In this week's issue, Hendrik Hertzberg, the magazine's main editorial writer, [2]calls the idea that "global warming is a hoax" a "denial of reality". He lumps it with birtherism and the ideas that "evolution is just another theory, on a par with the theory that the earth is six thousand years old." In case you are reading this blog for the first time, I'll say it again: Claims that humans have dangerously warmed the planet are based on climate models that are far from fully verified. That these models manage to fit past temperatures [3]means little because the models have many adjustable parameters. Alas, this was no over-zealous editing mistake.

Perfect Health Diet » Around the Web, Spring Arrives in Boston Edition (2011-04-30 09:28:55)

[...] Interesting posts this week: Do people biangulate? Chris Highcock gives us more reason to use a standing desk. A question I never would have seen [...]

q (2011-04-30 09:41:02)

sounds at different heights will reflect on different parts of the ear, and that will modulate the sounds a bit. the brain can absolutely tell the height of a sound and therefore the direction. you can call that triangulation if you want; i bet the algorithm is like it.

Allen K. (2011-04-30 17:28:20)

The reason bats have such weirdly shaped ears is exactly as q describes. There's a whole chapter devoted to them in The Blind Watchmaker. A tiger's growl is low-frequency enough to do the phase difference; high-frequency sounds don't refract around the head so well, and the brain does amplitude difference instead. Mid-range sounds are harder to locate.

Seth Roberts (2011-04-30 18:15:23)

Figuring out the direction from which a sound came narrows down the location of the sound source to a line. Triangulation narrows down the location of the sound source to a point.

Michael Parker (2011-05-02 10:54:38)

I thought triangulate meant to form a triangle, the two ears being two tips of the triangle and the origin of the sound the third point. To increase hearing sensitivity, a technique I learned was to open my mouth wide, and look at where the sound was coming from. I haven't tested this with rigor, but it seems to work. Opening the mouth seems to give me a more specific location on the vertical axis of origin.

## 6.5 May

### Percentile Feedback and Productivity (2011-05-01 05:00)

[1]

Warning: This post, written for the [2]Quantified Self blog, has more repetition than usual of material in [3]earlier posts.

In January, after talking with [4]Matthew Cornell, I decided to measure my work habits. I typically work for a while (10-100 minutes), take a break (10-100 minutes), resume work, take another break, and so on. The breaks had many functions: lunch, dinner, walk, exercise, nap. I wanted to do experiments related to [5]quasi-reinforcement.

I wrote R programs to record when I worked. They provided simple feedback, including how much I had worked that day (e.g., "121 minutes worked so far") and how long the current bout of work had lasted (e.g., "20 minutes of email" - meaning the current bout of work, which was answering email, had so far lasted 20 minutes).

I collected data for two months before I wrote programs to graph the data. The first display I made (example above)

showed efficiency (time spent working/time available to work) as a function of time of day. Available time started when I woke up. If I woke up at 5 am, and by 10 am had worked 3 hours, the efficiency at 10 am would be 60 %. The display showed the current day as a line and previous days as points. During the day the line got longer and longer.

The blue and red points are from before the display started; the green and black points are from after the display started. The red and black points are the final points of their days – they sum up the days. A week or so after I made the display I added the big number in the upper-right corner (in the example, 65). It gives the percentile of the current efficiency compared to all the efficiency measurements within one hour of the time of day (e.g., if it is 2 p.m., the current efficiency is compared to efficiency measurements between 1 p.m. and 3 p.m. on previous days).

I started looking at the progress display often. To my great surprise, it helped a lot. It made me more efficient. You can see this in the example above because most of the green points (after the display started) are above most of the blue points (before the display). You can also see the improvement in the graph below, which shows the final efficiency of each day.

[6]

My efficiency jumped up when the display started.

Why did the display help? I call it percentile feedback because that name sums up a big reason I think it helped. The number in the corner makes the percentile explicit but simply seeing where the end of the line falls relative to the points gives an indication of the percentile. I think the graphical display helped for four reasons:

1. All improvement rewarded, no matter how small or from what level. Whenever I worked, the line went up and the percentile score improved. Many feedback schemes reward only a small range of changes of behavior. For example, suppose the feedback scheme is A+, A, A-, etc. If you go from low B- to high B-, your grade won't change. A score of 100 was nearly impossible, so there was almost always room for improvement.

2. Overall performance judged. I could compare my percentile score to my score earlier in the day (e.g., 1 pm versus 10 am) but the score itself was a comparison to all previous days, in the sense that a score above 50 meant I was doing better than average. Thus there were two sources of reward: (a) doing better than a few hours ago and (b) doing

better than previous days.

3. Attractive. I liked looking at the graphs, partly due to graphic design.

4. Likeable. You pay more attention to someone you like than someone you don't like. The displays were curiously likable. They usually praised me, in the sense that the percentile score was usually well above 50. Except early in morning, they were calm, in the sense that they did not change quickly. If the score was 80 and I took a 2-hour break, the score might go down to 70 – still good. And, as I said earlier, every improvement was noticed and rewarded – and every non-improvement was also gently noted. It was as if the display cared.

Now that I've seen how helpful and pleasant feedback can be, I miss similar feedback in other areas of life. When I'm walking/running on my treadmill, I want percentile feedback comparing this workout to previous ones. When I'm studying Chinese, I want some sort of gentle comparison to the past.

Colin Z. Robertson (2011-05-12 03:09:57)

A few commenters on previous posts have asked for the R code for this system. I was going to add my voice to that chorus but then, hubristic programmer that I am, I thought: I could write that myself. Plus I was looking for a little project that would give me some experience with Mac programming. So I've spent a bit of time the last few days putting together this: <https://github.com/czr/Efficiency> It's currently extremely rough-and-ready. It lacks some of the features of Seth's system and contains numerous bugs. Runs on OS X 10.6. Use at own risk, etc.

Seth Roberts (2011-05-12 04:15:46)

Thanks. I have just finished putting together a workspace with the R code that will be uploadable from my website.

Colin Z. Robertson (2011-05-12 05:40:09)

Great. I'd love to see some of the details of how you do it (and see some R as well, since I'm unfamiliar with the language).

Percentile Feedback Update | Quantified Self (2011-07-19 08:01:48)

[...] March I discovered that looking at a graph of my productivity (for the current day, with a percentile attached) was a big help.... My "efficiency" — the time spent working that day divided by the time available to work — [...]

Calcatraz (2011-08-02 17:00:20)

I've been collecting similar data for the past month, but in a paper-based calendar with half-hour granularity. I am then digitizing it at the end of each week and doing some basic analysis (I watched how much TV?!). This has been useful in pinpointing the big areas I need to work on, but I know it is missing out on the minute-to-minute efficiency boost the constant feedback is giving you. I've tried direct digital entry before, but it has never stuck for more than a few days. I'm hoping I can slowly make the change from paper in such a way that the habit sticks. Do you have any tips? In particular how do you handle entry when you are away from the computer (if ever ;))? Looking forward to the day I have a system like yours happening - nice work!

Seth Roberts (2011-08-03 03:41:06)

When I do a non-computer task that counts as work, I just log starting it at my computer, do it, and then log ending it at my computer. I always found paper to computer transfer difficult and I avoid it as much as possible. I suppose my main tip would be that R is not so hard and you should probably try downloading the workspace and using it. You will need to learn a little bit of R.

## Demand Pricing and the Shangri-La Diet (2011-05-02 05:00)

Demand pricing (also called dynamic pricing) is adjusting the price according to demand. More demand, higher price. It is [1]being considered for movie tickets:

If a movie is hot, the price could rise to whatever the market will bear. For example, I'd have paid \$20 per ticket to see "Avatar" in 3-D when it first opened; maybe others would have been willing to pay even more. As demand becomes clear through lower ticket sales, prices would drop. So "Avatar" might cost \$15 a few weeks after opening, gradually making its way to \$10.

The theory behind the Shangri-La Diet says that body fat is adjusted in a similar way. When food is abundant, the set point (which controls how much fat you have) goes up (= you store more fat). When food is scarce, the set point goes down. This is how many storage systems work, of course; they increase the amount stored when the price is low and decrease the amount stored when the price is high.

Perhaps one day weight control will be explained to children by telling them it is like the price of airplane tickets: "When more people want to go to Los Angeles, the price goes up. When more food is available, your set point goes up . . ."

1. <http://www.latimes.com/news/la-fi-lazarus-20110426,0,6480866.column>

---

Miki (2011-05-02 07:19:40)

Seth As you probably know eating a lot of fat will not cause you to accumulate fat (That is my N=1 conclusion anyway). So the price of fat is cheap yet the body doesn't store it. In my opinion accumulating body fat is the body reaction to a perceived

shortage. The signal for food shortage is relatively large consumption of carbs which in ancient times happened only when the preferred food of meat (+ fat) was in short supply.

mk (2011-05-02 07:40:06)

thanks.

Turadg Aleahmad (2011-05-02 08:07:45)

Haven't you got that backwards? More food being available means greater supply, which should have the opposite effect on pricing.

Todd (2011-05-02 16:16:51)

Seth - Just checking...did the comment I sent earlier today get lost? Todd

Todd (2011-05-02 16:24:09)

Seth, I think the analogy between demand price and food abundance is not valid. Food abundance is the analogue of supply, and increased supply makes price ("setpoint") go down, not up. Animals like squirrels and bears tend to get fatter and hoard food in preparation for the scarcity of winter, and shed weight when fresh food is more abundant in summer. The better analogue for demand price is energy expenditure, which tends to make set point go down (at least under certain conditions). I think SLD is an effective diet, but I think your food scarcity argument is not the correct explanation. I proposed an alternate explanation based on the role that flavor plays in psychological conditioning of the vagus nerve and the hormonal control of appetite: <http://gettingstronger.org/2010/02/flavor-control-diets/> Todd

Seth Roberts (2011-05-02 21:15:12)

No it did not...just took a while to be approved.

Seth Roberts (2011-05-02 21:20:16)

Todd, don't confuse anticipatory changes in set point (e.g., bears) with reactive changes. I assure you that abundant food causes the set point to increase – otherwise we would be suffering from an epidemic of thinness.

Seth Roberts (2011-05-02 21:23:57)

Miki, I lost weight by drinking sugar water (carbs). The notion that carbs cause weight gain is wrong.

Seth Roberts (2011-05-02 21:29:22)

Higher set point corresponds to lower price. I'm afraid I don't see the problem, although yeah it is a bit hard to understand.

Alex C. (2011-05-03 09:33:21)

Seth, what is the critical flaw in Gary Taubes's reasoning regarding carbohydrates causing a spike in insulin, which in turn leads to fat accumulation? I know that that theory is inconsistent with your evidence regarding sugar water/Shangri-La, but Taubes marshals some fairly compelling evidence of his own. Not sure what to make of it all.

Miki (2011-05-03 11:05:25)

I doubt that a monotonic sugar or any other diet is a good enough simulation of anything. Low carb diets are causing weight loss (References can be provided on request) and I was merely proposing an evolutionary explanation for this fact.

Todd (2011-05-04 18:10:39)

Seth, I'm not convinced that the obesity epidemic can be blamed on the sheer "availability" of food. Many non-Westerners with abundant food don't have nearly the obesity we have in the U.S. and Westernized society. There must be other factors at play – most likely the unnaturally high levels of factors like fructose and certain fatty acids, which inflame insulin receptors & glucose transporters and disregulate the hypothalamus. In addition, highly flavored, palatable food in combination with calories induces

a magnified insulin response, rapid emptying of glucose and fatty acids from the bloodstream, and consequent overeating in the attempt to normalize blood sugars and fatty acids. Robert Lustig has mapped out the science behind this pretty convincingly. Your experience with drinking sugar water does not disprove Taubes' insulin theory of obesity. The amount of sugar calories you consumed was probably too small to elicit an insulin response strong enough to elicit the kind of blood sugar crash that leads to overeating. Strong, appetizing flavors magnify the preprandial insulin response that ramps up hunger – your flavorless calories tend to suppress this effect. Try consuming much larger amounts of sugar water or carbohydrates and doing it more frequently, and you'll find at some point the blood sugar swings will cause increased hunger and overeating. I've measured my own blood sugar after consuming small carbohydrate meals vs. larger carbohydrate meals and the difference is instructive. Todd

Seth Roberts (2011-05-05 05:09:38)

Todd, Taubes' theory about insulin causing obesity says nothing about a "blood sugar crash that leads to overeating". You say I consumed amounts of fructose too small to produce overeating. I don't remember that proviso anywhere in Taubes (that a mere 300 calories of fructose per day is harmless) – and in any case, keep in mind I lost a huge amount of weight. At the beginning I tried huge amounts of fructose water – much larger than I ended up with. They caused profound loss of appetite, not overeating.

Todd (2011-05-05 07:29:02)

Seth, Taubes' account of the connection between insulin, appetite and eating is carefully laid out in Chapter 24 of *Good Calories, Bad Calories*. Particularly noteworthy in this respect are the experiments of Jacques Le Magnen, including rat studies (on pp. 441-2) demonstrating how more palatable or familiar flavors induce a preprandial first-wave insulin response that "shuts down the mobilization of fat...and stores away glucose...As a result, hunger increases..." My point about fructose is different. Fructose doesn't induce any insulin response, so it is not involved directly in the above mechanism. However, over time, fructose can alter insulin sensitivity by impairing the GLUT4 receptors, and insulin resistance can make lead to overeating as higher levels of insulin (from larger carb/protein meals) are needed before glucose is readily transported into cells. However this is not a short term effect: in the context of a single meal or drink, Taubes' theory would predict that, since you could drink a lot of fructose without triggering insulin, appetite would be reduced since there is no insulin to store away calories. The same is not true for drinks containing glucose or sucrose (half of which is glucose), since large amounts of these will spike insulin and deplete blood sugar.

Seth Roberts (2011-05-06 03:25:31)

"Fructose doesn't induce any insulin response." What?! I have never heard that before.

Todd (2011-05-06 11:37:46)

Yes, it's a well-known fact. Fructose, unlike glucose, does not stimulate insulin secretion from the pancreas: <http://jcem.endojournals.org/cgi/content/full/89/6/2963> However, over a period of weeks, high levels of fructose in the diet can lead to impaired glucose tolerance, insulin resistance and reduced leptin levels: <http://www.ajcn.org/content/76/5/911>. So fructose consumption may ultimately lead to higher than normal insulin levels – when insulinogenic carbs or protein are ingested. This is not due to any direct action of fructose, but rather a gradual metabolic change by which the pancreas begins putting out more insulin to overcome the insulin resistance. Yet consumption of fructose by itself – as in your French sodas – will not cause any appreciable insulin response. Try repeating your French soda experiment, but add 300 calories of glucose or 600 calories of sucrose. I think you may find a different effect on appetite.

Todd (2011-05-06 11:48:00)

Seth, One more thought. Adding 600 calories of sugar to a soda may or may not stimulate rebound hunger, depending on the level of insulin resistance of the individual. For carb-addicted, insulin resistant individuals, I expect that would be sufficient. But I expect there is some level of sugar – it may be 1000 calories, it may be higher – that will set up enough of a swing in blood sugar to lead to hypoglycemic hunger. And this will happen with or without added flavor; flavor only enhances the effect. If a pure flavor-calorie association effect explained appetite and set point, it should not matter how many calories you ingest. And yet I think the fact that SLD works best with a limited dose of calories supports the idea that a small dose of calories will not provoke an insulin response, whereas a large enough dose will. The amount needed to trigger hunger will vary depending on

the insulin sensitivity of the individual.

Seth Roberts (2011-05-07 15:41:45)

Thank you for your comments, which have helped me learn about fructose metabolism. Leaving that aside, the French sodas I drank were not "fructose by itself". They were sweetened with either sucrose or high-fructose corn syrup. Many people have found you can lose weight by drinking unflavored sucrose water. Nor does your theory of why SLD works explain why unflavored oils work and why the sugar water must be unflavored.

Todd (2011-05-10 00:04:55)

Seth, I think my theory does offer an explanation for those facts. It is based upon several observations or hypotheses, leading up to conclusions #6 and #7, which I hope address your objections: 1. Hunger and weight gain are driven largely by having insulin levels above a certain threshold for more time each day than they are below that threshold. That doesn't mean just "insulin spikes" – it's the integrated area above vs. below the threshold over the 24-hour cycle. At the same time, raised insulin levels either pre- or post meal will increase hunger by making glucose and fatty acids less available. (Raised insulin during a meal is no problem). 2. Having insulin resistance (due to obesity) will make it more difficult to lose weight because insulin levels don't drop below the critical threshold as quickly, since the pancreas oversecretes even basal insulin, and hunger is more easily stoked. 3. Glucose (and starches or sugars that metabolize to glucose) and to a lesser extent certain proteins, will raise insulin levels. Small and/or infrequent glucose will not lead to weight, but large or frequent doses will. 4. Fats and oils (in the absence of insulin or insulinogenic carbs or protein) don't provoke an insulin response, and thus don't cause hunger or weight gain. Of course, there are often "stealth carbs" in many high fat foods, so you have to be careful with this one and use pure oils and fats. 5. Flavor, particularly familiar flavors, increase or amplify the insulin response, both before and during the meal, due to classical conditioning. (This has been demonstrated in animals and humans and tied to vagus nerve activation by taste sensors in the nose and palate). This serves a biological purpose in reading the digestive system to "recognize" and prepare for a meal. It is a kind of "feed forward" process control! See the work of Karen Teff documenting this. 6. Unflavored oils induce neither an inherent insulin response (direct stimulation) or a conditioned response (since there is no flavor), so they provide fatty acid energy to the bloodstream with no storage effect, hence they suppress appetite because the fatty acids remain available. 7. Sugar water will suppress appetite only if it is provided (a) in small doses and (b) without flavors that condition a significant insulin response. But large doses of sugar water will raise insulin. There is probably an optimum dose where a small dose of unflavored sugar adds available glucose to the blood stream but is too low to elicit a large enough insulin response to quickly store it away. But adding familiar flavor to the sugar will provoke a learned pre-prandial insulin response. This can especially be a problem when the flavor is very reinforcing and the sugar dose is low – whereby the enhanced insulin response leads to depletion of blood glucose and fat, causing hunger. 8. We perhaps need some critical experiment to decide between your theory of SLD and mine. First, my theory predicts that very large doses of unflavored sugar will not suppress appetite as well as smaller doses, and may actually stimulate hunger later on – there is a point where the SLD benefits "rolls over". I think your theory would not predict this. Second, my theory predicts that larger doses of unflavored oils will continue to suppress appetite, perhaps even better than smaller doses, so long as they contain zero carbs or protein. Furthermore, my theory predicts that even adding some flavor to oil will also work, because the insulin response from the flavor will be minimal combined with zero insulin response from the oil. I wrote about this theory on your forum, calling these flavored non-insulinogenic fat or oil calories "Platinum Calories". In short, my theory predicts different qualitative behavior for carbs and protein than for fats and oils. By contrast, I believe your theory lumps them together as "calories" and predicts no qualitative difference in their action. I hope I did misrepresent your theory; please correct me if I did. But you, or I or anyone can test out my predictions. There may be individual differences, so it would probably be best to have several different people try these experiments. Let me know if you'd like to do a joint test on this. I'm certainly willing to eat my words if I'm wrong. Todd

Seth Roberts (2011-05-10 17:58:37)

Todd, in an earlier comment I pointed out that when I started to drink fructose water, I started with a really large dose – much larger than I ended up with. The really large dose, as I said, produced profound appetite suppression and weight loss, not weight gain. This contradicts your first prediction. You might want to read the work by Israel Ramirez I cite for more examples of what your ideas don't explain.

justin (2011-08-02 05:58:55)

I'm only injecting a comment here as it seems the thread here is dead, but Seth, you note that "when I started to drink fructose water, I started with a really large dose — much larger than I ended up with." Assuming you meant sugar water (that contained sucrose or HFCS or glucose and not just pure fructose), this does not contradict Todd's alternative theory inasmuch as you had yet to develop a strong pre-prandial insulin response to the sugar water. The question is: had you continued drinking large doses of sugar water, would the profound AS continue or not? If it did, then this would be a problem for the insulin response theory Todd has developed here. On the face of it (and admittedly not knowing all the details of your initial experiment), there is no problem with Todd's alternative theory to SLD here.

Seth Roberts (2011-08-02 08:31:15)

It was pure fructose. No sucrose, HFCS or glucose.

justin (2011-08-02 10:54:38)

In that case, it definitely doesn't refute Todd's theory – having no insulin response from fructose, you'd expect profound AS.

Maha (2012-05-03 02:34:28)

Hi Seth, I have recently been diagnosed with insulin resistance. Before this i have been on the diet and have been having the oil regularly for over a month. However i have not lost any weight although my appetite has reduced. Does insulin resistance affect results? M Seth: Sorry, I don't know.

Joe (2011-05-03 08:06:40)

Quick question, Seth, as I'm not sure if you're still following the earlier butter threads: Is the half-stick of pastured butter now your only daily fat/oil supplementation? Or are you also still supplementing with 2T flax oil? (Or if not flax, what else?) Thank you.

Seth Roberts (2011-05-03 13:23:53)

Joe, in addition to the butter I still take a flaxseed supplement, now use ground flaxseed (66 g/day) rather than flaxseed oil. I grind the flaxseeds myself using a blender and eat it with yogurt. Whole flaxseeds are much easier to store than flaxseed oil, which must be kept cool. I suspect flaxseed oil goes bad faster, too.

Joe (2011-05-03 13:48:28)

Thank you.

JeffR (2011-05-03 18:20:50)

Can you explain what you mean by this? "Most epidemiology papers I've seen do too many tests, which has the same effect as throwing away data."

Seth Roberts (2011-05-04 02:42:59)

By too many tests I mean too many statistical tests – tests of hypotheses. So they get too many false positives. They don't correct for the number of tests done. They do too many tests in two ways: 1. They divide the data into many pieces (e.g., men and women) and test each piece separately. 2. They fail to combine across measures (combine correlated measures into one). For example, testing diastolic and systolic blood pressure separately, even though they are correlated. This has the effect of adding noise (false positives) – thus decreasing the signal to noise ratio. When you throw away data, you decrease the signal to noise ratio.

vic (2011-05-05 23:58:15)

interesting stuff re:epidemiologists doing too many tests, enjoyed that

## **Insider/Outsiders, Chinese History, and the Shangri-La Diet (2011-05-04 05:00)**

Darwin was an insider/outsider; so was Mendel. Insider/outsiders are close enough to their subject to have a good understanding and skills yet far enough away to have freedom. In the case of Chinese history, [1]a journalist named Yang Jisheng has filled that role. He wrote a book called Tombstone (Mubei) about the Great Famine (1958-61). He was able to write what professional historians could not:

Why are you the first Chinese historian to tackle this subject seriously?

Traditional historians [i.e., college professors] face restrictions. First of all, they censor themselves. Their thoughts limit them. They don't even dare to write the facts, don't dare to speak up about it, don't dare to touch it. And even if they wrote it, they can't publish it. And if they publish, they will face censure. So mainstream scholars face those restrictions.

But there are many unofficial historians like me. Many people are writing their own memoirs about being labeled "Rightists" or "counter-revolutionaries." There is an author in Anhui province who has described how his family starved to death. There are many authors who have written about how their families starved.

"If they publish, they will face censure." With respect to weight control, I am an insider/outsider. When I published The Shangri-La Diet, I did not expect censure. My colleagues (other psychology department faculty) wouldn't care

what I wrote about a different subject. To my surprise, I was censured – maybe a better word is denounced – by a nutrition education lecturer in the UC Berkeley Nutrition Department. The woman who denounced me had not seen my book. Based on what a reporter told her, she expressed her opinion of it in an email she sent to twenty people in her department and the chairman of my department. It said, in part:

I did give the SF Chronicle reporter my opinion of the diet making these points:

- one cannot possibly meet nutrient needs on 1200 kcals per day
- sugar and oils are not nutrient dense; they are calorically dense and thus dilute the nutrient density of the total kcal intake.
- 1200 kcals per day is less than the semi-starvation diet used in the only published formal study ever conducted in this country on human starvation (Ancel Keys, 1950)
- human semi-starvation is not a path to health whether one is discussing physical, psychological, or social well-being
- the results of single subject research are applicable only to that subject; they cannot be generalized to others.
- I cannot recommend this diet, in fact, I recommend against it.

In other words: Ridiculous. Her many misconceptions (e.g., she is unaware of many examples of path-breaking self-experimentation in the field of nutrition) aren't terribly interesting. What's fascinating is her decision to trash a book she hasn't read to a large number of her colleagues.

Thanks to Steve Hansen.

---

dearieme (2011-05-04 14:34:32)

"the only published formal study ever conducted in this country on human starvation (Ancel Keys, 1950)": set aside the fact that Keys was a crook, what on earth is the import of "in this country"? Isn't that carrying American Exceptionalism a little far?

Joe (2011-05-04 16:08:32)

Blogs need twit filters.

q (2011-05-05 10:47:14)

uh, i don't think she was saying you were nuts. i don't see any attack on your sanity or authority. and i don't see YOU being denounced. i see the diet being denounced, but that is completely different. the difference is that she's addressing what she sees as the facts, not the person behind them.

Seth Roberts (2011-05-05 12:25:19)

By "I was nuts" I meant "my claims were ridiculous". Maybe I am spending too much time in China and my English is going downhill...

Todd (2011-05-05 12:54:59)

Seth, I definitely agree with you. The woman who denounced your diet entirely failed to address the soundness of the supporting theory or data, relying entirely on a superficial view of what the diet was about – suggesting she hadn't really read the book. Furthermore, there is nothing in the SLD diet that forces you to eat 1200 kcal/day or any specific amount of calories; the beauty of the diet is that appetite and food intake will spontaneously adjust, and you can continue to eat normal, nutritionally balanced foods. Starvation means not getting enough nutrients to sustain health, and it may be that a temporary reduction to 1200 kcal/day or even less is fine, as long as you get essential nutrients, especially if you are overweight and

losing excess fat. If you look at Ancel Keys Minnesota Starvation Experiment (see Wikipedia on that) it was far from balanced – consisting of potatoes, rutabagas, turnips, bread and macaroni – a diet very poor in protein, fat, essentially fatty acids and minerals. No wonder the participants lost muscle mass and became food-obsessed and depressed. SLD is a far cry from the MSE! Todd

TalkingRat (2011-05-05 20:20:37)

Actually, I'm surprised a nutrition professor would generalize based on Key's study of young, active males. The assumption that 1560 calories will be starvation level calories is not the case, even for those subjects, whose maintenance level was 3200 calories. Starvation levels were achieved by extreme diet \*and\* a high level of activity, designed to burn 3000 calories. By design, they had a 25 % weight loss over 6 months. It must have been hard on his subjects. IMO, it is a good thing this is the 'only' US starvation study. There is a great deal of variation in calorie calculators, based on weight, age, gender, and level of activity. Even conservative calculators over-estimate my 1200 calorie maintenance level. The nutrition prof would probably call me a liar or a diet cheater, since I'd be gaining weight at her 'starvation' level. Fortunately, my doctor understands that patients are individuals, and people don't always present as a textbook case.

