical profession is more important than patients' lives. They'd be forced to say: we blew it, we made millions of sick people sicker. This generation won't do it. Neither did the one before. The fellow in the case above was an engineer. He discovered that doctors wouldn't listen to someone who wasn't a doctor. So he went to medical school and became a doctor. They still wouldn't listen to him. His book, btw, is "The Diabetes Solution". Seth: "They still wouldn't listen to him." That's an overstatement. Richard Bernstein, the engineer you refer to, pioneered home glucose measurement, which is now a billion-dollar/year industry. The idea spread from Bernstein to med school professors to standard of care. Bernstein's particular solution to high blood sugar, however – a very low carb diet – did not spread. I think with good reason: it is not a good idea. I found that walking one hour per day vastly improved my blood sugar. Eating a very low carb diet did not. When it came to the solution, I think Bernstein got it wrong.

charlie (2012-10-23 07:44:52)

@jimPurdy; I think the reversal of diabetes with bariatric surgery is in the 5 % range. It happens, but it is rare. Again, once you're a full blown diabetic you're going to be on drugs. Sorry.

Tuck (2012-10-23 07:58:06)

@charlie: or you could google it, and find out. "The clinical and laboratory manifestations of type 2 diabetes are resolved or improved in the greater majority of patients after bariatric surgery; these responses are more pronounced in procedures associated with a greater percentage of excess body weight loss and is maintained for 2 years or more. " <http://ukpmc.ac.uk/abstract/MED/19272486> Bariatric surgery simulates a low-carb diet, essentially. That's also often what is followed after the surgery. If you don't you gain a lot if not all the weight back. Leads one to think it's the diet, not the surgery, but clearly cutting part of your intestinal tract out is going to have some effect...

Tom (2012-10-23 07:58:27)

Actually, Seth, it's worse than that: Peter at hyperlipid suggests that the Look Ahead study was NOT halted early because of a supposed \*lack\* of difference in mortality between the study's arms, but rather because it was well on its way of proving that the ADA diet killed MORE people (all cause mortality in the intervention arm was HIGHER than the other arm – and significance was rising – when they cut off the study.) In other words, it's very likely that halting the study is a massive

cover-up that will permit the standard of care from being corrected, resulting in the continued pointless deaths of thousands of people. [high-fat-nutrition.blogspot.com/2012/10/look-ahead-trial-stopped.html](http://high-fat-nutrition.blogspot.com/2012/10/look-ahead-trial-stopped.html) [cardiosource.org/News-Media/Publications/Cardiology-Magazine/2012/10/Look-AHEAD-Trial.aspx](http://cardiosource.org/News-Media/Publications/Cardiology-Magazine/2012/10/Look-AHEAD-Trial.aspx) They will do anything to keep from proving the unsurprising conclusion that feeding diabetics huge amounts of carbohydrate (the ADA diet) for years kills them. Seth: Peter at Hyperlipid says nothing to support his view that it is "very likely" that more people died in the intervention arm than in the control arm. Or if he does, I didn't understand it.

MikeW (2012-10-23 08:21:49)

charlie's "old and very fat" comment got me looking at the study's participant metrics. I wouldn't call them old - the average age was 59 (look ahead's eligibility requirements were age 45-74). But yes they were very fat. The study specified a starting baseline BMI of at least 25, but the actual average BMI was 36! That bothers me more than the study's cost. Their stated goal was to study "a diverse sample of overweight participants"; the sample they ended up with had way too many morbidly obese individuals. Seth: I think the study designers believed that these people were going to be more easily helped than people who were less fat. It's a reasonable assumption. Which makes the failure to help them all the more damning.

Catherine Shaffer (2012-10-23 09:02:37)

I covered the Look Ahead study for my publication, and there's some misunderstanding here about the termination and what that means. The study did not fail. It was brought to an end by an independent data monitoring committee because upon analysis of the data, there was no chance of showing a difference in mortality between groups the test and control group. The study did not fail, it finished, and the data is valid and publishable and usable, and can be built upon for future studies. Although no benefit in terms of cardiovascular events was found for people with Type II diabetes, the study did confirm the benefits of the 5 % weight loss in preventing Type II diabetes and for some other health outcomes. There's been a huge gap between showing benefits for various surrogate health markers like blood pressure and actually proving that interventions can actually prevent heart attacks, which would be the ultimate holy grail of weight loss intervention. There is no data in the study showing that people in the weight loss group had higher mortality. The two groups were the same with no statistical difference. It's a tough problem, and one of the problems, you are correct, is that much of the conventional wisdom is wrong—for example on the value of a low fat diet. I would disagree, Seth, that the \$20 million was unjustified. There are countless small, retrospective studies on weight loss and diabetes interventions. What is needed is large, prospective studies to put many competing hypotheses to the ultimate test to see if they really have value. This was \$20 million well spent because it tells us in no uncertain terms that weight loss alone is not a cure for Type II diabetes. Jim Purdy, you are confusing Type I and Type II diabetes. The starvation cure was only temporary. It delayed death in diabetic children, but did not prevent it. No one can survive without a functioning pancreas, and diet can not cure a condition that is caused by the failure of a major organ. Insulin was a life-saving revolution and continues to be a valuable, life-saving, life-prolonging drug for people with Type II diabetes. Diet can be used to reduce insulin consumption in Type I diabetes, but can never eliminate it. Diet interventions absolutely can reverse or cure Type II diabetes, however, and progress on that is not hindered by the availability of insulin because insulin is an intervention of last resort for that group, anyway. Seth: I think the \$20 million would have been better spent on numerous small studies trying to understand what causes heart disease. Rather than on a test of a common-sense cure (weight loss). You mention "competing hypotheses" – that's exactly it, there weren't any competing hypotheses. There was just one idea, so simple-minded that to call it a "hypothesis" might be overstatement. There was no theory of heart disease that predicted that the intervention would not work – at least, the study organizers have not mentioned what that theory is.

Catherine Shaffer (2012-10-23 09:04:03)

"Insulin was a life-saving revolution and continues to be a valuable, life-saving, life-prolonging drug for people with Type II diabetes." I meant Type I, of course.

Carol (2012-10-23 09:49:42)

Institute of Medicine's standard 'recommended' diet for non diabetics is 225 to 325 grams of carbs a day. I went to the ADA site, and couldn't find a specific carb count, so I looked up a 'meal plan' (<http://www.diabetes.org/mfa-recipes/meal-plans/>) and the particular one, featuring "Asian Flavors" had 192g of carbs. Barely less than that recommended by the standard

American Diet. This is the current guidelines: [http://care.diabetesjournals.org/content/31/Supplement\\_1/S61.full.pdf%20html?sid=8c9f7471-103e-47c4-b288-fcfa7ab77b58](http://care.diabetesjournals.org/content/31/Supplement_1/S61.full.pdf%20html?sid=8c9f7471-103e-47c4-b288-fcfa7ab77b58) This stood out: •For weight loss, either low-carbohydrate or low-fat calorie-restricted diets may be effective in the short term (up to 1 year). (A) I wonder why the low-carb version isn't recommended more?

Tuck (2012-10-23 09:50:16)

"The primary objective of Look AHEAD is to examine, in overweight volunteers with type 2 diabetes the long-term effects of an intensive lifestyle intervention program designed to achieve and maintain weight loss by decreased caloric intake and increased physical activity. This program is compared to a control condition involving a program of diabetes support and education. The primary basis for the comparison is the incidence of serious cardiovascular events. Other outcomes, including cardiovascular disease risk factors, diabetes related metabolic factors and complications, and the cost-effectiveness of the intensive intervention are also studied." It failed because it was testing a hypothesis, and it demonstrated that that hypothesis was not correct. Losing weight and exercising did not affect the end point. The fact that it failed doesn't mean that nothing was learned... I agree with Peter @ Hyperlipid's hypothesis: they cut it short because it was demonstrating that the intervention wing had a worse outcome, like the ACCORD trial.

Tuck (2012-10-23 09:50:59)

Oops, here's the link to go with that quote: <https://www.lookaheadtrial.org/public/LookAHEADProtocol.pdf>

Paul N (2012-10-23 09:53:08)

Catherine, The press releases said there was no difference in cardiovascular events, they did not, specifically, say "all cause mortality". We'll have to wait for the final report, and hopefully the raw data set, to see what really happened. BUT, the central hypothesis of the trial was that the diet and fitness intervention, in obese diabetics, would reduce CV events - but, after 11 years, it didn't. Even "improvement" in other health markers - weight, treadmill fitness, blood pressure, HDL cholesterol, made absolutely no difference to CV events. so will they conclude that the diet does not work, and that many of the markers are not good indicators for CV health? If it means this paradigm is finally discarded, then the \$20m was well spent, if the results are buried, and the ADA diet remains unchanged, then we have a real problem.

Mark (2012-10-23 10:15:13)

Catherine, Here are two things that you might want to keep in mind when covering future studies: 1) the word "data" is plural (e.g., "the data [are] valid and publishable"); 2) The sentence "The two groups were the same with no statistical difference" is utterly wrong. It is statistically impossible to show that two groups are the same... "no statistical difference" really only means insufficient evidence to reject the null hypothesis, it provides absolutely NO support for the null hypothesis of no difference.

L (2012-10-23 10:55:40)

thanks mr jim purdy. great info i didnt know about.

Aaron (2012-10-23 12:42:47)

CarbSane Asylum is doing some posts about this study: <http://carbsanity.blogspot.com/2012/10/that-diabetes-study-that-ended-early.html> <http://carbsanity.blogspot.com/2012/10/more-on-look-ahead.html> In the first link she discusses the possibility that poor compliance to the diet probably had a significant impact on the results: "Does anyone out there truly believe that if your average 250 lb person complied with a diet of 1500 cal/day for a decade would still weigh nearly as much? It sounds like this study included a diet phase early on (6 months perhaps?) during which the participants lost weight, and then maintained the losses. Did they continue the exercise? These are details I'd like to see when this study is eventually published up. How many are even following the "rigorous program" to any degree?"

L (2012-10-23 14:19:41)

thanks,aaron

Tom (2012-10-23 15:46:37)

Carbsane goes on the warpath whenever there's any threat to her beloved carbohydrates. She has so much hatred for Gary Taubes that you'd think he gave her a wedgie in junior high or something.

Alex Chernavsky (2012-10-23 17:43:39)

Mark wrote, "the word 'data' is plural "

"It's time to admit that data has joined agenda, erotica, insignia, opera, and other technically plural Latin and Greek words that have become thoroughly Anglicized as singular nouns, taking singular verbs. No plural form is necessary, and the old singular form, datum, can be left to the Romans."

From, *Woe Is I: The Grammarphobe's Guide to Better English in Plain English* by Patricia T. O'Conner. Seth: I found 4 times as many Google results for "data is" than "data are", supporting what you say. Here is a discussion: <http://www.guardian.co.uk/news/datablog/2010/jul/16/data-plural-singular>

Nancy Lebovitz (2012-10-23 19:37:45)

Seth, the hard thing is that insomnia happens frequently, but CV events are rare. I'm not sure how self-experimentation could address them unless you had a really good surrogate measure.

Patrik (2012-10-23 21:46:54)

"To learn something, do the cheapest easiest study that will help. " In the technology space, this is akin to building what we call a Minimum Viable Product.

L (2012-10-24 00:01:11)

@tom: mr taubes is very tall and gives lots of free talks. i heard him talk at walnut creek, ca.

L (2012-10-24 00:07:43)

@alex chernavsky: ur knowledge of the ill effects of neuroleptic medication is helpful!!

L (2012-10-24 00:08:39)

@nancy lebovitz: what surrogate measure would u propose?

Tuck (2012-10-24 06:54:49)

"When it came to the solution, I think Bernstein got it wrong." Bernstein's a 70-something year-old Type 1 diabetic, who has no diabetic side effects (they all went away) and is in apparently perfect health. That's not too bad for "wrong". I work with a fellow who's teenage son is also a type 1 diabetic. After going through the usual BS, they went to see Bernstein. Now, when they go see their local doctor, the nurses call everyone over because "You never see a Type 1 diabetic with perfect blood sugar control!" No, you don't, unless you follow a VLC diet. My wife and I also reversed our pre-diabetes by going VLC: in my case, after failing with walking, running, mountain biking, going to the gym. At one point I was working out 12-16 hours a week. Never lost a pound, stayed prediabetic. I think Bernstein got the solution perfectly right. And you're right that they listened to him about measuring glucose, but they missed the point of the measurement. Seth: Bernstein's work was a huge advance, for which he deserves a Nobel Prize. Has Bernstein suffered any bad effects from extreme carb restriction? I am less sure than you that he is in perfect health. In your case, you tried walking one hour per day, and that failed?

L (2012-10-24 08:30:50)

@mr tuck: thank u!! im glad one can reverse it! i never knew it was possible because i always thought a diabetic had to take insulin. wow!!

Nancy Lebovitz (2012-10-24 10:51:57)

I have no idea what a good surrogate measure for CV would be. That's why I raised the question.

L (2012-10-24 18:05:54)

@ms nancy lebovitz: thanks!

Evelyn M. (2012-10-25 10:39:25)

Slightly OT - I'm surprised you haven't spoken about and linked to - <http://summaries.cochrane.org/CD009009/general-health-checks-for-reducing-illness-and-mortality> - as even the NYT has mentioned the results of this meta-analysis (albeit hidden in a small paragraph in Tuesday's science section, whereas it should have been on page one). The Cochrane Collaboration is the group that has shown that hormone-replacement therapy was a bad idea, that mammography causes more harm than good, etc., etc.

Tuck (2012-10-26 08:32:53)

Bernstein says he's in excellent health, with no ill effects from a long-term low-carb diet. In fact, all of his "progressive" diabetic complications regressed after going VLC. Jimmy Moore videoed Bernstein speaking a few years ago, where he discusses his symptoms and life: "Dr. Richard Bernstein (Part 1)-Nutrition & Metabolism Society Meeting-May 8, 2010" <http://www.youtube.com/watch?v=9VaNJO7KMgg&feature=relmfu> Timely: "Type 1 Diabetes No Match for Primal Lifestyle!" <http://www.marksdailyapple.com/type-1-diabetes-no-match-for-primal-lifestyle/> This fellow is effectively following Bernstein's protocol, including the basal/bolus insulin scheme. Agreed about the Nobel. Unfortunately, until the medical profession can admit that their approach for treating diabetes is an utter failure, he'll never get it.

Tony Mach (2012-10-27 06:16:27)

One observation about the "skeptics" community I share with your sentiment: They have very good instincts in going after the scientific "easy" target: all the alt-med, "integrative" and CAM quacks peddling their unscientific woo (though what the skeptics do is IMHO not very effective in combatting the obvious quack medicine). But when it comes to the scientific mainstream producing bad (or costly and useless) science (or rather non-science), they are completely lost. They decry the profits that the alt-med cancer quacks pocket with their useless, dangerous and costly treatments (and the skeptics are right to decry this fraud by the alt-med quacks), but how many billions have been spent on the war on cancer in the last decades, and with what results? The whole state of affairs of the medical science is depressing, especially considering the gap between potential for research and progress we have in our modern societies, and the results the medical science has produced in the last decades.

## **The Personal Scientist Who Knew Too Much (2012-10-24 05:00)**

The San Jose Mercury News recently ran [1] a story by Lisa Krieger about a father (Hugh Rienhoff) who found a single-amino-acid mutation that he believes causes his daughter's growth difficulties.

Born with small, weak muscles, long feet and curled fingers, Beatrice confounded all the experts.

No one else in her family had such a syndrome. In fact, apparently no one else in the world did either.

Rienhoff - a biotech consultant trained in math, medicine and genetics at Harvard, Johns Hopkins and the Fred Hutchinson Cancer Research Center in Seattle - launched a search.

He combed the publicly available medical literature, researching diseases, while jotting down each new clue or theory. Because her ailment is so rare, he knew no big labs or advocacy groups would be interested.

He did some of his own lab work in his San Carlos home, borrowing tools or buying them used online.

A few commercial labs, like the San Diego-based biotech Illumina, offered him help for free. And a wide array of pediatricians, geneticists and neurologists volunteered their opinions.

Over time, he zeroed in on a stretch of genes that control a growth hormone responsible for muscle cell size and number. And he knew he could further target his search – saving time and money by not sequencing Bea's entire genome, but only the exomes, which are the genes that code for proteins.

This is not a simple upbeat story. The father is a genetic researcher and doctor. I agree, he has made considerable progress in understanding the cause of his daughter's problem. Not addressed are two questions: 1. Why is he sure he has the right mutation? Perhaps his daughter has other mutations. I'm sure the father understands this, the journalist may not. 2. What about environmental causes? As [2]Aaron Blaisdell's story shows – Aaron has/had a single-gene genetic disease that vanished when he changed his diet – single-gene diseases may respond to environmental changes. Early work with bacteria emphasized this. If Rienhoff had spent equal effort in trying to find environmental changes that help, he might be further along in discovering them. An obvious place to start would be testing different diets. There is no sign he has done that. His knowledge of genetics, plus the brainwashing that doctors undergo (they are told genes are incredibly important), may have led him to waste a lot of time. Someone with less understanding of genetics may realize better than Rienhoff that knowing what genes have changed may be very little help in finding helpful environmental changes.

Thanks to Allan Jackson.

---

Alex Chernavsky (2012-10-24 05:53:12)

The classic example is phenylketonuria – a genetic illness that is easily (more or less) treated by severely restricting dietary intake of the amino acid phenylalanine. Surely Reinhoff is familiar with this disease and its treatment?

L (2012-10-24 18:17:16)

@ mr alex chernavsky: thats a great question. from what i have learned talking to random doctors at boston u or even a director at harvard med or even random harvard students: a lot of doctors are really dumb!! i talked w a new doc at boston u and he didnt know the high sugar content of grapes he was buying. he said hes not the doctor, i am the expert on blood sugar. i made him feel very embarrassed and he was blushing because i was showing how stupid he was in front of others. i made the harvard director cry and i offended her because i said i was bored talking w her at an expensive restaurant i didnt want to go anyways...oh well harvard med paid for my salad and olive oil. she ate lobster roll!!! \$60 she spent on herself!!!

## The Dark Side of Open Source (2012-10-25 05:00)

A friend writes:

David [her boyfriend, not his name] learned some of the new languages (Android being one ). He says that any programming involving Open Source software requires wading through undocumented code, sloppily written by guys who de facto require one to email them, asking for technical support.

And without the cooperation of these people, one has no chance in hell of figuring out what the next command syntax should be. And a lot of the guys who wrote the code are reluctant to cooperate, because their knowledge of how their own code is supposed to be written and how to run it is their only job security.

Coding for very simple operations, such as connecting an external camera to an Android cell phone, has been proving impossible. He's been working on it for 10 days now.

David has tried several flavors of Linux kernels and also several brands of smartphone drivers. But it always comes to the same thing. The software won't run, and there are maybe one or two wrong characters in 20,000 lines of code that made it break, and you don't know where to start looking. Because the error message doesn't tell you anything other than it won't run.

To be fair, I use R (which is open source) many times every day. It has far fewer bugs than the S-plus software it replaced. That it's free is a huge plus.

---

Jill (2012-10-25 05:07:38)

Also to be fair, you can get those same kinds of problems (sloppy code, useless error codes, and small syntax errors - sometimes involving invisible characters) with just about any code that you're working on.

Philip Kilner (2012-10-25 05:53:15)

Hi, Couldn't help but smile at this one - as Jill suggests above. none of these characteristics are particular to Open Source, and this seems to me to be a case where correlation does not imply causation! Equally in tune with the spirit of your blog, I'd suggest that your own daily experience is of more value than the assertions of a 3rd party... ;-) On a serious note, I use Open Source s/w for preference where I can, because the support is so much better, I think because people who have shared a problem enjoy sharing the solution. I also have to say that the assertion that "a lot of the guys who wrote the code are reluctant to cooperate, because their knowledge of how their own code is supposed to be written and how to run it is their only job security" is not true of any Open Source community that I'm involved with. Cheers, PhilK

ChristianKI (2012-10-25 05:56:34)

"Coding for very simple operations, such as connecting an external camera to an Android cell phone, has been proving impossible. He's been working on it for 10 days now." With closed source software such as the iPhone the task is also impossible: <http://stackoverflow.com/questions/12037169/is-it-possible-to-connect-an-external-camera-module-to-an-iphone-audio-jack> There no reason to expect this task to be easy. Smartphones aren't designed to make it easy extend them with external cameras. "The software won't run, and there are maybe one or two wrong characters in 20,000 lines of code that made it break, and you don't know where to start looking. Because the error message doesn't tell you anything other than it won't

run.” That’s a silly proposition. There’s a debugger that you can run to see where a program crashes. In Android you also have a log that provides you plenty of information about your program. David’s girlfriend doesn’t seem to understand much about programming and is maybe not the best person to fairly describe the downsides of open source.

Daniel Lemire (2012-10-25 06:26:42)

Just think how amazing it is that you can write a program that can interact with a freaking camera on a phone! That you even have a chance of trying to do it outside a corporate laboratory... and for almost no money down... is amazing. The argument that open source people obfuscate and hide their knowledge on purpose to keep their “knowledge” valuable is absurd. Yes, things can be complicated sometimes and issues can be undocumented, but that is not “on purpose”. It is just that life is complicated in general. Obviously, if Linux crashes and you email Linus Torvalds, he is not going to get back to you and explain how to fix the problem. But this just says that resources are limited while problems are plentiful and hard. There is much evidence that the authors of successful open source software go out of their way to help. What the author of these lines lack is perspective. Documentation? Go to Amazon.com: there is probably more books on programming with open source software than on any proprietary software (except maybe for the Windows stack). I am not saying that open source is always the best model. Sometimes, in practice, proprietary software works better. And there are evil people involved with open source software, I am quite certain of that. But the values behind open source are nothing like what is being described here. The programmers who pursue open source have motivations similar to the wikipedians. Sometimes they screw up, but they are very much motivated by the common good and by the hope that if they help people enough, their own status will rise up. Reputation is almost everything in open source and people care very much about it. They don’t obfuscate their work on purpose, and they try their best to produce the very best software they can (given the resources they have).

threepipeproblem (2012-10-25 06:34:52)

I agree... not a great explanation of why open source software often sucks.

Darrin Thompson (2012-10-25 07:00:31)

Sounds like the dark side of embedded hardware to me. Not unique to open source. There’s a community of Android modders who flash their phones to upgrade the Android OS a lot. When a new mod comes out, it’s common to see a bug list like, camera and MMS don’t work yet. Open source really is amazing in the macro but depending where you are in the open source world, your experience might be better or worse. Android’s relationship with the upstream Linux Kernel, for instance, has been a lot worse in the past. <https://lwn.net/Articles/514901/> I think your friend was very unlucky to end up in a bad spot. If he had been trying to build a web site with open source software he might have felt differently.

Mike Packard (2012-10-25 07:37:36)

One thing I like about open source software is that it has the potential to be better than commercial software due to purer motives. The purpose commercial software is to make money. Ideally the developers do this by providing the best software they can, but inevitably design choices will be influenced by the need to sell it (i.e. adding features vs. fixing bugs, flashy vs. useful interface, advertisements embedded, etc.). Anyone who has used software with the word “Enterprise” in the title knows what I’m talking about. The purpose of open source software—it’s only reason to exist—is to be good at its task. So the developers don’t have any motivation besides making the best software they can. It removes 1 layer of obfuscation between design and implementation.

RyanE (2012-10-25 08:40:05)

Another point about Open Source software: Sure, the developer may have moved on to other things, or doesn’t provide support, but at least they provide \*source\*, so you (in theory) should be able to figure it out. Try \*that\* with proprietary software. As most other posts have said, it’s usually a matter of complexity, and familiarity. Any large source base is going to be pretty opaque unless you’ve worked with it quite a bit.

jimrandomh (2012-10-25 10:17:42)

“Coding for very simple operations, such as connecting an external camera to an Android cell phone, has been proving

impossible. He's been working on it for 10 days now." That's not a simple operation at all, it's a hard project for a domain expert. I am not that domain expert, but I can see the overview, and it's likely that David's in \*way\* over his head. Android didn't support USB host mode at all before version 4, and a lot of hardware still doesn't (for electrical and power supply reasons, not just software reasons). Notice that this is the most recent version - ie, it hasn't been iterated on at all yet. Then you not only need to write a USB camera driver, against brand-new and therefore buggy APIs, none of the userspace camera libraries or apps support hot-swapping either, so you need to spin up in two more project contexts (a total of three distinct codebases to modify). It's not a documentation problem, a syntax problem, or a needle-in-a-haystack problem. It's mostly a domain knowledge problem: you need to know kernel development, and to have done it on a well-trodden path in a more forgiving context. Implying that developers are skipping documentation because it gives them job security is highly implausible. (It's because they're busy making things, they're not good at writing, they're not good at modeling what other people don't know, and/or they're lazy.)

Scott Pierce (2012-10-25 18:25:30)

That is just silly. Consider the motivation of the developers of any significant open source code base? It is pride and glory. You don't get that from submitting crappy software to github and then living life defensively over it. Just doesn't make sense. Some devs can be condescending because, frankly, they are just that damn smart but most find a sense of purpose and worth in helping others with their software and most open source projects are a hell of a lot better documented than most closed source projects because a lack of documentation or bad docs is considered a character flaw, countering the motive for publishing open source to begin with, glory. My guess is this individual has been raised on the idea that things should be easy versus simple. Seth: Are you saying your experience with open source has been different? Lots of predictions about human behavior based on theories about "motivation" have turned out to be wrong.

Peter (2012-10-25 19:54:45)

Yeah... not all open source projects are well-maintained, but this sounds like sour grapes.

Nancy Lebovitz (2012-10-26 12:20:21)

My best guess that for a lot of people, writing programs is more fun than designing good interfaces and doing user support. If you're lucky, the open source writer does care about the interface. Even so, programmers probably only want to answer interesting questions if they're not getting paid. Again, this is a problem if they also want open source to rule the world. However, I doubt very many programmers are deliberately hiding how to get good use out of their programs.

David C (2012-10-27 06:58:28)

Your friend doesn't know what she's talking about.

Alex R. Berg (2012-10-29 01:01:00)

Also, just to add a bit of salt in the wound, Android is far from typical open source. It (at least Googles version of Android) is mainly being developed by one huge company who makes money on it, just like iOS, Windows. Google makes more money if Android is easy on the developers, just like Apple.

Todd Fletcher (2012-10-29 10:10:03)

The internet runs in large part on Open Source. Just take Apache as one example. The fact is that Open Source software that gets a lot of use will be stable, but as you get down to much smaller projects they won't have gotten the attention and scrutiny to be as good. Similar to the way the accuracy of wiki articles increases with the number of contributors.

## **Quantified Self Utopia: What Would It Look Like? (2012-10-26 05:00)**

On the QS forums, [1]Christian Kleineidam asked:

While doing Quantified Self public relations I lately meet the challenge of explaining how our lives are going to change if everything in QS goes the way we want. A lot of what I do in quantified self is about boring details. . . . Let's imagine a day 20 years in the future and QS is successful. How will that day be different than [now]?

Self-measurement has helped me two ways. One is simple and clear. It has helped me be healthy. Via QS, I have found new ways to sleep better, lose weight, be in a better mood, have fewer colds (due to better immune function), reduce inflammation in my body, have better balance, have a better-functioning brain, have better blood sugar, and so on. I am not an expert in any of these areas – I am not a professional sleep researcher, for example. I believe that this will be a large part of the long-term importance of QS: it will help non-experts make useful discoveries about health and it will help spread those discoveries. Non-experts have important advantages over professional researchers. The non-experts (the personal scientists) are only concerned with helping themselves, not with pleasing their colleagues or winning grants, promotions, or prizes; they can take as long as necessary; and they can test "crazy" ideas. In a QS-successful world, many non-experts would make such discoveries and what they learned would reach a wide audience. Lots of people would know about them and take them seriously. As a result, people would be a lot healthier.

Self-measurement has also helped me in a more subtle way. It made me believe I have more power over my health than I thought. This change began when I studied my acne. I did not begin with any agenda, any point I wanted to make, I just wanted to practice experimentation. I counted my pimples (the QS part) and did little experiments. My results showed that one of the drugs my dermatologist had prescribed (tetracycline, an antibiotic) didn't work. My dermatologist hadn't said this was possible. Either he had done nothing to learn if worked or he had reached the wrong answer. What stunned me was how easy it had been to find out something important a well-trained experienced expert didn't know. My dermatologist was not an original thinker. He did what he was told to do by med school professors (antibiotics are a very common treatment for acne). It was the fact that I could improve on their advice that stunned me. I didn't have a lab. I didn't have a million-dollar grant. Yet I had learned something important about acne that dermatology professors with labs and grants had failed to learn (antibiotics may not work, be sure to check).

Skepticism about mainstream medicine is helpful, yes, but only a little bit. More useful is finding a better way. For example, it's useful to point out that antidepressants don't work well. It's more useful to find new ways to combat depression. Two years ago, the psychiatrist Daniel Carlat came out with [2] a book called *Unhinged* that criticized modern psychiatry: too much reliance on pills. No kidding. Carlat recommended more talk therapy, as if that worked so well. As far as I could tell, Carlat had no idea that you need better research to find better solutions and had no idea what better research might be. This is where QS comes in. By encouraging people to study themselves, it encourages study of a vast number of possible depression treatments that will never (or not any time soon) be studied by mainstream researchers. By providing a way to publicize what people learn by doing this, it helps spread encouraging results. In the case of depression, [3] I found that seeing faces in the morning produced an oscillation in my mood (high during the day, low at night). This has obvious consequences for treating depression. This sort of thing will not be studied by mainstream researchers any time soon but it can easily be studied by someone tracking their mood.

In a QS-successful world, many people would have grasped the power that they have to improve their own health. (You can't just measure yourself, you have to do experiments and choose your treatments wisely, but measuring yourself is a good start.) They would have also grasped the power they have to improve other people's health because (a) they can test "crazy" solutions mainstream researchers will never test, (b) they can run more realistic tests than mainstream researchers, (c) they can [4] run longer tests than mainstream researchers, and (d) no matter what the results, they can publicize them. In a QS-successful world, there will be a whole ecosystem that supports that sort of thing. Such an ecosystem is beginning to grow, no doubt about it.

Brian (2012-10-26 10:17:36)

QS offers many benefits, but one of the best benefits is avoiding mistreatment by medical professionals. Before QS, I was mostly a black box to myself and, consequently, medical and psychiatric professionals were often led to inappropriate treatments. If you track most things and can summarize it neatly, you'll no longer be subject to the inexplicable changes in sleep patterns, mood, energy, or weight that are the lynchpins of modern psychiatry. For example, this week the sun rises around 7:40 AM and the days are overcast. My mood and energy are noticeably lower. My sleep is disturbed because I started drinking coffee. Before QS, I was not sufficiently self-aware to reliably document these changes when talking to a doctor. So they're going to look for a medical explanation instead of a simple one.

### **Bacteria are Neither Good nor Bad (2012-10-27 05:00)**

Health experts call bacteria "good" and "bad". Bad bacteria make us sick. Good bacteria help us digest food, and a few other things. Let me propose another view. Any bacteria (i.e., bacterial species) will make us sick if it becomes too numerous – so all bacteria are "bad". All bacteria protect us against other bacteria – so all bacteria are "good". The terms "good" and "bad" are misleading. It is like saying a person is inherently rich or poor. Anyone, given a lot of money, becomes rich. Anyone whose money is taken away becomes poor. Low bacterial diversity or reduction of diversity makes it more likely that one bacterial species can overwhelm its competitors, producing sickness. When this happens, to say that the species (e.g., *H. pylori*) that became numerous "caused" the sickness (e.g., ulcers) is to seriously misunderstand what happened and how to prevent it from happening. We are taught that our immune system protects us from infection. We should be taught that bacterial diversity does the same thing.

The following story, from a reader of this blog, suggested these ideas:

My wife had a lot of problems, visceral fat that wouldn't go away being one of the most obvious symptoms. Every time I convinced her to try a ketogenic (= very low carb) diet, she would get sick. I went to NYC to see Paul Jaminet speak. He suggested that she likely had some type of gut infection or dysbiosis. Not a bad theory, as she'd undergone prophylactic antibiotic treatment to clear up an *H. pylori* infection. (Yes, I know, but at the time it seemed like the thing to do.)

She started putting on weight after that, which is typical.

Finally she gave VLC [very low carb] one last try. She wound up getting inflamed lymph nodes in her thighs. Our doctor was wondering if she might have bovine tuberculosis or the bubonic plague, either of which would explain her symptoms. (The nodes were inflamed, black-and-blue, and sensitive. This is a typical symptom of bovine tuberculosis, and the disease spreads from the gut to the body through the bowel. As we consume raw milk, this wasn't a crazy theory, but there have been no recorded outbreaks in Connecticut for years and years.) All the tests he did for an infection came back negative, but her symptoms clearly suggested she had one.

Finally she went to see a new OB-GYN. His nurse/dietician reaffirmed everything I'd been telling her, and she finally decided to go fully ketogenic. Once again, she got sick, but this time she decided to tough it out. Sure enough, after many weeks she started feeling better, and more importantly, the weight started coming off, and the visceral fat started reducing.

She did a stool test, and (I haven't seen the results yet) we were told that she had the obesigenic gut biota. So she started an intensive probiotic regimen. This helped her one negative from the ketogenic diet: constipation.

She's thrilled with the progress she's seeing, and her few lingering issues after going primal 2.5 years ago seem to be resolving. The constant yeast infections have abated, and she's planning a new wardrobe, heaven help me.

There are several interesting things here: 1. A very-low-carb diet made her sick. 2. This happened after antibiotic treatment. 3. Tests for infection were negative. 4. If she waited long enough, the low-carb-induced illness abated. 5. Probiotics helped. 6. Fermented foods didn't help. At the time of Paul Jaminet's diagnosis, says the reader, they were already eating plenty of fermented food: "Sauerkraut, yogurt, home-made kefir, the whole drill. No effect."

How can these observations be explained?

With some general ideas. Each bacterial species keeps similar species in check by competing for the same resources (food and location). No two species need exactly the same things but there is plenty of overlap. For example, Species 1 needs Resources A and B, Species 2 needs Resources A and C. They keep each other in check by reducing the supply of A. Suppose C = carbohydrate. By reducing C, a very-low-carb diet reduces the number of Species 2, making more A available. This allows Species 1 to greatly expand. Maybe this expansion kills off Species 2. Armed with vast amounts of A, Species 1 out-competes other competitors. Its numbers greatly increase, causing sickness.

The notion that some bacteria are good and others are bad is absurd because all are safe in small amounts and all will cause sickness in large amounts. If any one person was replicated in millions or billions of copies it would cause enormous damage, waste and disruption, no matter who it was. Suppose I was genetically replicated so that there were hundreds of millions of me. I only like a few singers, such as Michelle Shocked and Cat Power. There would be a huge undersupply of records by those singers and a huge oversupply of other music. The music industry would collapse. I am a certain size. There would be a huge shortage of clothes of my size and a huge oversupply of clothing of other sizes.

The bacterial ecosystem is not self-correcting. It is the opposite: disruptions tend to spread. Suppose you eat too little carbohydrate. This reduces Species 2 (which needs A and C = carbohydrate). This means there is more Resource A for Species 1 (which needs Resources A and B). Species 1 increases. By virtue of increased numbers, it pushes down its competitors for Resource B. These weakened competitors, which also need D, E, and F, begin to lose battles for those resources against other bacteria that need D, E, and F. They decline in number. No longer with substantial competition for what it needs (A and B), Species 1 multiplies unchecked and causes damage until A and B run out. (Which may be why the reader's wife, after a long illness, got better.) Fever fights infection because bacteria that grow best at one temperature (normal body temperature) do less well against competitors at a higher temperature.

The tests for infection failed to come up positive because they looked for too few bacteria. According to this view, there are thousands of bacteria inside us that can run out of control. You can test for only a tiny fraction of them. Fermented foods failed to help because they did not provide enough diversity.

We have a huge preference for diversity in what we eat. We much prefer a meal with three foods than one food, for example. The usual view is that this preference evolved because we need many nutrients (e.g., many vitamins)

to be healthy. Now I wonder. Maybe the protective effect of bacterial diversity was the main reason. If so, taking a multi-vitamin pill is not going to do much good, which is [1]what research suggests.

These ideas are obviously supported by evidence that fermented foods improve health and antibiotics harm health, which [2]I've covered many times. They are also supported by two recent studies with a different emphasis. One of them found that [3]teenagers who had more biodiversity near home had more bacterial diversity on their skin. (Maybe there are other important drivers of diversity besides fermented foods.) The other found that [4]people with sinusitis had less bacterial diversity in their nose than people without sinusitis and that increasing diversity tended to prevent sinusitis. Someday the 2005 Nobel Prize for "showing" that ulcers are "caused" by *H. pylori* will seem as medieval as the 1949 Nobel Prize for prefrontal lobotomies.

The practical consequences of this view include: 1. Antibiotics should be a very last resort. When given, they should be followed by treatments that restore bacterial diversity. The reader's story suggests restoration of diversity may not be easy. Plainly diversity should be tracked after antibiotics. 2. Epidemiological studies should not just ask how did the germs spread? They should also ask why were they allowed to do harm? Why didn't natural defenses – the immune system and other bacteria – suppress them to harmless levels? To the epidemiological neglect of immune function we can add neglect of this line of defense. 3. There should be convenient ways to measure one's bacterial diversity so each of us can learn where we are and what makes it go up and down. 4. Researchers should study what makes bacterial diversity go up and down. Here is [5]a recent study about this: old people living in an old-age home, who ate a restricted diet, had less bacterial diversity than people the same age who lived independently and ate more varied foods.. 5. Researchers should learn the correlates of high and low diversity. Take a group of people, measure their bacterial diversity, track their health for six months.

---

Tom Passin (2012-10-27 05:42:07)

Here are some articles and publications that support your arguments, including the newly published work from PLOS Pathogens that found a mix of six specific bacteria was effective in suppressing *C. difficile* infection in mice. Pax on both houses (summarizes the PLOS publication below) <http://paxonbothhouses.blogspot.com/2012/10/fecal-transplant-to-treat-clostridium.html> Bacteriotherapy Resolves Relapsing *Clostridium difficile* Disease in Mice <http://www.plospathogens.org/article/info%3Adoi%2F10.1371%2Fjournal.ppat.1002995> Tending the Body's Microbial Garden <http://www.nytimes.com/2012/06/19/science/studies-of-human-microbiome-yield-new-insights.html?pagewanted=all> How Microbes Defend and Define Us [http://www.nytimes.com/2010/07/13/science/13micro.html?pagewanted=all&\\_r=0](http://www.nytimes.com/2010/07/13/science/13micro.html?pagewanted=all&_r=0) I'm especially interested in this since I'm about to have major knee surgery and the docs will insist on hitting me with big jolts of antibiotics. Seth: Thanks for the links. I didn't know knee surgery led to antibiotics. Can you refuse the antibiotics?

Chuck (2012-10-27 07:07:38)

Can't remember now where I read an article/paper written by a leading gut flora doctor/researcher, but his recommendation was to eat a boring diet - the same few plants & animals on a regular basis. His theory is that a very diverse diet breeds too many "jack of all trades" bacteria - none of which are really good at their job. Where a simple/boring diet, breeds experts that are really good at their job. Of course a diet of junk/processed food will most likely breed a population of junk food junkie flora who are very good at their job - maybe, too good. Cheers

threepipeproblem (2012-10-27 07:08:26)

This is the best post on gut health / germ theory ever. Thanks!

Jim Purdy (2012-10-27 08:41:31)

As we learn more, we find that things are much more complicated than we thought, and much too complicated for the simplistic drug-everybody approach of doctors and their BigPharma friends. These things we do know, at least based on recent research: 1. Fiber is good food for gut bacteria, so eat lots of fiber from things like beans, which also have lots of protein. 2. Antibiotics disrupt the gut bacteria, so try to avoid antibiotics. 3. Antacids and proton pump inhibitors disrupt the gut bacteria, so try to avoid antacids. And here's the most important lesson: Doctors love antibiotics and antacids, so try to avoid doctors. Seth: Yeah. Antibiotics are said to be the most important medical advance of the last 100 years. Yet it is plausible they do more harm than good. What does that say about all the other "advances"?

Paul N (2012-10-27 09:14:11)

@ Jim, I wouldn't be so fast to recommend beans, many types (especially soy, kidney and fava) have various components that are irritable/detrimental to many people. We should also draw a distinction between soluble and insoluble fibre. It is the soluble fibre we really want - which gut bacteria ferment into short chain fatty acids, among other things- and this can come from many sources other than beans. The focus on "healthy whole grains" has led to many people getting too much insoluble fibre, which causes problems of its own, in addition to gluten and other grain proteins. But your general point of more (soluble) fibre is in the mark, as are your points 2 & 3 (4). It is amazing how much we are prescribed things that do not cure our ills, but prolong them.

Morris (2012-10-27 09:15:16)

There may be more to this story as my experience suggests. All bacteria are consumers of nutrients ie compete with human cells. Our bodies (the inside) are not perfectly sterile and so bacteria mass accumulates with age as the immune system has a capacity limit. Our cells receive incrementally ever smaller amounts of energy (nutrients) as they age ie become smaller with succeeding replications. I have been able to significantly reverse periodontal disease via measures to limit gut bacteria after decades of gradual decay.

Reanna (2012-10-27 09:22:08)

Very interesting! Do you have a citation for the fever theory? I've never heard that before.

Tom Passin (2012-10-27 09:31:16)

Seth: Thanks for the links. I didn't know knee surgery led to antibiotics. Can you refuse the antibiotics? Probably not, and they are probably a good idea even though they will do a number on my internal flora. The concern with joint replacements is deep infections under or around the implants that can't be effectively treated because of poor blood supply deep in the joint. So the docs want to avoid them at all costs. What's more annoying is that after you have a joint replacement, you have to take antibiotics before dental work - for life, apparently. Supposedly nasty bacteria from your mouth can get into the bloodstream during the dental activities. They can supposedly get deposited around the implant and cause one of those hard-to-treat deep infections. I've had a hip replacement for 20 years. Four years ago when I moved, I didn't find a new dentist and didn't have my teeth cleaned or examined for all that time. I had fixed my acid reflux by adopting a low carb diet, and I didn't want to undo that work by use of antibiotics. Finally I had to go to the dentist because I am required to get a dental clearance for the knee surgery. I had an exam and cleaning. Even though I have a lot of gum and bone recession extending back over more than 30

years, after those four years my teeth were fine and my gums were in better shape than four years earlier. What had changed? 1- low-carb diet. 2- stopped using toothpaste having a lot of glycerin (most of them ... for a while I brushed my teeth with Ivory soap). 3- I stopped flossing and started to clean between my teeth with a little "proxy" brush instead - I had found that flossing would start infections in my gums, and that doesn't happen when I use the proxy brush instead. So - no dentist, no flossing, no standard toothpaste but plenty of attention to cleaning my teeth safely, reduce carbs which cause lots of crud to build up on the teeth. Better results. Hurray!

MikeW (2012-10-27 09:49:52)

Well I can think of a few bacteria that are unequivocally "bad". Bubonic plague. Typhus. I wouldn't blame the Black Death depopulation of Europe on faulty immune systems. Or maybe you were only referring to gut bacteria, not to nasties directly injected into the bloodstream by insects or contaminated medical equipment. Seth: You mean "on faulty immune systems and too little microbial diversity"? Dosage also matters: Exposure to a large amount of Bacteria X may cause illness, exposure to a tiny amount may be safe. I am less convinced than you that exposure to tiny amounts of the bubonic plague bacteria would be dangerous if one had a well-working immune system and plenty of internal microbial diversity. At the time of the Black Death, people may have eaten narrow diets, low in some vital nutrients. Living conditions may have also caused first exposures to the bubonic plague bacteria to be large (dangerous) rather than small (safe). On the other hand, I think you're right. We can be exposed to a large amounts of certain bacteria without harm (e.g., the bacteria in yogurt) yet exposure to a large amount of certain other bacteria is dangerous. In that sense some bacteria are more dangerous than other bacteria.

Paul Jaminet (2012-10-27 11:56:15)

Hi Seth, Great anecdote and very plausible theory. But I'm not sure the anecdote fits the theory, since the ketogenic diet on which she recovered is presumably more restrictive (less varied, even lower in carbs) than the diet on which she got sick. To me that suggests that what we need is a story of diet-microbe equilibria, in which there are multiple microbiomes that can be in equilibrium with any diet, and you can get stuck in a bad equilibrium. Dietary changes can depopulate an overgrown species, leading to a new equilibrium which may be more healthful. Then probiotics/fermented foods may enable a shift back to the original diet but with a different microbial equilibrium. So this view is not "good bacteria / bad bacteria" but "good microbiome / bad microbiome" as in your theory; but it is not a story simply of "diversity good / nondiversity bad" even though it is a story of overgrowth of a nondiverse flora causing problems. The ketogenic diet may have created a nondiverse flora that is not abundant, so the symptoms disappeared. Best, Paul

Paul Jaminet (2012-10-27 11:59:29)

PS - It's also a good example of why chronic infections are often very difficult to heal. Often steps toward healing lead to an initial aggravation of symptoms (usually ascribed to "die-off" releasing toxic cell wall components), causing people to reverse course, as she backed away from VLC/ketogenic diets several times. Seth: The die-off explanation is certainly different than what I am suggesting here (that a change in diet that eliminates a vital nutrient - vital to one or more bacteria - may thereby "unleash" other bacteria). I have never seen any evidence that the die-off explanation is correct but I will look around for such evidence.

peter (2012-10-27 12:52:52)

there was a recent article in the new yorker about bacteria and, as i recall, how H. pylori is good in childhood (and how the absence of it in childhood may account for increase in ?asthma?. as i recall it was one or two issues back. Seth: Thanks. Yeah, I saw it. After I read it again I may post about it.

Yonat (2012-10-27 13:20:02)

You may be interested to read René Dubos (one of the discoverers of antibiotics) , who wrote similar things in the 1950's. From the May 1955 issue of Scientific American: "A new look at the biological formulation of the germ theory seems warranted. We need to account for the peculiar fact that pathogenic agents sometimes can persist in the tissues without causing disease and at other times can cause disease even in the presence of specific antibodies. During the first phase of the germ theory the property of virulence was regarded as lying solely within the microbes themselves. Now virulence is coming to be thought of

as ecological. Whether man lives in equilibrium with microbes or becomes their victim depends upon the circumstances under which he encounters them. This ecological concept is not merely an intellectual game; it is essential to a proper formulation of the problem of microbial diseases and even to their control."

Jim Purdy (2012-10-27 15:10:01)

Here's a fascinating article about a microorganism that can rapidly move in when its competitors die off: "Genetic Switch Underlies *C. albicans* Quick Change Act" <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3139635/> "In most people, *C. albicans* is just another member of the body's flora, harmlessly coexisting with other microorganisms in their host. Bacteria in particular are important competitors that keep its spread in check. However, if the environment suddenly changes, causing bacteria to die off, *C. albicans* quickly adapts and takes over. Usually the effects are minor. Elderly people who use dentures may experience a dry or burning mouth condition known as "thrush." Women who suffer from irritating yeast infections and most babies fussing over diaper rash are the victims of an overaggressive population of *C. albicans*. However, if the patient's white blood cells have been compromised, say because of chemotherapy or an aggressive steroid treatment, the effects can be devastating. Serious complications arise if the fungus enters the bloodstream, perhaps through a catheter, which *C. albicans* can only do while in the more benign yeast form. However, once in the bloodstream, the fungus can deposit throughout the body as invasive hyphae. At that point it becomes known as "hematogenously disseminated candidiasis," which proves fatal in 40 % of cases, even with the best modern treatments."

Roger Sweeny (2012-10-31 20:02:56)

This has nothing to do with human health but I thought it was cool. And it goes with the headline, "Bacteria are Neither Good nor bad." self-healing concrete with limestone producing bacteria [1]<http://www.bbc.co.uk/news/science-environment-20121303>

1. <http://www.bbc.co.uk/news/science-environment-20121303>

Roger Sweeny (2012-10-28 08:15:40)

The Lynn Margulis piece is great. But people should realize that it is almost 20 years old. (And, as far as I'm concerned, the Lee Smolin comment is the best.) Seth: Huh. I didn't know that. Thanks for pointing it out.

lef (2012-10-28 10:45:04)

I also find Lynn Margulis piece great. Also I find it strange that you don't see her mentioned (at least I haven't) in blogs related to "paleo diets or lifestyle". You see other people mentioned like Richard Dawkins. I find it strange because in the paleo diet community (choose whatever meaning you want) 1) we think we are heretics, 2) we think a lot about evolution, 3) we don't have heretical opinions about evolution. Heretical opinions in evolution doesn't have to mean young earth creationist. Lynn Margulis is an example of what else it can mean. I suppose is no accident I see her mentioned here 1) Seth is an original heretic 2) Seth pays attention to bacteria

dearieme (2012-10-28 13:40:07)

From Peter Hitchens in the Mail on Sunday. "When I read in August that the talented Hollywood film director Tony Scott had killed himself without any apparent good reason, I was fairly sure that pretty soon we would find that the poor man had been taking 'antidepressants'. Well, a preliminary autopsy has found 'therapeutic' levels of an 'antidepressant' in his system. I take no pleasure in being right, but as the scale of this scandal has become clear to me, I have learned to look out for the words 'antidepressant' or 'being treated for depression' in almost any case of suicide and violent, bizarre behaviour. And I generally find it." Seth: very interesting. Hitchens might be the best-known person to make this point.

Roger Sweeny (2012-10-29 12:29:49)

I found out this morning that Lynn Margulis died, on November 22, 2011, following a stroke, at age 73. She is the "hook" in a very good Charles Mann article about the history of homo sapiens. "Until Margulis's death last year, she lived in my town, and I would bump into her on the street from time to time." <http://www.orionmagazine.org/index.php/articles/article/7146>

### **"The Scale of the Scandal": Tony Scott's Suicide Quite Possibly Due to Antidepressant (2012-10-29 05:00)**

As [1] pointed out by dearime, the columnist Peter Hitchens recently made [2] the following comment in The Mail on Sunday:

When I read in August that the talented Hollywood film director Tony Scott had killed himself without any apparent good reason, I was fairly sure that pretty soon we would find that the poor man had been taking 'antidepressants'. Well, a preliminary autopsy has found 'therapeutic' levels of an 'antidepressant' in his system. I take no pleasure in being right, but as the scale of this scandal has become clear to me, I have learned to look out for the words 'antidepressant' or 'being treated for depression' in almost any case of suicide and violent, bizarre behavior. And I generally find it. The science behind these pills is extremely dubious. Their risks are only just beginning to emerge. It is time for an inquiry.

"[3] Tony Scott Suicide Remains a Mystery After Autopsy," wrote a Vanity Fair editor. The autopsy found that he had been taking the antidepressant Remeron, whose known side effects include suicide. SSRI's, of which Remeron is an example, cause suicidal thinking in people who are not depressed.

The psychiatrist David Healy was the first to emphasize this point. In 2000, after he began this research, he was offered a job at the University of Toronto. In a very unusual move, [4] the job offer was rescinded. Apparently psychiatry professors at the University of Toronto realized that Healy's research made the psychiatric drug industry look bad.

I don't think it's wrong to sell drugs that improve this or that condition (e.g., depression), even if the improvement

is slight. I do think it's wrong to make false claims to induce people to buy the drugs. In the case of depression, the false claim is that depression is due to a "chemical imbalance." No chemical difference has ever been shown between people who later become depressed and people who don't later become depressed. This claim, repeated endlessly, makes it harder to do research into what causes depression. If you figured out what caused depression, you could treat it and prevent it much better. This false claim does enormous damage. It delays by many years discovery of effective treatment and prevention of depression, a disease from which hundreds of millions of people now suffer.

This happens in dozens of areas of medicine. Dermatologists say "[5]acne is caused by bacteria". Most doctors appear to believe "ulcers are caused by bacteria". [6]Ear nose and throat surgeons claim that part of the immune system (the tonsils) causes illness. The "scale of the scandal" – medical school professors either (a) don't understand causality or (b) deceive the rest of us – is great.

Jim Purdy (2012-10-29 10:05:13)

Unfortunately, many – if not most – medical doctors have become nothing much except a massive sales force for drug companies. Because I refuse to take any drugs, I have had many unpleasant conversations with doctors, and I change doctors frequently. One time, on a first visit with a new doctor, I began by telling her that I refuse to take drugs. She looked genuinely puzzled, and more than a little angry, as she demanded to know, "Then why are you here?" Good question. Why do I go to doctors, anyway? Mostly, because they are the gatekeepers who can order lab tests for blood work and urinalysis, but all I want is the lab results, so I can do my own research. I don't want their opinions about the lab results, and I sure don't want any of their drugs.

JPB (2012-10-29 10:05:24)

Indeed, the scandal is great! In the meantime, one must question all medical advice and only do what seems to be in your best interests!!

WB (2012-10-29 10:57:31)

@ Jim who said: "Why do I go to doctors, anyway? Mostly, because they are the gatekeepers who can order lab tests for blood work and urinalysis, but all I want is the lab results, so I can do my own research." Jim, you don't have to go to a physician any more to get tests from the very same labs that you would use when you have your own doctor's Rx. See for example: <http://www.directlabs.com/Home/tabid/36/language/en-US/Default.aspx> The following from their website describes succinctly how it works: "DirectLabs is the leader in direct access laboratory testing. We offer a wide variety of important health and wellness blood chemistry tests directly to you online at extremely discounted prices. Confidential results are available online in as little as 24 hours for most tests. DirectLabs offers our customers private and secure online accounts called "MyDLS" where you will access your orders, print your lab requisition, and retrieve your results." I don't necessarily recommend this or any other source – there are any number of them that you could find and use after a simple Google search.

WB

WB (2012-10-29 11:12:58)

Seth, this critique is absolutely dead on. I'm sure the modus operandi of so many medical practitioners today is the reason why they are losing credibility among a growing number of intelligent individuals who have been able to inform themselves using excellent sites like yours, and others that are readily available on the Internet. (Of course some due diligence is always required and it's necessary for one to have his/her "bullshit meter" turned on much of the time as well. Also while in the doctor's office, I might add) :-). Eventually, this will bring about dramatic, positive change in the medical system. Unfortunately, it's not happening as fast as it needs to. WB

dearieme (2012-10-30 01:47:40)

<http://www.dailymail.co.uk/health/article-2224826/Why-drugs-dont-work-Scientists-discover-statins-arent-effective-40-patients.html> Are the 40 % (allegedly) for whom statins don't lower cholesterol particularly prone to side effects, or immune to side effects, I wonder?

Sara (2012-10-31 03:51:17)

I wanted to do a research project on a possible link between SSRI use and a certain type of crime - the kind where an apparently normal person with no criminal history flips out without warning and kills or maims someone. I had noticed in the news, and by following trials, that often they would report that the accused had been taking anti-depressants and, more often than not, that they had been self-adjusting the dose (usually taking more than usual because they weren't feeling right). I found these cases so interesting because they did not fit the usual criteria of murderous behaviour (poverty, violent background, bad family life, criminal connections) - they were usually educated, normal people that just one day lost it in the most dramatic manner. I was basically told that the university would definitely not support such a project, the reasoning being that there was no previous research suggesting such a link. Secretly I think they were envisaging being sued for 10 million dollars by an enormous pharmaceutical company. Seth: What a strange reason for turning down a research project: Because it's original. A horrifying story.

Joel Derfner (2012-10-31 08:20:48)

I think the phrase "chemical imbalance" is used more to explain to laypeople what's going on than as an actual scientific analysis. I'm not going to say that there isn't much more to be learned about SSRIs, but in my case at least they've helped me a great deal.

WB (2012-10-31 09:57:19)

@Sara You may very well be on to something important. Maybe you're already aware of some of the writing about this issue, but thought I would link to the following which might be of interest: [http://www.prleap.com/pr/192130/Acts of Senseless Violence: Police data may I.D. psychiatric drug use in violent crimes The mental health watchdog Citizens Commission on Human Rights announces the latest article by journalist Kelly Patricia O'Meara, who uncovers how police may already be obtaining information on psychiatric drug use by those committing violent crimes, yet be unaware of the vital relevance of this information. \[there is more info accessible at the link.\]](http://www.prleap.com/pr/192130/Acts-of-Senseless-Violence-Police-data-may-I.D.-psychiatric-drug-use-in-violent-crimes-The-mental-health-watchdog-Citizens-Commission-on-Human-Rights-announces-the-latest-article-by-journalist-Kelly-Patricia-O'Meara-who-uncovers-how-police-may-already-be-obtaining-information-on-psychiatric-drug-use-by-those-committing-violent-crimes-yet-be-unaware-of-the-vital-relevance-of-this-information.-[there-is-more-info-accessible-at-the-link.]) \*\*\*\* There seems to be a fair amount of material available on the topic that some others have been thinking and writing about. The apparently timorous response you got from the "university" points out that in certain situations it's probably only through government auspices (or maybe some independent private foundations) that potentially controversial research like this can be pursued without threat or corrupting influences. I hope you can find another way to pursue your research. WB

Jenny (2012-10-31 15:45:47)

I was taught over 40 years ago, that anyone taking an anti-depressant was at risk of suicide as they improved. The logic was that the physical apathy of depression improved ahead of the mental aspects - particularly the belief that you would never get better. This resulted in people who now had the energy to commit suicide (which they had not had before) but still had the unhappiness. To attempt suicide was logical. If true, this means that any antidepressant is problematic. Seth: I think there is a lot of truth to this. But I wonder if it is the whole problem with SSRIs. David Healy found that an SSRI, when given to non-depressed persons, caused "dark thoughts" - thoughts of suicide and violence.

Sara Lake (2012-11-06 18:06:57)

@Wb thanks for that. I certainly haven't given up on the idea. I think once I get past Masters level, I might have more luck. For a thesis, they generally like a bit of background research so that there is a good chance of getting a significant finding. Also the funding tends to revolve around certain areas that the professors are already researching and murderous SSRI users is not one of those. As well, I could already see problems with ethics: getting accurate info from psychs on what these people were taking (privacy act!) and, well, there just aren't that many people that go crazy in this way. Even if every single one of them was taking SSRI's, it would only be a drop in the bucket of total people taking them and therefore, not really indicative of anything.

## **Acne Caused By Pasteurized Dairy: How One Person Figured It Out (2012-10-30 05:00)**

A reader of this blog named Tony Mach [1] explains how he figured out that his acne was caused by pasteurized dairy products:

In summer 2010 my health problems got noticeably worse (unrefreshing sleep, strange pains, strange sensations in the skin and other stuff I don't want to share here 🤔), and I had to do something. Furthermore I was gaining weight, so I was suspecting something along the lines of diabetes or other metabolic problem.

As I was looking into dietary changes, I stumbled over Wolfgang Lutz's and Robert Atkins' work. Being an engineer by training, I figured that if blood sugar might be the problem (which, as it turned out, wasn't the case for me), then reducing carbs might be a solution (stop fueling the problematic sub-system) – so both Lutz and Atkins appealed to me. I thought let's give it a try. I was a bit frightened about such an radical change of diet – you read all kind of BS – but hey, I felt like I was going to die anyway.

Before the change, I ate a lots of white bread, some milk chocolate and drank lots of milk. First I reduced carbs – like Lutz suggested, I tried to aim for 6 bread units – but within days I noticed that some problems (like the strange pain and skin sensations) diminished right away. The acne cleared up noticeably. So I thought why bother with low-carb, let's go full no-carb (like Atkins suggests for some month).

And voila, with no-carb everything got better. I started to feel healthy for the first time in my life. I lost over 30 pounds, all health problems either went away or were almost gone, and life started to become enjoyable. This was a period of about two months over with most problems went away, some fast, some slower.

So for over half a year I was focused on the carbs=evil scheme, started eating cheese again (hey, no carbs!), when slowly some of the health problems returned and my weight started to rise again.

At that point I panicked a bit and made a huge mistake: I thought I can figure this one out too, I have to do something right away. So I trusted what some doctors had written about a pathogen (which I tested for with borderline results), how to cure it (with over the counter medications like Vitamin D and NAC and other stuff) and I thought let's try this too! The things I took made me worse, but as it was supposed to be a "die off"/"herx" reaction, I wasn't too alarmed. Turned out that experiment cost me almost an year until I got better again. So for about a year I was not in the mood for big experiments and personal stuff like moving to another city kept me busy.