Thomas Seay (2011-05-05 09:25:39)

The article on China is wishful thinking on the part of the writer. If draconian dialectics were in play, then there should have been a revolution ( a real one, not the "Cultural Revolution") during the 1960s when things were MUCH more repressive than they are today. Of course, there is the phenomenon of "rising expectations" that may seal the CPC's fate. Paradoxically, it is the capitalists of the world who don't really want to see a change in China. They like the cheap labor and absence of independent trade unions.

Seth Roberts (2011-05-05 12:35:38)

Thomas, if I were a CCP official, the last people in the world I would want to piss off would be Beijing University students. This is not rocket science. Yet look what they did . . . CCP officials know something important I don't.

Joseph Moroco (2011-05-06 07:43:30)

He who controls the present controls the past. He who controls the past controls the future. 1984 We shall see if the cp can pull it off. Good luck.

Seth Roberts (2011-05-06 08:30:06)

what about "he who clumsily controls the past"?

Joseph Moroco (2011-05-06 08:45:13)

Exactly the question. Will the connection between clumsy controlling of the past and Mao's "power out of the barrel of a gun" be enough to save totalitarian government? Not a betting man, but my guess would no, but a lot of dead people in getting there.

## **Tucker Max on Paleo: "I Started Feeling So Much Better" (2011-05-06 05:00)**

In [1]this interview, [2]Tucker Max talks about eating paleo.

Once I started doing this, I started feeling so much better. My brain felt like it worked better. Everything about me improved. So I kinda went down the rabbit hole, and I started reading up on diet and nutrition from alternate sources. Art De Vany, Robb Wolf, and Loren Cordain, they didn't invent it but they kinda popularized the concept of paleo eating. I realized that if you're just a normal person, and you have the normal ideas about diet and nutrition, everything you know is wrong.

If you ask me, Tucker's enthusiasm/support for paleo is huge. [3]Max Planck said progress happens funeral by funeral. I say it happens keg party by keg party – college students, more than anyone else, have open minds. A friend told me that when she was a freshman in college, her sociology professor criticized the textbook. Whoa! she thought. Textbooks can be criticized!? She had thought they were beyond criticism. As far as I can tell, American college students respect Tucker more than they respect anyone else. (My Tsinghua students may favor Nassim Taleb.) For example, [4]this recent tweet: "[5]TuckerMax is my idol. and he's on this paleodiet...so i think im going to do it too." I found no tweets about the dietary influence of Michelle Obama ("[6]coolest First Lady ever").

In spite of what the interview was shortened to say, Tucker got the idea of eating flaxseed oil from this blog, especially [7]Tyler Cowen's experience. He wrote to me about it at the time. I posted his comments about dental health ([8]here and [9]here) and sports injuries ([10]here, [11]here and [12]here) under the name Anonymous.

I am pleased to announce that Tucker will be talking at the upcoming Ancestral Health Symposium at UCLA. The title of his talk is::

From Cave to Cage: Mixed Martial Arts in Ancestral Health

Sorry Tucker Max fans, symposium tickets are sold out. But after the conference you will be able to see the talk on the website.

Tucker's latest book is [13]Assholes Finish First.

UncleLongHair (2011-05-06 19:03:27)

Never seen so many f-bombs and "dude"s in an article about diet and health. Great stuff!

Peggy The Primal Parent (2011-05-09 09:22:09)

So if we want to popularize the Paleo diet all we need to do is convert a few celebrities. Awesome. That should be a way easier job than a grassroots movement. I'm going to see if I can get started on that...

### Nine Years of Weights, More Shangri-La Success (2011-05-07 05:00)

[1]

Seeing [2]Alex Chernavsky's ten years of weights inspired David Hogg, a professor of entomology at the University of Wisconsin, to send me his weight data for the past nine years – see above. Like Alex, he found that the Shangri-La Diet worked where other methods failed.

He is 5' 10" and 63 years old. When his weight reached 205 pounds (in 2002) he decided to take serious action.

He began by increasing how much exercise he did, to "watch what [he] ate," and to take "diet" pills. I asked him about the diet pills. He replied:

On [the advice of a local supplement store owner] I began to take L-Carnitine, which has a variety of effects (including some evidence for weight loss?), and an ephedrine based diet supplement (I don't recall the name of the product). I took the ephedrine until its sale was outlawed (2006?), after which I started taking a NOW Foods product called Diet Support, which lists as major ingredients iodine, chromium, forskolin (from Coleus root), L-Carnitine, extract of Garcinia cambogia, green tea extract, and extract of Uva ursi leaf.

He described "watching what [he] ate" like this:

I started having a fruit smoothy with protein powder and flaxseed oil for breakfast (rather than eggs/cereal and toast) and I cut back from a full sandwich and fruit to a half sandwich and fruit for lunch. I did not modify what I ate for dinner but did attempt to eat less, and I tried to not snack between meals. I think all of this was somewhat successful, although I was hungry a lot and suffered regular setbacks.

He described his exercise like this:

My goal was to get some form of exercise daily. In reality I probably get exercise on average 5 days a week, but this was not too different than what I was doing previously. My primary means of exercise are bicycling and racquetball/squash, but I also golf (walking, not cart) and take a range of classes at a local health club that includes Pilates, spinning, and weight lifting.

In 2002 he increased how much exercise he did.

In 2002, in other words, he began to do conventional weight-loss things (eat right, eat less, and exercise more) plus take diet pills. This lowered his weight from 205 to 180 but not further, even though continued for years. So far the Shangri-La Diet has lowered his weight about 10 pounds. He does it like this:

I started out with sucrose water, after several weeks switched to ELOO (which did not seem to work for me, perhaps because it reminded me of popcorn?), quickly switched to fructose water, which I used exclusively for 6+ months, then switched again to walnut oil (the fructose water made me feel bloated). For the past approximately 4 months I have added fructose to the walnut oil, which I started to use up the large supply of fructose I ordered, but it actually seems to work the best of anything I've tried to date. I drink 2 tablespoons of walnut oil containing about a quarter of a tablespoon of fructose, twice daily.

My ideas about dietary control of the set point made a lot of sense to him.

At one time I believed weight gain or loss was purely a matter of calories in vs. calories burned. Up to age 30 that model seemed to explain my weight. After 30 it was not so simple, with my weight seemingly resistant to sustained loss or (in the short term) gain, and this led me to adopt the view that my weight was governed by an equilibrium or set point. This was easy for me conceptually. My professional interest at the time was insect population dynamics, and the prevailing view was that although insect population densities fluctuate (sometimes widely) through time, for a given species the fluctuations tend to occur around an equilibrium that is enforced through density dependent processes. However, I viewed my set point weight as "fixed", so my paradigm did not explain the upward drift in set point and weight. Your discussion of this, from an evolutionary perspective, made me rethink my idea of a fixed set

point and provided the perfect explanation for the upward drift in my weight (plus the way to convince the brain to decrease one's set point).

His data are an important advance in understanding. They cover a long period of time and allow comparison of the Shangri-La Diet to three popular weight-loss methods: "controlling what you eat", exercise, and various supplements ("diet pills"). No conventional weight-loss experiment covers as long a period of time.

### **Sterilities of Scale and What They Say About Economics (2011-05-08 05:00)**

You have surely heard the phrase economies of scale – meaning that when you make many copies of something each instance costs less than when you make only a few copies. Large companies are said to benefit from "economies of scale" – so there is pressure to become bigger. Every introductory economics textbook says something like this.

Here's what none of them say: The more of Item X made by one company, the more "sterile" Item X becomes, meaning the less Item X is able to spark innovation. Call this sterilities of scale. You have never heard this phrase – I invented it. (I cannot find it anywhere on the Web.) But it is just as obviously true as the notion that when you make more of something you can make each one more cheaply. If 100 widgets are made by one company, there is going to be less innovation surrounding widgets than if 100 widgets are made by 10 different companies. Sterility of Scale 1: When ten different companies make something, more people are studying and thinking about and pursuing different ways of making it than if only one company makes it. Sterility of Scale 2: The more profitable a single item becomes (due to low cost of manufacture), the more pressure not to change anything – not to kill the goose that lays golden eggs. Sterility of Scale 3: The larger the company, the more employees who care only about preservation of their fiefdom (comparing 10 companies of 10 people each to 1 company of 100 people). See how obvious it is that sterilities of scale exist?

The two concepts – economies of scale and sterilities of scale – are equally elementary. But only one is taught. Study of innovation should be 50 % of economics but in fact is close to 0 %.

This is why Tyler Cowen's The Great Stagnation [1] is so important – because it begins to point to this great gap. Jane Jacobs did so, but had little or no impact. (At a Reed Alumni Gathering I was seated next to a professor of economics. "What do you think of the work of Jane Jacobs?" I asked her. "Who's Jane Jacobs?" she replied.) I think human decorative preferences are so diverse (chacun a son gout, no accounting for taste) for exactly this reason, to avoid sterilities of scale. Diversity of preference makes it easier for many different manufacturers to thrive, which increases innovation. For example, diversity of furniture preference makes it easier for dozens of furniture companies to survive, thus increasing innovation surrounding furniture. Clayton Christensen's The Innovator's Dilemma describes many examples where large companies were much less innovative than smaller companies – so much so they often went bankrupt. Which suggests sterilities of scale can be fatal.

If there were more understanding that ten small things are going to be more innovative than one big thing, I like

to think that scientists would better understand the value of very small research and grant sizes would go down. An illustration of the general cluelessness is [2]someone who wrote to Andrew Gelman complaining that a sample size was only 30.

I started thinking about this after hearing Nassim Taleb discuss economies of scale (e.g., [3]here).

3. <http://www.simoleonsense.com/nassim-taleb-latest-paper-too-big-to-fail-hidden-risks-the-fallacy-of-large-institutions/>

---

gwern (2011-05-08 07:21:13)

> If 100 widgets are made by one company, there is going to be less innovation surrounding widgets than if 100 widgets are made by 10 different companies. So, was there more or less 'innovation surrounding' computers when there were dozens or hundreds of companies selling computer processor chips for thousands and hundreds of thousands of dollars, as compared to the handful now selling for hundreds?

Glen Raphael (2011-05-08 07:38:00)

I question sterility of scale #2 in this sense: the more profitable a single item becomes, the more \*potential competition\* is drawn out of the woodwork. More people \*outside\* Apple are spending more money and effort developing tablets now as a result of iPad being so visibly profitable; if it had been less profitable it wouldn't be seen as a valuable niche worth pursuing. All these competitors both provide innovation directly and incentivise Apple to keep innovating - concrete example: Apple \*had\* to add a camera in the latest iPad revision to keep in the running. Sterility of scale #1 also seems problematic in that real standardization of one product within a product category tends to spawn massive innovation in the form of add-on products. When automobiles are all handcrafted, there's not much of an aftermarket business opportunity making things like custom floor mats and spoilers and foglights. The iPhone and iPad may themselves be pretty "sterile" but the ecosystem they created in cases and apps and accessories is vibrant and would be much less so without a stable base to work on.

Glen Raphael (2011-05-08 07:51:00)

Sterility of scale #3 is much more plausible than the others. Though there are a couple of conflicting tendencies. One is that companies generally \*get\* really large by providing value to customers. To the degree that empire building interferes with profitability, it prevents company growth; the fact that one company won out suggests - doesn't prove, but does suggest - that it's the most efficient provider \*despite\* the tendency empire building. Still, that one is a real phenomenon. The term you might be looking for is "diseconomies of scale". [http://en.wikipedia.org/wiki/Diseconomy\\_of\\_scale](http://en.wikipedia.org/wiki/Diseconomy_of_scale)

David (2011-05-08 07:52:18)

Interesting. We agree and are in the process of trying to integrate innovation into our curriculum. There are some recent books by Baumol that are looking at this. And, there's Clayton Christensen's work as well. But, it's a challenge. In order for students to be able to "think outside the box," they need to know what's in the box. Though innovation certainly isn't a center of most micro theory, I disagree that this question hasn't been studied. There is a huge empirical literature on "the Schumpeter hypothesis," which is roughly that large concerns are responsible for innovation. His conjecture is that large firms get large because they are doing something right, and, absence some significant barriers to entry, they are going to have to continue to remain innovative or they will get caught by their rivals. Wal-Mart might be a good instance of a tremendously innovative

firm that had its profitability cut out from underneath it because its rivals mimicked its cost-saving measures. If you type "Schumpeterian hypothesis" into google scholar, you'll get plenty of discussion of this very topic. Here's where Schumpeter makes his case: [http://www.sp.uconn.edu/langlois/Creative %20destruction.htm](http://www.sp.uconn.edu/langlois/Creative%20destruction.htm)

David (2011-05-08 07:55:17)

Oh, and this, [www.schumptoberfest.com](http://www.schumptoberfest.com)

Glen Raphael (2011-05-08 09:20:31)

Sterility #1 might be best rephrased as "market competition encourages innovation", a concept that \*is\* taught. Sterility #2 is one of a variety of pitfalls profitable companies can fall into; the chief check on this is...market competition. Sterility #3 is one of a variety of pitfalls that can eventually limit the growth of large firms, aka "diseconomies of scale". Again, the chief check on this is market competition. So you could summarize all of these as "competition - including \*potential\* competition - encourages innovation." That is taught as the conventional wisdom. Economics tries to explain why the world look the way it does, so one learns that: (1) Competition produces variety and innovation (2) Economies of scale (including specialization of labor) produce large firms that reduce costs (3) Diseconomies of scale ultimately limit the size and/or effectiveness of large firms. To the degree that people don't learn (3) or insufficiently appreciate (1), there are calls to forcibly break up large firms. (Many such calls are misguided because they under-appreciate (2) or don't realize that government regulators themselves are also subject to (3).)

Sean Estey (2011-05-08 09:49:22)

Good stuff. As soon as I started reading this, I thought of NNT. In the updated version of The Black Swan, he goes further into depth on the concepts of fragility/anti-fragility that you linked to. I love how he uses mother nature as a model that economics should strive to follow. The hono genus has survived for 2.5 million years not because there was a premium placed on efficiency, but because there was an emphasis on redundancy: 2 eyes, 2 lungs, 2 kidneys, etc. We could have traded some of these redundant features for a bigger brain, more muscle mass, etc, but at some point you need to make some trade-offs to create a robust system resistant to natural shocks. Modern economics could learn a lot from mother nature.

Jan Leeman (2011-05-08 09:59:35)

I see evidence of sterilities of scale in the local public school districts in California. The small school district in a nearby town with just a few schools frequently runs single class experiments (e.g. does a multi-grade class work better for students?), but the large, well-funded district that my kids attend is proud of their ability to have every teacher doing the same lesson in every classroom every day. I think that Sterility of Scale 3 is applicable in this case.

Seth Roberts (2011-05-08 13:16:10)

Gwern and Glen, yes, a tiny fraction of products benefit from standardization – sometimes these are called "producer's goods" (e.g., nuts and bolts, chemicals for industrial processes), sometimes "platforms", sometimes "two-sided markets". If that's what you mean, I agree. That is another basic point about innovation missing from introductory textbooks. I am not saying sterilities of scale are the only thing that differs between large and small companies. In the case of platform goods, what you say is also important.

Seth Roberts (2011-05-08 13:25:39)

Here's the first sentence of the Wikipedia article you link to: "Diseconomies of scale are the forces that cause larger firms and governments to produce goods and services at increased per-unit costs." Nothing about innovation. The whole article mentions innovation in only one section. Of course economists know that innovation exists; they simply pay very little attention to it. (Just as epidemiologists know that the immune system exists but pay very little attention to it.) The Wikipedia article is one more example.

Seth Roberts (2011-05-08 13:38:06)

Thanks for the Schumpeter link. If I were trying to teach about innovation to college economics students, I think I would tell

stories about how a few products began. Then I would say: "You're lucky. Economists haven't studied innovation very much. They haven't come up with basic rules about what makes innovation large or small. So you can. I want you to study several examples of how products began and from those examples come up with testable generalizations about innovation." I might give the students links to stories of how products/services began or I might require them to find the stories themselves. This is a lot more exciting and educational than the usual stuff that is taught in intro economics and in this sense it is easier to teach about innovation than the more conventional stuff.

Glen Raphael (2011-05-08 16:33:56)

Have you read *The Wealth Of Nations* \_? Adam Smith had a very different model of innovation than you do and emphasizes sources of it that you might have overlooked. Consider Smith's example of a pin factory. Suppose we have ten firms making pins from scratch, where each person does *\*all\** the work involved in making each pin. You seem to imply that should be good for innovation because ten people will have ten different worldviews, ten different backgrounds. But now suppose one larger company applies assembly-line technology to making pins. One of the ways you get economies of scale is that at the new larger firm there's likely to be one guy who *\*all he does\** is sharpen, and he does this full time, hundreds or thousands of pins a day. Since all he thinks about is pin-sharpening and since he does so much of it, he *\*gets better\** at it. He is likely to invent new innovative processes to make pin-sharpening more efficient. Ten companies making 1/10th as many pins - or 100 companies making 1/100th as many - are not in a position to do this. For a firm that makes a few pins a day, sharpening is such a small part of the overall task/job that realistically they'll never make it much more efficient. Ten people take a lot longer to climb a learning curve than one person doing the same task ten times as often. Market concentration thus can enable *\*more\** technical innovation. Concentration of capital at industrial scale makes investments possible that have huge returns which weren't possible for smaller-scale producers to achieve. So that is one story economists tell about how innovation occurs. Now, it's not *\*quite\** clear what you mean by "innovation" in this context - does accomplishing the exact same goal more cheaply count? - but in the way economists define it they do have a story to tell. In their story (in which cost savings *\*do\** matter), economies of scale tend to matter a lot *\*more\** than diseconomies. It's not clear to me that they're wrong to think this. If you think they are, you need to make more of a case.

James (2011-05-08 19:48:48)

"Learning by doing" is a related concept in economics. Firms learn how to produce things better and more cheaply as they produce more, but there are diminishing returns and we don't learn as much from the 1000th unit as the 10th. [http://en.wikipedia.org/wiki/Learning-by-doing\\_%28economics%29](http://en.wikipedia.org/wiki/Learning-by-doing_%28economics%29) The idea was applied to Intel and microprocessors here, check out the graph on page 12: <http://www.antitrustinstitute.org/sites/default/files/scherer%20commentary.pdf>

Glen Raphael (2011-05-08 20:53:05)

Economies of scale are something you can measure or calculate. In [1]Smith's example, he ballpark-estimated that a combination of division of labor and learning-by-doing led to pins being hundreds or thousands of times cheaper than they otherwise would be. Now that we can calculate much more precisely how much innovation we get from scale, this helps economists explain questions like: "Why do firms exist at all? Why is there trade between nations? How do countries with relatively free trade prosper?" Diseconomies of scale seem a lot smaller in magnitude than that, but do help to answer second-order questions such as: "Why don't firms just keep growing and consolidating until one firm produces everything? Why don't we just let the government produce all the goods and give them away for free?" When you say "a tiny fraction of products benefit from standardization", I can't think of any products offhand that *\*aren't\** in that "tiny fraction". Standardized cars are a platform based on standardized tires which are based on standardized rubber...standardized computer chips enabled innovative computers, standardized computers enabled innovative software, then standardized software itself became a platform... standardized food staples made food cheaper and safer, standardized electronics made fires less likely, standardized thread made standardized cloth made clothes in standardized sizes and shapes... So: what products are you thinking of that don't benefit?

1. [http://www.debunkingeconomics.com/Marx/Smith\\_Pin.htm](http://www.debunkingeconomics.com/Marx/Smith_Pin.htm)

Seth Roberts (2011-05-08 21:33:05)

By "standardization" I meant being almost identical - as produced by one company. You are using the term more loosely.

I don't know what you mean by "standardized cars". In any case, non-platform products include all sorts of food, all sorts of clothes, all sorts of cleaning materials, all sorts of decorative stuff, all sorts of art, all sorts of furniture. The innards of many products ("producer's goods") are standardized, of course, as I said – tires, rubber, and so on. If you simply mean that elements of standardization touch most products – sure, language will do that. One does not need large companies to produce that effect – to make loaves of bread vaguely the same size, and so on. Language is involved with the sale of most products, and it enforces a certain amount of uniformity – a "loaf" of bread is taken to be a certain size. Likewise, uniformity among producer's goods (e.g., loaf pans) produces a certain uniformity among the final products. That will happen regardless of the size of bread companies. So long as bread companies don't make loaf pans. "Now that we have measured how much innovation..." – I see no measurement of innovation. I see a measurement of cost ("thousands of times cheaper"). I find nothing about specialization improving/increasing innovation in Adam Smith. Perhaps that is true, but as far as I can tell Smith missed it completely. I have never heard any economist say that specialization improves/increases innovation.

Glen Raphael (2011-05-08 23:30:40)

Specialization of labor *is* itself an innovation; that was one of the core theses of WoN. (Though he didn't use the exact word "innovation". Rather he referred to "improvements", including but not limited to "[1]improvements in the productive power of labor".) Finding a better production process that results in goods being thousands of times cheaper both *is* innovative and also *enables* additional innovation in all the downstream products. On cars: From the Model T onward, standardization in how cars are constructed on a large scale enabled vast improvements in quality and maintainability compared to when car-building was a craft, and also enabled a huge aftermarket in things like better tires or speakers or replacement headlights. In short, cars became a platform. Even art benefits from standardization of canvases and paint; furniture from standard fittings and cuts of wood and so on. (Human decorative preferences don't actually strike me as particularly diverse. There are only so many common themes/styles. If they were truly diverse, Restoration Hardware and Ikea wouldn't have been so successful)

1. <http://www.gutenberg.org/files/3300/3300-h/3300-h.htm#2HCH0001>

Seth Roberts (2011-05-08 23:42:44)

The question that interests me is whether Smith said anything about what makes innovation more or less likely. As far as I know he did not.

## **Meat Consumption and Weight Gain: Health Journalism Done Right (2011-05-09 05:00)**

[1]This article by Eoin O'Connell reports [2]a study in the American Journal of Clinical Nutrition (the top nutrition journal) that found a correlation between meat consumption and weight gain: The more meat you ate, the more weight you gained over five years. Meat is fattening! reported several newspapers.

Mr. O'Connell did something unusual for a health journalist: He thought for himself. I don't mean he applied a formulaic criticism (e.g., "correlation does not equal causation"). That's not thinking, that's knee-jerking. Mr. O'Connell read the paper. And he noticed an interaction: The correlation between meat consumption and weight gain depended on activity level. The study involved about 400,000 people. The researchers put each person in one of four activity levels: inactive, moderately inactive, moderately active, and active. There was a correlation between red-meat consumption and weight only for the two most active groups (moderately active and active). The original article reported that this interaction was significant:

The relation between red meat and weight gain was also stronger in physically active subjects compared with moderately inactive or inactive subjects (P values for interaction = 0.02)

The obvious implication of this interaction, as Mr. O'Connell says, is that meat caused muscle gain. Weight differences between more-meat and less-meat eaters were due to differences in muscle mass. This puts an entirely different spin on the results. The alternative explanation is quite plausible. I once had a grad student who was a vegetarian. When he was an undergrad, he told me, he and his roommate would go to the weight room and do similar sets. His room-

mate, who ate meat, rapidly gained muscle; he did not. Of course, meat = animal muscle.

Mr. O'Connell continued to the really interesting part of his article:

Perhaps not so surprisingly, the consideration that muscle is a form of weight gain does not appear in the newspaper articles but much more surprising is the fact that it does not appear in the original journal article either.

The AJCN article has fifty authors. Not one of them, apparently, noticed this all-important point! Nor did the reviewers for this prestigious journal. The article concludes: "Our results are therefore in favor of the public health recommendation to decrease meat consumption for health improvement." No, they're not, if the more meat, more muscle explanation is correct.

Most prestigious journal. Fifty authors. Huge expense. Total F-up in the sense that the final conclusion is probably wrong. (To be fair, the paper has plenty of value in other ways.) Congratulations, Mr. O'Connell, for noticing.

1. <http://www.significancemagazine.org/details/webexclusive/1044471/Meat-consumption-and-weight-gain.html>

2. <http://www.ajcn.org/content/92/2/398.abstract>

---

Lemniscate (2011-05-09 07:01:21)

It's a good example of how lazy the thinking and methodology of scientists can get once prejudices are well established. Red meat is seen as suspect and weight gain is assumed to be fat mass gain. It would have been nearly as easy to measure change in waist circumference, which would have given a better indication of metabolic risk. The conclusion is applied generally to "weight management", when all they're justified in saying is that active people could consider reducing red meat intake if they want to maintain a lower overall body mass. They could also conclude that inactive people shouldn't worry about their red meat intake's effect on their mass, but that wouldn't chime with public health prejudices. The incentive to bolster the public health message appears stronger than the scientific spirit, unfortunately.

Mark (2011-05-09 07:29:15)

Good catch! This is a great post!

chuck (2011-05-09 08:31:34)

Great find. This is the danger of only assessing weight rather than looking at body fat percentage. i believe the science has evolved enough to be able to use this measurement rather than weight or BMI. especially when exercise is involved in the intervention.

Tyler @ Evolutionary Health Systems (2011-05-09 10:32:12)

That's astounding. Fifty authors and nobody caught that... Wow.

Thomas Seay (2011-05-09 10:48:40)

Apparently this point never occurred to the people who came up with BMI either. I am 6'1 210 pounds but a competitive Olympic Style Weightlifter. I come up as overweight just like the other guy who is 6'1 210 pounds, sits on his couch all weekend watching reruns and hasn't done any exercise since 6th grade PE.

Aaron Blaisdell (2011-05-09 12:43:44)

@Thomas, Agreed! It's like measuring a bag of nickles to determine how rich you are. Doesn't matter if they're real copper-nickle clad nickles or lead-wood fake nickles. Same logic should be levied at standard calculations of BMI which is

agnostic to where the weight is coming from, fat versus muscle (it's both, of course, but the ratio is what really matters and is not determinable from conventional measures).

q (2011-05-09 14:32:26)

i don't quite understand though - why is more muscle not as bad as more fat?

Seth Roberts (2011-05-09 15:27:40)

obesity is almost always due to lots of fat, not lots of muscle. obesity is correlated with higher risk of many health problems.

Chris Sturdy (2011-05-09 19:23:44)

This is a great catch, Seth! Too bad more journalists weren't like this.

Pete Ballerstedt (2011-05-10 05:15:48)

Thank you for this post, Seth! Amazing ...

Linzi Jayne (2011-05-10 05:50:39)

Definitely food for thought! I am trying to gain weight at the moment and it isn't easy; so any related info' is much appreciated! I have been charting my (minimal!) progress on my blog <http://www.underweight-arewewhatweeat.blogspot.com>

Peggy The Primal Parent (2011-05-10 07:55:12)

Logical inconsistencies abound in medical literature, don't they. How bout the cholesterol myth and the fat makes you fat myth. Mark at MDA just posted today about how CLA supplements aren't beneficial after all. Seriously, the nutritional scientists don't know what they're doing most of the time. I think finding a wholly valid, well executed study would be a bigger feat!

Christopher Burd (2011-05-10 12:44:17)

"That's astounding. Fifty authors and nobody caught that... Wow." With 50 authors, I expect there was a 3- or 4-level hierarchy within the project, and a big budget. So, you can imagine an underling being afraid to criticize his boss and boss's boss, people he's unlikely to have collegial relations with. A more senior author ("manager" is perhaps the accurate term) might not want to risk discrediting the whole effort and earning the wrath of his peers (again, people he may not have true collegial relations with). I wonder if a team of 15 might be more likely to self-correct, since team members (even of different ranks) might be more likely to know and respect one another.

Seth Roberts (2011-05-10 15:24:39)

Christopher, yes, psychologists have studied this sort of thing. The effect is called "diffusion of responsibility". The more people who might take action (such as point out a mistake) the more passive each person becomes.

Crossfit WOD :: Crossfit Dublin (2011-05-10 16:16:35)

Greg (2011-05-11 06:42:59)

In defense of the 50 authors, probably 40 of them never read the article they authored

## **Liberation Therapy: Contradictory Evidence (2011-05-10 05:00)**

As you may know, an Italian surgeon named Paolo Zamboni has proposed that multiple sclerosis (MS) is often due to poor blood drainage from the brain. Improving drainage, he and his colleagues found, reduced MS symptoms. The surgery is called liberation therapy. From [1]this article (thanks, [2]SB) I learned of evidence contradicting Zamboni's

findings:

The studies were independently conducted case-control experiments designed to determine whether abnormal out-flow of blood in the head and neck is actually a defining feature of MS. Two of the studies appeared to confirm Zamboni's observations; the pooled results identified 31 cases of CCSVI out of 35 MS patients and none in 45 matched controls. Yet three other studies, from Germany, Sweden and Holland, with a pooled set of 97 MS patients and 60 matched controls, found no significant evidence of a difference in blood flow between those with MS and those without. In fact, when Doepp et al. attempted to replicate the Zamboni trial they did not find a single case of CCSVI in either the 56 MS patients or the 20 controls examined.

Wow. What intense disagreement. The failure-to-replicate studies used different ways of measuring blood flow so the disagreement is less stark than it appears from this description. But it is still remarkable.

This is highly newsworthy. I can't think of another case where two different labs have gotten such different results. Unfortunately the article is appalling in its one-sidedness (e.g., liberation therapy is said to have "known risks, unknown benefits").

1. <http://onlinelibrary.wiley.com/doi/10.1111/j.1740-9713.2011.00478.x/pdf>

2. <http://blog.sethroberts.net/2010/11/27/examples-of-ms-liberation-therapy/#comment-914703>

---

JeffR (2011-05-10 17:08:18)

How "highly newsworthy" this is depends on how much Zamboni isn't a crackpot. If it turns out liberation therapy is bunk, then of course we would expect results like Doepp's. And the studies in support of Zamboni were wishful thinking, perhaps consciously, perhaps not. This is precisely why controlled studies or observational studies with  $n > 1$  are so important. Anecdotes are fine for generating hypothesis but I'm always concerned with your (Seth's) enthusiasm for their results. Especially when this runs counter to what people in biology or public health are saying. Being right about some things discovered with self experimentation (probiotics, acne?) doesn't mean every self experimenter has discovered a medical breakthrough. p.s. I haven't read any of the papers.

Todd (2011-05-10 17:39:25)

My wife has multiple sclerosis and she has been evaluated by Dr. Michael Dake, a U.S. colleague of Zamboni's, for possible evidence of CCSVI. We'll find out the results next week. I too am struck by the stark differences in these different studies and am obviously determined to get to the bottom of what might explain the diametrically opposed conclusions. At this point, I have two hypotheses: (1) Zamboni's diagnostic method was not truly "blind" but involved an element of looking for what he wanted to see; (2) the diagnosis is objective and "blind", yet complex and subtle, and the measurement of "blood flow" is sensitive to the particular parameters used or to control of possible interfering factors – so that only those with the right technique or understanding can make the correct diagnosis. This second possibility is not uncommon in science – analytical methods are often riddled with artifacts or uncontrolled variables that mess up the analysis if you are not experienced. I'm hoping that the explanation is #2, but I'm realistic enough to realize it could be #1. And my wife and I don't want to take any chances on a procedure which is based upon a faulty hypothesis or wishful thinking. Todd

Seth Roberts (2011-05-10 17:52:43)

JeffR, a vast number of people (millions?) have taken Zamboni's results seriously. That's what makes it newsworthy. Were they all fooled? Or did the non-replicating research teams do a poor job? Why this disagreement shows "the importance of controlled studies or observational studies with  $n > 1$ " I don't understand. Both sides of this disagreement have such studies. To persuasively criticize self-experimentation, you need to point to self-experimental conclusions that turned out to be wrong.

This is unrelated to that.

Seth Roberts (2011-05-10 17:53:48)

Todd, keep in mind how hard it is to measure blood flow.

James A Donald (2011-05-10 19:34:30)

I have been following this debate for some time, and it is apparent that one side, or the other side, is lying. The theory that the proponents of liberation therapy are telling the truth involves more liars and a larger conspiracy than the theory that the opponents of liberation therapy are telling the truth. On the other hand, it seems obvious to me that those producing evidence against liberation therapy were committed to getting the results that they got, before they got these results, so I am inclined to think that liberation therapy does work, and its critics are lying, even though this theory requires a larger and more evil conspiracy than the converse theory.

Seth Roberts (2011-05-10 22:41:09)

If Zamboni were making all this up, I think we would have heard about it from jealous colleagues. I think that is impossible. On the other hand, I think measurement of blood flow in the brain is really difficult thus allowing the opponents to get the results they prefer – they simply do bad measurements. And since they like the results, they don't look further. I think the contradictory papers reflect bias. If the scientists who found contradictory results really cared about the question, they would have flown an MS patient in whom Zamboni et al. had detected CCVSI to their lab to make sure they could find CCVSI when it is present.

John (2011-05-11 05:54:54)

Acupuncture is similar as far as researchers drawing very different conclusions. Roughly speaking, all Asian researchers get positive results and Western researchers do not. More detail [1]here.

1. <http://www.johndcook.com/blog/2011/01/30/acupuncture-and-confirmation-bias/>

Ulysse (2011-06-18 03:46:15)

All this conversation about the right method of taking ultrasound pictures is misleading. The golden standard for finding venous obstructions is old fashioned venography accompanied by IVUS. But it's the underlying question that matters: Is MS of autoimmune or vascular origin? Under this perspective, Zamboni is hardly the first one to talk about blood flow problems. Putnam, Prineas, Behan, Lumsden and Franz Schelling have almost proven that MS is NOT autoimmune.

## **To Kill A Mockingbird Joke (2011-05-11 05:00)**

After the fantastic success of To Kill a Mockingbird, its author, Nelle Harper Lee, never wrote another book. She gave her last interview in 1965. A BBC documentary recently visited her hometown and recorded this:

They say if you meet her [Harper Lee] and don't recognize her, she is not happy. If you meet her and recognize her, she is not happy.

dearieme (2011-05-11 11:18:57)

Then she wouldn't like me: I've never read it.

Jesus Sanchez (2011-05-11 14:56:41)

I read this book in my quest to read Penguin's Top 100 Classics. I'm glad I picked this book early on because it set the tone for what I was looking for in a "classic". Honestly, I can understand why she never wrote again. St. Thomas Aquinas never wrote anything after he had a mystical experience. He said that after God showed him what He had, there was nothing else worth writing.

Seth Roberts (2011-05-11 16:03:00)

yes, To Kill a Mockingbird is about a hundred times more readable and enjoyable than most classics.

Allen K. (2011-05-12 16:51:01)

This reminds me of Michael Caine's line to his co-stars, before filming love scenes: "If, when we film, I have an erection, I apologize. If, when we film, I do not have an erection, I apologize."

John S. (2011-05-13 07:17:26)

I liked To Kill A Mockingbird, both the book and the movie. However, over the years I have come to have a more jaundiced view of this type of entertainment, the goal of which seems to be to make white people feel good about themselves. The second half of the 20th century saw an epic struggle for civil rights in this country. Why is it that when this era is portrayed in film, the heroes are always white? Why are the black characters usually so one-dimensional? This continues to the present day in films like The Blind Side, which again portrays affluent white folks coming to the aid of poor blacks. I don't know, it just seems patronizing. Like the only way black people can get ahead is if a noble white man comes along to help them out.

### **Seth Roberts Interview About Self-Experimentation (2011-05-12 05:00)**

For an article about self-experimentation and self-tracking to appear in Men's Fitness UK this summer, Mark Bailey sent me several questions.

In what ways have the results of your self-experimentation directly affected your daily life e.g. health / work / lifestyle changes?

1. Acne. My dermatologist prescribed two medicines. I found that one worked , the other didn't.
2. Weight. Found [1]new ways to lose weight (e.g., [2]nose-clipping).
3. Sleep. Found [3]new ways to sleep more deeply, avoid early awakening (e.g., [4]one-legged standing).
4. Mood, energy, serenity. Found that [5]morning faces make me more cheerful, more energetic, and more serene.
5. Productivity. After I started to track when I was working, I discovered that [6]a certain feedback system made me work more, goof off less.
6. Inflammation. Self-experimentation led me [7]to take flaxseed oil. In the right dose – which I determined via self-experimentation – it greatly reduces inflammation. As a result, my gums are pink instead of red. They no longer bleed when I floss.
7. Balance, reflexes. [8]Flaxseed oil improved my balance and quickened my reflexes – I catch what I would have dropped.
8. Blood sugar. I found that [9]walking a lot improves my blood sugar level.

9. Mental clarity. I found that [10]flaxseed oil and [11]butter improve how well my brain works in several ways.

Changes 1-6 are/were obvious. The rest are more subtle.

How long have you been self-experimenting?

About 35 years.

What are the main advantages of self-experimentation e.g. yields results specifically relevant to the individual and engages them directly in the process of finding solutions?

My self-experimentation has had three benefits:

1. Find new ways to improve health. Ways that no one knew about. I mentioned most of them earlier: New ways to lose weight, sleep better, be in a better mood, and so on. I find them to be much better (safer, cheaper, more powerful) than what was already available.
2. Test health claims made by others. I've done this many times. My interesting self-experimentation started when, as I said earlier, I measured the efficacy of two acne medicines my dermatologist had prescribed. I found that Treatment A worked and Treatment B did not work, which was the opposite of what I had believed. It's been claimed that drinking vinegar causes weight loss. I tried that, it didn't work. Many people say that exercise improves sleep. I found that aerobic exercise made me fall asleep faster but did not reduce early awakening. The most dramatic "test" of health claims made by others came when I discovered that butter improved my arithmetic speed – which meant it was likely that butter improved overall brain function. I took this to mean that butter was good for the rest of the body – in contradiction to the official line that saturated fats are bad for us.
3. Find best "dose" of a treatment. Many people have claimed that flaxseed oil is beneficial. I found they were right. I tested different amounts/day and found the dosage that produced the most benefit. The best dose (2-3 tablespoons/day) was much larger than you would guess from the size of flaxseed oil capsules and the suggested dose on bottles of flaxseed oil capsules.

What do you consider are the potential weaknesses e.g. lack of clinical precision / possible placebo effect?

Is too-high expectations a weakness? You could spend a lot of time and not learn anything useful. Which isn't so much a weakness as a fact of life.

In my experience, useful self-tracking and self-experimentation are slow. Other people's self-tracking projects often strike me as too ambitious – doing too much too soon. For example, they are tracking too many things. Or worrying too much about placebo effects. Because they are doing too much – carrying too much, you could say – they may get tired and stop before they have learned something useful.

From a psychological perspective, why is the use of data / numbers, as in self-tracking, so much more powerful and engaging than merely 'setting a goal'?

For one thing, it's more forgiving. When I set goals for myself, I often fail to meet them. That can be so unpleasant I give up. When you simply measure something, it's much easier to succeed – all you have to do is make the measurement. For another thing, it's more informative. By studying my data I can learn what controls what I'm measuring (e.g., sleep). Setting a goal doesn't do that.

Why, in a world dominated by numbers / statistics, has it taken so long for us to use data to learn about ourselves, our lives and our bodies?

You seem to be asking why has it taken so long to apply something so useful elsewhere ("numbers/statistics") to ourselves? I have a different starting point. I think it is science – which is more than numbers and statistics – that has been useful elsewhere. Numbers/statistics by themselves are little help. I also think health scientists (e.g., medical school professors) have used numbers/statistics to learn about ourselves – with little success.

In my experience, [12]you need four things to make useful progress on health: 1. Good tools. Computer, numerical measurement. 2. Experiments. You need to systematically change things. 3. Knowledge of what others have learned. You can't do experiments blindly, there are too many possibilities. You have to choose wisely what to change. 4. Motivation. You have to really care about finding something useful.

Professional scientists have Numbers 1-3 (tools, experiments, knowledge). Lacking Number 4 (motivation), they haven't gotten very far. Self-trackers have Number 1 (tools). If they have a problem, something they want to improve, they have Number 4 (motivation). Most self-trackers have Numbers 1 and 4. Without Numbers 2 and 3 (experiment and knowledge) they aren't going to get very far. What's so important about the self-quantification movement is they might get Numbers 2 and 3. They might learn to experiment. They might learn to study what everyone else has already learned. When that happens, I think they will make a lot of progress. They will discover useful stuff that professional scientists have missed. And the whole world will benefit.

What developments will need to occur before self-tracking can really grow in the future e.g. better analysis / devices etc?

More successful examples. More examples where self-tracking led to improvement. They will teach everyone how to do it usefully. I think these examples will show that self-tracking alone is not nearly enough, as I said. But maybe I'm wrong. We need examples to find out.

Adam G (2011-06-14 07:18:14)

It would be useful if Dr Tim Ball had actually read the Limits to Growth report before criticising it. If he had, he would have noted that it's projections are remarkably, sadly, on track and the authors did not in anyway predict collapse before this point in time. Here's a good summary by late energy banker Matt Simmons: <http://www.energybulletin.net/node/1512> Paul Ehrlich did not use computer models, and was certainly overly panicked when he wrote the Population Bomb. However, by ridiculing quotes like "In ten years [i.e., 1980] all important animal life in the sea will be extinct," it would be tragic to imply that since he was wrong, that the real situation is therefore rosy. The reality is terrifying enough: <http://www.guardian.co.uk/news/datablog/-/2011/jun/03/fish-stocks-information-b-eautiful#zoomed-picture>

Seth Roberts (2011-06-14 08:14:07)

You make good points.

## The Future of China (2011-05-14 05:00)

Recently I had dinner with two Tsinghua students I advise.

ME Do you know what "science fiction" is?

BOTH OF THEM Yes.

ME I have an idea for a science-fiction story. Five years from now, Tsinghua and Beida [Beijing University] students get together and decide to change the government. What do you think?

They were amused by this idea. However, here's what they said:

BOTH OF THEM Where's the science?

I explained that science fiction often takes place in the future.

---

No One (2011-05-14 09:39:20)

In American English (and possibly British English as well), "Science Fiction" has been modified sometime in the last 40 years to include what was originally called "Fantasy". The scenario you described is a fantasy happening in the future. There's no element of science (that would make it "science fiction") - I'm with your students on that one. Almost every science fiction story has some fantasy, or it wouldn't be interesting as fiction. "Star Wars" is pure fantasy - replace the light saber by magical swords and spaceships by dragons and you're there. On the other hand, most of Asimov's stories have a scientific element in them. And there are always stories that defy categorization - such as <http://www.amazon.com/Evolution-Man-How-Ate-Father/dp/0679750096> , which some people classify as science fiction, and some as historical fiction although "fiction" is the only descriptive characterization.

Kevin R. Bridges (2011-05-14 11:25:33)

That's a funny point, that Science Fiction is a broad enough genre that it doesn't always involve anything that has to do with science. Also, I might comment more if I got an email when comments were made in response. Is this by design?

Seth Roberts (2011-05-14 15:05:58)

no it is not by design. I agree that's an important feature. It is by neglect. I will look for a wordpress plugin that does that.

Kevin R. Bridges (2011-05-14 16:17:42)

Awesome. I would love that. You tend to blog a mixture of things that I strongly agree with, right alongside things I strongly disagree with, and I'd love to freely comment without adding "check that blog post" to my agenda. Thanks.

TomGinTX (2011-05-15 18:16:27)

## **The Signaling of Economists (2011-05-15 05:00)**

I like [1]this essay by Brad DeLong about the failure of economics professors. They didn't just fail to predict the recent economics crisis but they have failed, as far as he can tell, to learn from it. If you are naive, of course this is astonishing - but DeLong is not naive. Yet he is "astonished". That's interesting.

It's hard to imagine DeLong doesn't know what I am about to say. I imagine anybody with any academic sophistication is aware of it – especially economists. As Thorstein Veblen (an economist) pointed out in *The Theory of the Leisure Class* (1899), a great deal of what professors do, including economics professors, is about signaling high status. In economics, this is done by being highly mathematical. (Same in statistics. In art history, it is done by using big words. In engineering it is done by being theoretical. In many areas of science, it is done by using expensive equipment and having a large lab. In many fields it is done by being useless – e.g., preferring "pure" research over "applied" research.) This is no mystery. Economists think a lot about signaling. Michael Spence wrote an influential [2]paper (which included Veblen's phrase "conspicuous consumption") and book about it, for example, for which he won a Nobel Prize. ([3]More examples from economics.) But DeLong ignores the signaling of economists. Let me propose why economists haven't taken the steps DeLong is astonished they haven't taken: Because it would make them more useful and less mathematical. Thereby signaling lower status.

Why is signaling so common? It is basic biology, yes. But it is also convenient. Here is what Veblen didn't say: It is so much easier to signal than to make progress. Among animals, it is much easier to signal you will win a fight than to actually win one. Among professors, it is easier to use big words than to write clearly. DeLong wants economists to choose progress over signaling. Shouldn't an economist not be astonished when the lower-priced option is chosen?

Joseph Dantes (2011-05-15 05:30:40)

Instead of writing an insightful comment, I will simply signal that I understood your point.

Andy (2011-05-15 06:10:24)

Why do you think the signal DeLong sends is credible? My experience with his blog and debates is that he cares a lot more about status, affiliation, and scoring debate points than progress and understanding.

Sonic Charmer (2011-05-15 06:29:29)

Given that what Professor DeLong evidently 'learned' is that we need "more old-fashioned Keynesians and monetarists" (i.e. more people like him, given more authority/prestige), I'm inclined to say there's signaling all around. But frankly the problem with economics is worse than merely the science being overwhelmed by signaling. It's that the science is pseudo-science, or scientism. What is this 'economics' that people like DeLong practice? Well, there are equations and letters. They invent concepts ('aggregate demand'), give them letters, and play with them in equations on chalkboards. They think they are doing something meaningful here. Then their prescriptions (at least the ones who are 'Keynesian') are all rooted in thinking of the economy in metaphor as if it is a giant hydraulic machine - 'velocity of money', 'boost aggregate demand', 'stimulus' - using mathematical and scientific concepts straight out of 19th century thermodynamics and suchlike. And then it doesn't work. (Unemployment is still near 10 %, four years into the 'recession'.) And what is their prescription? MORE! More 'Keynesians'. This is more akin to bloodletting than it is to a Veblenesque signaling game.

Gunnar (2011-05-15 08:11:17)

Money is just numbers on paper. The only value it has is the value that people \_believe\_ it has. The current USD is not even money, it is a Federal Reserve Note - which is a fancy name for a piece of paper with numbers on it. Real money would be silver and gold coins for example, which carry inherent value. The US deficit results from the US government borrowing those FRNs from the Federal Reserve instead of printing numbers on paper themselves. The people profiting from this scheme

are the owners of the Federal Reserve, who unsurprisingly invented this scheme. These systems are built on lies and deception. Those are really big lies, which makes it hard to understand them. But once you break the barrier it gets easier. Be well.

Jon (2011-05-15 08:51:45)

I thought the Austrians called this recession. Theirs isn't an exact science since they use praxiology to determine things (from what I understand). I talked to people that sold their homes before the crash because it was that obvious, the Austrians were calling it about 4 years in advance. Keynesians are either really off in understanding or they're just liars.

Glen Raphael (2011-05-15 08:52:23)

Nobody knows how to entirely prevent recessions or bubbles. Some people have theories on the subject, but few that are well proven. Most of the relevant economic theories are more descriptive than prescriptive - they can tell you what's happening, but not how to fix it. That doesn't mean macroeconomics isn't a science, just that it's a science like Astronomy, focused on things that are large, slow-moving and hard for us puny humans to change. DeLong thinks "more stimulus" and "more regulation" would have made things better, while others argue at least as credibly that the stimulus made things worse and the regulatory bodies were part of the problem. DeLong doesn't really want "economists to choose progress over signaling", he just likes to signal via claims of "astonishment" that his side is right and should be given more resources. Any time things go badly, anyone can claim "if only they'd listened to me more, things would have been better" but that doesn't mean these claims are credible.

Roger Sweeny (2011-05-15 09:07:37)

Seth, You give two different reasons why economists do too much useless math and theory, and not enough useful prediction and prescription. They are morally different and have different implications. At the end of the second paragraph, you say they do it "Because it would make them more useful and less mathematical. Thereby signaling lower status." Most of us find that morally reprehensible, and hope that shame and introspection will lead economists to better results. In the last paragraph, you say, "It is so much easier to signal than to make progress." Economies are incredibly complex things--and, of course, there is no such thing as an economy that is not also a society and a polity. Economists have failed to answer many important questions because those questions are probably impossible to answer. Even super-intelligent people who cared nothing for status and only wanted to be useful would not be able to answer them. Perhaps my own experience influences me too much but I went through a very high status graduate economics program. I left before picking up a degree because I felt that the important questions couldn't be answered and I didn't want to play pretend.

Seth Roberts (2011-05-15 19:42:55)

Roger, yes, those are two different reasons, I agree. I have a lot to say about the rest of your comment, too, but at the moment don't have time to figure out how to say it.

Paul Sherrard (2011-05-16 14:59:21)

Dr Roberts, I'm wondering how you square the economic crisis with Jane Jacobs' idea that there is no class struggle, only the struggle between innovation & status quo. The recent crisis was the result, not of a defense of the status quo by the powerful, but of a prolonged attack on the status quo on their behalf (the status quo being the Depression-era financial regulatory apparatus). In addition, a huge transfer of wealth from lower to higher classes was effected not by quashing innovation but by embracing it (in financial instruments such as mortgage derivatives and default swaps, to say nothing of innovative accounting practices, risk assessment methods, etc).

Sean Estey (2011-05-16 17:41:42)

Paul, I would argue your assertion that the financial crisis was caused by deregulation. It was in fact the introduction of new legislation beginning in the 70's, including affordable housing policies and land restriction laws, which led to rising house prices, which enabled the bubble in the first place. Creative financing was a downstream consequence of these facts, not the initial cause. In a completely free market, this entire mess would not have occurred.

Paul Sherrard (2011-05-16 18:30:19)

Sean: Interesting idea, but I don't see how it makes much difference to my question. The banking-finance industry spent the past few decades lobbying heavily against the status quo (regulation), and innovating fervently in the use of new instruments and practices (derivatives, creative accounting, etc)—contra Jacobs, who posits entrenched power supporting the status quo and resisting innovation.

Stephen M (Ethesis) (2011-05-16 18:35:56)

Ah, but applied economics, which is really applied statistics (think Freakeconomics for a popular example) is both math and useful. But it is micro economics, not macro.

Seth Roberts (2011-05-17 21:08:42)

Paul, I don't have a simple answer as to the cause of the financial crisis but I do think that derivatives and the like were a kind of pseudo-innovation. They had three strange properties: 1. They solved no obvious problem. 2. They were opaque – the people who bought them didn't understand them. For example, they didn't understand how the rating agencies worked. (By comparison, I really do understand how my laptop works.) 3. They were created with little trial and error. Calling this innovation is like calling a new version of three-card Monte innovation. Civilization has been built on countless innovations that 1. solved obvious problems, 2. are understandable by the people who buy them, and 3. involved vast amounts of trial and error. So the financial innovation you are talking about is a special case. It is really about people nearly at the top of society (Wall Street) figuring out new ways to rip off everyone else. That is different than figuring out stuff from which everyone gains.

Ragout (2011-05-18 09:44:55)

"Derivatives" is a very broad category. Mostly, they function like insurance, and solve the same problem as other kinds of insurance: they transfer risk to those best able to bear it. Mostly, they are perfectly understandable. What's so hard to understand about wheat futures or a put option or a credit default swap? I'm no financial historian, but I think it's safe to say that derivatives have existed for at least a century, and there has been a lot of trial and error over the years. So, criticisms of "derivatives" as a whole are based on ignorance. Certainly, there are particular types of derivatives that fit your critique, complex instruments that solve no obvious problem. In general, I think the purpose of these derivatives is to reduce taxes or get around regulatory restrictions (interest-rate swaps may be an example). Thus their opacity is deliberate: the intention is to keep the government from understanding how taxes and regulations are being avoided.

Paul Sherrard (2011-05-18 09:56:16)

Thanks for the replies! 2 things: (1) The derivatives did solve an "obvious problem" from the banks' perspective: the problem of getting toxic mortgages off their books. And, as is becoming quite clear from the Levin report, this was fully understood by the banks to be their function. (2) A new version of 3-card monty IS innovation. As sure as a better mousetrap is. You can amend Jacobs' idea to exclude antisocial innovation, but I don't see how you can deny that antisocial innovation is still innovation.

Roger Sweeny (2011-05-18 12:19:01)

Seth, 1) Derivatives purported to solve a problem that has been obvious to bankers since there have been bankers: as things change, you don't know how many of your borrowers are going to repay. Derivatives were supposed to lower that risk. Many financial regulations are also supposed to reduce the riskiness of the financial system, so bankers didn't feel too bad when they also used some derivatives "to ... get around regulatory restrictions" (to quote commenter Ragout). 2) For most people, most innovations are opaque. In Arthur C. Clarke's famous formulation, "Any sufficiently advanced technology is indistinguishable from magic."

Roger Sweeny (2011-05-18 12:25:14)

(continued) Most people who buy laptops have absolutely no idea how they work. Some bankers, and some economists, thought they knew how the rating agencies worked.

Seth Roberts (2011-05-20 05:53:03)

Those are fair points. I was trying to say that the new financial products were innovations quite different than the innovations Jacobs was talking about.

Roger Sweeny (2011-05-22 07:35:09)

Seth, I thought this might tickle you. It's from William Allen's memoir of his life as an economist: "All this is not to suggest that mathematics, so prized by the Economics Establishment, was to be denigrated in the mansion of economics—but mathematics was not to be allowed to evict economics and make itself sole, or even major, inhabitant of the mansion. ... By a generation after Cournot, such notables as Walras [1834-1910], Marshall [1842-1924], Edgeworth [1845-1926], and Fisher [1867-1947] were among those who championed mathematical techniques as an essential tool in the economist's toolbox. But used unwisely and naively, it turns economists into pretentious parasites on the rest of the community." [http://econjwatch.org/file\\_download/452/AllenMemoirSept2010.pdf](http://econjwatch.org/file_download/452/AllenMemoirSept2010.pdf) p.15

### **Morning Faces Therapy for Bipolar Disorder (2011-05-16 05:00)**

In 1995, I discovered that [1]seeing faces in the morning improved my mood the next day. If I saw faces Monday morning I felt better on Tuesday – but not Monday. The delay was astonishing; so was the size of the effect. The faces not only made me cheerful, they also made me eager to do things (the opposite of procrastination) and serene. This is the opposite of depression. Depressed people feel unhappy, don't want to do anything, and are irritable. Eventually I found that the mood improvement was part of a larger effect: morning faces produced an oscillation in mood (below neutral then above neutral) that began about 6 pm on the day I saw the faces and lasted about a day. As strange as this may sound, there was plenty of supporting data – the connection between depression and insomnia, for example.