But slowly I introduced "safe starches" into my diet (like plantains), because I kept reading one should not go too much low-carb. I tried out self-made sourdough rye bread (makes me enormously hungry, so I stopped again) and at one point I thought: What the heck, I'm going to eat ice cream today. Three hours later I got slightly noticeable pimples and local inflammation (I think they are called nodules) and after another roughly 3 hours the acne was prominent.

After that, my suspicion was that milk might be bad for me, but maybe some properly “ripe” cheese like hard cheese (properly digested by bacteria) might be OK. So I waited for the acne inflammation to go away and tried again with a Parmesan cheese. Bingo, acne again, and again in the 3 to 6 hour time frame.

So I didn’t touch milk or dairy again, but now I looked for raw milk cheese, as I read something about it being possibly better. After a while I found raw-milk-cheese, tried it – and got no acne. Tried again, after some time, with another brand – again no acne. Tried cheese from pasteurized milk – acne.

As I still have health problems, I am still in the process of figuring out things. Next up for me is trying to get rid of beef for a week or two, to see if that might be a problem for me.

In summary:

- I was not very systematic in my experiments, and had some lucky moments.
- All the macro-nutrient ratio paradigms are IMHO BS and not applicable for the majority (might make sense if someone has real/major metabolic problems like T1DM, etc.)
- Having said that, in my view some carb foods come with baggage: e.g. cereal grains and (pasteurized) milk
- A quickly reacting, non-dangerous, clearly visible (objective) surrogate health marker (in my case acne) is worth its weight in gold [I agree, canary in coal mine. In this case it isn’t clear what else besides no acne was gained by avoiding pasteurized dairy. – Seth]
- With such a marker, one should completely eliminate suspicious foods (in my case \*ALL\* dairy) and then introduce it again (two or three challenges)
- For me, pasteurized dairy = acne, raw dairy = no acne
- Milk chocolate is dairy [A friend’s mother said, “If I’m ever in jail, bring me some chocolate.” She’ll break out. – Seth]
- Some surrogate health markers (e.g. weight) reacted “funky” for me: I changed my diet to no-carb, my weight went down, and without any big changes [in diet or exercise] my weight started to climb again. [Same thing happened to [2]Alex Chernavsky. – Seth]
- For most of the health problems that went away, I don’t know exactly what food (Cereal grains? Dairy? Vegetable oils? etc.) caused what problem
- As I felt like I was going to die on my old diet, I am not particular keen on going back full scale to my old diet to see if after one or two month all my old symptoms return, to determine which food caused which symptom... [Better to test the old foods one at a time. – Seth]
- Medical science and several MDs helped me diddly squat
- Paleo blogs were much more helpful than the medical community

I can only guess why raw milk and cheese are less harmful than pasteurized milk and cheese. Maybe milk and cheese contain acne-causing chemicals that leak into the blood. Maybe raw milk, which contains bigger entities than pasteurized milk, does a better job of plugging the holes from digestive system to blood.

Mehmet Koseoglu (2012-10-30 05:27:18)

Maybe you are already aware but there are some studies linking milk consumption to acne: <http://nutritionfacts.org/video/skim-milk-and-acne/> You may also be interested in the nutritionfacts.org website which provides nice short videos regarding the latest research on nutrition. Although (I believe) it cherry picks studies to promote veganism, it is very informative. For example, I am sure you will be interested in how the bacteria in the mouth affects athletic performance: <http://nutritionfacts.org/video/dont->

use-antiseptic-mouthwash/

August (2012-10-30 06:37:26)

I'll get a pimple if I eat anything with casein, soy, or wheat in it. I have heard that there is a cross-reactivity with milk and wheat, but I don't know if a similar protein is in soy or not. I won't even eat stuff with soy lecithin, but what's really annoying is when I try some supplement only to find it is made with soy. In some cases, I think the supplement making process may purify whatever they are taking out of the soy to the point where it isn't a problem any more, but it is still a bit of a gamble.

Thomas W (2012-10-30 09:00:50)

Real Parmesan IS raw milk cheese.

David Johnston (2012-10-30 09:25:33)

Not all Parmesan is created equal. <http://www.italianfoodnet.com/eng/food-and-wine-news/item/fake-parmesan-wins-the-us-best-cheese-award>

Kent Akselsen (2012-10-30 10:05:57)

When you have multiple allergies, it is very difficult to figure out which foods are the culprits. I had terrific results identifying my food allergies with the Meridian Valley E95 Basic and A95 Food Panels. I had severe Rheumatoid Arthritis that did not respond to any of the dozens of treatments that my board certified rheumatologist tried over a period of several years. A holistic doctor suggested we try the Meridian Valley Food Panels, so we drew blood and sent it off. The results were very accurate when I checked them through elimination diet, and most of my symptoms went away when I eliminated dairy, eggs, wheat, and beef from my diet. Unless you can find a doctor already using the Meridian Valley tests, you will have to order a test kit and prepay for the test. And of course you must have a doctor willing to draw the blood and ship it. Meridian Valley is in Renton, WA. Their phone number is 425-271-8689. Seth: very interesting, thanks.

Paul N (2012-10-30 12:25:24)

Many people do better on raw than pasteurised milk. For a whole bunch of information about raw milk, you can check out; <http://www.realmilk.com/> It is known that some of the milk proteins are denatured by pasteurization. For some people, their digestive system reacts to these and their body mounts an immune response to it. Acne is often the result of gut irritation and/or mild autoimmune conditions. Powdered milk is even worse, and any product that has "modified milk ingredients" has powdered milk, or worse. Skim milk is one example - it is "fortified" with powdered milk to make it taste less watery. For many people, they have trouble with skim milk and non fat yogurt - which we are all told to eat - but do fine with full fat milk and yogurt - the fats are somehow protective. Clearly, Tony is more sensitive to this, and acne was the way it was manifested. There are many raw aged cheeses available - under USDA rules, a cheese can be made from raw milk if it is aged for more than 60 days. Not all aged cheeses are raw, so check the labels. A final thought, most cows in the US are Holstein-Friesian, which produce milk with type A1 casein protein. Other cows, like Jersey, Guernsey, Dexter, all Indian breeds, buffalo, sheep, goats, horses and humans produce milk with type A2 casein. Many people are sensitive to A1 casein but not A2 - the people who can only drink goats milk. This is often mistaken for "lactose intolerance". You can read more about A2 milk here; <http://www.westonaprice.org/thumbs-up-reviews/devil-in-the-milk>

Koanic (2012-10-30 19:08:42)

I could be mixing stuff up here, but I thought I heard that the fat droplets in pasteurized milk became too small and pass through cell walls, whereas unpasteurized doesn't have that problem. Maybe Dave Asprey said this?

dearieme (2012-10-31 04:05:03)

I see from the Telegraph that there's a Canadian Cardiovascular Congress going on. I suspect that this might provide you with a target-rich environment, Seth.

wikiderm (2012-10-31 05:36:13)

My research for years has focussed on the dairy hormonal impact on acne. These stories make me more and more interested in learning about the possibility of an antigenic cross-reactivity between the proteins in milk (from mammary glands) and the proteins in sebaceous glands. Could an allergy to one cross-react with the other? There is NO science on this to date. BOTH glands are epidermal appendages and so should share antigens.

### **"Must Prescribe Antibiotic, Must Prescribe Antibiotic ... " (2012-10-31 05:00)**

Jim Purdy, who often comments here, told me the following story:

Recently, a health professional ordered two tests for infectious bacteria in a small foot wound (I think the tests were for gram negative or gram positive bacteria, or maybe aerobic and anaerobic). Even before the bacterial tests came back, she wanted me to start on antibiotics. Instead I waited. The first results showed a very low level of a harmless bacteria, so I was glad I hadn't started antibiotics.

When I saw her again, a few weeks later, I asked about the second set of bacterial tests. She claimed that there had only been one test, but I insisted she check again. She left, and came back a few minutes later and said that she had found the second results, and there had been no bacteria.

Surely the health professional knew that antibiotics are overprescribed, that antibiotic resistant bacteria have become a serious problem, that antibiotics are dangerous, and yet she not only failed give the wound a chance to heal on its own, she failed to allow test results to guide what she did. No wonder she forgot about the second test.

---

charlie (2012-10-31 05:43:29)

I think the real mystery is why you are seeing a "health professional" for a small foot wound. Again, sub-clinical. I wish you would focus on system that really have destructive antibacterial systems, such as India or Russia. That is the real danger, not this sub-clinical stuff.

Jim Purdy (2012-10-31 08:12:30)

Charlie, I have type 2 diabetes, so any "sub-clinical" open foot wound can quickly become a serious problem for me. I check my feet daily, but I don't see the point of taking unnecessary antibiotics. For that matter, I don't like to take any medications. I prefer to let my body try to heal itself, without a lot of BigPharma chemicals.

Drewfus (2012-10-31 18:31:24)

Unnecessary prescription of antibiotics would likely result in the atrophying of the immune system. This would result in an increased susceptibility to disease, and this in turn would likely result in more trips to the doctor. The business model of the medical establishment is anti-social.

dearieme (2012-11-01 03:02:38)

Hello, hello: every retreat must start with a first pace. <http://www.telegraph.co.uk/health/healthnews/9645346/Statins-side-effects-war-ning-when-combined-with-other-drugs-regulator.html>

charlie (2012-11-01 07:45:52)

@JimPurdy; good luck with that. As I've said before, self-experimentation is brilliant at sub-clinical issues. However, once you've got a major problem, trying to be smarter than your doctor has moved you into Jenny McCarthy territory. Seth: Jim Purdy was told by a team of doctors that if he didn't have his leg amputated he would unquestionably die. That's a major problem. Thinking life without a leg wouldn't be worth living, he refused the amputation. He recovered. Jenny McCarthy has not had similar experiences, as far as I know.

Adam (2012-11-02 07:16:14)

One of the Chinese pharmacists I work with noticed a doctor prescribing antibiotics for a patient with diarrhea. She then asked me why doctors prescribe antibiotics for diarrhea when antibiotics are well-known to \*cause\* diarrhea. At least she's thinking about it!

Robin (2012-11-02 09:15:26)

I went to my GP once because of a sore throat. He immediately prescribed antibiotics and a ton of other stuff. So I asked - Isn't my problem a virus? Sore throats usually are. He was taken aback and simply said... "yes it is but you know these sore throats often develop into bacterial infections so you should take antibiotics just in case." I live in Singapore where you get the drugs directly from the doctor. This place seems to have an extremely high rate of antibiotic use and very low levels of understanding about how to use them. I've met several people who said they "stopped taking them halfway through the course" because they felt better and saved the rest for the next time they got ill. They save the leftovers then pop them like they are echinacea to ward off a cold.

## 7.11 November

### Vitamin D3 in Morning Improves Sleep After All (Story 26) (2012-11-01 05:00)

Adam Clemans (28 years old, about 80 kg, pharmacist, lives in Shanghai) [1]commented on a recent post that Vitamin D3 didn't seem to improve his sleep ("I can't say I noticed any improvement in my sleep from Vitamin D"). He took 4000 IU in drop form right after he woke up.

I wrote him for details. I said that since 4000 IU was the lowest dose I found effective, he might want to try a higher dose. Adam answered my questions and said he would try a higher dose. Two weeks later he wrote again:

I started taking 4 drops (8000 IU) of Vitamin D3 1st thing in the morning (up from 2 drops or 4000 IU); my sleep seemed to improve immediately and quite dramatically. I had been struggling with middle-of-the-night awakening for a week or so, but after the change I slept like a brick or a baby (pick your metaphor). I would like to experiment with this more before I say I am sold on it, but for now it seems to be working well.

He'd been doing the higher dose for two weeks. Hard to explain as a placebo effect.

1. <http://blog.sethroberts.net/2012/10/10/two-more-vitamin-d-stories-it-eliminates-colds-and-improves-sleep-when-taken-in-the-morning/#comment-1034197>

libfree (2012-11-01 06:07:04)

Any thoughts on the form of Vitamin D3 you take? I notice he is taking it in drop form.

gwern (2012-11-01 08:40:13)

> He'd been doing the higher dose for two weeks. Hard to explain as a placebo effect. No, I mean it's not like a high-status elite person or thought-leader might have told him to do something different and eager to please, he responded. There's not the slightest chance of that, it's beyond hard to explain.

charlie (2012-11-01 09:13:02)

@gwern; exactly. However, at least there is a theory linking early morning Vitamin D to sleep patterns. I'm going to try 4000 IU for a month.

Antonio (2012-11-01 09:33:40)

I wonder what would be the consequences of the higher intake on D3 for long time periods ....

Jonathan Shewchuk (2012-11-01 14:24:33)

libfree: Dr. William Davis, cardiologist, has mentioned repeatedly on his blog that when his patients have taken D3 in tablet form, often their blood levels have not risen as much as anticipated, and sometimes not at all. Based on his experience, he insists on D3 dissolved in oil, usually in the form of gels. I think the drops work too, though probably better if they're taken with some fat, as D is fat-soluble. Davis has hundreds of patients whose serum D levels he monitors, so he speaks from great direct experience of which pills do and don't raise those levels. (He also notes that D2 pills are useless.)

David Johnston (2012-11-01 15:40:22)

Antonio, check out Chris Masterjohn's writings on the how A, D and K2 each work in combination to cover for the toxicity of the others. So it's wise to not just take large doses of D3. Also take A and K2 at the same time.

John Weston (2012-11-01 21:50:12)

The Half life of Vitamin D is measured in weeks(3-4). Consequently it takes months to get close to a steady state blood level so taking it morning or evening is immaterial. 4000 IU/day or 28,000 IU once a week is almost identical. A two week test is not long enough for benefits to really manifest. To jumpstart blood levels, about 3 weeks of your daily dose should be a good start. So at 4000 IU per day, 84,000 IU take once or spread over a couple of days would avoid the months otherwise needed to get to steady state blood levels. The prescription dosage taken is a single 50,000 IU dose taken weekly so this appears to be safe. Seth: If "taking it morning or evening is immaterial" why do many people find the time of day makes a difference (morning much better than evening)? The usual view of how Vitamin D acts, which you describe, can't explain this.

Adam (2012-11-02 07:09:58)

I usually eat about 8 eggs fried in butter for breakfast, along with fish oil capsules, so I doubt I'm lacking fat with my Vitamin D. Just a couple of typos Seth, my family name is Clemans with an "A" & I live in Shanghai, not Singapore. I'll update this thread if there's any further change in my sleep. I'm open to the possibility that it could be a placebo effect, or it could just be that my sleep pattern returned to normal after whatever disturbed it. The problem is, sleep is so valuable to me that I'm not really willing to experiment in ways that might harm it (moving Vitamin D administration to the evening, for example). Seth: I am stunned that I typed Singapore in place of Shanghai. If I were you I would vary the time of taking Vitamin D by an hour, see if that makes a difference. Or by a half hour. I found those changes made a noticeable difference, sometimes improving the effect.

Sam (2012-11-02 19:19:07)

New article by the Hartford Courant about a recent vitamin ad. Not to say that vitamins are ineffective—just that the media can go overboard in claiming how much they can do: <http://www.courant.com/news/opinion/hc-op-barreca-women-in-ad-unreal-1102-20121101,0,2875260.column>

Jim breed (2012-11-02 21:36:18)

Gwen, I unwittingly reduced my d dose from 5000 to 1000 while traveling earlier this year. I noticed a change in my sleep pattern for the worse and then I found out from my wife that the dosage had been reduced. I wrote up my observations and Seth printed them earlier this year. I wasn't expecting this result.

Adam (2012-11-03 03:53:30)

I found some interesting stuff this afternoon that has convinced me a temporal effect of Vitamin D isn't so far-fetched after all. While it is true Cholecalciferol has a long half-life, Cholecalciferol is just one part of a complicated network. It is metabolized into an intermediate in the Liver that is then metabolized into Calcitriol (the active form) in the Kidneys. Calcitriol has an inhibitory effect on gene expression of PTH that is delayed by hours. Say it takes 14 hours for a bolus of Cholecalciferol to increase Calcitriol which then inhibits PTH synthesis. The half-life of PTH is measured in minutes, not days or hours, so we would have a drop in PTH levels around bedtime if we took our Cholecalciferol in the morning. This is all speculation, but it does make it seem much more plausible in my mind.

Guv (2012-11-05 03:12:00)

from a quick google, it would seem that a lot of minerals and hormones in the body follow a diurnal rhythm. including Calcitriol (1,25-dihydroxyvitamin D) and PTH (Parathyroid Hormone). here are 2 studies, <http://www.ncbi.nlm.nih.gov/pubmed/11980-618> <http://jcem.endojournals.org/content/82/1/281.full> so may be it's feasible that supplementing with D3 at the right time & enough of a dose may reinforce theses diurnal variations (increasing the "amplitudes"). If this was the case, then it would make sense that timing (when you supp D3) would be very important. or, another scenario might be that the d3 supp timing is 'correcting' a screwed up rhythm. i have heard anecdotes of people supplementing with melatonin to adjust to new times zones, may be D3 in the mornings might have a similar effect. some food for thought

Jenny (2012-11-07 15:35:36)

I recently started taking my D3 (4-5000IU a day, a.m.) in droplet form, having taken gel caps. I find the droplets work even better - but I am coeliac, and put this down to the chronic coeliac malabsorption problems - even when gluten-free. BTW, I had one set of D3 gelcaps, extracted from lanolin rather than fish oils. Within a week I started feeling slightly off, and within 2 weeks I developed acute joint pain. I checked and found other people reporting the same, so immediately swapped back to fish oil derived D3, and my joints recovered after 3-4 days.

## **A Theft in China (2012-11-02 05:00)**

A friend of mine was at a KFC in Beijing. She returned from the bathroom to find her purse was gone. She called the manager. The police came in 15 minutes. At the police station, she saw security footage, which showed that her purse had been taken by an 11-year-old girl. "Heart-breaking," said my friend.

---

Mac (2012-11-02 06:10:11)

Really? This would happen in any big city in America. Your friend should have kept her purse on her person. Seth: My friend is from South Korea, where she says this would never happen. For all I know, you're right that this would happen in any big American city. I would be interested in the results of experiments - leaving purses unattended, seeing what happens - to find

out how often this happens in different places.

Alex Chernavsky (2012-11-02 10:19:48)

Here's a somewhat related article about Japanese honesty in turning-in lost items:  
<http://www.nytimes.com/2004/01/08/world/never-lost-but-found-daily-japanese-honesty.html>

Antonio (2012-11-02 10:55:31)

Honestly, what she did was kind of dumb. She cannot travel. Sorry.

Alex (2012-11-02 11:08:23)

If she routinely leaves her purse unattended while she's in the bathroom, it's remarkable to me that having her purse stolen is remarkable to her.

William Ryan (2012-11-02 11:52:36)

@Mac/Antonio/Alex: Aside from illustrating the concept of blaming the victim, did it ever occur to you that the friend's response to the crime could be the impetus of Seth's post? Empathy vs anger??? @Antonio: Aren't you making an assumption that she's traveling? I don't see anything specifying visitor or resident. Perhaps she's a native and this post is highlighting the point I made above.

BenSix (2012-11-02 16:44:06)

*Really? This would happen in any big city in America.* It's no less heartbreaking for being common!

Minji Ko (2012-11-02 21:54:01)

Here I see the story of mine! I live in China since I was a 13-year-old kid and it was the first time happening to me. I came back within a minute after I left. When I came back, the girl was still nearby, looking at me pointing at the chair where I put my purse, asking people if they had seen someone taking it, and finally calling the manager. Then she ran outside of KFC. It happened on Sunday, but till Friday I couldn't even know if the police checked the other footage or not, so I went to the police office yesterday. At there, what I could hear them saying that the girl cannot be a student so that it was impossible to find the girl (Why this excuse?) But "fortunately", I persuaded a police officer, so he and I went to the mall (where KFC is) and checked the other video footage. The girl left the KFC and went into the mall, walked a little, met her mother. And most surprisingly, she, with her mother, took the elevator and went to the ice rink! The police and I were so shocked to see this, because the entrance fee and the rental fee was not so much reasonable for average Chinese people (about \$10 for 90 minutes) For more, we also found that she was holding her ice rink membership card in her hand... She seemed to be so excited going skating since she never stopped smiling as if she had never even touched my purse. It is heartbreaking that not only had I to say goodbye to my purse, and all the important stuffs like credit cards, and my driver's licence, this little innocent-looking girl who seemed not at all poor but rich took my purse, and seemed to have no sense of guilty or something. And I don't think I will be able to understand why the police made a such excuse.

Antonio (2012-11-03 01:03:28)

Well if she is a native her lack of care with her own stuff is even more remarkable. She cannot really travel; certainly not US; maybe (with luck) to Scandinavia in the low season.

kxmoore (2012-11-04 00:16:04)

how did she know the child was 11? Seth: it's an estimate.

## Movie Grosses and Nobel Prizes (2012-11-03 05:00)

In Edward Jay Epstein's new piece [1]Gross Misunderstanding, in the Columbia Journalism Review, he writes

By focusing on the box-office race that is spoon-fed to them each week, journalists may entertain their audiences, but they are missing the real story.

Something similar happens with the Nobel Prizes. Journalists print what they are told – Scientists X and Y did beautiful "pure science" about this or that – and thereby miss the real story. In the case of Nobel Prizes in Medicine, the real story is the long-running lack of progress on major diseases (cancer, heart disease, depression, etc.).

1. [http://www.cjr.org/cover\\_story/gross\\_misunderstanding.php](http://www.cjr.org/cover_story/gross_misunderstanding.php)

---

Jim Daley (2012-11-04 15:38:47)

There is also a national bias against certain diseases that don't match the liberal media agenda. We have just gone through a month-long propaganda campaign to eliminate breast cancer. I support all efforts to find a cure for breast cancer...but where the heck is the strong effort to find a cure or even a good palliative for osteo-arthritis? I'll wager more people suffer from the latter than the former! Seth: Yes, why isn't it "find a way to prevent" breast cancer rather than "find a cure"? A "search for a cure" helps mainstream medicine. Prevention research, the opposite: fewer people sick, less profit. Yet women obviously benefit much more from prevention research.

Adam (2012-11-04 18:32:05)

Benjamin Franklin is quoted as saying: "An ounce of prevention is worth a pound of cure." This is always my response when people start asking ridiculous hypothetical questions of morality too ("would you kill the old woman or save the 6 infants from the train car?"). Life is more complicated than black & white dichotomies. What can we do NOW to prevent the old woman & 6 infants situation from occurring at all?

Peter (2012-11-14 08:18:33)

Interesting point about Sedaris. I read a couple of his books long ago and I can't say I ever thought about it at the time (I see now that I missed a big 2007 story about this in TNR) ...but thinking back now it's obvious that his stories must have been heavily embellished. I wonder who the most honest modern memoirists are. Even more, I wonder why the non-fiction label is so valuable. So much celebrated fiction is semi-autobiographical that there's clearly an audience for that too, but I guess the audience for "memoirs" is larger or less crowded? Seth: I think the non-fiction label is valuable because other things equal a true story is more impressive than a fictional one. For example, "I was kidnapped by aliens." If true, much more impressive.

### **Posit Science: Does It Help? (2012-11-05 05:00)**

Tim Lundeen pointed me to [1]the website of Posit Science, which sells ( \$10/month) access to a bunch of exercises that supposedly improve various brain functions, such as memory, attention, and navigation. I first encountered Posit Science at a booth at a convention for psychologists about five years ago. They had reprints available. I looked at a study published in the Proceedings of the National Academy of Sciences. I was surprised how weak was the evidence that their exercises helped.

Maybe the evidence has improved. Under the heading "world class science" the Posit Science website emphasizes a few of the 20-odd published studies. First on their list of "peer-reviewed research" is "the IMPACT study", which has [2]its own web page.

With 524 participants, the IMPACT study is the largest clinical trial ever to examine whether a specially designed, widely available cognitive training program significantly improves cognitive abilities in adults. Led by distinguished scientists from Mayo Clinic and the University of Southern California, the IMPACT study proves that people can make statistically significant gains in memory and processing speed if they do the right kind of scientifically designed cognitive exercises.

The study compared a few hundred people who got the Posit Science exercises with a few hundred people who got an "active control" treatment that is [3]poorly described. It is called "computer-based learning". I couldn't care less that people who spend an enormous amount of time doing laboratory brain tests (1 hour/day, 5 days/week, 8-10 weeks) thereby do better on other laboratory brain tests. I wanted to know if the laboratory training produced improvement in everyday life. This is what most people want to know, I'm sure. The study designers seem to agree. The [4]procedure description says "to be of real value to users, improvement on a training program must generalize to improvement on real-world activities".

On the all-important question of real-world improvement, [5]the results page said very little. I looked for the published paper. I couldn't find it on the website. Odd. I found it [6]on Scribd.

Effect of the training on real-world activities was measured like this:

The CSRQ-25 consists of 25 statements about cognition and mood in everyday life over the past 2 weeks, answered using a 5-point Likert scale.

Mood? Why was that included? In any case, the training group started with an average score of 2.23 on the CSRQ-25. After training, they improved by 0.07. (Significantly more than the control group.) Not only is that a tiny improvement (percentage-wise) it is unclear what it means. The measurement scale is not well-described. Was the range of possible answers 1 to 5? Or 0 to 4? What does 2 mean? What does 3 mean? It is clear, however, that on a scale where the greatest possible improvement was either 1.23 (assuming 1 was the best possible score) or 2.23 (assuming 0 was the best possible score), the actual improvement was 0.07. Not much for 50-odd hours of practice. Although the website seems proud of the large sample size ("largest clinical trial ever"), it is now clear why it was so large: With a smaller sample the tiny real-world improvement would have been undetectable. Because the website treats this as the best evidence, I assume the other evidence is even less impressive. The questions about mood are irrelevant to the website claims, which are all about cognition. Why weren't the mood questions removed from the analysis? It is entirely possible that, had the mood questions been removed, the training would have produced no improvement.

The first author of the IMPACT study is Glenn Smith, who works at the Mayo Clinic. I emailed him to ask (a) why the assessment of real-world effects included questions about mood and (b) what happens if the mood questions are removed. I predict he won't answer. A friend predicts he will.

Alex Chernavsky (2012-11-05 14:02:33)

See also this article from the *New York Times* (Oct. 31): "The Brain Trainers" I've only had time to read the first few paragraphs, but Posit Science is mentioned in the article (along with some other companies that are similar). Seth: The NY Times article suggests that parents with learning disabled children will pay enormous prices for training (e.g., \$10,000/year) and the training does help. That's a considerably different target population than the one aimed at by the Posit Science website: old people.

L (2012-11-06 00:13:52)

@ Professr Roberts: Maybe you can start a website to sell your math test to professors who need to measure brain function

L (2012-11-06 00:23:15)

@ Professor Roberts: Can you post Dr Smith's email address? I can't find it and I just spent one hour looking for it. Seth: smitg@mayo.edu

Henry Mahncke (2012-11-06 10:39:56)

Dear Dr. Roberts, I'm the CEO of Posit Science, and an author on the IMPACT papers - I saw your blog post and thought I could shed some light on your questions. Generally, this information is covered in our publications, but was too detailed to have on our web pages. They are great questions! 1) Active Control: We picked an active control that was comparable to what doctors currently recommend - which is to stay cognitively active. People in this group learned from educational DVD's (like Cosmos, History of Art, and so forth) and took quizzes each day on what they learned. This was a good control for our study because we could match the time spent on cognitive training, and people enrolled in this arm believed that this activity could help their cognitive function - so we could maintain the study blind for participants. 2) Self-Report Measure: The CSRQ has 25 questions, with questions like "I have felt I have a good memory", rated 1 (almost always) to 5 (hardly ever) over the past two weeks of time. In clinical trials like this, the best way to consider the magnitude of the effect is an effect size measure - we use the standard Cohen's d measure. On this measure, the effect on standardized neuropsychological tests is about 0.25, which is equivalent to 10 years of cognitive function. The effect size on the self-report measure was about the same, indicating that the improvement in objective measures of cognition matched the improvement in subjective measures - people really noticed the changes in themselves. There are a few mood questions on the CSRQ, because mood and cognition are related, however repeating the analysis with the mood questions removed doesn't affect the results - the effect is the same just considering the core cognition questions. We are proud of the clinical trials that we and our scientific collaborators have run - we think that this kind of evidence is crucial to the field of brain training, and we're proud to have been involved in all of the largest and best executed studies in the field. Thanks for your interest in our work! Best regards, Henry Mahncke CEO, Posit Science

Seth's response to Dr. Mahncke: Thanks for your answers. I understand what you say about the control group. About the size of improvement on the all-important real-world measures, however, I disagree that "the standard Cohen's d measure" is a good way to measure effect size. For an academic audience, maybe, but I am sure that the typical visitor to your website has no idea what that is. To convince me that your treatment reduced cognitive age by ten years, I would want to see three things: (a) All the questions of the CSRQ-25 so I could see what is being measured. (b) How the CSRQ-25 score (with the mood questions omitted) varies with age. You seem to say that the average score gets worse by 0.07 in 10 years. I am unsure that this is the case. I saw no evidence supporting that claim. (c) The effect of the IMPACT treatment on the score-versus-age function. It would be especially good to see the score versus age function separately for the two groups in the IMPACT study. A graph showing both functions (one for each group) would make it much clearer if your claim of 10 years improvement is reasonable.

ChristianKI (2012-11-14 17:39:38)

When it comes to Brain training I would like to see how Posit Science compares to Anki. Anki is also mentally challenging and I would expect similar effects on the measures that the IMPACT studied. On the other hand Anki has the additional advantage of helping you learn knowledge. Seth: I agree, that would be a good comparison.

## **Want to Sleep Better? Through Personal Science? (2012-11-06 05:00)**

If someone sleeps well, it's tough to kill them. If someone does not sleep well, it's tough to keep them alive. Robb Wolf quoted someone to this effect at the last Ancestral Health Symposium. One reason it's plausible is [1]better sleep improves immune function. For example, why are colds more common in winter? Well, flu bouts peak during the light minimum (December) rather than the temperature minimum (February). Less light makes sleep worse, so this supports the idea that colds are more common in winter due to worse sleep. Likewise, [2]heart attacks are more common in the winter, suggesting that better sleep would reduce heart attacks. [3]I stopped getting obvious colds when my sleep got much better. [4]Vaccinations are much less effective if the person vaccinated is kept awake the following night.

I've found new ways to improve my sleep: [5]avoid breakfast, [6]standing a lot, [7]morning light exposure, [8]one-legged standing, and [9]eating more animal fat. I've confirmed [10]Tara Grant's discovery of the value of Vitamin D3 in the morning. I've made these improvements via low-tech tracking, good experimental design and data analysis, and wise choice of treatment.

I want to find out if my method and findings can help others. I am looking for people who would like my (paid) help improving their own sleep. In [11]my search for people to try brain tracking, I judged interest and motivation partly by willingness to pay and it worked well.. If you are interested, please submit an application (see below).

At least at first, I'll only pick one or two people. I'll do whatever I can to help the chosen applicants measure their sleep, choose wisely what to test, do useful experiments, and analyze the data. They can have as much contact with me as they want.

There are four ways you might benefit from this: (a) Sleep better. (b) Learn how to use personal science to improve your health in other ways. (c) Help everyone learn if the treatments you try have value. (I will try to publicize the results, whatever they are.) (d) Help everyone learn the value of personal science to being healthy.

If this might interest you, please email [sleep.where@gmail.com](mailto:sleep.where@gmail.com) with your answers to the following questions:

1. Name, age, sex, job, location.
2. Phone number (good times to call), skype id (if any).
3. What's wrong with your sleep? For how long have you had this problem or problems?
4. How have you tried to improve your sleep? What happened?
5. How many colds do you get in a typical year? How long does a typical cold last?
6. How much would you pay for the first month (after a free consultation)?
7. How much would you pay per month after the first month?

---

Tom (2012-11-06 05:18:07)

A quick note: Ray Cronise is finding that cold stress (cool baths , showers) helps sleep. Also , I've found that transdermal magnesium before bed helps sleep. Seth: The magnesium might be worth a try. what brand and dose of transdermal magnesium do you use? I found cold showers produced weight gain and mental slowing.

Tom (2012-11-06 08:02:42)

Transdermal magnesium is typically sold at "magnesium oil." (The 'oil' is a misnomer; it's called that because magnesium dissolved in water has a slippery feel.) The 'magnesium oil' products are typically sold in small, pretty bottles at big markups, but i noticed that the ingredients were just magnesium chloride and water. Bulk magnesium chloride is very cheap, and I got mine here: [bulkreesupply.com/brs-bulk-magnesium-chloride-aquarium-supplement.html](http://bulkreesupply.com/brs-bulk-magnesium-chloride-aquarium-supplement.html) I mix a few tablespoons of the powder at a time in a pint of water and keep it in a small bottle in my shower/bath. Occasionally I will sit in the bathtub, pour some of the mixture onto a clean sponge and take a sponge bath of it before bed. (If I have the concentration too high, there will be a slight stinging sensation like a mild sunburn that disappears immediately upon rinsing off.) The soporific effect doesn't happen every time, and I suspect may depend on how magnesium replete one is (that's conjecture). When it happens, 30 minutes to an hour after the sponge bath I'll begin to feel very sleepy. I don't think it's a placebo effect, though. The first time it happened was when I tried a sponge bath mid-day and wound up so sleepy that I wound up sleeping the rest of the day. One benefit of taking magnesium transdermally is there is no laxative effect (which is common when taking magnesium orally.)

Guv (2012-11-06 16:22:09)

if you are in a hurry to buy some magnesium oil (magnesium chloride), you may find smaller quantities in the supermarket. probably in the asian section & labelled as Nigari. It's used as a coagulant for making Tofu. [http://en.wikipedia.org/wiki/Magnesium\\_chloride#Culinary\\_use](http://en.wikipedia.org/wiki/Magnesium_chloride#Culinary_use)

johnG (2012-11-08 13:41:50)

I've found that eating carbohydrates an hour or so before bedtime has helped a lot. Also, the Vit D helps.

Jim E (2012-11-14 17:37:18)

Seth I just watch a video explaining the vitamin D and sleep connection. It also gives the protocol for getting the right amount. Lots of opportunity for personal science. This link came from a comment on Emily Dean's blog. <http://www.youtube.com/watch?v=h7cbBB1c0IM>

guv (2012-11-15 02:04:33)

Hi Jim E, thx for the link, do you know at what time in the video she "gives the protocol for getting the right amount" i only have a mobile connection at the moment which is tight on bandwidth & expensive cheers

gwern (2012-12-02 21:03:43)

Speaking of magnesium, I've been messing with another common biological metal: potassium. Rather than improving my sleep like magnesium reputedly does, potassium seems to be damaging my sleep quality. It's weird since I can't think of any reason why this would be happening, and the only research I've found is an old study where potassium improved sleep quality!

gwern (2012-12-03 10:55:58)

Also, the first link is broken. I think Roberts meant "Sleep and Immune Function", Ganz: > Scientists are only beginning to fully understand the purpose of sleep and its underlying mechanisms. Lack of sleep is associated with many diseases, including infection, and with increased mortality. Lack of proper sleep is an important problem in the intensive care unit, and interventions have been designed to improve it. Sleep is associated with immune function, and this relationship is partially based on the physiological basis of sleep, sleep architecture, the sleep-wake cycle, cytokines and the hypothalamic-pituitary axis.

## **Journal of Personal Science: How Much Salt Should I Eat? (2012-11-07 05:00)**

by Greg Pomerantz

The Journal of Personal Science, [1]suggested by Tom and encouraged by Bryan Castañeda, will contain articles about using science to help yourself. This is the first one. It previously appeared [2]on Greg's blog. If you have written something or plan to write something or are thinking about writing something that might be included, please let me know. – Seth

I spent a few weeks this summer conducting a self-experiment on salt sensitivity and blood pressure. The experiment included a three week phase on a low carb whole foods diet with no added salt, followed by a moderately extreme salt loading phase. This post is a summary of my results.

I learned a lot from the experiment and came out of it with at least one bit of useful information. Will I try to restrict salt in my diet? No, I don't think salt restriction can work for me. From now on I will ensure that I get sufficient salt on a daily basis.

### **Summary**

These are the main points I learned during the experiment, from most to least interesting.

1. Salt restriction caused impaired thermoregulation. In hot weather, my cardiovascular system was not able to sufficiently lower my body temperature. This resulted in an elevated heart rate and hypothermia (up to 101.5 degrees in one instance). This can be dangerous, so be careful if you try this at home.
2. No clinically meaningful change in blood pressure. Systolic pressure was unchanged, though salt loading may have caused a small rise in diastolic pressure. This does not rule out long term negative effects from chronic salt loading (see discussion below), but it does show that, as [3]previously discussed, my kidneys seem to basically work and can regulate my blood pressure through the maintenance of fluid and electrolyte balance in response to changes in my sodium intake.
3. Salt reduction may increase susceptibility to skin infections. Three days into the salt restriction phase, I came down with what was probably a staph infection in my right eyelid. This responded to antibiotics but it came back once I went off them. Since adding back salt I have had no problems with skin infections and no more antibiotics.
4. Possible strength loss. I did not perform well in the gym on my usual strength training program.

5. My taste for salt adapts quickly to restriction and loading. I experienced no cravings even when my sodium intake was too low. I can't just "listen to my body". Likewise, while the salt loading phase was difficult for the first two or three days, my taste rapidly adjusted to the added salt.
6. Bodyweight changes. I experienced substantial changes in body fluid levels (e.g. 6 pound weight gain within two hours of the transition from the salt restriction to the salt loading phase).

Conclusion: A low carb paleo diet must include added salt (for me). Can others do without? Perhaps, and some scientists such as [4]Loren Cordain and Tim Noakes (e.g. [5]this podcast episode 18 at 1:03:50) seem to think they can. Skip ahead to read my further musings on this question.

Study Design

The experiment had three phases. First, I did a one week lead-in phase (phase I) where I made no changes to diet or salt consumption. The purpose of phase I was to establish a blood pressure baseline through daily morning measurements (see Measurement Methods below).

This was followed by a three-week sodium restricted phase (phase II) during which I did not add any salt to my food. In addition, during phase II only, I avoided naturally salty foods such as shellfish. My sodium intake during phase II was limited to the sodium in the foods I was eating. Note however that there were one or two restaurant meals per week during this time where I was not able to strictly control for added salt. Sodium consumption on phase II was estimated to be between 800mg and 1000mg per day. phase II was originally scheduled for two weeks, but was extended due to the aforementioned infection and antibiotic use.

Finally, phase III was a salt-loading phase during which I added an additional 5 grams of sodium to my diet, for a total of nearly 6 grams of sodium per day including the sodium naturally occurring in my food. The supplemental salt during phase III consisted of hand harvested French Celtic sea salt ([6]Eden Foods, Inc.) and was measured daily on an [7]AMW-1000 digital scale. Because the Eden French Celtic sea salt is approximately 1/3 sodium by weight according to the label, the 5 grams of supplemental sodium per day was provided by approximately 15 grams of sea salt. Note that different varieties of salt will contain different percentages of sodium by weight. Sea salts vary significantly due to variations in residual water content (not, as commonly assumed, by the presence of other minerals). Please consult the label or a friendly analytical chemist for guidance.

The diet throughout this experiment consisted of meat, fish, eggs, coconut oil, butter, and non-starchy vegetables. In addition, I typically consumed a banana, an ounce (28g) of almonds and a bit of dark chocolate each day. Potassium intake was fairly consistent at around 4 g/day. Table 1 shows a typical day's macronutrient intake. Given the macronutrient ratio, I believe it is likely that the diet was ketogenic.

Table 1. Approximate daily macronutrient intake.  
Macronutrient

grams
calories percent (calories)
Carbohydrate
50
200 6.6 %
Protein 155 620 20.5 %
Fat 245 2205 72.9 %
Total 3025

100 %

## Measurement Methods

I measured blood pressure daily first thing each morning while seated, with the cuff of an [8]Omron HEM-711 placed on the left upper arm over the brachial artery. I followed guidelines described by [9]Agena et al (see Chart 2 of the linked paper). Each day's blood pressure value was determined by averaging the first three measurements taken that morning. My first measurement of the day was typically higher than the average of the second and third measurements (systolic: +5, diastolic: +4, average over all three phases). This is referred to as the "alarm reaction" and is related to the more commonly known "white coat syndrome", where the presence of a doctor elicits a stress response and therefore an innacurately high blood pressure reading. My alarm reaction seems to be due to the fact that I get slightly stressed out about seeing what my blood pressure is, even when I measure it myself. Therefore I experience a slight rise in blood pressure while waiting to see the first reading each day. I kept all three readings for this experiment. My "true" normal blood pressure is on average slightly lower than these results which include the first "alarm" reading.

## Results

I summarized my qualitative findings in the executive summary above. If you skipped that because you are not an executive, you can go back and read it now. Below are graphs showing my blood pressure and bodyweight during the three phases. [10]

Figure 1: Possible mild elevation in diastolic blood pressure during the salt loading phase. Each point is the average of the three morning blood pressure readings for the day. Red = phase I, green = phase II, blue = phase III. Curves from ggplot2 "geom\_smooth()" using default parameters.

[11]

Figure 2. No change in systolic blood pressure.  
[12]

Figure 3: Bodyweight.

Figure 3 shows my daily bodyweight, measured each morning before consumption of any food or fluids. Note that my previous health goal (the [13]415 deadlift) involved an intentional increase in bodyweight and therefore significant excess calorie consumption. My current diet is lower in calories and Figure 3 therefore should show a long term downward trend in bodyweight. Salt restriction clearly resulted in a rapid decrease in bodyweight over the first few days of phase II. There appears to be a stabilization towards the end of the salt restricted phase. The salt loading in phase III produced a very large initial weight gain, followed again by stabilization around the same level seen at the end of the salt restriction phase. As salt is primarily stored in bones and extracellular fluids, an increase in salt would

be expected to correspond to an increase in extracellular fluid (since the body's bone mass should change slowly). The bodyweight changes shown in Figure 3 therefore reflect changes in extracellular fluid levels. While salt loading at the levels used in phase III produced a large acute change in body fluids, this was restored to normal over approximately 5 days. Since my extracellular fluid volume was evidently restored within 5 days, it is not surprising that salt loading had no significant effect on my blood pressure. What is somewhat surprising was that there was no evidence of a temporary increase in blood pressure during the few days in which my extracellular fluid volume was in fact elevated. This suggests that there is an additional regulatory element working to restore blood pressure homeostasis at a shorter time scale than the dominant kidney-fluid mechanism previously discussed on the blog [14]here. Thanks to [15]Mako Hill for guidance with [16]ggplot2, without which these plots would look less nice.

## Discussion

This experiment demonstrated to me that a low carb paleo diet with no added salt is potentially dangerous for me. Impaired thermoregulation is a big deal and would have been a life-threatening issue if I had to hunt for my food in a hot climate. Not only was my body temperature elevated in warm weather, but my pulse was elevated as well, suggesting my cardiovascular system was unable to restore my body temperature to normal. I'm clearly not salt sensitive, and I do not function well with a low salt diet. However, genetic studies suggest the ancestral human genotype is associated with high levels of salt sensitivity and ability to function with very low sodium intakes. How did humans evolve these traits? And why don't I seem to have them?

## A Faustian Kidney Bargain

[17]Susumo Watanabe has proposed an interesting hypothesis about the evolution of sodium metabolism in hominids. The theory is laid out in a 2002 paper called "[18]Uric Acid, Hominid Evolution, and the Pathogenesis of Salt-Sensitivity," published in the journal *Hypertension*. It goes something like this. At some point during the evolution of our common ancestor with gorillas and chimpanzees, a series of mutations inactivated the gene for urate oxidase, an enzyme that breaks down uric acid. As a consequence, we have much higher blood levels of uric acid than other mammals. These mutations seem to have occurred between 24 and 8 million years ago, during the miocene, when our ancestors were believed to be subsisting primarily on [19]fruits and leaves. This diet would have been exceptionally low in sodium. Since there is evidence of multiple independent mutations in this gene in multiple primate lineages, it is thought that mutations deactivating urate oxidase were strongly selected. In rats, uric acid raises blood pressure acutely, but also causes renal vascular disease via renin/angiotensin systems. This over time makes the rats more salt sensitive. If there is very little salt available, salt sensitivity can be a good thing. Watanabe argues that, where salt is scarce, high uric acid is beneficial (via multiple pathways) for preventing blood pressure from going too low. In addition to causing kidney disease, high uric acid causes other problems, like gout, and is associated with heart disease. So this looks like an engineering tradeoff with a number of downsides, but some benefits in the context of a miocene diet that was even lower in sodium than the lowest current estimates for paleolithic diets. The organism with this adaptation is supposed to partially destroy its kidneys on purpose in order to maintain sufficiently high blood pressure. This miocene environment is long gone. However, it is much easier to [20]break a gene than to put it back together. Our urate oxidase gene has been broken more than once and it would take quite a long time to fix it. It's kind of a crazy theory. I'm not sure I believe it but it is interesting to think about.

## Some Hypotheses

During this experiment, I was eating almost exclusively meat, fish (often with bones), eggs and vegetables, plus added calories from butter, coconut oil and olive oil. The diet was grain, legume and dairy free and, as mentioned, possibly ketogenic. This would be considered by many online diet and health personalities to be a good low carb paleo diet, even though of course processed fats like butter and coconut oil are not Paleolithic foods. So I want to discuss a few possible ways to resolve the apparent impossibility of eating this way without added salt.

## Hypothesis 1: Low Carb, Low Crab, or Low Salt: choose any two

I have been eating a low carb diet, and my experiment suggests that, in that context, low salt is not a good idea. It is possible that a healthy human diet can be either low in carbohydrates or low in salt, but not both. A great deal of evidence suggests that ketosis was not the norm for our paleolithic ancestors (see e.g. [21]Kuipers et. al. 2012 for

a thorough review of paleolithic diet research). In fact it would have been quite a struggle for me to eat this sort of macronutrient ratio without modern refined fats such as butter and coconut oil. Or ready access to marine mammal blubber (but then again the Inuit are not my paleolithic ancestors). In contrast to the online paleo diet scene, most low carb diet advocates seem to line up behind the recommendation for ample supplementary salt. My result accord with that clinical experience. Low carbohydrate diets are usually said to have a diuretic effect in this community, at least in the initial stages (e.g. [22]M.R. Eades, [23]Jenny Ruhl). It is possible that my problems were caused by the interaction between diet-induced ketosis and salt restriction, and I would have done just fine without salt if I had some more carbohydrates. This hypothesis would be straightforward to test. In order to keep my sodium intake sufficiently low during the salt restriction phase, I had to remove shellfish such as oysters and mussels from my diet. Crab is also salty and makes for a handy pun. It seems likely that daily shellfish consumption would have pushed my sodium intake into the healthy range. While shellfish does not get much attention these days in the paleo club, there is ample support (again see [24]Kuipers et. al.) that it was an important contributor to actual paleolithic nutrition.

Hypothesis 2: Humans must drink blood. Or eat salt.

File this one in the "[25]teen paranormal romance" department. This hypothesis states that the ancestral human diet was not as low in salt as commonly assumed. Sodium is the body's primary extracellular cation, and most of it is located [26]in the blood and other extracellular fluids. A pint of blood contains about 1.6 grams of sodium (see, e.g., these livestock [27]reference ranges for blood sodium). That much blood per day should have been more than enough to push me into the healthy range of sodium consumption. On the other hand, salt depletion set in pretty quickly for me (probably 3-4 days), so this hypothesis assumes that fresh blood was consistently available to inland populations that did not have ready access to shellfish or sea water. I find this hypothesis intriguing because of the fact that my putative ancestors were commanded not to drink blood ([28]Genesis 9:4, [29]Leviticus 17:13, [30]Deuteronomy 12:15-16), and that [31]salt is used in this tradition specifically to remove blood from meat before it is eaten. Presumably blood drinking was outlawed because it was thought to spread diseases and not because of [32]tacky pop-culture connotations. Were my ancestors salting their meat not just for its preservative qualities, but also to make up for the reduction in sodium intake due to their prohibition on drinking blood?

Hypothesis 3: I'm Not (Genetically) a Paleolithic Human

Some say the human genome has hardly changed in the past 10,000 years. However, the hard evidence points to a number of significant evolutionary changes since the advent of agriculture, the classic example being lactase persistence (see [33]Cochran and Harpending 2009 for a thorough argument on the rapidity of recent human evolution). Genes associated with hypertension and salt sensitivity are also apparently under strong evolutionary pressure. Alan Weder discusses this in an [34]article published in 2007 in the journal Hypertension about evolution and hypertension. It is worth reading as an example of excellent science writing. My experiment clearly demonstrates that I am not salt sensitive. This is not surprising given my European ancestry. As discussed by [35]Weber, the genetics of salt resistance seem to correlate with adaptations to colder climates. It seems possible that in the course of such adaptation, my ancestors lost the ability to function optimally on a low salt diet.

Is a High Salt Diet Safe?

It is possible that, as much of mainstream medicine believes, a high salt diet actually is unhealthy over the long term. There is nothing in this experiment that contradicts that belief. Just because I am resistant to the short term blood pressure effects of salt loading, that does not mean I am immune to whatever long term negative effects a high salt diet may have. While epidemiological studies have their problems, it seems unwise to discount their findings altogether. [36]Edward Frohlich has argued that, notwithstanding the fact that most people's blood pressure does not respond to acute increases in sodium intake, sodium is nevertheless responsible long-term for increases in blood pressure. He argues that excess salt causes kidney damage over time (as with uric acid this is mediated by renin/angiotensin systems), resulting long-term in an increase in blood pressure. While much of this research is based on studies done on rats (including those of the "[37]spontaneously hypertensive" variety), this line of thought is worth looking into and I will continue to do so.

L (2012-11-07 07:42:03)  
Thanks! Great article!

gwern (2012-11-07 09:12:58)

Nifty stuff but the conclusions seem overstated. Conclusions #1 & #3 are not data-based but retrospective & subjective, and about rare things in the first place: what, do you get staph every other day? How could you draw any conclusion about rare events like that? #4 could have been quantified but I don't see any graphs for it. #5 is reasonable but the claim about listening to your body sort of begs the question that either of the salt extremes were unhealthy enough that you should have noticed. #6 doesn't mention that the weight returned to normal; when I see 2 spikes on the graph corresponding to both transitions, I

wonder to myself 'is this a Hawthorne effect where the stress of changing entirely his diet causes him to overeat a little bit?'

Greg (2012-11-07 10:17:34)

Gwern, thanks for your comments. Re 1 and 3: The likelihood that these two changes (which had never happened to me before) were coincidences is much lower than the likelihood that they were caused by the intervention. Both outcomes have biological plausibility (though I have not seen prior reports associating infections with salt restriction). I would not necessarily call these "discoveries" but they are important observations that should be reported. Re 4: there was some level of quantification but not enough to graph in a useful manner (there are insufficient data points). This observation has more to do with how I was feeling. Re 5: given impaired thermoregulation, infection and strength loss, I have concluded that the low salt diet was unhealthy. However, I did not crave salt and my appetite adjusted to the lower intake. There is a body of literature on this question which I did not write up – the existence of sodium appetite in humans has been a controversial topic. It seems clear at this point that it does exist when sodium levels are critically low, but that it is extremely difficult in humans to deplete sodium to the extent necessary. My experiment did not reach the requisite level, nor should anyone attempt it without medical supervision. See the paper by Geerling and Loewy for an excellent discussion of this ("Central Regulation of Sodium Appetite", *Experimental Physiology* 2008). Re 6: increase in extra cellular fluid is the only explanation I can think of that could describe an 8 pound change in body weight in this time frame, but I'm open to suggestions if you can think of a better one. I am fairly certain that I did not eat an extra 8 pounds of food for dinner.

gwern (2012-11-07 11:57:14)

> Re 1 and 3: The likelihood that these two changes (which had never happened to me before) were coincidences is much lower than the likelihood that they were caused by the intervention. Both outcomes have biological plausibility (though I have not seen prior reports associating infections with salt restriction). I would not necessarily call these "discoveries" but they are important observations that should be reported. I don't follow. You mean you, in advance, expected that staph and thermoregulation problems would occur and this is why you are rejecting the null? What's the base-rate for either of these, combined with the selection effect of watching like a hawk for any change whatsoever? If you weren't expecting in advance those specific two problems, then you are misframing the problem all the way from the start: now the right question is, what is the base rate of any out of the ordinary event at all? (Quite high - as the old point about the lottery goes, it's surprisingly for a particular person to win, but it's not surprising that any particular person won. See also Littlewood's Law.) > Re 4: there was some level of quantification but not enough to graph in a useful manner (there are insufficient data points). This observation has more to do with how I was feeling. I see. > Re 6: increase in extra cellular fluid is the only explanation I can think of that could describe an 8 pound change in body weight in this time frame, but I'm open to suggestions if you can think of a better one. I am fairly certain that I did not eat an extra 8 pounds of food for dinner. I don't see an 8lb change graphed... Where's this 8lb stuff coming from? Your graph can't even show an 8lb change since it only spans 6lbs, from 155 to 161. I see 1 datapoint for the first phase, almost useless, and variation within the second phase far exceeding variation between the second phase and third phase. I also see a second phase which is increasing just before the transition and decreasing just after the transition. Or, look at the weight graph: between the last green point and the first blue point is 2lbs. 2lbs isn't much of a change, it looks like there are other places in the graph where 2lb shifts occur (and speaking from my personal experience, 2lb shifts happen all the time for me despite no salt experiments).

Greg (2012-11-07 14:33:12)

I do not have a null hypothesis to reject because I was not testing a hypothesis regarding infections or thermoregulation. I'm not seeking to prove or disprove these associations. I reported these results because they are highly unusual (they never happened before) and because they are biologically plausible. They are interesting observations, not discoveries. Why would I keep them a secret? The 8 pound shift is not graphed. The graph shows daily weight, measured consistently as described under Figure 3, not intra-day weight changes. Weight varies more during any given day than from day to day due to food and water consumption and excretion.

[...] journal of personal science: in which a man determines how much salt he should [...]

johnn (2012-11-11 10:13:36)

Greg, Thx for the thoughtful and detailed note on your experiment w salt. I loaded salt and small amount of potassium bicarbonate and magnesium citrate into gel capsules and 2-3 of those (4-6 gms) during hiking at high altitude. I found it largely offset my loss of physical endurance at high level of exertion since going low carb. Other situations that this method of salt supplement helps me personally are: fasting (reducing a slight headache), preventing mental fatigue (during long distance driving). 6 lbs of fluid retention is a lot. I never notice it personally. Is there noticeable sign?

James (2012-11-13 02:45:40)

Hi there, When going low carb, you'd better not restrict salt or you will suffer from some quite undesirable side-effects, the most common one being constipation. I also think, IIRC, that you will start losing potassium due to salt depletion. You don't want that ... Anyway, as soon as you go low carb, you have to increase your intake of salt. 5g/day of sodium should do.

Greg (2012-11-13 18:39:18)

Johnn, thanks for the comment. Salt loading at high elevation makes sense since it is easier to lose fluids up there (via respiration). Curious if you have noticed any effect of the magnesium? I took it for a while and it didn't seem to do anything. The 6 pound gain was certainly noticeable, largely because I was just ending the low salt phase during which I was dehydrated. I got a moderately bad headache but felt fine in the morning. James, I have heard the advice to add salt during "induction" of a low carbohydrate diet but not so much emphasis on it once adapted (I've eaten low carb for years). It is quite possible that low salt would have worked better with more carbs in the diet, though I did not experience constipation or the other symptoms typically associated with the initial low carb adaptation period. 5g/day of sodium is quite a lot - is that recommended after adaptation to low carb and if so by whom?

James (2012-11-14 03:20:51)

Hello Greg, Thanks for you feedback on this. A while back, I had read the book called "The Art and Science of Low Carbohydrate Living" by Phinney and Volek and I remember something about low carb - high fat diets and salt intake. I am not sure whether you have to maintain the 5g/day of sodium low carb post-adaptation but I can look it up again, I must have the book around here. FYI, I did experience a little bit of constipation at the beginning, but it is all fixed.

ob (2012-11-21 02:58:14)

A few thoughts You would like reading some of the literature where the have salt loaded the victions, I mean subjects. I think there was some food mixed in with the salt somewhere. I have read studies where they fed subjects up to 20grams of salt a day! Amphibians, mammals and then humans all evolved from the sea and our bodies mineral composition is similar to sea water but a bit more dilute. When we left the sea we had to carry a bit of it around inside us and balance input (diet) and output(excretion in urine and sweat). Salt excretion rate is influenced by insulin levels. if you insulin is low you tend to lose more salt. Conversely if you insulin is high you retain more fluid and salt. The salt hypertension link is pretty weak with experiments showing a change of only a few mmHg with large changes in salt content in diet. Some of the salt hypertension link may be a de facto meaasurement of insulin and metabolic syndrome rather than salt per se. Paleo style diets are very low salt- input minus output will allow balance to be maintained until one begins to exercise or is in a hot climate as salt s lost thru sweating. Peak sweat rates can result in a loss of 1-3g sodium/hour. People on a low sodium diet will sweat less salt but still significant amounts eg 1g/hour under hard working conditions. Natural meats, vegetables and fruits will amount to a similar order of magnitude with urinary loss of say 0.5 g or so per 24 hours. Hot weather and exercise tip the balance. Low carb style diet with ketosis would mean that negative sodium balance and hyponatremia is pretty much inevitable under these conditions. Persistence hunters, who high heat tolerance, meant they could hunt down prey vulnerable by a less developed internal heat management system. However, they would have lost a lot of salt... So, there must have been other sources of salt in the diet. As well as shellfish there may have been other "salt sources"" eg -blood consumption is known as well as

liver consumption (with blood), -certain plants accumulate salt - marine species mentioned -mineral waters- these vary in salt content some are quite significant, traditional eskimos cooked with "öld" sea ice which was mildly salty, the waters we get from the water company generally have low mineral content. geophagy is in some cases from clays etc that contain significant amounts of salt but it may have other roles as well, many mammals\birds will use natural salt licks and early humans may have done the same- eventually social evolution may have meant they learnt to carry the salt lick around with them. some animals will lick each other as a cleaning and social ritual- have never heard of primitive humans doing so. Salt like many dietary and environmental factors seems to be something that there are certain amounts needed to achieve an optimal outcome. Many of the low carb "gurus" recommend adding 1-2 grams of salt to diet a day. Certainly worth doing during hot weather or on days when you active exercise. Still trying to work out a better guideline (that doesn't involve consuming blood, eating dirt or similar practices).

Greg (2012-11-22 08:37:18)

ob, thanks for your post. I agree with everything you said. While the salt-hypertension effect is small on a population level, it can be quite large (or even slightly inverse) in individuals. There are a few studies out there showing individual responses in addition to group averages. It would benefit personal science tremendously if more studies reported data in this way. Do you have a good reference for the insulin/sodium connection? My insulin levels were low before going low carb, so I question that theory a bit, even though the guideline to add salt to a low carb diet is widely supported by the clinical experience of doctors working with these diets - it's only the "why" I'm questioning.

### **Positive Psychology Talk by Martin Seligman at Tsinghua University (2012-11-09 05:00)**

Here at Tsinghua University, the Second Annual Chinese International Conference on Positive Psychology has just begun. The first speaker was Martin Seligman, a professor at the University of Pennsylvania and former president of the American Psychological Association (the main professional group of American psychologists). Seligman is more responsible for the Positive Psychology movement than anyone else. Here are some things I liked and disliked about his talk.

Likes:

1. Countries, such as England, have started to measure well-being in big frequent surveys (e.g., 2000 people every month) and some politicians, such as David Cameron, have vowed to increase well-being as measured by these surveys. This is a vast improvement over trying to increase how much money people make. The more common and popular and publicized this assessment becomes - this went unsaid - the more powerful psychologists will become, at the expense of economists. Seligman showed a measure of well-being for several European countries. Denmark was highest, Portugal lowest. His next slide showed the overall result of the same survey for China: 11.83 %. However, by then I had forgotten the numerical scores on the preceding graph so I couldn't say where this score put China.
2. Work by Angela Duckworth, another Penn professor, shows that "GRIT" (which means something like perseverance) is a much better predictor of school success than IQ. This work was mentioned in only one slide so I can't elaborate. I had already heard about this work from Paul Tough in a talk about [1]his new book.
3. Teaching school children something about positive psychology (it was unclear what) raised their grades a bit.