After I had observed the effect on myself hundreds of times, I urged a friend with bipolar disorder to try it. Recently he wrote me about how it has helped him.

Here is the very short story of my experience with this treatment.

I have used your treatment since 1997. As an indication of its effectiveness, from 1999 to 2003 I was completely off of medications, and now I've been off again since August of last year.

I was severely ill when I began the treatment. I was first hospitalized in 1985 for manic psychosis, and I was hospitalized later for suicidal thoughts and then again for psychosis. In 1997 I was 46 years old, taking Prozac, Depakote, and Moban (an anti-psychotic), and I was barely functioning.

The initial reaction, after three days of the treatment, was astonishing. It felt like a giant headache was just lifted off me. But the [new] clarity of mind enabled me to see my awful condition, and I had acute suicidal thoughts for a day or two. After that initial bounce, the improvement in mood was more subtle, but definitely correlated to how early I started looking at faces.

The early years of the treatment were often rocky. You were still working out some of the kinks in the treatment. The biggest surprise came when you found that exposure to fluorescent lights at night cancelled the effect of the faces. Another problem, also having to do with fluorescent lights, arose when I added early-morning bright-light therapy: the start-time and duration had to be adjusted by trial-and-error. At least six times I was one step away from becoming delusional, and then the treatment would pull me back within 48 hours. You were indispensable during those early years because I could call you and you would give me advice and the will to pull through.

By 2003, I had made some good progress. I had moved back to Berkeley, I was living with “normal” roommates instead of with other bipolar guys, and I had even been able to work for short periods. But along the way I had accumulated several minor pains. Back pain and stress made it difficult to get more than 4 hours of sleep. Sleeping pills did not solve the problem. I was scared that I would have to return to the mental health system; I would be a failure at the only thing I ever cared about [using the face treatment to stay out of the mental health system]. I made a pathetic attempt at suicide and wound up back in Herrick Hospital.

It was back to the crappy life—dulling medications, the psychiatrist and the psychotherapist, the support group, a volunteer job. Then, in 2006, the publicity for your diet book motivated me to try the “faces in the morning” treatment again. By that time, you had found that using a mirror was as effective as using videotapes [such as C-SPAN Booknotes recordings], which greatly simplified the process.

By 2009 I had reduced my doses of Prozac and Depakote to only 10 mg and 250 mg, respectively. (I hadn’t needed Moban since 1999.) In August of 2010, dissatisfied with my low energy level, I decided to go off medications completely again. Getting off of Prozac and Depakote gradually was tricky, because Prozac, which can induce mania, has a plasma half-life of about 10 days, while Depakote, which is anti-manic, has a half-life on the order of only 10 hours.

Today, most people would no doubt say that I’m still a loser. No matter, I’m able to enjoy life and relate to others in ways that I never could my entire life. I’m a Total Believer in the treatment. I don’t proselytize, though. People automatically reject the idea, and in any event I don’t want to be (directly) responsible if the treatment doesn’t work for someone. (Example: My nephew has clinical depression; he also has guns. If he tried this treatment, went off of medications, and then for some reason killed himself, my sister would never speak to me.)

The most difficult aspect of the treatment for me has been simply going to bed early. Even though I feel better the earlier I go to sleep, 10:45 pm is the best I can do on a regular basis.

To sum up, I believe you have discovered a powerful anti-depressant treatment that, in my case, has been effective for severe bipolar disorder. As a complete substitute for medications, however, it has entailed serious risks, and it requires substantial discipline to maintain. It is also important to note that “face therapy” is not the only alternative therapy that I use. In addition to the bright-light therapy that I mentioned above, I currently take 3 grams of omega-3 per day in the form of fish oil capsules.

There are a few more details and observations in these blog posts:

Levy (2011-05-16 06:07:41)

This is a very inspiring story. Of course, parts of it are, well, very hard to read. Moving back to Berkeley was quite a move. And the ups and downs, well, all one can say is, More power to you. Do you ever get to a gym? You might look for a tough, and we mean that in terms of discipline, gym atmosphere. Maybe a martial arts type. These things can do wonders. Keep moving forward.

Joe (2011-05-16 15:52:31)

Re the above: with the looming phase-out of the incandescent bulb in favor of the CFL, one has to wonder if we're heading into a period of low-level yet omnipresent mental illness (one that may dwarf the effect of the low-fat experiment we're mired in.) BTW, Seth, when it comes to "automatically rejected ideas", you are the thought-leader. :-)

Around the Web; It's Anthropology Week! | Perfect Health Diet (2011-05-21 11:45:42)

[...] from Seth, his "morning faces therapy" has produced a great result for a man with bipolar disorder. We believe that "circadian rhythm therapies," and bio-rhythm restoring techniques generally, [...]

Michelle Mendoza (2011-05-27 12:08:25)

This is truly a great story. I love hearing about ways people can conquer their personal issues to become successful.

Andy (2011-08-27 11:56:26)

This is a really interesting read. I love reading inspiring stuff like this I was diagnosed with Bipolar at the age of 17 and really had a torrid time at School because there was confusion between me just been a moody teen and Bipolar. Thankfully mental health is taken more seriously these days and the NHS do a fantastic job. (in the UK) There is a stigma still attached to mental health issues. its a real shame that in this day and age that this is an issue For people researching bipolar I write a Blog that is full of my personal experiences and information. I hope you find it useful. Mental Health has positive side that is often overlooked. <http://www.lithiumandchips.com> (for the blog)

### **Comment on "Morning Faces Therapy For Bipolar Disorder" (2011-05-17 05:00)**

In [1]yesterday's post, a friend of mine with bipolar disorder told how he used [2]my faces/mood discovery. It allowed him "to enjoy life and relate to others in ways that I never could my entire life," he wrote. Partly because it allows him to stop taking the usual meds prescribed for bipolar disorder, which have awful side effects.

What do I think about this?

To begin with the obvious, I am very happy that something I discovered has helped someone else. Practically all science has no obvious use. (A tiny fraction is eventually helpful.) In experimental psychology, my field, I can't think of a single finding that's helped many people. Because of this background, managing to help someone via science seems like a fairy tale. It's too soon to say the story has a happy ending – it isn't over – but it is beginning to have a happy ending.

Thank heaven for blogs. Something like my faces/mood discovery is difficult to publicize, yet without accumulation of evidence it will go nowhere. It wouldn't be easy to publish in a psychiatric or psychotherapeutic journal because

I'm not a psychiatrist or psychotherapist. Even if published, the chances of interesting psychiatrists and psychotherapists are low because it doesn't involve a treatment you can make money from ([3]gatekeeper syndrome). It should greatly interest persons with bipolar disorder but they are not the typical readers of the scientific literature on mood disorders. However, like all sufferers, they search the Internet.

In my internal calculus, the story provides what I think of as "industrial strength" evidence. Industrial-strength evidence is evidence that something works in practice, not just in the lab. In a laboratory setting, which to some extent includes me studying myself, you try to keep things constant. You want to reduce noise. Noise reduction makes signals clearer. An effect you can see easily in a lab experiment, however, may be too small to matter outside the lab, where more powerful forces push people around. Whether your lab experiment – in which you have managed to control Force X – has practical value depends on the size of Force X relative to other forces at work outside the lab. An example is the theory behind the Shangri-La Diet. Does that theory tell us anything useful about why people are fat? Does it explain the obesity epidemic, for example? I knew the theory had plenty of truth because it had led me to several new ways of losing weight and had helped me lose considerable weight and keep it off forever. But that was far from showing (a) it was the only thing that controls weight or even (b) one of the big things. Lab experiments can't do that. It's been claimed that obesity is due to a virus. Experiments support the idea. Yet the idea is irrelevant to everyday life, I'm sure. No one has written *How to Lie With Laboratory Science* but it could be written. The only way to find out if a "true" idea explains enough of reality to be useful is to use that idea in real-world situations. Which is what my friend did.

But that isn't the biggest thing. The biggest thing, from my point of view, is that what my friend has done helps keep this idea alive. When it comes to ideas, grow or die. My friend's story keeps the idea alive by expanding it. It gives it a new and personal dimension. It isn't just about mood measurements, it's about living a reasonable life. I've given talks about this idea, but this story makes it much easier to talk about to a general audience.

Joseph Dantes (2011-05-17 05:20:27)

May I suggest the following: You need to look at faces, right? So here's how you accomplish that. And this ties in with something Tim Ferriss talks about... how when he's writing late at night, he avoids depression by having his favorite movie on silent loop in the background. I find motion to be too distracting. So I don't do movies. But I have a wide computer screen... so I have some extra screen real estate. So in the morning, I wake up and read all my interesting RSS stuff and simultaneously play a random slideshow of softcore porn hotties. If faces are good, the rest of the body is even better, right? Seriously though, it's a little weird to just look at faces but very natural to look at naked women, who incidentally have faces with expressions on them. And once you realize that the faces in particular are beneficial, you start paying more attention to the subtleties of the facial expressions, which heightens the enjoyment and the positive effect. And this is something you can leave on all day, for

a steady mood boost instead of just a morning thing. Why not? A favorite comes up and you involuntarily smile. Now that's solid evidence of mood lift. Anyway, to build your collection I recommend stumbleupon's adult section and phapit.com. I use geeqie for the slideshow but I'm on linux, I'm sure someone can recommend a lightweight windows slideshow viewer.

Bob (2011-05-17 10:53:36)

Seth, You wrote: "In experimental psychology, my field, I can't think of a single finding that's helped many people." And: "Industrial-strength evidence is evidence that something works in practice, not just in the lab." A couple of months ago I commented on another post of yours that the logic of subject sampling applied equally to task sampling and that in order for the results of experiments to generalize outside the lab and outside the sample it was necessary to sample tasks and environmental conditions just as we sample subjects. Your reply was that the history of experimental psychology demonstrated that such sampling was unnecessary. I chose not to reply at the time because it was apparent that we have a different understanding of the history of experimental psychology. It is my understanding that the history of experimental psychology is one of failure to discover much of anything that stands up over time and is of any benefit to anyone. Since you say part of that above, maybe you would be willing to toss out examples where the (poor) design of psychological experiments over the last sixty or seventy years has lead to robust, generalizable results.

Seth Roberts (2011-05-17 21:00:35)

"It is my understanding that the history of experimental psychology is one of failure to discover much of anything that stands up over time." My field of experimental psychology is animal learning. In that field, the phenomena of reward learning and Pavlovian conditioning have been repeated thousands of times in countless laboratories. Those two discoveries stand up fine. And they come from experiments that I'm sure you'd describe as poorly designed. There is no sampling of subjects, much less tasks and environments. Is this research "of any benefit to anyone"? Well, the theory behind the Shangri-La Diet is firmly based on Pavlovian conditioning experiments. Without those experiments, no theory – as you can see from what happens when people who don't understand Pavlovian conditioning theorize about weight control. In any case, the Shangri-La Diet has helped many people lose weight. Such as me. The theory behind SLD is not based on any one finding – it is based on many findings put together.

Seth Roberts (2011-05-17 21:10:58)

The faces need to be lifesize. And they are only effective in the early morning. In case you're not joking.

Joseph Dantes (2011-05-18 00:15:10)

I'm not joking. I find it remarkably effective in mitigating the depressive effects of long hours at the computer. Otherwise my mood drops below the point where I can sustain productive work. You do have to make a conscious effort to focus on the facial expressions. Perhaps that's why less than life-size facial photos didn't work. While I appreciate the insight on the importance of the morning exposure, and have started using that to good effect, I also enjoy benefits all day long. Perhaps the naked women increase engagement incentives, whereas faces alone lose their appeal.

Joseph Dantes (2011-05-18 00:21:39)

By focusing on the facial expressions, I mean two things 1. Reading the micro-expressions 2. Engaging or mirroring her state with your own emotions In other words, using her face as a window into her soul, at the moment captured on the photograph. This activates the emotional and social aspects of the brain for a split second, then allowing you to return to your more logical work-mode feeling refreshed. Facial recognition and engagement seem to be a key part of that area of the brain. And of course, I enjoy the "moment" created on an erotic level as well. Which intensifies its emotional vividness.

Porn Productivity Hack – Facial Engagement Edition | Rough Drafts of a Koanic Soul (2011-05-20 11:09:37)

[...] This was originally written as a series of comments in response to Seth Robert's post, Morning Faces Therapy For Bipolar Disorder. [...]

Jazi yechezkel zilber (2011-05-28 03:27:41)

Regarding sampling tasks, environments etc. I am against these procedures that make experiments impossible and very costly. The main thing experimentalists need to learn is to do \*valid\* experimnts (i.e. Avoid anything that biases results etc.). But then proceed to do as much ezperiments as possible in as cheap costs (time energy money) as possible. The present science goes the opposite. Many useless rules for "correct protocol" making things costly and very limited. Then also forgetting the essential critical thinking about validity, confounding parameters etc. Making results costly AND useless

## Percentile Feedback Workspace Available (2011-05-18 05:00)

I have put a requested R workspace on my website so that you can download it. The [1]percentile feedback workspace compares your productivity (time spent working/time available to work) today to previous days. When I started using it, I became more productive. [2]Here is an introduction. [3]Here are all posts about it.

This is not for everyone. You need R installed to use it (of course) and you'll need to know at least a little R. You must edit a function called save.ws so that the workspace is saved in the right place. I have used it under Windows XP.

1. [http://sethroberts.net/about/2011-05-20\\_percentile\\_feedback.RData](http://sethroberts.net/about/2011-05-20_percentile_feedback.RData)

Joseph Dantes (2011-05-18 10:07:13)  
Sweet thanks!

Brian Newman (2011-05-18 12:00:57)  
Thank you!

Ulrich (2011-05-18 13:09:51)  
Great, thanks.

## Six Signs of Profound Stagnation in Health Care (2011-05-19 05:00)

In [1]a recent interview, Tim Harford, the Underground Economist, said,

That's what makes medicine such an effective academic discipline.

By "that" he meant certain methodologies, especially randomized experiments. I disagree with this assessment. My opinion is that health care is in a state of profound stagnation, unable to make much progress on major problems.

Here are six signs of the stagnation in health care (by which I mean everything related to health):

1. The irrelevance of Nobel Prizes. Year after year, the Nobel Prize in medicine is usually given for research that is so far useless (e.g., telomere research) or irrelevant to major health problems.
2. The obesity epidemic. Starting in 1980, obesity rates climbed fast. Thirty years later, doctors seem to know no more about how to cure obesity than in 1980. Low-fat diets, popular in the 1980s, are still popular! Low-carb diets are ancient – the Banting diet became popular in the 1860s.
3. Ancient treatments for depression still popular. SSRIs were introduced in 1988. Cognitive-behavioral therapy began in the 1980s, combining earlier ideas. Neither works terribly well – and notice how different they are.
4. The high cost of ineffective care. Americans pay much more for health care than people in other rich countries, yet American health is no better. All that new technology that Americans are paying for isn't helping. In [2]an article complaining about our education system, Joel Klein, the former head of New York City schools, wrote, "unlike in health care . . . in education, despite massive increases in expenditure, we don't see improved results." Actually, that's exactly what we see in health care when we compare America to other countries. Tyler Cowan makes this point in The Great Stagnation.
5. Statins. A defender of modern medicine would claim that statins were an important innovation. They are heavily prescribed, yes. Yet in recent tests they have been [3]stunningly ineffective – so much so that the earlier favorable evidence has been questioned.
6. The stagnation has become invisible – the normal state of affairs. Allowing Harford to make that comment. Harford, like Dr. Ben "Bad Science" Goldacre (whom Harford praises), believes you judge science by whether it follows certain rules. By making various rules (e.g., the need for placebo controls) and then following them, medical researchers have drawn attention – at least Harford's and Goldacre's – away from lack of progress. They're making progress, they say, because they're following self-imposed rules. Well, what if the rules make things worse? (For example, placing high value on placebo controls may draw attention away from non-pill treatments.) Better to judge by results.

What do you think are the clearest signs of health-care stagnation – if you agree with me about this?

Nancy Lebovitz (2011-05-19 05:34:40)

How about the idea that the obesity epidemic is a problem, considering that "overweight" people live a little longer than "healthy weight" people? [1]Chart.. [2]Article about chart. I'm not convinced that medicine is stagnating in all areas- people do seem more apt to recover from cancer than they used to be.

1. [http://www.amptoons.com/blog/wp-content/uploads/2006/09/rr\\_by\\_bmi.png](http://www.amptoons.com/blog/wp-content/uploads/2006/09/rr_by_bmi.png)
2. <http://www.amptoons.com/blog/2009/02/05/should-a-59-160-lb-woman-want-to-lose-35-pounds/>

charlie (2011-05-19 05:54:35)

That 75 % of all medical expenses go to maintaining someone's life for an extra six months....

john (2011-05-19 06:30:24)

First, many health care revolves around ideas that are questionable in the first place (like statins), and many doctors dismiss nutrition as being silly. Americans in general have terrible diets, and it's a long way from improving. It seems like preventive medicine just means going to the doctor more often, so he can diagnose you. I think the technology point you made ties in well with nutrition/prevention. Everything is developed for diagnosis and treatment, but treatment is often ineffective because of unhealthy lifestyles. Of course, nobody considers that—we just keep pushing "better" "treatments."

vs (2011-05-19 07:57:59)

A clear sign of health-care stagnation: it's not helping us live longer. From David H. Freedman's recent book "Wrong": On distinguished professor put it to me this way in an e-mail note: "Our life expectancy has almost doubled in the past seventy-five years, and that's because of experts." Actually, the vast majority of that gain came earlier in the twentieth century from a very few sharp improvements, and especially from the antismoking movement. As for all of the drugs, diagnostic tools, surgical techniques, medical devices, list of foods to eat and avoid, and impressive breakthrough procedures and technologies that fill medical journals and trickle down into media reports, consider this: between 1978 and 2001, according to one highly regarded study, U.S. life spans increased fewer than three years on average—when the drop in smoking rates slowed around 1990, so did life expectancy gains.

Jazi zilber (2011-05-19 09:13:19)

The problem is with imposing too many rules and procedures, while researchers have no real understanding of why these are needed. Designing a formal study nowadays, involves you in a myriad of useless rules, most of which are perfectly unrelated to getting valid results. Randomising groups + double blind, is not the main barrier to having results. Most of the effort get spent on endless more details that naive students are told in school that has nothing to do with getting scientifically reliable results (think approval committies). It is absurd. They say you need many studies to prove something, which is empirically true, but laughable logically. If you do one really good experiment, you got to get valid results. The reason so many experiments get refuted is because people do experiments in invalid ways, or have no idea how to handle data. They only know that you need much work and endless procedures. I wrote elsewhere on the problem of focusing on the measurable and on what experiments are easily done, The academic bias. <http://yzilber.blogspot.com/2008/08/academic-bias.html>

dearieme (2011-05-19 09:38:09)

Thanks, Nancy. It seems that a fatso like me is somewhat safer than someone in the lightest subset of the "normal" range. By the by: my cardiologist told me recently that the results of my angiogram were "normal". I asked him whether he meant "normal" as in commonplace, or "normal" as in desirable. He goggled at me; I inferred that not only had no-one ever asked him before, but that he'd never himself reflected on it before. Doctors, eh?

Joe (2011-05-19 10:05:21)

"How about the idea that the obesity epidemic is a problem, considering that 'overweight' people live a little longer than 'healthy weight' people? Chart.. Article about chart." I wonder how and when they calculate those weights? At death? After 12 months of radiation/chemotherapy, for example? Until we know more about things like that, the chart really isn't meaningful. At least not to me. Joe

kxmoore (2011-05-19 10:44:16)

Seth, perhaps a failure to understand science lies at the heart of our healthcare follies. Here is a great video by Tom Naughton. Funny too. [http://www.youtube.com/watch?v=y1RXvBveht0&feature=player\\_embedded#at=221](http://www.youtube.com/watch?v=y1RXvBveht0&feature=player_embedded#at=221)

nix (2011-05-19 11:51:11)

I disagree with you on the stagnation of mental health treatments. In the past five years, medication advances for mental illness have been tremendous. There is a much greater understanding of the nuances of mental illness and many, many more medication options available. As someone who has had a lifelong struggle with dysthymia and major depressive disorder, I can attest to that personally. After trying treatments and giving up so many times earlier in my life, I was amazed and relieved by just how much the field has changed. "SSRIs were introduced in 1988. Cognitive-behavioral therapy began in the 1980s, combining earlier ideas. Neither works terribly well — and notice how different they are." But combined they've been shown to be quite effective. I believe, very strongly, that the main problem in the treatment of mental illness in America is the disconnect between therapy/close observation and medicating. (I can't speak for the rest of the world as I'm not familiar with other mental healthcare systems.) The standard in the USA has been for a psychiatrist to see a patient once a month for 15 minutes. Unless they're getting reports from the patient's therapist, there's no way the psychiatrist would be able to accurately assess for themselves how well the patient is doing. The doctor would be relying 100 % on the patient's self-assessment and their observation of the patient. That day's mood or recent circumstances can easily taint a patient's perception so that the report they give their physician would be inaccurate (and even more likely, incomplete). Even the doctor's observations could easily be misinformed. For instance, the patient might have just had a hard time finding a parking spot after running later than they'd have liked to the appointment. That's not a major enough life event that they would necessarily mention it, but it would affect their body language and behavior. Even more than that, the standard protocol has been to wait 2-8 weeks between making medication adjustments (changing doses or prescriptions), which, to someone suffering from severe mental illness, is an eternity-especially when they're fully aware that if that next switch doesn't work, they'll have to wait several more weeks to try something else that's new. It's no wonder so many patients give up on meds, especially when those adjustments are often made on faulty information. A health care provider meeting with a patient on a weekly basis or so and providing both therapy and medication fixes all those problems. But it's a rare patient who even knows that option even exists. Psychiatry is the black sheep of the medical field, and it doesn't help that some of the medical students who end up in the field are there because they weren't good enough to get into their first-choice specialty and they see it as a cushy job. It has the lowest malpractice rate of any medical specialty, dermatologist-like hours (without the uber-high competition to get into the field), and so on. I'm actually starting grad school next January to become a psychiatric mental health nurse practitioner so that I'll have the prescribing rights but will still be able to do therapy. /soap-box :)

Darrin Thompson (2011-05-19 12:31:57)

Autism.

eric (2011-05-19 19:48:57)

OK, I'll bite on Point 1. Barry Marshall recently got a Nobel for demolishing entire industries (with a bit of personal science) and I note the 'so far useless' qualifier in the example of telomeres. The 'health' of the ends of chromosomes and 'health/redox state' of cells are correlated and life can be debilitated and short in diseases where telomere repair is compromised. E.g., ataxia telangiectasia, which is kind of a disease of premature aging, in part is caused by loss of DNA repair and subsequent chromosomal instability. It is in fact a genetic, genomic/cancer, neurodegenerative and metabolic doozy that includes immune, insulin signaling and cellular respiration irregularities etc. It may turn out that telomeres are the useless bit of research into genomic and metabolic damage repair mechanisms but that will only be obvious in hindsight. For a not uncontested metabolic and nutritional slant on cancer management - including the possible link between telomerases, glucose metabolism and cellular respiration - see Seyfried 2010 'Cancer as a metabolic disease'.

Kevin R. Bridges (2011-05-19 20:10:30)

I wanted to point out that you appeared on the Discover Magazine blogs today. [http://blogs.discovermagazine.com/discoblog/2011/05/19/ncbi-rofl-holy-correlation-batman/?utm\\_source=feedburner&utm\\_medium=feed&utm\\_campaign=Feed%3A+DiscoverDiscoblog+%28Discoblog%29](http://blogs.discovermagazine.com/discoblog/2011/05/19/ncbi-rofl-holy-correlation-batman/?utm_source=feedburner&utm_medium=feed&utm_campaign=Feed%3A+DiscoverDiscoblog+%28Discoblog%29)

Seth Roberts (2011-05-20 05:35:25)

Barry Marshall, "personal science"? No he did his self-experimentation as part of his job, not to help himself. It isn't much of a

counterexample because ulcers are not a major health problem and because the bacterium that supposedly causes ulcers lives harmlessly in a billion people. The big and important question that Marshall failed to answer is what distinguishes infected people who get ulcers (1 %?) from infected people who don't get ulcers (99 %?).

Seth Roberts (2011-05-20 05:39:58)

It isn't progress to come up with 20 more medications. Number of treatments doesn't matter, what matters is their effectiveness. It's progress to come up with something that works much better than existing treatments.

Seth Roberts (2011-05-20 05:42:39)

The weights are often measured prospectively. For example, in 1970, and the death rate after 1970 is measured.

Seth Roberts (2011-05-20 05:45:57)

yes, that's a good example: little improvement in life expectancy.

Seth Roberts (2011-05-20 05:53:34)

thanks, hadn't seen it.

Allen K. (2011-05-20 13:36:56)

The fact that cancers are still treated with one drug at a time, rather than with a cocktail as the AIDS activists helped make standard for AIDS sufferers. In both cases the disease is a moving, evolving target, and the best outcomes come from hitting it on all fronts. (Google results about "treatment-naïve" patients; they do better on new drug treatments than ones who have already had other, \_unrelated\_, drug treatments.) Of course, giving someone several drugs is bad science. (And more expensive, and with more chance of weird side-effects, yadda yadda yadda.)

Nancy Lebovitz (2011-05-21 02:30:13)

I wonder how much stagnation in medical care is the result of lack of knowledge, and how much is the result of inadequate practice. For example, I've got a lot of anecdotal evidence that it's hard to find a doctor who will listen and think. (The estimated percentage is pretty low- would people care to post their own estimates? I'm concerned that I've been anchoring the responses I've been getting because I've been giving a number.) There've been the work showing that doctors aren't reliably washing their hands, and that checklists make a huge difference to hospital outcomes.

tom (2011-05-22 06:09:45)

The joke was the Tennessee family that sent its recently-adopted Russian son back to Russia in April 2010 after he proved difficult. [http://www.msnbc.msn.com/id/36322282/ns/world\\_news-europe/](http://www.msnbc.msn.com/id/36322282/ns/world_news-europe/) The story was 6 months old when the cartoon got published in Oct 2010. I am adjusting down my opinion of Manjoo (and his many readers who-according to him-did not know the inspiration for the cartoon). Mankoff was just answering another random question in an open internet forum.

Seth Roberts (2011-05-22 08:16:20)

Tom, thanks for explaining the mysterious cartoon. After reading the news story from which the cartoon derived (the boy sent back to Russia), I think the original story is incredibly sad and not something to make cartoons about.

## **Percentile Feedback R Workspace Updated (2011-05-21 05:00)**

I fixed a few problems and eliminated the one Windows-specific function so it can be used with Macs.

The new version is [1]here.