Dislikes:

1. Three years ago, Seligman got \$125 million from the US Army to reduce suicides, depression, etc. (At the

birth of the positive psychology movement, Seligman proclaimed that psychologists spent too much time studying suicide, depression, etc.) I don't mind the grant. What bothered me was a slide used to illustrate the results of an experiment. I couldn't understand it. The experiment seems to have had two groups. The results from each group appeared to be on different graphs (making comparison difficult, of course).

2. Why does a measure of well-being not include health? This wasn't explained.

3. Seligman said that a person's level of happiness was "genetically determined" and therefore was difficult or impossible to change. (He put his own happiness in "the bottom 50 %".) Good grief. I've blogged several times about how the fact that something is "genetically-determined" doesn't mean it cannot be profoundly changed by the environment. Quite a misunderstanding by an APA president and Penn professor.

4. He mentioned a few studies that showed optimism (or lack of it) was a risk factor for heart disease after you adjust for the traditional risk factors (smoking, exercise, etc.). There is a whole school of "social epidemiology" that has shown the importance of stuff like where you are in the social hierarchy for heart disease. It's at least 30 years old. Seligman appeared unaware of this. If you're going to talk about heart disease epidemiology and claim to find new risk factors, at least know the basics.

5. Seligman said that China had "a good safety net." People in China save a large fraction of their income at least partly because they are afraid of catastrophic medical costs. Poor people in China, when they get seriously sick, come to Beijing or Shanghai for treatment, perhaps because they don't trust their local doctor (or the local doctor's treatment failed). In Beijing or Shanghai, they are forced to pay enormous sums (e.g., half their life's savings) for treatment. That's the opposite of a good safety net.

6. Given the attention and resources and age of the Positive Psychology movement, the talk seemed short on new ways to make people better off. There was an experiment with school children where the main point appeared to be their grades improved a bit. A measure of how they treat each other also improved a bit. (Marilyn Watson, the wife of a Berkeley psychology professor, was doing a study about getting school kids to treat each other better long before the Positive Psychology movement.) There was an experiment with the U.S. Army I couldn't understand. That's it, in a 90-minute talk. At the beginning of his talk Seligman said he was going to tell us things "your grandmother didn't know." I can't say he did that.

1. <http://www.nytimes.com/2012/08/26/books/review/how-children-succeed-by-paul-tough.html?pagewanted=all>

---

vimal (2012-11-09 08:10:52)

Having read a lot of Seligman, I know he talks about the Lykken finding that 50 % of "the pleasant life" is heritable and 50 % is environment/choices.... "The first drawback is that it turns out the pleasant life, your experience of positive emotion, is heritable, about 50 percent heritable, and, in fact, not very modifiable." [http://www.ted.com/talks/martin\\_seligman\\_on\\_the\\_state\\_of\\_psychology.html](http://www.ted.com/talks/martin_seligman_on_the_state_of_psychology.html) He must have forgotten to mention that part, but I think it's a core part of his ideas. Seth: There it is again. The idea that "heritable" implies "not modifiable". It was everyday conversation among Berkeley psych profs 30 years ago that the genes/environment dichotomy was pure nonsense. Sometimes the point was put like this: Is the area of a rectangle determined by its height or its width?

Derrick Yoder (2012-11-09 08:29:16)

Thank you for sharing this information, but I am confused by some of your critiques. under dislike #1: you give the \$125 million dollar grant as a prior, then give a hazy remark about one slide being confusing. Is this really about the results of the Comprehensive Soldier Fitness initiative? If so, the results are organized here: <http://www.authentic happiness.sas.upenn.edu/newsletter.aspx?id=1552>. If not, perhaps you could clarify. dislike #3: I think what you are referring to is what Positive Psych calls a "setpoint". PP's happiness formula is  $h = s + c + v$ , or happiness = setpoint + conditions + voluntary actions. Seligman never claims that genes determine happiness, rather he says there is a setpoint that can be managed through meditation, cognitive behavioral therapy, or psychopharmaceutical drugs like prozac. I don't think it's fair to over-generalize Seligman's supposed over-generalization, given the scope of his research. The rest of your critiques seem to essentially say 'he doesn't know as much as he thinks he does.' Again, I don't think it is fair to base such judgments on a 90 minute lecture. If I, for instance, read one of your blog posts about vitamin d3 that does not mention dosage, and relate it to my experience saying 'well I've been doing 1000 UI every night and my sleep hasn't improved', I would be doing myself a great disservice by not looking at your other blog posts before reaching reaching a conclusion Seth: Thank you for your comments, especially the link to the Comprehensive Soldier Fitness Initiative. The appearance of a bizarre and incomprehensible graph in a talk by an extremely prominent psychology professor is what stunned me. Believe me, I would rather have the military spend \$125 million on a perfectly plausible psychology-related program than on 5 tanks. It strikes me as a good investment. "Seligman never claims that genes determine happiness" – in his talk, he said that because happiness was so genetically determined, it was hard to change it. Maybe there's a first time for everything? Yes, my comment about China's "good safety net" is a comment about his ignorance. I doubt that somewhere else he shows that he actually knows that China doesn't have a good safety net. If anywhere in his writing Seligman showed that he understood heart disease epidemiology basics, I believe he would not have said what he said. My last criticism – where are the treatments that help people? – is not a comment about ignorance. It is a comment about lack of results.

Richie (2012-11-09 12:01:23)

He must have misspoke or you must have misunderstood him. The premise of positive psychology is that happiness is \*not\* determined by either genetics or circumstances and can be profoundly changed by individual effort. Seth: He really said this. I didn't misunderstand him. Because it was so hard to change happiness, he said, positive psychology should also study other things, presumably easier to change. Maybe positive psychology started with that premise ("happiness is \*not\* determined...") but it turned out to be wrong. There were lots of things in his talk that it would be nice if they were true but evidence was not presented that came anywhere close to showing they were true.

Robbo (2012-11-09 17:05:27)

"It is hard to change happiness" If that is a given, is the implication: a) You need to put some actual work in to improve your happiness, or b) Don't bother, it would take actual work. If a), it would be great to have specific things to try out and evaluate in your n=1 laboratory, but I thought Seligman had done quite a bit of this in his popular books. However, I don't think you are wrong in being disappointed at shortcomings in clear communication, useful and new content, and statements contrary to your own knowledge about China. Seth: The audience was psychology professors who do research about happiness and related stuff. The implication was: do research on other aspects of well-being, they will probably be easier to change. This is a perfectly reasonable conclusion. Not because happiness is "mostly genetic" but because in fact it has been hard to change in research studies. (Leaving aside my work with morning faces, which found big effects on happiness.)

Alex Chernavsky (2012-11-09 18:18:07)

From what I understand, David Lykken (and collaborators) at the University of Minnesota showed that identical twins raised apart are far more similar in their happiness levels than are fraternal twins raised apart. Doesn't this fact argue in favor of a strong heritable (and not very modifiable) component for happiness? Seth: These are findings about predictability. The more heritable a trait, the more you can predict a child's value on the trait from his parents' values on that trait. How much you can modify anything depends above all on how well you understand it (e.g., how much you can control your weight depends on how well you understand how weight is controlled). Just because something is highly heritable doesn't mean it is hard to understand. I doubt there is any correlation.

A Reader (2012-11-09 19:08:14)

I believe that Seligman also advocates that you can't change your weight, which is contradicted by your Shangrila Diet research. While I don't have the book now, I believe it was covered in "What You Can Change and What You Can't." I no longer have the book so I can't fact check my memory.

Lemmy Caution (2012-12-05 16:14:27)

"I believe that Seligman also advocates that you can't change your weight, which is contradicted by your Shangrila Diet research. While I don't have the book now, I believe it was covered in "What You Can Change and What You Can't." I no longer have the book so I can't fact check my memory." This is the book: [http://www.amazon.com/What-You-Change-Cant-Self-Improvement/dp/1400078407/ref=la\\_B001ILOB78\\_1\\_5?ie=UTF8&qid=1354748794&sr=1-5](http://www.amazon.com/What-You-Change-Cant-Self-Improvement/dp/1400078407/ref=la_B001ILOB78_1_5?ie=UTF8&qid=1354748794&sr=1-5) It was an interesting investigation into what is changeable and what is not changeable based on the literature. here is some guy's summary: The results are sobering: from the range of most frequent psychological afflictions, only a few will reliably be relieved by treatment. You can - with appropriate help from a responsible mental health professional - do something about - panic attacks - specific phobias (snakes, spiders, flying, etc.) - sexual dysfunctions. With other problems, such as depression and addiction, "moderate relief" is the best psychiatrists have to offer, often (when psychoactive medication is used) at a considerable price. Beyond that, - enjoy your sexual orientation, - enjoy your weight (dieting will improve it upwards, in the long run), - stop blaming unsatisfactory results of your adult life on your childhood and your parents - it won't do you any good, and there is much less of a causal relationship anyway.

## Japanese Discouragement of Foreign Visitors (2012-11-09 23:28)

In [1]a post about Tokyo, I said it was a tragedy that there were so few foreigners there. You might think that someone in power in Japan would figure out that America's biggest strength is that foreigners want to move there ([2]for example), but apparently not. A Tokyo University student told me today that at her school, the dormitory for foreign students is one hour away from the campus.

1. <http://blog.sethroberts.net/2012/01/20/the-beauty-and-tragedy-of-tokyo/>

2. <http://www.ronunz.org/1994/11/07/value-added-why-national-review-is-wrong/>

---

expatLeftCoaster (2012-11-10 03:04:13)

Have a look sometime at the JET program, which brings to Japan every year thousands of young college grads from the US, Canada, UK, Australia, South Africa - - even New Zealand - - to work as assistant language teachers in jr and sr high schools. They do on average a 2 or 3 year stint here (many of em placed in rural communities) and thereby fill some of the void left by Japanese universities and grad schools in particular which, for whatever reason, fail to draw foreign students the way N American and European universities can. Seth: All JET visitors teach English. Sure, the Japanese power structure grasps that English is an important language. They can afford to import people to teach it, yes. I know two people who have been in that program. One did stay in Japan afterwards, although she feels horribly like an outsider.

bjk (2012-11-11 21:45:49)

What I liked about Japan was that it was distinctive. It wasn't Manilla and it wasn't one drab apartment building after another, like Seoul. And you can walk the streets of Tokyo at any time of the night. What other major city can that be said about? Maybe the next frontier in happiness research is the benefit of homogeneity. Mangan had a post recently about diversity and heart

disease.

### The Power of the Willat Effect: Rinsed versus Unrinsed Tea (2012-11-10 05:00)

During my last visit to New York I bought a new black tea. I started drinking it a few weeks ago. I brewed it various ways (different amounts of tea, different steeping times, etc.) but had a hard time telling which way was best. This morning I decided I would learn how to brew it by making paired comparisons (two cups of tea made the same way at the same time except for one difference). The fascinating thing, as I've said, about these side-by-side comparisons is that they produce hedonic changes. They change how much you like this or that. I call this [1]the Willat Effect after my friend [2]Carl Willat who caused me to notice it.

This morning I made two cups of the new tea. The two cups were brewed the same except in one case I "rinsed" the tea before brewing. Rinsing means I poured a bit of hot water on it and quickly got rid of the hot water. Rinsing tea removes from the final product whatever is transferred from the tea to the hot water in the first few seconds. In China, rinsing tea is common; in the United States, very rare.

I tasted the two cups (rinsed and unrinsed) side by side. The rinsed tea tasted much better. The unrinsed tea had something weird about it. Ugh, I thought, I can't drink this. I threw out the unrinsed tea. Over the previous few weeks, I had happily drunk the new tea unrinsed many times. Now I found it repulsive.

1. <http://blog.sethroberts.net/category/human-evolution/my-theory-of-human-evolution-directory/willat-effect/>

2. <http://www.carlsfinefilms.com/>

---

Sean (2012-11-10 11:40:33)

Wouldn't you want someone else to prepare this for you to make it a blind side-by-side test? Otherwise you could spend the rest of your life rinsing tea for the placebo effects. Seth: I have found the effect to occur whether or not I prepare the drinks.

Adam (2012-11-10 16:31:14)

Interesting! My Chinese mother-in-law tells me that if there are bubbles on the top of my tea, I should blow the bubbles to the edge & then pour them off. I don't know if this is widely practiced, but she seems to have learned it from her father. Sometimes I do it if I notice, but I've never done a side-by-side comparison to see if it makes any difference in taste. Could these 2 be linked?

Gayle (2012-11-10 17:31:34)

Hmmm... I wonder if this would work with coffee grounds, too...

Drewfus (2012-11-11 00:31:49)

Seth, what happens when the teas are tasted blind, in regards to not knowing how their preparations differ? *"Over the previous few weeks, I had happily drunk the new tea unrinsed many times. Now I found it repulsive."* Is that purely because of the taste, or because you know the tea has been unrinsed, and are reacting based on that higher level knowledge, or both? Seth: If it had been done blind, I am sure the results would have been the same. To answer your second question: Purely because of the taste. There is nothing inherently wrong with unrinsed tea.

Kirk (2012-11-11 12:01:27)

I agree, rinsing produces a better flavor. The rinsed tea has a rounder and cleaner taste and the sharp edges have been removed. My bake-off compared .5 of an ounce of an organic Assam, using 4 oz. of water, steeped for 2 minutes. After 3

rounds of tasting, I poured the unrinsed tea down the drain.

Jon K (2012-11-11 15:34:30)

I'm pretty sure that rinsing tea removes or greatly reduces the amount of caffeine present. Whether this is directly related to the change in taste, I don't know. But it is interesting because many people drink tea (especially black tea) at least partially for the caffeine.

Txomin (2012-11-11 19:13:23)

Sure. Weak tea is good.

Greg (2012-11-11 20:24:29)

The Willat effect is real and it is very dangerous. Last year I did a few side-by-side taste tests with the Keurig coffee machine at my workplace. Now I can't stand to drink any of it and can only enjoy direct trade hipster coffee that is roasted in Brooklyn.

Drewfus (2012-11-12 08:20:25)

Seth, thanks for the reply. I've more or less asked the same question as Sean (above) so i'm glad i didn't get into trouble for that. Regardless, this (Willat) effect is important, so i've started testing on myself. With green tea, i noticed a small but worthwhile improvement. The rinsed tea has a cleaner taste - especially the aftertaste. I'm slightly concerned that i'm imagining this, so will organize some blind testing. Maybe using a microwave oven to spin the tea cups, so i forget which is which! Seth: there is an easy test for whether you are imagining the difference. use identical tea cups. Put little labels on the bottom of the tea cups (e.g., R and U). Pour rinsed tea into the R cup and unrinsed tea into the U cup. then close your eyes and switch them a bunch of times (not counting how many times). you will soon lose track. Then open your eyes and do the comparative tasting. decide which cup holds the rinsed tea and see if the label on the bottom of the tea cup shows you are right.

Alex Chernavsky (2012-11-13 11:49:21)

I'd like to propose a phenomenon which I'll call the reverse-Willat effect. On a couple of occasions, I did side-by-side comparisons and found that - contrary to my expectations - the samples tasted remarkably similar.

Jenny (2012-11-17 16:57:51)

The evening after I read this, I was chatting to 2 Chinese friends (here in England) about this. They were amazed because they always 'rinse' their tea. So I tried it, and prefer it, finding it less bitter. I haven't tried it with T-bag tea yet, only loose tea. One of the ladies also told me that, having been an avid coffee drinker (8 cups a day), she gave up coffee for 6 months, and now finds that all coffee has an after-taste of peppermint - which she doesn't like.

- [3]The Beijing Interceptors.
- [4]doctor complains about over-prescription of opiates. The author, a doctor named Susana Duncan, complains about several things, including "a system where symptoms are treated but the source of pain remains". Treatment of symptoms rather than identification of causes is overwhelmingly true of the whole health care system, not just treatment of chronic pain. One example is depression. Anti-depressants do not reduce whatever caused the depression. Another example is high blood pressure. Blood-pressure-lowering drugs do nothing to eliminate what caused the high blood pressure. Duncan was once science editor of New York magazine, which may have something to do with her ability to cogently criticize the system.

Cool links especially "chocolate: what is the best dose?" Helpful and interesting read!

Jim Purdy (2012-11-11 23:18:48)

Doctor Susana Duncan said: "It is not clear that private medical practice as we know it will survive at all under these cuts." One can only hope that she is correct! Considering how pathetic and unscientific and profit-driven the USA's medical system is, the best thing for public health might be to do away with the whole private medical system. I'm not a religious believer, but I suspect that faith healing charlatans would do less harm to the public health than the broken system we have now. At least the money-grubbing faith healers wouldn't be turning millions of people into painkiller addicts. jimpurdy1943@yahoo.com

## Measuring Yourself to Improve Your Health? Want to Guest-Blog? (2012-11-12 05:00)

What surprised me most about [1]my self-experimental discoveries was that they were outside my area of expertise (animal learning). I discovered how to sleep better but I'm not a sleep researcher. I discovered [2]how to improve my mood but I'm not a mood researcher. I discovered that flaxseed oil improved brain function but I'm not a nutrition researcher. And so on. This is not supposed to happen. Chemistry professors are not supposed to advance physics. Long ago, this rule was broken. Mendel was not a biologist, Wegener (continental drift) was not a geologist. It hasn't been broken in the last 100 years. As knowledge increases, the "gains due to specialization" – the advantage of specialists over everyone else within their area of expertise – is supposed to increase. The advantage, and its growth, seem inevitable. It occurs, say economists, because specialized knowledge (e.g., what physicists know that the rest of us, including chemists, don't know) increases. [3]My theory of human evolution centers on the idea that humans have evolved to specialize and trade. In my life I use thousands of things made by specialists that [4]I couldn't begin to make myself.

Here we have two things. 1. A general rule (specialists have a big advantage, within their specialty, over the rest of us) that is overwhelmingly true. 2. An exception (my work). How can this be explained? What can we learn from it? I've [5]tried to answer these questions but I can add to what I said in that paper. The power of specialization is clearly enormous. Adam Smith, who called specialization "division of labor", was right. The existence of an exception to the general rule suggests there are forces pushing in the opposite direction (toward specialists being worse than the rest of us in their area of expertise) that can be more powerful than the power of specialization. Given the power of specialization, the countervailing forces must be remarkably strong. Can we learn more about them? Can we harness them? Can we increase them? The power of specialization has been increasing for thousands of years. How strong

the countervailing forces may become is unclear.

The more you've read this blog, the more you know what I think the countervailing forces are. Some of them weaken specialists: 1. Professors prefer to be useless rather than useful (Veblen). 2. A large fraction (99 %?) of health care workers have no interest in remedies that do not allow them to make money. 3. Medical school professors are terrible scientists. 4. Restrictions on research. Some of them strengthen the rest of us: 1. Data storage and analysis have become very cheap. 2. It is easier for non-scientists to read the scientific literature. 3. No one cares more about your health than you. These are examples. The list could be much longer. What's interesting is not the critique of health care, which is pretty obvious, but the apparent power of these forces, which isn't obvious at all.

I want to learn more about this. I want learn how to use these opposing forces and, if possible, increase them. One way to do this is find more exceptions to the general rule, that is, find more people who have improved their health beyond expert advice. I have [6]found some examples. To find more, to learn more about them, and to encourage this sort of thing (DIY Health), I offer the opportunity to guest-blog here.

I think the fundamental reason you can improve on what health experts tell you is that you can gather data. Health experts have weakened their position by ignoring vast amounts of data. Three kinds of data are helpful: (a) other people's experiences, (b) scientific papers and (c) self-measurement (combined with self-experimentation). No doubt (c) is the hardest to collect and the most powerful. I would like to offer one or more people the opportunity to guest-blog here about what happens when they try to do (c). In plain English, I am looking for people who are measuring a health problem and trying to improve on expert advice. For example, trying to lower blood pressure without taking blood pressure medicine. Or counting pimples to figure out what's causing your acne. Or measuring your mood to test alternatives to anti-depressants. I don't care what's measured, so long as it is health-related. (Exception: no weight-loss stories) and you approach these measurements with an open mind (e.g., not trying to promote some product or theory). I am not trying to collect success stories. I am trying to find out what happens when people take this approach.

Guest-blogging may increase your motivation, push you to think more ("[7]I blog, therefore I think") and give you access to the collective wisdom of readers of this blog (in the comments). If guest-blogging about your experiences and progress (or lack of it) might interest you, contact me with details of what you are doing or plan to do.

John Lawrence Aspden (2012-11-12 06:26:10)

Hi Seth, after four months I'm convinced your diet works: <http://johnlawrenceaspden.blogspot.co.uk/2012/11/shangri-la-diet-month-four-s-uccess-im.html> I'm still not convinced about the scarcity of food -> loss of appetite theory. It looks like a just so story, and it could equally well go scarcity of food -> eat everything you can get your hands on. But I think your diet works for me. Is anyone showing any interest in doing a large scale randomized trial? Seth: Thanks for your excellent blog post. No one has contacted me about doing a randomized trial, I'm afraid. About the theory behind the diet. The theory came before

the diet and led me to it. That a theory produces a diet that (a) works and (b) is very counter-intuitive seems to me to be excellent evidence for the theory. I too was/am skeptical of evolutionary explanations but they have helped me find surprising cause-effect relationships several times.

Koanic (2012-11-12 06:35:24)

I find that Filemaker is a useful program for collecting data, for those of us unfamiliar with and intimidated by R. It is a database program that allows one to design one's tables, fields and forms. This is really what you need to collect personal data. For example, right now I'm measuring sleep onsets and durations, and psychomotor test scores with subjective notes. Both have autogenerated timestamp fields. This is to provide feedback on a polyphasic sleep experiment. In a single database, I can store pretty much every type of self tracking data I collect over my lifetime. Handy. At a more zoomed out level, I track every day that I get to my journaling habit, which serves as a good proxy for conscientiousness and overall health. I use the website "don't break the chain" for this. I believe that the act of tracking should be designed so that in itself it increases your discipline without adding onerous load to your day.

Jim Purdy (2012-11-12 07:41:29)

Seth, in any discussion of specialist and non-specialist behaviors, I think we should consider the natural herding behavior of most people, both specialists and non-specialists. Many animals, including people, feel a instinctive sense of security in numbers. In the wild, the animal that strays from the pack is the most likely to be targeted by predators. That herding or pack instinct is very powerful, because it has been selected for over many millions of years of Darwinian evolution. In many professions, it can be career-damaging to resist the pressure to conform. In my own long-ago profession as a news reporter, pack journalism was and is the expected behavior. When I was with UPI in the 1960s and 1970s, the competition between AP and UPI was so intense that being first with a story, by 4 or 5 seconds, was all-important. The result was very sloppy journalism, and the dumbing down of news consumers. And that trend of 40 years ago has only gotten worse, especially with the relentless pressure from the fake journalists at Fox News. When Fox makes up a story, even a typically bogus story, pack journalism kicks in and soon all the media, even the once-esteemed New York Times, are soon imitating Fox. That herding tendency is true not just in journalism, but in other fields, especially medicine. When I once complained to a doctor that he wasn't paying attention to me, he adamantly insisted that it "would be malpractice" for him to listen to his patients instead of following national guidelines. Self-experimentation may be the only way for most health consumers to find out what works for them. BigPharma certainly is not the solution. jimpurdy1943@yahoo.com Seth: I agree. This is one aspect of what I mean when I say non-professionals have more freedom than professionals. Non-professionals can test "crazy" ideas (e.g., "crazy" ideas about how to lose weight or sleep better), professionals cannot.

Joe (2012-11-13 14:03:59)

"especially with the relentless pressure from the fake journalists at Fox News" Why pick on Fox News? They're all the same. "Fake journalists" everywhere you look. NBC, MSNBC, CBS, ABC, BBC, etc. Ditto for newspapers.

Greg (2012-11-13 19:31:32)

I can think of a few important cross-disciplinary contributions to biology in the 20th century – Linus Pauling: physicist, and a founding father of molecular biology (also a health self-experimenter). Max Delbruck: astrophysicist who made significant discoveries in microbiology. Alan Turing: founding father of computer science, founding father of computational biology. Carl Woese: molecular biologist, revolutionized the science of evolution. Seth: Delbruck changed fields. He was a professional biologist. Woese is a professor of microbiology, which is where his contributions are. If he were a professor of physics, I'd agree with you. Sure, the people who start a field are going to by definition come from outside that field. E.g., Ebbinghaus (one of the originators of experimental psychology) was a philosopher.

Alexander Boland (2012-11-19 11:50:33)

My two main areas of interest are (1) mitigating my ADHD (I've been taking medications on and off since I was a teenager and don't like that) and (2) more recently, dealing with energy levels. Recently I was feeling very sluggish on a daily basis at work and easily getting energy crashes right before and right after lunch. The main culprit here was probably the medications I take;

during a period of time where I was off of them but on a low-carb diet, my energy levels were very stable. That aside, I started engaging in a relatively simple self-experiment but it's not very formal and doesn't have much in the way of data. I got a hunch, from a Leangains.com post on cortisol and breakfast, that having coffee with my breakfast was causing serious insulin spikes and leaving my energy in an extremely volatile state. Lately, I've started waiting around an hour after a meal before having anything caffeinated. The results are mixed, but generally good. That said, this week I have a lot of energy despite the tactic failing me last Thursday and Friday. Odd too because this weekend I was feeling a bit "blah" and was out late drinking a lot. I'm wondering if it was just much needed rest (I don't take medications on weekends), or if it had something to do with consuming carbohydrates (I was eating more carbs than usual, partially to nurse hangovers.) I sometimes find that strategically placed carbohydrates have a positive effect on me. This all feels a bit too vague and simple to talk about on your blog but I thought it wouldn't hurt to talk about my most recent adventure in self-monitoring.

Chuck (2012-11-14 09:37:01)

The problem I have with the black tea/diabetes correlation is that they don't take into account what these populations that consume the most black tea are not consuming that the populations with the lowest black tea consumption, and higher levels of diabetes are consuming. If one population consumes copious amounts of Crisco, wheat flour and sugar, and small amounts of black tea, is it really the low level of black tea consumption that exposes them to higher rates of diabetes, or is it CWS? The myopic focus on one element of a population's diet is what is wrong with all dietary advice today. Population diets are complex and synergistic. All elements of the diet must be taken into consideration if we are to understand why some populations are more prone to contracting a particular disease or metabolic condition. It may be the tea that leads to lower levels of diabetes

in these particular populations, but how do we know it's not the cigarettes they smoke? Cheers Seth: Very likely these studies adjusted/corrected for smoking.

Paul N (2012-11-24 00:59:47)

There is actually lots of evidence for the the health benefits of CLA. One of the theories as to why it works so well is that being a trans fat, and the \*only\* natural source is mammal milk (and grass fed ruminant fat), that bacteria and pathogens just can't digest it. Grassfed beef has five times the cla of grain fed. There is also CLA sold as a supplement, but made from sunflower oil. It has a slightly different chemical structure and is not nearly as effective, though the vegans won;t believe that, of course. Being in mammal milk also suggests it is vital for infant health and possibly brain development. [1]This study found that CLA was a "potent inhibitor" of colon cancer. This supports the empirical results like that of the Tuoli people in NW China, who are dairy herders and have the lowest rates of colon cancer in the country. It might also explain why reduce butter and beef consumption over recent decades has coincided with an increase in colon cancers - it used to be 37th most common cancer and now is 3rd. The fact that (normal) colon cells live on butyric acid might have something to do with this too...

1. <http://www.ncbi.nlm.nih.gov/pubmed/16563722>

### **Bayesian Shangri-La Diet (2012-11-15 06:20)**

In July, a Cambridge UK programmer named [1]John Aspden [2]wanted to lose weight. He had already lost weight via a low-carb (no potatoes, rice, bread, pasta, fruit juice) diet. That was no longer an option. He came across the Shangri-La Diet. It seemed crazy but people he respected took it seriously so he tried it. [3]It worked. His waist shrank by four belt notches in four months. With no deprivation at all.

Before he started, he estimated the odds (i.e., his belief) of three different outcomes predicted by three different theories. What would happen if he drank 300 calories (2 tablespoons) per day of unflavored olive oil (Sainsbury's Mild Olive Oil)? Aspden considered the predictions of three theories.

I called my three ideas of what would happen [= three theories that make different predictions] if I started eating extra oil Willpower, Helplessness and Shangri-La. (1) Willpower (W) is the conventional wisdom. If you eat an extra 300 calories a day you should get fatter. This was the almost unanimous prediction of my friends. Your appetite shouldn't be affected. (2) Helplessness (H) was my own best guess. If you eat more, it will reduce your appetite and so you'll eat less at other times to compensate, and so your weight won't move. Whether this appetite loss would be consciously noticeable I couldn't guess. This was my own best guess. (3) Shangri-La (S) is your theory. The oil will drop the set point for some reason, and as a result, you should see a very noticeable loss of appetite.

[4]More about these theories. His original estimate of the likelihood of each prediction being true: W 39 %, H 60 %, S 1 %. He added later, "I think I was being generous with the 1 %". After the prediction of the S theory turned out to be true, the S theory became 50 times more plausible, Aspden decided.

I like this a lot. Partly because of the quantification. If you were a high jumper in a world without exact measurement, people could only say stuff like "you jumped very high." It would be more satisfying to have a more precise metric of accomplishment. It is a scientist's dream of making an unlikely prediction that turns out to be true. The more unlikely, the more progress you have made. Here is quantification of what I accomplished. Although Aspden could find dozens of online reports that following the diet caused weight loss, he still believed that outcome very unlikely. Given that (a) the obesity epidemic has lasted 30-odd years and (b) people hate being fat, you might think that conventional wisdom about weight control should be assigned a very low probability of being correct.

I also like this because it is the essence of science: choosing between theories (including no theory) based on predictions. The more unlikely the outcome, the more you learn. You'd never know this from 99.99 % of scientific papers, which say nothing about how unlikely the actual outcome was a priori – at least, nothing numerical. I can't say why this happens (why an incomplete inferential logic, centered on p values, remains standard), but it has the effect of making good work less distinguishable from poor work. Maybe within the next ten years, a wise journal editor will begin to require both sorts of logic (Bayesian and p value). You need both. In Aspden's case, the p value – which would indicate the clarity of the belt-tightening – was surely very large. This helped Aspden focus on the Bayesian aspect – the change in belief. This example shows how much you lose by ignoring the Bayesian aspect, as practically all papers do. In this case, you lose a lot. Anyone paying attention understands that the conventional wisdom about weight control must be wrong. Here is guidance towards a better theory. If not mine, you at least want a theory that predicts this result.

2. <http://johnlawrenceaspden.blogspot.com/2012/07/shangri-la-diet.html>
3. <http://johnlawrenceaspden.blogspot.com/2012/11/shangri-la-diet-month-four-success-im.html>
4. <http://johnlawrenceaspden.blogspot.com/2012/07/shangri-la-diet-experiment.html>

---

Tuck (2012-11-15 08:07:49)

"I can't say why this happens (why an incomplete inferential logic, centered on p values, remains standard), but it has the effect of making good work less distinguishable from poor work." I think you just answered your own question. There's a whole industry of academies, scientists working at those academies, and journals those scientists publish in to advance at their academies that depends on good work being less distinguishable from poor work. A better standard might reveal that a lot of those scientists aren't doing valuable work... Seth: Why would a journal editor care about protecting them? My favored explanation is inertia.

jimrandomh (2012-11-15 10:47:54)

One of my preferred theories (not mentioned here) is regression to the mean: diet is part of a very complicated system, and making a big change to your diet is akin to taking a reroll; if your health is below average it has a good chance of being an improvement, simply by regression to the mean. Shangri-La is unusual in that it has a high change-size-to-effort ratio (10+ % of calories without needing to learn any recipes or discard any foods).

Kayode (2012-11-15 12:46:27)

Seth, Any good books on understanding p values, bayesian probability and how its used in scientific research? I have a hard time grasping these concepts. Seth: John Kruschke's book: <http://www.indiana.edu/~kruschke/DoingBayesianDataAnalysis/>

random\_process (2012-11-15 13:59:52)

Seth, I tried the Shangri-la diet but not rigorously enough. I wanted to make another go at it since the other diets that work (like low carb) are proving too hard for me. I tried with flax seed oil and nose clipping but there was always a after taste. I like flax seed oil but fear that the it was not flavorless enough to qualify. Will taking fish-oil capsules satisfy as "taste less calories" instead of extra-light olive oil? thanks for your blog - it is a trove of ideas! :) Seth: Yes, capsules = smell-less calories. However, you have to take a lot of capsules/day (about 30, too many, in my opinion) to get enough calories. You might try rinsing your mouth with water after nose-clipping flaxseed oil.

Alex Chernavsky (2012-11-15 21:19:16)

I bought a noseclip used by swimmers, but it wasn't tight enough, and I could still taste whatever I was consuming. I now pinch my nose shut with my hand when I take coconut fat, and I drink four or five mouthfuls of warm water (after sloshing it around my mouth first). When I drink flaxseed oil, I don't pinch my nose. Perhaps I should - maybe I'd lose more weight if I did. Seth: Some of the noseclips I've used are adjustable. Some aren't.

Scott Pierce (2012-11-16 23:18:36)

I read the book when it came out and followed it for a short while but here recently I realized that I had been following the protocol unwittingly. I had been taking MCT oil to drive up my ketone levels. It is almost completely flavorless and has other benefits as well if anyone wants to give it a try. I recommend the Now brand easily found on amazon. Seth: Since you started the MCT oil (how long ago?), has your weight changed?

Paul N (2012-11-25 00:05:38)

Jim Purdy (2012-11-16 22:06:55)

Animal self-medication? Really? So animals, living in the wild, are able to take actions to ward off diseases and pathogens? You mean that millions of years of Darwinian evolution have selected for healthful behaviors? Nobody who understands evolution should be surprised. But BigPharma and their shill salespersons (a.k.a. MDs) keep insisting on drugs and surgeries and devices that interfere with naturally evolved healing processes. Do very many medical schools even bother to teach courses – or majors – in evolutionary medicine to medical students? Of course not! BigPharma companies and their shill doctors would lose billions in annual profits if people would follow other animals' examples and just eat fresh natural foods. JimPurdy.blogspot.com jimpurdy1943@yahoo.com

Paul N (2012-11-18 21:03:46)

The FBI investigation into the Petraeus affair has widened - it turns out that people - everywhere - have been having sex, and [1]for quite some time!

### **Taobao's Double Eleven: World's Biggest eHoliday (2012-11-17 05:00)**

Do the heads of eBay and Amazon know about the Chinese shopping site [1]Taobao (like eBay without auctions)? If so, why don't they imitate it? Maybe they can't match its bigger selection (e.g., food, detergent) and better prices, but they could imitate the better seller feedback and instant communication (chat boxes) with sellers.

In [2]my theory of human evolution I propose that we have ceremonies, rituals, and festivals (and associated holidays) because they caused trading that would otherwise not have taken place. Ceremonies and so forth increased the demand for certain goods – gifts and high-end clothes, for example. These goods are important economically far out of proportion to their volume or monetary value or daily use because they increase innovation. They help the most skilled artisans– the ones most likely to innovate – make a living.

The leaders of Taobao understand this function of festivals/holiday and have put it to use: They have created new festivals/holidays. The biggest is Double Eleven (November 11), which started five years ago. On Double Eleven, a large fraction of taobao merchants have discounts, big (50 %) and small (5 %). Sales have grown each year and this year reached about \$3 billion,[3] according to one site. According to a Chinese friend, the sales were about \$10 billion. CyberMonday (about \$1 billion in 2011) is far behind

I have never read about this function of ceremonies, festivals, etc., in any economics book or paper. Double Eleven shows their economic force. This neglect is an example of what I consider the biggest problem with modern economics: lack of attention to and lack of understanding of innovation.

## How I Read (2012-11-18 05:00)

In [1]a review of a book by Alice Munro, Charles McGrath, who edited her at The New Yorker, wrote:

Many of these stories are told in Munro's now familiar and much remarked on style, in which chronology is upended and the narrative is apt to begin at the end and end in the middle. She has said that she personally prefers to read stories that way, dipping in at random instead of following along sequentially,

That's what I do. Most books I find are improved if I start in the middle and hop around. Doing so adds difficulty and mystery, which otherwise they are deficient in. Same reason I usually like reality shows more than scripted shows, scripted shows lack that attractive raw edge. Spy magazine had an article about writing guidelines for a woman's magazine. The guidelines said start in the middle: Talk about someone ("he" this, "he" that) before identifying them.

A few great writers (Vladimir Nabokov, Jane Jacobs, Tolstoy) I don't do this with. Some true crime (The Stranger Beside Me by Ann Rule) I don't do it with. But most books benefit.

1. [http://www.nytimes.com/2012/11/18/books/review/dear-life-stories-by-alice-munro.html?nl=books&emc=edit\\_bk\\_20121116&r=0&pagewanted=all](http://www.nytimes.com/2012/11/18/books/review/dear-life-stories-by-alice-munro.html?nl=books&emc=edit_bk_20121116&r=0&pagewanted=all)

---

Terry Elliott (2012-11-18 07:06:37)

I have read many places that reality shows are scripted, too. Sad, isn't it ? Seth: A reality-show producer told me they do stuff to increase conflict.

Aaron Blaisdell (2012-11-18 08:47:14)

Doing this with a novel would give me an anxiety attack. But I love to ski around at random or at least nonlinearly in text books.

TomGinTX (2012-11-18 11:05:24)

Have you ever heard anyone say "uh" in a reality show?

Chuck (2012-11-18 14:03:19)

"The guidelines said start in the middle: Talk about someone ("he" this, "he" that) before identifying them." This is exactly how my wife talks. She'll start a conversation in the middle of the story she is relating. I've gotten use to it and can follow along quite well (once I ask who "he", "she", "them" etc are). When we're with company, I sometimes have to stop her so the other listeners, who have puzzled looks on their face, can catch on/up. Funny thing is, it never bothers her, she just keeps on telling her story, always with a smile and a laugh. Cheers

Alex Chernavsky (2012-11-18 14:37:58)

Chuck, I've noticed that not many people know how to tell stories in a coherent, engaging fashion (at least, not when those stories are at all involved). In a related matter, I've also noticed that very few people know how to give a good lecture.

Adam (2012-11-18 16:13:16)

My mother & grandmother used to always have conversations in pronouns. No one else in my family could ever figure out who or what they were talking about, but they knew somehow.

Paleo Retiree (2012-11-18 22:22:44)

My wife does that thing with pronouns too – zooming into stories and anecdotes without telling anyone who she's talking about. But I believe it's something many women tend to do. The novelist Tom Perrotta once wrote about a guy whose woman was upset with him and talking in ways he couldn't follow, but "Dave knew better than to ask her to clarify her pronouns." My wife tends to get a bit annoyed when I stop her and ask her who she's referring to – evidently I'm expected to be totally on board with her thought processes. Or maybe just to read her mind, I'm not sure which.

Alex (2012-11-19 15:42:18)

I'm with Aaron on this one. I would be anxious skipping around a narrative. It would spoil my sense of the writer's structure. I have no trouble with nonlinear storytelling, such the series "Damages" on FX or the movie "Memento", but I would not enjoy skipping around the story myself. On the other hand, when I tell my husband a story you would swear I wrote it out on cards and then shuffled them before reading aloud. We'll have to ask Deborah Tannen if it's just a wife thing.

## **Flaxseed Lowers Blood Pressure (2012-11-18 05:00)**

[1]A new study found that ground flaxseed powerfully lowers blood pressure:

A patient population with peripheral artery disease (PAD) was selected as ideal to benefit from dietary flaxseed. . . . Patients received 30g of milled flaxseed (or placebo) each day over 6 months. [I eat 50 g/day – Seth] . . . No significant adverse events were associated with flaxseed ingestion. . . . SBP in the placebo group increased by 3 mmHg and DBP remained the same over the experimental period. However, SBP levels were 10 mmHg lower ( $P<0.04$ ) and DBP was 8 mmHg lower ( $P<0.004$ ) in the flax group compared to placebo. In the flaxseed group, patients with a SBP  $<140$  mmHg at baseline did not receive an anti-hypertensive effect but patients who entered the trial with a SBP  $>140$  mmHg at baseline obtained a sustained and significant 15 and 7 mmHg reduction in SBP and DBP, respectively, during the six months. . . . one of the most potent anti-hypertensive effects ever observed by a dietary intervention.

This supports my belief that we can improve our overall health by trying to improve our brains (which are more sensitive than the rest of the body). I have blogged about flaxseed oil [2]many times. I became interested in it when I noticed it improved my balance. Balance measurements showed that the optimal dose (2-4 T/day) was higher than flaxseed oil manufacturers suggested. Then I and others noticed that taking this amount of flaxseed oil produced [3]big improvements in gum health. Tyler Cowen, for example, [4]no longer needed gum surgery. Go home, said the

surgeon.

Thanks to Grace Liu.

---

David (2012-11-18 08:51:09)

it says milled flaxseed, not flaxseed oi. Could lignans or other constituents of the milled seed contribute to the effect, or is it the oil? The excerpt doesn't say what underlies the mechanism for BP modulation. Seth: That's a good point. You're right, it could easily be the lignans not the oil that produces the BP improvement.

Paul N (2012-11-18 11:25:34)

An interesting [1]review article from 2004 investigated numerous cardiovascular benefits of flaxseed, flax meals (no oil) and flax oil (no lignans). The results? "Flaxseed contains 35 % of its mass as oil, of which 55 % is alpha-linolenic acid (ALA). Flax meal, which is devoid of oil, contains the lignan secoisolariciresinol diglucoside (SDG). Flaxseed, flaxseed with very low ALA, flaxseed oil, flax lignan complex (FLC), and SDG reduce the development of hypercholesterolemic atherosclerosis by 46 %, 69 %, 0 %, 73 %, and 34 %, respectively, in the rabbit model. FLC and SDG slow the progression of atherosclerosis but have no effect in regression of atherosclerosis. Suppression of atherosclerosis by flaxseed is the result of its lignan content and not the result of ALA content." The study goes on to say; "Flaxseed and flaxseed oil do not have antioxidant activity except they suppress oxygen radical production by white blood cells. Flaxseed oil/ALA has variable effects on inflammatory mediators/markers (interleukin [IL]-1beta, IL-2, IL-4, IL-6, IL-10, tumor necrosis factor-alpha, interferon-gamma, C-reactive protein, and serum amyloid A). Doses of ALA less than 14 g/d do not affect inflammatory mediators/markers, but 14 g/d or greater reduce inflammatory mediators/markers." if flaxseed oil is 55 %ALA, and you need a minimum 14g of ALA, then you need 25g of flaxseed oil, which is about 30mL. Seth's dose for noticeable reduction in inflammation of 2tbsp is 40 mL, so in great agreement with this study! So flax oil is anti-inflammatory, and flax meal is anti-atherosclerotic, sounds like ground flaxseed, rather than just oil, is the way to go. Flax does have a bunch of phytoestrogens, and their effects -good or bad- are not all known, but one well known effect is to induce premature birth in pregnant women. Finally, there are some toxins in flaxseed (not oil) -cyanogenic glycosides - which can be reduced by [2]fermentation And, our old friends, lactobacillus, [3]can do this This might explain why my flax sourdough (made with kefir whey) bubbles/expands much more than my buckwheat sourdough - getting rid of all that cyanide!

1. <http://www.ncbi.nlm.nih.gov/pubmed/19568181>
2. <http://www.ncbi.nlm.nih.gov/pubmed/22530603>
3. <http://www.ncbi.nlm.nih.gov/pubmed/10634708>

Jim Purdy (2012-11-18 13:56:48)

Seth said: "This supports my belief that we can improve our overall health by trying to improve our brains" Wouldn't protecting the blood-brain-barrier be a good first step to improve our brains, by keeping out disruptive chemicals and pathogens? If so, should we avoid man-made chemicals that cross the blood-brain-barrier - things like sugar alcohols, antihistamines, and ace inhibitors? Better yet, let's avoid all unnecessary drugs and the doctors that prescribe them.

Alex Chernavsky (2012-11-18 14:48:10)

@Paul N, do you ferment your own flax seeds? If so, what is your procedure? I'm interested in trying it. Thanks.

Nina (2012-11-18 16:37:20)

I take flaxseed oil regularly but have noticed no improvement in bp or gum health as a result. I made pizza last night with flaxseed and almond crust and was surprised to see my blood pressure was much lower than it had been for weeks.

Paul N (2012-11-18 20:59:36)

@ Alex, The procedure is, really, quite simple. Get some Kefir - store bought or (much better, and surprisingly simple) make your own. I use kefir instead of yoghurt as kefir has yeasts in it. Get some flour - I make flax "flour" by putting flax seeds in a coffee grinder. I then mix this 50/50 with buckwheat flour, though I have also done it with rice, quinoa, amaranth and sorghum flours (I used to use wheat and rye in my pre-paleo days) In a quart size canning jar (or other non-metallic container) mix 1 part kefir to 2parts (by volume) flour, and then add enough water to make a soft paste (not a thick dough). Jar should be no more than half full. Leave it on the countertop overnight and then put it in the fridge, and leave for another day, or two. It is then ready to use. To keep a continuous culture, which I do, you simply add enough flour (and water) to at least double the volume, and put 1/3 to 1/2 of that back into the container - and use the rest for whatever it is your are making. The culture gets better with each "generation" When I am making a batch of something, I make up the mix from the sourdough starter and leave it out overnight - it will double in volume. if making something like pancakes, involving eggs, only add these right before you cook. I also mix in a saturated fat, like butter or coconut oil - the saturated fats help protect the omega3s against oxidation. Rye traditionally makes the best (most active) sourdoughs, but I have found my 50 % flax to be even more active. Using 100 % flax doesn't give very good texture. Do not use high heat when cooking with flax... Warning - making sourdough (and kefir) is addictive! All you could ever want to know (and then some) about kefir, and where I got the sourdough concept from, is at [1]Dom's Kefir Site

1. [http://users.chariot.net.au/~dna/kefir\\_cheese.html#kefir-straightjacket-pizza](http://users.chariot.net.au/~dna/kefir_cheese.html#kefir-straightjacket-pizza)

Alex Chernavsky (2012-11-19 06:58:20)

Paul, OK, thanks. You're not concerned with the micro-organisms breaking-down the omega-3 fatty acids in the flax? Also, do you use the culture as simply a starter when making something else (like sourdough bread), or is the culture ever the main ingredient in the dish? Are there recipes? Thanks again.

Bruce McCullough (2012-11-19 16:33:34)

Seth, Do you take both flaxseed oil and flaxseed meal? Bruce Seth: Yes. flaxseed oil in Berkeley, ground flaxseed in Beijing.

Paul N (2012-11-24 00:07:24)

Hi Alex, I really have no idea what the microbes do or don;t do to the ALA in flax, that's an interesting topic to research! I do know that kefir grains work best i whole milk, they do some kind of digestion on the butterfat, though I don;t know what, specifically. As to the culture, I keep the quart jar about 3/4 full. I sometimes take some out and just mix some eggs and cook directly as pancakes or dumplings. i don;t make bread anymore but if i was then I would use half the jar to start the bread mix (and let it sourdough for a day or two) and then top up the jar with fresh flour and water (and a pinch of salt). Be aware that sourdoughing whole grain flour (even buckwheat) can make for really \*sour\* dough. As for recipes, well,the theme of Seth's site is self-experimentation, and that's how I approach cooking in general!

DanD (2012-12-13 09:35:12)

Seth, how big of an issue is rancidity / freshness in regard to flaxseed or flax oil? Some sources seem to say I'll be in danger if I don't buy the oil or flaxseed every few days, freeze it, only grind it the day I'm consuming it. What do you think is a sensible regimen regarding avoiding rancid flax? Seth: I discovered it was a big issue. At one point I got flaxseed oil in China. I later discovered it was inactive. Presumably due to too much time at room temperature. Now I used freshly ground flaxseed. Haven't had trouble with inactivity. I freeze the flaxseeds when they arrive (at my apartment) but they are not frozen before that (e.g., for months after being harvested). And they sit at room temperature in my apartment for a week or so.

DanD (2012-12-14 21:53:05)

I appreciate the help. May I ask how you know whether the flax has become inactive? Is there a physical effect that fails to occur in that case? Thanks again. Seth: I was measuring how fast I can do arithmetic. When I switched from the Chinese flaxseed oil

to the American flaxseed oil (better refrigerated) I suddenly got faster. I had previously found, using American flaxseed oil, that flaxseed oil produces this effect (faster arithmetic). That's how I learned that the Chinese flaxseed oil was inactive – or less active.

### No More Antioxidants (2012-11-20 04:11)

[1]This fascinating blog post by Josh Mitteldorf points out that antioxidants, once believed to reduce aging by reducing oxidative damage, have turned out to have the opposite effect. By reducing a hormetic effect, they make things worse. I'm a friend of Bruce Ames, one of main proponents of the free radical theory of aging. I've heard him talk about it a dozen times. The turning point – the beginning of the realization that this might be wrong – was [2]this 1994 study, which found that beta-carotene, a potent antioxidant, increased mortality. Bruce did not have a good explanation for the counter-theoretical result. However, Mitteldorf doesn't mention an important fact which doesn't fit his picture. Selenium, a potent antioxidant, also powerfully reduces cancer. Don't stop taking selenium.

I also like [3]this theoretical paper by Mitteldorf about why aging evolved (turning off certain genes reduces aging) and how its evolution – not easily explained by conventional evolutionary ideas – is part of a range of phenomena that the conventional ideas cannot explain. One reason, maybe the main reason, that aging is adaptive is very Jane Jacobsian: it makes the community more flexible. Less likely to repeat old ways of doing things.

Thanks to Ashish Mukarji.

1. <http://joshmitteldorf.scienceblog.com/2012/11/19/anti-oxidants-a-disappointment-or-worse/>
2. <http://www.ncbi.nlm.nih.gov/pubmed/8127329>
3. [http://www.protein.bio.msu.ru/biokhimiya/contents/v77/pdf/bcm\\_0716.pdf](http://www.protein.bio.msu.ru/biokhimiya/contents/v77/pdf/bcm_0716.pdf)

---

Sarah Madden (2012-11-20 05:13:35)

Hi Seth, I think there is more to this than just anti-oxidants = bad. That trial with beta carotene is confounded by the addition of synthetic alpha tocopherol. We know from other trials that synthetic fat soluble vitamins are bad news. The effect of vitamin e is not even that consistent: <http://www.ncbi.nlm.nih.gov/pubmed/19267994> I personally take a low dose natural vitamin e supplement that includes mixed tocotrienols (which balance tocopherols) and ultrathione, a highly absorbable version of glutathione, the so-called 'master anti-oxidant', I've had great results with both. Namely glowing skin and good stable mood. I think hormetic stress is important, in fact that is how polyphenols found in vegetables and exercise benefits are now thought to come about, but that doesn't mean the chronic oxidative stress we experience in modern life is not to be avoided and mitigated where possible. Seth: The trial was not confounded. Betacarotene and vitamin e were varied separately. There were four groups, on other words.

Jim Purdy (2012-11-20 08:00:38)

Three take-away lessons that I get from all these changing and contradictory studies – and all the drug recalls – are very simple: 1. All the smug self-proclaimed experts are not as smart as they think they are. 2. We should be very careful about interfering with biological processes that have been selected for over millions of years of Darwinian evolution. 3. We should be especially careful about all the highly profitable new drugs, devices and surgeries. As for me, I'm perfectly happy to let other people

be the guinea pigs taking – and dying from – all the addictive painkillers, antidepressants, proton pump inhibitors, and other magic BigPharma potions.

vimal (2012-11-20 08:52:37)

Does the 1994 study and the vast majority of all vitamin studies show that supplementing with isolated chemically derived vitamins is neutral at best and negative at worst? One wonders if the 1994 study results would have been different had one group eaten carrots and the other not eaten carrots. Seth: If you include animal (usually rat or mouse) experiments, I believe the answer is no, they don't show that. The vast majority of vitamin experiments with isolated chemicals (lab chow with chemical X vs lab chow without chemical X) have produced positive results. That's where the concept of vitamin came from. In these studies the animals were made sure to have a deficiency in the vitamin. Whereas human studies often fail to make sure there is a deficiency.

Nancy Lebovitz (2012-11-20 13:27:34)

If I remember correctly, the idea that antioxidants would slow aging was very abstract. The takeaway might be that biology is sufficiently complex that experiments and knowledge of specific mechanisms are essential.

dearieme (2012-11-20 17:14:11)

O/T: the flu. <http://www.independent.co.uk/life-style/health-and-families/health-news/scientists-urge-ministers-tell-truth-on-overhyped-flu-vaccine-8336184.html>

Sean (2012-11-21 01:14:58)

"The vast majority of vitamin experiments with isolated chemicals (lab chow with chemical X vs lab chow without chemical X) have produced positive results. That's where the concept of vitamin came from. In these studies the animals were made sure to have a deficiency in the vitamin. Whereas human studies often fail to make sure there is a deficiency. " Good point, Seth. The argument I've heard for why the CARET study possibly failed, from the Eades, is that the immune system uses free radicals and that supplying one specific anti-oxidant could actually compromise that process. Hence the need to supply a natural smorgasbord of anti-oxidants and their raw materials to let the body select what it wants to use. But I've heard the same argument used for vitamins, whereas it's clear that extracted or isolated vitamins will always cure their associated deficiency diseases. I'm pretty much agnostic on anti-oxidants at this point.

Jenny (2012-11-21 10:30:02)

Seth - I can't get through to Mittleldorf's theoretical paper. Is that generalised or just from here. Seth: I fixed the link. It should be easier now.

George @ the High Fat hep C Diet (2012-11-21 11:55:24)

There are certain diseases - hepatitis, pancreatitis, and various types of poisoning are good examples - where antioxidants - pretty much generically and indiscriminately - can save your life. Otherwise, beneficial antioxidants fall into groups: 1) antioxidants that are also pro-oxidants, so don't suppress important ROS signalling. Co-enzyme Q10, carnitine, ascorbate. 2) components of antioxidant enzymes; selenium, zinc, copper, manganese, iron and NAC/cysteine/glutathione. 3) plant polyphenols that stimulate the formation of enzymes as in 2) and may not even be antioxidant in vitro except as chelators of free iron. Fat soluble antioxidants are valuable in some contexts - mixed carotenoids or astaxanthin protect against UVA in summer, tocopherols protect against the oxidation of the PUFAs that naturally contain them. Apart from grossly purified or otherwise unnatural forms of some fat-soluble antioxidants - as in CARET - where the vitamins were, to be fair, combined with smoking, which no-one thinks is a good idea - it is hard to discover much harm in the clinical literature. There's not a lot of benefit either, but I imagine that a varied approach tailored to the needs of each patient - which has NEVER been the kind of medicine subject to published analysis, yet is the only responsible way to practice - can produce marked benefit - this was certainly my experience.

George @ the High Fat hep C Diet (2012-11-21 11:56:24)

Sorry, 3) above should read "in vivo" Carry on.

George @ the High Fat hep C Diet (2012-11-21 17:10:14)

Should a healthy person supplement antioxidants? Maybe not. Should an unhealthy person try those antioxidants that are most likely to be of benefit for their symptoms? Why not? If you can relieve pain or reverse degenerative disease with supplements, and you do notice improvement, and you have avoid the added risk of using drugs, maybe you've achieved something. Many effective antioxidants, such as polyphenols, curcumin, astaxanthin, acetyl-carnitine, lipoic acid have anti-inflammatory effects or metabolic effects that might overshadow their ability to quench free radicals. Free radical signalling is significant in the cytosol, between mitochondria and nucleus, and promotes (via FOXO1) elevations in glutathione and antioxidant enzymes - it is self regulating. When this self-regulation breaks down (because minerals or protein is deficient, toxins are involved, or hyperglycaemic conditions are causing maladaptive signalling, i.e. oxidative stress) then supplementary antioxidants are cytoprotective.

pond (2012-11-24 09:31:54)

I once read a book by the professor who called himself the "Father of Antioxidants" and he wrote about the anti- and pro-oxidant effects. He boosted the notion of 5 antioxidants that work in concert: one would produce oxidants that another would gobble onto, and so on in a ring. C, E, selenium I think were 3 of the 5. According to this notion, doing a study of one antioxidant alone would lead to contradictory results, depending on whether the other antioxidants were being consumed in diet in enough quantities. The synergistic notion makes sense in evolutionary biology terms, since traditionally we consumed all vitamins in our diet.

La Revue du Net Paleo #19 | Paléo Lifestyle (2012-11-27 01:59:00)

[...] Une découverte étonnante sur les antioxydants. [...]

George @ the High Fat hep C Diet (2012-11-27 17:50:51)

You could explain the CARET study without mentioning ROS signalling. High vitamin A intakes disordering cell growth signalling in people already deficient in vitamin D; high carotene intakes in oxidative stress conditions forming toxic apocarotenoids, which further disrupt vitamin A signalling. The net effect could also be immunosuppressive. I'm not saying this does in fact explain it, but there are other pathways involved other than the antioxidant effect. "A common explanation of the effect is that when retinoic acid is liganded to RAR-beta (Retinoic Acid Receptor beta), the complex binds AP1 (Activator Protein 1). AP1 is a transcription factor that binds to DNA and in downstream events promote cell proliferation. Therefore, in the presence of retinoic acid, the retinoic acid:RAR-beta complex binds to AP1 and inhibit AP-1 from binding to DNA. In that case, AP1 is no longer expressed, and cell proliferation does not occur. Cigarette smoke increases the asymmetric cleavage of beta-carotene, decreasing the level of retinoic acid significantly. This can lead to a higher level of cell proliferation in smokers, and consequently, a higher probability of lung cancer. Another  $\beta$ -carotene breakdown product suspected of causing cancer is trans-beta-apo-8'-carotenal (common apocarotenal), which has been found in one study to be mutagenic and genotoxic in cell cultures which do not respond to  $\beta$ -carotene itself." <http://www.news-medical.net/health/Beta-Carotene-Side-Effects.aspx>

## **The Physical Spacing Effect: New Way to Learn Chinese Works Shockingly Well (2012-11-22 05:00)**

Two years ago I taped a bunch of Chinese flash cards (Chinese character on one side, English meaning on the other) to my living room wall (shown above). I'll study them in off moments, I thought. I didn't. It was embarrassing when guests pointed to a card and said, "What's that?" But not embarrassing enough.

A few weeks ago, I can't remember why, I decided to test myself: how many do I know? About 20 %. I'll try to learn more, I thought. I was astonished how fast I learned the rest. It took little time and almost no effort. I didn't need "study sessions". I glanced at the array now and then, looked for cards I didn't know yet, and flipped them to find out the answer. After a few days I knew all of them.

I had been using conventional methods (flash cards studied in ordinary ways, Anki, Skritter) and an unconventional method ([2]treadmill study) to learn this material for years. In spite of spending more than a hundred hours on each method, I had never gotten very far. I might get to 500 characters and backslide due to lack of study. Treadmill walking while studying made studying much more pleasant, but I found I would still prefer to watch TV rather than study Chinese. Maybe part of the problem was too many days skipped. After you skip four days, for example, you have a discouragingly large number of cards to review. Plainly these methods work for others. They didn't work for me.

After my success with the two-year-old cards, I put up another array (8 x 13). I already knew about 40 % of them. I learned the rest in a day or so. Then I put up a 10 x 12 array. I tested myself on them one morning. I knew 30 of them. I studied them during the day for maybe 30 minutes in little pieces throughout the day. The next morning I tested myself again (about 12 hours from the last time I had studied them). Now I knew 105 - I had learned 75 in one day, almost effortlessly. That day I studied for a few minutes. The next morning I tested myself again. Now I knew all but one of them.

I did not notice any facilitation of learning when I studied flash cards while walking around. In that case, unlike this one, (a) they were in roughly the same position relative to my body and (b) had no consistent physical location. I noticed the same facilitation of learning during a Chinese lesson in a cafe. I was having trouble remembering three Chinese words (e.g., the Chinese word that means graduate). I wrote each of them on a piece of paper with the English on one side and the Chinese on the other. I put the three pieces of paper at widely-separated places on the table. I studied them briefly, a few seconds each. That was enough. Five days later I still remember them (having used them a few times since then). This happened in a place (a cafe) with which I wasn't familiar, unlike my living room. Maybe the general principle will be it is much easier to learn an association if it is in a new place.

It's very early in my use of this method, but I doubt it's a fluke. It connects with several things we (= psychology

professors) already know. 1. The mnemonic device called [3]the method of loci. You put things you want to learn in different places in a well-remembered landscape (e.g. different places in a building you know well). Usually the method is used to learn lists, such as the digits of pi or the order of cards in a deck. You place different items in the list in different places in the imagined place. Then you "walk" (in your imagination) through the imagined place. The method dates back to ancient Rome. 2. [4]The power of interference. Thousands of experiments have shown that learning X makes it harder to learn similar Y. X and Y might be two lists, for example. The greater the similarity, the bigger the effect. What you learn on Monday makes it harder to learn stuff on Tuesday (proactive interference); what you learn on Tuesday makes it harder to remember what you learned on Monday (retroactive interference). To anyone familiar with these experiments, my discovery has a simple "explanation": spatial interference. 3. Evolutionary plausibility. The study of printed materials (e.g., books) is so recent it is hard to imagine our brain has evolved to make it easy. In contrast, thousands and millions of years ago we had to learn about things in different places. Learning about food and danger in different places was especially important. When language arrived, the necessary learning (at first, attaching names to objects) is quite similar to my learning because the named objects were in different places. The study of vitamins and to some extent my work (especially the power of morning faces) show how hard it can be to figure out what we need for our brains and bodies to work well. How non-intuitive the answers may be.

These results suggest a new mnemonic device: Stand in front of an empty wall and imagine on the wall the associations you want to learn, each association in a different place like flashcards. This is a fast way of putting each association in a different place.

Adam (2012-11-22 05:59:55)

Interesting! I know what you mean about falling behind on Anki reviews. I have over 1500 cards due right now in my Intermediate Mandarin deck. It may even be possible to use locations in a similar way within a program like Anki. I was trying to remember that the Tuberoinfundibular pathway is in the Arcuate nucleus & that the Arcuate nucleus is in the Hypothalamus. I had a couple of cards to memorize these & just kept failing over and over again. At last, I figured it out: Step 1. Chunk Hypothalamus, Arcuate nucleus, & Tuberinfundibular pathway together into one piece: HAT. (1st letter of each name) Step 2. Create a spatial schematic. Mine is: Hypothalamus Arcuate nucleus Tuberoinfundibular pathway (Hopefully my spaces are not parsed out! Should be on the 2nd line & on the 3rd) For whatever reason, this makes it incredibly easy for me to remember the components & their relation to one another. I can see it in my head, whereas before I was just \*describing\* it in my head.

Adam (2012-11-22 06:01:28)

Ha... parsed out my spaces AND my description of my spaces. It should be like this: Hypothalamus \_ \_ Arcuate nucleus \_ \_ \_  
\_Tuberoinfundibular pathway

Txomin (2012-11-22 06:21:09)

Learning kanji is tough as fluent speakers (native and otherwise) will tell you. Anyway, the problem with these approaches is a lack of context. Take the plunge and read. A lot. Seth: One reason I am surprised how well this works is the lack of context. Thanks for the advice.

Javeux (2012-11-22 06:26:22)

I used Anki to review Chinese characters for Japanese (about 2100 everyday-use ones), but it would've been much harder without using Heisig's mnemonic system to initially "learn" them. It's all a waste of time if you don't actually get any practice though. Reading isn't such a big deal, but writing requires quite a bit of effort for me. I've been trying to learn shorthand, which is a whole other beast, since writing them out in full looks ridiculously unnatural. Luckily, people generally type nowadays instead.

august (2012-11-22 09:41:42)

hmmmm, outside my office is a wall-sized whiteboard, as in the entire wall is a whiteboard. i wonder if it would be helpful to write on that wall but spaced far apart as a way of studying? i can put it up, then glance at it as i walk by.

Tom (2012-11-22 10:06:16)

Fascinating, and it makes sense.

Robert Simmons (2012-11-22 12:30:15)

I seem to be a bit slow today, but could you spell out exactly what the technique is? You seem to be testing yourself with flashcards, then hanging the ones you don't know on the wall to look at occasionally. Is that right/100 % of it? Seth: That's close. Yes, it is very simple. I just hung a deck of flashcards on the wall. I knew some of them sort of. The technique: Put the flashcards you want to learn on the wall (as in the picture). Study them. That's all. Result: I learned them much much faster and with much less effort than I did with other ways of studying flashcards.

tim perkis (2012-11-22 13:46:52)

This effect of 'memory loci' really is a strong one, and ignoring it is one major flaw of book e-readers. There is a tactile and spatial component to navigating and remembering the contents of a physical book that is almost completely missing in ebook readers. Unfortunately, the current thinking seems to be that the indicator of current position in a book is a distraction, and the trend is to hide it most of the time. I think it actually needs to be made more prominent and ever-present Seth: Yes, that's a good point.

Robert Simmons (2012-11-22 14:52:40)

So I guess where I'm confused is how this differs from what you were doing in the first paragraph. Is it that now you actually study them, whereas before they just hung there and you mostly ignored them? Seth: That's right. What's new is that I put a little bit of effort into learning them.

Brent Durbin (2012-11-22 15:30:39)

I've also been studying Chinese, with varying degrees of motivation, over the past couple years. It is a constant process of relearning things I have forgotten. But after a break, I find that I usually come back strong, relearning what I had forgotten and picking new things faster than in the past. I have noticed that it gets easier and easier to learn new characters - I assumed that it was because I have become more familiar with the radicals, tones, sounds and connections between the characters. So while there may be something to the physical spacing, don't discount the previous hundreds of hours you've spent "preparing" your mind to learn. Seth: You make good points. The sudden jump in learning speed - I never came anywhere close to learning 75 characters in a day - is what impresses me.

jack in davao (2012-11-22 20:20:08)

One other thing you might try with those flash cards on your wall, which I've found generally helpful, is to print the characters in colors according to tone (e.g. all first tone characters are blue, etc). Seems to make remembering the tones much easier, at least for me, when I see the character in my mind I see it in color and subconsciously that seems to make me associate it with

the tone.

Adam (2012-11-22 21:18:54)

Anki has a Mandarin plug-in that automatically converts pinyin into color-coded text. Sometimes the tones it selected were wrong though & I didn't find it that helpful, but maybe I didn't give it enough time. One thing I used temporarily when I was struggling with tones was to visualize the characters in a location associated with the tone. The rising tone characters were in the attic, the declining tone characters in the basement, the 3rd tone characters on a teeter-totter, & the flat tone characters were images in the flat glass table in my dining room. If I see the character for rabbit, I know it is rabbit. I might not remember what tone it is though. Then I remember, the rabbits are all running wild in the basement & I know that rabbit must be 4th tone.

Three Pipe Problem (2012-11-23 11:27:41)

This is great. I think this is relevant to graphical user interfaces (GUI's) in software and web design. As you experiment with different matrix sizes and so forth, you may want to have a look at Fitt's Law, for example, and think about the matrix density as something to play with. The classic PC/Mac desktop is basically a detailed grid of things that one might think would be hard to remember the location of. But people perform well at this, many people even prefer messy desktops since they have little trouble remembering where things are. I once had a coworker who would occasionally just cut and paste most of the shortcuts on his Desktop (including the \*old\* "Old Desktop" folder) into a folder called "Old Desktop", which was then placed in a corner of the new (mostly blank) desktop. This created a series of fossilized "layers" of desktops. He was quite fast at finding even old, obscure things with this. The Windows Phone and new Microsoft Windows 8 user interface (formerly called Metro) conventions seem to rely on this sort of capability, and take it to the next level. Similarly, if you think about the detailed sequence of relatively precise locations many people learn with muscle memory in order to quickly navigate hierarchical menus, it's the same – people are good at mapping positioning to recall of lots of items. What I wonder is have you tested in a way that neutralizes the positioning during recall. In other words, is your learning still great when you can't look at the matrix during recall? Seth: I have done a test where the recall test for two types of study – conventional, with everything in one place, and new, with different things to be learned in different places – and found a huge advantage for the new way. However, it was just one test. I will do more tests where the testing method is the same for the two types of learning.

Ian (2012-11-23 23:41:48)

A wonder if this relates to Night Sky constellations with their different positions and shapes - not that far removed from the Chinese characters you're studying. Maybe this is how we evolved to read in the first place, by pointing to different constellation and naming them.

Neil K (2012-11-25 16:43:57)

This makes perfect sense. Look up "memory cathedral" - it's a memory technique used for centuries, where you imagine things you need to remember being in a giant building. I listen to a lot of podcasts on my iPhone while I'm walking around, and I try to always vary my route. I find that if I ever relisten to those podcasts, I am immediately transported back to where ever I was when I first heard it.

August (2012-11-26 09:45:59)

I've failed to keep up my Anki studying as well. It seems to me it ought to be part of the browser and keep track of everything- emails, feeds, flashcards, etc... As a separate program it ends up being something I remember I am supposed to be doing whenever I am doing something else; if it were integrated almost everything (including TV) could be in it. This would be especially useful for those of us trying to limit light exposure at night- maximize our use of daylight computer hours. Seth: cool idea.

ryan (2012-12-19 08:40:03)

I'm having a hard time wrapping my head around this. It's so simple, and un-intuitive. Placing knowledge and sticking it on a place. So now we have a mandarin wall, a programming wall (with different colors), and maybe a to do list on a fridge. Maybe that's why people put it on the fridge. It's accessible and people frequently goes to the fridge. Now we just need more walls. LOL

---

Adam (2012-11-24 17:26:27)

The H. pylori study might also mean that NSAIDs & Aspirin are safer than we think if the background rate of Ulcers is higher than previously believed. There were a couple of studies with long-term Aspirin use that showed no increase in the risk for GI bleed (WARFASA & ASPIRE, for those interested).

Jim Purdy (2012-11-24 23:09:27)

Ineffective ulcer treatments and ineffective flu vaccines are just minor parts of the unscientific disaster known as modern medicine. Much more harm is caused by the millions of unnecessary prescriptions that doctors write for addictive painkillers and antidepressants and steroids. Instead of spending billions of dollars on new health care programs, here are my suggestions:

1. Let's completely shut down the entire US medical system, with exceptions for obvious (and fixable) problems like broken bones.
2. If anybody feels sick, give them free placebos in the form of Peanut M & Ms. Nuts and chocolate have proven health benefits, unlike most BigPharma junk.
3. Let's retrain all MDs to become public school teachers. Maybe they'll develop some humility when they discover that, unlike adult patients, kids of all ages are more likely to ask "Why?" or say "No" – or just laugh – when an arrogant old fool in a long white coat says something totally stupid.
4. After at least 10 years as teachers, the former MDs could be evaluated. Those that have actually developed humility and skills at listening and explaining could return to medicine. Those who are still arrogant fools could be sent to different jobs, like working with large carnivorous animals in wildlife sanctuaries. Lions and tigers will enjoy the new protein sources.

## Thirty Years of Breast Cancer Screening May Have Done More Harm Than Good (2012-11-25 05:00)

[1]A recent op-ed in the New York Times by H. Gilbert Welch, a co-author of Overdiagnosis, describes a tragedy of ignorance and overconfidence. The current emphasis on regular mammograms began thirty years ago. They will prevent breast cancer, doctors and health experts told hundreds of millions of women. They will allow early detection of cancers that, if not caught early, would become life-threatening. The campaign was very successful. According to [2]the paper cited by Welch, about 70 % of American women report getting such screening.

It is now abundantly clear this was a mistake. If screening worked perfectly – if all of the cancers it detected were dangerous – the rate of late-stage breast cancer should have gone down by the amount that the rate of early-stage breast cancer went up. Over the thirty years of screening, the rate of (detected) early-stage breast cancers among women over 40 doubled, no doubt because of screening. (Over the same period the rate of early-stage breast cancers among women under 40 barely changed.) In spite of all this early detection and treatment, the rate of late-stage breast cancer among women over 40 stayed essentially the same. All that screening (billions of mammograms), all that chemo and surgery and radiation, all that worry and time and misery – and no clear benefit to the women screened and those who paid for the screening, treatment, and so on. Roughly all of the "cancers" detected by screening and then, at great cost, removed, aren't dangerous, it turns out.

Quite apart from the staggering size of the mistake and the long time needed to notice it, screening has been promoted with specious logic.

Proponents have used the most misleading screening statistic there is: survival rates. A recent [3]Komen Foundation campaign typifies the approach: "Early detection saves lives. The five-year survival rate for breast cancer when caught early is 98 percent. When it's not? It decreases to 23 percent." Survival rates always go up with early diagnosis: people who get a diagnosis earlier in life will live longer with their diagnosis, even if it doesn't change their time of death by one iota.

Did those making the 98 % vs. 23 % argument not understand this?

I applaud Welch's research, but his op-ed has gaps. A unbiased assessment of breast cancer screening would include not only the (lack of) benefits but also the (full) costs. Treatment for a harmless "cancer" may cause worse health than no treatment. Maybe chemotherapy and radiation and surgery increase other cancers, for example. What about the effect of all those mammograms on overall cancer rate? Welch fails to consider this.

Welch also fails to make the most basic and important point of all. To reduce breast cancer, [4]it would be a good idea to learn what environmental factors cause it. (For example, maybe [5]poor sleep causes breast cancer.) Then it could be actually prevented. Much more cheaply and effectively. Yet the Komen Foundation and the Canadian Breast Cancer Foundation say "race for the cure" instead of trying to improve prevention.

LemmusLemmus (2012-11-25 05:44:53)

Another - albeit nonfinancial - cost of positive screening results is that people worry, and quite a bit. This is the aspect Gerd Gigerenzer emphasizes in his book about the topic.

idyll (2012-11-25 07:34:15)

Trying to get my head around this phrase 'harmless cancer'. What cancer would that be? Seth: Almost all of them, apparently, when it comes to early-stage breast cancers.

Judy B (2012-11-25 09:19:59)

Even with articles like this, the medical industry will not change their guidelines. Mammography (and the attendant procedures, drugs, etc.) simply makes too much money! I would also like researchers to look at that other sacred cow: colonoscopy. I have never seen anything about the numbers needed to treat or the harm that can be done with this procedure...

MikeW (2012-11-25 09:45:27)

Research into cancer prevention is worth pursuing, but so is the development of reliable screening tools. I think few would dispute that when cancer is detected and treated early - before metastasis - lives are saved. That's why Welch's findings are so surprising. What I get out of the op-ed isn't that cancer screening is useless, but that for some reason mammography is a poor screening tool. Maybe breast tumors that eventually advance to late-stage cancer grow so quickly that a biennial mammography is unlikely to catch them in time. Or maybe it's a mistake to focus on gray and white blotches on a mammogram; we should be looking at biochemical blood markers instead. In any case, early detection should still be a major emphasis in cancer research. Seth: The op-ed makes me think the whole thing should be investigated: how did such a big mistake come to happen? Was evidence ignored? Misleading? Or what?

Tom (2012-11-25 10:30:00)

LemmusLemmus wrote: *Another – albeit nonfinancial – cost of positive screening results is that people worry, and quite a bit.* They're not too happy with having their breasts hacked off for no reason, either.

LemmusLemmus (2012-11-25 11:05:09)

Tom: I would think that only happens when it's been confirmed that things are really serious - but I don't know, and maybe that's wrong.

Zach (2012-11-25 12:05:23)

LemmusLemmus: recall the anecdote in the Gigerenzer book of the German doctor who committed suicide upon learning that mammograms only had a 10 % chance of having cancer. He had recommended a mastectomy to anyone who screened positive.

Jim Purdy (2012-11-25 13:03:55)

If you take your well-running car to some auto repair chains for a free diagnosis, you can count on getting a report that says your car needs \$500 worth of repairs. If you feel fine and go to some doctors for a checkup, you can count on getting lots of prescriptions for addictive junk. At least the car shop won't turn you into a crazed drug addict. Skip the doctor, and just get an oil change and a car wash.

LemmusLemmus (2012-11-25 13:46:16)

Zach: No, I don't - apparently it's too long since I've read the book (five years?).

Pensamentos desconexos | Blog Pra falar de coisas (2012-11-25 17:08:24)

[...] 2. Porque testes como mamografia e PSA podem fazer mais mal do que bem. (aqui tem um link). [...]

anon (2012-11-26 06:07:00)

It's far worse than just unnecessary worry and unnecessary mastectomies. Tamoxifen is often prescribed for breast cancer (and for pre-cancerous masses that get picked up on mammograms). The side effects of Tamoxifen include endometrial (uterine) cancer. In other words, current screening and treatment practices are actually, literally causing cancer in previously cancer-free patients.

dearieme (2012-11-26 07:05:48)

Remember Gigerenzer's point that German oncologists recommend breast screening for their patients but not for their wives or themselves.

Murray H. Seltzer, M.D. (2012-11-26 11:25:36)

The above article and some of the comments are about as relevant as those who have never had a sexual experience but feel qualified to write and comment about sex. My qualifications to discuss the subject of screening are that I have been involved in breast cancer screening and surgical operations for over 40 years. Money was not the motivation. Decreasing true misery was the motivation. First you must accept that people do get breast cancer. There may be differing levels of aggressiveness but you cannot always define the level as easily as may be thought. Most of you were not present when we did "radical mastectomies" requiring multiple blood transfusions as the only treatment. Most of you were not there when such patients frequently required post operative psychiatric care. Most of you were not there when radiation was primitive and we did not even have good chemo. So yes, there is waste, false positives, anxiety and increased cost. All of it worth it when 80 % + of the patients can have lumpectomies and save their breasts, require less psychiatric care, and have better qualities of life. Don't throw out the baby with the wash. Refine the indications and frequency required for screening mammography. Perhaps every 2 or 3 years rather than annually. Find ways to reduce cost by having technicians read films rather than radiologists and only have radiologists for more difficult situations. The cynicism and false expertise noted above are offensive to those of us who have been on the front lines, seen the worst and are truly happy for the not-so-perfect improvements that we currently have. Seth: What is the evidence that screening mammograms have done more good (you call them "improvement") than harm? I don't see it. When you say that screening mammograms "save their breasts" you fail to understand the study that Welch describes. It concluded that essentially all of the "cancers" detected by screening mammograms do not endanger breasts.

Evelyn M. (2012-11-26 11:57:31)

Once again, there doesn't seem to be any discussion of the cost of the mammography program. Why is no one ever willing to mention the vast sums of money wasted on so-called "preventive" medicine instead of encouraging people to see a physician only when they are troubled by an actual symptom?

Judy B (2012-11-26 12:28:42)

Amen, Evelyn! Predictable response from Dr. Seltzer. We need to be doing more questioning of guidelines and protocols rather than less!

Tom (2012-11-26 16:59:49)

Seth Roberts wrote: *What is the evidence that screening mammograms have done more good (you call them "improvement") than harm? I don't see it. When you say that screening mammograms "save their breasts" you fail to understand the study that Welch describes. It concluded that essentially all of the "cancers" detected by screening mammograms do not endanger breasts.* Michael Eades wrote an interesting post on his Protein Power blog a year or so ago where he talked about the surprising fact that (in his opinion) virtually no physicians are competent to read scientific papers, even in their fields. In Eades' opinion, what they can understand is "Case Reports" – basically chronological stories of an individual patient's experience. That said, the fact that they don't know how to read a study doesn't mean that they don't think they already know everything in it. :-) Seth: That understates it. Dr. Seltzer failed to understand an op-ed in the New York Times about his own area of expertise.

Jason (2012-11-26 21:17:33)

ACR/SBI: Bleyer and Welch Breast Cancer Screening Article in NEJM Deeply Flawed and Misleading The article by Bleyer and Welch[1] in the New England Journal of Medicine, which suggests that screening mammography finds many cancers that would not advance to kill patients, is based on false assumptions. The thesis depends on their suggestion that the incidence of breast cancer is much higher than would have been expected had screening not been initiated. The authors suggest that the baseline incidence of breast cancer would have increased by 0.5percent each year, when in fact, the data show that it would likely have increased by twice that amount. The incidence of invasive breast cancer has actually increased by 1percent per year for decades.[2] In 1940, it was 60/100,000. By 1980, prior to any screening, it had risen to 100/100,000.

If there had been no screening, and the rate had continued to increase as it had for 40 years, the incidence in 2008 would have been over 130/100,000. In fact, due to prevalence screening, where new women who have never been screened enter the screened population each year, and lead time (cancers found earlier due to screening), the incidence of breast cancer, without any "overdiagnosis" would have been expected to be even higher than 130/100,000. In reality, it was lower even than that, at 127/100,000. Therefore, not only is there no evidence of the authors' claimed "overdiagnosis," but it is likely that treatment of ductal carcinoma in situ (DCIS) over the past decades has reduced the incidence of invasive cancers. This is in addition to the observed 30 percent reduction in deaths each year due largely to screening. While the authors observe that screening is associated with a reduction in advanced stage cancers, they fail to recognize the fact that a reduction in advanced stage disease is not required to have a reduction in deaths from screening. Staging is a crude effort to group cancers for purposes of trying to understand how they respond to therapy. Unfortunately, there are deaths from breast cancer among women with all stages of these malignancies, even the very earliest, DCIS. The thesis by Bleyer and Welch is simply wrong. Misleading articles, based on faulty assumptions and methodology are counterproductive. If such misinformation is used to determine screening guidelines and recommendations, the cost may be lost lives. Seth: Thanks. This can be found at <http://www.itnonline.com/article/acrsbi-bleyer-and-welch-breast-cancer-screening-article-nejmdeeply-flawed-and-misleading> It would be more interesting if (a) it was attributed to someone and (b) it didn't make a big mistake in the very beginning. Bleyer and Welch did not suggest that "the incidence of breast cancer is much higher than would have been expected had screening not been initiated" – that is, that screening increased breast cancer. They concluded that screening did not lower the rate of life-threatening breast cancer. The stuff about the incidence of breast cancer is irrelevant. No one says that screening is supposed to change the rate of breast cancer – it just detects some breast cancers earlier than they would otherwise be caught.

Tana (2012-11-27 08:32:17)

Seth, here is an interesting site to check out- <http://www.breastcancerchoices.org> They have a lot of information that most doctors don't talk about, including the connection between iodine deficiency and breast cancer.

Links & comment « Rhymes With Cars & Girls (2012-11-27 08:40:51)

[...] push for lotsa breast cancer screening may have done more harm than good. Nice going, [...]

Theragingwalrus (2012-12-04 04:06:50)

I'm having a hard time grasping your take on the 98 % vs 23 % issue - could you spend a few words on that? Seth: If a disease is detected earlier it will be survived longer, even if nothing else changes. Even if it is not treated. Breast cancer left untreated would be survived longer if it were detected earlier. So the mere fact of better five-year survival does nothing to support screening campaigns. Reasonable comparisons were available: age-equalized rates of dying of breast cancer for women who are and are not screened, for example. Results of experiments, even better. Yet the proponents of screening chose a grossly misleading comparison. Why?

## **The Emphasis on Education in China (2012-11-28 05:33)**

One of my students grew up and went to high school in Nanjing, population 8 million. Her acceptance to Tsinghua was such a big deal that when her acceptance letter reached the local post office they called to tell her. The post office also alerted journalists. When the letter was delivered to her house, there were about 20 journalists on hand. One of them, from a TV station, asked her to say something to those who failed.

dearieme (2012-11-28 06:33:40)

When I was a lad (and far fewer of us went to university) the results of our Finals would be published in the papers. So if I told you the year, you could look me up in the Telegraph or Times and see whether I got a First, an Upper Second and so on. The contrast between this and the American custom of secrecy in such matters is striking. Things change: a few years ago one undergraduate at Cambridge objected to having his name and College shown on the results lists. He got his way.

joe king (2012-11-28 14:32:42)

"asked her to say something to those who failed." Yes, I want fries with that!

Jim Purdy (2012-11-28 21:26:50)

Joe King, is there anything wrong with working in a restaurant? Isn't that honest work?

garymar (2012-11-29 14:02:27)

Don't students who fail to reach Tsinghua, but still have high scores, get a slot in the next tier of universities? Seth: Yes. In that sense the reporter's question is bizarre. But I suspect the reporter could argue that it is not so bizarre.

James (2012-12-02 02:34:49)

Seth: Have you seen this [1]piece that touches on the problems with living in China? Relevant quote: "The domestic Chinese lower education system does not educate. It is a test centre. The curriculum is designed to teach children how to pass them. In rural China, where we have lived for seven years, it is also an elevation system. Success in exams offers a passport to a better life in the big city. Schools do not produce well-rounded, sociable, self-reliant young people with inquiring minds. They produce winners and losers. Winners go on to college or university to take "business studies." Losers go back to the farm or the local factory their parents were hoping they could escape." Seth: Thanks. Yes, I read that article, but I'd forgotten that part.

## Assorted Links (2012-11-29 05:00)

- [1]Experiments suggest flu shots reduce heart attacks and death. Huge reduction: 50 %. The new report (a conference talk, not a paper) is a reanalysis of four earlier experiments. I was surprised to learn that the CDC uses heart attack outbreaks to locate flu outbreaks, implying that the new finding is not a fluke – there really is a strong connection. I already knew heart attacks are more common in the winter, which also supports a connection with flu.
- [2]Une histoire des haines d'écrivains by Boquel Anne and Kern Etienne. Published 2009. About literary feuds. One of my students was reading a Chinese translation.
- [3]Correspondences between sounds and tastes.
- [4]Report on fraudulent Dutch research. "The 108-page report says colleagues who worked with Stapel had not been sufficiently critical. This was not deliberate fraud but 'academic carelessness', the report said." I doubt it. Based on my experience with Chandra, I believe Stapel's colleagues had doubts but did nothing from some combination of careerism (doing something would have cost too much, for example a lot of time, and gained them nothing), ignorance (not their field), and decency (they saw no great value in ruining someone). I wonder if the report considered these other possible explanations (careerism, ignorance, decency).

Thanks to Tim Beneke.

---

dearieme (2012-11-29 07:17:13)

My GP's waiting room (NHS) is festooned with posters urging patients over 65, and those with heart problems, to get a flu jab.

MikeB (2012-11-29 08:26:08)

Scientists urge ministers: tell truth on 'over-hyped' flu vaccine The vaccine given to millions of people each year in Britain is "over-promoted" and "over-hyped" and the protection it offers against the seasonal illness has been exaggerated, scientists claim. Professor Osterholm, an US public health adviser whose report "The Compelling need for game changing influenza vaccines" was published last month, said: "Our report is very comprehensive. It took three years, we reviewed 12,000 peer reviewed papers and interviewed 88 experts from around the world. We took no money from the private sector or governments - we had no conflicts of interest. "The most striking outcome is that we have over-stated the effectiveness of the influenza vaccine. That has had a very dampening effect on the development of new vaccines." <http://www.independent.co.uk/life-style/health-and-families/health-news/scientists-urge-ministers-tell-truth-on-overhyped-flu-vaccine-8336184.html>

dearieme (2012-11-30 04:22:22)

@MikeB: the two pieces of work may be compatible if you interpret the Indy article as saying that flu vaccine does only a mildly useful job at shortening flu episodes and keeping people out of hospital, and interpret the conference talk as saying "but it seems to do a fine job at preventing heart attacks". Still, it's always worth remembering that "All medical research is rubbish" is a better approximation to the truth than almost all medical research.

MikeB (2012-11-30 11:23:02)

@dearieme: I like your quote "All medical research is rubbish" is a better approximation to the truth than almost all medical research What are the chances that this research is true and important? 1 in 10000? Meanwhile, here is something to consider: Both of the following statements can be true at the same time: Healthy people taking statins reduce their heart attack risk by 33 %. Healthy people taking statins have a 99 % chance of receiving no benefit. Reductions in relative risk don't matter as much when overall risk is low. Let's say your risk of having a heart attack over 5 years is 3 per cent. Let's say a statin reduces that risk to 2 per cent. Relative risk has fallen by a third, right? But the real reduction in risk (known as the 'absolute risk reduction') is just 1 per cent (3 per cent minus 2 per cent).

Jo (2012-11-30 13:51:21)

I found the second part of the article about flu shots even more interesting than the reduction in heart attacks. A second study they discussed showed that patients with ICD's or implantable cardiac defibrillators (the small units that shock your heart back into rhythm if it stops or otherwise gets out of rhythm - so this is a separate subset of patients with heart problems) had fewer ICD shocks during flu season if the patients had gotten a flu shot. For someone with an ICD getting shocked is unpleasant (and scary), which is why the researchers picked up on it but what would be the connection with a flu shot??? Very interesting but why this would work is a mystery.

dearieme (2012-11-30 15:51:59)

At least the reduction in number of ICD shocks is, I imagine, "hard data": the ICDs are presumably interrogated regularly, so there's no need to rely on the accuracy of people's reports?

Adam (2012-11-30 18:10:00)

@MikeB Likewise if your risk for having a heart attack goes down, but the chance of that heart attack being fatal goes up, have you really benefited?

### How Helpful Are New Drugs? Not So Clear (2012-11-30 20:13)

[1]Tyler Cowen links to [2]a paper by Frank Lichtenberg, an economist at Columbia University, that tries to estimate the benefits of drug company innovation by estimating how much new drugs prolong life compared to older drugs. The paper compares people equated in a variety of ways except the "vintage" (date of approval) of the drugs they take. Does taking newer drugs increase life-span? is the question Lichtenberg wants to answer. He concludes they do. He says his findings "suggest that two-thirds of the 0.6-year increase in the life expectancy of elderly Americans during 1996-2003 was due to the increase in drug vintage" – that is, to newer drugs.

An obvious problem is that Lichtenberg has not controlled for health-consciousness. This is [3]a standard epidemiological point. People who adopt Conventional Healthy Behavior X (e.g., eat less fat) are more likely to adopt Conventional Healthy Behavior Y (e.g., find a better doctor) than those who don't. For example, a study found that people who drink a proper amount of wine eat more vegetables. Another reason for a correlation between conventionally-healthy practices is mild depression. People who are mildly depressed are less likely to do twenty different helpful things (including "eat healthy" and "find a better doctor") than people who are not mildly depressed. (And mild depression seems to be common.) Perhaps doctors differ. (Lichtenberg concludes there are big differences.) Perhaps better doctors (a) prescribe more recent drugs and (b) do other things that benefit their patients. Lichtenberg does not discuss these possibilities.

A subtle problem with Lichtenberg's conclusion that we benefit from drug company innovation is that drug-company-like thinking – the notion that health problems should be "solved" with drugs – interferes with a better way of thinking: the notion that to solve a health problem, we should find out what aspects of the environment cause it. I suppose this is why we have Schools of Public Health – because this way of thinking, advocated at schools of public health, is so incompatible with what is said and done at medical schools. Public health thinking has a clear and impressive track record – for example, the disappearance of infectious disease as a major source of death. There are plenty of other examples: the drop in lung cancer after it was discovered that smoking causes lung cancer, the drop in birth defects after it was discovered that folate deficiency causes birth defects. Thinking centered on drugs has done nothing so helpful. Spending enormous amounts of money to develop new drugs shifts resources away from more cost-effective research: about environmental causes and prevention. Someone should ask the directors of the Susan K. Komen Foundation: Why "race for the cure"? Wouldn't spending the money on prevention research save more lives?

---

js (2012-12-01 16:07:06)

This is a little uncharitable it seems to me. Drug vintage isn't correlated with BMI, smoking status or a large number of medical conditions. If what you're saying were true, we wouldn't expect this. Those using newer drugs should be healthier. You need

to have a more sophisticated story to refute Lichtenberg's argument. Seth: I think Lichtenberg – and anyone else who wants to know the value of new drugs – should consider these alternatives. Perhaps there is data that will help assess them. Lack of significant correlation with BMI, etc., isn't much of an argument. Let's take BMI. Maybe current advice about how to reduce BMI isn't very good? Lots of people are health-conscious and weigh more than they would like. Take smoking. Maybe this is heavily determined by culture? Take Medical Condition X. Maybe we don't know how to prevent Medical Condition X? So that even people who do conventionally healthy things (e.g., "eat healthy") still have Medical Condition X at the same rate as those who don't eat healthy. Maybe these indices of health (BMI, etc.) are insensitive? Because if people live longer, shouldn't they be healthier (weigh less, etc.) while they are alive? Quite apart from that, lack of significant correlation with BMI, etc., does nothing to refute the possibility that good doctors help their patients in important ways besides prescribing newer drugs.

dearieme (2012-12-01 18:07:21)

But what is healthy eating? Obviously it must include fish and chips for Friday lunch, bacon and egg at least once a week, the occasional beer, a glass of wine with dinner most evenings, toast and marmalade at breakfast, lots of tea and coffee, and plenty of smoked salmon, sardines, mackerel pate, pork pies, muscat grapes, cherries in brandy, hummus and olives, apples and cheese, duck, lamb, roast vegetables, baked potatoes, watercress sandwiches, parsnip soup, ... and generally Things I Like. Obviously.

Robbo (2012-12-02 14:07:21)

"the disappearance of infectious disease as a major source of death. " Are not drug companies are due a lot of the credit, for example through developing the manufacture of penicillin ? Without drugs, would not infectious diseases such as tuberculosis still be a terrible scourge ? Seth: Drug companies did not invent vaccines. Far from it.

dearieme (2012-12-02 15:23:29)

"developing the manufacture of penicillin ?": the key steps were done at Oxford, not by drug companies.

js (2012-12-02 18:30:28)

It is a bit of a stretch to say that the new drug vintage patients are likely to be healthier on unobservables when they are not healthier on observables. Obviously it is theoretically possible as you point out, but why is it probable? I completely agree with the doctors point, by the way. That is a valid criticism of this research design. Seth: What do you mean by "the doctors point"? I'm afraid I don't understand.

Adam (2012-12-02 19:34:42)

Tuberculosis vaccine was developed by the Pasteur Institute, a non-profit, and Streptomycin was discovered at Rutgers University.

js (2012-12-03 10:17:51)

I meant that physicians who prescribe newer vintages might help their patients in other ways. This is a different from saying that patients who are prescribed newer vintages are different from those who aren't. Seth: Thanks for clarifying that.

## 7.12 December

### More Sitting, More Diabetes: New Meta-Analysis (2012-12-03 05:00)

The first evidence linking exercise and health was a study of London bus workers in the 1950s. The drivers, who sat all day, had more heart attacks than the ticket takers on the same buses, who were on their feet all day. It was a huge advance – evidence, as opposed to speculation. The results were taken countless times to imply that exercise reduces heart attacks but epidemiologists understood there were dozens of differences between the two jobs. For example,

driving is more stressful than ticket taking. Maybe stress causes heart attacks.

The first time I learned about this study, I focussed on two differences. The ticket takers were more exposed to morning sunlight (on the top deck of double-decker buses) and they were on their feet much more. Maybe both of those things – morning sunlight exposure and standing a lot – improve sleep. Maybe better sleep reduces heart attacks. The London data were not consistent with the claims of aerobic exercise advocates because the ticket takers did nothing resembling aerobic exercise.

Later[1] I discovered that walking an hour/day normalized my fasting blood sugar levels – another effect of "exercise" (but not aerobic exercise). I had data from only one person (myself), but it was experimental data. The treatment difference between the two sets of data being compared (no walking versus walking) was much sharper, in contrast to most epidemiology. I am sure the correlation reflects cause and effect: Walking roughly an hour/day normalized my blood sugar. This wasn't obvious. The first thing I tried to lower my fasting blood sugar levels was a low-carb diet, which didn't work. I discovered the effect of long walks by accident.

[2]A recent meta-analysis combined several surveys that measured the correlation of how much you sit with other health measures. The clearest correlation was with diabetes: People who sit more are more likely to get diabetes. Comparing the two extremes (most sitting with most standing), there was a doubling of risk. Because people who stand more walk more, this supports my self-experimental findings.

I found pure standing (no walking), or leisurely (on-off) walking, did not lower fasting blood sugar (which I measured in the morning). After I noticed that walking an hour lowered blood sugar, I tried slacking off: wandering through a store or a mall for an hour. This did not lower fasting blood sugar. I concluded it had to be close-to-nonstop walking. Someday epidemiologists will measure activity more precisely – with Fitbits, for example. I predict the potent part of standing will turn out to be continuous walking. Long before that, you can see for yourself.

1. <http://blog.sethroberts.net/2010/07/18/fasting-blood-sugar-reduced-by-walking/>

2. <http://www.ncbi.nlm.nih.gov/pubmed/22890825>

---

jofx (2012-12-03 14:34:30)

I wonder if there's any data on supermarket workers (shop floor vs checkout?). I worked in one for a few years and was incredibly unfit and ended up developing prediabetes, despite walking around (non-constantly) for the best part of 28-hours a week. It was funny how 5-minutes of light jogging practically knocked me out when I first attempted exercise, despite the "workout" I was getting from the job. HIIT helped turn me around, and you can find some studies that show the same kind of results, e.g. doubling the insulin sensitivity of a group of Iranian women in 12-weeks. Seth: I know of a study that found a correlation between jobs that required a lot of standing (such as supermarket checkout clerk) and MORE heart disease. That is, lots of standing in one place appeared to be bad for you. I agree about HIIT, that's what I do.

Celso (2012-12-03 15:36:45)

I've been leaning towards unsubscribing to your blog for a while, your writing has lost quality over the last few months. You have become too biased. Aerobic exercise has extremely positive effects on the body, and the way it functions, but you always depict it in a negative light. Either you hate aerobic exercising and should have a disclaimer whenever you mention the subject, or present data to the world that proves aerobics is not worth people's time (good luck with that). Otherwise you'll discredit everything else you write about, and that would be a shame. Thank you for the useful information on other subjects, I will no longer subscribe to you. Seth: Saying that non-aerobic exercise is good – which is what I say here – is not the same as saying aerobic exercise is bad.

peter (2012-12-03 16:00:38)

i was concerned with post-meal blood sugar and found that a relatively short walk after a meal (i.e., 15- 20 minutes) lowed my blood sugar 2 hours after a meal from 148 to around 100. So i do this twice a day. I also take cinnamon (ceylon not cassia; the latter, i understand, may dangerously thin one's blood) My recent recent blood test was well below 90. "While the two species of cinnamon share certain characteristics such as antimicrobial, and in terms of inhibiting the growth of fungi and yeast, and regulating blood sugar, their contents differ much in terms of the amount of coumarin, which is a naturally occurring substance with strong blood-thinning properties. The coumarin level in Ceylon cinnamon is negligibly small, while that in Cassia cinnamon is an appalling 1200 times higher. The ingestion of large amount of coumarin or consumption of coumarin over a prolonged period of time can cause serious health damages and a negative impact on the liver and kidney. German FDA has warned against consuming the excessive intake of Cassia bark due to its coumarin content. " Seth: Very interesting. Maybe my walking would be more effective if it were done right after meals.

dearieme (2012-12-03 16:12:58)

How about two 15 minute cycling trips per day?

Adam (2012-12-03 16:48:33)

@peter Congratulations & great job at taking responsibility for your health. In China they have a saying "百步走，活九十九" which means "walk 100 steps after a meal & live to 99 years old". Folk wisdom isn't \*always\* useless.

Txomin (2012-12-03 17:49:55)

Ticket takers also interact with an unusually high number of people.

Javeux (2012-12-04 07:36:39)

Celso, I think the data on resistance training and HIIT in particular is evidence that aerobic enthusiasts may be wasting (a relative amount of) their time, at least if using that time efficiently to improve their health is their goal. I think exercise of almost any kind should be encouraged over sedentary lifestyles, but I just wish aerobics wasn't the go-to solution for diabetics and others struggling with health problems, when there are much more effective, time-efficient alternatives that the general public seems oblivious to.

charlie (2012-12-05 07:45:05)

How is vigorous walking for an hour non-stop NOT "aerobic" exercise? Celso is quite right. This blog is way too self absorbed. Goodbye. Seth: Who said it was "vigorous" walking? It is/was ordinary walking. I've done thousands of hours of aerobic exercise. There's a big difference.

Ashish (2012-12-17 18:38:15)

The Ikea JERKER line, discontinued but often available on Craigslist, includes a couple of excellent standing desk models. It's by far the best thing I've done for my home office. Standing desks allow quite a bit of movement-in-place - it's not the same as being, say, a cashier. And, I hope it goes without saying, you want to be barefoot when you stand.

---

dearieme (2012-12-04 05:10:14)

As I understand it, heart disease rose from ca 1920-60 for reasons no-one understands, and has fallen since then for equally inscrutable reasons. (That doesn't stop medical men claiming the credit for the fall, of course.) Some people have discerned the pattern as resembling that of an infectious disease. As for diabetes, some of the rise will just be an artefact of changing the

blood sugar threshold used in the definition of diabetes, and some - at least in Britain - will be an effect of economic incentives: our doctors are now paid a bonus for diagnosing diabetes. There's nothing in the Guardian article to suggest that the diagram that has got the journalist's knickers in a twist shows age-corrected figures, so a third effect will be that diabetes is partly a disease of ageing, and we are an ageing society. Now, I ask myself, why do people lie - for that is effectively what they are doing - when they cite figures uncorrected for these effects. Why do they lie? Seth: I have no doubt that diabetes is increasing adjusted for age. For example, childhood diabetes is rapidly increasing. Because of the connection with obesity - which is obviously increasing, corrected for age - the increase in diabetes is not surprising. I hadn't realized the heart disease pattern suggests an infectious disease but lately I have been seeing more and more evidence that points that way.

Doug (2012-12-04 08:10:16)

God heals, and the doctor takes the fees. Benjamin Franklin

Rashad (2012-12-04 08:49:13)

Regarding lighting, I recently came across this program called f.lux which adjusts the color of your computer monitor based on time of day to more closely resemble natural light cycles. I found the default changes a bit too much, but at moderate settings it seems great. <http://stereopsis.com/flux/>

dearieme (2012-12-04 09:25:44)

"I have no doubt that diabetes is increasing adjusted for age." That statement sounds plausible to me: but then why must it so often be accompanied by lies? Because suppressing mention of the three effects I mentioned is lying: "suppressio veri".

dearieme (2012-12-04 09:26:33)

Why do you wish to draw our attention to unnecessary wisdom about tooth extractions?The Seth: The larger problem of too much medicine is important, I believe.

dearieme (2012-12-04 09:32:43)

By the by, I have long joked that Americans have a life expectancy below that of (say) Britons or Germans because Americans get too much dental treatment. Many a true word ...

Nancy Lebovitz (2012-12-04 12:31:19)

Do you have anything specific about an increase in childhood diabetes? Seth: [1]This article mentions a four-fold rise in Japan.

1. <http://care.diabetesjournals.org/content/27/7/1798.long>

Jo (2012-12-04 13:58:47)

I ignored the advice of several dentists when I was in my 20's who insisted I needed to have my wisdom teeth extracted - mostly because their warnings about future problems were so vague and they couldn't give me any actual numbers as to what my chances were of developing a problem, it always seemed as if they were relying on one or two individual horror stories they had seen among hundreds of patients rather than the actual likelihood of something occurring.

Alex Chernavsky (2012-12-04 14:32:37)

When I was in my late teens, I was told that I would probably need to have all four wisdom teeth removed. I naively agreed to it. When I had the first two removed, I experienced very unpleasant complications. First, i had an allergic reaction to the pain medicine. Then, the bleeding wouldn't stop, and I had to return to the oral surgeon for additional sutures. The anesthetic didn't work well for the second suturing, and I experienced a fair amount of pain during the procedure. I still have the other two wisdom teeth. They have not caused me any problems. And, to their credit, none of my subsequent dentists have made an issue of it over the years.

Nancy Lebovitz (2012-12-04 21:35:16)

Thanks for the link. It looks as though juvenile type 2 is very rare, though definitely increasing. Have you read a book called Diabetes Rising? It claims that diabetes has been increasing for the past century, and there isn't any theory which explains the increase.

Paul N (2012-12-05 15:55:36)

Article from earlier this year from the Chicago Tribune stating that diabetes rates among US teens [1] have doubled in the last decade. The "good" news was that teen obesity rates had stabilised at 20 %(!) (another 15 % overweight). Of course, their dietary advice is to eat "healthier" including, of course, more whole grains and low fat dairy. I am increasingly of the opinion that these American health officials are causing the epidemics they are observing. They also seem to still be of the opinion that obesity is causing diabetes, and therefore people should eat low fat, and whole grains, to avoid obesity. which they have been saying for decades now...

1. [http://articles.chicagotribune.com/2012-05-21/news/sns-rt-us-diabetesbre84k0x7-20120521\\_1\\_full-blown-diabetes-full-blown-type-sugar-levels](http://articles.chicagotribune.com/2012-05-21/news/sns-rt-us-diabetesbre84k0x7-20120521_1_full-blown-diabetes-full-blown-type-sugar-levels)

dearieme (2012-12-06 05:00:37)

"diabetes rates among US teens have doubled in the last decade" I dare say, Paul, but how big would the increase be if you allowed for the redefinition of what constitutes diabetes, and for the changing incentives for diagnosis (including that common incentive, fashion)?

Paul N (2012-12-06 12:07:52)

@ Dearieme, That is a good question, and I'm sure there is some fuzziness about the definition, especially for "pre-diabetes". What can't be argued is the shocking increase in overweight/obese teenagers in recent decades, so I'd wager that, regardless of the definitions, the actual incidence of diabetes has likely matched that rate, if not exceeded it. Given the links to things like sitting and diabetes, I expect modern teen behaviour - lots more time in front of a screen of some sort and less outside doing something - can only make it worse. It seems to be worst amongst black, latino and native american people - who also happen to be the poorer end of town. I suspect a combination of genetic susceptibility, and diet - eating even more cheap carbs, junk food etc - is at work here. We can argue about the definitions, but I don't think there's any debate that there is an increasing problem. After all, that's why the name was changed from "adult onset" diabetes to "type 2 diabetes"...

## **Who is the Richest Person in China? (2012-12-05 06:31)**

If you open the American edition of Forbes, you will find articles about the richest people in America. If you open the Russian edition, you will find articles about the richest people in Russia. If you open the Chinese edition, you will find articles about the richest people in America.

A Russian friend of mine noticed this. He happened to know an sophomore economics major at Tsinghua. It is incredibly difficult to get into Tsinghua and the economics major is the most desirable major of all. To be an economics major at Tsinghua you need a test score that is in something like the top 1 out of 100,000. Staggeringly high. My Russian friend asked the Tsinghua economics major, "Who is the richest person in China?"

The economics major didn't know. He seemed a little angry. "Why should I know? We've never been taught that," he said.

---

dearieme (2012-12-05 07:28:45)

"Why should I know? We've never been taught that": sounds like the sort of laddie who fails Oxbridge entrance interviews.

Richard Sprague (2012-12-05 07:39:20)

The authoritative Chinese publication on rich people is HunRun: <http://www.hurun.net/usen/NewsShow.aspx?nid=349>

Tom (2012-12-05 17:52:49)

Off topic, but a story you might like, Seth: The enteric coating commonly used in aspirin may render it useless in up to 40 % of the population, at least in terms of cardiac protectiveness. (The study didn't indicate whether aspirin's ability to relieve pain was also disabled.) <http://www.nytimes.com/2012/12/05/business/coating-on-buffered-aspirin-may-hi de-its-heart-protective-effects.html> The study was funded by Bayer, which sells mostly coated aspirin.

Adam (2012-12-05 17:54:55)

The richest man in China is Li Ka-Shing (李長春) as far as I know. "Richest person of Asian descent in the world" according to Wikipedia.

Tim Beneke (2012-12-06 11:20:35)

Li Ka-Shing is also quite a philanthropist – he funded a very nice building on the Berkeley campus that is named after him.

Adam (2012-12-06 16:36:29)

Can someone explain to me how Li Ka-Shing can be the richest person of Asian descent in the world but NOT be the richest man in China? He lives in Hong Kong, which is in China last time I checked. Are the other richest people in China not of Asian descent? Their names certainly seem Chinese...

## **Bariatric Surgery Linked to Acetaminophen Poisoning (2012-12-06 05:00)**

Acetaminophen is a pain killer found in many over-the-counter drugs, such as Tylenol, NyQuil and Sudafed. It can cause liver failure. [1]A new study at the California Pacific Medical Center in San Francisco reports that people who have had bariatric surgery seem to have a much higher risk of this:

Among 54 patients who had suffered acetaminophen-induced liver failure over a three-year period, 17 percent had had weight-loss surgery. . . . Less than 1 percent of the general population has had the surgery.

The study controlled for the possibility that people who have bariatric surgery are more likely to have liver failure unrelated to acetaminophen:

The researchers looked at 101 cases of acute liver failure seen at California Pacific Medical Center, more than half of which were caused by acetaminophen poisoning. Among the nine patients [of the 101] who had had weight-loss surgery, all of them had liver failure caused by acetaminophen overdose.

The article, by a reporter named Erin Allday, goes on to say:

At this time, there is no reason for bariatric surgery patients to be alarmed, and they should continue using acetaminophen if that's their preferred pain medication or their doctor has prescribed it.

Allday attributes this bizarre advice to unnamed "researchers and weight-loss surgeons." Of course bariatric surgery patients should be alarmed and cut down or stop using acetaminophen.

The next time someone says "correlation does not equal causation" or belittles epidemiology tell them about this case.

Thanks to David Archer.

Jim Purdy (2012-12-06 07:13:38)

The amazing wonders of modern medicine. But never fear. In another thousand years, maybe medicine will start to make a little progress. Maybe. [jimpurdy1943@yahoo.com](mailto:jimpurdy1943@yahoo.com)

Seth Roberts (2012-12-06 14:17:50)

I suspect this is an example of a general rule: ALL medicines and surgeries make ALL other medicines and surgeries more dangerous. If you take Drug A, Drug B becomes more dangerous. The term "drug interaction" obscures the truth that the interactions are always bad.

Adam (2012-12-06 16:43:26)

Seth, that is not completely true. Some drug interactions are actually sought out because they will have additive effects. Taking 2 blood pressure drugs is technically a drug interaction because they both cause lowering of the blood pressure (duplication of therapeutic effect), but in many cases that is the point. In HIV therapy, Ritonavir is used not as an antiviral drug, but because it inhibits the enzyme that breaks down other antiviral drugs, thereby "boosting" them. Seth: "Drug interaction" refers to changes in effectiveness or danger. Taking two blood pressure drugs at once does not reveal "interaction" unless their effects change. Sure, some drugs are specifically designed to make other drugs/surgery work better. Or reduce their side effects. The most common example is analgesics: Make surgery more bearable. They are exceptions to the rule, yes.

Txomin (2012-12-06 19:50:35)

It is dangerous to generalize. We would be far worse off without modern medicine. Seth: Yes, some parts of modern medicine unquestionably help, at least short-term. I have a harder time than you assessing the long-term effects, in particular the effects on innovation. For example, how have antibiotics influenced our understanding of disease?

Nancy Lebovitz (2012-12-07 00:21:02)

Also, people who've had bariatric surgery may be less able to absorb some medicines- a friend had to have her antibiotic dose increased when she had pneumonia.

Tom Myers (2012-12-08 06:03:16)

Anderson's response to Page's Long Tail study should be found at the top of a Google search for its title: "More Long Tail debate: mobile music no, search yes" But maybe that title is enough. :-)

Liz (2012-12-13 00:16:02)

Antibiotics wreak such havoc with the body's microbiome, it would be good to see stool transplants become a standard treatment/follow-up after a course of antibiotics, even if clostridium difficile is not causing problems. Obviously it would be preferable to use the patients own stool, as mentioned in the closing paragraphs of the article. The big question though - will people be able to get over the yuck factor? I suspect a majority will not....

## Online Teaching Versus What? (2012-12-09 05:00)

Is online teaching (e.g., [1]MOOC) a big deal? In [2]an essay ("Why Online Education Works"), Alex Tabarrok argues for the value of online education (meaning online lectures) compared to traditional lectures. A friend told me yesterday that MOOC was "a frontier of pedagogy". No doubt online lectures will make lecture classes cheaper and more available. Lots of things have gone from scarce/expensive to common/cheap. With things whose effects we understand (e.g., combs), the result is straightforward: more people benefit. With things whose effects we don't understand, the results are less predictable. Did the spread of sugar help us? Hard to say. Did the spread of antibiotics help us? Hard to say. It may have helped sustain simplistic ideas about what causes disease (e.g., "acne is caused by bacteria", "ulcers are caused by bacteria") reducing effective innovation. Do we have a good idea of the effects of lectures (or their lack of effect), or a good theory of college education? I don't think so. Could their spread help sustain simplistic ideas about education? Maybe.

As books spread, the teaching of reading increased. Everyone understood that books were useless if people couldn't read. The introduction of PCs was accompanied by user interface improvements. This helped PCs become influential-not restricted to hobbyists. Will online education be accompanied by similar make-it-more-palatable changes? I have heard nothing about this. Their advocates seem to think the current system is fine and if it could only be available to more people...

Online lectures will make much difference only if the cost and quality of lectures is the weakest link in what strikes me as a process with many links. It would be a coincidence if the link that can be most easily strengthened turned out to be the weakest link. For example, is the cost of lectures the main thing driving up the cost of college? That

would be wonderful if it were true, but I haven't seen evidence that it's true. At Berkeley, for example, there has been enormous growth in the administrator-to-faculty ratio.

Here are two arguments used to argue that online lectures are a big step forward:

It will help people in poor countries, like Zambia. There is a long history of people in rich countries misunderstanding people in poor countries. Several years ago I was in Guatemala. I heard about a school being built by a (rich country) religious group in a poor area. After two years, the American running it wanted to leave. No member of the community took it over. It disappeared. "Maybe they didn't want a school," said the graduate student who told me about it. Maybe few people in Zambia want online lecture classes. (I have no idea.) If so, the benefit will be small.

It will save labor. Each lecture will be viewed many more times. Saving labor is not always good. It is plausible that the growth of online lectures will mean fewer college professors. Colleges and universities are among the few places where people do research and almost the only places where they do unrestricted research. Most of the research is useless; a tiny fraction is enormously useful. At the moment, lectures subsidize research. By giving lectures, professors are allowed to do research. Fewer professors, less unrestricted research, less innovation. "Wasteful" lecturing might be labor we shouldn't save.

One thing I like about online classes is the possibility they will connect people who want to learn the same thing, like ordinary classes do. They can help each other, encourage each other, and so on. I have no doubts about the value of this. (I find language partners – I teach them English, they teach me Chinese – way more pleasant and helpful than tutors.)

At Berkeley, I tried to find good lecturers. With two exceptions (Tim White and Steve Glickman) I failed. Almost all lectures, even those by brilliant researchers, were dreary. ([3]A shining exception by Robin Hanson.) They suffered from a lack of stories and a lack of emotion. (At Tsinghua, things are worse. A friend who majors in bioengineering told me that 80 % of her teachers lecture by reading from the textbook.) The power of professors over students in some ways resembles the power of doctors over patients. Just as there is little pressure on doctors to understand disease (if antibiotics have bad effects, it doesn't harm the doctor who prescribed them), there is little pressure on most professors – at least at the elite research universities that produce online lectures – to understand education. At Berkeley, many professors say they teach their undergraduate students "how to think" or "how to think critically". In fact, they were teaching their students to imitate them. The simplest form of education. This is neither good nor bad – it depends on the student – but it is the opposite of sophisticated.

A few months ago I assigned my Tsinghua students (freshmen) to read 60 pages of [4]The Man Who Would Be Queen by Michael Bailey, a book full of stories and emotion. Any 60 pages, their choice. No test, no written assignment, no grade. One student told me it was the first book in English she'd ever finished. It was so good she couldn't stop reading. My assignment had changed real-life behavior: what my student read in her spare time. Maybe it changed her tolerance of homosexuality and the tolerance of those around her. My assignment (not a textbook or academic paper, not a fixed reading) and evaluation (none) differed from conventional college teaching. Experiences like this make me wonder what fraction of important learning during college happens due to lecture classes. (In my case, the fraction was zero.) If the fraction is low, it suggests that online learning won't make much difference.

---

TimG (2012-12-09 07:02:57)

As I read this, I could not help but consider that blog posts - such as this one - are akin to online lectures ("micro-lectures", perhaps?), and that the explosion of blogs and blog readers exemplify the potential value of MOOC. At the same time, there is no doubt that blog quality and readership varies widely, suggesting that MOOC, for MOOC's sake, is a grossly naive concept. Quality of content is paramount. Easy, free/inexpensive access to poor quality lectures cuts both ways: the customer, having little investment in acquiring the lecture, is likewise predisposed to promptly drop that lecture if its quality is in the least substandard. Just as a blog's readership can readily rise and fall with the quality of the posts. This may ultimately improve online learning, as long as lessons are taken from successful online lectures and applied to new attempts. The question for me is whether the "old dogs" (the run-of-the-mill lecturers) have the willingness and/or capacity to change. My guess is that they generally do not. Seth: I like the blog/lecture comparison. When I was in college, I tried to find good books about the subjects I wanted to learn about. A good book about genetics, for example. These were never textbooks. They were often histories of the subject (a series of stories) or memoirs (a series of emotional stories). Nowadays I might try to find a good blog on the subject. Lots of blog posts convey emotion.

Robbo (2012-12-09 07:03:05)

"It would be a coincidence if the link that can be most easily strengthened turned out to be the weakest link." A truth that applies almost everywhere. I am following the internet Harvard Computer Science course and can share some observations. Some parts of the academic process scale up readily, like lectures and design of assignments. Others, like marking assignments, not so much. For me, most of the learning takes place when working on the assignments. The fact that it will be seen and marked helps me to focus on finishing. I expect the future will unbundle research from teaching undergraduates and there will be just a few, expert lecturers. There are other issues which come with eliminating the campus as where the students are - in particular cheating is going to be harder to police. It could be that learning and credentials get unbundled, so you learn online with Harvard, but to get a certificate you go to an office and take a paper and pencil test under controlled conditions - a bit like Gmat or US bar exam. Seth: Thanks. "For me, most of the learning takes place when working on the assignments." I agree. For me, there is little learning without doing. This is what I mean about an incomplete theory of higher education. How important is doing? If it is 100 % or 95 %, yet most courses (outside math, engineering, foreign languages, etc.) provide only a little, then we should be trying to increase doing.

Glen Raphael (2012-12-09 07:22:25)

When I was at Berkeley, John Searle (philosophy department, class was Speech Theory) was an impressive lecturer - he walked the stage like an actor, using a full dynamic vocal range. Different vocal accents, changes in pitch, changes in volume and body language and a full command of the material. Alan Dundes (folklore professor, class was "Forms of Folklore") was just so fascinated by his subject matter that he made the students fascinated too. Also, if you ever have the chance to see economist David Friedman lecture you should do so (I first saw him guest-lecturing at Stanford). He's more in the mold of Robin Hanson - defending unusual positions through interesting stories that make connections that wouldn't have occurred to the audience. Seth: I once had dinner with Alan Dundes. Strangest dinner ever. In an hour, he told fifty jokes. Very enjoyable. Many years earlier, I had attended one of his classroom lectures. He was extremely funny - again, nonstop jokes - but the psychoanalytic theory that he used to explain them seemed worthless. This was the strange case, the only one I can think of, where the delivery was great and the content was poor.

Javeux (2012-12-09 07:37:47)

I haven't tried anything on Coursera, but I like the format of Udacity and Khan Academy. The lectures are much shorter, focused and digestible, and they have great software to make the experience interactive and reinforce what you learn. Typical lectures and lecture notes generally offer a lot less than the course book if you can stand to get through it. The benefit of uni is more in the coursework, exams, guidance from professors and the structure and motivation a course provides. I found it harder to make use of the MIT OpenCourseWare materials than go through a Udacity course.

Tom (2012-12-09 15:14:46)

The price of a university education really started to skyrocket once the law was changed to make it impossible to discharge college debt through bankruptcy.

garymar (2012-12-09 19:46:27)

In scholarly conferences, the value of getting together lies not so much in the presentations, as in the kibitzing that goes on in the hallways in-between, and the lunches and dinners where people get together to talk. The unstructured bits are very valuable, but there has to be a *structure* to hang them on. Seth's students wouldn't have followed his informal recommendation to read a certain book if they weren't already interacting with him within a formal structure. So it looks like you need both. Seth: It wasn't an informal recommendation. It was a homework assignment. I can't imagine an online lecturer saying "read any 60 pages and I won't test you on it".