1. [http://sethroberts.net/about/2011-05-20\\_percentile\\_feedback.RData](http://sethroberts.net/about/2011-05-20_percentile_feedback.RData)

---

Hamish Barney (2011-05-21 22:56:47)

I'm interested in trying your program. I've downloaded the workspace and installed R (ver 2.13.0). When I load the workspace into R though it doesn't seem to do anything. Sorry for the ignorance but could you please give me some tips on how to get started with the software? Thanks a lot! Hamish

Seth Roberts (2011-05-22 00:08:08)

You have to know a little bit of R to use it. R workspaces don't "do something" when loaded. You need to run the functions they contain. I'm afraid my advice to you is to study R.

Hamish Barney (2011-05-22 04:25:56)

I was just confused about the way a workspace would work given the way workspaces work with other IDEs that I have used. I assumed it would show the set of files with the source code for the percentile feedback software. I work as a software

developer so I'm not adverse to getting my hands dirty. That also means that I know how hard it is to understand other peoples code and how they intended it to be used no matter how well written it is. For those interested in using this software I've done a little bit of fiddling and reading about R. Running "c(lsf.str())" from the R prompt will give you a list of the functions that were loaded as part of the workspace. You can view the source for a given function by typing its name at the prompt (e.g. "work.start"). This will also give you a clue about the parameters the function expects. The software expects a file ('C:/percentilefeedback.RDataTmp') to exist in order for most of the functions to work. I created an empty file but that didn't placate it. I'll keep fiddling. If anyone gets it to work let me know what steps you followed. Seth, have you considered putting the source code into a version control system like bitbucket.org or github.com?

Seth Roberts (2011-05-22 08:06:04)

Thanks for the suggestions and info. I didn't know about bitbucket.org and github.com. To see the workspace contents, type ls() To see the program in action, type work.plot()

Joseph Dantes (2011-05-26 11:46:42)

I didn't have much luck with installing this in Ubuntu and it doesn't look like I will. For total noobs, .rdata's are autoloaded when R is started in that directory. I'm gonna try it in Wine.

Joseph Dantes (2011-05-26 12:10:25)

I got it semi working in Wine. The first time I ran work.plot(), no result. Then I tried fix(save.ws). Didn't edit anything, just closed the editor. Ran work.plot() again. This time it appears I have all Seth's work data, except my trend line doubles back and terminates in the upper left hand corner. Pretty screwy. No idea where to go from here. Maybe releasing it to Github will build a community that can troubleshoot/document. I went through the functions, trying them all, didn't wind up much the wiser, got a number of different errors. A basic instruction set would include: 1. How to clear seth's data 2. How to enter new data

Seth Roberts (2011-05-27 07:32:22)

It works with Windows XP and Mac. Haven't tried Ubuntu.

Zans (2011-06-19 09:38:14)

Great script, Seth. Could you upload your arithmetic one as a downloadable workspace as well? Somehow i is not displayed properly on my browser so when I try to run it I get many error messages.

## **Morning Faces Therapy For Bipolar Disorder: A Story (Part 1: Background) (2011-05-22 05:00)**

In the mid-1990s I discovered that [1]seeing faces in the morning raised my mood the next day. If I saw faces Monday morning, I felt better on Tuesday – not Monday. This discovery and many other facts suggest that we have an internal oscillator that controls our mood – in particular, how happy we are, how eager we are to do things, and how irritable we are. For this oscillator to work properly, we must see faces in the morning and avoid faces and fluorescent light at night.

In rich countries, almost everyone gets nothing resembling the optimum input. One of the problems this may create is bipolar disorder. A week ago I posted [2]how a friend of mine used my faces/mood discovery to control his bipolar disorder. After that post, a man I'll call Rex wrote to me thanking me – that post had inspired him to try to control his own bipolar disorder that way. Before knowing anything about whether he would be successful, I decided it would be good to follow and record what happens. Either way – successful or not – it should be revealing.

I am going to post his story in several parts. The first few parts are background.

My first full-blown bipolar episode was at 29 years of age. (I am now 37.)

I was a civil engineer working for the government in an Eastern State. I had self-diagnosed myself as having Seasonal Affective Disorder (SAD), also known as the morning blues. The symptoms are mild to severe depression, lethargy, apathy and weight gain. A form of treatment for SAD is the light box. Mine is an Apollo GoLite Box. As soon as I read about this device, I was excited. It came via UPS. I plugged it in during my lunch break soon after it arrived. By the end of the work day my mind was in overdrive. I was a total motor mouth, with racing racing thoughts and unusual activities such as inventing things, writing songs and books for the first time. Friends knew I was totally not myself. I went without sleep for days at a time. I began drinking heavily and not going to work. My mind could not rest. Alcohol or extreme exercise were the only medicine. I stopped eating, lost about 30 pounds in 30 days. I became paranoid and shut everyone out of my life including my friends, family, and co-workers. I was buying hundreds of books and dozens of bottles of supplements. Overall I was turning into a different person with new interests.

Finally my parents stepped in because of my isolation and irresponsible behavior. This led to a three week outpatient clinic stay in Illinois. Right away I was diagnosed as Bipolar I. I was vaguely familiar with it, but was quite stunned I had it. On the other hand, it was a huge relief to have a name to this craziness I was feeling. I was put on four medications and went through extensive therapy, including talk therapy, group therapy, family talks, and letter writing. It was a wonderful experience that helped me to deal with painful past experiences. It had an excellent scheduled program with early-morning group therapy and prayer. [Note the morning exposure to faces.] This was a Christian-based psychiatric clinic. Then daily small classes on mental health issues, then one-on-one discussions with a licensed therapist and plenty of other group activities and meals on the town. Lots of love, support and scheduled work.

That was an ideal setting. After three weeks I came home. I slowly went back to those sad, frustrated days. The drugs seem to stop working. My moods began turning sad or mad, for no particular reason. [Note that this downturn happened soon after exposure to morning faces – via group therapy – stopped.] The frustrations of an unfulfilled, boring and dead-end career grew worse. Maybe the worst was a lonely life. Silence in the mornings and only late-night television before bed.

The disappointments of my life were bad, but the bipolar manifestations of the highs and lows seemed to magnify all emotions to the nth degree. My medications were replaced by the new ones, without expired patents. Perhaps I have been prescribed ten different anti-depressants overall, sometimes in combinations, but I only found relief in narcotics such as prescription xanax or klonopin.

They truly numbed the pain, but led to regrettable behavior. I took to cutting myself as a sort of punishment for the unwarranted guilt and self-absorption (for feeling depressed and angry) and to ease the pains with the endorphin releasing that was given by cutting with a razor blade. It seems insane now, but at the time it was the quickest release. These cuttings not only led to my first surgery, but led me back into a different psychiatric hospital in Vanderbilt at age 31. I had a tendon transfer surgery from my the top of my wrist to closer to my thumb, where I had severed my tendon. It was very embarrassing to my family and myself. I came clean to my employer and became eligible for FMLA (The Federal Medical Leave Act).

During these last couple of years, my manias have been much rarer and weaker. I faithfully take my medication daily. I still experience mild depression, but to a lessor extent, a more numbing feeling. I still feel sad but not the weepy, nostalgia I felt overwhelmed with previously.

To be continued.

---

Joseph Dantes (2011-05-22 05:43:34)

Damn. I see a lot of my potential life trajectory there. Except for me it was heavily diet driven. But the faces and light were definitely factors that have impacted me as well.

Scott Pierce (2011-09-14 04:29:03)

Hi Seth, For the last few weeks, I have been looking for more efficient ways to add faces to my morning. I tried the bloggingheads (without sound) but I wasn't thrilled with the result. Then I came across picasa. I have been using picasa's face recognition to catalog my family's pictures and once I had them all tagged by the face that was in the picture, I could easily create slideshows. Then, after uploading them all to the web, I started using a web browser and running slide shows as more convenient. But now I just run a generic slideshow of all the faces on picasa. I never see the same slideshow twice and I can run it as long as I want.

### **Health Care Stagnation: Sleep (2011-05-23 05:00)**

The January 2011 issue of Bottom Line/Health has an article called "Dirty Drugs" about popular drugs with bad side effects. It is based on an interview with an assistant professor of medicine at Harvard named James Rudolph. It contains the following:

Insomnia. Most OTC drugs taken for insomnia, including the allergy medicine Benadryl and sleep aid Sominex, contain diphenhydramine. It can cause constipation, difficulty concentrating, urinary retention, and trouble with eye focus – and stays active in the body for 12 to 18 hours, which can cause next-day grogginess.

My advice. Avoid taking diphenhydramine for insomnia.

Better. Practice good sleep habits. Examples: Go to bed at a reasonable hour, and maintain the same schedule every night. Exercise regularly but not within two hours of bedtime – it will make falling asleep more difficult. Take a warm bath before bed to help you relax.

I agree, insomnia drugs are bad news. But the "better" advice could be a hundred years old.

[1]Effect of one-legged standing on sleep. [2]Six signs of the profound stagnation in health care.

---

charlie (2011-05-23 08:02:09)

Great point, but I'd say sleep – along with nutrition, weight loss, and a variety of other syndromes – are sub-medical. How many people see a doctor complaining about sleep disorders? And given the costs, should they?

Patrick (2011-05-23 11:11:51)

You're keeping up on Bottom Line all the way other there in Beijing?!

Nancy Lebovitz (2011-05-23 17:28:38)

charlie, sleep apnea is one major cause of sleep problems, and while the medical solutions (CPAP etc.) don't work for everyone, they seem to work very well and safely for a lot of people. CPAP strikes me as being somewhat in the spirit of Seth's approach— I don't know whether it started with self-experimentation, but it does seem like a fresh, practical look at a problem.

Seth Roberts (2011-05-23 17:44:14)

There are several anti-insomnia drugs.

Randy (2011-05-23 20:34:30)

I recently discovered that eating fresh spinach helps me sleep quite a bit better, so I've started eating spinach salads with dinner. Without fail, when I wake up the next morning I can tell I had a much deeper sleep than normal. I've never noticed this effect with cooked spinach or frozen spinach, only fresh. What I've read indicates it's due to the magnesium. I've been meaning to try a magnesium supplement to see if I get the same effect, but haven't gotten around to it yet.

Sam Schulman (2011-05-23 23:40:06)

"I'd say sleep — along with nutrition, weight loss, and a variety of other syndromes — are sub-medical." I agree - and a good sign of its sub-medicality is that the Dr. Rudolph's advice to those with sleep problems is "go to bed and get a good night's sleep - oh, and don't have sleep problems."

Seth Roberts (2011-05-24 06:25:33)

That's fascinating, Randy, I will test it on myself.

B.B. (2011-05-25 13:56:43)

I am curious about your views on using melatonin. I find it helps with sleep. Also, the amino acid typtophan seems to help relaxation to help sleep.

*Graduate school in the humanities is for the already-privileged.* Especially the Art department. The hottest girls were always in the Art dept. Their moms were trophy wives, and their daughters could study art, secure that their trust funds would cover that pesky "making a living" thang. :-)

### **"Stuff of Seth": Faces/Mood and Anticipatory Waking (2011-05-25 05:00)**

After trying the Shangri-La Diet, [1]Jazi yechezkel zilber found that other aspects of my research ("stuff of seth") were relevant to his life:

Years ago, I was part of a community where people would be up early praying etc. For an hour and then eat together. I noticed that going there in the morning was good for me, but was puzzled by the effect. I hypothesized it was the social effect per se.

At some point, I stopped this (what the hell do I have with religion and prayer?) and noticed that I got depressed. I remember that the depression came with a delay. It was funny to see it, as I could not make sense of it. But this I remember well. The depressive effect was not the same day as not going to the prayers but tomorrow (or later?).

I was not having early awakening then. Afterwards, I started having periodically early awakening, I cannot remember the frequency, but it was there and annoying. Now when going to the community, I had two hours between awakening and eating. Whereas at home I would eat immediately after waking. Another thing that puzzled me was how I came to wake up naturally \*before\* my scheduled wake-up time. I used to wake up much later. With food anticipation it makes perfect sense. I woke up two hours before conditioned feeding.

The Amish have extremely low rates of depression – and eat communal breakfasts. The story about early awakening reminds me of a student who told me when you told us this in class I didn't believe it but lately I started waking up too early and was puzzled until I realized I had changed my breakfast.

1. <http://boards.sethroberts.net/index.php?topic=8001.msg103539#msg103539>

---

q (2011-05-25 06:44:07)

do people who ride mass transit in the morning have lower rates of depression?

Seth Roberts (2011-05-25 09:01:34)

You need to look people straight in the face to get the benefits. What you see during a conversation. I have found that is very hard to do via mass transit.

dilys (2011-05-25 12:16:28)

I do think "stuff of Seth" is a phrase that will have legs... This material interests me because I expect some day in the middle distance to look at retirement-and-beyond housing programs. I notice that the most well-regarded place in my city has excellent

dinners, but people are on their own for breakfast and lunch. It strikes me that if I moved there – or elsewhere – I would try to spearhead a cadre to have breakfast together, even if they are not a natural seamless social group otherwise. (Fortunately I enjoy cooking and serving simple meals.) The retirement programs sponsor lots of social features for the apparent purpose of keeping depression at bay; but not in the relatively early morning. In fact, I now think I will keep my ear to the ground in my current homeowner's association for a chance to set up something. And do some very simple kind of record-keeping of the results. Here's to further testing of Stuff of Seth!

Rachael (2011-05-25 16:09:18)

The waking up thing works in the other direction too: I had a really hard waking up on time for years, I started eating a higher protein/fat breakfast with about double the calories of my old breakfasts and now I wake up on my own about an hour before my breakfast time, which is great, since I lie in bed and read and have time to get dressed, etc.

Seth Roberts (2011-05-25 21:31:43)

around the same time I discovered that breakfast is bad for sleep I discovered that the faces you would see at a communal breakfast are very good....

Thomas Seay (2011-05-26 09:19:21)

Happy for Dennis. I am sure though that the Paleo diet is not optimal for everyone. It is a very seductive narrative that our ancestors ate such and such and that that is the way we should eat. However, leaking through the cracks over on PaleoHacks are stories of people not doing that well on Paleo. I already ate pretty well before trying Paleo (I've been doing it for a few months now, though I am starting to abandon it now) and the results have been pretty dismal. Reduced libido, reduced muscle mass, chapped lips, more sensitive to stress, poor sleep.

Nancy Lebovitz (2011-05-26 11:04:46)

Thomas, thanks. Information about failures of various techniques intended to improve quality of life can be hard to find. \*\*\*\*\*  
Supposing that low cholesterol levels are bad for people and those low levels aren't caused by drugs, what can people with low cholesterol do about it?

## **The Romance of Tracking (2011-05-28 22:05)**

I am at the First Quantified Self Conference in Mountain View. The attendees are much more relaxed and cheerful than at the academic conferences I've attended, presumably because they chose to come. Some are from Europe. My overall take is that the conference's theme is the romance of tracking, in the sense that the typical presentation is something like: isn't it wonderful that I'm measuring this? Or hypothetical. (Of course, the research presented at typical academic conferences is almost never shown to have practical value.) I think this is entirely reasonable. In my experience, it is very hard to learn something clearly useful and takes a long time. For example, I measured my sleep for about 10 years before figuring out how to improve it.

[1]Sean Ahren's presentation was one of the best I heard, and illustrated the difficulty. He has Crohn's Disease. He wondered if hookworms would help. Day by day, he measured how much pain he felt, and for some of the time took hookworms. There was no clear difference between the two periods (with and without hookworms). He learned plenty of useful stuff – how easy/difficult it was to do the measurements, what the data look like, the apparent ineffectiveness of one brand of hookworms – but when contrasted with the goal of learning how to reduce pain from Crohn's, it doesn't seem like much. Perhaps the average Crohn's sufferer would say it's great you're doing this but think how does this help me? I think his observations lasted about 8 months. Perhaps if he continues for 6 years, by then the amount of learning will be larger and more tangible. Overall it's a good example of the way scientific progress and job don't mix well. When you have a job, you make tangible progress quickly: you fill someone's order, for example. They wanted something, you gave it to them. Tangible. Whereas trying to clearly improve one's Crohn's Disease might take ten years. Too long if your motivation is connected to making a living. Too long for professional scientists.

At a breakout session on sleep experiments, I learned that someone had great success wearing blue-blocking glasses (which look orange) after 9 pm. Something I want to try. I've heard about these glasses before but these results were especially impressive. The glasses quickly reduced how long it took him to fall asleep. Someone else was told he had sleep apnea. But when his acid reflux got better, so did his sleep.

You can read about many talks, including mine, in great detail at [2]Ethan Zuckerman's blog.

1. <http://seanahrens.net/>

2. <http://www.ethanzuckerman.com/blog/>

---

Wilhelm (2011-05-29 05:30:15)

This blue-blocking glasses thing sounds interesting. And it makes totally sense. I have noticed improvements in my sleep by looking in a daylight lamp (the ones against winter depression) throughout the day. And the newest iteration of these lamps does only use blue light. So it is the blue part of the light that seems to do the job in the eyes. And of course in the evening

we want want to avoid simulating it to be midday. So blocking away the blue part might be very helpful (especially when one is looking a lot in computer displays or works in a bright environment). I will definetly try this.

Chase Saunders (2011-05-29 07:32:26)

Seth, check out a program called Flux (F.lux?) which gradually filters blue out of your computer monitor after sunset.

Cakeb Cooper (2011-05-29 09:11:25)

Do you know if the blue blockers were a common 'over-the-counter' variety, or medical grade specifically designed to block out the blue wave lengths that can disrupt sleep in the evening? I remember years ago trying to find blue blockers specifically made and marketed for the latter, but never could find any so just settled for some amber clip-ons, but I've always wondered if there as good as those used in the John Hopkins sleep research where I first got the idea from.

Kira (2011-05-29 09:14:21)

Hi Seth, You might find the article on this topic at: <http://www.psycheducation.org/depression/LightDark.htm> to be useful. We have started using the amber glasses with our daughter who is ultradian cycling bipolar, hoping to reset the circadian rhythm. You might be interested in the Dark Therapy link on that page. We are also considering some blue light therapy or a dawn simulator in the winter months (we are in Canada so winter days are short).

TomGinTX (2011-05-29 15:00:37)

I bought a Pair of BluBlockers many years ago. I think I got them mail order. That was before the net. Now You can get them at <http://www.blublocker.com/>

## **Snoring and the Shangri-La Diet (2011-05-29 13:00)**

Over at the SLD forums, [1]Newbie Numpty has lost about 50 pounds in four months. His starting weight was 320 pounds. Recently [2]he reported:

My wife tells me that I have stopped snoring - this is something I've done for years (decades) so it could actually mean that I am now at a lower body fat that I have been for a number of years - no way to tell. But a great thing for sleep quality - I've spent money on nose strips and mandibular extension devices to help with this, SLD is again a cheaper fix!

1. <http://boards.sethroberts.net/index.php?topic=7776.0>

2. <http://boards.sethroberts.net/index.php?topic=7776.msg103604#msg103604>

---

Robert Conn (2011-05-30 03:03:23)

Let me tell you from personal experience diet is everything wehn it comes to stopping snoring and has changed my life. I lost 10 kilos and was able to stop snoring in 6 months

q (2011-05-30 05:05:47)

it stopped my snoring as well. i attributed it to weight loss pure and simple.

## Why Does Personal Science Matter? (2011-05-30 05:00)

"Why does personal science matter?" is the title of [1]my talk at the First Quantified Self Conference, which I gave two days ago. My answer to that question is personal scientists are more likely to make useful discoveries than professional scientists. Relative to professional scientists, personal scientists have two big disadvantages (less resources, less knowledge) and three big advantages (more time, more freedom, and more desire to be useful). Over the last half-century, the disadvantages have been getting smaller – the personal scientists have been catching up – causing them to overall move ahead of (= have a greater likelihood of making useful discoveries than) professional scientists.

The data behind this answer fall into two groups: (a) the profound stagnation in health care and, by contrast, (b) innovation from personal scientists. A self-serving example is obesity. Mainstream treatments for obesity are ancient. The "eat less, move more" advice was common in the 1950s. Low-fat diets became popular starting in the 1960s. The first popular low-carb diet was introduced in 1864. In contrast, the Shangri-La Diet is based on new ideas. It took far longer to develop (about 15 years) than any professional weight-control researcher would have time for.

I worked harder on this talk than any talk I have ever given. I gave [2]a kind of rough draft a month ago and more recently I practiced it three times. After that I tried to memorize a few sections, such as the beginning and the end. The feedback has been the best I've gotten for any talk I've given so the whole thing has been great. I feel strongly about the overall message, which I don't think is obvious, especially to me. It took me a very long time to have a good answer to why I was finding useful stuff (about acne, weight, sleep, and mood, for example) that the experts didn't know.

## Highlights of the First Quantified Self Conference (2011-05-31 14:17)

The First Quantified Self Conference happened last weekend in Mountain View. It resembled a super-duper QS meetup: more talks, more varieties of expression (short talks, long talks, booths, posters, breakout sessions, panels), people from far-flung places, such as Switzerland, and more friends.

Above all, it felt sunny, after a long overcast. Something I'd done most of my life was now enthusiastically being done by many others. Other highlights for me:

Talking with [1]Steve Omohundro, an old friend I hadn't seen in years. After I saw him on the attendee list, I aimed it at him. After it, he came up and said he really liked it. Mission accomplished :-). Like so many smart people, he has started to eat paleo.

Meeting John de Souza. I really admire what he has done at [2]Medhelp ("the world's largest health community"). I like to think that, in the future, the first thing you'll do when you have a serious health problem will be to contact others who've had that problem.

[3]Christine Peterson's poster. She measured her sleep with a Zeo for three months. Her poster showed how various things, such as caffeine consumption, correlated with sleep measurements, such as REM time. I believe the most important Zeo measurement is how long you are awake during the night (less is better). Christine's data showed a strong correlation between her score on Zeo's [4]Sleep Stealer's index (you get points for all sorts of things, such as alcohol consumption, that studies have shown disrupt sleep) and how long she was awake at night. With a high score, she was awake twice as long (about 1.5 hours) as with a low score. This shows the practical value of the Zeo. Assuming that the correlation reflects cause and effect, it's now clear how she can improve her sleep (reduce her Sleep Stealer score). It also shows that what's true for other people is true – in the sense of helpful – for her.

The difference between two breakout sessions. Robin Barooah and I ran two breakout sessions about self-experimentation. In the first (many attendees), we talked about 15 % of the time. In the second (six attendees), we talked about 5 % of the time. In the second, but not the first, it became clear that everyone had something they wanted to talk about. If they could talk about it, they were pleased.

Migraines. I met a woman who used self-experimentation to figure out that her migraine headaches were due to common household chemicals. Doctors had repeatedly told her she had a brain tumor. One doctor had proposed trying twenty-odd medicines one by one until one of them worked.

Speaking advice. Melanie Cornwell, a friend of Gary Wolf's, gave me advice about [5]my talk. I'm sure her advice will help me in the future.

Mood improvement via sharing. At an excellent mood measurement breakout session run by Margie Morris, I learned how Jon Cousins had tracked his mood for several years and then started to share it with a friend. The sharing had a huge positive effect. He has started [6]a website called Moodscope to help others do this. At the same session Alexandra Carmichael told about sharing mood ratings with someone who, at first, was not an especially good friend but who became her best friend. The sharing improved her mood ratings and curiously their moods become more synchronized.

So I enjoyed the conference on several levels: socially, professionally, and intellectually. Above all, as I said, it was a relief to finally meet others with similar values and goals.

eri (2011-06-01 00:04:21)

Yes, it was very much like a super-duper QS meetup! I really enjoyed myself and look forward to the next one. What I didn't like was not having enough time to see everything! So, thanks for this summary. I'd really like to check out Christine's poster. Do you happen to know where there might be a copy online? Also, what speaking advice did you receive? (Incidentally, I asked Christine for speaking advice at the conference. I'll be doing my first keynote at OSCON this summer and wanted her input. I also got great recs!)

Seth Roberts (2011-06-01 05:29:30)

I will post Christine's poster in a few days. The speaking advice I got isn't easily summed up. Here is some of it: 1. Have less text on slides. 2. Have more of a punchline for the two slides about Nobel Prizes. 3. Start with a story. 4. Connect what I am saying to my job as a psychology professor. 5. More numbers (data) to support assertions. E.g., number of people using the ketogenic diet.

Karen Herzog (2011-06-01 14:20:46)

@Seth, I enjoyed reading your QS conference highlights and appreciate the speaking tips. Like @Eri, I wished I had had more time to see all the amazing projects, talks, breakout sessions, etc. I only attended the conference for a couple of hours on Sunday due to illness, so next year's will be that much more charming. @Eri, I'll be posting QS posters online soon. Stay tuned. Two favorites public speaking and presentation blogs are Presentation Zen <http://bit.ly/iF30u9> and Speaking about Presenting <http://bit.ly/jXziK3>. You might like this tip article, "Uncovering Steve Jobs' Presentation Secrets." <http://buswk.co/jJlsQn> Good luck with your talk!

eri (2011-06-02 23:30:02)

Karen & Seth - thanks for all! Karen, I'm enjoying the reading material. I just confirmed speaking at TEDxSOMA on the 18th, so it's going to come in so handy!

### **Weak Iced Tea and the Shangri-La Diet (2011-06-02 05:00)**

Pat McGee of Grand Prairie, Texas, learned about the Shangri-La Diet last week and realized the theory behind it explained something strange that had happened to him:

A couple of years ago I unpacked my scale and was astonished to see that I had lost 25 lbs sometime in the couple of years before that. [He went from 165-170 pounds to 140-146 pounds. He is 5 feet 8 inches tall.] I was mystified as to why, as I could point to no changes in anything I thought might be relevant in my life.

Last week, I found out about the SLD and read the first few chapters of the book. I realized that about three years ago, I had switched from sodas [with sugar, such as Coke and Pepsi] to weak iced tea. I did this mostly because I was feeling cheap and didn't feel like paying for bottled sodas any more. I use 5 small teabags and a cup of sugar per gallon, steeped for about 6 minutes with a little lemon juice. Basically I want something that's got just enough flavor that it's not plain water.

When you are 5'8" and 170 pounds, losing 25 pounds without trying (from BMI 26 to 22) is astonishing. Not only that, he has kept it off. His story is a little different than mine because I didn't stop drinking anything – certainly nothing as fattening as Coke or Pepsi.

Here is a new use of the ideas behind the Shangri-La Diet – namely, identifying what caused massive accidental weight loss. Obviously others can use his discovery. From a theoretical point of view, he replaced strongly-flavored drinks with a weakly-flavored one. According to conventional ideas about weight control, this should have no effect.

It is also an interesting example of behavioral engineering because he switched from standard soft drinks (such as Pepsi) to his concoction without difficulty. His drink was pleasant enough. It derived pleasure from flavor (tea), sweetness (sugar), and sourness (lemon juice). A little salt would have allowed him to reduce the flavor even more.

Joseph Dantes (2011-06-02 05:30:16)  
So THAT'S why Southern girls stay slim.

dearieme (2011-06-02 05:48:46)  
Tea should be weak, coffee strong and soda abjured. Everyone knows that?

rphil (2011-06-02 05:49:51)  
interesting story but the 'surprise' of weighing one's self and discovering one has unexpectedly lost 15 % of one's body weight is hard to believe. how much did his pants/waist size change? i fluctuate between 190 and 205 and even a 5lb change pushes me an inch in waist size. no way he lost that much weight and didn't have to change all of his pants to a dramatically smaller waist size - like 2-3 inches at least. And if he had tailored clothing like suits?