Tom (2012-12-09 21:58:00)

**Three Dozen Private-College Presidents Earned Over \$1 Million in 2010** In 2010, the latest year for which data is available, the highest paid president, with \$3,047,703 in total compensation, was Bob Kerrey of the New School in New York City. Mr. Kerrey, who left the job in December 2010, received a \$1.2 million "retention bonus" and a payout of more than \$620,000 in deferred compensation on top of his base salary of \$602,593. Among the 493 colleges with budgets greater than \$50 million, the highest paid sitting president was Shirley Ann Jackson of Rensselaer Polytechnic Institute, at \$2,340,441. ... [nytimes.com/2012/12/10/education/three-dozen-private-college-presidents-earned-over-1-million-in-2010.html](http://nytimes.com/2012/12/10/education/three-dozen-private-college-presidents-earned-over-1-million-in-2010.html)

Alexander Boland (2012-12-10 06:38:35)

I always had trouble paying attention in class, which had the fortunate side effect of giving me a lot of practice at teaching myself mathematics from textbooks. That said, I actually recently tried Khan Academy because I wanted to review linear algebra (planning to teach myself group theory). Before that, I thought the idea of online education was hokey BS for reasons similar to things you said above. I was pleasantly surprised—there was an amazing sense of clarity. But I think that it's for a fundamentally different reason than people think: **I was able to pause and rewind.** I could therefore skip through segments that weren't important and play others multiple times. Also, it meant that if I spaced out or had to go to the bathroom, there was no problem. And what makes this such a valuable supplement is that while many lecturers are far from perfect, there is something about watching someone giving a tutorial that's fundamentally different than reading a textbook. As for what scheme will actually work, that's a great question. I think the only straight answer I can give is that the education system as it is now is unsustainable, and when things break, we will hopefully see some serious creative destruction that leads to innovations about how people will be taught. Seth: The Khan Academy makes much more sense to me. One reason is that elementary school teachers may have trouble with or dislike math and science – at least, compared to Khan's teachers. Another reason is that everyone should learn to read, write, do arithmetic, and so on. A third reason is that Khan stuff frees teachers to give special attention to students who are having trouble mastering the material. That's not the case with MOOC's. I do think there's something to be said for adding a personal element to learning. An emotional connection with the teacher. Which might happen much better with a video than a book. But I have never heard the advocates of on-line learning mention this much less say how it will happen.

Jill (2012-12-10 07:07:40)

I think online lecturing needs to be considered as only a single tool of online learning. I learn a lot online (as mentioned above, blogs are an important piece of that), but I have never WATCHED an online lecture. I can probably count on one hand the number of YouTube videos that I've seen - it's just not my thing. On the other hand, my husband does most of his online learning (car repair, art techniques, languages, etc.) by watching videos. Hopefully, as MOOCs increase, the purveyors of learning will keep in mind that different students have different learning styles - and, of course, certain subjects work better in certain formats.

Kajal Sengupta (2012-12-10 17:38:02)

The concept of online learning is recent if I am correct and it is imperative that at the beginning there will be lot of adjustments readjustments to be made. While I agree that we can not equate the learning environments of online and offline education

but if adopted in a proper way backed by field studies this mode can work wonders for those who cannot afford the luxury of online courses.

Jon (2012-12-11 02:17:40)

I went to school (electrical engineering - EE) with a guy that would skip the lectures (would attend for pop quizzes, etc., of course) and would copy his homework from other people. He had straight A's and was the president of the student IEEE. He would take 18 credit hours or more (unheard of for EE). How did he do it? He learned best by studying from the books. No need to attend lectures. Unfortunately, the system caused him to jump through hoops that only slowed him down from being productive and getting to work on a real job. I e-mailed him looking for work after losing my first job as a EE. He wasn't in the business of EE anymore, he followed the money and was a hedge fund worker, not sure what exactly he was doing. My point is, people learn differently and the current one-way college trip is valuable only marginally. It seems because it is subsidized by the government to such a great extent that it has become much more valuable than it would otherwise be. Why is it valuable? Maybe because it acts as a screener for employers that shows the person is willing to stick with it for a long time? I've left EE also for computer programming. Rather than go through another 2-4 years to get a CS degree I'm teaching myself. Books are great, stackoverflow is a great resource, programming themed blogs is great, creating an actual product while teaching myself is great, creating a meet up group in my area is great, connecting with other programmers is great. I think if I were to join a company and learn more closely with programmers would also be invaluable (something I will likely not do since I don't want to move and work regular office hours - 32 hour weeks is too nice). My best resources for learning? 1) Doing the actual programming. 2) Reading programming books. 3) Reading code written by others. 4) Writing about my code that I have written. 5) Asking questions on forums about problems I run into. Seth: Very revealing, thanks.

Jon (2012-12-11 02:22:10)

Oh, last comment. One of the guys in my programming meetup group I started loves doing research (on electronics). It seems he is making little to no money. He open sources his findings. My point? I think there is a lot of research going on out there. People love to tinker and learn. If they are passionate about what they learn then they want to share what they find out with others.

## **Why Do Fermented Foods Improve Health? A New Idea (2012-12-11 05:35)**

I became interested in the health value of fermented foods after I noticed a curious coincidence. Humans have three mysterious food preferences: for (a) sour food, (b) food with umami flavor, and (c) food with complex flavor. I realized that all three preferences made bacteria-laden food more attractive. Bacteria change sugars to acids, increasing sourness. They break down proteins, creating glutamate, which produces umami flavor. And the many chemicals they introduce into a food make its flavor more complex. After I noticed this, I came across many studies that supported the idea that fermented foods are good for health. I also found studies that suggest the bacteria in our digestive system are crucial to health.

This raised the question: What fermented foods to eat? How many? How often? To begin to answer these questions, it would help to know how bacteria in our food help us be healthy. There were two obvious answers:

1. Stimulate the immune system. The bacteria in fermented food are inherently safe: they are specialized to reproduce on/in food, which is so different than inside the human body. But the immune system doesn't know this. If this was one benefit of fermented food, you could study which ones to eat by measuring immune system activation. Unfortunately, that is nearly impossible.
2. Improve digestion. Many people have digestive problems and some of them are helped by fermented foods. Obviously they contain bacteria that digest food. I don't have digestive problems so I can't study this by figuring out which fermented foods help.

Recently, I have begun to think there is a third reason:

3. Place competition. To make us sick, outside bacteria need to stick inside us. To digest our food, the surfaces of our digestive system, such as the inside of our intestines, is much more porous than other surfaces, such as our skin. It is our digestive system, therefore, that is most vulnerable to dangerous microbes. The totally-safe microbes in fermented foods compete for sticky spots with other, more dangerous microbes. If there are plenty of safe bacteria – say, billions in a serving of yogurt – they may do a lot to protect us against the dozen or so similar dangerous bacteria we might get from touching the same surface as a sick person. I think of a wooden floor where the lumber is not quite well-fitted. If you want to protect what's below that floor from black sand (dangerous), an excellent method would be to pour an enormous amount of white sand (safe) on the floor.

If Effect #3 (place competition) is the main reason fermented food protects us from disease, it implies that dead bacteria work as well as live bacteria (in contrast, live bacteria do not digest food, Effect #2). This might explain the potency of alcoholic beverages such as wine, where most of the bacteria are dead. It also suggests that what matters is diversity of where bacteria stick and how much they stick. It might someday be possible to feed people (non-radioactive) bacteria and learn where in the body they end up.

---

Nancy Lebovitz (2012-12-11 05:40:39)

Your second point (harmless bacteria stimulate the immune system while being harmless) reminds me of a possibility for why very spicy food gets liked– it's pain without danger.

Todd Fletcher (2012-12-11 10:16:43)

I have a half-baked theory that inadequate digestive flora leads to obesity: it makes foods with lots of white flour and sugar more palatable because they're easily digested by such people. Denser foods like meats with a lot of fat and high protein or raw fruits and vegetables don't digest so easily so they avoid them. Then they get addicted to the blood sugar spikes. No idea if this makes sense or not but there you are. Seth: As Nancy says, lots of people avoid carbs but are still fat. Alex Chernavsky tried a low-carb diet. Initially he lost a lot of weight. After a year or so he started to regain the lost weight. At that point he changed his diet. Short-term weight loss caused by his low-carb diet was not easily sustained for a long time. I don't agree that simply eating white flour and sugar is fattening (or avoiding them is thinning). It's more complicated than that.

Nancy Lebovitz (2012-12-11 14:14:32)

Probably a half-baked theory, or at least you'd need to check on a good sample of fat people. Simple carbs aren't good for me, so I don't eat a lot of them. I like fat and protein more. I'm still fat. Your theory might apply to some proportion of fat people, but biology is complicated.

Bosco Ho (2012-12-11 14:46:14)

Really enjoy reading your stuff here on fermented foods. As for your theory about why bacteria is healthy for us, apropos point number 3, this sounds to me like exactly the same reasoning for the medical technique of fecal transplant [http://www.slate.com/articles/health\\_and\\_science/medical\\_examiner/2011/01/the\\_enema\\_of\\_your\\_enemy\\_is\\_your\\_friend.html](http://www.slate.com/articles/health_and_science/medical_examiner/2011/01/the_enema_of_your_enemy_is_your_friend.html)

Cliff Clayton (2012-12-11 18:13:02)

We can add this to the list of "evolutionary" ways that modern living has short changed human physiology. 1. Industrial foods are unnatural. 2. Artificial light disrupts circadian rhythms. 3. Artificial heat prevents cold adaptation. 4. Modern refrigeration restricts the need for food storage via fermentation. Are there any I missed? Seth: I think you've missed about a hundred. For example: 1. Modern living reduces human contact in the morning. 2. Modern timing of food interferes with sleep.

Nancy Lebovitz (2012-12-11 23:15:47)

Modern news contributes to constant anxiety.

Jim Purdy (2012-12-12 00:17:45)

Human contact in the morning – or any other time – irritates the snot out of me. But I love peace and quiet. I don't have a TV or a radio, and I keep the sound turned off on my computer. You're the psychologist, Seth, but is there really anything wrong with enjoying peace and quiet? If I'm happy, what's wrong with that?

Txomin (2012-12-12 04:17:55)

A while back you mentioned the Nobel Prize in medicine. This could be interesting to you: <http://www.rationaloptimist.com/blog/induced-pluripotent-stem-cells-change-the-ethical-debate.aspx>

Cliff Clayton (2012-12-12 15:34:00)

A possible 4th reason we like fermented foods. (not my idea). New microbes are a source of genetic material for our epigenetic mechanisms to use for genetic adaptations to environmental stresses. IE they are inventory in our junk DNA parts list.

Toxicologia (2012-12-14 12:07:04)

The fermented foods are producing enzymes that aid in the absorption of nutrients and digestive capacity.

dearieme (2012-12-15 04:40:54)

"1. Industrial foods are unnatural." All cooked foods are unnatural.

## **Few Doctors Understand Statistics? (2012-12-12 05:00)**

A few days ago I wrote about a study that suggested that people who'd had bariatric surgery were at much higher risk of liver poisoning from acetaminophen than everyone else. I learned about the study from [1]an article by Erin Allday in the San Francisco Chronicle. The article included this:

At this time, there is no reason for bariatric surgery patients to be alarmed, and they should continue using acetaminophen if that's their preferred pain medication or their doctor has prescribed it.

This was nonsense. The evidence for a correlation between bariatric surgery and risk of acetaminophen poisoning was very strong. Liver poisoning is very serious. Anyone who's had bariatric surgery should reduce their acetaminophen intake.

Who had told Allday this nonsense? The article attributed it to "the researchers" and "weight-loss surgeons". I wrote Allday to ask.

She replied that everyone she'd spoken to for the article had told her that people with bariatric surgery shouldn't be alarmed. She did not understand why I considered the statement ("no need for alarm") puzzling. I replied:

The statement is puzzling because it is absurd. The evidence that acetaminophen is linked to liver damage in people with bariatric surgery is very strong. Perhaps the people you spoke to didn't understand that. The size of the sample ("small") is irrelevant. Statisticians have worked hard to be able to measure the strength of the evidence independent of sample size. In this case, their work reveals that the evidence is very strong.

If the experts you spoke to (a) didn't understand statistics and (b) were being cautious, that would be forgivable. That's not the case here. They (a) don't understand statistics and (b) are being reckless. With other people's health. It's fascinating, and very disturbing, that all the experts you spoke to were like this.

I have no reason to think that the people Allday talked to were more ignorant than typical doctors. I expect researchers to be better at statistics than average doctors. One possible explanation of what Allday was told is that most doctors, given a test of basic statistical concepts, would flunk. Not only do they fail to understand statistics, they don't understand that they don't understand. Another possible explanation is that most doctors have a strong "doctors do everything right" bias, even when it endangers patients. Either way, bad news.

1. <http://www.sfgate.com/health/article/Bariatric-surgery-and-acetaminophen-risk-4091180.php#ixzz2EDa0Ttm6>

---

ck (2012-12-12 08:25:01)

"17 percent had had weight-loss surgery. . . . Less than 1 percent of the general population has had the surgery." The rate of general population might be misleading. What if bariatric patients have a much higher probability of taking acetaminophen? What the researchers should have looked at is the rate of liver poisoning of acetaminophen users in general vs. acetaminophen users who had bariatric surgery. Maybe some researchers really do not understand statistics. Seth: Sure, the evidence could be improved. This is always true. The sort of evidence I discuss resembles the first evidence that smoking causes lung cancer.

Tom (2012-12-12 08:40:22)

Seth, please consider rewriting/expanding this blog post into an Op-Ed piece. It belongs in the NY Times.

Dennis (2012-12-12 09:06:15)

I second what Tom said.

ChristianKI (2012-12-12 09:29:34)

If your only information about a study is the information that's contained in a press article about the study, it's a bad idea to start criticizing researchers who are familiar with the study. "Statisticians have worked hard to be able to measure the strength of the evidence independent of sample size. In this case, their work reveals that the evidence is very strong." That claim is wrong. Observational studies produce frequently results that don't replicate even when the P values are under 0.05. See Ioannidis. Maybe acetaminophen is more effective in people who had bariatric surgery and as a result those people are more likely to take acetaminophen than the general population. More importantly, how many who take acetaminophen actually develop liver poisoning? How many bariatric surgery patients who don't take acetaminophen develop liver poisoning? How does that risk compare to the advantages that acetaminophen provides? Instead of contacting the reporter, how about contacting the person behind the study and asking them why he thinks that the reporter wrote "there is no reason for bariatric surgery patients to be alarmed"? Seth: By "strength of evidence" I meant the p value. The p value is very low. Statisticians have indeed worked hard to compute p values independent of sample size. This study unquestionably makes use of acetaminophen more dangerous for those who have had bariatric surgery. Someday the uncertainties will be resolved – until then, a causal explanation of these results (bariatric surgery makes acetaminophen more dangerous) remains plausible. Which is why acetaminophen should be avoided – at least, avoided more than before these results. Thank you for your suggestion

that I contact the researcher. That's a good idea. Of course I can do both: contact the reporter and the researcher.

Jonathan (2012-12-12 11:52:30)

By synchronicity, Prof. Bruce Charlton today put up a blog post about how when he did research in epidemiology, he came to understand that his fellow researchers don't understand and cannot interpret statistics—including not only the researchers running clinical trials, but even the professional statisticians. <http://charltonteaching.blogspot.com/2012/12/the-uk-census-in-rationalistic-s-ecular.html> So why would anyone expect doctors to?

Alex Chernavsky (2012-12-12 15:46:04)

Speaking of incompetent mathematicians, does anyone remember that infamous newspaper column written by Marilyn vos Savant? She outlined a brain-teaser with a very counter-intuitive solution (the puzzle is called the Monty Hall problem). Many people, including some professors of mathematics, sent her nasty letters, claiming that she was wrong. She was not wrong. You can see some of the letters here: <http://marilynvossavant.com/game-show-problem/> Here, for example, is a note from someone named E. Ray Bobo, Ph.D., of Georgetown University:

You are utterly incorrect about the game show question, and I hope this controversy will call some public attention to the serious national crisis in mathematical education. If you can admit your error, you will have contributed constructively towards the solution of a deplorable situation. How many irate mathematicians are needed to get you to change your mind?

Alex Chernavsky (2012-12-12 15:49:27)

An interesting follow-up question is whether any of Marilyn's critics apologized to her later. Apparently, not many did: <http://answers.google.com/answers/threadview/id/510729.html>

Glen Raphael (2012-12-12 20:39:36)

A friend of mine is a doctor who majored in math at Berkeley as an undergrad. He said that in med school and residency, being the one doctor in the room who actually can do and understand mathematics was kind of like having a superpower.

Kim Øyhus (2012-12-13 03:07:25)

Marilyn's answer is wrong, as are all the rest. The true answer here is kind of meta, because the probabilities are very dependent on why the host does what he does, and what he does, such as what he would have done if another door had been chosen. All answers assume that the host behave in a specific way, and when they assume differently, they get different probabilities. The true answer is that there is not enough information to calculate probabilities. The REALLY interesting part is how this answer escape virtually all people, even experts. It seems to be some kind of blind spot in normal humans.

Margaret (2012-12-13 10:16:09)

First, @Kim, you're so right. There's really no clear answer to the Monty Hall problem, at least at the level of real life people on the real life show. I wonder why "smart" people can't see that? Secondly, I don't really have enough information to tell, but I doubt that these experts are as bad at statistics as you're saying. A more likely explanation is that they don't feel that they have the authority to change policy regarding bariatric patients and acetaminophen. It's the whole "trusting authority" problem. Don't trust regular people with information. It might cause a panic!! Just let this new information about bariatric patients slowly percolate up the chain of command to whoever makes policy announcements and in 4 or 5 years, you'll see bariatric surgeons telling their patients to avoid acetaminophen. Problem solved! [sarcasm] Seth: "They don't feel they have the authority to change policy." That's a good way to put it. That's what I was trying to get at with my second possible explanation, they have a strong "doctors do everything right" bias.

Jordan (2012-12-13 10:40:15)

I could not agree with you more. My mom is currently in ICU. She is a type 2 diabetic. Her blood glucose is tested every 6 hours. No matter the level, she gets insulin - the amount depends on what "the sliding scale" tells the nurse to do. Her blood sugars are below 100 about half the time and they STILL give her insulin. I argued over and over with the nurse and MD on staff to

NOT give her insulin if it was 120 or below. I finally had to sign a release. And they still did not like it. Simply, MD's (nurses and therapists) are unable to think. And when they think like you suggest (as they do), it's a bad combination.

Kris (2012-12-13 15:02:09)

Marilyn is wrong. Look at the chart on her page. Game 3 and 6 are never played because the host does not open the door with the auto. She just lost track of her variables. "Door #3" is the door that the host opens, not actually Door #3 and the host opened another door.

Kris (2012-12-13 16:49:11)

Nope, I am wrong. I ran a simulation. With no switching you have .33 chance of picking correctly. does not matter if a door is revealed. You have a .66 chance on picking the incorrect door. In this case the host reveals the other incorrect choice, and a switch puts you on the correct door guaranteed. If you picked the right door (.33) initially, then the switch moves you to the wrong choice.

Matt (2012-12-13 22:44:23)

@Kim The true answer is not "meta" or ambiguous, because the host's actions are described with no ambiguity in the problem statement. There are three doors, and after the contestant makes his choice the host opens a door that does not have the car behind it.

Kim Øyhus (2012-12-14 02:41:31)

Matt, there is a LOT of ambiguity in this problem, as stated by Marilyn vos Savant. She states that the host knows what's behind doors. This means the host can change behaviour depending on that. This dependence can change probabilities a lot. For instance, the host could open another door only when you choose the one hiding the car, to tempt you away. She gives us just one scenario: You choose door 1, host opens door 3, showing a goat. But since we lack information about what the host do depending on where the car is, we cannot calculate probabilities. We do not know how likely other scenarios are. To simplify: Why did the host open that door? Answer: We do not know.

Alex Chernavsky (2012-12-14 06:28:05)

Kim, the mathematicians (and others) who objected to Marilyn's answer didn't do so based on the ambiguity that you described. They seemed to assume the scenario that Marilyn intended (though perhaps didn't express unambiguously). So I think we can still conclude that the objectors were spectacularly wrong.

Kim Øyhus (2012-12-14 06:43:41)

Alex, yes. In other words, they guess what she means, and luckily get that right, and then proceeds to think wrongly, even after being corrected. To me, that behaviour seems very typical, very human, and quite disappointing. To me, the Monty Hall problem was very confusing, and the confusion did not go away when I saw the explanations. When the absence of information was pointed out to me, everything became obvious, even all the other explanations, as just variations on how people fill in that blank, which they do not see, like the blind spot, which it might be a cognitive equivalent of.

nari (2012-12-14 07:38:55)

I agree with Tom too.

Jeremy (2012-12-21 14:38:27)

What was the difference in risk of the outcome for the two groups in the study? Large correlation doesn't suggest anything to me either, because there's no quantification of the size of the association. Seth: I don't understand the question. Which two groups? The essential finding is that people who'd had bariatric surgery seemed have about 20 times higher risk of acetaminophen poisoning than everyone else.

## Why Quantified Self Matters (2012-12-14 05:00)

[1]Why Quantified Self Matters is the title of a talk I gave yesterday at a Quantified Self conference in Beijing. I gave six examples of things I'd discovered via self-tracking and self-experiment (self-centered moi?), such as how to lose weight (the Shangri-La Diet) and be in a better mood. I said that the Quantified Self movement matters because it supports that sort of thing, i.e., personal science, which has several advantages over professional science. The Quantified Self movement supports learning from data, in contrast to trusting experts.

If I'd had more time, I would have said that personal science and professional science have different strengths. Personal science is good at both the beginning of research (when a new idea has not yet been discovered) and the end of research (when a new idea, after having been confirmed, is applied in everyday life). It is a good way to come up with plausible new ideas and a good way to develop them (assess their plausibility when they are still not very plausible, figure out the best dose, the best treatment details). That's the beginning of research. Personal science is also a good way to take accepted ideas and apply them in everyday life (e.g., a medical treatment, an idea about deficiency disease) because it fully allows for human diversity (e.g., a medicine that works for most people doesn't work for you, you have an allergy, whatever). That's the end of research.

Professional science works well, better than personal science, when an idea is in a middle range of plausibility – quite plausible but not yet fully accepted. At that point it fits a professional scientist's budget. Their research must be expensive (Veblen might have coined the term conspicuous research, in addition to "conspicuous consumption" and "conspicuous leisure") and only quite plausible ideas are worth expensive tests. It also fits their other needs, such as avoidance of "crazy" ideas and a steady stream of publishable results (because ideas that are quite plausible are likely to produce usable results when tested). Professional science is also better than personal science for studying all sorts of "useless" topics. They aren't actually useless but the value is too obscure and perhaps the research too expensive for people to study them on their own (e.g., I did research on how rats measure time).

In other words, the Quantified Self movement matters because it gives all of us a new scientific tool. A way to easily see where the scientific tools we already have cannot easily see.

1. <http://blog.sethroberts.net/wp-content/uploads/2012/12/2012-12-13-Why-QS-Matters.pptx>

---

Cliff (2012-12-14 16:02:18)

The democratization of research, no?

Nancy Lebovitz (2012-12-15 18:05:31)

The other value of quantified research and other sorts of self-experimentation is for people who are sufficiently non-standard that the usual methods aren't working for them, though perhaps that counts as a variant of the beginning of research. Seth: That's what I mean by quantified self being useful at the "end of research". The end of research is the point at which research has found "usual methods" to solve a health problem. The usual methods work well for most people. To find out if they work for you, you need to measure yourself. If they do not work, you need to measure yourself to find something that does work.

## Radical Thought at Johns Hopkins Medical School (2012-12-15 05:00)

Brent Pottenger, who is a medical student at John Hopkins, writes:

Today, as a required activity for our Hopkins Med endocrinology course, we watched excerpts Supersize Me and Tom Naughton's Fat Head. Our professor then engaged us in a discussion comparing the two films. Our professor told our class that the lipid hypothesis is incorrect, said that the USDA Food Pyramid is the product of corn and wheat subsidies (and lobbies), and definitely stirred up some uneasy responses from my classmates.

I asked Brent what had made them uneasy.

What the professor said contradicted what they believe. Every professor before this has demonized saturated fat, meats, etc., so this was the first time someone questioned that belief.

How did they express their unease?

They expressed unease by getting up and leaving the lecture hall, by whispering in disgust to their neighbors, etc. – you could see it on their faces. Then, some of the more curious classmates who are always inquisitive followed up with genuine questions, wanting to know more about the validity to the statements made in Tom's movie about Ancel Keys, the McGovern Report, the USDA, the science of the lipid hypothesis, etc.

---

Chuck (2012-12-15 08:40:59)

That blasphemous heretic of a professor obviously is in need of a frontal lobotomy or at the very least leaching until he recovers his senses. Cheers

Michael (2012-12-15 10:35:05)

Sigh. Another generation of misinformed technicians readying themselves to dispense pabulum and and prescriptions to a unsuspecting public. I'm heartened to learn that there are a few professors out there who are challenging their students to use what they are learning and think.

Kim Øyhus (2012-12-15 14:51:19)

Perhaps most people are evolved to accept dogma, because the alternative was to be rejected by religious society. This could be tested by measuring concentration of dogma acceptance with respect to long term type of society.

Txomin (2012-12-15 16:56:49)

As long as it is not understood, a given notion is never knowledge but belief. This applies to everyone and to everything.

nc289 (2012-12-15 19:01:33)

It's Johns Hopkins, not John Hopkins! Seth: Thanks. I thought it must be either Johns Hopkin or John Hopkins.

dearieme (2012-12-16 14:33:01)

I was in hospital last week and took the opportunity to explain to a young cardiologist about Ancel Keys and his lies. She'd never heard this tale before, and, I suspect, didn't believe a word of it. Worse, I'll bet my bottom dollar that she had no intention of googling around a bit to see what's what. A different young registrar told me that he'd had a look at the photos resulting from my angiogram a couple of years ago. Not only was there no significant narrowing, he said, but there were no deposits at all. Clean as a whistle. Ah, said I wisely, it's my bacon and butter diet! Seth: Good to know. During a year when I ate lots of butter, my deposits decreased. Your experience supports my hope that it was cause and effect – the butter decreased the deposits.

Credulous (2012-12-16 16:55:41)

"It's Johns Hopkins" Is that like Childrens Hospital?

Wil B (2012-12-17 17:56:30)

@ Credulous: Johns Hopkins is a major medical institution in Baltimore, Md.

Janknitz (2012-12-17 18:04:30)

I'm sorry for the patients of the arrogant ones who refused to consider information from a professor who challenged their beliefs. Those a patients who will never be heard or truly cared for by these physicians.

chuck(also) (2012-12-17 18:54:48)

it is an endocrinology class at a top 10 in the world med school. couldn't the teacher just let the science speak for itself? it is what it is, opinion be damned.

## Assorted Links (2012-12-16 05:00)

- [1]"Light" Ph.D. – a less expensive research degree
- [2]Umami Burger expands
- [3]A diuretic reduces autism symptoms. Does water balance influence brain function in people without autism?
- [4]This Amazon reviewer is almost always disappointed and his one-star reviews are fun to read. I suggest that ratings (book ratings, product ratings, etc.) compare the rating to other ratings given by the rater. A 5-star rating is more impressive if a rater's average rating is 2 than if it is 5. I suggest percentiles. For example, rating = 5 (90 %ile) is more impressive than rating = 5 (50 %ile). I'd also like to know the average percentile across raters.
- [5]Lack of variation in heart rate predicts infection in neonates. The writer (Mike Loukides) is too surprised ("astonishing connection"). Many studies have found associations between too-little variation in heart rate and serious health problems.

Thanks to Adam Clemens and Patrick Vlaskovits.

---

Three Pipe Problem (2012-12-16 05:51:34)

Okay devil's advocate on the reviewing concept: I have personally observed that I am more likely to review products I have a problem with. Let's say this is also true of the serial 1-star reviewer you linked to. Then there are many products that he \*would have\* rated more highly, had he written a review. If he had included these reviews would it change the meaning of any of his existing reviews? I say no. Therefore looking at his "spread" gives no extra information. Seth: The interesting comparison is not Person X (fewer reviews) compared to Person X (more reviews). The interesting comparison is Person Y's five-star review to Person X's five-star review. Surely you agree that five stars means different things from different people. The additional information I suggest is one way to begin to take account of that – to try to adjust for individual differences.

Nancy Lebovitz (2012-12-16 08:58:53)

My filter for amazon reviewers is whether they seem to care about the same things I care about. I'm not interested in how picky they are.

Tom Passin (2012-12-16 09:31:16)

At Amazon, I usually start out looking at the 1-star ratings. Mostly they are worthless, but once in a while you can get a real sense of valid problems. It's mostly a skimming operation. Then I look at the 2-stars. These seem to be rather better and more thoughtful. Then I look at the 4's. I find that too many of the 5-stars are either fanboys or brand new users, and most of them sound pretty credulous. This approach has worked pretty well for me as best I can tell. There are a lot of books I didn't buy because of it, for one thing.

RAD (2012-12-16 11:12:34)

What I find astonishing about Mike Loukides article is how he can start with a fundamental misunderstanding of heart rate variability (HRV) and weave it into an elaborate story that is disconnected from reality. Heart Rate Variability occurs during respiration with heart rate being higher during inhalation and lower during exhalation. Lack of variation occurs when the body is stressed for a variety of reasons. Machine learning over vast amounts of real time data to detect subtle patterns is an over complication of the lessons learned at Sick Kids. Low HRV is a telltale "spike" that indicates the presence of a stressor. You only need a minute or so of heart rate data to calculate the HRV and the value could easily be reported by an inexpensive device like a finger Pulse Oximeter but they don't currently. I think the lesson from the Sick Kids research is that HRV is simple and highly predictive compared to other data being gathered. HRV should be watched as closely as heart rate, blood pressure, blood oxygenation, and body temperature in patients. Perhaps IBM is partially at fault for trying to put a Real Time Big Data spin on results that show HRV is a powerful but essentially low-tech tool. Seth: Good point.

dearieme (2012-12-16 14:26:53)

Shouldn't a "light" PhD be called something else?

R. Jones (2012-12-16 23:25:59)

This is not related to the links, but cessation of masturbation and internet porn (abstaining for 4+ days) gave me greatly increased energy. I speculate that porn and masturbation are major dopamine sinks for the brain and when you stop, your dopamine responses get tied to something else. I am surprised that so few people talk about this. Is it one of those obvious things? It's an awkward topic and many people assume that you are a religious zealot when you start talking about the downfalls of masturbation.

Txomin (2012-12-17 02:27:32)

A PhD is not necessary to get published. I did before getting mine and so have many. Affiliation tends to matter more for those that pervert the peer-review process.

Tom (2012-12-17 09:24:58)

I think RAD has identified why IBM is pushing their big data approach so hard – IBM doesn't have an algorithm that can calculate HRV efficiently. The algorithm does exist, though: [www.ncbi.nlm.nih.gov/pubmed?term=pd2i](http://www.ncbi.nlm.nih.gov/pubmed?term=pd2i) I would disagree, however, with his assertion that HRV is an 'essentially low-tech tool' – the math that can extract the HRV needle from the haystack of autonomic noise is very complex.

Gayle (2012-12-17 19:34:50)

Bookworm has put up a review of a book by an autistic teenager. It is absolutely stunning. Their minds are all there, but they are unable to express themselves through their bodies. After the horrors of repetitive rote teaching of knowledge he had already absorbed, he finally was helped by a teacher who understood. He was finally able to communicate through an alphabet board. <http://pjmedia.com/lifestyle/2012/12/10/everything-you-think-you-know-about-a-utism-is-wrong/> #comment-307587 His book: <http://www.amazon.com/exec/obidos/ASIN/0988324709/pjmedia-20>

shtove (2012-12-23 18:28:17)

Barry Ritholz has a thoughtful post on Amazon reviews: <http://www.ritholtz.com/blog/2012/12/amazon-changes-its-review-policy/> I sample the 5 & 1 star reviews, tend to be swayed by the quality of the reviewer's writing. Postmodern approach, which sometimes fails.

## **Best Books of 2012 (2012-12-17 05:00)**

In order of quality (best first):

1. The Dictator's Handbook: Why Bad Behavior is Almost Always Good Politics (published 2011) by Bruce Bueno de Mesquita and Alastair Smith. The best book about political science I have read. A leader always needs supporters. The essential difference between dictatorships and democracies is how many. Full of data and examples that this view – the whole theory is a bit more complicated – explains. [1]Econtalk interviews.

2. Antifragile: Things that Gain From Disorder by Nassim Taleb (copy sent me by author). Full of original ideas. It may be unprecedented that a serious thinker so anti-establishment has so loud a voice. Much of the book is about a generalization of hormesis, the observation that a small amount of Treatment X can be beneficial even though a large amount of Treatment X is deadly. For example, a small amount of smoking is probably good for you. Taleb goes beyond this to say that in some things, the hormetic benefit (the benefit from small amounts) is much larger than in other similar things. You can fulfill the same function (governance, banking, science) with a system where the entities benefit a lot from small shocks (which Taleb calls "anti-fragile") or a system where the entities benefit not at all from small shocks. Systems where small shocks cause benefits tend to suffer less when exposed to large shocks. In my personal science, I have benefited a lot from day-to-day changes in my life (e.g., it led me to discover that butter improves my brain function and flaxseed oil improves my balance). In large science, day-to-day variation is only harmful. The core idea is that hormesis-like dose-response functions exist outside of the drug/poison/mice/rat/health experiments in which they were discovered.

3. Confessions of a Microfinance Heretic: How Microlending Lost Its Way and Betrayed the Poor by Hugh Sinclair (copy sent me by publisher). By "microfinance" he means microcredit. Sinclair convinced me that the belief that microcredit is a wonderful thing for poor people is one of the big delusions of our time. It is a wonderful thing only for the institutions that give it out (at exorbitant interest rates, usually). Sinclair sums it up like this (pp. 217-8): "Give

a man a fish and he'll eat for a day. Give a woman a microcredit loan to buy a fishing boat, and the CEOs of the MFI [microfinance institute] and the microfinance funds will eat for a lifetime." Sinclair continues: "There is too much at stake [for the CEO's] to allow any genuine scrutiny."

1. [http://www.econtalk.org/archives/\\_featuring/bruce\\_bueno\\_de\\_mesquita/](http://www.econtalk.org/archives/_featuring/bruce_bueno_de_mesquita/)

---

David Scrimshaw (2012-12-17 07:25:42)

It seems there's no hyphen in "antifragile" (Just mentioning it to help people searching for the book at their libraries.)

Nancy Lebovitz (2012-12-17 10:36:01)

It seemed to me early on that the administration work of microcredit as originally conceived was very time-consuming and could only be done as a charity. This means that trying to make a profit (or perhaps even a living) at offering microcredit turns it into money-lending.

Griff (2012-12-19 17:14:34)

Seth, I am now very envious of you as you received a copy of Anti-Fragile from Nassim Taleb, who is likely my favorite living author. I missed the opportunity for a signing in D.C.

Sean (2012-12-18 08:41:56)

I can't imagine how the island nation of Japan which is the size of California but has a population of 130 million could possibly function with say, the population of California. It would be utter mayhem, dogs and cats sleeping together etc. A shrinking population is only a problem for pyramid schemes such as social security.

dearieme (2012-12-18 17:03:19)

Ahoy, Seth. O/T but fascinating. <http://www.ft.com/cms/s/0/0b7af978-493a-11e2-9225-00144feab49a.html#axzz2FS2ccPqR>  
I have speculated along these lines myself in various comment sections - but that was mere conjecture by a medical ignoramus. I wonder how good their evidence is? Seth: Because antibiotics are routinely used to fatten cows and pigs, it is a far-fetched idea.

## **Twenty Dead Schoolchildren in Newtown, Conn. (2012-12-19 05:00)**

Adam Lanza, the Sandy Hook shooter, was taking medication, according to a neighbor. Here's [1]what someone said in 2008: "Every young, male shooter [who] has gone on a killing spree in the United States also has a history of treatment with psychotropic drugs — typically SSRI antidepressants. These shootings have three things in common: 1) The shooters are young males. 2) The shooters exhibit a mind-numbed disconnect with reality. 3) The shooters have a history of taking psychiatric medications."

Lanza was considered by his mom to have Asperger's. No doubt that, and the associated isolation, had something to do with the medication. As I point out every year at Nobel Prize time, the research methods favored by the health-care establishment have done little to reduce major diseases, such as depression. With few exceptions, year after year little progress is made on figuring out the environmental cause of anything, including Asperger's and autism. The result of this lack of progress is that almost every serious health problem, including mental health problems, gets treated with drugs or surgery rather than prevented or treated safely with necessary nutrients (as scurvy is treated with lime juice). The little progress that is made in finding environmental causes is undervalued. The researchers who figured out that smoking causes lung cancer didn't even get a Nobel Prize. The effect of failing year after year to find environmental causes is that people take more and more drugs with little-known or unknown side effects, which are almost always bad. [2]The association of SSRI antidepressants and violence is still unknown to many people, for example. The problem has been made worse by drug companies hiding data. As Ben Goldacre says in *Bad Pharma*, one of the worst cases involved an antidepressant called paroxetine, whose manufacturer (GlaxoSmithKline) withheld data about its tendency to cause suicide. My work has suggested that [3]a lot of depression may be due to lack of exposure to faces in the morning, an idea utterly different than the neurochemical theories of depression favored by psychiatrists. I am sure that seeing faces in the morning is safer than taking psychiatric drugs.

1. <http://psychdrugs.wordpress.com/2008/07/29/antidepressants-violence-and-school-shootings/>

2. <http://www.plosmedicine.org/article/info:doi/10.1371/journal.pmed.0030372>

3. <http://escholarship.org/uc/item/2xc2h866>

Dennis (2012-12-19 06:52:21)

What's worse, if many of these autism or Aspergers cases are a result of overdiagnosis, then many of them shouldn't be treated with antidepressants to begin with.

Alex Chernavsky (2012-12-19 08:06:26)

The single best exposé of the dangers of psychotropic drugs is this book: [1]*Anatomy of an Epidemic: Magic Bullets, Psychiatric Drugs, and the Astonishing Rise of Mental Illness in America*, by Robert Whitaker. The author is an award-winning investigative reporter. Unlike many anti-psychiatrists (such as the lunatic Scientologists and their head wing-nut, Tom Cruise), Whitaker is a very sensible guy and has no ideological ax to grind.

1. <http://www.amazon.com/Anatomy-Epidemic-Bullets-Psychiatric-Astonishing/dp/0307452425>

Javeux (2012-12-19 09:15:28)

I told my doctor I was a stressed for years, and managed to get a handle on it with mindfulness, lifestyle changes, and a lot of practice. I said it still felt like there was a lingering susceptibility to stress, despite my new-found above-average coping ability. For example, waking up in a "bad mood" or starting to feel easily antagonised in the afternoon. I figured years of exposing myself to stress probably left some physical damage somewhere that would require more than just "switching off" the habituated stress response. I don't know if there was a communication issue or not, but my doctor offered me SSRIs as a "solution". I said I didn't feel they would address a susceptibility when I felt I had the psychological side under control, and I expressed my concern about the side-effects. It's also worth mentioned that at no point was I depressed. He said he couldn't see any physical cause and that SSRIs weren't addictive like prozac (I was thinking more weight-gain, hair loss, impotence, osteoporosis etc...). It wasn't until a while later when I started messing around with a glucometer that I saw I was getting wild postprandial swings in blood glucose (10.7mmol/L to 5.4 within 25-minutes), and mild hypoglycaemia at night time. I'm not going to claim this explains everything, or that the device is 100 % accurate, but 5-weeks of exercise (2x resistance, 1x HIIT per week) and taking care to balance meals to avoid BG spikes has done wonders for mood and also aches/pains etc already. I can't understand why my doctor would consider SSRIs as a \*first\* option without any evidence other than a subjective impression from a poorly communicated consultation. It's no wonder so many children are ending up on these things, and it really worries me what could've happened if I'd taken up the offer. Would I ever have been able to diagnose the BG problem? Would the hormonal changes that result from SSRIs have masked or worsened it in any way? Sometimes I think the term "evidence-based" is just a empty buzzword when it comes to medicine. Seth: Good story. Medicine is now evidence-based by comparison to what it used to be.

dearieme (2012-12-19 11:28:15)

Isn't there a correlation problem here? Young men sufficiently mad to mass-murder infants are probably sufficiently mad to have been diagnosed and put on drugs. You can't really conclude that the drugs must be to blame for the murder, can you? Seth: Some psychiatric drugs are debilitating, i.e., disabling. It is far from obvious that people sufficiently able to do a school shooting must be on psychiatric drugs. Because of this, the drug-school shooting correlation deserves scrutiny. My belief that psychiatric drugs may cause (= increase) violence is based on experiments. People get placebo or drug. People in the drug group are more violent than people in the placebo group. It is becoming more accepted that some psychiatric drugs cause suicide. There are similarities between killing yourself and killing others.

Paul N (2012-12-19 14:25:37)

There is an article about this on Daily Kos [1]Something has changed, but what? It has a list of these shootings, who did them and what drugs they were on - scary stuff! I suspect big pharma will (anonymously) back calls for tighter gun control to keep the spotlight off themselves.

1. <http://www.dailykos.com/story/2012/12/16/1170660/-Something-Has-Changed-But-What>

John Eels (2012-12-19 14:56:25)

I read the article you mentioned (here's what someone said in 2008). I'm upset. The more I read about psychotropic medications from critical authors, the more I realize how little, if at all, they benefit patients taking them. In some instances there are

short-term benefits, but long-term outcomes (more than five years) are worse for those taking psychotropic substances. This applies to antidepressants, antipsychotics, and tranquilizers. Psychotropic substances make you sicker, not better. Educating people gives them power. You are most invested in your health. Big pharma doesn't care, and is ready to misinform, disguise, and lie to keep profits high. Doctors are misinformed and base their decisions on ostensibly scientific pamphlets provided by pharmaceutical companies. A young doctor once explained monoamine hypothesis to me using a cartoon. In the bottom corner of the cartoon was an antidepressant logo. It's messed up.

Pat (2012-12-19 16:42:00)

I wonder if your imagination will work for morning faces? i.e., 20 minutes of eyes closed and just picturing a face in your mind's eye? I mention this because of the practical difficulty of viewing artificial morning faces.

Matt (2012-12-19 21:51:25)

Watching a morning talk show for twenty minutes seems way way way easier and more practical than imagining faces with your eyes closed for 20 minutes. Seth: Morning talk shows have a low density of the necessary faces: life size looking at the camera. Long ago I used Booknotes (C-Span), now I use bloggingheads.tv.

Jane (2012-12-21 15:20:23)

I got chemical sensitivities very suddenly 25 years ago. I moved into a new empty cabin and discovered that my moods were influenced by a new rug, the new telephone, a ladder which had been covered with wood stain, and so on. Then an environmental doctor suggested I test myself for propane allergy and sure enough, when I turned off the gas, I lost depression and went from 11 hours sleep a night to 9. She suggested I do a trial without wheat and voila! less depression and aches and no more constipation. Later I got rid of mercury, and last of depression was GONE. I wake up happy every day. I knew a woman who was depressed, and had tried all kinds of talk therapy to get over it. I suggested maybe she was allergic to coffee, because she talked about her coffee a lot and people are often allergic to their favorite foods. Two days later, she came by: you were right, it was the coffee! Bottom line, many mental and emotional states from anxiety to schizophrenia are caused by intolerance to chemicals and foods and molds. I have read of a severely autistic kid who became totally normal when they figured out her particular food allergies. Another woman lost 20 pounds and got over her depression when she found out she was allergic to dairy. I have a theory that the Unibomber was allergic to chemicals: he went over the edge when he worked in a chemical factory. Also, I suspect that some are allergic to the antidepressants. Seth: Very interesting. Especially the coffee story.

Cathy (2012-12-21 18:51:53)

Check out the work of David Healy - the psychiatrist who drew the most attention to the link between SSRIs and suicidality (as well as other forms of violence). This YOUTUBE video outlines the manipulations that were used to approve and promote SSRIs. It's also a serious challenge to the thinking behind evidence based medicine - as has been taken up in this blog, as well. Very sobering. <http://www.youtube.com/watch?v=A3YB59EKMkw>

blaohoal (2012-12-22 17:04:41)

Paul: Rampage killings are not a recent or even modern phenomenon. ie: [http://en.wikipedia.org/wiki/List\\_of\\_rampage\\_killers](http://en.wikipedia.org/wiki/List_of_rampage_killers): [\\_Americas http://en.wikipedia.org/wiki/Running\\_amok](http://en.wikipedia.org/wiki/Running_amok)

Jacob (2012-12-27 13:43:55)

I think this version is more correct: 1) The shooters are young males. 2) The shooters exhibit a mind-numbed disconnect with reality. 3) The shooters had easy access to firearms. There is not conclusive evidence of SSRIs causing violence, only a vaguely understood correlation. Like the NRA focusing on video games, turning the discussion from gun control to SSRIs wanders from the realm of statistics and into conjecture territory. Focusing on SSRIs distracts from the larger problems of gun and mental health services (in general). Just my 2¢, respect to Seth and all other commenters. Seth: The evidence about SSRIs and violence collected by David Healy is considerably more than "a vaguely understood correlation." It isn't all correlational, either. Healy did an experiment.

Erin (2012-12-27 14:19:33)

Two things, a friend of mine was on Prozac briefly and she said it made her have extremely violent thoughts/urges. It was all she could do to keep herself from hurting herself or others. GAPSdiet.com I am not affiliated but believe in Dr Campbell-McBride's theories/results very strongly. I have a nephew with aspergers and he does much much better on GAPS (which removes dairy, gluten and all processed foods from the diet and restores beneficial bacteria).

Marlen Casserly (2013-01-05 00:30:57)

aspergers is inherited and currently there is no permanent cure for it.\* Our web blog <http://www.foodsupplementcenter.com/niacin-for-depression/>

## **One Reason for French Longevity: Molded Cheese (2012-12-20 05:00)**

[1]A new article emphasizes the benefits of cheese, especially "molded" cheese, such as Roquefort and Gorgonzola. Fermentation, if that is the right word, is essential:

The advantageous properties of cheese appear dynamically during the ripening process. Cheese which has been ripened for longer has been shown to be more effective in restoration of glucose tolerance, prevention of [2]steatosis [fat deposition inside a cell] and adipose tissue oxidative stress than short-ripened specimens. This data suggests that organic substances responsible for the health benefits of cheese emerge not merely due to mixing the ingredients required for cheese production, but rather as a result of a complex time-dependent enzymatic transformation of the cheese core controlled by probiota, temperature, humidity and possibly other factors.

Only in South Korea and Japan do people have less heart disease than in France, says the article. Readers of this blog will quickly see what South Korea, Japan, and France have in common. All of them eat much more fermented food than most people in rich countries. South Korea: kimchi. Japan: miso and pickles. France: cheese and wine.

Thanks to Peter MacLeod.

1. [http://www.lycotec.com/Imperox\\_files/Could\\_cheese\\_be\\_the\\_missing\\_piece\\_in\\_the\\_French\\_paradox\\_puzzle.pdf](http://www.lycotec.com/Imperox_files/Could_cheese_be_the_missing_piece_in_the_French_paradox_puzzle.pdf)
2. <http://en.wikipedia.org/wiki/Steatosis>

---

dearieme (2012-12-20 09:46:36)

Pah, what about Stilton, or Blue Cheshire, or Shropshire Blue? The British wolf 'em down and still die of heart attacks. Though your implicit point, that Americans might usefully eat grown-up cheeses, may be good. [http://en.wikipedia.org/wiki/List\\_of\\_British\\_cheeses](http://en.wikipedia.org/wiki/List_of_British_cheeses)

Chuck (2012-12-20 10:07:22)

Dave Asprey - the Bulletproof Exec - would certainly disagree. He feels that mycotoxins in moldy (aged) cheese are more damaging than any benefit derived from the cheese. When it comes to food and health, does anyone really know? I'm at the point where I only eat what doesn't disagree with me, only when I feel like it and not too much, regardless of what any health expert/layman says. Cheers

Paul N (2012-12-20 10:12:20)

While the Poms (Brits to the non-Aussies out there) do make some really good molded cheeses, that does not mean everyone eats them. When I lived there for six months I noticed that most people preferred milder cheeses. Stilton seemed to be regarded as an "upper class" cheese, and many "ordinary folks" wouldn't eat it for that reason - and that it is normally 2-3x the price. Cheese aside, I didn't see much eating of sauerkraut or the like, and ordinary yogurts don't count for much, in my opinion. They do drink a lot of fermented liquids - i.e. beer - but I don't think that counts for much, either.

John (2012-12-20 11:26:31)

I've noticed that over time, as I refine my diet, I appreciate more and more fermented foods. They have a strong, complex flavor but are usually very simple dishes overall. Chuck, You don't have to treat each person as a guru; why not just look into it? I think the observational evidence and much that Seth has posted here is quite strong.

dearieme (2012-12-20 11:31:57)

Well, Paul, all true Britons eat Stilton.

Chuck (2012-12-20 15:15:47)

John, I don't treat each person as a guru, and I have spent many years "looking into it". That's how I came to the conclusion that nobody really knows. Yes, they have great sounding theories/hypothesis, but very little unbiased hard data to back them up. Since reading the Shangri-La Diet six years ago, I have questioned conventional wisdom. That's why I read Seth, Asprey, Kruse and Peat, as well as Wolff, Sisson, Taubs and Attia. They have lots of ideas and interesting things to try, but it's not a one size fits all world. Fermented foods give me acid reflux. Raw dairy does not. Hot coffee with butter and MCT oil (bulletproof coffee) gives me acid reflux. Cold coffee with raw milk, cream and MCT oil does not. A couple of tablespoons of butter on a homemade coconut bar or a plain rice cake does not. I eat, what most would call, a regular meal (protein, starch & fruit) once a day - dinner. I drink a 16oz glass of water with 3/4 tsp of pink sea salt as soon as I get up. I follow that up with a 16oz coffee drink (1/2 coffee & 1/2 milk, cream & MCT), plus a coconut bar with 1 1/2 tbs of butter. Later I'll have 16oz on milk with cream and coco - maybe more coffee. Maybe a rice cake with butter in the afternoon, and another coconut bar with butter after dinner - maybe not. I also take some supplements - mainly minerals - because I don't believe our food supply is all that nourishing. Does that leaf of kale really have all the nutrients the governments claims it has? Who really knows? Now, would any of those bloggers/authors/doctors, etc., mentioned above call that a "perfect" diet? No. Would I recommend anyone else doing this? No. But after years of suffering from acid reflux, and slowly gaining weight on a "healthy" diet, I'm now weight stable - where I was in my twenties - forty some years ago - and no acid reflux. If you're broken - metabolically - you need to try everything to get un-broken. If you're not, you can just rock-on until you are - maybe you never will be - or try some of the ideas put forth here, and elsewhere, and maybe stay un-broken for a while longer. You never know - who does? Cheers P.S. I know, this way too long of a response.

Evelyn M. (2012-12-20 20:42:32)

Seems to me that the cheeses noted in the article are those created with the help of various kinds of fungi. Mushrooms themselves are more often found in recipes for French and Italian food than in the cuisines of northern Europe, so perhaps total fungal consumption should be considered as well.

Daniel Lemire (2012-12-21 06:39:54)

Isn't beer fermented just like wine? Yet I don't see Germany on your list.

Chuck (2012-12-22 09:53:07)

Daniel - Beer is a high calorie carbohydrate that also contains gluten. Cabbage (sauerkraut/kimchi) and cucumbers (pickles) are low calorie carbs. Cheese is a high calorie fat. So there's more to the story than just fermentation. Cheers

## False Confidence About What Caused the Newtown Massacre (2012-12-20 12:51)

New York magazine commenters are usually smart and well-informed. Which is why this comment, on [1]an article about "the forgotten victim", Nancy Lanza, the shooter's mother, stands out:

They say money cannot buy happiness [Adam's father is apparently rich], but when dealing with someone with a mental illness, it can go a long way toward paying to fix unhappiness – it can pay for good doctors, proper medication [emphasis added], care-givers/guardians, all the tools required to secure a property and keep the "patient" safe, AND giving the mentally ill person his ideal living situation, limiting the snits and tantrums that can lead to real anger, which, in turn can lead to acting out.

No doubt this particular commenter is smart and well-informed. Which makes the fact that he or she is perfectly sure that "proper medication" exists so scary, at least if this person had any control over me or anyone who mattered to me. It reminds me of people who think that if you're fat all you have to do is eat less.

1. <http://nymag.com/daily/intelligencer/2012/12/nancy-landa-rarely-counted-as-sandy-hook-victim.html>

---

TMS71 (2012-12-20 13:50:36)

I don't know what 'proper' medication is but if effective medication really existed there would be many fewer problems with schizophrenia. I'm not an expert but from what I understand schizophrenia meds have tons of nasty side effects and all they do is suppress symptoms, they don't exactly restore schizophrenics to a normal state. Schizophrenia is a horrible disease and there is no really effective treatment for it. It doesn't matter if you're rich. Also in the Adam Lanza case it seems his condition deteriorated very quickly, not really giving his mother much time to think about what to do about it. Seth: Well put. It isn't just schizophrenia. No psychiatric drug restores the person who takes it to a normal state, as far as I know. Lithium, given for bipolar disorder, causes massive weight gain, for example.

Zach (2012-12-23 18:38:02)

TMS71, what are your standards for effective medication? No one claims that medication for schizophrenia (or, as far as I am aware, any other mental illness) is intended to be curative. The sole objective is to treat the symptoms, and of course there will be trade-offs, and the effects may be marginal in cases. Seth: I think it's a narrow reading to assert that the proper medication reference asserts that such a thing necessarily exists. However I do believe that for some mental illnesses, including schizophrenia, there are medications for which the balance between symptom alleviation and side-effects lies clearly in favor of the drug for many (perhaps most) individuals. My sister has schizophrenia, and my family spent three years trying to help her without medication. Those years were wasted as best we can tell, whereas with medication she has made steady progress for the past six years. I think it is likely that many patients are worse off with the medications they take than they would be otherwise. Your concerns about antidepressants are likely well-founded. However, I don't think this is necessarily contradictory with them having substantial benefits for many users as well. I've been thinking about this the past couple of days. For many of these drugs, we don't have a clear understanding of how they work. I suspect that in many instances we have barely identified some (potentially) faulty mechanism and are in essence trying to hit the TV on its side, hoping the image clears up. Sometimes this makes matters worse; sometimes it improves them. However, if the effect is consistent on the individual level and the harm is reversible, then there is every reason to try it out. It is important to be aware that some people are suffering, and I appreciate what you do in highlighting this issue, as most people seem to underestimate it substantially. However, sometimes it seems like you think positive outcomes never happen, which troubles me. Seth: With schizophrenia it's hard to imagine a cure (restoration to normal). Presumably it is due to developmental mis-wiring that is not reversible. With depression and

bipolar disorder, however, it is entirely possible that sufferers could be cured in the same sense that giving Vitamin C for scurvy produces a cure. What is hard for outsiders and even insiders to see is how much the current emphasis on drugs makes it harder to do the research that would find the causes of depression and bipolar disorder. There may be short-term gain (people with depression suffer less) but long-term cost (a cure is less likely to be found within the next ten or twenty or thirty years). From this point of view the question of "how good are drugs?" is more complicated than just adding up the costs and benefits for the current group of people taking them.

Peter Fleming (2012-12-31 13:23:09)

ThisWhole over medicating is way out of control. There are fantastically loyal people out there who have very proud very well respected backgrounds. They maybe a bit aggressive. They may be a bit odd. They are given shit medication and get beaten to a pulp by some punk. Then you have made an enemy who has real power. Women are the words culprits for pestering men to see a shrink. All that happens is men learn to hate and avoid women. It is the cause of womens problems not the cure. If you don't like a Mans behavior get him of of your life. Don't have the arrogance to call him ill. It is a dangerous world. If you take away his survival skills and he is hurt women become his true enemy. Just stop trying to play shrink and we might survive this fucking medication induced fiasco we call the world. Do Gooding morons. Bettera punch in the face than a premeditated fire arm blood bath on kids.

### **Shangri-La Diet Tip: How to Drink Flaxseed Oil (2012-12-21 05:00)**

A good way to do the Shangri-La Diet is to drink flaxseed oil between meals. It pushes down your setpoint and also supplies omega-3. Alex Chernavsky, for example, [1]has had success with this. You will probably want to make the flaxseed oil smell-less. Here's how:

I read something on Amazon by one of the people who reviewed your book and it's worked for me. I take a small sip of water and keep it in my mouth and then take the tablespoon [of flaxseed oil] with my nose closed with the water in still in my mouth and swallow. Then I take a another drink of water and then I swish my mouth out with water and after all of it is done I have no residue of flax oil taste. It sounds like a lot to do but it really isn't.

Lately I've been doing the Shangri-La Diet by eating a daily bowl of yogurt, ground flaxseed (50 g), honey and fruit with my nose clipped shut. It tastes great because it is creamy, sour and sweet and has a variety of textures. It has a fair amount of calories (400?) so it's good for weight loss. I have to push myself to drink flaxseed oil but I have no trouble eating this.

1. <http://blog.sethroberts.net/2012/03/13/ten-years-of-weights-including-two-years-on-the-shangri-la-diet/>

---

Keimpe Wiersma (2012-12-21 06:52:09)

Why not try the original Budwig Recipe? Flaxseed oil mixed with Cottage cheese (or quark). It's creamy, delicious, and energizing, and it has been my breakfast for several years (even before I heard of the Shangri-La diet). I put some (lightly roasted) sesame seeds and some (pure) sunflower seeds in for a little extra flavour. No honey or fruit (which is perfectly healthy, but because of the sweetness might nullify the 'Shangri-La principle' of tasteless calories).

Brian (2012-12-21 13:33:29)

I nose-clip about five minutes before, rinse my mouth out with water, take a shot of flaxseed from a shotglass (2 tablespoons), and then rinse my mouth thoroughly with water once again before removing the nose-clip. Unless it's a little old, I don't have a problem drinking it straight most days, but I try to break the calorie-flavor association as suggested in the book.

dearieme (2012-12-22 07:33:33)

Of boiled potatoes: is it better to use salted or unsalted butter on them?

Evolutionarily (2012-12-22 10:38:53)

1) What does it say about our aversion to the taste of flax compared to say butter (or sugar)? 2) My method is 1 large glass of COLD low-sodium V8 tomato juice (500mg Potassium), 1-2 tablespoons freshly fine-ground flax seeds, tablespoon coconut oil, and lately throwing in some pure gelatin as an experiment. Stir it up and it goes down well if you drink it in one or two goes as I do and just feels like drinking chilled thick'ish tomato juice.

Eugene (2012-12-22 13:38:30)

I take my flaxseed oil right after my half teaspoon of cinnamon. Easy process and I can't taste the flaxseed oil at all.

Paul Blossom (2012-12-23 07:00:17)

I'm not sure I understand. I thought that it was tasteless calories, or unusual tasting calories that caused the setpoint to change. But you talk about how the yogurt-flax seed mixture tastes good, and how you are on the diet by eating that. What am I missing? Seth: It is calories without smell that lower the set point. I eat the yogurt-flaxseed mixture with my nose shut. There is no smell but it tastes good because it is sour, sweet, creamy, etc.

Keimpe Wiersma (2012-12-23 09:23:42)

Hi Paul: I was suggesting people try this (quark+flax OIL - not seeds) mixture as an alternative way to down their flaxseed oil. If you don't mix it with anything it's tasteless (and kinda smell-less) and has no bad taste (and no after taste either). I myself however am not taking it as part of any diet in particular (I'm already very athletic and well built ;-) but because it's the quickest and easiest way to have a breakfast that will keep you satisfied until lunch. And then there's the supposed anti-cancer effect of the mixture, but that's another story.

Arnold (2012-12-25 12:02:11)

Hi Seth! I wonder what your opinion is on the position of Ray Peat concerning polyunsaturated fatty acids, especially in fish and seed oil. ...declaring EPA and DHA to be safe, the FDA neglected to evaluate their antithyroid, immunosuppressive, lipid peroxidative (Song et al., 2000), light sensitizing, and antimitochondrial effects, their depression of glucose oxidation (Delarue et al., 2003), and their contribution to metastatic cancer (Klieveri, et al., 2000), lipofuscinosis and liver damage, among other problems. From raypeat.com/articles/articles/fishoil.shtml Seth: I'm not interested in the binary category safe/dangerous. What interests me is what intake is optimal. A substance that is harmful at a high dose may be helpful at a lower dose. The references may be helpful but I would look at them differently than Peat.

Arnold (2012-12-27 02:33:53)

What made you change your answer? Your first response seemed more aggressive and angry. Seth: Yes, that's why I changed it.

Aliya (2013-01-09 09:56:32)

I just started this diet 5 days ago and I do flax seed oil, walnut oil, and the light tasting olive oil. I recently read an article about the health benefits of safflower oil, is this an oil I can implement on this diet as well? Thank you! Seth: Safflower oil is high in omega-6, which is pro-inflammatory. I avoid it for that reason.