Tomas (2011-06-02 05:54:13)  
Seth, the temperature of the drink should be considered as well. There are weight-loss plans that basically recommend you to drink as much as 2 litres of cold water daily. The logic behind is that your body must "heat" the liquid, which means you burn energy, at least part of which is fat. Which makes sense, considering that polar explorers and climbers in high altitudes prefer warm drinks in order to conserve energy. That is to say that I do not dismiss your explanation, I only suggest additional mechanisms that may be involved.

Tomas (2011-06-02 05:58:31)  
Regarding my previous comments see the comment section here <http://high-fat-nutrition.blogspot.com/2011/05/energy-expenditure-in-obese-vs-slim-non.html>

Jeff (2011-06-02 06:12:57)  
Not to discount the shangri-la effect, but much of his weight loss can be attributed to the reduction in intake of calories by eschewing the soda. Soda especially can have an amplifying affect on weight gain if you're vulnerable to the metabolic syndrome/insulin effects of all those sugar calories. Tomas, From a purely thermodynamic point of you burn an extra 37 (kilo)calories for every liter of ice cold water you drink. I'm guessing there are some inefficiencies in the system, but I don't think it's that significant. And there's a good chance all his sodas was ice cold or at least refrigerator cold.

justin (2011-06-02 06:17:31)  
I've started noticing a correlation between my general food cravings and my consumption of diet sodas – more diet sodas = more cravings. Replace with carbonated water (La Croix) and my cravings become more controllable. All of this makes me think that the danger of the diet soda is that it's like a 1/0 increase in flavor sensations. Since there's such strong flavor but so little reward, the brain is confused and seeks out additional consumption (more soda, perhaps more food?) as it seeks the caloric reward that it expects to accompany the flavor. Anyone else notice something like this? Struggling a bit to explain what I think is going on here, so curious if anyone has observed similar things and if they could put a theory to their experience.

Seth Roberts (2011-06-02 06:19:55)  
Hundreds of studies and millions of people have found that reduction of calories produces no long term change. Suppose you eat less than usual today, for example. It won't change your weight a month from now. As for temperature, his ice tea was as cold as his sodas.

Tomas (2011-06-02 06:24:11)  
justin, I have a similar experience. I am generally weary of foods and drinks that make me consume them more and more until I am "mechanically" full, ie. I would still eat more, but my stomach can't take anymore and I feel a bit sick. Eliminating such foods completely is the best way to go for me.

Seth Roberts (2011-06-02 06:24:21)  
rphil, I think he knew he'd lost weight without weighing himself, he just didn't have the details until he weighed himself. If you

use a belt you might not have to get new pants.

Seth Roberts (2011-06-02 06:28:39)

Justin, if you usually drink the diet sodas with other food they may produce cravings because they become unusually strong signals for calories – the smell of the diet soda becomes associated with the calories of the other food. (And your surroundings become associated with the smell. Surroundings -> smell -> craving.) However, if you drink diet sodas away from other food I can't explain this.

BlueMorrissey (2011-06-02 07:23:21)

In response to Justin. I have had serious diet soda addiction through the years. At one time I switched to Mineral Water(Pellegrino) most of the day to help my sleep. I definitely noticed a reduction in cravings and lost some weight. It is so expensive and our Sams quit carrying it, so I rarely buy it anymore, but have been able to limit my diet soda intake with the help of supplements.

Tom Passin (2011-06-02 08:28:03)

@BlueMorrissey - I too had a serious diet soda addiction. I kicked it when I ended up in the hospital, heavily doped up for a week. I used that time to get past the withdrawal symptoms. It worked well but I can't really recommend using this method on purpose. However, changing from diet soda (and any caffeinated drink) to water had no effect on my weight (about 40 pounds too many).

nix (2011-06-02 08:32:07)

BlueMorrissey- I invested in a carbonator and bottle of trace mineral drops and make my own sparkling mineral water at home now from tap water. I drink so much more water (much more enjoyably) and I have spent almost nothing. I highly recommend looking into doing something similar. Here's the mineral drop I use (it lasts years): <http://bit.ly/mbMltm>

Cakeb Cooper (2011-06-02 08:45:37)

Seth, getting into possible biological pathways, do you think one of the major factors might be Dopamine 'food reward' pathways overriding the Leptin 'satiety' pathways that are supposed to make us stop eating. I've been reading up on Dopamine and addiction, and am beginning to suspect it may be directly correlated with the Set Point theory of weight regulation.

Nancy Lebovitz (2011-06-02 09:59:07)

Which diet soda it is might matter - I've got a little anecdotal suggesting that aspartame in particular increases appetite.

vs (2011-06-02 10:07:46)

In response to Justin and others- I also find diet cola seems to increase cravings and induces me to drink more diet cola. It may be best for some people to avoid it, even if just to save money as Pat did with regular cola. I would also be curious if anyone has a theory on this. A starting position might be that some diet soft drinks still impact blood sugar and insulin, whether through caffeine and/or artificial sweeteners: "Dr. Atkins' New Diet Revolution" recommends diet soft drinks sweetened with sucralose rather than aspartame. Dr. Atkins notes sucralose does not raise blood sugar. He also encouraged people to avoid caffeine, as excessive caffeine can cause unstable blood sugar. In "Good Calories Bad Calories" Gary Taubes describes the animal research of Stylianos Nicolaidis, where rats secreted insulin in response to the mere taste of a sweet substance. It did not matter whether the sweet substance was sugar or a no-calorie sugar substitute.

TomGinTX (2011-06-02 18:33:46)

@Nancy: anecdotal - like that word. @rphil: Maybe he wore stretchy pants. 8-)

Thoughts on Obesity Inspired by Stephan | Perfect Health Diet (2011-06-02 18:39:10)

[...] by subtle changes in the intensity of flavors and flavor associations. Seth Roberts today has a post illustrating this: a reader lost almost all excess weight simply by shifting from Coke and Pepsi to iced tea flavored [...]

Pat McGee (2011-06-02 19:25:14)

Hi rphil, I don't know how much my waist size changed. I retired a couple of years before that and switched from fitted pants to elastic waistbands, since I didn't have to dress up anymore. I might have noticed something the once I had to wear a suit, but wearing the suit was so unpleasant in itself that I didn't. Pat

Chuck (2011-06-02 19:32:08)

He also cut his sugar intake in half - assuming he consumed the same amount of tea as he once did cola. A gallon of cola has 100 tsp of sugar and a cup of sugar (his weak tea recipe) is 48 tsp.

Pat McGee (2011-06-02 19:32:44)

Hi Jeff, I don't think switching away from drinking soda had anything to do with it. Remember that I switched from sodas to sugared water (well, weak tea), not to plain water with no calories. With a cup of sugar per gallon, I think it had around the same number of calories. Or at least I once counted calories given my typical consumptions of each and decided that it wasn't enough to make a difference, much less that much difference. Pat

BlueMorrissey (2011-06-02 19:33:51)

Thanks nix. I will definitely check that out. I will drink more water period, if it is mineral water. Something about the carbonation that helps replace the diet soda. Come to think of it vs. I began the switch to mineral water when I was doing Atkins. It was his recommendations that helped me make the change. That did help with the diet and helped me lose about 60 lbs on it. My moods eventually became so awful while doing super low-carb that I cannot stick with it. I just try to stay away from sugar now. SLD is so much easier and takes away many of those cravings, and especially diminishes the desire to get seconds.

BlueMorrissey (2011-06-02 19:39:20)

Nancy, it was/is Diet Mt. Dew mostly, but also Diet Pepsi. Yes aspartame.

Pat McGee (2011-06-02 19:42:48)

Hi Chuck, I actually do drink more weak tea than I did sodas. When I did the soda thing, I also drank about as much ice water as I did soda. Well, without measuring, it seemed to me to be about the same. When I switched, I pretty much quit drinking ice water at all and now just drink tea. Water is so boring. I find it interesting that I didn't think to put these little details in my initial description. Y'all's questions pushed me to remember and to describe them. It's a good thing I wasn't trying to publish this in a scientific journal - the referees would have bounced it for being irreproducible. (and JIR probably wouldn't have taken it as being too factual.) Oh, another detail, which I don't know whether it matters or not: from Labor Day to Memorial Day, I still always had two sodas a week when I volunteered at the Monday Night concert and got them free. I did take bottles of frozen tea to the summer music festivals instead of buying sodas. Pat

dearieme (2011-06-03 12:42:06)

Fizzy mineral water can be very cheap - Tesco, the British supermarket chain, sells a two litre bottle for 16p - that's ca 27 cents. We always have a couple in the fridge.

Chris L (2011-06-04 17:06:16)

I lost 5-10 lbs as well when I stopped drinking Soda. I believe it came not from caloric deficit (I notice there is no mention of how much soda he drank)...but from the reduction of sugar. Couldn't this particular anecdote be explained by Paleo diet principles? Admittedly, there could be overlap between the two, but I see this as one of the weaker examples of Shangri-la proof that have been presented.

Seth Roberts (2011-06-04 18:39:30)

I don't remember anything in paleo principles about weak flavors being less fattening than strong flavors.

Chris L (2011-06-05 09:31:07)

Sorry...I wasn't talking about the strength of flavors. I was talking about the amount of sugar (not the amount of calories). That was exactly my point. I think there is another way to interpret these results...in terms of carbs as opposed to strength of flavor. The paleo story...carbs stimulate insulin which stimulates fat storage....cutting carbs (and keeping calories constant) would stimulate fat loss because of the hormone changes. I hope I don't come off too grumpy. I do mean all of this in good faith. Big fan of the self-experiments you do and I own a copy of the Shangri-la diet (even loaned it out with my recommendation).

Seth Roberts (2011-06-05 20:30:05)

I see. Thanks for clarifying that. Since I lost weight by drinking sugar water – that is, by consuming more sugar – I am the last person you will convince that eating less sugar inevitably causes weight loss, as the paleo story has it.

### **Flavor-Calorie Learning: Root Beer Floats (2011-06-03 05:00)**

After having guests over for dinner, my friend Carl Willat realized he had the ingredients for a root-beer float: Haagen-Daz vanilla ice cream and A & W root beer. He hadn't thought about root beer floats in years. He made one. The next day he made another one. He ran out of root beer, bought some more. The day after that, another one. They seemed to taste better and better each day. He ran out of ice cream, bought some more. The next day, another root-beer float. The next day, another one. Toward the end of the week, he found himself thinking: When am I going to have one tomorrow? He had to force himself to stop buying ice cream and root beer, and after a while he didn't think about them anymore.

At the heart of [1] the theory behind the Shangri-La Diet is the idea that we learn to associate flavors (more precisely, smells) with calories. Here is a vivid example.

I've noticed this learning with liquor. A few months ago I bought my first bottle of rum – to flavor yogurt. Sometimes I drank the rum without yogurt, and it tasted better and better.

1. <http://sethroberts.net/about/whatmakesfoodfattening.pdf>

---

John W (2011-06-03 05:50:09)

An interesting experiment might be to try to learn to like something that you currently don't like. Cucumbers for example in my case. According to this model, if I pair cucumbers with a source of calories like yogurt and eat them on a regular basis this way, I should start to like them.

justin (2011-06-03 07:21:47)

@John, I'm not sure it would – yogurt is fairly bland (unless it's particularly sour) as are cucumbers. The flavor might not be strong enough to trigger the association.

Elizabeth Molin (2011-06-03 08:11:56)

Add chopped fresh mint to the cucumber and yogurt.

dearieme (2011-06-03 08:27:54)

Buy decent bread and just make cucumber sandwiches. Yum, yum.

insert name here (2011-06-03 15:37:19)

Eat pickles instead of cucumbers? That might add enough flavor to start the association?

Seth Roberts (2011-06-03 15:38:20)

John W, yes, this should work. You could also sprinkle the cucumbers with sugar – that should make you like the smell of cucumbers. Several years ago I heard of an experiment that did just that: caused people to like vegetables more by adding sugar. The preference remained after the sugar was removed.

Seth Roberts (2011-06-03 16:08:24)

what matters is the strength of the smell. Saltiness, sweetness, and sourness don't count.

Nancy Lebovitz (2011-06-03 18:49:55)

How does this square with foodies– people who are generally up for trying new flavors?

Seth Roberts (2011-06-04 10:01:32)

I think trying new flavors helps you be thin.

Nancy Lebovitz (2011-06-06 05:42:12)

Have you checked this theory on foodies? I'm one of those people who has a streak of "I've never heard of that, let me try it", and I'm moderately fat. I grant that I don't get new flavors that often, but mere newness (as distinct from something like strong bitterness, which I simply don't like) is fun rather than off-putting.

### **Christine Peterson's Zeo Research (2011-06-04 05:00)**

[1]Christine Peterson's poster of her Zeo research was one of the highlights of the QS conference for me, [2]as I said. Here's why.

The correlation between Sleep Stealer score and time awake. When her Sleep Stealer score was 5 or less, she was awake about an hour during the night. When her score was more than 5, she was awake about two hours – a big difference. There should be a big difference, but you could fail to see it for a thousand reasons. The large difference is a validation of the whole thing – above all, an indication that her Zeo is working correctly.

Even when her Sleep Stealer score is low, she is awake a long time. This means there are major determinants of sleep depth not captured by the Sleep Stealer score. With the right Sleep Stealer score – assuming the correlation reflects cause and effect – she can improve from two hours to one hour (one hour difference) but that leaves one hour. This implies that the determinants of time awake not in the Sleep Stealer score are just as important as those that it contains.

Even when she is at the best level of important factors, she is awake a long time. When she had no drinks, she was awake 56 minutes/night. When other people didn't disrupt her sleep at all, she was awake 54 minutes/night.

The average wake time for women 50-59 is half an hour. That's a lot of lost time, day after day, night after night. Note however that the data is from Zeo users, who may have worse sleep than average.

It only took three months to collect the data. This isn't on the poster. Yet this is a solid contribution, in the sense that I learned from it. With perhaps nine months of data and better data analysis, it might be publishable. The main point such a paper would presumably make is that even when you do everything right (Sleep Stealer score = 0) you're still awake a lot. This point is nowhere in the sleep literature.

Christine, if you would like to sleep better I suggest:

1. Don't eat breakfast until at least three hours after you wake up.
2. Get at least one hour of sunlight early in the morning – e.g., 6 to 7 am. You can do this by working outside. (I work outside several hours every morning.)
3. [3]Stand on one leg to exhaustion four or more times per day. (I do it six times/day.) You can do this while reading – it should not reduce your free time.

1. [http://blog.sethroberts.net/wp-content/uploads/2011/06/QS\\_ChristinePeterson\\_rev.pptx](http://blog.sethroberts.net/wp-content/uploads/2011/06/QS_ChristinePeterson_rev.pptx)

---

### Questions About One-Legged Standing and Sleep (2011-06-05 05:00)

Rajiv Mehta asked some questions about [1]using one-legged standing to improve sleep. I do three sets of two (left leg, right leg) each day.

Q. How do you spread out your three sets (have you found some minimum time between sets, say 3 hours)?

A. I make sure there's at least 4 hours between sets. The effect was weaker with only 2 hours between sets. The time of day doesn't matter but for convenience I usually do one set in the morning, another set in the afternoon, and a third set in the evening.

Q. They say exercise before bed is not a good idea. Do you make sure your last set is at least X hours before bed?

A. No. If anything this particular exercise will make you more sleepy, not less.

[2]Using the Tonic app for this.

1. <http://blog.sethroberts.net/2011/03/22/effect-of-one-legged-standing-on-sleep/>
2. <http://tonicselfcare.blogspot.com/2011/06/bobbing-for-sleep.html>

Wayne (2011-06-05 18:53:39)

Seth, I continue to be impressed by this phenomenon. I'll give a smidgen of background followed by a few questions ... I'm a psychophysiolgologist, and have taught sleep hygiene principles to clients for 20 years now. I've also had to be very careful to manage my sleep thoughtfully myself because of how I'm wired. When I use this technique, my sleep is consistently better than when I don't. There is something going on here beyond just an exercise effect, because the quality of sleep with this technique is different in a way that is hard to articulate. It's almost like a "drugged" sleep without any of the negative side effects of a drug. I haven't been able to get regular exercise for some time now because of injuries, and so until I incorporated this technique I was missing that crucial component of my sleep hygiene. I'm going on memory here, but it seems to me that the sleep this technique gives me is qualitatively different from the sleep I'd have the night after "ordinary" strength training or aerobics. Now for some things I'd love your feedback on: 1. DIFFERENT EXERCISES One of my injuries is a knee injury, and I have been cautioned that my quads are too strong for my hamstrings (this may have figured into injury). I'm told that the quad/hamstring balance is critical. For a long time I was doing this technique by standing on one leg, with the knee a little bent in order to make it more work. I've stopped doing that for now until the knee issues are better sorted out. Now I do these in rotation on different days: one very slow ab curl, one "superman" (get on stomach, arch back with arms and legs extended like superman flying), a slow push-up, etc. As best as I can tell, the same phenomenon is at work with these various iterations, as long as I am working a group of large muscles to the fatigue point. I'm not clear if any of them deliver superior results with sleep though. I'm interested in your thoughts on this, and also have you considered calling this something other than "standing on one leg"? I've found myself tagging it "interspersed isometrics" but that is really gangly. It would be interesting to know if anyone else is using other muscle groups. It might be possible to have some small but positive effect on overall strength and fitness by switching methodically between muscle groups. 2. You wrote earlier about "signaling molecules" playing a role, and I wonder if you can share more about that. Is that a hypothesis or have such been identified? I wonder if you could increase your "dose" by doing to different sets in a row (stand L leg, stand R leg, ultra slow situp, ultra slow superman). If each muscle group sends signaling molecules, then I wonder what's the impact of such a large dose vs. multiple smaller doses. 3. That leads to my final question for the night: I'd be interested to start tracking this sort of thing more systematically. What would you recommend? I have a Mac at home, and also use an Android phone. Any ready made programs that would do the job well? It would be nice to have a way to track the impact of various exercises to tease apart what works best for myself. Thanks! Wayne P.S., if the impact on my sleep is typical, I think you've happened upon perhaps the most powerful behavioral tool for improving a person's sleep!

Seth Roberts (2011-06-05 20:40:20)

Thanks, Wayne. To answer your questions: 1. I haven't done much with other muscle groups. It's so easy to get the effect via one-legged standing: I can read at the same time I stand on one leg. I couldn't read or watch TV while doing the other exercises you describe. But I completely agree that for overall fitness it would be better to use more than just your legs. I haven't considered other names, no. "standing on one leg" is really clear, although I agree it's not the essence of it. The essence is probably use large muscles to exhaustion. 2. The signalling explanation is just a hypothesis. I'm sure you can increase your dose by using different muscles besides the legs, but it is easier, at least for me, to increase the dose by doing the legs more than once - waiting until the signalling molecules are resynthesized, which seems to take about 4 hours. The molecules just seem to swim in the blood with no noticeable effect until you are asleep. For example, at the end of the day I can't tell how much one-legged standing I've done. Only the quality of my sleep will reveal that. 3. To measure the effect objectively you can use a Zeo or WakeMate. I haven't yet done this but plan to. I'm sure the one-legged standing reduces how often you wake up in the middle of the night. You can use either one to measure the reduction in waking up at night. The WakeMate is much cheaper and works with an Android phone. But you don't need any technology at all to make the measurements I did. Just rate how rested you feel when you wake up in the morning. If you make these measurements I'd be very curious to see what you find out.

Wayne (2011-06-06 05:26:22)

Thanks Seth. I just ordered the WakeMate - had been thinking about the Zeo but like the WakeMate price a lot better. Looks like it will travel well as well. For something so simple there are actually a number of variables, such as exercise used and timing of the exercises. Do you have any thoughts about how to proceed most efficiently to test out some of these factors? Warmly, Wayne

Seth Roberts (2011-06-07 16:48:52)

To test the effects of various exercises and so on, I suggest you proceed with slow and simple designs. Such as ABA. Do one thing for one or two weeks, then do another thing for one or two weeks, then go back to the first thing.

TomGinTX (2011-06-07 17:25:59)

Seth, I tried standing on one leg to improve my sleep. It did not work at all. Every time I dozed off, I fell over.

## **Andrew Solomon on Right to Death (2011-06-05 20:55)**

[1]From The New Yorker website:

My brother and I had by then been authorized by Willie's next of kin to make his medical decisions. When we asked to discontinue life support, the hospital began putting up barriers; they did all they could to prevent our doing what Trish, my brother, my father, I, and everyone else who knew and cared about Willie agreed he'd have wanted. . . . Hospital officials repeatedly accused me of murdering him, and wildly misrepresented New York State law relevant to his case. We had, with his biological family, the legal right to decide on his behalf, and having to duke it out with these doctors exacted a great cost we should not have had to pay.

Ugh. I am sorry Andrew did not name the hospital.

1. <http://www.newyorker.com/online/blogs/newsdesk/2011/06/on-my-mother-and-dr-kevorkian.html>

---

Sam Schulman (2011-06-05 21:27:31)

That's bad. This would be worse: My brother and I had by then been authorized by X's next of kin to make his medical decisions. When we asked to continue life support, the hospital began putting up barriers; they did all they could to prevent our doing what Y, my brother, my father, I, and everyone else who knew and cared about Willie agreed he'd have wanted. . . . Hospital officials repeatedly accused me of wanting to keep him alive against his will, at enormous cost, and wildly misrepresented New York State law relevant to his case. We had, with his biological family, the legal right to decide on his behalf, and having to duke it out with these doctors exacted a great cost we should not have had to pay.

Haggus (2011-06-05 21:56:14)

I can so relate to Mr. Schulman's comment. Unlike the state of New York, where I live (north of the 49th), the law states doctors have the final say on who gets to live or die, regardless of family wishes.

Sam Schulman (2011-06-05 22:39:42)

Sorry - left off conclusion: since error is inevitable, that it is better for docs and hospitals to err on the side of not-pulling-the-plug than it is to err on the other side, particularly since absolute knowledge about when end of life is coming is rarer than anyone admits. Certainly the self-interest of many "stakeholders" is on the side of pulling the plug - weary family, crowded hospital, profit-seeking insurer (or spending-averse govt), etc. etc. - all against one patient who signed a paper in good health but is unable now to communicate. He'll have the rest of his life to be dead - what's the hurry? Given the urgency and activity of the hospital in Solomon's example, I wonder whether there was a genuine medical disagreement about the patient's condition that Solomon scants.

Seth Roberts (2011-06-06 01:48:51)

I suspect the self-interest of the hospital was on the side of not pulling the plug. As a general rule, hospitals make less money when they are less crowded. It was in nobody's self-interest to accuse the patient's legal guardians of murder.

Sam Schulman (2011-06-06 19:26:27)

Without reference to Solomon's story: my father, an academic neurologist practicing 50s-80s, had numerous instances of family/friends eager to pull plug, never in doubt, even when there wasn't a plug to pull - it's human nature. He had admirable control of his temper; not everyone does. But as Haggus says, mores change, and the gravitational pull is toward institutional control of death, as in Canada, and even more so in the Netherlands. Pain is horrible, and easy to sympathize with - but who bothers to imagine the horror of watching someone kill you when you happen not to want to be killed; and the greater horror of anticipating your own killing. Seth, I encourage you and your readers to look at Florence Nightingale's classic 19th century book "Notes on Nursing: What it is and What it is Not." There is a tremendous amount of concern about the patient's state of mind - and the necessity of avoiding whispered conferences at bedside. The patient always imagines the worst, and thinks his death is being discussed (all based on Nightingale's beautifully observed experience) which has a dreadful affect on recuperation and recovery. Even though medicine lacked most of what works in modern medicine, there was an absolute commitment to the patient that made a difference - and is vanishing these days. The fine-sounding right to die is not going to be a benefit for most of us.

Gunnar (2011-06-07 11:55:22)

There is no death. Get over it. It's proven that some people remember former lives. Do your homework.

### Assorted Links (2011-06-06 05:00)

- [1]How one obscure sentence upset the New York Times by Renata Adler. A great and revealing story. My explanation of the Times's over-the-top hostility to Adler's book (Gone: The Last Days of The New Yorker) differs from Adler's. She says it was due to her lack of deference, whereas I suspect currying favor with Charles McGrath, the editor of the New York Times Book Review, was a big part of it. In Gone, Adler criticized McGrath, who was apparently very upset. Gone is the rare critique that combines negativity and deep familiarity. Usually you have one or the other.
- [2]fish oil and joint pain
- [3]life and death consequences of job choices
- [4]one more reason for health care stagnation. Innovations excluded by hospital purchasing groups.
- [5]pickled vegetables and cancer. Alas.
- On the other hand, [6]yogurt linked with lower risk of colon cancer. [7]This study points in the same direction.

Paul Sherrard (2011-06-06 07:45:24)

Speaking of yogurt, did you ever happen to read Abbie Hoffman's yogurt-making tips from *Steal This Book*? They sound pretty sensible to me, but I've never tried to use them to the letter: "...Begin by going to a Turkish or Syrian restaurant and buying some yogurt to go. Some restaurants boast of yogurt that goes back over a hundred years. Put it in the refrigerator. Now prepare the culture in which the yogurt will multiply. The consistency you want will determine what you use. A milk culture will produce thin yogurt, while sweet cream will make a thicker batch. It's the butter fat content that determines the consistency and also the number of calories. Half milk and half cream combines the best of both worlds. Heat a quart of half and half on a low flame until just before the boiling point and remove from the stove. This knocks out other bacteria that will compete with the yogurt. Now take a tablespoon of the yogurt you got from the restaurant and place it in the bottom of a bowl (not metal). Now add the warm liquid. Cover the bowl with a lid and wrap tightly with a heavy towel. Place the bowl in a warm spot such as on top of a radiator or in a sunny window. A turned-off oven with a tray of boiling water placed in it will do well. Just let the bowl sit for about 8 hours (overnight). The yogurt simply grows until the whole bowl is yogurt. Yippie! It will keep in the refrigerator for about two weeks before turning sour, but even then, the bacteria will produce a fresh batch of top quality. Remember when eating it to leave a little to start the next batch..."

Darrin Thompson (2011-06-06 09:35:44)

That pickle thing sounds fishy. They've got clearly elevated cancer rates but when they try to isolate the pickles the results are mixed? Sounds like they've identified a non-factor.

Tomas (2011-06-07 03:32:11)

Well I was laughing all the while reading the pickles study. Live with the fear, your days are cucumbered!

Seth Roberts (2011-06-07 16:52:28)

Those suggestions do not agree with my experience. You can get really thick yogurt using milk – no need to use cream. Use a long fermentation time, such as 24 or 30 hours, at constant temperature. And I found that my yogurt improved when I used less starter. I use 1/4 teaspoon – much less than Hoffman's 1 tablespoon. However, you can certainly get thin yogurt using this recipe.

## **Conway's Law and Science (2011-06-07 05:00)**

[1]Conway's Law is the observation that the structure of a product will reflect the structure of the organization that designed it. If the organization has three parts, so will the product. In [2]the original paper (1968), Conway put it like this:

Any organization that designs a system (defined broadly) will produce a design whose structure is a copy of the organization's communication structure.