## Is Jimmy Moore's Ketosis Diet the Shangri-La Diet in Disguise? (2012-12-22 05:00)

I have recently encountered three examples that suggest low-carb diets don't work well long-term:

1. Alex Chernavsky [1] tried a low-carb diet in 2002. Starting at 270 pounds, he lost 70 pounds. A year later, he started to rapidly regain the lost weight. He stopped the diet.
2. A "medical professional" [2] started at about 260 pounds (she's 5'3"). After reading Wheat Belly, she gave up wheat. "After several months of being wheat free I lost 10 lbs. But that's where it stopped." Then she did full low-carb. "From May to July I did what basically was Atkins induction. I lost 20 lbs but then the weight loss stopped."
3. [3] Jimmy Moore lost a lot of weight eating low-carb. Starting in 2004 at 410 pounds, he lost 180 pounds. Then he gained half of it back, ending up near 300 pounds in early 2012.

The theory behind the Shangri-La Diet (SLD) says unfamiliar food will cause weight loss because its smell is not (yet) associated with calories. As the food becomes familiar, its smell becomes associated with calories. Weight loss due to unfamiliarity will disappear. Going low-carb usually involves eating unfamiliar foods. They become familiar. This explains low-carb weight regain. The theory explains partial low-carb success (e.g., Jimmy Moore didn't regain all the lost weight) by assuming that the high-carb foods (e.g., soft drinks) given up produced stronger smell-calorie associations than the low-carb foods (e.g., steak) that replaced them.

Recently Jimmy Moore [4] has been losing weight again. Starting at 306 pounds, over 7 months he has lost 60 pounds. He believes that to lose weight with a low-carb diet, there must be sufficient ketones in your blood – you must be at the optimal level of ketosis. "In order to be fully keto-adapted and to start burning stored body fat for fuel, ketone levels must be between 0.5 to 3.0 millimolar," he wrote. To be fully keto-adapted, he began measuring his ketone level regularly. His first test showed that his ketone level was 0.3. "Holy cow, that could be one of the reasons why I'm not seeing my weight go down!" he wrote. He began adjusting his diet to put his ketone level between 0.5 and 3.0 millimolar, which involved changing protein intake as well as carb intake.

He changed his diet in various ways (mainly protein reduction) and started losing weight. In what I've read, he does not describe his current diet or earlier diet in detail, but does [5] say this:

I will tell you that I've drank liberal amounts of water and 2 Tbs Carlson's liquid fish oil daily along with my regular daily vitamins during this experiment.

Which sounds exactly like the Shangri-La Diet. Alex Chernavsky lost considerable weight and has kept it off [6] doing almost the same thing with flaxseed oil.

My guess is that he is losing weight because of the fish oil. The theory behind SLD makes two predictions: 1. If Jimmy stops the fish oil and continues the ketone level adjustment, he will stop losing weight. 2. If Jimmy stops the ketone level adjustment but continues the fish oil, he will continue losing weight.

I asked Jimmy for comment. Here's what he said:

It's an interesting theory, but not one I want to particularly test out since I'm still doing so well at accomplishing what I am aiming for right now – fat loss, mental acuity and great overall health [all due to the fish oil, I believe – Seth]. Perhaps once this period of testing NK [nutritional ketosis] is over in May, I can add in your suggestion as another testing point.

The theory behind low-carb dieting has never made any correct predictions, as far as I know. It does not explain why the lost weight is often regained. If it turns out Jimmy Moore's weight loss is due to his ketone adjustment, that will be the first correct prediction of the theory.

In contrast, the theory behind SLD led me to five new ways to lose weight (eating bland food, eating slowly-digested food, drinking unflavored sugar water, drinking oil with no smell, eating food nose-clipped). That's roughly the same as five correct predictions, two of them (drinking sugar water, drinking oil with no smell) counter-intuitive.

Jimmy Moore's weight loss may eventually show you can lose weight via SLD even when you don't realize you're doing SLD.

John W (2012-12-22 05:35:52)

Have you been following all the recent interest in the "Potato" diet among Paleo enthusiasts? It also seems like the Shangri-la in disguise (bland food version). What is amazing is the number of bizarre ad-hoc theories that are flying around to explain why it works, when both you and Stephen Guyenet would have predicted it easily!

Txomin (2012-12-22 06:37:50)

Overeating is overeating independently of the amount of carbs in a diet. And, by necessity, overeating creates a surplus that the body has to do something about. Portion control, people, portion control. Substitute quantity for quality and your grocery bill won't notice the difference.

Tom (2012-12-22 08:32:54)

John W, I don't see what a potato-only binge has to do with Shangri La. Txomin, just eat less? Brilliant! I can't believe no one's ever thought of it!

KevinF (2012-12-22 09:15:30)

Dude this is seriously lame. Let's just say don't spend your Nobel Prize money til the check clears, know what I mean? Seth: "It is lame" because . . . ?

RAD (2012-12-22 09:26:36)

Seth, It is not clear to me whether you believe your Shangri-La Diet acts by reducing appetite or by changing how the body responds to the same number of calories (or both?). If someone is counting and maintaining a constant intake of overall calories and only changes whether or not they are consuming odourless calories between regular meals, do you predict any difference in weight gain/loss? My apologies if you have answered this before. Seth: I believe it acts by reducing the bodyfat set point. Which reduces appetite until the new lower level is reached. I don't know if set point changes cause metabolic changes so I cannot answer your prediction question.

Chuck (2012-12-22 09:43:41)

Jimmy Moore consumes 85 % of his calories from fat - fish oil, coconut oil, MCT and butter - I think this is more than just the SLD effect. Removing just the fish oil may or may not effect the outcome - it would depend on what he replaced those calories with - if he replaced them at all. Metabolism is very complicated - very interdependent - so much we still don't know. Cheers

Nancy Lebovitz (2012-12-22 11:04:39)

I give Jimmy Moore a lot of credit for having a reasonable theory and testing it.

Kirk (2012-12-22 11:37:41)

Whether JM is practicing SLD depends upon whether some portion of calories are flavorless and are consumed in the midst of a flavor-free window. Perhaps you could ask? As far as I can tell, there are two versions of the potato diet. Those who add flavor (butter, sour cream, salt, herbs, spices) may be losing weight due to (a) avoiding SAD foods and (b) satiety from eating root vegetables. Those who eat potatoes without any flavoring not only get (a) and (b) but also (c) negative alliesthesia and (d) reduced calorie intake due to avoiding tasty oils. I can distinguish the taste of plain potatoes from the taste of white rice from the taste of plain yogurt, and thus I do not consider these foods to be SLD-flavorless unless they are eaten nose-clipped. Paul Jaminet advances another hypotheses for why people rebound from a diet: the diet restricts nutrients the body needs, therefore over time the body's stored reserves are consumed, and thus eventually the body acts: the deficiency must be corrected by eating other foods. See his answer to the question about the potato diet at [www.latestinpaleo.com/blog/2012/12/16/perfect-health-diet-qa-with-paul-jaminet.html](http://www.latestinpaleo.com/blog/2012/12/16/perfect-health-diet-qa-with-paul-jaminet.html).

Chuck (2012-12-22 12:40:46)

Here's a very recent, and informative, podcast interview with Jimmy Moore - <http://www.fatburningman.com/jimmy-moore-nutritional-ketosis/> He's diffidently not using bland, or unusual, foods for his current n=1. Also, when he hit 230 lbs (he's 6'3"), he said he stopped trying to lose weight and added more carbs to his diet. That's when the rebound started. So I think there is more to the low-carb rebound stories than, oh gee, I don't know what happened, I didn't change a thing, meme. Kirk - There's also a third potato diet, the middle-way, so to speak, ala Free The Animal. RN uses a tad of fat per potato and sufficient supplements so he doesn't fall into Jaminet's hole of nutritional deficiency. He's also drinking raw (or lightly pasteurized) milk. Seems to be working for him. Cheers

libfree (2012-12-22 15:49:29)

@seth I agree with you on a lot of things but this is not one of them. I've kept long records of my path towards being a reasonably weighted person and the low carbs - high fat thing is the one that worked and worked for the long term. One day I looked back at my logs and realized that my longer term weight losses involved lower carbs and higher fats. Some things about low carb - high fat. 1. Appetite is reduced. While I have large meals, I only have two of them and my calories remain higher. 2. I have more energy and capacity. I measure this during my workouts. I put in strenuous exercise every day and keep logs of my perceived exertion (you have to be careful, caffeine and other stimulants can throw you off) and I have more energy off the carbs in long distance cardio. 3. The science seems sound from an evolutionary view. Having developed very large brains, we needed large sources of energy to fuel them. Fat is a very good source of this. Seth: "The science seems sound"? The test of a theory is whether it makes correct predictions. I agree, low-carb diets cause weight loss. Whether they cause weight loss for the reason their proponents say is a more difficult question. I am unable to find any correct predictions their theory makes. For example, their theory predicts that you should gain weight if you add sugar water to what you eat. Exactly the opposite happened. The brain needs sugar (glucose) - I fail to see how your evolutionary argument supports low-carb diets over high-carb ones.

Txomin (2012-12-22 16:09:29)

Tom, sarcasm has no effect on weight. The idea of portion control is as old as time (and as effective). It is after all biology 101. Yet, all you have to do is read this thread to realize that it has been dismissed or forgotten even if any and all diet programs end up there nonetheless. I say, start from the top and, instead of making strange choices (that can only produce strange results), gradually substitute quantity for quality, thus learning to eat better while enjoying it more at no additional expense. Seth: Why

do you think portion control works? Has it worked for you, for example?

Tom (2012-12-23 07:25:31)

Nonsense. "Just eat less, you gluttonous fatty," has been a catastrophic failure for the past 40 years. It's not "biology 101"; it's actually sanctimonious nonsense that's endlessly repeated by moralizing people who don't know any better.

Kurt (2012-12-23 12:26:19)

I've been doing a similar NK lifestyle, inspired by the same book that inspired Jimmy (the art and science of low-carb performance.) I've achieved great results with NK so far, primarily in the form of near-complete appetite suppression and weight loss, without any 'side effects' in terms of fatigue, etc. I typically eat one, very high-fat meal in the morning, and usually don't eat much (if anything else) the rest of the day. Part of that however includes adding coconut or MCT oil to my coffee... As I was drinking it the other day, the SLD came to mind. I'd read the book years ago but never really achieved any results (doing the LTOO variant)– but I've always liked the idea. I don't know if it's applicable given the taste/smell of coffee/coconut oil in my own example, but would you consider the coffee/oil part the overlap with SLD? If so, and if I wanted to experiment with it, would you think it sufficient to replace that fat with an equal amount of other more "familiar" fat (like say from butter), and see if my results change? Just curious, I find it all pretty fascinating... Seth: Maybe the calories in the coconut or MCT oil are not becoming associated with the coffee smell. I can't say why that would happen but it's possible. To test this idea, just stop adding the coconut or MCT oil to the coffee and see if the results change. It is the strength of smell-calorie associations that matters. Familiar foods tend to have strong associations, unfamiliar foods weak (or zero) associations. Unclear if you would smell the butter when added to the coffee so hard to predict the effect. Were you doing low-carb before you started the NK diet? How long have you been doing the NK diet? What was your starting weight and how much weight have you lost? I think it is well-established that going from an ordinary diet to a low carb diet causes weight loss, both long-term and short-term. What's less obvious is that NK is better than other low-carb diets.

Is Jimmy Moore's Ketosis Diet the Shangri-La Diet in Disguise? | Online Diets and Weight Loss (2012-12-23 13:20:42)

[...] See the article here: Is Jimmy Moore's Ketosis Diet the Shangri-La Diet in Disguise? [...]

Kurt (2012-12-23 13:55:20)

Yeah, I went from strict vegetarian to low-carb (under 50g) about a year and a half ago because i felt awful & kept gaining weight eating 'healthy' stuff like whole grains/fruit. LC has been amazingly consistent for stabilizing/maintaining my weight, but i never really lost any significant amount. More recently, I started my NK test by cranking up dietary fat and reducing protein. With a few minor 'breaks', I've been in ketosis (measured via blood meter) for about 3 months. I'm down 15 lbs in that time (starting 255), just going slow and steady. I've been drinking the coffee/oil nearly every single day, which seems to have the biggest effect on appetite suppression for me. In my case, NK appears to work significantly better than my general LC diet for weight-loss, but I can't really conclude the mechanism. The NK explanation (higher-fat, moderate-fat, low-carb => keto-adaptation => accessing body fat more readily) seems very different than the potential SLD explanation, but I don't know which (if either) is really going on. Seth: Maybe fats produce weaker smell-calorie associations than carbs or protein so anything that causes you to eat more fat is likely to lower your setpoint (assuming the theory behind SLD is true). Adding calories to a highly-familiar smell (coffee) that is already associated with zero or few calories may not produce strong smell-calorie associations. The system that forms smell-calorie associations stops paying attention to familiar smells. In contrast, with a new smell, pairing that smell with lots of calories should produce a strong smell-calorie association.

Jill (2012-12-26 09:00:09)

How does the smell-calorie association work if you switch from a highly-familiar smell (coffee) that is already associated with a LOT of calories (i.e., lots of cream) to coffee with essentially no calories (no additives)? Seth: The smell-calorie association should become weaker.

My Nutritional Ketosis Success: Is It The Calories Or The Ketones? (2012-12-28 12:13:43)

[...] I'm taking daily, self-experimenting blogger and author Seth Roberts says I'm simply doing his Shangri La Diet in disguise.

But I was already taking fish oil prior to beginning this in May [...]

Derek (2012-12-30 20:50:53)

Wow, this has got to be the worst diet blog I have ever had the misfortune to stumble upon. I want my 10 minutes back! (That I lost reading this smelly garbage). Smells associated with calories?!?! What kind of "scientific method" did you use to cook that one up? In squandering my time reading through your article on Jimmy Moore's NK success, I noted that you make tons of baseless conjectures with no science to back any of them up. Please take down your blog. As a physicist and mathematician it is painful reading such utter tripe, even if only having to do so once. Seth: There is a vast literature on flavor-calorie associations, better described as smell-calorie associations. See the work of Anthony Sclafani, for example.

Donna (2013-01-01 15:47:59)

Derek- I am just a poorly educated nobody, so I didn't realize it was "Garbage" and "Tripe." In my ignorance, I just read Seth's book, tried it...and it worked! I guess it is a good thing I didn't finish my degree. :>) -Donna

### **A Brief History of Antibiotics (2012-12-23 05:00)**

[1]This excellent article by Carl Zimmer gives a brief history of the development of antibiotics. It makes the usual points that the microbes within us improve our health and killing them (with antibiotics) can have bad effects. [2]One study found that children given antibiotics had a higher risk of developing inflammatory bowel disease (IBD) later in life. Giving antibiotics to a child younger than one year was especially dangerous – the risk of IBD increased by a factor of 6.

The article makes the minor mistake of taking seriously what researchers say about number of species:

Each of us is home to several thousand [bacterial] species. . . . [3]My own belly button, I've been reliably informed, contains at least 53 species.

Counting the number of species inside us is like [4]measuring the length of the coast of England. The more closely you look (in the case of coastlines, the shorter the ruler you use), the larger the number you will arrive at. I'd be surprised if the researchers who count bacterial species adjust for this.

What I found most interesting about the article is it says nothing about fermented foods. Apparently the connection is not so obvious.

4. [http://en.wikipedia.org/wiki/How\\_Long\\_Is\\_the\\_Coast\\_of\\_Britain%3F\\_Statistical\\_Self-Similarity\\_and\\_Fractional\\_Dimension](http://en.wikipedia.org/wiki/How_Long_Is_the_Coast_of_Britain%3F_Statistical_Self-Similarity_and_Fractional_Dimension)

dearieme (2012-12-23 06:45:11)

Ahoy, Seth. If you type The sin of bad science into google and then click on the FT link you can read this article without wrestling with their paywall.

shtove (2012-12-23 17:50:55)

First time I've come across that point about the number of species. Similar to the notion of Mandelbrot fractals.

derp (2012-12-23 22:45:40)

Nice story. Now could you please beat up one or more of these idiots who coerce their doctors into prescribing antibiotics for the common cold?

Kevin (2012-12-24 00:32:39)

Brilliant article on immunotherapy in nytimes today: <http://www.nytimes.com/2012/12/23/magazine/is-the-cure-for-cancer-inside-you.html?src=me&ref=general&pagewanted=all>

LisaW (2012-12-24 16:25:07)

Interesting article. Just a quick correction: IBD is short for Inflammatory Bowel Disease, which is a collective term for the two serious inflammatory bowel conditions - Crohn's disease and Ulcerative Colitis. This is not the same as irritable bowel. Seth: Thanks for the correction.

Greg (2012-12-24 16:53:36)

"Counting the number of species inside us is like measuring the length of the coast of England." There are different definitions for the term "species" throughout biology and the use of this word in reference to bacteria appears to be controversial. Apparently enough scientists think bacterial species don't exist that you can publish a peer-reviewed paper in 2012 called "Bacterial species may exist, metagenomics reveal." Carl Zimmer certainly knows this and has written about it, though I personally find the use of the term to be confusing to those of us who like to dig deeper. I think it is possible that some scientists are using the term without due care, but good microbiology papers will be clear on what they mean by the word if they use it at all. It is sometimes defined with agonizing rigor. Mostly I've seen "species" used to refer to "operational taxonomic units" (OTUs), defined as a specified level of sequence similarity in a particular segment of genetic material (e.g. certain variable regions of 16S ribosomal RNA). The boundaries between OTUs depend on what level of sequence similarity you specify (in other words, the size of the ruler you are using to measure the coast of England). OTU classifications vary from one paper to another and can depend, for example, on which software is used to crunch the sequence data (see e.g. <http://hmpdacc.org/HMQCP> for the Human Microbiome Project). Seth: Good points. Even when the definition of "species" is made clear, there is still the problem of coverage. As you sample more and more exhaustively, the number of species will get larger and larger.

Handoko (2012-12-31 07:45:12)

Its an interesting brief... but in My personal opinion, its suggested to choose a natural antibiotic that can be found surround us. they're still the best we get.

### Assorted Links (2012-12-24 05:00)

- [1]Unusual fermented foods, such as shio koji (fermented salt, sort of)
- [2]David Healy talk about problems with evidence-based medicine. Example of Simpson's paradox in suicide rates.
- [3]The ten worst mistakes of DSM-5. This is miserably argued. The author has two sorts of criticisms: 1. Narrow a diagnosis (e.g., autism): People who need treatment won't get it! 2. Widen a diagnosis (e.g., depression) or

add a new one (many examples): This will cause fads and over-medication! It isn't clear how to balance the two goals (helping people get treatment, avoiding fads and over-medication) nor why the various changes being criticized will produce more bad than good. Allen Frances, the author, was chair of the committee in charge of DSM-4. He could have written: "When we wrote DSM-4, we made several mistakes . . . . The committee behind DSM-5 has not learned from our mistakes. . . ." That would have been more convincing. That the chair of the committee behind DSM-4, in spite of feeling strongly about it, cannot persuasively criticize DSM-5 speaks volumes.

- [4]The Lying Dutchman. "Very few social psychologists make stuff up, but he was working in a discipline where cavalier use of data was common. This is perhaps the main finding of the three Dutch academic committees which investigated his fraud. The committees found many bad practices: researchers who keep rerunning an experiment until they get the right result, who omit inconvenient data, misunderstand statistics, don't share their data, and so on."

They look like teepees.

## Elements of Personal Science (2012-12-26 05:00)

To do personal science well, what should you learn?

Professional scientists learn how to do science mostly in graduate school, mostly by imitation, although they might take a statistics class. Personal scientists rarely have anyone to imitate, so have more need to understand basic principles. There are five skills/dimensions that matter. Here are a few comments about each one:

1. Motivation. In conventional science, the scientist does it as part of a job and subjects are paid. Neither works here: It isn't a job and you can't pay yourself. My original motivation was wanting to learn how to do experiments (for my job – experimental psychologist). After I discovered how useful it could be, I started doing personal science to solve actual problems, including early awakening and overweight. On these two subjects (sleep and weight control) conventional scientists seemed to have made and be making little progress, with a few exceptions (such as Sclafani, Cabanac, and Ramirez) in the area of weight control. Here my motivation was lack of plausible alternatives. Now I now see personal science like playing the lottery, except it costs almost nothing. Most of the time nothing happens, once in a long while there is a big payoff. An example of the lottery-like payoff is that for ten years I measured my sleep, trying to figure out what was causing my early awakening. One day it suddenly got worse (when I changed my breakfast). That led me to realize many things. Another example is I measured my brain function with an arithmetic test for several years. One day it suddenly improved (due to butter).

2. Measurement. Conventional scientists almost always use already-established measures because they improve communication. In contrast, a personal scientist wants a measure that is especially sensitive to the problem (e.g., insomnia) to be solved or the question to be answered (e.g., did flaxseed oil improve my balance?). Communication is

much less important. Psychologists use [1]Likert scales (rating scales with 5 or 7 possible answers) to measure internal states but they almost always use inexperienced and unmotivated subjects. When I've measured internal states (e.g., mood), I have a lot of motivation and eventually have a lot of experience and find I can make much finer distinctions. Unlike conventional research, I care enormously about the convenience of the measurement. For example, it should be brief.

3. Treatment choice. You don't want to do a lot of experiments that don't find any effect, so you need to choose wisely the treatments you test. Scanning the internet (what has cured insomnia?) and reading scientific papers (what are standard treatments for insomnia?) hasn't worked for me, although it's better to try anything than to try nothing. One thing that's worked is to test large surprising effects I hear about. An example is Tara Grant's discovery that restricting her Vitamin D to the morning improved her sleep. Also successful is measuring the problem for a long time, in search of outliers. When the problem suddenly gets better or worse, I test whatever unusual happened just before that. For example, when I switched from oatmeal breakfast to fruit breakfast, my early awakening suddenly got worse. I started testing various breakfasts. A third successful strategy is to combine the first two strategies with evolutionary thinking, giving bonus points if the treatment I'm thinking of testing provides something present in Stone Age life but absent now. For example, this is one reason I decided to test the effect of standing a lot. Stone Age people must have been on their feet more than most of us.

4. Experimental design. The hard part is knowing how fast the treatment effect rises and falls. If it rises and falls quickly, your experiment should be very different than if it rises and falls slowly. In most cases, what I study rises and falls slowly and the best design is some variation of ABA. Do A for several days, do B for several days, do A for several days. It is much easier to do a condition for too few days than too many so I try to err on the side of too many days. The hardest lesson to learn was to realize how little I know and avoid complex designs with untested assumptions.

5. Data analysis. Statistics books and classes emphasize statistical tests, whereas in practice what matters are simple graphs (e.g., what you measure versus time). I make one or more new graphs every time I collect new data (e.g., I make a plot of my weight versus time every time I weigh myself) but rarely do t tests and the like. I've learned to make several graphs at different time scales (e.g., last week, last month, etc.), not just one graph.

I believe these factors combine in a multiplicative way to determine how much you learn. If any is poor, you will learn little. They provide a way of asking yourself what you've learned after you've done some personal science. For example, where did I get the idea for the treatment? Presumably, with experience, you slowly get better at each of them.

Thanks to Brian Toomey for encouraging me to write this.

---

dearieme (2012-12-26 08:59:22)

Maybe I should try inhaling tiny quantities of stone dust every day? Seth: I agree, not obvious why that is a bad idea.

Nancy Lebovitz (2012-12-26 21:21:25)

Have you explored [1]squatting? I'm reasonably sure that people without chairs do a good bit of it.

1. [http://en.wikipedia.org/wiki/Squatting\\_position](http://en.wikipedia.org/wiki/Squatting_position)

Brian Toomey (2012-12-26 23:12:54)

After speaking with you Seth it occurred to me that you would also want to include data presentation, which would take two forms: 1) presentation to people interested in personal science, similar to this blog, and 2) presentation to the general public like your SLD book. The later would focus on getting people to try an intervention, and would be simple, including direct advice and visualizations or rich media where possible.

Alex Berg (2013-01-05 12:05:35)

And thank you to you Seth for writing it. I find it hard to keep up with the measurements when I don't really seem to learn from them. Seth: Great point.

Babar (2012-12-27 09:43:37)

Mathematicians lament has been expanded and released as a short book as well- possibly that would answer some of your questions.

Chuck (2012-12-27 10:30:06)

I would be very interested to know what Frederick Hoelzel's diet and exercise routine was between the mid 1930s to the mid 1950 (age 45 to 65), because looking at his picture taken in 1955 at age 65, it's quite apparent that he is lean and muscular (he also appears to be small boned like myself) with very smooth skin - if you don't look at his head/face you would think he was

in his 20s. Cheers

## Department of Self-Presentation: The GiveWell Mistakes Page (2012-12-28 05:00)

The GiveWell website has [1]a page ("Our Shortcomings") that is a list of mistakes. A good idea, sure, what about execution?

It starts badly. Here is the stated reason for the page:

Because we are a startup organization working in areas we have little experience with, it is particularly important that we constantly recognize and learn from our shortcomings. We make this log public so as to be up front with any potential supporters about ways in which we need to improve.

The second sentence alone would have been fine.

The first item is called "overaggressive and inappropriate marketing." I'd call it "dishonest marketing".

I once attended a short talk, before PowerPoint, in which the speaker, Herb Terrace, a Columbia University psychology professor, put a slide in backwards. He struggled to fix it. It was funny and memorable. Maybe I should make similar mistakes on purpose, I thought. I have no idea if the GiveWell mistakes page is a reasonable summary of their mistakes. As Renata Adler [2]pointed out, the New York Times corrects trivial mistakes and leaves major blunders uncorrected ("there are, as a rule, no genuine corrections. These departments are cosmetic"). But the GiveWell mistakes page does three things well. (a) It's a readable summary of what they do and their goals. In contrast, I found [3]their "About" pages unhelpful. (b) It makes them more attractive. As confessions of difficulties and problems and weaknesses usually do. (c) It draws attention to them. It is an original and thought-provoking thing to do. The next time I teach a class, should I include "mistakes I made last time I taught this class"? Maybe.

Kirk (2012-12-29 12:20:31)

I tried the sitting/rising test. Sitting is more difficult than standing. I use my left hand (non-dominant) for support. It took about ten trials before I was able to sit, using the left hand for support, without the final inches being a controlled fall. I may keep practicing this. I find it annoying that my score is at best 8.

dearieme (2012-12-29 15:09:44)

We own a sofa from which none but the young can arise without a struggle. To my wife's amusement, I do it by rolling into a kneeling position on the floor, and getting up from there. "Elegant!" I say, but she demurs.

aaronblaisdell (2012-12-29 22:44:47)

I remember my first (and so far only) time to down hill ski. It was a few years ago at the Winter Conference on Animal Learning and Behavior held at Winter Park, Colorado. I took lessons, of course, so I could learn appropriate technique. The instructor taught us how to unhinge the skis from our feet whenever we fell down so that we could stand up. Afterward, we would then be able to reattach the skis. This seemed like a lot of needless work to me and I asked why we couldn't just get up again without taking off the skis? "You'll see!" was their response. Well, I fell a lot (not surprising). When I did fall, it was usually by sliding backward onto my butt. From this position, it was quite easy actually to rise up in a squat position. Perhaps it was the fact that I had started doing weighted squats as part of my weekly exercise routine for the two years prior to the ski trip that helped. Perhaps the extra strength and power I had from eating a paleo diet helped, too. I was surprised how easy it was, and how much quicker to immediately get up to resume skiing than to take the skis off, get up, and put them back on, which was quite a pain in the tuckus. To this day, I find it quite easy to lower myself to a sitting position on the floor, and to rise again smoothly and easily. Now, the low and sagging couch at my aunt's house, that's another matter altogether!

## **Never Be Alone in a Hospital (2012-12-30 05:00)**

[1]The Health Care Blog post titled "The Empowered Patient" by [2]Maggie Mahar exists, as far as I can tell, because much hospital care has considerable room for improvement and many mistakes are made – for example, patients are

given the wrong drug. One commenter (MD as Hell) said he has worked in hospitals more than 30 years and has some advice, including

1. Never be alone in a hospital
2. Never go to a hospital unless you have no alternative
3. Do not let fear motivate you to be a consumer of any part of healthcare

In the comments, several doctors expressed their dislike of the whole idea of "patient participation". For example,

Patients manage the process. Really? I'm sure your plumber or mechanic love you and this philosophy so much they hug you when you greet them.

Plumber and mechanic errors are not the #3 cause of death in America, as [3]Marty Makary says about medical errors.

Here is another argument against patient participation:

The huge problem that barely anyone wants to talk about is [the assumption] that patient (and family ) participation are always (or even just mostly) beneficial. This is a completely unfounded assumption. Please read Dr. Brawley's book "How we do harm" to read 2 long and IMHO representative anecdotes of patient/family centeredness resulting in net harm. . . . Lack of patient involvement and medical errors are hardly on top of the list of pressing flaws of the US health care system . . . Profit centeredness resulting in overtreatment of the insured and undertreatment of the underinsured are the main issues.

If medical errors are the #3 cause of death in America, they are one of the most serious flaws of the US health care system. The doctors who dislike patient participation in this comment section do not propose a better way to reduce mistakes, a better way to spend the time and mental energy required by patient participation. Maybe their annoyance is a good thing. Maybe they will be so annoyed they will reduce errors in other ways.

It is bizarre that patient involvement cannot be easily dismissed. I cannot think of another profession (accountants, bus drivers, carpenters, dentists, elementary school teachers, and so on) where anyone says never be alone with them. Sure, hospital patients are highly vulnerable but that vulnerability is no secret. It could have led to a system, similar to flying (airplane passengers are highly vulnerable), with an extremely low rate of fatal error. My own experience supports patient involvement. The biggest motivation for my self-experimentation, at least at first, was my self-experimental discovery that a powerful acne medicine my dermatologist had prescribed (tetracycline, an antibiotic) was no help. My dermatologist had shown no signs of considering this a possibility. When I told him about my experiment (varying the dose of the antibiotic) and the results (no change in acne), he said, "Why did you do that?" Later a surgeon I consulted about a tiny hernia [4]was completely misleading about the evidence for her recommendation that I have surgery for it.

---

babar (2012-12-30 07:43:44)

ok, then how about Never Let Your House Be Alone with a Plumber

dearieme (2012-12-30 08:36:47)

When you are very ill/tired/worried, your ability to participate fruitfully may be limited. Still, I wish I had participated more over the years whenever I was well enough to do so. In recent years the probable best thing I did was veto the GP's recommendation to take statins, a decision made when I was none of ill/tired/worried. I also now incline to the view that the patient is probably the only actor in the drama who will try to weigh up everything involved - or, at least, everything he (thinks he) understands. The specialists are specialist, the GP can give you only a fraction of his attention - it's up to you to, at the very least, ask some critical questions.

Jeff (2012-12-30 10:01:57)

Taleb brings up the airplane example a lot in his writing. The pilot has as much to lose as you do if the plane goes down so it is in his interest to be vigilant. That is not to say that the doctor is unconcerned for your welfare as a patient but they simply do not have as much to lose as you do if something goes wrong with your treatment. Having "skin in the game" is a great motivator for attention to detail.

ChristianKI (2012-12-30 13:25:06)

As far as advice of what do when you are in hospital I think the post lacks something. Write down what they are doing with you and when they did it. You are in a bad mental state. You shouldn't try to rely on your memory.

Adam (2012-12-31 00:18:40)

@Jeff re: "Skin in the game" Easy solution: Just as the pilot loses his life along with the passenger's if he crashes, mandate that any surgeon who performs the wrong surgery must have the same surgery performed on themselves. Not that amputating the wrong limb is common (AFAIK), but if the surgeon lost his arm too when he accidentally took little boy Tommy's, that'd be quite the dis-incentive!

Paul N (2012-12-31 17:11:15)

If medical errors are the #3 cause of death, then it seems that the statistics on those errors, and the doctors/hospitals who made them, should be made public, continually (i.e. online) Just like it is possible to find out how many cases a lawyer wins/loses, so too with the medical profession. If it is measured \*and\* publicised, it will get managed. The trick being to have an objective way of measuring the errors...

## How to Find a Doctor (2012-12-31 02:45)

David A. Pfister, a Bay Area oncologist, was named "Best of the Bay Oncologist" in 2010 by KRON-TV, according to a Yelp reviewer. He was named one of America's "Top Doctors" by [1]US News, based on a "peer nomination process." The biggest doctor rating site, at least in America, is HealthGrades. A [2]HealthGrades survey of Dr. Pfister's patients (n = 31) asked Would you recommend Dr. Pfister to family and friends? Dr. Pfister's score - halfway between "mostly yes" and "definitely yes" - put him close to the national average.

The "Best of Bay" comment was one of seven Yelp reviews of Dr. Pfister that filtered out (= downgraded) by Yelp's filtering algorithm. The filtered-out reviews were much more positive than the reviews that passed the filtering process. In the five passing reviews, Dr. Pfister received an average rating of 1 out of 5, with comments to match:

He was chronically late, and had poor time-management skills. . . . This was the third and final time that he's made me wait at least an hour past my scheduled appointment time (requiring me to leave before seeing him). [2008]

He was 30+ min late, unfriendly and unapologetic. His bedside manner is horrific and he talked me into having a procedure that ended up being painful and unnecessary. The office is completely disorganized. There are records of deceased patients out in the open in the bathroom. [2011]

When I visit his office, the only thing he wishes to discuss with me are the results of my recent labs. If it were up to him, my appointment would last 2 minutes. . . . All my other doctors have told me for years I should get my care elsewhere. Typical visits consists of 2 hours waiting, 5 minutes with the doctor. [2010]

He is consistently late, as much as two hours, to his first appointments of the day. He arrives completely disheveled, hair sticking up and shirt untucked as if he was up half the night drinking. He also forgets your history and has to be reminded who you are, despite continual and regular appointments. Finally, if you ask questions he becomes very defensive and has even yelled at me for asking questions. [2009]

Which view of Dr. Pfister is more accurate, KRON-TV or Yelp? In March 2012, [3]his license was suspended. He "admitted he has a psychiatric problem and a substance abuse problem." The Yelp reviews that passed the filtering algorithm, with their complaints about lateness, poor grooming, and disorganization, predicted the suspension (assuming that doctors with low yelp scores are more likely to be disciplined). HealthGrades has yet to figure out there is anything unusual about Dr. Pfister. He is not listed on [4]vitals.com.

I came across Dr. Pfister while glancing through yelp ratings of Berkeley doctors. His low rating surprised me. A yelp reviewer linked to the license suspension.

My conclusion: When looking for a doctor, check yelp. Yelp's filtering algorithm, which emphasized the low reviews, really works. In California, you can search [5]state records for licensing board disciplinary actions but such actions are very rare.

Thanks to Bryan Castañeda for a long conversation about detecting bad doctors. In [6]Unaccountable (which should have been on my [7]Best Books of 2012 list), Marty Makary says that hospitals and surgeons are in many ways unaccountable for their mistakes. Yelp is a countervailing force.

Tom (2012-12-31 12:35:40)

Off topic, Seth, but thought you'd be interested in this quote from the URL below: "Before Dr. Pringle started the study, a colleague suggested she was wasting her time: to prove that something doesn't age would take far longer than the duration of a research grant, perhaps longer than a researcher's career or even life. But she stood her ground." [www.nytimes.com/2013/01/01/science/studying-seemingly-immortal-lichens-in-a-place-for-the-dead.html](http://www.nytimes.com/2013/01/01/science/studying-seemingly-immortal-lichens-in-a-place-for-the-dead.html)

Matt (2012-12-31 14:18:20)

While this scenario may have proved to be the more accurate portrayal, Yelp is a crooked organization. Yelp's filtering "algorithm" goes something like this: 1. Business begins receiving Yelp reviews of varying rank. 2. Yelp contacts business, asking them to pay money to hide low ranked reviews. 3a. Business pays Yelp: low ranked reviews are hidden. 3b. Business does not pay: Any positive review is filtered within a couple of days. Yelp claims that they filter when they suspect that the business solicits for positive reviews. While that is likely also true, the scenario I laid out, is also true. <http://www.eastbayexpress.com/ebx/yelp-and-the-business-of-extortion-20/Content?oid=1176635>

Vince (2013-01-02 18:10:30)

(Disclosure: I work for Yelp.) Matt, your scenario is simply not true. Yelp's review filter, which works to help consumers in precisely the manner described in Seth's blog here, is applied equally to all business listed on Yelp, advertiser or not. There is no connection between how reviews are displayed on Yelp and advertising. As is described in numerous places on our website, Yelp advertisers pay to advertise (primarily local/search advertising, just like on the major search engines) and do not gain the ability to control the review content on their Yelp listing. Neither does Yelp penalize businesses that decline to advertise. The filter helps consumers trust and benefit from Yelp (as described here), which is why 84 million of them used our service on average last month. Seth: Thanks. Did Yelp reply to the East Bay Express article? I read it when it was published and still remember it. I do not remember any rebuttal.

Matt (2013-01-03 08:46:44)

Sounds like we need an undercover investigation :) because the internet is full of stories like the one I heard from the business that warned me about Yelp reviews. You would think that my legitimate review that I placed on that organization's Yelp page wouldn't be filtered out, seeing that I'm a unique IP address, etc. But the business absolutely predicted that any positive review that was placed would be filtered within a matter of days, and that this all started soon after he declined the ad payment. A quick internet search to back up my personal experience revealed that East Bay article as well as other stories.

Vince (2013-01-03 17:22:28)

Seth: Yes, Yelp did reply to the EBE article and published a number of rebuttals on our corporate blog. You can find them at: <http://officialblog.yelp.com/2009/02/kathleen-richards-east-bay-express.html> <http://officialblog.yelp.com/2009/02/east-bay-express-story-starts-to-unravel.html> Matt: We also published a number of posts on our blog about how our filter works and why some businesses may have come to believe in a grand (but untrue) conspiracy theory. Some good ones are here: <http://officialblog.yelp.com/2010/02/lady-justice-needs-a-lawsuit-filter.html> <http://officialblog.yelp.com/2010/03/additional-thoughts-on-last-weeks-lawsuit-or-how-a-conspiracy-theory-is-born.html> As you can see, there have actually been some undercover investigations by the media and even some lawsuits brought making the same allegations; none of them found anything to substantiate the claims and the suits were dismissed with prejudice. The bottom line is, regardless of how much or how many businesses want to believe in an easily disproved conspiracy theory, it simply isn't true. That's why consumers trust Yelp and use it every day to connect with great local businesses. Which also happens to be our mission.

## **Interview with Doron Weber, Author of Immortal Bird, About What He Learned From a Hospital Tragedy (2012-12-31 20:50)**

[1]Immortal Bird by [2]Doron Weber, a program director at the Sloan Foundation, is about his son, Damon, who had a rare medical condition, and his son's heart transplant operation (cost = \$500,000) at New York Presbyterian/Columbia

University Medical Center. Damon died after the operation. The post-operative care was so bad his father sued. "Three years into the lawsuit, the medical director [of the hospital] claimed Damon's post-op records couldn't be located," [3] said the New York Times.

How can such tragedies be prevented? To find out, I interviewed Doron Weber by email.

SETH Let's say someone lives in a different part of the country – Los Angeles, for instance. What would you tell them about picking doctors to do a difficult expensive operation?

DORON I believe the key step before making any major medical decision is to gather as much information as possible. In my son's case, we talked to everyone we knew at his regular New York hospital (New York Presbyterian) for their recommendation, and then we compared that information with experts at half a dozen other hospitals in New York and across the country who had a good reputation for his operation. I had established contacts at many of these hospitals, usually through physicians or scientists who I knew, either personally or professionally. But sometimes I would just get the name of a leading doctor and call him or her cold. They didn't always respond but often they did, especially if you could make the case sound interesting. And I found that most doctors are very decent people who will try to share their knowledge, albeit succinctly. I got the best results by being polite but determined and I didn't require a long conversation—though some physicians were truly generous with their time—because in the end, you just want to know what they would do or who they would go see if it was their son or daughter.

I also traveled with my son to meet many of these experts at places like Children's Hospital of Philadelphia, Boston Children's, and the Mayo Clinic in Minnesota. During my son's long illness, I found 3-4 key advisers—medical people who I respected and trusted, who would take my calls (one was my cousin, another the friend of a friend), and who were willing to work with me as my son's case developed. These wonderful physicians would not just give intelligent medical advice seasoned by experience but they would send me the latest medical journals and articles for any possible leads. And they would direct me to other experts. Good people tend to know other good people.

If there was one mistake I made, it was to rely too much on data and statistics—they do matter, and they worked to extend and enhance my son's life for several years—and not to listen to my own instincts. The physician whom I consider responsible for my son's death—and against whom I have a still-pending lawsuit—was someone whom I had a bad feeling about from the start. (See *Immortal Bird* for examples.) But she had a great reputation, everyone kept extolling her and her hospital had the best outcome data for my son's operation. Also my son wanted to stay at that hospital. So I suppressed my doubts and reservations and made the correct statistical calculation but a disastrous human one.

SETH What about screening doctors by asking about their legal record? For example, "Have you ever been sued for malpractice?" If so, going down the list of cases and learning about each one. And: "Have you ever been disciplined by a medical board?"

DORON Before my son's wrongful death, despite all my information gathering, it never occurred to me to inquire about a physician's legal record and whether he or she had ever been sued for malpractice. Now I know better. It would be very helpful to know if, and how many times, a physician has been sued before, even if it not definitive, because many doctors and hospital insurers settle out of court with strict confidentiality rules. But at least it gives you a preliminary context. And of course there are also frivolous lawsuits but if the same doctor was charged three times for the same alleged infraction, it is worth heeding. I have been most amazed at how many people, when I tell them about my medical lawsuit, describe how they or a loved one were horribly mistreated by a physician or hospital and came close to filing a lawsuit—but they didn't go through with it because of the stress and the long, uphill battle and the years and expense involved. (Our own lawsuit has been active for six years but is on a contingency basis because we could not have afforded it otherwise.) Almost everyone has a personal hospital horror story—if a conversation ever flags, just bring up this subject—but most people shy away from challenging the hospital and the doctors with their big

reputations and deep pockets. I also found people who did not understand that they had been mistreated because it was too painful to confront and they preferred to accept the hospital's misleading explanation. I think beyond a record of being sued, every physician should have to post a record of all patient histories, which minimally would include diagnosis, length and type of treatment, and outcome for each case. In no other field does the consumer have less information on which to base a decision, and yet in no other field are the stakes so high.

SETH Based on your experience with your son, what are the first things we should change about our health care system?

DORON For me the greatest problem with our health care system is that it is no longer about health care but about the health business. Many hospitals have been taken over by private equity firms while even the non-profits are under pressure to reduce costs at the expense of patient outcomes. So I think we have to find a way to return the patient to the center of the health care system and ensure that everything else revolves around his or her well-being. Efficiency and controlling costs matters but health care is not just another business and should not be run by business managers. I like the Mayo Clinic model where doctors are under salary so can take their time and not worry about insurance and where physicians at the same hospital consult with one another and take a more holistic, multidisciplinary approach. I also think continuity of care is absolutely critical and each patient needs one assigned physician who will take full responsibility and oversight for his/her care and be held accountable, regardless of how many specialists or other doctors the patient sees.

#### Success on the Shangri-La Diet (2013-01-02 05:00)

Over at Mark's Daily Apple forum, [1]someone named heatseeker posted this:

I hesitated to post a thread about this because I feel like these forums have been overrun with "fad" diets and hacks lately--and because it's honestly so bizarre-sounding that I feel a little silly admitting it--but my success on the Shangri-La Diet has been such that I felt I should share. I've had serious body fat setpoint issues since, oh, college, I guess--six years--and after watching my setpoint slowly creep up throughout my 20s with absolutely NOTHING making any difference, I'm finally losing weight steadily. I've lost 13lb and it's still coming off like clockwork. Nothing else in my diet or exercise regimes changed, and I've experienced no strength losses (I've continued to make gains, actually).

I use refined coconut oil, 2tbsp/day. I was using unrefined at first but the flavor was too strong.

Has anyone else done the SLD, and had success? I just felt like I should spread the word, because I know there are some other setpoint-challenged people on these forums, and this has been a big breakthrough for me.

"I haven't heard about it," responded zoebird. Then someone posted several links.

1. <http://www.marksdailyapple.com/forum/thread74412.html>

---

Nancy Lebovitz (2013-01-02 09:38:46)

"Nothing else in my diet or exercise regimes changed," I thought SLD worked by lowering appetite. Do you think he's eating less without noticing it?

dearieme (2013-01-02 10:10:38)

Nancy, maybe rather than meaning that he ate the same amounts of everything, he meant that he ate things in the same proportions. Seth: That is how I interpreted it.

Nancy Lebovitz (2013-01-02 13:00:37)

It's also possible that whatever effort he made to regulate his eating didn't change.

heatseeker (2013-01-03 10:11:39)

Hi all, it's heatseeker here. Amazing that my post over there somehow wound up here! Anyway, just to clarify, when I said "nothing else in my diet or exercise regimes changed", I meant that I wasn't purposely doing any other diet/weightloss method, and I didn't suddenly increase my exercise. I was trying to make it clear that it was the SLD that was the affecting factor.

Obviously my food intake changed as a result of SLD—that's why it's working, natch—but it wasn't like I started SLD while also doing other things that might have affected my weight. Love the MDA boards to death, but some of the commenters over there have a tendency to pick apart any claims, and I was worried I'd get a lot of "well you went low carb/did more crossfit/stopped eating dairy/started eating vitamin D/etc., and THAT'S why you're losing weight" naysayers. I was just trying to make it really clear that SLD was the only variable in suddenly having success losing weight. Also I'm a chick. Carry on. :) Seth: Thanks for the explanation.

Meegs (2013-01-04 03:59:06)

It works for me as well, but people think I'm crazy. They can't make sense of the idea. But I lost 10 pounds, and even through the holidays I maintained the loss. I stopped it for a while and tried eating low-reward foods, but the cravings came back. I found myself eating bagels and chips again. So I'm back on Shangri-La, and it feels great to be in control of what I eat.

Nathen (2013-01-06 17:54:46)

A friend of mine has been trying to gain weight for many years with no success. Based on your theory, what should she try? Seth: eating foods with (a) lots of calories, (b) that are quickly digested (= high glycemic index) and (c) taste exactly the same each time you eat them (= factory food, chain restaurant food). An example is Coke with sugar.

LeConz (2013-01-13 16:33:53)

Did it ever occur to you (Seth) that a normal carb-diet might for some people be a Anti-Shangri-La diet? I changed my eating pattern recently to a low-carb-diet as I needed to loose some weight. First thing I realized was that I needed about 3 hours less sleep, my digestion worked perfectly AND I lost a non-stop craving for food. The last point is the most important. I learned that I'm coeliac with overweight. This appears to be rather illogical as coeliac disease reduces calorie intake due to malabsorption in the bowels. As I read about the Shangri-La diet I realized that this diet is the exact opposite of my former diet. During the Shangri-La diet the brain realizes there is more nutrients than should be there; The conclusion is that the food eaten has a higher caloric value and less needs to be eaten. The set-point gets lowered, hunger is reduced. During a diet with gluten the bowel doesn't work properly and the brain realizes there is less nutrients there than should be; The conclusion is that the food eaten has a lower caloric value and more needs to be eaten. Because I don't eat gluten anymore my hunger vanished. As I feel really good now I can understand why some people get so fanatic about the paleolithic diet. Quitting gluten when you are coeliac is a true revelation. Nonetheless it might work in the same way as the Shangri-La diet. The Shangri-La diet is more important as it is a general concept that can be user universally for all kinds of diet plans. P.S.: I learned today that pigs are fattened with artificial sweetener. This makes sense as the animal tastes more nutrients than there actually is and can be recognized by the brain. Therefore the animals hunger is increased and it fattens faster. Seth: The Shangri-La Diet is based on two assumptions: 1. Set-point control of weight (old idea). 2. Control of set-point by smell-calorie associations (new idea). What you are describing as the Shangri-La Diet is the old idea. What you describe does not say the new idea is wrong but it cannot be explained by the new idea. The experience you describe suggests that the new idea is incomplete. It suggests, at least to me, that you were hungry because you weren't getting all the nutrients you needed from your food. Your brain was making you hungry so that maybe you would eventually eat the nutrients you needed. That's different from the new idea (assumption #2). It's not so clear your experience is consistent with the old idea either but that's a more complicated discussion.

dearieme (2013-01-03 05:47:42)

My wife wonders about her BP so if anyone can direct me to a graph like Taleb's, but for women, I'd be grateful.

dearieme (2013-01-03 05:59:46)

The Levitt piece is revealing. "Three hours later, we are still at the hospital. It is difficult to set up home oxygen on the weekend, and the pharmacy apparently has difficulty filling a prescription for a common drug": you can get service like that on the NHS, free. "In this era of molecular biology, the most valuable medication was morphine, a drug that has been available for almost 200 years." Many British doctors believe that American doctors cause - or rather permit - a great deal of unnecessary pain for their patients by underprescribing morphine. Anyway, once it had been determined that the poor woman was riddled with cancers, perhaps palliative care might have been the wise thing to do from the beginning? <http://www.newswithviews.com/Howenstine/james181.htm> <http://www.dailymail.co.uk/health/article-2211442/I-want-enjoy-days-waste-having-chemo-Doctor-Kate-Granger-tells-shes-stopped-treatment-prolong-life.html> Seth: Dr. Levitt might have written this: "In this era of molecular biology, and 100 years of Nobel Prizes in Medicine, the most valuable medication turns out to be morphine, a drug that has been available for almost 200 years."

Alex Chernavsky (2013-01-03 07:53:47)

With regard to graduate school for literature: About ten years ago, there was a wonderful essay written by a disillusioned young woman who (foolishly) went to Yale to get a PhD in literature. Here's how the article starts:

I am sitting in a windowless conference room. The walls are lined with sets of leather-bound books with gold-lettered spines. 'The ode must traverse the problem of solipsism,' a young man is saying. He pauses for a long time. Underneath the table, one leg is twisted around the other. A stretch of gaunt white ankle shows between trouser and sock. 'In order to approach participating in.' He pauses again, his body knotted like a balloon creature made by a children's entertainer. Finally, in one rush: 'The unity which is no longer accessible.' My fellow students utter a long soft gasp, as if at a particularly beautiful firework. 'Brilliant,' says the professor. 'Very finely put. But I didn't quite understand it. Could you repeat it?' I write the sentence down in my notebook, like everyone else in the seminar. *The ode must traverse the problem of solipsism before it can approach participating in the unity which is no longer accessible.* When I have pieced it together, I realise he is talking nonsense. I am struck by the thought that literary criticism - at least as it is practised here - is a hoax.

See, "[1]Letter from Yale", by Helena Echelin.

1. [http://web.archive.org/web/20010728081217/http://www.zmag.org/letter\\_from\\_yale.htm](http://web.archive.org/web/20010728081217/http://www.zmag.org/letter_from_yale.htm)

Kirk (2013-01-03 11:35:36)

Regarding sleep in hospitals . . . Several years ago I had a reaction to the anesthesia used during an operation. They investigated me for days to determine what had happened. That first night they woke me every two hours to take a blood sample. Plus I listened all night to the random beeps from medical machines and the sounds patients made in adjoining rooms due to a severe flu outbreak. The next morning I felt sleepy. Then the day nurse came in, introduced herself, and lectured me on how tired I looked and how I should be getting my sleep. @dearieme, You might find this paper about BP of use: <http://www.math.ucla.edu/scp/publications/mortality.PDF> . Seth: Thanks for the blood pressure reference. I sent it to my mom, who takes blood pressure medicine.

dearieme (2013-01-03 13:38:43)

@Kirk: fascinating - I am in your debt. I was taken not only by the fact that common guidelines for systolic bp are/were too high, but the way that this became clear by applying just three bits of common sense, namely (i) using all-causes death as their measure of merit, (ii) categorising the data by age and sex, and (iii) exploiting percentiles as a 'natural scale' for bp. (I say "common sense" in the reasonably precise sense of "that's what an engineer or physicist would do"). I was also taken by their discussion of the benefits that some bp-lowering drugs afford by mechanisms distinct from the actual lowering of bp. Many statin-sceptics suspect something similar - that the category of patients for whom statins bring a benefit are gaining from effects of their statin distinct from its effect in lowering cholesterol. By the by, apologies for being greedy, but can you by any chance provide a copy of the "commentary on page 159" referred to at the foot of the paper? Anyway, I repeat my thanks.

q (2013-01-03 14:27:13)

other studies than framingham seem to indicate that mortality goes up at lower blood pressure values - you can google this as well as i can. a brief survey of this makes me think though that 140 is not an important number.

Kirk (2013-01-03 16:40:34)

@dearieme I stumbled on that article by a lucky web search. Sometimes authors of articles published in paywall journals have obtained an agreement with the journal to allow the author to place the paper on a personal website (or, ahem, think they have the right but haven't read the fine print). The Lancet is a paywall journal. If you have a local university system which indulges the local taxpayers, you might be able to borrow that issue from them.

Alex Chernavsky (2013-01-03 19:37:28)

Medical school libraries sometimes allow public access to their journals and books. That's true of the University of Rochester. I've been there many times.

Patrik (2013-01-04 23:39:17)

This is tragic story. "Overnight admission to the hospital is recommended for "observation" and rest prior to the trip home. Fifty years of experience have taught me that admission to an academic hospital is not restful. I have stopped counting the patients who want to be discharged to get some rest." I don't want to descend into hyperbole but based on the my recent experiences with hospitals and rest (lack thereof), namely, the birth of my son and my appendectomy - I contend that lack of restful sleep post-intervention has MASSIVE iatrogenic effects and is weakening (killing?) people. As Robb Wolf says: "If someone sleeps well, you can't kill them; if they sleep badly, you can't keep them alive." The night after my appendectomy I, like Kirk (above), was woken up and checked up on ceaselessly, ostensibly for my benefit. Not to mention torture by the hideous and inhumane cacophony of monitoring devices beeping away mercilessly. The next morning, I, literally, begged them to allow me to sleep without interruption for a few hours so I gain enough strength to go home and heal through sleep. Our experience with the birth of my son was not dissimilar - post-birth all through the night, nurses came in to "check" on my wife and son ceaselessly, again, ostensibly, for our benefit. Result, none of us slept and all three of us were exhausted. We opted out of another night in the hospital and went home.

## Rent-Seeking Experts (2013-01-04 05:00)

Two thought-provoking paragraphs [1]from Matt Ridley:

From ancient Egypt to modern North Korea, always and everywhere, economic planning and control have caused stagnation; from ancient Phoenicia to modern Vietnam, economic liberation has caused prosperity. In the 1960s, Sir John Cowperthwaite, the financial secretary of Hong Kong, refused all instruction from his LSE-schooled masters in London to plan, regulate and manage the economy of his poor and refugee-overwhelmed island. Set merchants free to do what merchants can, was his philosophy. Today Hong Kong has higher per capita income than Britain.

In July 1948 Ludwig Erhard, director of West Germany's economic council, abolished food rationing and ended all price controls on his own initiative. General Lucius Clay, military governor of the US zone, called him and said: "My advisers tell me what you have done is a terrible mistake. What do you say to that?" Erhard replied: "Herr General, pay no attention to them! My advisers tell me the same thing." The German economic miracle was born that day; Britain kept rationing for six more years.

This is standard libertarianism. I like the stories but I don't agree with the interpretation. I don't think it is "economic planning and control" that causes stagnation in these examples. I believe it is expertise – more precisely, rent-seeking experts who know too little and extract too much rent. There are libertarian experts, too. They too are capable of doing immense damage (e.g., Alan Greenspan), contradicting Ridley's view that "economic liberation" always causes prosperity. In both of Ridley's examples, the experts give advice that empowers the experts. In the first example, Cowperthwaite is told by "LSE-schooled" economists to "plan, regulate and manage the economy." All that planning, regulation and management require expertise, in particular expertise similar to that of the experts who advised it. Which you cannot buy – you have to rent it. You must pay the experts year after year after year to plan, regulate, and manage. Because the advice must empower the experts, there is a strong bias away from truth. That is the fundamental problem.

Freud is the classic rent-seeking expert. You are sick because of X, Y, and Z – and if you pay me for my time week after week, I will cure you, said Freud. Curiously no treatment that did not involve paying people like Freud would work. Curiously psychoanalytic patients never got better. Therapy lasted forever. You might think this is transparently ridiculous, but professors at esteemed universities such as Berkeley still take Freud seriously. Millions of people pay for psychotherapy. The latest psychotherapeutic fad is cognitive-behavioral therapy – which again requires paying experts to get better, week after week. Berkeley professors take that seriously, too.

Evidence-based medicine advocates are among the newest rent-seeking experts. Like Freud, they focus on process (you must follow a certain process) rather than results. (What they call process in other contexts is called ritual. Rituals always empower experts.) Rather than trying to learn from all the evidence – which might seem like a good idea, and a simple one – evidence-based medicine advocates preach that only a tiny fraction of the evidence (which you need a Cochrane expert to select and analyze) can actually tell us anything. Again, this might seem transparently ridiculous, but many people take it seriously. Evidence-based medicine has an amusing twist which is that its advocates tell the rest of us how stupid we are (for example, "correlation does not equal causation").

The workhorses of the rent-seeking expert ecology – the ones that extract the most rent – are doctors. They are incapable of giving inexpensive advice. However they propose to help you, it always involves expensive treatment. This might seem like a recipe for crummy solutions, but again many people take a doctor's advice seriously (by failing to do their own research). My introduction to the world of rent-seeking solutions was the dermatologist who told me I should take antibiotics for my acne. I was to take the antibiotics week after week – and because I was taking a dangerous drug, I should also see my doctor regularly. During these regular visits, the doctor never figured out that

the antibiotic did nothing to cure my acne. I learned that by self-experimentation.

Like anthropologists who fail to notice their own weird beliefs (a recently-deceased Berkeley professor of anthropology took Freud seriously, for example), the profession that came up with the rent-seeking concept has failed to notice that many of them do exactly that.

One clue that you are dealing with a rent-seeking expert is that they literally ask for something like rent. Religious experts tell you to attend church week after week. Psychotherapists want you to attend therapy week after week. Psychiatrists tell you to take an anti-depressant daily for the rest of your life. My dermatologist told me to take an antibiotic daily (and to renew the prescription I needed to see him). And so on. As these examples suggest, rent-seeking experts thrive in areas of knowledge where our understanding is poor. Which includes economics.

[2]"Rent-seeking experts" in education.

More What I call "standard libertarianism" [3]Tyler Cowen calls "crude libertarianism". Maybe I should have called it "off-the-shelf libertarianism". In addition to what Tyler says, which I agree with, I would say that governments and their "central planners" have sponsored innovation (e.g., the Internet, the greenback, basic scientific discoveries) much better than Ridley seems to give them credit for. Innovation is a huge part of economic development.

2. <http://www.home-education.biz/news/26/60/Nazi-education-law-backed-by-Ofsted/>

3. <http://marginalrevolution.com/marginalrevolution/2013/01/in-which-countries-is-crude-libertarianism-most-and-least-true.html>

---

Mark Cancellieri (2013-01-04 06:00:40)

I actually agree with Matt Ridley. There is a distinct correlation between economic freedom and prosperity. Here is just one index of economic freedom. <http://www.heritage.org/index/> With all due respect, it is laughable to associate Alan Greenspan with libertarianism. He headed the Federal Reserve and was incredibly interventionist in the economy. The job of the Fed is to centrally plan the money supply (although that was supposedly not the original intent), and we can see the disastrous consequences of this central planning. There was no "economic liberation." There was instead massive government intervention: artificially low interest rates, political "affordable housing" goals by Fannie Mae and Freddie Mac, the FHA, Sarbanes-Oxley, BASEL capital standards, and on and on. Seth: You don't remember that Greenspan admitted he was wrong? My point is that when an expert has little understanding and requires a lot of rent, any intervention is likely to do more harm than good. The ideology of that expert is irrelevant. The empirical generalization Ridley noticed – which I agree with – he explained by saying economic control is bad. I am saying the same set of observations can be explained by an idea that applies more widely. My explanation implies that the real reason that economic control is bad is that the economists involved are too ignorant and seek too much rent. With more knowledgeable economists seeking less rent, economic control would turn out much better.