Here is an example:

A contract research organization had eight people who were to produce a COBOL and an ALGOL compiler. After some initial estimates of difficulty and time, five people were assigned to the COBOL job and three to the ALGOL job. The resulting COBOL compiler ran in five phases, the ALGOL compiler ran in three.

A consumer – someone outside the organization who uses the product – wants the best design. Conway's Law implies they are unlikely to get it.

I generalize Conway's Law like this: It is hard for people with jobs to innovate – for reasons that outsiders know nothing about. Whereas persons without jobs have total freedom. An example is a politician who promises change but fails to deliver. The promises of change are plausible to outsiders (voters) so they elect the politician. However, being outsiders, they barely understand how government works. When the promised changes don't happen, the voters are "disillusioned".

To me, the most interesting application of the generalized law is to science. In my experience, people who complain about "bad science", such as [3]John Ioannides and [4]Ben Goldacre, have the same incomplete view of the world as the "disillusioned" voters. They fail to grasp the constraints involved. They fail to consider that the science they are criticizing may be the best those professional scientists can produce, given the system within which they work. Better critiques would look at the constraints the professional scientists are under, the reasons for those constraints, and how those constraints might be overcome.

"Much research is conducted for reasons other than the pursuit of truth," writes Ioannidis. Well, yes – people with jobs want to keep them and get promoted. They want to appear high status. That's not going to change. It's absolutely true that drug company scientists slant the evidence to favor their company's drug, as Irving Kirsch explains in [5]The Emperor's New Drugs. But if you don't understand what causes depression and you're trying to produce a new antidepressant and you want to keep your job . . . things get difficult. The core problem is lack of understanding. Lack of understanding makes innovation difficult. Completely failing to understand this, Ioannidis recommends something that would discourage new ideas: "We must routinely demand robust and extensive external validation—in the form of additional studies—for any report that claims to have found something new."

Truly "bad science" has little to do with what Ioannides or Goldacre or any [6]quackbuster talks about. Truly bad science is derivative science, science that fails to find new answers to major questions, such as the cause of obesity. Failure of innovation isn't shown by any one study. Given the rarity of innovation, it is unwise to expect much of any one study. To see lack of innovation clearly you need to look at the whole distribution of innovation. Whether the system is working well or poorly, I think [7]the distribution of innovation resembles a power law: most studies produce little progress, a tiny number produce large progress. The slope of the distribution is what matters. Bad science = steep downward slope. With bad science, even the most fruitful studies produce only small amounts of innovation.

Just as outsiders expect too much from professionals, they fail to grasp the innovative power of non-professionals. Mendel was not a professional scientist. Darwin was not a professional scientist. Einstein did his best work while a patent clerk. [8]John Snow, the first person to use data (a graph) to learn the cause of an infection, was a doctor. His job had nothing to do with preventing infection. To improve innovation about health (or anything else), we should give more power to non-professionals, as I argued in [9]my talk at the First Quantified Self Conference.

David (2011-06-07 19:10:48)

Just to help a little to prove your point..."It is hard for people with jobs to innovate": <http://edge.org/conversation/geoffrey-west> But, "Much research is conducted for reasons other than the pursuit of truth"... yes, he is right: <http://edge.org/conversation/the-argumentative-theory-anyway...> nice post!

Robbo (2011-06-07 21:32:45)

"the science they are criticizing may be the best those professional scientists can produce, given the system within which they work. " Are you familiar with the work of W E Deming ? Your remark here reminded me strongly of his statement on Quality (in the context of industrial production) that it is c 96 % determined by the system in which the worker is working, and c4 % by the worker. Hence, if you want to improve quality, you should focus on improving the system. Sounds to me like Science is the same.

Nathan Myers (2011-06-08 00:17:46)

The best supported widespread cause of obesity I know of is the one that very strongly correlates antibodies to a particular rhinovirus with obesity. Unless somebody can show that only obese people catch that cold, or that only obese people continue to express that antibody, it really looks as if this particular cold actually leaves a propensity to obesity in its wake. The mechanism remains unknown Does it cause addiction to fructose? Reduced metabolic rate? Increased muscle pain after exercise? Insatiety? Your guess is as good as mine, maybe better. I wonder if anybody is actually looking into it, as a day job. The best we can do now is to stay away from fat people suffering colds.

Seth Roberts (2011-06-08 05:22:38)

yes, I know about and like Deming's work.

Nancy Lebovitz (2011-06-08 14:53:12)

Nathan, staying away from fat people with colds won't help you. If the theory is correct, the crucial cold happened before the person got fat. In fact, if the theory that you become immune to the specific rhinoviruses which have made you sick in the past, then it's slightly more risky to be around thin people with colds than fat people with colds.

RandomReal[] (2011-06-09 07:21:44)

Seth, Thanks for alerting me to Conway's Law - I had never heard of it. I agree with your thoughts on quackbusters. Making a life of debunking creationists and homeopaths does not lead to anything new and innovative, nor does it lead to a better understanding of evolution and disease. If only they would train their eye to uncover foundations of some modern scientific beliefs, say climate science. But, they would be branded as heretics. An aside. I find creation science/ID and popular climate science to be quite similar: both are lazy and unimaginative. Creation scientist: I can't imagine how such complexity arose, therefore god must have done it. Climate scientist: I can't think of a natural explanation for this observed change in the weather,

therefore it must be CO<sub>2</sub>. I don't want to cast aspersions on all climate scientists, since some are actually doing interesting stuff. But, you will never hear about their work in the popular scientific press. Derivative science is indeed pernicious. My thesis adviser had a name for it: sandwich science. Take two slices of known and insert a little unknown between them. Voila! Science! An mpu (minimal publishing unit)! My model of the scientific enterprise is one of a hunter/gatherer society. Most scientists are gatherers. They go out and do their experiments and gather data. Hunters work on the edges of knowledge and explore new lands. They are not productive according to the gatherer metric and are often wrong. Nevertheless, the hunters are the innovators and are necessary for the advancement of science. The two need each other to survive. Indeed, the mythology of science celebrates the hunters (e.g., Einstein), allowing them to be tolerated and to feed from the gatherer's work. This tolerance derives from the need for fat and protein (new theory to explore) that the hunters provide. But, just as hunter/gatherer societies evolved into farming societies, the pursuit of science has evolved. The current academic/industrial scientific complex resembles farms on which scientific results are grown. Along with this farming society come the politicians and bureaucrats with their rules and regulations that will eventually lead to the depletion of nutrients (innovation) from the scientific soil. My tongue in cheek saying is: Scientists figure out how things work. Engineers figure out how to make things work. Businessmen figure out how to sell it. Politicians, thinking themselves experts in all of the above, come in a screw things up.

Seth Roberts (2011-06-09 09:57:18)

I agree, especially with this:

Making a life of debunking creationists and homeopaths does not lead to anything new and innovative, nor does it lead to a better understanding of evolution and disease.

I also like your comparison of creation science and climate science. I would add two things. One is that having a job pushes the job holder toward playing it safe. Playing it safe and science don't work well together, as you say. The other is that rules and regulations about science, ostensibly for the benefit of the public, flourish and grow ("IRB mission creep") because jobs are created to enforce them. The more paperwork the bureaucrats can generate, the more people they can hire to process the paperwork, the larger their budget, and the more important they feel. This is a disaster for the public, which has no idea of the deadening effect of IRBs.

RandomReal[] (2011-06-10 09:23:44)

"IRB mission creep" My best personal experience were my two stints at NIH. My first started in the early 90's. My sign up, papers, contract, finger printing, etc. involved 2 bureaucrats and about 1.5 h. The only mandatory courses that I needed to take were in radiation safety and laboratory safety. During that time, Clinton & Gore were on the "efficiency in government" kick and Harold Varmus held them to their word. The campus was amazingly open. You could walk onto campus (parking was impossible) and into any lab on campus, save the Human Genome Center which was under constant threat from animal rights activists. Amazingly, hardly anything changed while I was there except it became easier to get orders processed. From the late 90's to 2005, rules, regulation & bureaucracy exploded. The formal paper signing took almost a whole day. It was interspersed with talks from bureaucrats (powerpoint-bulleted enhanced). Funny thing was radiation and lab safety were not required, but perhaps 8 other online courses were. Being bureaucratically-challenged, I ignored them until a frantic call came from the Institute's main office saying that I would not get paid until I completed them. Moreover, it had been turned into "Fort NIH". The past openness was gone. There were some labs where I could not just drop in as I passed by: I had to call in advance and have my name put on a list and then I could pass through airport like security. The best science, there and elsewhere, was performed in laboratories (Sections in NIH speak) which had 5-10 members and there was an active community of related labs with weekly interaction. The size of these communities was 100-200 researchers in which ideas and materials flowed freely. The small labs were under constant assault from the Empires of NIH headed by Gallo-like lab chiefs seeking to conquer and expand. These labs produced interesting results inversely proportional and mpu's geometrically proportional to their size. I haven't looked at the numbers but I would expect that bureaucracy creep has increased overall spending without a similar increase in spending on research and bench science. Sorry for the ramble, but I'll end with one last question: Is there an equivalent to the Paleo Diet for institutions?

Seth Roberts (2011-06-10 21:54:15)  
that's a fascinating comparison.

## How To Make Kefir: What I Didn't Know (2011-06-08 05:00)

Kefir is much easier to make than yogurt because you ferment the milk at room temperature, once you have the starter culture. I've made it about ten times. The most recent batch was the easiest and best because I learned two things from the woman who gave me the starter:

1. Ferment it until there is a line of separation. There eventually form a line of clear liquid between the curds (top) and the rest (bottom). This took about two days. In the past I didn't know how long to wait.
2. After fermentation, separate the curds from the rest by putting it through a colander. This provides good separation. You drink the liquid, use the solids to make more kefir. In the past I tried to spoon out the kefir grains.

If I had to choose between kefir and yogurt I'd choose kefir. Not only is it easier to make but it is [1]far more complex. Unlike yogurt, it's a drink. I drink more often than I eat so there are more opportunities to consume it.

I suspect you can make kefir by putting store-bought kefir into ordinary milk. I haven't tried this, however.

1. <http://en.wikipedia.org/wiki/Kefir>

---

Charles (2011-06-08 05:31:00)

In my experience, kefir is a more powerful probiotic. Everyone is different, of course, but I've seen more healing of long-standing gut issues happen from consumption of kefir. And as you say, it is easy to make.

SB (2011-06-08 06:55:45)

"you ferment the milk at room temperature, once you have the starter culture." Do you mean you don't have to heat up the milk before adding the starter?

Mike H (2011-06-08 07:28:48)

Mark's Daily Apple talked about kefir a couple weeks ago. <http://www.marksdailyapple.com/homemade-coconut-milk-kefir/>

Kim Øyhus (2011-06-08 09:20:59)

Lazy mans kefir: I just buy a carton of kefir, and let it ferment for about two days at room temperature, so the carton gets roundish. Then I shake it, open it, drink some, and put it in the fridge. The point, in addition to me being lazy, is that it is not legal to sell sufficiently fermented kefir, so I let it ferment some more.

Seth Roberts (2011-06-08 11:04:31)

right, you don't heat the milk before you add the culture.

Richie (2011-06-08 11:37:49)

Yes, mixing store-bought kefir with milk works. I mix 1/2 cup kefir with a gallon of whole milk, heat to about 100 degrees, and then pour in jars and let sit on the counter for 24-48 hours.

Seth Roberts (2011-06-08 11:41:12)

that's very good to know.

Erik Cisler (2011-06-08 15:52:52)

This works well with pasteurized milk?

Seth Roberts (2011-06-08 19:23:24)

yes, it works with pasteurized milk.

NuLu SLD (2011-06-09 03:31:45)

It works with pasteurized milk directly from the fridge. No need to heat or warm. I used store bought kefir for a few batches and then got some grains and have been using it for 14 months. But I read on the net that store kefir is prepared with starter culture which does not contain as many types of probiotics as grain fermented kefir. I asked one manufacturer about it but did not get a response. I prefer grains because of that. Kefir helped with my hay fever. Did not clear it completely but alleviated the symptoms. I am a believer.

Erik Cisler (2011-06-09 14:45:45)

Fantastic. Thanks.

BPT (2011-06-10 10:05:21)

The best way is to use raw whole milk, kefir grains, and allow to ferment for two days or so at room temp. Heating can kill some of the valuable microorganisms, and you don't want to do that. Also, the higher the ambient temp (to a point), the faster the fermentation process happens. Store-bought kefir has been pasteurized, so many of the microorganisms that make up the kefir colony have been killed. The resulting kefir is then less nutritionally valuable. Making kefir from the store-bought stuff is not the best technique for this reason.

Todd Fletcher (2011-06-10 11:12:02)

Kefir has cured my excema completely. I know because if I stop drinking it it comes back within about 1-2 weeks. It's also helped my hay fever too. So I'm really happy to hear how easy it is to make.

Mitch Cooper (2011-06-13 06:44:22)

Hi Seth, where do you buy your kefir at in Beijing? Thanks!

Seth Roberts (2011-06-13 08:47:43)

I have not seen kefir for sale in Beijing.

guna (2011-06-29 20:19:31)

hi, I've been trying the trader joes strawberry flavored kefir, but would like to make my own :-). so to get started I am looking for the starter culture/grain..could you please let me know where can buy/get the culture?. Thanks. much appreciated.

AI (2011-07-06 09:17:45)

Lots of very good info about kefir here: <http://users.sa.chariot.net.au/dna/Makekefir.html>

Ludovic Gallant (2011-12-25 20:34:09)

Have you heard of water kefir ? It's something I intend to try soon!

jackie (2012-04-27 08:59:16)

I am interested in beginning making yogurt and kefir. Where do I obtain kefir grains? Can store bought yogurt/kefir work? Seth: You can use store-bought yogurt to make yogurt, yes. It is hard to get kefir grains. You can probably use store-bought kefir to make kefir, but I haven't tried it.

## **Paleo Diet versus Mediterranean Diet (2011-06-09 05:00)**

[1]A 2010 study (via [2]Whole Health Source) compared a Paleo diet with a Mediterranean diet. For twelve weeks, twenty-nine volunteers could eat as much as they wanted, whenever they wanted. Half ate Paleo ("lean meat, fish, fruit, vegetables, root vegetables, eggs, and nuts"), half Mediterranean ("whole grains, low-fat dairy products, vegetables, fruit, fish, and oils and margarines").

The main result was that the Paleo food was "more satiating per calorie". The Paleo eaters ate less but no more often than Mediterranean eaters. The paper does not report weight loss. (See [3]an earlier report of the same experiment for that.)

I suspect the Paleo diet was less familiar than the Mediterranean diet (of course I can't be sure from the descriptions). [4]My theory of weight control says familiarity matters: less-familiar food pushes your set point lower than familiar food because its smell-calorie associations are weaker. The smells of less-familiar food is less associated with calories than the smells of more familiar food. With a lower set point, you will need less food to feel full.

If familiarity matters, this causes big problems for clinical studies. It means that short-term results (e.g., after 6 months) may be quite different than long-term results (e.g., after 2 years) – and most clinical trials last about six months. Short term, says my theory, any new food will cause weight loss. Indeed, a wide range of diets that cause dieters to eat new foods, such as the cabbage soup diet, cause short-term weight loss. Over the long term, however, the new foods become familiar and, according to my theory, the set point goes back up as the new smell-calorie associations are learned. Indeed, on most diets there is great long-term weight regain. If familiarity matters, we need data sets lasting a long time (e.g., [5]nine or [6]ten years) to understand weight control. Such data sets allow enough time for the chosen diets to become familiar so that (a) the diets being compared are equal in familiarity and (b) we can see their long-term effects – which may easily be different from their short-term effects.

Thanks to Steve Hansen.

1. <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3009971/>

2. <http://wholehealthsource.blogspot.com/>

3. <http://www.ncbi.nlm.nih.gov/pubmed/17583796>

4. <http://sethroberts.net/about/whatmakesfoodfattening.pdf>

5. <http://blog.sethroberts.net/2011/05/07/nine-years-of-weights-more-shangri-la-success/>

6. <http://blog.sethroberts.net/2011/04/22/ten-years-of-weight-measurements/>

Peggy The Primal Parent (2011-06-09 10:04:16)

Your theory supports the idea to eat local, in season food. If people eat whole foods (which itself encourages weight loss) and rotate foods every three months or so, they would never gain weight because every three months they would be eating new foods, hence causing weight loss! Cool.

R.K. (2011-06-09 14:36:28)

Puzzling, then, how an experiment could radically change the subjects diet and yet weight stays stable. From <http://wholehealthsource.blogspot.com/2011/05/food-reward-dominant-factor-in-obesity.html> : "The first thing they report is what happened when they fed two lean people using the machine, for 16 or 9 days. Both of them maintained their typical calorie intake ( 3,075 and 4,430 kcal per day) and maintained a very stable weight during this period."

bjk (2011-06-09 15:54:22)

If I eat a monotonous, non-rewarding diet, does that counteract the effects of familiarity? Because I can lose weight eating the same thing every day, it solves the problem of what to eat, which is half the problem.

Seth Roberts (2011-06-09 17:07:07)

I'm not sure what you mean by a "non-rewarding" diet. But, yes, if you eat bland foods you will lose weight. Cabanac and his colleagues found that. Foods with weak smells do not form strong smell-calorie associations.

Seth Roberts (2011-06-09 17:09:18)

I explain those results by assuming that when the set point is already low, changing the diet doesn't lower it. Only when the set point has been raised by smell-calorie associations do you get the loss-followed-by-regain effect.

Seth Roberts (2011-06-09 17:10:09)

The Sensa system of Alan Hirsch changes the flavorants (sprinkled on food) every month. So perhaps there is significant smell-calorie learning within a month.

Robbo (2011-06-10 22:47:36)

I don't think this is a Mediterranean diet since it contains " low-fat dairy products and margarines". I would also question what oils were included (only olive oil = Mediterranean) The hilarious thing is, by travestying the Med diet, the study owners probably thought they were improving it.

Carlos (2011-08-24 03:14:32)

One thing that bothers me about this studies is how often they make up the "mediterranean diet" Being from Spain I can assure you that the proposed diet does not resembles our traditional food. whole cereals were unheard of until a decade or so. Low-fat dairy was a niche product and margarine was started to being use at the beginning of the 90's (and because it spreads easier on bread) Another thing that always bothers me is how devoid of legumes are these "so called" mediterranean diets. I don't know about the rest of the mediterranean countries but in Spain legumes are a staple food.

Nick (2012-03-04 10:55:00)

I agree that novelty has additional effects outside of the traditional norm. Usually not controlled for in studies. I also find this effect in other areas like exercise and pointless to state the obvious "learning". I'd like Seth to comment on the effects of chronic novelty as applied to food or anything else for that matter. Would this cancel out the "set point" mechanism in the long run and force the body to seek an alternative. What would that alternative be?

## The Curious Amazon Rank of The Shangri-La Diet (2011-06-10 05:00)

When The Shangri-La Diet was published (2006), I enjoyed checking its Amazon rank. The rank got worse. I checked less often. Eventually it was usually above 100,000 and I barely checked at all.

A few months ago, I noticed it was much better than I expected – maybe 40,000. How did that happen? Were sales improving? To find out, I subscribed to RankTracer, which records Amazon rank every hour and plots the results.

Here are the first two months of data from RankTracer:

[1]

This resembles the graphs that RankTracer makes. Whether the rank is steadily improving isn't clear. Here is the same data with a logarithmic y axis:

[2]

Now steady improvement is obvious.

I'm pretty sure that slowly increasing sales five years after publication is extremely rare. But a bizarre sales record is entirely consistent with two recent comments on the SLD forums. One is [3]this:

It does work, and it is totally boggling that something so counter-intuitive would work. . . . You don't have to devote your life to starving and working out. One of the best-kept secrets of all time.

The other is [4]this:

I refuse to get drawn into 'how crazy' it sounds ... I just like the results.

---

Alex Chernavsky (2011-06-10 05:49:56)

"Now steady improvement is obvious". I don't have your experience with data analysis, but the improvement isn't obvious to me. There seems to be a lot of noise in both plots. Can you explain further?

SB (2011-06-10 05:56:59)

Steady improvement is not obvious to me either. Also, rank of your book should be extremely dependent on sales of other books. So this graph is just a comparison and says nothing about absolute sales.

Jay Cobal (2011-06-10 07:04:08)

a very well followed biologist Dr. Stephen Guyenet has posted recently about this exact theory which caused quite a stir in the nutritional blog sphere (<http://wholehealthsource.blogspot.com/>), no doubt the references made to your work in this field were noted and likely resulted in people seeking you out and buying your book. kudos!

Seth Roberts (2011-06-10 07:12:55)

yeah, that's a good point. I hadn't thought of that. On the other hand, being mentioned here or there should simply produce a spike in sales. Perhaps there are such spikes – too small to be clear – but a series of spikes would not produce steady improvement across months, except by coincidence.

Joe (2011-06-10 09:27:28)

Another dataset: <http://www.google.com/trends?q=seth+roberts&ctab=0&geo=all&date=ytd&sort=0>

Erik La Gattuta (2011-06-10 11:47:23)

I heard about fat set point in exactly that way, from Stephen Guyenet's recent posting and interviews. That is what led me to buy the book last month and also read this blog on a regular basis. Mark Sisson has also been singing Seth's praises recently. It would be interesting to compare the uptick in sales to the blog readership over time.

Jim (2011-06-10 13:38:14)

I agree with Jay above. I've seen recent mentions by Tim Ferriss and Quantified Self (of course), as well as Stephen Guyenet and others like this one by Melissa McEwen <http://www.huntgatherlove.com/content/can-complex-flavors-cause-weight-loss>

Seth Roberts (2011-06-10 21:57:42)

If you fit a straight line to all the points in the lower graph it would have a negative slope. (I did so and the slope had a very high t value – that is, was extremely unlikely to be negative by chance.) Perhaps next time I make such a graph I will include a fitted straight line.

David (2011-06-11 09:30:44)

It seems a simple moving average would help see the longer term trend better.

Noumenon (2011-06-14 07:10:00)

Man, I should submit that RankTracer graph to Junk Charts. Why would you graph something where higher is better with higher at the bottom, and why would you produce a graph that gave equal weight to a move between 50,050 and 50,000 and a move between #50 and #1?

Seth Roberts (2011-06-14 08:12:25)

It is reasonable to plot a rank of 1 lower than a rank of 100 – because 1 is less than 100. But you are right about the weighting.

Paul Jaminet (2011-06-17 09:57:17)

I think referrals from blogs is a likely explanation. My blog linked to you a number of times starting Feb 26, and did two dedicated posts Mar 22 and Mar 24, with more posts since. We have 24,000 monthly unique visitors. An Amazon sales rank of 40,000 is probably about 2 copies per day. That could easily be generated by blog referrals. You might try checking your referrer traffic to see where web traffic was coming from, and also go back farther than April to see when the sales surge started.

Jazi yechezkel zilber (2011-06-18 04:09:20)

Tim Ferriss can be a cause. He sold millions of books, and Seth has a chapter, and an additional piece in the "bonus" chapters online.

Jazi yechezkel zilber (2011-06-18 04:12:24)

Evidence. Checking "customers who bought this also bought" on amazon, gives the 4 hour body in tje second page, and i see other items that are frequently bought by ferriss followers

Noumenon (2011-06-18 06:10:10)

*It is reasonable to plot a rank of 1 lower than a rank of 100 — because 1 is less than 100.* Not in sales ranks, it's not. But maybe I'm just projecting because I personally had trouble flipping the graph upside down to understand it.

## Two Years of Weight Measurements (2011-06-11 05:00)

[1]

This shows [2]Justin Wehr's weight over two years. He is 26 years old and 6 feet 2 inches tall – at 140 pounds, very thin. The record begins with a switch to a vegan diet. Over three months he lost seven pounds but gradually regained the lost weight, even though his diet didn't change. In the middle he suddenly gained five pounds on a trip to Alaska and Seattle and then gradually lost it.

He describes his diet like this:

My diet was pretty average Midwestern meat and potatoes sort of thing prior to going vegan-ish, and I emphasize the ish. I've been vegan-ish since I started tracking weight, meaning that I don't buy meat or dairy products at the store, but I'll happily eat whatever sounds good off of a restaurant menu or whatever is being served when I'm eating at someone else's place. I intentionally keep my diet very boring. I eat an absurd amount of peanuts and raisins, I estimate in the range of 600 - 900 calories per day. Besides peanuts and raisins, most of my calories come from lentils, frozen vegetables, and bread + olive oil. I drink almost exclusively water, with a few swigs of OJ most days, and have a glass of wine or a bottle of beer on occasion.

The features of this data that interest me are (a) weight loss when he changed what he ate (first three months) and (b) gradual regain of the lost weight (after that). Few theories of weight control can explain the regain. However, [3]the theory behind the Shangri-La Diet can. It says that he initially lost weight because he shifted to foods with relatively weak flavor-calorie associations – weak because the foods were relatively new. As he ate them again and again, the flavor-calorie associations got stronger and this raised his set point.

1. <http://blog.sethroberts.net/wp-content/uploads/2011/06/weight-chart-6-10-11.png>

2. <http://wehrintheworld.blogspot.com/>

3. <http://sethroberts.net/about/whatmakesfoodfattening.pdf>

---

Edward Edmonds (2011-06-13 20:17:29)

I recently bumped into your theories looking for something to explain the same patterns, I've never tracked my weight data like Justin but I've found the exact same pattern with weight loss and your diet-SLD-seems like a sound idea. I haven't had a chance to read your book but I did buy the ebook, and am looking foward to reading about your ideas. I've always noticed that when I eat a variety of foods my stomach stays flat vs. when I eat e.g. paleo or a LC, Ray Peat or some variation/combo of

that. I'm an undergrad anthropology student and I think exploring this idea will make for some interesting papers for class; I think you have a good model here. It's too bad that this idea doesn't have more exposure this is really a breath of fresh air and seems to be able to explain a lot more about weight loss/gain than your standard eat this stay away from that. There is real intelligence in this idea. I'd really be interested to see how regulation hormones change during the weight loss and weight gain periods.

---

nansen (2011-06-14 14:31:57)

I went to a Math library to look up the Halmos article. The statement that you quote is immediately qualified in the second paragraph. Halmos says that of course he is being idealistic, and that only a select few can realistically follow his dictum (for learning math).

### Salt is Good, Says New Study (2011-06-13 05:00)

[1]A new study in JAMA found higher salt consumption strongly associated with less death from heart disease. The association with total mortality (more salt, less death) was almost significant. To grasp the strength of the evidence, see [2]this. Yes, it's a correlation, but I don't know of any examples of such a strong correlation reversing (so that more salt is now correlated with more death) when now-unknown confounders are taken into account. In 1998, [3]Gary Taubes argued that the benefits of salt reduction were greatly overstated. The new study did find more salt correlated with higher systolic blood pressure but in the big picture (mortality) that didn't matter. If all those warnings about salt had any effect, the new study suggests their effect was negative.