Txomin (2013-01-04 06:24:11)

Greenspan describes himself as libertarian something or other... which could mean Austrian liberalism or anything whatsoever. I too agree Greenspan is decidedly in whatsoever territory. And I too agree with Ridley. Ideally, political regulation of economic affairs works. In practice, it amounts to no more than a leech.

rezzrovv (2013-01-04 07:10:58)

When you have so many variables involved in a system as diverse as a semi-free economy, you can't "rent" expertise knowl-

edgeable enough to fulfill the role necessary for central management to work. Wasn't that Hayek's main premise? The more free an economy, the greater likelihood individuals seek their own self-interest filling the vacuums necessary for a viable economy. A central planner can decide how many steak knives need to be manufactured for New York City or entrepreneurs can see the potential profit and provide them doing so with far greater efficiency. I don't disagree with the rent-seeking paradigm you describe but think the economy might not be the best example. Also, I like the concepts of cognitive-behavior therapy. I don't claim anything other than intuition but it would seem to me the idea of changing the structure of thoughts to effect change in behavior does have a finite end of therapy with much greater potential result than talking therapies. Seth: Hmm. One "concept" of cognitive-behavior therapy is to ignore the environmental causes of things. For example, the environmental causes of depression. I wonder if you like that.

Three Pipe Problem (2013-01-04 07:42:01)

1) Greenspan admitted he was wrong long after he abandoned most of his libertarian principles. Compare his recent writing to his chapters in Ayn Rand's Capitalism: The Unknown Ideal and you will see two different philosophies. Of course, Rand claimed she was not a libertarian, and disliked libertarians. I think you are using the term in a very general way that does not correspond very closely with how many libertarians view libertarianism. 2) That being said, most of what libertarians like or dislike about government can be equated to rent-seeking on one level or another. For example, look at the libertarian position on professional licensing. They don't dislike it because it is bad in some vague, unspecified way. They dislike it because it's a power grab by insiders, allowing them to charge higher rates than they would in a free market.

Daniel Lemire (2013-01-04 08:28:28)

I agree with other commenters... Greenspan does not favor economic freedom. Rather he works for the financial system and as an "expert" in the financial system, he made sure that this system and its experts played an increasingly important role in the economy. Not long ago, the financial industry was a relatively minor industry. Under Greenspan, it grew and grew in importance, along with the compensation for financial experts. The USA is not getting freer, it is getting more bogged down in crony capitalism. In effect, I agree with Ridley.

Leslie (2013-01-04 09:14:11)

Psychoanalysis is something I wouldn't bother with, for the same reasons you gave; you don't necessarily get better, therapy can last forever, it's expensive. I did have a very successful experience with cognitive behavioral therapy though. For many years I used to have a real problem with panic attacks, so I found an MD with an interest in non pharmaceutical treatment of mental health problems. I did three half hour sessions of cbt, which virtually eliminated the panic attacks. On the now rare occasion when I get one, it feels much more mild than in the past. You can also find computerized cognitive behavior therapy programs online, which are free. I haven't tried them, so can't comment on effectiveness. Seth: Interesting. I think it would be better to figure out the environmental cause of panic attacks and eliminate that cause, as we eliminate scurvy by giving people adequate Vitamin C. A subject in a morning-faces experiment of mine found that at the same time that the faces raised her mood, they also eliminated the minor panic attacks she frequently had.

Darrin Thompson (2013-01-04 09:15:03)

Like all the other commenters I thought: Greenspan? GREENSPAN???? If you want to find an example of a libertarian rent seeker maybe go for the jugular and accuse Ron Paul of rent seeking. He is, after all, a doctor.

Tuck (2013-01-04 10:13:09)

Great post. Greenspan was a libertarian who took the job of a central planner. I think you can attribute his failure to the latter fact, rather than the former. The central libertarian argument against central planning was that the planner can never know what the sum of all the people, with all their experiments and individual knowledge, know. I think Ridley at you are in perfect agreement, Seth, although approaching it from too different perspectives. You starting at the micro, and he's starting at the macro. You're at different ends of the elephant, in otherwords. ;) The expert can never know as much as all the individuals he interacts with know. Seth: I don't think I am in agreement with Ridley's explanation. I am in agreement with his empirical generalization, namely that central economic planning has a terrible record.

CC (2013-01-04 12:56:52)

Seth, interesting post, but you should be aware that (as far as I can tell) you're using the term "rent seeking" in a way totally different from the way economists use it. It could be confusing to readers. Someone correct me if I'm wrong. It's a very cool concept you've introduced though, so it'd be good to find a catchy name for it. Seth: "Totally different"? What is the difference?

CC (2013-01-04 17:21:36)

Quoting wikipedia: "In economics, rent-seeking is an attempt to obtain economic rent by manipulating the social or political environment in which economic activities occur, rather than by creating new wealth. One example is spending money on political lobbying in order to be given a share of wealth that has already been created. A famous example of rent-seeking is the limiting of access to lucrative occupations, as by medieval guilds or modern state certifications and licensures." and "Rent ... is obtained when a third party deprives one party of access to otherwise accessible transaction opportunities, making nominally "consensual" transactions a rent-collection opportunity for the third party." An example would be convincing the government that everyone should have to buy product X only from me and not anybody else, because I'm the only one who provides it safely. What you're describing is a system where experts convince people that the only acceptable treatment for some problem is to make recurring payments to those experts to provide dubious services. There's not necessarily government restriction of options, but rather there's just a commanding respect for those experts that allows them to dupe us. Like I said, it's a very cool concept you've introduced. Anyway, I really like your blog and I hope you'll keep posting as often as you have been. Btw, I'm a fan of both ELOO for AS, and zinc picolinate for acne. The zinc wasn't a miracle cure for me, but it did help quite a bit with no real effort required on my part. So go pat yourself on the back for improving some random internet stranger's life. :) Seth: Thanks. I didn't know about using zinc picolinate for acne, but it's got to be better than taking an antibiotic. Did Freud manipulate the "social environment" of his day? Hard to say, the term is vague. People chatted enthusiastically about his work – is that the social environment? He certainly manipulated the intellectual environment. So I am talking about rent-seeking in a broader sense, yeah. Maybe the definition of rent-seeking should be expanded to say "social or political or intellectual environment".

CC (2013-01-04 17:44:21)

Interesting, Seth. Yeah, rent seeking typically refers to using the law to restrict people choices so that they have to enrich you somehow. You're saying that there's some notion of "generalized rent seeking" where you manipulate social conventions so that people enrich you. Cool. I should point out, though, that economists are using the word "rent" in a weird technical sense. Requiring licensing to become an interior decorator is an example of rent-seeking, but no one's renting anything (in the everyday sense of the word). You're using the word "rent" in a figurative sense. Doctors convince you to rent them in the sense that you have to drop by once a month so that they can say "yup, keep taking those drugs I prescribed." Maybe this is why you never hear the medical establishment pushing the SLD! You don't need to rent a doctor to execute the diet. Seth: I agree. Many good solutions to everyday health problems are ignored by doctors, quite possibly because you don't need to rent a doctor for them. I wonder if that is part of the reason for the strictures of evidence-based medicine: To make more sure you choose a treatment that requires a doctor (e.g., prescription drug). As you say, economists expanded the notion of "rent" in their use of "rent-seeking", I am expanding it again.

Adam (2013-01-04 19:42:20)

Seth said, "With more knowledgeable economists seeking less rent, economic control would turn out much better." How about no economic control and no rent-seeking? What sorts of economic control do you advocate? Seth: The underlying problems are poverty (poor people seek more rent than rich people) and ignorance (the less experts know, the worse advice they give; the less their audience knows, the more gullible they are). In the case of economics, the ignorance perpetuates the poverty. I don't advocate any particular economic control. I advocate better economics research. For example, as I have blogged, economists pay far too little attention to the causes of innovation. Judging from economics textbooks, they don't even understand or recognize simple things about innovation, such as war is a cause of innovation.

dearieme (2013-01-05 04:46:19)

"they don't even understand or recognize simple things about innovation, such as war is a cause of innovation." That's a special case of the general problem that economists don't study enough Economic History.

MikeB (2013-01-05 13:15:28)

Joseph Schumpeter, prophet of innovation I think Schumpeter is the most penetrating analyst of capitalism who ever lived. He saw things other people didn't see, partly because he lived in 7 different countries. He also served briefly as Austria's finance minister and worked for 3 years as an investment banker, where he made a fortune that he promptly lost in a stock market crash. So he wasn't a typical academic, even though he spent most of his career as a professor, including almost 20 years at Harvard. As for my title, here's the quotation that inspired it: "Without innovations, no entrepreneurs; without entrepreneurial achievement, no capitalist returns and no capitalist propulsion." Schumpeter wrote this sentence during the Great Depression of the 1930s. Many, many smart people of that time believed that technology had reached its limits and capitalism had passed its peak. Schumpeter believed the exact opposite, and of course he was right." <http://innovationzen.com/blog/2007/05/10-/schumpeter-prophet-of-innovation/> Seth: Faint praise. I'm sure many people believed "the exact opposite". What did Schumpeter figure out about what makes innovation more or less likely? Something less obvious than war increases innovation, I hope.

Peter (2013-01-06 20:01:55)

Libertarianism as I understand it is a political philosophy marked by a preference for less, or even no, control of society by the State. Rent-seeking is vastly strengthened by state control. For example, as educated and affluent as I am, I still must do business with the medical rent-seekers if I want medicine or medical tests since the state has a gun pointed at those who might help me outside of the medical profession. The matter of experts and their rent seems somewhat unrelated to the idea of libertarianism. Suppose the experts employed by the Soviet commissars extracted little or no rent, would theirs be a libertarian society? I'd also point out that some economists study innovation. For example, see the blog "Organizations and Markets". I'm not clear on what is meant by "war increases innovation". Wars also increase death and destruction of property. Surely this is a bad thing. Also, suppose that among the many killed in the Iraq and Afghanistan wars is a young and undiscovered innovative genius or that society is impoverished by the wartime destruction of capital and resources to the point that a crucial laboratory is not built. I think a better question is whether the innovation in weapons and war tactics outweigh the unrealized civil society innovation that is lost. Seth: "War increases innovation": see <http://www.ingenious.org.uk/Read/Conflict/Waristhemotherofinvention/> for examples of specific inventions. More broadly, war upsets the power structure among the losers. All sorts of things previously blocked by the top-ranked people are able to move forward. Likewise, when property is destroyed, it creates a demand for replacements, which will be more modern. I'm not saying that the benefits of war outweigh the costs, I am just saying that one effect of war is an increase in innovation. A simple analogy is forest fires, which have beneficial effects.

Rent-Seeking Expert, I Abjure Ye! | Brown Pundits (2013-01-07 17:04:02)

[...] Seth Roberts, a twist on Matt Ridley's post on the European [...]

Phil Goetz (2013-01-08 14:23:50)

Re. cognitive behavioral therapy: Why do you believe it doesn't work? Seth: I don't believe that. Many therapies, including cognitive behavioral therapy, produce modest improvement. The fact that therapies based on much different theories produce the same improvement is one support for my view that CBT is little better than earlier therapies. My problem with CBT is that there is no serious interest in environmental causes. For example, the environmental cause of scurvy is lack of Vitamin C. Once you know that, you can easily and safely cure scurvy. What are the environmental causes of depression? Lack of CBT in everyday life? Surely not. Many facts about depression don't fit that theory, such as the strong correlation between depression and insomnia. The fact that CBT produces modest improvement means little. It is perfectly possible to modestly improve Disease X without having any idea what caused it. Think of duct tape.

Lemmy Caution (2013-01-10 19:08:09)

cognitive behavior therapy is particularly effective for panic attacks: [http://www.paniccure.com/Approaches/CBT/-overcome/overcome\\_panic\\_attacks.htm](http://www.paniccure.com/Approaches/CBT/-overcome/overcome_panic_attacks.htm) A panic attack is really nothing more than bodily sensations of anxiety and a catastrophic misinterpretation of those sensations as dangerous. Your belief that you are in danger results in increased anxiety, which then leads to more sensations and more catastrophic thoughts, creating a vicious cycle between bodily sensations, distorted thoughts, and anxiety, which can rather quickly result in a panic attack. The real problem is actually your mistaken belief

that you are in danger – not the panic itself – since panic is in fact an appropriate emotional reaction when you are convinced that you may be in danger. However, your belief is untrue, and when you understand this on a deeper level, you will master your panic. – My bet is that depression is harder to deal with because much of the time there is no real false belief. Depressives tend to be more realistic than non-depressives. you could probably cure yourself of panic attacks. Seth: What are the environmental causes of panic attacks? I don't know, do you? Perhaps eliminating the environmental causes would be more effective than CBT.

Lemmy Caution (2013-01-15 16:49:52)

If cognitive behavior theory really does "result in 80 % to 85 % of people becoming panic free, usually within eight treatment sessions " why worry about environmental causes that no one can figure out. Plus, panic disorders seem like they would be very likely to be helped by the placebo effect. Anything can break the cycle of catastrophic thoughts if you think it will. My bet is a google search "panic attack and x" where x is almost anything will find someone who believes it will help with the panic attacks. I randomly searched for x = milk and aspirin. <http://www.livestrong.com/article/353540-foods-that-help-panic-attacks/> <http://www.doctorslounge.com/psychiatry/forums/backup/topic-1848.html> This study found the environmental factors to be general ill health, separation from a parent by death or divorce, high interpersonal sensitivity, low social class, and unmarried marital status: <http://www.ncbi.nlm.nih.gov/pubmed/8245920> Seth: Why worry about environmental causes? Because, once found, they are likely to lead to a better solution (cheaper, more powerful, longer lasting). The environmental factors you list (ill health, etc.) are correlated with a large number of problems, there are probably factors more specific to panic attacks.

## **How to Write: Lessons From My Writing Class (2013-01-05 05:00)**

I just finished teaching an undergraduate class called [1]Academic Writing at Tsinghua. One semester, pass/fail, about 10 students. The last assignment was list six things you've learned. Combining the answers, I came up with this:

1. Don't tell readers what they already know. This came up a lot when I discussed how to write a personal statement. "Your university has an excellent program in X" – no, don't say that.
2. To make your writing moving, focus on your own thoughts and emotions. Moving = evoking emotion. Evoking emotion was enormously important, I said.
3. Use simple words and sentences (don't show off). As one student put it, "Received the blames from one class, changed all my GRE words into understandable words."
4. Give examples.
5. Avoid boasting (say "I like X", don't say "I am good at X").
6. Do not write about things that are "too big".
7. Have clear connections between sentences. We spent several classes on the various ways adjacent sentences can be related.
8. Say things that are honest and true. In contrast to what you think your reader wants to hear. A friend asked for advice on her personal statement for a graduate school application. She sent me a revised version. I thought the unrevised more honest version was better.
9. Begin with something interesting.

I asked which of these lessons they already knew. The consensus answer was #1 (don't tell readers what they already know) and #4 (give examples). Their personal statements flagrantly violated #1. One student said they had learned it, yes, but needed to be reminded.

[2]Jon Cousins of [3]Moodscope, in town for a Quantified Self conference, gave [4]a guest lecture. From his talk the students came away with four main things:

1. Copy someone's writing you admire.
2. Imagine your audience. Are they busy? Curious?
3. Write as you speak.
4. Revise after a period of time. Like a month.

Another of Jon's lessons was use punctuation sparingly. An editor told him, "Using an exclamation mark is like laughing at your own joke."

1. <http://www.samebook.net/index.php/group/show/id-53>
2. <http://vimeo.com/16691352>
3. <http://www.moodscope.com/login>

---

Alex Chernavsky (2013-01-05 06:27:49)

I used to help organize an annual writing contest for high school students. The judges (myself included) had to grade hundreds of essays on a scale of one to ten. I was often stunned by the other judges' grades. Essays that I thought were fabulous would receive mediocre scores, and execrable essays would score highly. So, with regard to application essays, you are at the mercy of some drone (or drones) in the admissions office. *Write as you speak*. I think that's bad advice. In his book, *The Language Instinct*, Steven Pinker [1]quotes from a transcript of Nixon's Watergate tapes:

PRESIDENT: The grand jury thing has its, uh, uh, uh view of this they might, uh. Suppose we have a grand jury proceeding. Would that, would that, what would that do to the Ervin thing? Would it go right ahead any way?  
DEAN: Probably. HALDEMAN: If you do it in executive... PRESIDENT: But then on that score, though, we have...let me Just, uh, run by that, that...you do that on a grand jury, we could then have a much better cause in terms of saying "Look this is a grand jury, in which, uh, the prosecutor..." How about a special prosecutor? We could use Peterson, or use another one. You see he is probably suspect. Would you call...

1. <http://books.google.com/books?id=l7dryHvwDiMC&pg=PA221&lpg=PA221&dq=%22the+grand+jury+thing+has+its+uh%22&source=bl&ots=VXpbIvU98L&sig=26p0vpqKMgoNyWdIcQB18LYMaIM&hl=en&sa=X&ei=hynoUJ-ZMcan0AHlrYGGQAQ&ved=0CDIQ6AEwAA#v=onepage&q=%22the%20grand%20jury%20thing%20has%20its%20uh%22&f=false>

bjk (2013-01-05 12:02:21)

Begin with something interesting . . . I never read the first paragraph, usually most articles begin with the second paragraph. Like starting a speech with a joke, I think the audience is a little sick of this approach. You might want to save the interesting open for later. Seth: As I told my students, one New Yorker (magazine) editor would routinely cross out the first paragraph of stuff given to him to edit. I often do that. I also agree about jokes. Bad idea to begin with a joke. It is as if you have nothing

actually interesting to say.

Tom (2013-01-05 13:33:18)

If you don't open with something interesting you just lost all your readers. Except maybe your mother.

Tom (2013-01-05 13:41:51)

James Altucher has a bunch of good posts on this, but here are two. [www.jamesaltucher.com/2012/12/10-more-rules-of-writing/](http://www.jamesaltucher.com/2012/12/10-more-rules-of-writing/) [jamesaltucher.com/2011/03/33-unusual-tips-to-being-a-better-writer/](http://jamesaltucher.com/2011/03/33-unusual-tips-to-being-a-better-writer/)

Jonathan Shewchuk (2013-01-05 18:44:42)

Like Alex, I don't understand the "write as you speak" advice. Perhaps it would be good advice for the minority of people who become overly formal in their writing. But most people don't speak well at all. I find that experience in writing has changed my speech, because I spend a lot of my writing time thinking about how to say things clearly. For example, I use the passive voice when speaking much less than I used to.

Christopher Burd (2013-01-06 11:48:50)

*Write as you speak. I think that's bad advice.* Writing literally like you speak is bad advice, of course. What works (for me) is trying to write a sort of idealized version of the way I speak, if that makes sense.

Christopher Burd (2013-01-06 11:53:30)

*As I told my students, one New Yorker (magazine) editor would routinely cross out the first paragraph of stuff given to him to edit. I often do that.* Another editor's trick is to replace the introduction with a summarising passage from the conclusion. The idea is that by the end of the piece, the writer finally knows what they are trying to say and are so sick of writing that that they are finally writing succinctly.

Judy (2013-01-14 18:39:22)

Great reminders! Although it may seem like common sense, I always forget these tips. Especially when I'm so eager to just be done with my writing and I don't wait 24 hours to edit. Thanks for the tips! Judy

## **How to Write: What One Student Learned (2013-01-06 05:00)**

Yesterday I gave lessons from my academic writing class based on all student answers. One student, Wang Lingjie, did an especially good job saying what she learned. Here are four things:

Lesson 1: Be genuine. In the last class, Seth showed us a pair of personal statements and its revised form. [I showed a personal statement before and after revision.] Rethought about it, I do feel that the original form would be more like a true person who want to tell his story and show his willingness for a master's degree. [In class, Lingjie had preferred the revised version.] True self expressed more like a vivid individual.

Lesson 2: Keep the sentence simple. Chinese students normally have their technique to produce a fancy article. One of the tips is their substitution list, by which they can switch normal words into long and seemingly educated ones. This kind of decoration seems like showing off. Also, when I went on to write personal statements according to the college's requirements, I understand the importance to be succinct under words limitation.

Lesson 3: Talk to your readers as you speak. I get the inspiration from the guest speaker [Jon Cousins].

Then I took on to read my passages out when I write twitters for my internship. Though the effect of the new promotion tone has not emerged yet, I personally like the latter ones better.

Lesson 4: Raise readers' emotions. Stories help. I realized its importance when we discussed Ashley's 3 outlines. [Students wrote 3 outlines on the same subject.]

---

dearieme (2013-01-06 17:59:23)

Ahoy, Seth. here's a scandal I hadn't heard about. <http://www.guardian.co.uk/world/2013/jan/06/france-scandal-weight-loss-drug>

vimspot (2013-01-06 23:16:26)

Is it possible that their writing will have improved from a western perspective, but that they will be penalized for not following the status quo?

Sam (2013-01-08 10:35:01)

That Mother Jones lead article is fascinating - here's an interesting discussion of some of the methodology and other issues that you may enjoy as well: <http://hisscienceistootight.blogspot.com/2013/01/the-link-between-leaded-gasoline-and.html>

Sean Estey (2013-01-08 12:22:29)

Seth, I read Nature of Economies after being introduced to some of her economic views on this blog, and I was blown away. It's the closest thing to a general theory of economics that I've ever come across. Reading Antifragility by Nassim Taleb, I can detect a strong Jacobs influence in his tendency to look to mother nature for economic guidance. But it's tragic that her influence hasn't made a dent in mainstream thinking. Probably due to the fact that her bottom-up views don't leave much room for economic planners. Seth: I believe that Taleb, who is also anti-planner, is having more of an influence than Jacobs ever had. Maybe the Internet has a democratizing effect.

B.B. (2013-01-11 13:59:34)

Clearly, lead is bad news, and there is experimental evidence it harms health. No disagreement. Let's get the lead out. That is not the same thing as agreeing that lower lead caused lower crime rates. Here is some pushback from Jim Manzi: <http://www.nationalreview.com/corner/337398/lead-and-crime-jim-manzi>

Erikku (2013-01-28 02:45:03)

Dear Seth, regarding your practice of delaying breakfast in order to prevent early awakening, does coffee count as breakfast? I usually drink black unsweetened coffee (and water) when I wake at 4 or 5am, but otherwise delay food until 11 or 12. Thanks! Seth: Food with no calories doesn't count as breakfast. On the other hand, the effect of caffeine is unclear. It probably causes some sort of anticipation - whether helpful or harmful, hard to say.

## **Brain Tracking: Early Experience (2013-01-09 05:00)**

Brain tracking - frequent measurement of how well your brain is working - will become common, I believe, because brain function is important and because the brain is more sensitive to the environment (especially food) than the rest of the body. You will find it easier to decide what to eat if you measure your brain than if you measure other parts of your body. For example, I have used it to decide how much flaxseed and butter to eat. I have used R and the methodological wisdom of cognitive psychologists to make brain tracking tests. Alex Chernavsky, who lives in upstate New York, recently tried the most recent version:

In August, [1]Seth solicited readers to help him test a new brain-tracking program. I said I was interested. I had a number of reasons for volunteering:

- My job involves working a lot with computers, so I thought I had a decent shot at ferreting out any bugs or usability issues.
- I have been [2]tracking my weight daily for over eleven years, so I was confident that I would have enough motivation to do the test on a regular basis.
- I have a long-standing interest in neuroscience, so I was eager to help advance the field, even if in a very small way.

- I'm in my late 40s, and I've noticed a distinct increase in my forgetfulness. There are probably other, less-noticeable decreases in my cognitive function. Thus I have an interest in finding ways to boost the performance of my brain. Hacking brain function is obviously much easier if you can assay it via a quick, reliable proxy (i.e., reaction time).

The program itself was relatively easy to set up. The code is written in a free, open-source scripting language called R, so you have to install R on your Windows computer in order to run the program. Upon downloading the script (which is contained within an R workspace), you have to edit a function to specify the Windows folder that contains the workspace file. After that, you're ready to go.

The three-month pilot study did not involve testing any hypotheses with regard to the effectiveness of interventions (for example, measuring reaction times before and after flaxseed oil). My task was simply to perform the test once or twice a day.

Taking the test involves hitting a number key (2 through 8, inclusive) to match a random target number that is displayed on the screen. The program measures the latency of your response. If you hit the wrong key, the program forces you to repeat the same trial until you press the right key. Reaction-times from these "correction trials" are not used in any subsequent data analysis. A session consists of 32 individual trials and takes about four minutes to complete.

I performed the test daily for three months, although I did miss two days. The test stopped short of being fun, but it was certainly not onerous. The biggest hassle was having to wait for my laptop to boot into Windows. If I had to do the pilot study over again, I would install R on both my home and my work desktop computers, so I could perform the test more easily (perhaps as a way to take a short break from whatever other task I happened to be working on).

The original plan was for me to email the R workspace to Seth once a week or so. However, I suggested to Seth that we could improve efficiency by using a shared DropBox folder. He agreed, and that is the method we adopted. Using this system, Seth had ongoing access to the latest data, and he could also easily make any bug-fixes or other edits that would take effect the next time I ran the script.

I did identify one bug in the script. After each trial, the script briefly displays some feedback in the form of your reaction-time (in milliseconds) for that trial, your cumulative average for that session, and a percentile figure that compares your latest speed with past trials for that same target key. I noticed that the percentile scores didn't seem to make sense for some of the keys. Seth examined his code and agreed that this was indeed a bug. He made some adjustments and the bug was fixed.

I found that over time, as expected, my scores improved substantially. They seemed to plateau after six weeks. However, my accuracy suffered. During the third month of the pilot study, I made a conscious effort to reduce my error rate. I had some success, but I also found myself frustrated by my inability to reduce the errors as much as I would have liked. Making errors, despite my best efforts, was the only vexing part of taking the test.

1. <http://blog.sethroberts.net/2012/08/28/want-to-track-your-brain-function/>
2. <http://blog.sethroberts.net/2012/03/13/ten-years-of-weights-including-two-years-on-the-shangri-la-diet/>

---

Peter Andrews (2013-01-09 06:42:25)

Seth and Alex, You might want to consider using free, open source, RStudio server to have a shared R environment. This would allow central tracking by Seth. [http://www.rstudio.com/ide/docs/server/getting \\_started](http://www.rstudio.com/ide/docs/server/getting_started) In any case, RStudio is an improvement over the standard R gui.

Mark (2013-01-09 07:28:53)

I have also been a Guinea pig to test this software and am close to finishing up my third month. However, I still quite enjoy doing the test, have had no difficulty doing it at least twice most days, sometimes more. I've also improved over time, as expected (learning effects), and also plateaued at about 6 weeks. However, I also did some self testing. I'll send more detail to Seth later, which he may or may not decide to post here, but I've been testing the effects of adding a heaping tablespoon of coconut oil to my coffee every morning. I've turned this treatment on and off several times, and without fail each time I see a large improvement with the CO... I've even done some modeling to remove the over time effects and to control for within trial correlation, and the CO effects are still there. I'm known as an extreme skeptic, but I think these results are real.

Jenny (2013-01-09 16:40:57)

Just a comment on Alex's weight loss chart. Has anyone tried using coconut oil after any method that loses weight, ie low carb or walks, and seeing if that holds the weight loss stable? ie was it specific to following the Shangri-la diet, or just any method of weight loss?

Alex Chernavsky (2013-01-09 21:19:30)

Peter, thanks for the tip. Will check it out.

Paul N (2013-01-09 22:26:04)

@ jenny, Coconut oil seems to be one of the single best things you can eat - (in normal eating, not just as the Shangri-La oil) for continued weight management and metabolic health. I have read the books on it by Bruce Fife and also Mary Enig, lots of good information from those two. The more of your calories that come from that instead of other fats (or carbs), the more active and leaner you become (applies to farm animals too). Taken before meals, it suppresses appetite. Taken with meals, it makes other fats easier to digest. It stabilises gut flora. It helps reverse alzheimers. It is good for your skin. and on and on... It seems to be one thing that almost everyone - except the seed oil industry and the USDA - agrees is healthy. 2 tablespoons a day seems to be the consensus for an an effective dose. I take most of mine as chocolate - get 85 % cacao and melt with equal amounts of butter and coconut oil, add some stevia and shredded coconut and cool in silicone ice cube trays. As good as any bought chocolate. To get the shangri-la effect with this you would have to eat it with your nose pinched, and that's just a waste of chocolate!

Nathen (2013-01-10 16:50:45)

How are you accounting for your probable increase in skill over time at the reaction-time task?

William (2013-01-17 09:33:48)

Can you release your code? Perhaps on Github or something? I'd love to see it and implement my own tracking! Seth: A friend and I are making an iPhone app.

## Undisclosed Risks of Common Medical Treatments (2013-01-10 05:00)

Millions of tonsillectomies have been done, mostly to children. Were any of their parents told that tonsils are part of the immune system (taught in high school biology and known since the 1960s)? A Cochrane Review of tonsillectomies (the "highest standard" in evidence-based medicine) fails to mention that tonsils are part of the immune system. A recent study found tonsillectomies associated with a 50 % increase in heart attacks. (I write about tonsillectomies [1]here.)

Are tonsillectomies unusual? Several recent news stories suggest no, they aren't. Failure to tell patients the full risks of medical treatment may be common:

1. Undisclosed risks of hernia surgery. [2]From the Wall Street Journal: "More than 30 % of patients may suffer from long-term chronic pain and restricted movement after surgery to fix a hernia . . . studies show." The article says "many patients don't consider" this risk – meaning they don't know about it. A Berkeley surgeon named Eileen Consorti told me I should have surgery for a hernia I could not detect. I have previously written about her claim that evidence supported her recommendation when no such evidence existed – or, at least, no one including her has ever found it. I said I wanted to see the evidence because there were risks to surgery. She replied that none of her patients had died. I was shocked by the incompleteness of her answer. There are plenty of bad outcomes besides death – as the Wall Street Journal article shows.

2. Undisclosed risks of sleeping pills. A book called [3]The Dark Side of Sleeping Pills by Daniel Kripke, a professor of psychiatry at UC San Diego, goes into great detail about risks of sleeping pills that few doctors tell their patients. For example, one study found that "patients who took sleeping pills died 4.6 times as often during follow-ups averaging 2.5 years [than matched patients who did not take sleeping pills]. Patients who took higher doses (averaging over 132 pills per year) died 5.3 times as often." Insomnia alone was not associated with higher mortality. Tomorrow I will post Dr. Kripke's answer to the question "why did you write this book?" [4]Here is a website about the dangers of Ambien.

3. Undisclosed risks of anticholinergic drugs. [5]From the [6]NY Times: "After [7]following more than 13,000 British men and women 65 or older for two years, researchers found that those taking more than one anticholinergic drug scored lower on tests of cognitive function than those who were not using any such drugs, and that the death rate for the heavy users during the course of the study was 68 percent higher. That finding, reported last July in The Journal of the American Geriatrics Society, stunned the investigators." Anticholinergics are "very very common" said a researcher. They include many over-the-counter drugs, such as "allergy medications, antihistamines and Tylenol PM".

4. Undisclosed risks of statins. [8]A recent NY Times story says "the Food and Drug Administration has officially linked statin use with cognitive problems like forgetfulness and confusion, although some patients have reported such problems for years. Among the drugs affected are huge sellers like Lipitor, Zocor, Crestor and Vytorin." Prior to this official linkage, the reports of forgetfulness and confusion were mere anecdotes that evidence-based medicine proponents ignore and tell the rest of us to ignore.

5. Undisclosed risks of metal-on-metal hip replacements. They leak dangerous amounts of metal (e.g., cobalt) into the rest of the body. "Despite the fact that these risks have been known and well documented for decades, patients have been kept in the dark," says [9]a recent article in the BMJ. By 2007, the danger was so clear that a British regulatory committee said that patients must sign a form saying they've been warned. This didn't happen – a surgeon told the BMJ that "surgeons were unaware of these discussions." Other materials could have been used.

These six treatments (tonsillectomy, hernia surgery, sleeping pills, anticholinergic drugs, statins, and hip replacement) are so common they raise a scary question: What fraction of the risks are patients usually told?

The surgeon or drug company gets paid no matter what happens to you. Malpractice lawsuits are very rare on a per-patient basis – and no one will be sued for performing a tonsillectomy on a child who gets a lot of colds or prescribing sleeping pills to someone who has trouble sleeping. In a Freakonomics podcast, Steve Levitt said that doctors terrify him. And his father is a doctor. Given the undisclosed risks of common treatments, he is right to be terrified.

Thanks to Allan Jackson, Alex Chernavsky and Tim Beneke.

Korben Dallas (2013-01-10 06:43:06)

Well at least SSRI's are a pretty safe treatment for a very common disease, so it isn't all bad.

Alex Chernavsky (2013-01-10 11:28:02)

Undisclosed risks of psychiatric medicines, as described in an interview with investigative reporter Robert Whitaker: "[1]Psychiatric Drugs: An Assault on the Human Condition" (the title is a bit over the top, but the interview is good)

1. <http://www.thestreetspirit.org/August2005/interview.htm>

Nancy Lebovitz (2013-01-10 11:32:30)

The risks associated with bariatric surgery aren't as well known as they should be.

CC (2013-01-10 16:36:37)

Does anyone else think these number sound too crazy to be correct? For instance: "patients who took sleeping pills died 4.6 times as often during follow-ups averaging 2.5 years [than matched patients who did not take sleeping pills]." 4.6 times the mortality? And tonsillectomies increase heart attack risk by 50 %? Does this even sound credible? Seth: You are welcome to examine the studies from which these estimates come.

Adam (2013-01-10 18:21:59)

There was a big (non-randomized) study that showed people who take sleeping pills have the same increase in mortality risk as people who smoke. It was on emedicine if you want to dig for it.

Jenny (2013-01-11 15:36:36)

There are 2 major risks with bariatric surgery that no-one I know who has had it was told about. As mentioned in one of last May's New Scientist - disrupting the neural net around the gut can cause fascinating changes in taste - fish tea for example - which may reverse. And more serious changes in the size of short term memory - downwards - which will not reverse.

aaronblaisdell (2013-01-13 09:36:01)

I'm not surprised that anticholinergic drugs are associated with impaired cognitive function. I've just completed a study in which an acetylcholine antagonist was injected into rats either systemically or directly infused into the dorsal hippocampus. While this treatment did not affect a simple instrumental discrimination (positive patterning), it impaired performance on a more complex instrumental discrimination (negative patterning) known to be dependent on hippocampal function.

Ryan (2013-01-13 09:39:46)

I unfortunately have a fairly large inguinal hernia and surgery of course has been recommended. The surgeon I found to do the procedure (in the next couple months) is a professor of General Surgery and has written various publications regarding the best methods/materials for preventing chronic pain and fixation issues with the surgery. At the surface, this appealed to me before I even spoke to him because he is a doctor who at least recognizes the issues with the surgery. Upon consulting with him, he told me that the method he uses is laparoscopic (he has done primarily laparoscopic hernia repairs at a hernia repair center at university hospitals for nearly 10 years) and that he uses newer, large pore, lightweight meshes in the repair. He said that many of the chronic pain issues are tied to the older method of using a mesh plug and overlay with the open repair, which placed a lot of mesh material over nerves which lead to chronic pain. He then went on to describe that by using a single lighter weight mesh, implanted behind the muscular fascia via laparoscopy, placing the staples used to hold the mesh away from the nearby nerves, that he has not encountered any patients long-term that have dealt with chronic pain issues. His explanation seemed to be on-par with research I had read, and has left me feeling more confident about the procedure I will undergo. What are your thoughts on the matter based on what I have described? Seth: Sounds reasonable to me. I had laparoscopic surgery for a hernia and did not have further problems.

Rebecca (2013-01-17 13:30:18)

Really interesting stuff. I'm on a SSRI (citalopram) after a lot of consideration and a lot of nothing else working well enough. But some of my allergy and asthma drugs that my doctor believes I should take regularly are anticholinergics, and I've always felt quite negatively about taking them every day. The trade off of how I felt on them was rarely worth the benefit to my asthma.

## **Sleeping Pills are Very Dangerous (2013-01-11 05:00)**

Do you know how dangerous prescription sleeping pills are? I didn't, and I do sleep research.

I came across Dr. Daniel Kripke's book [1]Dark Side of Sleeping Pills while finishing [2]yesterday's post on undisclosed risks of medical treatments. I had written an almost-complete draft a year ago. One line in the draft said "undisclosed risks of sleeping pills" with no additional information. I couldn't remember why I'd written that so I googled "dangers of sleeping pills" and found Dr. Kripke's book. I was unaware the evidence was so strong. I asked Dr. Kripke to tell the story of how he came to write it. He replied:

It is almost a life-long story.

As a young psychiatrist, I learned that the American Cancer Society had done a questionnaire survey of a million people which showed mortality related to long and short sleep. [People who sleep less or

more than average have higher death rates.] In 1975, I asked if they would collaborate with me on a more complete analysis of the data on sleep length and insomnia. As a control variable, we included analysis of their one question about sleeping pill use. To my surprise, it looked like sleeping pill use was a strong predictor of early death, while insomnia was not (if you controlled for sleeping pill use by insomniacs).

There were many reasons why these results needed further study, so I asked if I could refine the questions for the new Cancer Prevention Study II (CPSII) which the American Cancer Society commenced in 1982 with 1.1 million participants. Imagine my surprise when I observed that sleeping pill use was associated with a comparable mortality hazard ratio as cigarette smoking! These studies, and about 20 more done all over the world with similar results, had two important limitations: in general, the studies did not identify the sleeping pills used and did not measure whether those taking sleeping pills at the start of the study continued the drugs, or whether those who were not taking sleeping pills (the comparison group) started taking them. So another study was needed.

Meanwhile, sleeping pills were never my main scientific concern. I was mainly interested in bright light treatment of depression and trying to understand how light worked. When I saw that patients needed information about light treatment, I wrote a very short book called "Brighten Your Life", but it wasn't long enough to publish, so I added information about sleeping pills to make it longer. When we found no publisher for the book, I made the information available at two web sites: [3][www.BrightenYourLife.info](http://www.BrightenYourLife.info) and [4][www.DarkSideOfSleepingPills.com](http://www.DarkSideOfSleepingPills.com). I found that the web site about sleeping pills was more popular than the advice about light treatment—indeed, one of the most popular sources about sleeping pills at Google. Therefore, over the years, I have worked to revise and update both web sites to try to help patients. It costs some money to program and maintain the web sites, but people write me to tell me how they have benefited. I see so much misinformation coming from the drug companies that I want people to have an alternative source.

Five or six years ago, my friend Dr. Bob Langer was working at the Geisinger Health Research Center, which had access to electronic health records about sleeping pill use from a large number of people. It took us five years to plan a study, obtain approval from ethics committees, retrieve the complex data from computer files in anonymized form, and analyze the very complex results. When these were published by the medical journal *BMJ Open*, the new information became available at [5]<http://bmjopen.bmj.com/content/2/1/e000850.full>. It is an interesting web site which includes more data in a supplement to the main article and some comments and debate about the article. The interest in the article was world-wide, with stories on the BBC, at Agence France Press, in major newspapers in Japan, India, and China, and even mentions in far-off places like Myanmar and Ruanda. The new data showed that people taking drugs such as zolpidem and temazepam had about 4.6 times the mortality rate of people of the same age and sex who took no sleeping pills. The new data confirm that sleeping pills might cause as much death as cigarettes, and also some cancer, so I feel a big responsibility to make the information available. There may be hundreds of thousands of lives at stake. People need to know that sleeping pills are too risky to use, and I wish I had more help in telling people.

Recently we updated the *Dark Side Of Sleeping Pills* and *Brighten Your Life* and made them available together in [6]a Kindle book, which is easy to purchase at Amazon and read off-line. The books have some new information which we have not yet had a chance to put in the web sites.

Even with, now, more than 20 scientific papers showing that taking sleeping pills is associated with more death and more cancer, many people don't believe it. They imagine there is some other explanation, though nobody has been able to demonstrate an alternative explanation. Of course, statistical association is not quite the same thing as proof of causality, but if it is good enough for the American Cancer Society to advise avoiding cigarettes, it is enough evidence of risk to stay away from sleeping pills, in my

opinion. The problem is that the drug companies have never done a controlled trial study large enough to prove one way or another whether the sleeping pills cause death and cancer, and I think they never will. The cigarette companies have never tried to prove that cigarettes are safe, and they know better than to try. It is the same. Whereas the FDA requires the very large studies for heart and diabetes drugs and so forth, the FDA has dropped the ball with sleeping pills. For more information about that, please see the Kindle book. There is, however, a new alternative to large, expensive, and dangerous controlled trials called a [7]Mendelian randomization study, which uses the new genetic methods to determine causality when a genetic variation causes a risk factor such as sleeping pill usage. Since the genetic data already exist to do the Mendelian randomization studies, it is a matter of doing the difficult statistical analyses. I hope scientific colleagues will join in this task, because I can't do it by myself. It is crucial to determine for sure the risks of sleeping pills. Too many lives are at stake.

Sleeping pills are astonishingly dangerous for something that is treated as more or less safe. In some cases, they are associated with a five-fold increase in death rate after only a few years of use. Cigarette smoking is associated with only [8]a two- or three-fold increase in death rate after long use. And doctors don't prescribe cigarettes. Is there anything else treated as safe that is associated with such a large increase in death rate? I can't think of anything.

1. [http://anesthesia.ucsd.edu/education/visiting-professor/Documents/Bigatella\\_Anti\\_psync\\_death.pdf](http://anesthesia.ucsd.edu/education/visiting-professor/Documents/Bigatella_Anti_psync_death.pdf)

John S. (2013-01-11 10:05:40)

Thanks for this. I am incapable of sleeping more than six hours per night. It's just the way I am. I used to worry about it, but then I decided to embrace it and use those extra hours in the morning for self improvement. I take on-line courses, sometimes watching the lectures on a treadmill at the gym. My only problem is that my physician thinks I (and everyone else) need 8 hours per night. I am continually being offered sleeping pills. I prefer not to take them, and it's good to know my instincts are basically correct.

Nancy Lebovitz (2013-01-11 10:30:34)

I'm wondering about the big risks of hypnotic drugs study- " Data were adjusted for age, gender, smoking, body mass index, ethnicity, marital status, alcohol use and prior cancer". The data wasn't matched for sleep problems, so it's possible that the drugs aren't more dangerous than insomnia. Seth: I agree. What's also possible, and plausible, is that sleeping pills increase mortality by a large amount. I don't know of any study showing that insomnia is associated with anything close to the same

increase in mortality.

ChristianKI (2013-01-12 10:18:23)

How much years of life are we talking about for a five-fold increase in death rate? Seth: Let's say you're 40 years old and your expected total lifespan is 80 years. Then you have a roughly 1/40 chance of dying each year. If you have a 5/40 chance of dying each year, your expected total lifespan goes down to 48 years – a loss of 32 years of life.

Peter (2013-01-12 12:08:35)

Paul Jaminet's new edition of The Perfect Health Diet discusses the health effects of disrupted circadian rhythms. I wonder if, particularly in the case of cancer deaths, what's showing up in the data as an association between sleeping pills and death is that people with disturbed circadian rhythms are more likely to use sleeping pills. Seth: Yes, that is possible. In [1]this study, however, "sleeping pill use was associated with significantly increased mortality after control for reported sleep durations and insomnia."

1. <http://archpsyc.jamanetwork.com/article.aspx?articleid=206050>

More Dangerous Than Cigarettes | Les Jones (2013-01-12 13:14:43)

[...] Sleeping Pills are Very Dangerous: [...]

Christopher Burd (2013-01-12 18:54:21)

*Let's say you're 40 years old and your expected total lifespan is 80 years. Then you have a roughly 1/40 chance of dying each year. If you have a 5/40 chance of dying each year, your expected total lifespan goes down to 48 years — a loss of 32 years of life.* But this 40-year-old doesn't face a 1/40 chance of dying in Year 1. His risk of death starts out far below 1/40 in his early 40s and end up far above 1/40 in his late 70s. I doubt that quintupling the death rate would really push his life expectancy below 50, although I don't have the patience (or, really, the skill) to work it out mathematically.

babar (2013-01-12 18:56:21)

uh seth, your arithmetic is completely wrong. if you have a life expectancy of 40 years from now, you don't have a constant 2.5 % chance of dying each year. you have a small chance of dying in your 40s, a somewhat larger chance of dying in your 50s, and so on. if i'm 40 and healthy my chance of dying in my 40s is pretty low - i don't know exactly but maybe 3 %? say that goes to 15 %. that means an 85 % chance of making it to 50 - already a 48.5 life expectancy, and that's if everyone kicked at 50, so it's quite quite a bit larger. Seth: Right. It was an approximation to give a rough idea of what the answer would be.

B.B. (2013-01-15 10:28:29)

Is melatonin classified as a sleeping pill? It can be used as a supplement and causes drowsiness. Seth: No. This study was about prescription sleeping pills.

## Hard to Say Whether Medicine Does More Good Than Harm (2013-01-12 05:00)

[1]A draft article by Spyros Makridakis about blood pressure and iatrogenics takes issue with [2]the statement that "The treatment of hypertension has been one of medicine's major successes of the past half-century." Over the last half-century, the article says, the death rate for people with high blood pressure decreased by almost exactly the same amount as the death rate for people without high blood pressure. Apparently "one of medicine's major successes" is a case where the health benefit no more than equaled the health cost – leaving aside what the treatment cost in time and money.

Because very high blood pressure (systolic > 180 mm Hg) is quite dangerous and blood pressure drugs really work, this is a surprising outcome. Makridakis points out that doctors start treating high blood pressure when it rises above systolic = 140 mm Hg, a point when there is little or no increase in death rate. [3]This article tells doctors to immedi-

ately prescribe drugs when systolic blood pressure is above 160. Yet death rate clearly increases only when systolic blood pressure is above 180. Makridakis concludes (as do I) that blood pressure drugs have significant health costs as well as benefits. The drugs are so often prescribed when they do no good and the costs are so high that the overall health costs of blood pressure treatment have managed to be as high as the overall benefits. Even when handed a relatively easy-to-measure problem (high blood pressure) and a relatively simple solution (blood pressure drugs), our health care system managed to achieve no clear gain. If this is "one of medicine's major successes", medicine is in bad shape.

The last paragraph of Makridakis's article makes a surprising statement: "We strongly believe that medicine is extremely useful." It does not explain this belief, which is contradicted by the rest of the article. I was puzzled. I wrote to the author:

I recently read your paper on "High blood pressure and iatrogenics". The main part makes good sense. Then it ends with something quite puzzling: "We strongly believe that medicine is extremely useful." No doubt a few areas of medicine are extremely useful. For large chunks of medicine, it is hard to tell whether they do more good than harm, because so many drugs and other treatments have undisclosed or unnoticed bad effects.

For example, tonsillectomies – for a long time the most common operation – is associated with a 50 % increase in mortality in one study. The notion that cutting off part of the immune system is a good idea makes as much sense as the idea that cutting out part of the brain is a good idea. Another example is sleeping pills. They are associated with a three-fold increase in death rate soon after they begin to be taken. I am not saying that medicine overall does more harm than good. I am saying that a strong belief about the outcome of such an assessment (does medicine overall do more good than harm?) doesn't make sense.

Makridakis replied:

Thank you for your email. The paper you mention is a draft posted for comments. I agree with you that my statement is wrong. It should have read: : "We strongly believe that medicine can be extremely useful". For instance, this could be the case in treating heart attacks, strokes, traumas from car accidents or bullet shots. But in most other cases the harm from treatment can be greater than the benefits. In addition, the harm from preventive medicine can exceed its value. Thank you for pointing out this mistake to me.

Puzzle resolved.

---

Caleb C (2013-01-12 10:27:09)

Reminds me of Kurt Harris, an MDs, view of medical nihilism: "I won't expand much on the influence of medical school hazing and 23 years of reading xrays, CTs, MRIs, et cetera, but this has been a huge influence, especially in making me a medical nihilist.

A medical nihilist posits that in a world where the entire medical system (alternative and complementary not exempted) disappeared in some selective rapture, that the net effect would be positive for the economy, and no worse than neutral for the aggregate level of health and wellness" I'm a healthcare provider as well, and I firmly believe Kurt's assessment of our profession is correct. Of course, I more or less believe it could be extended to most of the top elite fields; education, politics, finance, government, lawyers, medicine; if they were to disappear in a selective rapture the net effect would be positive for the economy, and often times result in a huge aggregate increase in human satisfaction and enjoyment of life. I guess it shouldn't be a surprise that elites will, if allowed, rig the social system so that they capture more wealth than they contribute in utility. At least the old aristocratic elite would risk their lives to protect you from the Viking raiders every now and then, and on average had pretty good tastes in what arts and science they promoted. Comparing state sponsored art these days to the cathedrals, I can't help but think our societies elites are far inferior in quality:)

Robbo (2013-01-12 14:05:18)

Wow ! "Thank you for pointing out this mistake to me." Both of you deserve great credit over this exchange.

Greg (2013-01-12 19:43:31)

Makridakis borrowed a graph from an article by statistician Sidney Port. Here's another one by him about blood pressure and mortality, showing why researchers that may not be experts in statistics can find linear relationships where the true effects are nonlinear. <http://www.math.ucla.edu/scp/publications/EHJ.pdf> This doesn't appear to be a popular reading of the data. Framingham's senior investigator responded and claimed to refute Port's analysis "without resorting to any type of statistical modeling" (or even having a statistician listed as a co-author). Not sure what to think, except that I'd sure like to see more statisticians writing/co-writing medical papers. <http://hyper.ahajournals.org/content/42/4/453.long>

Kim Øyhus, viking raider (2013-01-13 01:40:38)

They assume high blood pressure is a defect. They do not ask why the body raises the blood pressure. If the body is trying to achieve something by raising blood pressure, such as trying to avoid something worse, then pressure lowering medicine will make something worse happen.

dearieme (2013-01-13 02:36:24)

"Thank you for pointing out this mistake to me." I'm with Robbo.

dearieme (2013-01-13 02:52:40)

In Greg's second link: "However, the more relevant outcome is CVD mortality and the CVD events promoted by hypertension unconfounded by non-CVD mortality, which could be associated with low BP." Against which I observe: (i) Relevant to what? Says who? (ii) All cause mortality has the advantages of (a) not being potentially polluted by errors re cause of death, and (b) being useful to anyone who's fairly relaxed about how he dies but less so about when he dies. (iii) It begs the question to assume that CVD events are promoted by hypertension, probably in general and certainly when the debate concerns what constitutes hypertension. (iv) "non-CVD mortality, which could be associated with low BP": I'm trying to decide whether this remark is (a) mere windy assertion, (b) question-begging, (c) evidence of not having grasped the point of the paper they are criticising. These categories are not mutually exclusive. The paper in the first link is altogether on a higher intellectual plane than the one in the second. That doesn't guarantee that it gets closer to the truth, but it stacks the odds in its favour. Seth: I wouldn't say that CVD mortality is "more" relevant, but it is relevant. I think the authors were trying to say this: Let's assume 1. High blood pressure causes CVD mortality. 2. Low blood pressure does NOT cause mortality but is associated with many diseases that do (these diseases cause both death and low blood pressure). If these assumptions are true, by looking at the CVD mortality vs. blood pressure function, you get a better idea of what will happen if you lower blood pressure than if you look at the all-cause mortality vs blood pressure function.

dearieme (2013-01-13 03:21:54)

Again concerning Greg's second link: (i) "Without resorting to any type of statistical modeling" - ha bloody ha: even a primitive bit of statistical analysis is statistical modelling. It reminds me of Monsieur Jourdain's discovery that he has "been speaking

prose all my life, and didn't even know it!" But at least M. Jourdain realised! (ii) A second remark with an anti-intellectual flavour: "the value that the logistic splines analysis of Port et al ...". I've used splines myself (admittedly decades ago) but I have to say that the use of splines doesn't seem to me to be central to the Port et al analysis - they are just a nifty tool. The remark is intended, I suppose, to imply to a readership of medics that Port et al are using some fancy-dan trick to pull the wool over their eyes. The key parts of that analysis are instead (to quote myself) three bits of common sense, namely (a) using all-causes death as their measure of [negative] merit, (b) categorising the data by age and sex, and (c) exploiting percentiles as a 'natural scale' for bp. (I say "common sense" in the reasonably precise sense of "that's what an engineer or physicist would do.") Is it too rude to suggest that engineers and physicists tend to be better with numbers than medics?

Kim Øyhus, physicist (2013-01-14 13:10:27)

A feedback system failing, are what the curves in the article look like. I am thinking about negative feedback, where something tries to homeostase something else, and succeeds, but eventually fail, and blood pressure rises, perhaps as a consequence, or symptom, or direct cause. The curve is flat, with a slight increase, like a feedback system with low amplification and no integration, and the suddenly increases, like from a saturated negative feedback with too big input. It should be possible to map feedback systems like that from their effects.

### **The First John Maddox Prize (2013-01-13 05:00)**

The panel that chose the winners of the first John Maddox Prize – Colin Blakemore, a British psychologist, Tracey Brown (Sense About Science), Phil Campbell (Nature), and Brenda Maddox – deserve a prize for Most Contentious Award. [1]The Maddox Prize is supposed to be awarded to people who have excelled at:

any kind of public activity, including all forms of writing, speaking and public engagement, in any of the following areas:

- Addressing misleading information about scientific or medical issues in any forum.
- Bringing sound evidence to bear in a public or policy debate.
- Helping people to make sense of a complex scientific issue.

The first winners, announced in November, were Simon Wessely, a British psychiatrist, and Fang Shi-min, a Chinese journalist. Criticism of Fang is [2]here. Criticism of Wessely is [3]here (in the comments) and [4]here. One of his papers is [5]here. Wessely is best known for promoting the use of cognitive behavioral therapy (CBT) to treat people with chronic fatigue syndrome (CFS). In particular, "he and his colleagues demonstrated substantial overlap in symptoms between chronic fatigue syndrome and clinical depression. . . . He subsequently developed a treatment approach using cognitive-behavioural therapy techniques, which in many cases brought about substantial improvement."

The puzzle is that this is considered significant. Maybe people with CFS are depressed because they have CFS? Maybe this is why CBT helps them? [6]A statement explaining the reward does not answer this objection. As for Fang, I have no idea if he deserves the prize. I would be surprised if members of the prize committee could judge for themselves the accuracy and value of his work.

Alex Chernavsky (2013-01-13 09:56:17)

Fang Shi-min (also known as Fang Shimin and Fang Zhouzi) was described favorably in a *New York Times* piece in 2010: <http://www.nytimes.com/2010/10/07/world/asia/07fraud.html>

Alex Chernavsky (2013-01-13 11:37:37)

CFS sufferers tend to insist that their condition is not psychosomatic. I'm less convinced. Psychological illnesses are well known to be highly influenced by culture. Perhaps there is something about modern Western culture that predisposes people to CFS. For a look at a bizarre psychological condition that's rare in the West but common in the East, see this article about *koro* (the belief that one's penis has either been stolen or is retracting into one's body): <http://www.kuro5hin.org/story/2002/9/16/81843/6555>

dearieme (2013-01-13 18:03:32)

Was this one of the most expensive scientific lies ever told? [http://www.science20.com/news\\_articles/radiation\\_effects\\_did\\_nobel\\_prize\\_winner\\_hermann\\_muller\\_lie-82835](http://www.science20.com/news_articles/radiation_effects_did_nobel_prize_winner_hermann_muller_lie-82835) Seth: Yes. I mentioned it here: <http://blog.sethroberts.net/2011/09/22/assorted-links-127/>

Anna (2013-01-14 13:26:21)

Alex, I suggest you watch the documentary 'Voices from the Shadows'. It can be seen here: <http://mubi.com/films/voices-from-the-shadows> another informative website: <http://mpkb.org/home/alternate/psychosomatic> #historical\_examples\_of\_psychologizing\_problems\_with\_organic\_causes If you're not willing to spend an hour and \$3 learning about the condition, you have no right to claim it is psychosomatic.

dearieme (2013-01-14 17:21:41)

Cheating seems to be spreading from science to poetry. <http://www.guardian.co.uk/books/2013/jan/14/poetry-competition-winner-plagiarist> Seth: Really surprising, since it seems obvious he would be caught.

## What Should Your Cholesterol Be? (2013-01-15 05:00)

According to [1]the Mayo Clinic website, lower levels of cholesterol are better. For total cholesterol, says the Mayo Clinic, below 5.2 mmol/L (= 200 mg/dL) is "desirable". A level from 5.2 to 6.2 mmol/L is "borderline high", and above 6.2 mmol/L (= 240 mg/dL) is "high".

[2]A 2011 study from Norway, based on 500,000 person-years of observation, found drastically different results. For both men and women, the lowest levels of total cholesterol (below 5.0 mmol/L) were associated with the most death. For men, the best level was intermediate – what the Mayo Clinic calls "borderline high". For women, the safest levels were the highest.

If high cholesterol causes heart disease, as we are so often told, the pattern for women makes no sense. For a long time, experts have told us to limit egg consumption because eggs are high in cholesterol. However, a [3]new study shows that egg consumption has no association with heart disease risk.

Via [4]Malcolm Kendrick. I also like [5]his post about whether statins cause muscle pain.

FYI - broken links to the Norway and egg studies. Seth: Fixed, thanks.

Nancy Lebovitz (2013-01-15 09:07:06)

Suppose the medical establishment did come to believe that low cholesterol was very dangerous. Do you think they'd come with an effective treatment?

Kirk (2013-01-15 12:11:27)

The data from the China Study also shows that mortality increases as total cholesterol drops.

Jonathan Graehl (2013-01-15 13:34:10)

Obligatory "causation is not correlation" counterpoint: old and dying people are made to lower their cholesterol, and if young people lowered it they would be fine or even healthier. (I think it's 70 % likely to be causal)

Txomin (2013-01-15 17:13:17)

Which kind of low cholesterol is associated with a greater mortality? Natural or statins-induced?

BenSix (2013-01-16 09:33:24)

At least some evidence suggests that cholesterol levels [1]decrease with age in older men and women.

1. <http://circ.ahajournals.org/content/96/1/37.full>

Adam (2013-01-16 16:58:56)

The great tinkerer, evolution, developed Cholesterol as an intricate part of the way the human body works over millions of years. To think that medicine can understand the complexities of the situation and improve upon it seems quite arrogant & foolish. This part seems to recognize that humans are not living as intended: "In the Diet, Obesity, and Gene (Diogenes) Project, increased protein consumption together with a modest reduction in glycemic index was beneficial for weight control. Substituting protein for carbohydrate also partly resulted in lower blood pressure, improved lipids levels, and concomitantly reduced cardiovascular risk. Higher vitamin D intake might have beneficial effects on the reduction of visceral adipose tissue and other cardiovascular risk factors. Another possibility is that lifestyle factors associated with egg consumption might have obscured a positive association between egg consumption and risk of coronary heart disease and stroke. However, regular egg consumption tends to be associated with unhealthy lifestyle factors such as smoking and physical inactivity." In other words, eating too much sugar, being inactive, not getting enough vitamin D, & smoking are unnatural & harmful behaviors for humans. I feel 1000 % more confident that addressing these 4 things would be more effective & less dangerous than attacking Cholesterol. Seth: The evidence that high cholesterol causes heart disease is close to zero. Because of this, it is likely that roughly everything mainstream experts say about cholesterol will be wrong. It's like starting an argument "let's assume 1 = 0." With that assumption, you will reach a lot of wrong conclusions.

Tim Banks (2013-01-18 20:15:41)

In the United States heart and arteriosclerosis are the leading cause of premature deaths but in Japan deaths due to cardiovascular diseases are insignificant! We have to wonder why! Japanese eat a lot of fish that contains omega 3 oil, a fat known to reduce plaque in the arteries thereby reversing atherosclerosis. Omega 3 unsaturated fats increase the HDL or high-density lipoproteins and their particle size that are essential for keeping the arteries from blocking. Microbiology and biochemistry are very complex sciences and many phenomena are not at all understood. Many anomalies exist. As mentioned above, omega 3 in fish oil reverses artery plaque yet it contains significant amounts of dietary cholesterol and its molecular is extremely similar! Seth: The French also have a low rate of heart disease – and they eat much less fish than the Japanese. There is one clear similarity between the French diet and the Japanese diet: Both eat a lot of fermented food, far more than other countries.

Peter Andrews (2013-01-30 07:30:23)

... and fermented foods contain Vitamin K2 which reduces vascular calcification...

### **"The Most Influential Tree in the World" (2013-01-17 05:00)**

The title comes from Andrew Montford's new book [1]Hiding the Decline (copy given me by author) about Climate-gate. From an introductory section:

When the figures were published the extraordinary lack of data underlying the blade of the Yamal hockey stick caused a minor sensation. In fact the high point at the end of the graph was shown to have been based on only four trees, and only one of these had the hockey stick shape. McIntyre dubbed it 'the most influential tree in the world'.

Most of Hiding the Decline is about the inquiries that followed Climategate. I enjoyed reading about smug powerful people making fools of themselves and the fairy-tale-like consternation created by two unlikely events: 1. A non-scientist ([2]Steve McIntyre) gets involved in the global warming debate. As in a fairy tale, McIntyre is free to speak the truth. In particular, he is free to question. Professional climate scientists cannot speak the truth for fear of career damage. 2. The release of the Climategate emails. As in a fairy tale, a sudden burst of truth about bad behavior previously hidden.

Hiding the Decline is as well-written as a book by a professional writer but this is a book no professional science writer could write due to its investment in an officially-wrong point of view. There are lots of badly-written books from tiny-minority points of view. The appearance of a well-written one, joining Montford's earlier [3]The Hockey Stick Illusion, is no small deal. How much free speech do we have? It depends on the medium. Maybe the sequence from less to more censored is: 1. Conversation. 2. Email and other private writing. 3. Blog post. 4. Poorly-written book. 5. Article in minor magazine. 6. Well-written book. 7. Article in prestigious magazine. 8. Textbook. From one step to the next (e.g., from conversation to email), views become less diverse. This book is disagreement with the official line high up the tree.

One reason we enjoy certain jokes is that they speak a forbidden truth. When you can't usually say it, the truth is funny. The forbidden truth aspect of Hiding the Decline is another reason I enjoyed it so much.

Does the story have a happy ending? Montford thinks not:

As we look back over the ten years of this story, the impression we get is of a wave of dishonesty, a public sector that will spin and lie, and mislead and lie, and distort and lie, and lie again. . . . Despite the emails showing, apparently incontrovertibly, that FOI laws were flouted with the full knowledge of senior figures in university, there have been almost no discernible repercussions for anyone involved. . . . The response to [Climategate] was an extraordinary failure of the institutions and of the people who are paid to protect the public interest – a failure of honesty, a failure of diligence, a failure of integrity.

My view is different. The institutions (University of East Anglia, Penn State, and so on) and officials (e.g., Vice Chancellor of the University of East Anglia) "failed" only in their ostensible purpose. Their actual purpose centers on protecting the people who created or hired them (see *The Dictator's Handbook*). At this they succeeded, but suffered a large loss of credibility. To me, Climategate is the story of how two people – Steve McIntyre and the hacker of the Climategate emails – both with zero official standing, had a huge effect on worldwide public discourse. (A Google search for Climategate returns about 2 million hits.) They exposed dishonesty in powerful and heretofore respected people (science professors) on a matter far more important than expense accounts. They pushed the rest of us a non-trivial distance toward seeing the truth. I didn't know that was possible, and I'm glad it is.

[...] Seth's Blog » Blog Archive » "The Most Influential Tree in the World" [...]

## No Stagnation in My Kitchen (2013-01-18 05:00)

Stagnation of innovation is often illustrated with kitchens. In 1996, [1]Paul Krugman wrote, "I live in a house with a late-50s-vintage kitchen, never remodeled. The non-self-defrosting refrigerator, and the gas range with its open pilot lights . . . it is still a pretty functional kitchen." (Illustrating, at least, his lack of change.) [2]Tyler Cowen said "if he were to introduce his grandmother to a modern American kitchen, it wouldn't be all that earth-shattering for her." [3]David Brooks mentioned lack of innovation in many things, including "appliances". Last week, [4]the Economist said:

Take kitchens. In 1900 kitchens in even the poshest of households were primitive things. . . . Fast forward to 1970 and middle-class kitchens in America and Europe feature gas and electric hobs [= burners] and ovens, fridges, food processors, microwaves and dishwashers. Move forward another 40 years, though, and things scarcely change.

For a long time I wanted to go to the giant kitchen and housewares trade show in Chicago every summer, until [5]this article convinced it would be the same old stuff with tiny variations.

In contrast, my kitchen has changed greatly in the last ten years. Here's how:

1. Tea-brewing equipment. Soon after I started practicing the Shangri-La Diet (calories without smell), I started drinking lots of tea (smell without calories).
2. Electric tea kettle (heats water for tea better than microwave).
3. Kitchen scale (for tea and flaxseed). I discovered that flaxseed oil and, later, ground flaxseed improved my brain function and gums.
4. Noseclips. For the Shangri-La Diet.
5. Yogurt maker. I believe that fermented foods are essential for health.
6. Kombucha brewing tools (e.g., glass jars).
7. Spice grinder (for flax seed).
8. Soup cooker (for pork belly and miso soup). Eating lots of pork belly improved my sleep.

I would like to make more fermented foods. I hear that in South Korea I can get a machine that makes both natto and yogurt.

My kitchen changed because my ideas about health changed. My ideas about health changed because of my research. I found a new way to lose weight. I had a new explanation of why we like foods with complex, sour, and unami flavors (so that we will eat more fermented food). Self-experimentation convinced me that I was seriously omega-3-deficient, thus the flaxseeds. I discovered that if I eat a lot of animal fat, I sleep better.

I believe kitchen stagnation reflects stagnation in our thinking about health. Every October, I point out that the Nobel Prize in Medicine has again been given to research that is so far useless. "Molecular medicine has come nowhere close to matching the effects of improved sanitation," says the Economist. Could mainstream health researchers be trapped by their desires to show off (no cheap equipment), to be respected (no "crazy ideas"), and to produce a steady stream of publications (no time to test implausible ideas)? Could having goals other than the truth (such as respectability) make it harder to find the truth? People who have written about stagnation in innovation do not seem to have considered these possibilities.

Tony (2013-01-18 05:30:32)

What do you mean by soup cooker? Is this different than a blender or slow cooker? If so, I want one! I tried to google "soup cooker" with not much luck. Seth: [1]Here is a picture. Like a slow cooker but more choice of temperature and duration.

1. [http://www.google.com/imgres?imgurl=http://image.made-in-china.com/2f0j00bvCTLWyBZtkL/Computerized-DCrockery-Pot-Soup-Cooker-KZB50-B-.jpg&imgrefurl=http://www.made-in-china.com/showroom/jians-rita/product-detailhqbmlDyoXnkL/China-Computerized-DCrockery-Pot-Soup-Cooker-KZB50-B-.html&h=305&w=300&sz=82&tbnid=kH4WrtiPbvExrM:&tbnh=97&tbnw=95&zoom=1&usg=\\_\\_hXVqm0syNxYtDYqwgEK9VCJtGD4=&docid=Bx5dNFGrlKGeIM&sa=X&ei=GI35UJvGKMS1rQHfsICIBg&ved=0CIgBEPUBMAY&dur=419](http://www.google.com/imgres?imgurl=http://image.made-in-china.com/2f0j00bvCTLWyBZtkL/Computerized-DCrockery-Pot-Soup-Cooker-KZB50-B-.jpg&imgrefurl=http://www.made-in-china.com/showroom/jians-rita/product-detailhqbmlDyoXnkL/China-Computerized-DCrockery-Pot-Soup-Cooker-KZB50-B-.html&h=305&w=300&sz=82&tbnid=kH4WrtiPbvExrM:&tbnh=97&tbnw=95&zoom=1&usg=__hXVqm0syNxYtDYqwgEK9VCJtGD4=&docid=Bx5dNFGrlKGeIM&sa=X&ei=GI35UJvGKMS1rQHfsICIBg&ved=0CIgBEPUBMAY&dur=419)

Rashad (2013-01-18 08:06:00)

Here is a different take on kitchen stagnation, framing it mostly as a wealth distribution issue. [http://www.slate.com/blogs/moneybox/2013/01/10/myth\\_of\\_kitchen\\_stagnation.html](http://www.slate.com/blogs/moneybox/2013/01/10/myth_of_kitchen_stagnation.html)

Tom (2013-01-18 08:17:29)

Seth's point makes more sense. None of his new equipment sounds very expensive. His kitchen changed because what he eats changed, not because he has more money. Professional chefs may buy immersion circulators, blow torches, French tops, pressure cookers, and blast chillers, but they need to be on the bleeding edge to prepare great tasting food extremely quickly. Most people would not, regardless of how much they made. Maybe the Romneys have a blast chiller and an immersion circulator, but I wouldn't bet on it.

dearieme (2013-01-18 10:06:29)

Everyone in Britain has 1 - 3. We also have 5 & 7. About "Kombucha brewing tools (e.g., glass jars)": would our old wine-making equipment do? I too would like to know what a Soup cooker is. Seth: To make kombucha you need glass jars of the right size. Mine hold about a gallon.

Paul N (2013-01-18 12:36:37)

An approximate American equivalent of the soup cooker is the [1]VitaClay Chef It has an unglazed clay crock, can be set at various temperatures, from slow cooking pot roasts, to rice cooking, to yoghurt making. For pot roasts, it cooks faster than crock pots, and then decreases the temperature, too keep it warm but no overcooked. Also has programmable delayed start and a few other good features. I bought one of these for my partner for Xmas. Both she and I are long time crock pot users and we both agree this is better, and produces better tasting food, than any of our crockpots. We have used the yoghurt setting for making kefir, and also for sourdoughing bread. I am normally not a fan of countertop plug in appliances (other than the kettle), but this one has earned its place in my kitchen.

1. <http://vitaclaychef.com/>

Paul N (2013-01-18 12:47:50)

On the topic of kitchen innovation, I think the focus on "equipment" has led to a lack of innovation on "food" and even true "cooking" Here's a great article from Mark Bittman of the NY Times on the topic[1]Your kitchen is tiny - so what> ; "I asked my friend the chef Mario Batali what he thought about all this[people disparaging my small kitchen and basic equipment]. "Only bad cooks blame the equipment," he said. "I can make almost every dish in my restaurants on four crummy electric burners with a regular oven — as can just about anyone else who cares to." I couldn't agree more. The focus on bigger kitchens, with more stuff, has moved the focus from the food itself. It has allowed people to own more gadgets and buy and store more varieties of prepared/processed foods in larger volumes (often resulting in spillage and waste) while the overall quality (and knowledge) of home food preparation has decreased.

1. [http://www.nytimes.com/2008/12/14/weekinreview/14bittman.html?\\_r=0](http://www.nytimes.com/2008/12/14/weekinreview/14bittman.html?_r=0)

Jonathan Shewchuk (2013-01-18 20:16:00)

My favorite new kitchen technology is my sous vide cooker. The custardy eggs you get when you heat them at 148 F for an hour are superb. The way it tenderizes short ribs and chuck roast and anything with cartilage is amazing. And I like that I can leave a roast in it and take it out anywhere between 8 and 48 hours later, still cooked medium, so I don't have to know in

advance when I'll be eating. Seth: Thanks for the suggestion.

Carl Willat (2013-01-19 09:36:44)

I want a bread oven with steam injection.

Paul N (2013-01-19 13:05:24)

@ Carl You can get almost the same result as a steam oven, with this no-knead method and a cast iron pot [1]No Knead Bread. A google search of Mark Bittman and no-knead bread will come up with a few interesting variations on this technique, but the cast iron pot is always the "steam oven" I suppose a bread machine - or even a domestic range - could be made with a steam "system" - but that sounds expensive for home kitchen equipment. And there's nothing to break, leak or become obsolete with the pot.

1. <http://www.nytimes.com/2006/11/08/dining/08mini.html?ref=dining>

dearieme (2013-01-19 18:02:20)

"Seth: To make kombucha you need glass jars of the right size. Mine hold about a gallon." Our wine making jars do too (though of course our gallon is bigger than yours). When the weather warms up enough that we can risk a trip into the attic, we'll have to see whether we can find them.

WR (2013-01-21 20:53:49)

Perhaps you realize, but stagnation ala TC is not about what you actually have, but what you could get. Nothing you list is new, and if anything it's evidence of stagnation. Soup, Yogurt, Kombucha, Tea, etc—not new. Nor are the various apparati you cite new (except perhaps to you), with the one exception being your own nose clipping discovery. The whole point is that once you invest glass jars ("pick the low-hanging fruit"), they prove pretty hard to improve. And gallon glass jars have been around since the 1800's. Maybe your point is that despite stagnation in the latter sense, there is still room for plenty of individual improvement in quality of life? Seth: What I wrote has a non-trivial point. My kitchen changed because my ideas about what to eat improved. That's progress. Other people's kitchens did not change at least partly because – my example makes clear – their ideas about what to eat did not change. In other words, underneath the technological stagnation noticed by TC and others lies scientific stagnation – in particular, stagnation in our understanding of health. I don't think that has been obvious to people who write about stagnation and its causes. Sure, my new ideas led me to choose from existing stuff in new ways. But as the new ideas (e.g., about fermented food) spread, new technologies will come along that do a better job of using those ideas.

Tina D. (2013-01-22 12:24:38)

Yes. I have limited space in my kitchen, so I need to pick and choose what I use, and it revolves around my diet. I like stews and soups and braises, so a slow cooker is essential, but not a panini maker because I don't really like sandwiches. And, as my ideas about food changes - I am slowly becoming a paleo and fermented fan - I'm sure my equipment will change. My friends and I now have 6 gallon plastic buckets to make our sourkraut. I've a fan of only using what I need (although my closet tells me otherwise) but it's really hard to do so when we live in a culture that rewards stuff for the sake of stuff.

Txomin (2013-01-19 05:42:49)

Even if the climatologists had acted with caution, respect, and integrity (which they blatantly haven't), they should still be held accountable for the huge misdirection of resources and funds that has taken and continues to take place. The environmental cost of so-called "bio-fuels" alone is appalling.

Ief (2013-01-19 11:04:24)

Since you are interested in hormesis did you find surprising your brain-test results when you removed your mercury amalgams? If both results like your brain-tests and the ones you link at hormesis articles are true then for low dose stressors we have, some times good some times bad. Some of the bad can probably be interpreted as hormesis because good for something inside you (cancer cells or a microorganism) in a small time scale (months) can be bad for you (and for this thing inside you) in a bigger time scale (several years until it kills you). Also something bad in our culture might have been good in another, we would probably call many shamans (who were respected persons in their tribes) mentally disturbed. The properties of mind that are respected have changed and I am wondering how I should interpret your decreased performance in your arithmetic tests. So some times I end up thinking that whatever will turn out to be true we will be able to talk about hormesis. I do not imply by this that this knowledge is not useful. Seth: Yes, I was surprised. Partly because the brain test results are very hard to improve for a long time. (Now and then they get better for a single test.) Removal of the mercury amalgam fillings caused an apparently permanent improvement. Partly because the improvement was so clear.

Of the current generation of leading British politicians, this chap may have the highest IQ and most sensitive political antennae. <http://www.telegraph.co.uk/comment/columnists/borisjohnson/9814618/Its-snowing-and-it-really-feels-like-the-start-of-a-mini-ice-age.html>

Jenny (2013-01-21 16:15:45)  
Thanks. Enjoyed reading it.

M&M (2013-02-14 15:58:06)

I had mercury amalgams fillings removed from my teeth about 10 years ago. I personally find it interesting that my migraine headaches have subsided from once a month to now only 4 times a year. For me, the findings are pretty clear.

## **Fecal Transplant Roundup (2013-01-20 05:00)**

[1]A new study has found that fecal transplants work better than antibiotics for clearing up a common and dangerous infection:

Such transplants cured 15 of 16 people who had recurring [= difficult-to-get-rid-of] infections with *Clostridium difficile* bacteria, whereas antibiotics cured only 3 of 13 and 4 of 13 patients in two comparison groups.

*Clostridium difficile* infections often result from antibiotic treatment. It is a big step forward for modern medicine to manage to grasp that the bacteria in our bodies protect us from infection. [2]Here is a blog about the value of fecal transplants; [3]here is another blog.

The comments contain many interesting details:

I spent Thanksgiving of 2012 in ICU and almost died from C-Diff. It was a harrowing experience for both me and my family. It required two months of care, recuperation and doses of vancomycin. My hospital bills are outrageous. [Fecal transplants are much cheaper – Seth] I am praying it doesn't return, having just finished my last dose of vancomycin. I had a dental implant and was on clyndamycin for two weeks and that was the culprit. Dentists should be required to inform patients that C-Diff could be a reaction to that specific antibiotic. I [4]was not warned about this being a possible side effect.

Our mother was hospitalized at a major university hospital and came down with C. diff. The antibiotics they gave her to fight the infection finally destroyed her kidneys and hearing and she decided that life was not worth living in that condition.

We have using this "treatment" for years and years in horses with difficult intestinal issues which didn't respond to other medications. We pass a slurry of fecal material from a healthy horse ( often mixed with electrolytes and baking soda) directly into the stomach of the sick horse. It works in almost all cases.

After my gut microflora was destroyed by 9 months of antibiotics for Lyme disease, I got C. diff this past June. Was flabbergasted that NONE of my doctors, ALL of whom prescribe antibiotics, ( & hopefully read the NYT or the INTERNET) [knew] about fecal transplants! I ditched my Lyme doctor (who said along with my GI & GP): "Take Flagyl" (which didn't work) and then Vancomycin. No thanks. Wasn't going to wait around for the C. diff to corrode my guts or till I was almost dead, so I went right to Dr. Brandt for a transplant and in ONE day the symptoms were gone.

I had recurring c diff for 12 months.Tried a myriad of antibiotics and a colon cleanse.Nothing worked. I was getting sicker and weaker by the day, not to mention very depressed. I was "beyond" desperate.

My husband (an internist) performed a fecal transplant (using my brother's stool—close DNA donor) at home (hanging the saline/stool bag from the ceiling fan!) 3+ years ago. I have been healthy ever since.

[A doctor:] This important study . . . is a big step in the right direction, however the study is quite small. [A doctor who doesn't understand statistics even after it is explained in plain English. The evidence from this "small" study is very strong. In case you didn't understand the numbers, the article says it in words: "the antibiotic groups were faring so poorly compared with the transplant patients that it was considered unethical to continue". – Seth] A larger RCT is needed before this becomes standard of care [implying that his or her lack of understanding of statistics is the norm – Seth]. Since no one is currently in position to reap monopoly profits from this treatment, I predict the study will be a long time coming. [Which, if true, implies that doctors' lack of understanding of statistics will kill a lot of people.–Seth]

The majority of cases of *C. difficile* infection occur in the hospital where they were usually brought on by use of broad-spectrum antibiotics destroying the natural balance of intestinal flora in the gut. A great many people outside the hospital setting walk around healthy colonized by *C. difficile* without becoming infected. Others become colonized while in the hospital, a virtual surety if you stay long enough. Broad-spectrum antibiotics wipe out bacteria that normally out-compete *C. difficile* at different niches within the intestinal ecosystem. [In other words, gross overuse of antibiotics has created a new ecosystem – modern hospitals – where *C. difficile* thrives. – Seth]

After a reaction to an antibiotic caused C Diff which lasted almost a year, was treated with multiple antibiotics of which Vancomycin was the only one that kept it at bay, having had a number of courses without success, meanwhile weight was down 25 lbs and health was deteriorating as in my opinion Vancomycin also presented some problems of its own, teeth browning, lethargy etc. C Diff ruins body and soul. After a lot of research was lucky to have found a doctor who checked out the fecal transplant history/procedure and performed the transplant. The feces donor was my brother having first had blood & feces testing. The transplant was a success, after suffering C Diff for almost a year my quality of life is great - normal.

The [squeamish] tone of this article is enraging. [It begins "The treatment may sound appalling". The headline calls it "This, er, Option". – Seth] I contracted ulcerative colitis when I was fifteen, and the squeamishness of my parents and doctors in my small town prevented me from accessing real care. More concerned with being grossed out than dealing with the problem at hand, I was allowed to go a year without receiving proper care. As a result, I ended up with such extreme internal bleeding that I was sent unconscious to the intensive care unit at Swedish Hospital in Seattle, three hours away from home, where a surgeon removed my entire colon. He chided my parents and local doctors for not seeking help from a specialist sooner; had they done so, I would not have been in such dire condition. I spent the next year of my childhood in the hospital. All this is to say: get over feeling grossed out by the human body and consider any possible treatments that might work. If this one does, great. Ditch the whole "ew" reaction because it stands in the way of saving lives.

I was plagued for decades with room-clearing gas and stomach cramps. Yogurt and probiotics didn't stand a chance against the established bad bugs. Then I went for my first colonoscopy (which gave me a whistle-clean gut.) I was told I could have anything I wanted. First thing, I drank a full quart of organic kefir. I haven't had a problem since. [Very interesting. Before a colonoscopy, you take something special to clean out your gut.–Seth]

Thanks to Alex Blackwood and Karen Goeders.

derp (2013-01-20 07:21:19)

The doctor you cited indeed is not familiar with statistics. Though he is right that the sample size is small, the effect is large. Furthermore, he seems to have no clue regarding previous studies. Showing the same effect over and over again creates a different statistic - you cannot simply view one study in isolation. This has been repeatedly critized and led to statisticians proposing non-frequentist (read: Bayesian) statistics for medical research (cf. Goodman, Ann. Intern Med. 1999;130(12):1005-1013). Even when using a pooled analysis (Gough et al., Clin Infect Dis. 2011;53(10):994-1002), the treatment effect is so large that instead of arguing, it calls for immediate development of treatment protocols (i.e. donor eligibility, disease screening of the donor, amount & frequency & mode of delivery of the transplant, ...). Seth: Good point.

Jazi Zilber (2013-01-20 13:51:59)

FDA is already blocking innovation here They want to disallow it until fully controlled by them. Likewise, FDA fight AGAINST smokeless cigarettes. Unbelievable! We have a certain killer cigarettes. We have a seemingly safe alternative - synthetic cigarettes. Yet it is "not approved here" and FDA fight against it!

John Eels (2013-01-20 15:44:24)

I can't resist but ask a very practical/utilitarian question. What would you advice a friend to do if he suffered from SIBO (small intestinal bacterial overgrowth)? Seth: I don't know.

Jonathan (2013-01-21 00:40:00)

The horse tale is particularly interesting. It implies that a fecal transplant can be done via the stomach. Perhaps, if a sufferer can't find proper medical transplant, in an emergency they might be able to self-treat by eating feces? Seth: Good point. One person uses ice cubes. Which she swallows.

Adam (2013-01-21 04:30:27)

Of course the FDA is blocking innovation. That is pretty much just what they do. It makes sense when you discover that they are largely funded by the pharmaceutical companies.

dearieme (2013-01-21 04:41:47)

I was about to raise the issue of repugnance, but probably some people wouldn't give a s...

Paul N (2013-01-21 14:51:44)

An alternative - and perhaps less "icky" means to the fecal transplant, is a microbiota transplant by inserting kefir grains into the colon - seems to have the same effect, at least in the case described here; [1]How I corrected ulcerative colitis with kefir grains This and the kefir example in the story above suggest that feces aren't the only way to do this. Part of the problem is likely that many probiotics don't survive the stomach/small intestine, so placing them directly in the colon gets around this.

Howard Lundy (2013-01-21 16:06:50)

Good roundup...A fecal transplant (FT) pretty much saved my uncle's life. He had the C. diff colitis infection and was in progressive decline. About 3 days after the FT he started feeling normal again.... get the word out! Visit my advocacy blog for more information at <http://fecaltransplant.info> or [www \[dot\] fecaltransplant \[dot\] info](http://www.fecaltransplant.info)

dearieme (2013-01-21 17:17:11)

Ahoy, Seth: <http://www.guardian.co.uk/lifeandstyle/2013/jan/19/what-doctors-wont-do>

Michael (2013-01-28 13:39:24)

Thank you for referencing my website FecalTransplant.org. A quick note I wanted to make was that I used Fecal Transplant to cure myself of Ulcerative Colitis, which was not caused by Clostridium Difficile bacteria. Most of the studies that are now making headlines in the United States are for its application for c. diff bacteria, however its uses go far beyond just that bacterial infection, but also to diseases like Ulcerative Colitis or Crohn's Disease that are not recognized as being caused by bacterial infection by doctors in the U.S. It is my belief that many disease currently known as autoimmune disorders are actually caused by infection by an unknown pathogen. Seth: That's an interesting idea. Is there evidence for it? I might put it differently. That many diseases are caused by UNDERINFECTION, a new concept to many doctors.

Lemmy Caution (2013-01-30 17:25:18)

Fecal transplants seem like a good idea. I would like to know how dangerous the procedure is though.

Teri (2013-02-07 17:30:44)

A fecal transplant healed me from coliltis in October 2012 after 3 1/2 years of suffering. Read my blog -<http://healed-from-uc.blogspot.com> It WORKS! I am symptom free and drug free!!!

### **Best Introduction to the Shangri-La Diet? (2013-01-21 21:43)**

[1]A long thread at Mark's Daily Apple may be the best introduction to the Shangri-La Diet. It is dramatic (people object, people say the diet is crazy), varied (many voices, many sorts of data), responsive to feedback (questions and objections are answered) and no doubt more convincing than my book (because it isn't by me). The helpful elements include:

1. An introductory success story (from a woman named heatseeker) that I have[2] already blogged about.
2. Someone makes a common Paleo objection – it works because of macronutrient ratios. "You have stumbled on the perfect macro ratios for you!" Heatseeker says this is unlikely because she barely changed her macro ratios. She answers many other questions and objections (e.g., "how do you choke down the coconut oil?").
3. Someone says it didn't work for them ("neither did anything else").
4. Link to [3]a talk by me ("You Had Me at Bacon") that puts the diet in the context of my other work, such as the effect of pork fat on sleep.
5. Link to [4]Alex Chernavsky's results, which are most impressive [5]in context.
6. Emphasis that the flavorless calories can be anything so long as they are flavorless (i.e., have no smell, which can be achieved by eating them nose-clipped). As heatseeker says, she lost weight via flavorless fat, I lost weight via flavorless sugar, so the success cannot be due to the fat. It is more complicated than that.
7. A confident naysayer: "I started eating less and now I'm lean for life. It really is that simple."
8. Link to [6]a scientific paper by me about the underlying theory.

9. Heatseeker says: "I would say that after four years of eating according to TPB [The Primal Blueprint by Mark Sisson], and 2-3 years of really strict adherence, absolutely every promise made by Mark came true-EXCEPT the fat loss." That Diet X works better than a credible alternative (in this case, TPB) is more interesting than the observation that it works better than nothing.
10. A link to me talking about "[7]what food makes my brain work best". More context.
11. "Has been incredibly easy to follow, even while at work," says someone who is not heatseeker.
12. Independent discovery: "38 years ago our gym teacher had one of the overweight girls (we had 2) in gym class doing this! By the time we hit our Christmas break she had lost most of her pudge!! This is a true story. I remember because the girl's parents were not informed and the gym teacher almost got fired for 'experimenting' on the said pupil. What saved her was people finding out that the girl had been caught by the teacher barfing up her lunch in an effort to lose weight (bulimic) so to keep her from going down that path and to gain her trust as a confidant etc she helped her by showing her a method she herself had used to control hunger which was eating a fat source between meals. Fantastic eh??? I had never heard anything quite like this until I read this thread."
13. Bonus side effect: "Last night I slept through the night! Completely! I did not even slightly stir for any reason. . . . I have not slept through the night in YEARS!!!!!!" More reason to think that lack of certain fats impairs sleep.
14. Psychological effect: "What is happening here with the SLD? I feel calm and neutral to food." You may remember [8]research that suggested self-control is like a muscle. One similarity is the more you use it the stronger it gets. Several people have said that as soon as they started SLD, they were able to overcome other addictions, such as smoking and coffee. Maybe this is because years of struggling with food, day after day, had left them with very strong self-control. Before SLD, their self-control was exhausted pushing away urges to eat. As soon as SLD got rid of those urges, their very strong self control made it easy to quit smoking or whatever.
15. Two reluctant yea-sayers: "I coincidentally started trying this as a gesture of support for a desperate friend of mine . . . The whole concept is ludicrous and it's probably just placebo effect . . . I'm kind of embarrassed to admit that this has worked for me. 10 lbs down" (Person 1). "If there weren't so many people saying this works for them, I'd think it was the stupidest thing in the world" (Person 2).

dearieme (2013-01-22 04:31:28)

I see plenty of advice to the effect that losing weight can reduce the HbA1c of diabetics, even to the point of apparently curing them. Do you have many/any people attributing such a result to the SLD? Seth: No, haven't heard many stories like that.

Morex (2013-01-22 09:40:28)

Hi Seth. Hello from Mexico! I stumbled upon SLD while reading Freakonomics a couple of weeks ago and I have been doing great. It's a life changing thing and a total revolution. But I will write to you about that in a couple of months, after I get more results with my experiments. I am writing here because of coffee. A few hours after I started SLD (almost 2 weeks ago) my cravings were gone, but not the craving for coffee. I love it and I have invested time and effort to become an "expert". I would drink up to 3 liters of coffee in a regular morning. But not today. Just as my craving for food disappeared a week ago, my craving for coffee is gone today. I just had a couple of cups. So here's a crazy and non-scientific theory of mine: Could it be that the cravings for coffee (and other substances) vanish because people doing SLD learn to disassociate taste from food? Or taste from substances? Since taste is no longer in the picture, could it be that coffee loses importance? I don't know. Just some thoughts. Seth: Thanks for your comments about SLD. That's good to hear. Your experience with coffee is fascinating. Here's another possible explanation: Part of your craving for coffee came about because you drank coffee with food. The taste of the coffee became associated with the calories in the food. Take away the food – because you are eating less – and the craving for coffee gets weaker.

Joanna (2013-01-22 14:56:00)

Interesting compilation of info/comments. Any data or thoughts on whether a fat works better/the same/less well than using a sugar as you did when you devised SLD? Seth: Good fats work much better than sugar because of the positive side effects (better skin, sleep, brain, less inflammation). Sugar does not improve skin, etc. I have blogged, with data, many times about the last three (sleep, brain, inflammation). The skin improvement produced by the fat is obvious.

pat (2013-01-23 13:00:02)

I was thinking of giving up snacking, but maybe I should do shangri-la diet for lent.

Joanna (2013-01-24 12:48:54)

Thanks Seth. I was thinking the same thing, that the fats (the right ones) are good for you in other ways. The down side is that a sugar source, before mixed with water, is much more portable than most fats. Which makes the diet easier for travel and work.

q (2013-01-28 13:45:03)

in my life the "calm and neutral to food" effect is more important than the weight loss. (but i'm only mildly overweight.)

q (2013-01-28 14:01:39)

seth, while i have your ear, one question i always had was why the size of the window was supposed to be an hour. how did you arrive at this - why isn't it half an hour or 45 mins or two hours or 15 mins or whatever? Seth: Rat studies suggested the flavor and calories must be ingested no further apart than an hour to become associated. It's meant to give the idea rather than be ironclad. I forget the details of the studies.

## **Personal Science = Insourcing Your Health (2013-01-22 05:00)**

I recently blogged about [1]undisclosed risks of medical treatments. For example, sleeping pills are associated with [2]a big increase in death rate. Patients are rarely (never?) told this. One reason risks are undisclosed is ignorance: Your doctor doesn't know about them. Another likely reason is that you and your doctor have different goals. If a treatment harms you, your doctor is not harmed, in all but a few cases. If you refuse a treatment (such as a surgery), your doctor may make less money. This pushes doctors to overstate benefits and understate costs.

This is the simplest case for personal science: You care more about your health than any expert ever will. The experts have advantages, too (such as more experience with your problem) so it is not obvious that personal science will be better than expert advice – you have to try it and find out. When I started to study my acne, I was stunned how easy it was to improve on what my dermatologist had told me.

[3]A recent article in The Atlantic ("The Insourcing Boom") describes a similar revelation at General Electric. GE executives wondered if they could build a certain water heater (the Geospring) just as profitably in America as in China. They looked at it carefully:

The GeoSpring in particular, Nolan says, has "a lot of copper tubing in the top." Assembly-line workers "have to route the tubes, and they have to braze them—weld them—to seal the joints. How that tubing is designed really affects how hard or easy it is to solder the joints. And how hard or easy it is to do the soldering affects the quality, of course. And the quality of those welds is literally the quality of the hot-water heater." Although the GeoSpring had been conceived, designed, marketed, and managed from Louisville, it was made in China, and, Nolan says, "We really had zero communications into the assembly line there."

To get ready to make the GeoSpring at Appliance Park, in January 2010 GE set up a space on the factory floor of Building 2 to design the new assembly line. No products had been manufactured in Building 2 since 1998. . . .

"We got the water heater into the room, and the first thing [the group] said to us was 'This is just a mess,' " Nolan recalls. . . . "In terms of manufacturability, it was terrible." . . . It was so hard to assemble that no one in the big room wanted to make it. Instead they redesigned it. The team eliminated 1 out of every 5 parts. It cut the cost of the materials by 25 percent. It eliminated the tangle of tubing that couldn't be easily welded. By considering the workers who would have to put the water heater together—in fact, by having those workers right at the table, looking at the design as it was drawn—the team cut the work hours necessary to assemble the water heater from 10 hours in China to two hours in Louisville.

In the end, says Nolan, not one part was the same.

So a funny thing happened to the GeoSpring on the way from the cheap Chinese factory to the expensive Kentucky factory: The material cost went down. The labor required to make it went down. The quality went up. Even the energy efficiency went up. . . . The China-made GeoSpring retailed for \$1,599. The Louisville-made GeoSpring retails for \$1,299.

That's what happened when designers and manufacturers were no longer so far apart. As far as I can tell, the designers at GE had no idea such big improvements were possible, just as I was shocked how easy it was to do better than my dermatologist.

There are dozens of ways to bring the incentives of doctor and patient closer together but that would be like trying to bring the Chinese workers and GE designers closer together. Personal science is much easier. No one besides you needs to change. It corresponds to insourcing: insourcing responsibility for your health.

---

dearieme (2013-01-22 07:53:11)

When I've designed instruments I've always gone through everything with my instrument maker so that the design can be practical for him to manufacture: it has always led to improvements. It's amusing to learn that for GE the penny has only recently dropped. The next step should be to sack the dimwitted executives who were in charge before. Seth: Yes, I agree. It should not have been the great revelation it apparently was.

derp (2013-01-22 12:17:26)

> If you refuse a treatment (such as a surgery), your doctor may make less money. This pushes doctors to overstate benefits and understate costs. I'm very much disappointed to hear such talk from a psychologist who should know better. It is a very simple case of extrinsic incentive bias. Doctors don't do it because of the money – at least most of them, with your typical greedy bastard here and there. Why do we doctors overprescribe and overoperate? Most people expect us to, and we have grown to cater to the "do something" mentality. No patient wants to hear simple truths. Health improvement requires actual work on the patients side, such as smoking cessation, getting enough sleep, experiment with your diet etc. Often, the most important thing for your health is not "do something", but "stop doing something". (I hear ya, N. Nassim Taleb...) Most people \*want\* the easy fix, and we can give it to them. Our big-pharma-sponsored professional institutions and conferences play down any reference to possible harm, even censor or ignore it. Most of us choose to ignore it, too, because most of our colleagues ignore it. And given that the majority says there is no harm, there can't be! Completely logical, isn't it? As a medical professional, I highly recommend seeking medical treatment only if your condition is sufficiently severe. Everything else will quite probably harm you. Thank you. Seth: Learn more psychology and you will learn that people are often wrong about their motives. So, for example, a doctor is a bad person to ask what motivates doctors. People's real motives often turn out to be different than what they say, to put it in plain English. The error is always in the direction of making themselves look better – as you do in your comment. Look at studies on extrinsic motivation bias and you will see that the bias is about stated motives, not actual ones. See Atul Gawande's article about this (about why there are enormous cost variations in medical care from one place to the next) for evidence against your view that doctors overprescribe and overoperate because "most people expect [them] to". The differences he found between where health care spending was high and where it was low seemed to be due to differences between the doctors in the two places, not between the patients in the two places. Can you point to any evidence supporting your view (blame the patient)? "Most of us choose to ignore [possible harm], too, because most of our colleagues ignore it." Here I agree, psychology research supports this explanation. I also agree that drug company presentations are a plausible initial cause (that is reinforced by conformity).

derp (2013-01-22 16:39:48)

Seth, thank you for your elaborate response. I have just finished reading Atul Gawandes "The Cost Conundrum". As I can only talk for continental-European health care sytems that are still largely driven by non-profits and local and state agencies, I cannot completely follow the "it's the money" theory; maybe the US is simply not comparable, because of the details of its healthcare "system"[1] or its entrepreneurship culture. Most colleagues I meet seem to be interested in "not working more than 9 hours a day" and "doing less night-shifts". Either we have a severe case of all of us lying to each other (and ourselves) or the "it's the money" theory is deeply insufficient. If I was lying to myself and went 6 years through med school because I'm a greedy bitch, I'd love to find out how I can stop lying to myself. (No sarcasm here, I'd really appreciate to know every self-deception of my brain.) For all the insufficiencies that exist in the system, a blog comment will not suffice, as we both know. I'd like to exclusively focus on the "doctors do it because of the money" thing, because from everything I observed, that is not how 99 % of us operate. I've seen enough greedy folks in the economy department at the university, though. They even admitted to greed. OK. I will stop here because I don't want to sound like that whiney blog commentator who loves to argue with the blog owner just to make a point. Thank you for your time reading and responding to my opinionated emissions. [1] I am deeply sorry for having to put that word in quotation marks, but you might have noticed that the USA is ridiculed for its healthcare system by virtually every other first world country.

## Are Low-Carb Diets Dangerous? (2013-01-23 05:00)

[1]A link from dearieme led me to [2]a recent study that found low-carb high-protein diets – presumably used to lose weight – associated with heart disease. The heart disease increase was substantial – as much as 60 % in those with the most extreme diets. (A critic of the study, Dr. Yoni Freedhoff, called the increase in risk "[3]incredibly small".) Four other studies of the same question have produced results consistent with this association. No study – at least, no study mentioned in the report – has produced results in the opposite direction (low-carb high-protein diets associated with a decrease in heart disease).

I find this interesting for several reasons.

1. I learned about the study from [4]a Guardian article titled "What doctors won't do". A doctor named Tom Smith said, "I would never go on a low-carbohydrate, high-protein diet like [5]Atkins, [6]Dukan or [7]Cambridge." Fine. He didn't say what he would do to lose weight. [8]The psychological costs of obesity are huge. The popularity of low-carb diets probably has a lot – or everything – to do with the failure of researchers to find something better. I have never seen people who criticize low-carb diets appear aware of this. I disagree with a lot of Good Calories Bad Calories but I completely agree with its criticism of researchers.

2. There has never been a good explanation of the success of low-carb high-protein diets (why they cause weight loss), although this has been well-known for more than a century. (A good explanation would be a theory that made predictions that turned out to be true.) Such diets require a big change in what you eat. A big change is likely to have big health consequences in addition to the weight loss, and those side effects could be either good or bad. It now appears bad is more likely. With a good theory of weight control, you should be able to find a much smaller change that produces the same amount of weight loss as a low-carb high-protein diet. Because the change is much smaller, it should have much smaller side effects. Much smaller side effects (unknown whether they are good or bad) are much less likely, if bad, to outweigh the benefits of the weight loss. I have never come across a low-carb advocate who seemed to understand this (that we don't know why they work and it would be a very good idea to find out).

3. The Japanese are remarkably healthy (live very long), slim, and have very little heart disease, yet eat lots of rice. Which makes absurd the notion that all high-carb diets are unhealthy or fattening.

4. [9]The comments on the low-carb study are mostly critical and the criticisms are terrible. For example, Dr. Yoni Freedhoff, who [10]blogs about weight control, says, "The paper's basing all of its 15 years worth of conclusions off of a single, solitary, and clearly inaccurate, baseline food frequency questionnaire". The authors of the study correctly reply that inaccuracy would reduce the associations.

5. Until nutrition scientists do better research, our best source of nutritional guidance may be what we like to eat. Evolution shaped us to like foods that are good for us, at least under ancient conditions. We like carbs and we don't like foods high in protein (lean meat is barely edible) so a low-carb high-protein diet is on its face a bad idea. This is why I find it plausible that the low-carb high-protein association with heart disease reflects cause and effect (low-carb high-protein causes heart disease) and that in particular a high-protein diet causes heart disease. (Too little of the right fats?) We very much like fat. Under ancient conditions, the fat people ate was mostly animal fat and, before that, if you believe in aquatic apes, fish oil. It is quite plausible that lactose tolerance spread so quickly throughout the world because at the time everybody was starved of animal fat – high-fat mammals had been hunted to extinction – and dairy products were a good source of it.

---

dearieme (2013-01-23 07:12:07)

Judging by mesolithic middens in Scotland, my ancestors (or a few of them) ate plenty of mussels and hazelnuts.

rif (2013-01-23 07:50:00)

I am confused by this post. The vast majority of low-carb diet suggestions I see are not low-carb high-protein, but instead low-carb, moderate-protein, high-fat. In particular, the Paleo community would never [afaict] suggest just replacing all your carbs with lean protein. Seth: The article discussed low-carb high-protein diets. Their selection, not mine. Yeah, maybe the title of my post is confusing.

Tuck (2013-01-23 08:08:54)

From the study: "The questionnaire used in the study was self administered and recorded information on several lifestyle variables (including detailed smoking and alcoholic drinking habits), anthropometry, and history of diagnoses of major diseases and conditions, including medical diagnosis of hypertension. For the assessment of physical activity, women rated their overall level of activity (that is, activities in the house and occupational and recreational physical activity) on a five point scale with examples attached to levels 1 (low), 3, and 5 (high). Dietary intakes were assessed with a validated food frequency questionnaire..." Self-reported food studies are unreliable enough that they cannot be used to draw conclusions, even from an epidemiological perspective. The margin of error is often very wide, and there's widespread recognition of this fact in the epidemiological literature. "The authors of the study correctly reply that inaccuracy would reduce the associations." How can they know this? If all they have is inaccurate data, they can't state that the better data would swing the results one way or the other. If they have better data, why didn't they use it? "Limitations in the assessment of dietary energy intake by self-report" "...Comparisons of measured energy expenditure with energy intake from either weighed or estimated dietary records against energy expenditure have indicated that obese subjects, female endurance athletes, and adolescents underestimate habitual and actual energy intake. Individual underestimates of 50 % are not uncommon..." <http://www.sciencedirect.com/science/article/pii/S002604959590204X> "The most popular among these diets emphasise reduction of carbohydrate intake, thereby encouraging high protein intake,7 as high fat diets are generally avoided in most Western societies." Atkins is a low-carb, high-fat, moderate-protein diet. Not high-protein. A diet that is too high in protein induces a state called "rabbit starvation", which will kill. Rabbits are high-protein, low-fat. Adding fat to the diet cures the condition. It's possible that lower, but still high levels of protein aren't great for you, but you won't find out via a study of this nature, as the error rate would be too high. "The Japanese are remarkably healthy (live very long), slim, and have very little heart disease, yet eat lots of rice. Which makes absurd the notion that all high-carb diets are unhealthy or fattening." Too much rice and too little of everything else is certainly harmful: it leads to the condition known as "beri-beri" which killed many Japanese sailors before their navy figured out that it was caused by a high-rice diet. Moderate amounts of rice in the diet seems perfectly consistent with good health, as the Japanese demonstrate. "Until nutrition scientists do better research, our best source of nutritional guidance may be what we like to eat." Agreed, within reason. "Hyper-palatable" foods that, for whatever reason, cause us to over-eat them are the

primary cause of the obesity epidemic. Even the Japanese, as they adopt more Western-style foods, are seeing their obesity rates increase. Interesting point about dairy and the gene for lactose tolerance. Lactose tolerance isn't seem necessary for consumption of dairy, however. Most Masaai, for instance, are not lactose "tolerant", as they cannot break down lactose into glucose; yet they do just fine on a high-dairy diet. Great post! :)

Stuart Buck (2013-01-23 08:14:06)

*The authors of the study correctly reply that inaccuracy would reduce the associations.* Random inaccuracy would dilute statistical significance, but there is no reason to think that inaccuracy in food questionnaires is random. Selection bias very likely plays a role – more responsible people who think more about their health are probably more likely to report having eaten certain foods (whatever is thought to be "healthy"), thus inflating any supposed relationship between those foods and better health outcomes. Seth: Your argument is reasonable and makes additional assumptions that may or may not be supported by evidence (I don't know). It is not what the critic said.

Chuck (2013-01-23 08:22:48)

I see the anti-low-carb folks fighting an old battle - low carb - high protein (the old Adkins diet) vs the USDA high carb food pyramid, when the low carb advocates are rapidly moving to a low carb - high fat paradigm (LCHF or HFLC). And, what is the per capita consumption of carbohydrates of the Japanese vs the USA? What about sweeteners? What about total calories? I would bet they're all much lower. And what is the metabolic difference between short grain Japanese rice and American dwarf wheat, HFCS, and sucrose. Saying the Japanese eat lots of rice is misleading because it doesn't say anything about what they don't eat, and what they eat with it. Cheers

Paul N (2013-01-23 10:22:19)

While we can question whether "low carb" diets are dangerous, I think the better question, here, would have been "are high protein diets dangerous" - which the evidence suggests that they are. And even then, some high protein diets -e.g. lots of processed soy - are likely to be more dangerous still. I think, as do many others, it is time to move past the discussion of macronutrient ratios as if they alone were the determinant of healthy diets. A malnourishing diet (i.e. deficient in essential micronutrients) is bad for health, as is a diet full of toxins/antinutrients or foods that are not tolerated (e.g. wheat, soy, MSG, many processed foods) The evidence of successful hunter gather societies around the world shows that different ones had good health with widely varying macronutrient ratios - but they all had adequate nutrition. If we take the Paul Jaminet view of white rice - a toxin free, but micronutrient poor, starch, then eating lots of it is fine, as long as you are still getting adequate nutrition from other foods. Japan today seems to be following many of the other traditional societies, where rice and other traditional foods being replaced by, in the words of Weston Price "the displacing foods of modern commerce" - with predictable results. The continued obsession of the media, and many food/medical researchers with simple calories and macronutrients ignores the greater problem of malnutrition and toxic foods.

libfree (2013-01-23 11:56:59)

I'm not going to repeat the arguments above, I mainly agree with them on the High Protein part. I personally am on the High Fat, low carb, moderate protein diet and am, by all measurements, healthier than I have ever been. More importantly, its not something I have to work at or worry about anymore. I don't think that it should surprise anyone that different people from different parts of the world could have different dietary requirements. 23andMe puts my ancestry into Eastern and Northern Europe. For most of evolution, my ancestors probably didn't have access to plentiful carbohydrate sources for large parts of the year. I agree with the statement that the body wants things that are good for it. Evolution never prepared us for buying sugar by the pound. Those signals could very easily lead you astray in our modern world. On that same note, you might desire carbs a lot because you need some carbs or some carbs re beneficial and they were harder to obtain. Your desire made you take the extra steps needed to get those nutritious carbohydrates that you needed.

Adam (2013-01-23 17:15:19)

Be careful generalizing about who likes what. I love high protein foods like chicken & beef jerky. I did a high fat, low carb diet for a while & had to force myself to eat enough fat – after a while it lost the appeal. It is also probably important to look at the characteristics of the people who are eating a lot of protein. If they are average & immobile, maybe it has one effect. If they

are a professional bodybuilder, maybe it has another. Personally, I eat a lot of protein, but only in the 48 hour window after a heavy weight lifting session. Same for carbohydrates. The rest of the time I am either fasting or eating some fat.

peter (2013-01-23 21:22:57)

the study involved Swedish women. I understand from a Swedish woman i knew, that the Swedish diet lacks vegetables, especially in the winter (or perhaps only in the winter, i can't recall); so all they eat (at least for significant part of year) is protein. if one doesn't eat vegetables then, one will be subject to all sorts of diseases, including heart disease. Paul N alludes to this when he says "A malnourishing diet (i.e. deficient in essential micronutrients) is bad for health, as is a diet" My understanding is that many micronutrients are provided by vegetable. also, Seth, i wonder if you eat a low carb diet, and i wonder what part of Taub's book relating to carbs you find incorrect. Seth: I eat a fairly low-carb diet, yes, to keep my blood sugar low. The part of Taubes's book I disagree with is the part where he explains why low-carb diets cause weight loss. The theory, in other words.

Jonathan (2013-01-23 22:37:48)

Seth, I'm surprised you say "There has never been a good explanation of the success of low-carb high-protein diets." Is there a flaw in the theory that less carbohydrate means less insulin, and lower serum insulin permits lipolysis to occur? (Other than the fact that protein also raises insulin, so low-carb moderate-protein high-fat diets are even more successful.) Seth: "Flaw in the theory"? Yes. It fails to explain dozens of facts. Here's one: Increasing the water content of rats' food makes them fatter. Another flaw is that it has failed to make correct predictions.

Alexander Boland (2013-01-24 12:03:55)

I'm going to have to contest you on (4). I see what you're saying, but the problem with basing something off a single observational study is this: If the study is randomly chosen, then you're right that there's a higher chance of error. On the other hand, because of the randomness of that kind of evidence, it's also easier to find spurious correlations. Of course, I imagine that the doctor you mention could have made the point I made by finding observational data that contradicts the study in question. Seth: Adding noise does not make it easier to find spurious correlations. You can only find a spurious correlation if there is no actual correlation – that is, if what you have is pure noise. Adding noise to noise just gives you more variable noise. Tests for association adjust for amount of variation. I agree when you say that a good critic would have simply pointed to data that contradicts the study in question. None of the critics did, if I remember correctly.

Jim (2013-01-25 15:36:31)

I think there are some long term experiments that show that macronutrient ratios don't affect cancer much. Kitavens ate high carb, Inuits low carb, both were fine. I wonder about the real causes, for example <http://digressionalty.blogspot.com/2013-01/calorie-restriction-monkeys-fed-30-sugar.html>

Greg (2013-01-27 20:08:33)

Seth, I agree with others that the Swedish study is so weak as to be almost uninteresting. Their statistical model adjusts for fat consumption, so it looks like they are only testing the effects of substituting carbs for protein. As demonstrated by the first line of the abstract, these researchers don't understand that a low carbohydrate diet is high in fat (if they don't know what it is, why are they studying it?) If there is a benefit to high fat consumption, we can't tell from this research. There are a number of interesting biases reported in the way people respond to food frequency questionnaires. For example, those with medical conditions will report eating 1.5x as much meat as those without (<http://jn.nutrition.org/content/136/2/459.full>). I didn't see any evidence they adjusted for this sort of thing, despite claiming their questionnaires were "validated." I eat a low carb diet, though I freely admit that I don't have any idea why it works. The commonly cited theories are clearly wrong as you point out, and I wish more people were honestly trying to figure it out. Seth: They believed, like many people, that fat consumption affects weight. So they adjusted for it. I fail to see the problem. As for the bias problem, inaccuracy will reduce associations, not increase them. Sure, someone else with different assumptions would do a different analysis. Until we know for sure their assumptions are wrong – and we are far from that point – their work is worth paying attention to. If they got the wrong answer, the lack of contradictory evidence (studies that got the opposite answer) is striking and not explained by any of their critics.

Greg (2013-01-27 22:11:54)

I think that, by controlling for fat, the paper did not test the hypothesis that replacing carbs with fat has an effect on cardiovascular events. They might have tested the hypothesis that replacing carbs with protein increases cardiovascular events, but I think that result is more easily explained by the fact that unhealthy people systematically overstate their meat consumption. Since the bias is directional, couldn't it create, and not just mask, an association? I haven't done an exhaustive search, but I think the Nurse's Health Study does contradict the finding, and with a larger sample size (<http://ajcn.nutrition.org/content/71/6/1455.long>, see Table 3). Seth: Yes, inaccuracy in the sense of bias can create a false association. I should have been clearer about that. I agree, the meat/poor health bias really does make plausible an alternative explanation that the authors should consider. I am less convinced than you. Is the bias large enough to explain the results? Maybe it is too small. Maybe there are offsetting biases. The study you point to did not specifically study the effect of protein replacing carbs, it studied the effect of carbs replacing everything. I used "low-carb" to mean "low-carb high-protein". Again, I should have been clearer.

Giselle Carslon (2013-02-13 03:16:07)

The way I see it and according to what I've read from <http://products.mercola.com/zinc-supplements/> it is important to take track of a persons nutritional needs especially if you are in a low-carb diet. Since your are reducing those foods that you eat, the nutrition absorption is reduced and in this case we are prone to many deficiencies that may weaken our immune defense.

## Creating More Diversity (2013-01-23 06:30)

Like [1]Tyler Cowen, I found [2]this interview with Harvard professor of genetics George Church bizarre, in the sense of un-self-aware. Here is the most telling part:

SPIEGEL: Wouldn't it be ethically problematic to create a Neanderthal just for the sake of scientific curiosity?

Church: Well, curiosity may be part of it, but it's not the most important driving force. The main goal is to increase diversity. The one thing that is bad for society is low diversity. This is true for culture or evolution, for species and also for whole societies. If you become a monoculture, you are at great risk of perishing.

"The main goal is to increase diversity". Fine. Yet in Church's own classes – if he is like 99.9 % of professors I know – he treats all the students the same (same lectures, same assignments, same tests, same grading scheme), apparently not understanding that such treatment decreases diversity.

When I was a graduate student, I had lunch (along with other graduate students) with Richard Herrnstein, another Harvard professor (of psychology). Herrnstein was on Harvard's admissions committee. The perfect candidate, he said at lunch, would be a flute-playing football player with perfect SAT scores. [3]Jane Jacobs describes an equally dispiriting lunch with a Harvard professor of urban studies.

What is it about Harvard professors? As [4]Ron Unz says, "the elites they have produced have clearly done a very poor job of leading our country."

1. <http://marginalrevolution.com/marginalrevolution/2013/01/surely-harvard-faculty-would-never-say-anything-like-this.html>
2. <http://www.spiegel.de/international/zeitgeist/george-church-explains-how-dna-will-be-construction-material-of-the-future-a-877634.html>

3. <http://www.youtube.com/watch?v=-Si4fhHfGTs>

4. <http://www.theamericanconservative.com/articles/the-myth-of-american-meritocracy/>

---

Jennifer R (2013-01-23 12:37:54)

I absolutely agree that treating all students the same, decreases diversity along with real learning. This is something that is discussed in the homeschooling world and a few good schools often.

D (2013-01-23 13:59:54)

I'm still reeling from the Unz piece. In particular, our current "elites", who are not the old elites. Depressing... Seth: Unz complains (and I agree with him) about Harvard admissions. As my post indicates, I also wonder about the quality of teaching at Harvard and other elite schools. People often complain about groupthink (everyone thinking the same) at the top of our government. I've heard the same complaint about the French government: Everyone at the top went to the same school and thinks the same.

D (2013-01-23 14:09:55)

And IIRC, Unz targets Harvard at being one of the worst offenders in using a "holistic" criteria for selecting UNDERqualified whites (in particular, Jewish) who then become our next cohort of elites.

Sarah (2013-01-23 15:35:02)

This reminds me of a quote from Alain de Botton (I'm paraphrasing) There is nothing like climbing to the top that convinces people that the system is working. Seth: Or being born at the top.

CC (2013-01-23 18:42:05)

D- got a link for that or are you just spouting nonsense? I've never heard of Ivy League admissions being \*easier\* on whites, let alone Jews. Seth: That Ivy League admissions are "easier on Jews" is one of Unz's main points. His data revealed this. Maybe he was also surprised, I forget.

CC (2013-01-23 19:33:43)

Seth: I've looked over some of his writings, and his main point seems to be that Ivy Leagues discriminate against Asians, much as they used to discriminate against Jews. He does complain a bit about seemingly lower standards for Jews nowadays, but a lot of people have pointed out that he's conflating Jews with "half-Jews", and the relative numbers of those two groups has changed dramatically in recent decades. Details aside, I'm amazed that in the age of affirmative action and discrimination against Asians, that anyone could claim discrimination in \*favor\* of whites. It doesn't seem mathematically possible! (But maybe I missed something.) Seth: You mean "discrimination AGAINST (non-Jewish) whites"? Or do you mean "discrimination in favor of Jewish whites"? I don't understand your point. Discrimination against Asians obviously favors someone else, why not whites? Or Jews?

CC (2013-01-23 19:36:37)

I should add that I'm not an expert on his claims about Jews; I merely found the comment about overall laxer standards for whites to be odd.

D (2013-01-24 09:24:07)

To be clear, if you actually read Unz' paper (it's about 45 pages if you print), there is heavy, heavy discrimination against Asians and non-Jewish whites at the Ivy level. And there is basically AA for white Jews as well as the standard groups known to benefit from AA. Now we all knew Asians were getting screwed and we all knew whites got screwed, but the surprising parts of his paper are just how bad Asians and non-Jewish whites get hosed, and how much a boost Jewish whites get for being Jewish. This latter claim was certainly the most shocking, as I had always assumed Jewish overrepresentation in all

academic circles awas simply due to cognitive and/or personality differences, but you can't come away from reading Unz' paper and still believe that's the case for the Ivy league schools at present. Seth: I agree with all this. Let me add that Unz also makes a point similar to mine: That elite schools, while claiming to want diverse students, do a poor job of reaching that goal.

Christopher Burd (2013-01-24 14:18:33)

My understanding that the pro-Jewish bias is actually a bias against certain classes of non-Jewish whites. A study a couple of years ago suggested that anything suggesting a conservative orientation (e.g., membership in Young Farmers of America) was the kiss of death for applicants. Obviously, this bias would hit non-Jewish whites far more heavily than Jews. I wonder how applicants with an obvious Orthodox or Hassidic background fare against Evangelical Christians.

D (2013-01-24 14:57:06)

Christopher Burd, I'm not so sure that would be enough to explain the disparity, but I do think plain bigotry explains a lot of this. I'm guessing it's assumed that a non-Jewish white kid from Idaho must (apart from basking in the glow of his Christian white privilege) spit tobacco, wear a cross and carry around a pitchfork when he's not hunting or trying to find black people to harass or lynch. That abstract image is very easy to hate for someone who still (amazingly) maintains some group victim status, and sees that guy as an enemy.

### **Late Comment on Battle Hymn of the Tiger Mother (2013-01-24 20:11)**

Amy Chua wondered if all the pressure to practice (piano, older child, violin, younger child) she put on her two children was worth it. But then there were moments like these:

In a glass-windowed room overlooking the Mediterranean, Sophia played Mendelsohn's Rondo Capriccioso, and got bravos and hugs from all the guests.

Which I found the most chilling sentence in the whole book. Her daughter's recognition ("bravos and hugs") made Chua very happy. But did it make Sophia happy? Chua doesn't answer that question. She doesn't follow the sentence I've quoted with "I could see how pleased she was" or "Years later she would say what a good time she had". Nope, the chapter ends there.

Jonathan Graehl (2013-01-24 20:59:12)

That's a fruitful sentence to ponder. If Sophia didn't earn at least some subtraction-of-suffering reward from praise well-earned, then it would be a chilling narration from the mother. As a child pianist, albeit under considerably less pressure, I can assure you that once you've submitted to the work necessary to prepare (and especially if you've shirked it a little), having a performance come off well (on however large a stage) is a potent reward, no matter the dislike of practice. What puts me off is just the status-brag "glass-windowed room overlooking the Mediterranean" (so you know, the people in that room must be AMAZING).

In Alice Miller's *The Drama of The Gifted Child* (previously called *the Prison of Childhood*) where a child's will is disciplined and often broken into obedience, it makes one wonder whose life wish the child is fulfilling, her own or her mother. Indeed chilling stuff.

With what else would one equip one's window but glass? An old sheet of polythene held in place by drawing pins? Waxed brown paper? Seth: Good question. Maybe the editor was so stunned by what she was reading – the whole book is an enormous surprise – that she forgot to edit.

Tom (2013-01-25 03:05:46)

I go partner dancing a lot, and one thing I've noticed about many Asian women is that they are often sexless. They may be dressed sexily; they may look extremely attractive – but it's all a performance. They are like terrified children putting on a show, like six-year-old Wizards of Oz at the controls of a mannikin that looks thirty and alluring. I think it's a pathology that is passed down through the generations: the young don't get to enjoy their youth, and they age into mothers that are enraged and determined to get back that which has been lost – which is of course impossible. So they try harder and get angrier, demanding ever more from the doppelganger, pushing the pathology down another generation. Something different but analogous happens with enraged, narcissistic Jewish-American mothers and their castrated, humiliated sons. The women often think they are more fabulous than they are, and the men think they are worthless.

Years later one of her kids will try to commit suicide, but by then we'll all have moved on to new reality entertainment. Tom (above) is right on all counts.