Perhaps people who eat less salt are more credulous (they believed the experts) – and this damages them in other ways? Perhaps they rely on doctors more, for example. It is hard to interpret this finding in a way that makes mainstream health care look good. A [4]New York Times article about the study points out that "the new study is not the only one to find adverse effects of low-sodium diets." And it reports what someone at the Centers for Disease Control

said:

Dr. Peter Briss, a medical director at the centers, said that the study was small; that its subjects were relatively young, with an average age of 40 at the start; and that with few cardiovascular events, it was hard to draw conclusions.

Dr. Briss fails to understand statistics. Ordinary statistical calculations take sample size and number of events into consideration when indicating the strength of the evidence. That's the one of the main purposes of those calculations. As for "relatively young," I know of nothing to suggest that the effects of sodium reverse with age – so it is irrelevant that the subjects were relatively young. That someone at the CDC is so clueless is remarkable.

---

Dennis Mangan (2011-06-13 05:25:02)

The link to JAMA goes to a registration page; here's the abstract to the paper from PubMed:  
<http://www.ncbi.nlm.nih.gov/pubmed/21540421>

ChristianKI (2011-06-13 05:42:04)

Is there a cost effective way to measure your own blood sodium concentration for daily tracking?

Dennis Mangan (2011-06-13 05:47:05)

*Is there a cost effective way to measure your own blood sodium concentration for daily tracking?* Sodium in blood or urine is easy to measure in a medical lab - the analysis takes under a minute - but in this study they would have measured 24-hour urine excretion, which involves collecting all urine over a day. Not very convenient. Also, blood concentrations of sodium are tightly regulated in healthy people, so presumably blood levels wouldn't give the required information.

Cakeb Cooper (2011-06-13 07:38:10)

I bet the mechanism is iodine up-regulating the thyroid. If the coastal Japanese are any example, humans can experience health benefits from very high iodine levels. Many of the patients I see in my practice suffer from low thyroid hormone. Yet another national health problem inflicted on us by public health advice.

Joseph Dantes (2011-06-13 08:00:50)

Question - it seems to me the correlation != causation bias here is strong. What if people who already regulate the sodium intake are doing it consciously and deliberately? And what if they're doing it because of pre-existing health concerns? That would explain a higher mortality rate.

Seth Roberts (2011-06-13 08:46:55)

The authors did not consider this idea. They merely say their results are not consistent with current recommendations. The health of the three groups (low, middle, high tertile of salt intake) appears about the same. However, those in the highest tertile drink more than those in the other two tertiles. Drinking (alcohol) seems to reduce heart disease mortality. Perhaps that has something to do with these results.

Jake (2011-06-13 08:47:45)

A better thing to do is test whether salt affects your blood pressure. A small minority of people are sensitive to salt. You can determine if you are one of those people by doing what I did. One week before your salt free diet, take daily blood pressure readings. Then go on a salt free diet for a week and take daily blood pressure readings. Compare the two weeks of readings, if there is no decrease in blood pressure during the salt free week, you are not sensitive to salt. I saw no change in my blood pressure so I ignore all salt free propaganda.

Dennis Mangan (2011-06-13 09:25:26)

Re correlation and causation, in many studies the healthy user effect causes spurious correlations, e.g. people who eat more vegetables are healthier in part because they're already healthier and they're smart and likely to pay attention to diet. I think it can be ruled out here because the healthy users would be more likely to lower their salt consumption. It was the "unhealthy users" who had lower mortality.

Michael (2011-06-13 09:28:21)

I remember Robb Wolf making a comment in a podcast that salt consumption will lower cortisol levels via aldosterone.

q (2011-06-13 10:32:13)

what i've understood is that some people excrete salt better than others (related to renal function), and that those who excrete salt poorly have a link between heart disease and salt intake. further, it's not clear that it's mediated through directly raising blood pressure - it could be indirect. if someone is sensitive to salt in this way, it weakens their heart over time, which causes blood pressure. so @jake, i don't think your test is meaningful.

Timothy Beneke (2011-06-13 10:35:58)

Let me throw in some inarticulate skepticism about drawing any conclusions. It's just too hard to interpret, given that so much of our other knowledge that is supposed to help us control for confounds is itself shaky and based on correlation - and it controls for confounds based on other shaky knowledge. It's a guessing game based on knowledge drawn from other guessing games... Seth: Regarding light/moderate alcohol consumption and its health benefits - there is correlational evidence from a 2009 study that people who drink a lot also exercise a lot, which throws a monkey wrench into the benefits of alcohol. A summary of the data: "Light, moderate, and heavy drinkers worked out 5.7, 10.1 and 19.9 minutes more per week, respectively. Also, drinking resulted in a 10.1 percent increase in the probability of vigorous physical activity." (<http://www.livescience.com/7910-exercisers-drink-alcohol.html>) The study was published here. (<http://www.healthpromotionjournal.com/publications/journal/ib2009-09.htm>)

Jake (2011-06-13 11:28:23)

Q: My test is meaningful. If salt is going to give you problems the first place it is going to show up is in a blood pressure rise. There may be other effects but blood pressure will always be affected.

Ashish (2011-06-18 11:30:44)

"But among the study's other problems, Dr. Briss said, its subjects who seemed to consume the smallest amount of sodium also provided less urine than those consuming more, an indication that they might not have collected all of their urine in an 24-hour period." This seems to me like a pretty important (possible) flaw in the study.

Seth Roberts (2011-06-19 19:07:05)

Ashish, such a difference ("less urine") between subjects would not produce differences between groups on other measures, unless being careless is somehow health-promoting. It's hard to see why that would be. If Briss is saying that subjects in the lowest-sodium group probably ate more sodium than recorded, that makes the results more impressive (because a smaller difference in sodium was correlated with the same heart disease difference) rather than less impressive.

JBG (2011-06-20 16:16:13)

Hunter-gatherers seem to have eaten very little sodium. That puts a heavy burden of proof on those who would claim that high sodium intake is healthful, a burden that I would say this one study doesn't come within a mile of meeting.

JBG (2011-06-20 16:20:33)

Cakeb Cooper's comment about iodine might well be the explanation for the study's results.

Sans (2011-06-21 23:28:13)

This reminds me of your article on Salt and Lyme disease, where the author claimed that salt kills parasites within the body. Do you think there is a connection?

lemmy caution (2011-07-15 13:29:13)

I agree with Taubes but there can be problems with small sample sizes. If a small sample size test is found to be "statistically significant" that necessarily means that the effect found is going to be pretty large. Maybe there is a large effect, but a lot of times this large effect disappears when they get around to doing a large sample size test.

Freedom from Health » Salt ad makes my blood pressure rise! (2011-09-14 20:29:35)

[...] I'm not too worried. Recent studies suggest that the conventional wisdom that salt leads to heart disease is [...]

Joanna (2012-04-30 14:58:50)

Hi Seth, I wondered if I could pick your brains (please!); I've been trying to use the SLD theory to inform my food choices - I understand that less flavour will mean a weaker flavour/calorie association, but I was wondering about salt. If I'm trying to lose weight - would salt not contribute to the strength of the association? I hope not! Also - just to clarify - if I ate a potato - would it be better to have it without any spices added - just have it plain - and this would help to lower my set point? ( due to its blandness), or maybe I could have it with spices but vary the spices each day. I was also wondering how far apart you could eat a food before the flavour/calorie association would kick in - so if you had something with a certain flavour/calorie combination once a week - would that be enough for the brain to start to recognise it and raise the set point when you ate it? thankyou! Seth: 1. I don't think salt has any effect on flavor-calorie associative strength. 2. I found that eating bland foods doesn't work very well. Don't think that eating potatoes without spices is going to do much. 3. Yes, you can certainly learn a flavor/calorie association if you eat that food once/week.

Joanna (2012-05-01 06:01:07)

Thanks for answering my questions! I have another question about food and was wondering if you might know the answer or be interested in it yourself. I found it totally interesting in your book - the thing about adding water to food making it more fattening. Was wondering about soup though, cos I've read loads of evidence for soup being really good for filling you up. Just wondered - is soup somehow different to bread because the water is incorporated in a different way? Seth: I remember a study where just having soup for lunch instead of something else caused weight loss. Surprising. I don't know why soup has this effect.

Joanna (2012-05-02 14:22:41)

Hi Seth, just to let you know, in case you were wondering... I found a study; 'Water incorporated into a food, but not served with food decreases energy intake in lean women' It found that when the food was eaten as a soup; energy intake was about 1209kj, when the food was eaten not as a soup but with water served alongside; energy intake was about 1657kj and with no extra water served, about 1639kj was consumed. So eating foods as a soup has quite a significant effect on calorie intake. Been thinking about how best to eat in the SLD way - and it seems as though eating low energy dense foods is one of the most important ways that we can eat to feel full on fewer calories. Do you think eating low energy dense foods somehow lowers the set point by creating a weaker flavour calorie association? Seth: Yes, that is a reasonable possibility.

## The Second Immune System: A New Way of Treating Cancer (2011-06-13 11:37)

[1] This is a great documentary about a new cancer treatment invented by a Texas doctor named Stanislaw Burzynski. You can watch it for free until June 20 (and perhaps later, since an earlier deadline was extended).

1. <http://articles.mercola.com/sites/articles/archive/2011/06/11/burzynski-the-movie.aspx>

---

Cancer Cure Exposes The Cancer In Our Institutions « Rhymes With Cars & Girls (2011-06-13 20:25:35)

UncleLongHair (2011-06-14 06:33:53)

I would love to believe that this guy is on to something. But the facts are pretty scarce. He has reportedly treated about 8,000 people at his clinic. Treatment costs between \$30-60k (from the web site). There are absolutely no numbers available for his success rate, remission rate, etc. There are about a dozen success stories on the web site. 8,000 patients at \$30-60k apiece is \$240-480 million. The total dollars is probably less than that adjusted for inflation and the treatment was probably not that expensive when he started out. Even so, that is a heck of a lot of money for a small clinic to bring in, and he can't be bothered to publish any results?

Seth Roberts (2011-06-14 08:10:55)

You're complaining that he hasn't published enough? According to this anti-Burzynski article <http://www.quackwatch.org/01QuackeryRelatedTopics/Cancer/burzynski1.html> he has "published profusely". "There are absolutely no numbers..." The documentary gives the numbers you ask for.

Joe (2011-06-14 12:43:53)

Apparently one can still watch the video for FREE, because I just did. It made me very, very angry. It should make anyone who watches it very, very angry. It also made me ashamed to be an American. That this can happen in this country? Unbelievable. I don't know a better way to put it. To UncleLongHair: The numbers are available in the film. On the other hand, you seem to be missing the point. It's not the numbers, it's the way the government and Big Pharma work together to steal, cheat, lie, and to KILL people, and still are. In my opinion, it's time for torches and pitchforks. Joe

Seth Roberts (2011-06-14 14:10:28)

Yes. At first it seems paradoxical. In a health care system desperately in need of innovation, two government or quasi-governmental agencies (the Texas Board of Medical Examiners and the FDA) do their best to block innovation. Later, of course, it makes sense: Because established powers are allowed to do this sort of thing, that's why we have profound stagnation.

UncleLongHair (2011-06-14 14:42:40)

I stand corrected, my facts about the lack of results from Burzynski's treatments came from various websites such as Mayo Clinic, Dr. Weil, and cancer.org, who must be trotting the party line about the trials being ineffective, which it turns out are likely based on flawed trials that were done intentionally incorrectly. In the documentary, Burzynski claims a 27.5 % success rate in curing cancers otherwise thought to be incurable. This is astonishing because the cancers are otherwise uniformly fatal. He doesn't give a whole lot of other numbers, but through the absurdly lengthy and intense legal campaign by the FDA, they never contested the effectiveness of this treatment. Assuming the documentary is mostly true, what bothers me more about the poor treatment of Burzynski is the fact that what looks to be a very viable treatment for cancer has been tied up in this stupid pissing contest for more than 20 years. Burzynski made his discoveries in the 1980's and the treatment is only now

being seriously studied. It makes you wonder how many other treatments for how many other diseases will never see the light of day.

JeffR (2011-06-14 16:41:45)

I'd urge caution for anything in health research if no other researchers are duplicating the results. The evils of the FDA aside, there are a lot of researchers that want to help cure cancer.

Kim Øyhus (2011-06-15 00:01:54)

Perhaps fermentation can produce antineoplastons.

## Chinese University Press Plagiarizes Free Course Materials (2011-06-15 05:00)

A Chinese university press has printed [1]course materials from Yale's free online classes. Yale has complained, okay, but the incident reminds me of something Stan Ulam attributed to John von Neumann: "It's amazing what you can accomplish if you are willing to give someone else the credit."

Via [2]Andrew Gelman.

1. [http://chronicle.com/blogs/wiredcampus/yale-u-complains-that-chinese-university-press-plagiarized-free-course-materials/31609?sid=wc&utm\\_source=wc&utm\\_medium=en](http://chronicle.com/blogs/wiredcampus/yale-u-complains-that-chinese-university-press-plagiarized-free-course-materials/31609?sid=wc&utm_source=wc&utm_medium=en)

2. [http://www.stat.columbia.edu/~cook/movabletype/archives/2011/06/further\\_wegman.html#more](http://www.stat.columbia.edu/~cook/movabletype/archives/2011/06/further_wegman.html#more)

---

Adam (2011-06-15 05:41:37)

Who cares? Yale was not going to make any money from these materials and substantial effort was invested into making a tangible product out of them (i.e. translating them into Chinese and using physical resources to print them).

Michal (2011-06-15 06:54:02)

Yale was going to be payed just not in money. The payment they requested was recognition. Clearly someone added something to it for the Chinese market but that is beside the point.

Thomas Seay (2011-06-15 12:14:59)

Chinese plagiarize something? No, all they have to do is make a few changes and it is no longer plagiarism. I was shocked when I saw the 2001 "Beijing Bicycle". It was such an out and out copy of De Sica's classic, "Bicycle Thief" that it was unbelievable that the director would have the guts to put it on the international market. All he had to do was say that he had adapted it from De Sica's movie, and that would have been ok. But I have never seen him say that in any place....and I looked.

Robbo (2011-06-15 22:51:28)

It reminds me of another old saying. There was a firm that used to sell a kit of body parts so that you could make a Ford Escort look like a Porsche 911. When Ferdinand Porsche was asked if he was bothered about this, he said. "No, I but would be really worried if there was a kit to make a Porsche look like a Ford".

Larry (2011-06-16 11:21:20)

A variant of the von Neumann quote, "There is no limit to what a man can do or where he can go if he doesn't mind who gets the credit," is allegedly one of Ronald Reagan's favorites. I think he meant the sentiment for others, though, since a sign featuring

these words is, without a hint of irony, available for purchase in the gift shop of the vast and wildly expensive hilltop shrine Reagan built to himself in Simi Valley, California. <http://tinyurl.com/RRDeskSign> ([http://www.reaganfoundation.org/store/product/\\_Ronald\\_Reagan\\_Quote\\_Desk\\_Plaque-1194.aspx](http://www.reaganfoundation.org/store/product/_Ronald_Reagan_Quote_Desk_Plaque-1194.aspx))

### **Tucker Max on Omega-3 and Writing Ability (2011-06-16 05:00)**

Re-reading [1]an old post recently, I found this comment by Tucker Max:

I took four tablespoons [of flaxseed oil] a few hours ago, instead of the regular two, thinking that maybe I could load up and it might help me get back to normal quickly. The pain is pretty much the same, and I just brushed and my gums bled, so obviously the flaxseed oil takes more than a few hours to affect those problems. But—and I haven't measured this with reaction tests like you do—I feel considerably more mentally alert right now. I don't know if I felt like this before, and maybe I didn't notice it because it came on slowly, or maybe I need four tablespoons at once to see a difference, but I really do feel the difference.

By coincidence I had noticed the same thing the day before: I was distinctly sharper than usual a few hours after drinking flaxseed oil (two tablespoons), as measured by my arithmetic test. I had noticed the same thing twice before – years earlier – but had decided not to study it in detail because it was much easier to study the long-term effects of flaxseed oil.

I wrote Tucker to say he had been right. He replied:

Yeah, there's zero doubt in my mind now that fish oil/omega 3 is crucial to brain function. If I don't take it, I can't write effectively.

That's very interesting. Sure, drugs have short-term effects. If you ingest caffeine, for example, it will make you more awake for a few hours. But drugs are dangerous. The notion that a necessary nutrient has benefits that last only a few hours is new. (The notion that a necessary nutrient can make us distinctly sharper will also be new to most people, but not to readers of this blog.) Perhaps we should eat omega-3 every few hours. You've heard of RDAs (Recommended Daily Allowances). Perhaps the future will contain RHAs (Recommended Hourly Allowances).

If you haven't been reading this blog for several years, see [2]these posts for background. Flaxseed oil also will make you smarter long-term, e.g., the next day. The short-term effect is in addition to the long-term effect.

2. <http://blog.sethroberts.net/category/nutrition/omega-3/omega-3-directory/>

---

BlueMorrissey (2011-06-16 06:34:27)

Today is my 4th day in a row of taking 4 tablespoons of flaxseed oil. I've been taking it in the mornings. Beginning early yesterday I felt a big difference in my mental clarity and focus. I am studying for a professional exam most of the day, so it is

more obvious how my brain is functioning. Also, my mood was wonderful for no special reason. I'm sold on flaxseed oil.

Alex Chernavsky (2011-06-16 06:37:02)

For what it's worth, I take 3.5 tablespoons of flaxseed oil every day around lunch time. I've never noticed any effect on my mental abilities. In fact, the only thing that's ever had a noticeable effect on my sharpness is sleep. I am chronically sleep-deprived. On those rare occasions when I actually get enough sleep, I feel significantly happier and more-alert during the day.

mike kenny (2011-06-16 07:04:57)

is the energy gotten from omega-3 meant to encourage us to go get more omega-3? for example, you're a cave man and you stumble upon a stream w/lots of fish in it, easily gotten. you grab some, eat them, feel mentally alert, and then go back to the stream and catch more fish--the mental vigor helps you fish more effectively. the cave man who didn't get pep might not go back and get more fish, and lose out on getting a valuable nutrient. just a theory. but then you might expect sea food or other sources of omega-3 to have an addictive quality, and I don't know if they do. some people do love sushi, but I think most think flax seed tastes weird.

Ben Brinkley (2011-06-16 08:45:08)

I've seen a fast-acting effect of omega-3 on balance that I think anyone could replicate: walking on railroad rails. On vacation and hiking with my wife and kids, I tried walking along some railroad rails. I hadn't done this in fifteen years or so, and remembered that it was hard -- a game of how many steps can I go before I fall off. But now I found it was trivial! I could walk on a rail as long as I wanted, even turn around on the rail and walk backwards. The next morning I wanted to have some more fun with my new abilities, but rail-walking was just as hard as I remembered it from years before: I could only go ten or twelve steps before losing my balance. What was the difference? Day 1 the rail-walking was about 90 minutes after taking my fish oil capsules (about 3g of EPA+DHA). Day 2 it was about 15 minutes after taking them. Not enough time to get to my brain. Sure enough, on the return leg of my Day 2 hike, about an hour later, my rail-walking superpowers had come back. I remember thinking, "Do circus performers and fighter pilots know about omega-3???"

JJ (2011-06-16 09:48:33)

Years ago, I did multiple tests on mental performance and memorization using Omega 3 Fish Oil, and I came away convinced that the fish oil had a big impact on my ability to retain and use information. I was listening to Japanese language instruction in the car, and on mornings where I had taken fish oil the previous night, I recalled information learned the previous day more often and was able to learn new information more quickly. It was pretty dramatic and I performed the test a number of times as some nights I would forget to take the fish oil. I considered that it could be the placebo effect, but I also noticed differences in performance and then would try to remember if I had taken the fish oil the previous night; in other words, I noticed the memory effect before connecting it to the supplement.

Jahed (2011-06-16 12:10:04)

I'm curious about the mechanism at play here. Isn't the omega 3 in flaxseed oil very poorly utilized due to the enzymatic processes involved? I believe the idea was that ALA, the primary omega-3 in flaxseed oil, has only 10 % conversion to EPA and even less DHA, therefore it would be better to consume fish oil? Does anyone have numbers comparing their mental clarity on fish oil as opposed to flax?

Jonathan Graehl (2011-06-16 12:44:17)

The short term boost could be mostly caused by the caloric content, assuming an overall trend of weight maintenance or loss. Could someone point me to experiments that rule out this obvious explanation? I recall Seth's long-term omega-3-oil arithmetic-performance experiments controlling for the calories (even comparing against the same amount of some other type of fat). The same should be done in demonstrating a short-term performance enhancement.

Seth Roberts (2011-06-16 14:38:46)

That "ALA poorly converted to EPA" conclusion was based on people with little ALA experience. Experience with a food induces (increases the concentration of) the enzymes you need to digest it. This is very well known to at least some biologists. It was the basis of a Nobel Prize in the 1950s.

Seth Roberts (2011-06-16 14:40:07)

Yeah, and what about gymnasts? On a plane I sat next to the mother of an Olympic caliber gymnast and told her about the balance-enhancing effects of omega-3. But her son never contacted me. That's a very persuasive story about rail walking.

Seth Roberts (2011-06-16 14:46:13)

Alex, after I took flaxseed oil for the first time, I didn't notice any change in sharpness. But I did notice an improvement in balance when I did something difficult requiring balance (putting on my shoes standing up). You may need a challenge to easily notice the difference.

Jahed (2011-06-16 23:00:47)

Seth, thanks for indulging my curiosity. Is there any other reason to use flax instead of fish oil (heavy metal contamination?) I recently switched over from flax to fish oil (this one, in particular: <http://www.bodybuilding.com/store/asc/sea.html>) because of the high amounts of EPA/DHA delivered per serving (I still use 15 ml). I was just thinking that, sure, your conversion after prolonged use could be way higher, 60 % or more, but why not just consume EPA/DHA directly from fish oil? Did you conduct some other subjective "feel" type test for fish oil and find it lacking, or did you just luck into flax's benefits and decide it was good enough? Cost? Sorry for the deluge of questions! Thanks for your responses.

Nathan Myers (2011-06-17 02:31:03)

I once walked a mile on a rail without stepping off. I hadn't had any n3 oil, and couldn't have said what it was. Nowadays, at my age, it seems to make a difference, but I doubt I could walk that mile with or without. I'm curious how the "n3" known to chemists turned into "ω3" in marketing text.

Seth Roberts (2011-06-17 08:36:58)

The omega naming system came from a chemist and is older than the n naming system. The details are discussed in a chapter in *The Queen of Fats*.

Jazi yechezkel zilber (2011-06-18 00:47:00)

It is possible that the hurly effect is due to low depositories in the system. What is interesting is what happens when a person has enough omega 3 for a long time. Is there then a strong sort temr effect? Talking from an evolutionary perspective. We are wired for high variability in food sources. Does not make local effect impossible, but suggests that the healthy ways of things are not on having a short term nessecity of food sources (but a long term need for healthy food etc.)

Sonia (2011-06-22 08:54:46)

As a result of your years of self-experimentation, have you discovered that certain types of flaxseed oil are more effective than others? Whenever I go to buy flaxseed oil, I feel overwhelmed by the options and I'm never sure what exactly I should be looking for. I've consistently heard that unrefrigerated flaxseed oil isn't worth buying, but that's about it. I saw your response to a reader's comment in 2007, saying that you took Spectrum Organic (Original Formula) back then. Is that still the case, or have you found something else works better, or that maybe something new in the market is more potent?

## **Self-Tracking as a Source of Political Power (2011-06-17 05:00)**

The more certain you are the more power you have to convince others and convince yourself. You may want to convince them that change is needed – e.g., that a polluting factory should be shut down or cleaned up. China has a huge

problem with industrial pollution, as [1]this report describes. Children are especially at risk.

The danger to those in power posed by self-tracking – in particular, blood tests that measure lead – is shown by this quote from the report:

Even parents who were able to access [lead] testing for their children reported difficulties in obtaining the results of the tests conducted. Many parents in Yunnan and Shaanxi reported that test results from their children's lead tests were withheld completely. Some parents in Yunnan and Shaanxi told Human Rights Watch that they never saw any test results. Others were allowed to see the results from initial testing but were prevented from seeing the results from follow-up testing.

My daily arithmetic tests (how fast can I do simple arithmetic, such as  $3 + 5$ ) have the same purpose as the lead tests: to assess the quality of the environment. If my scores get worse, it may reflect poisoning. Comparison with a blood test for lead highlights strengths and weaknesses of my arithmetic test.

#### Strengths

1. Sensitive to many things. Can detect any bad influence on the brain, not just lead.
2. Free in the sense that the cost is zero (so long as you have a laptop).
3. Unrestrictable. No one can deny you access.
4. Fast. You get the results immediately.
5. Great sensitivity. You can test yourself as often as you want. The more tests you do the more easily you can detect a change.
6. Variability known. By looking at a graph of your data (score vs. day) you can judge the natural variability – essential for judging the importance of a deviation. With lab tests, the variability is rarely known to the person whose blood was tested or the doctor that reviews the results.
7. Measures what you care about. You care about health. Brain health is part of that. Sure, high levels of lead are bad, but what about low levels? Is there a hormetic effect? The dose-response function isn't obvious.

#### Weaknesses

1. Unconventional. A lead test is easier to understand.
2. Unspecific. If a score is bad (= if I get slower) it isn't clear why. If you have too much lead in your blood the cause is likely to be obvious (e.g., polluting factory, lead in food).
3. Sophistication needed. The arithmetic test is sensitive to hundreds of environmental factors, I'm sure, so identifying the cause of any change inevitably requires sophistication. For example, perhaps you need to control the time of day. Another example is that you need to control/allow/adjust for practice effects.

If the Chinese parents were able to measure their children's brain functions themselves, they might be far more outraged – and therefore far more powerful.

1. <http://www.hrw.org/en/node/99441/section/5>

---

Oxonian (2011-06-17 06:59:40)

Interesting. Can you elaborate on the tests you use to measure cognitive performance? Can they be found online? Thanks.

Seth Roberts (2011-06-17 11:04:26)

The test I use cannot be found online. But you can watch a video about its use here: <http://vimeo.com/14281896>

dearieme (2011-06-18 07:44:54)

I took an exercise-for-heart-patients class this week. While we cooled off afterwards we were addressed by a young dietician. When one chap challenged her about cholesterol in the diet she said the "recent" research showed that it didn't matter; it was fat, and type of fat, in the diet that mattered. Some progress? P.S. the same chap had a further interesting question - he invited her to look at the twenty or so patients in the class. "Only three of us are fat" he said; "what's up?".

dearieme (2011-06-18 07:47:21)

P.P.S. "it was fat, and type of fat, in the diet that mattered" - meaning, of course, "mattered for the worse".

Jeff (2011-06-20 19:00:56)

The quackwatch article was a great read. Thanks.

## The Torchlight List by Jim Flynn (2011-06-19 05:00)

In college and afterwards, I tried to educate myself by reading well-written stuff. At first, I went through back issues of The New Yorker in the Caltech library. Later I stuck with books. For example, I learned about molecular biology by reading The Eighth Day of Creation. [1]The Torchlight List by Jim Flynn (discoverer of the Flynn Effect, the slow increase in IQ scores) has the same underlying philosophy: a good way to learn is to read books you enjoy.

The Torchlight List describes 200 books in pleasant narrative prose that Flynn both enjoyed and found educational. Here are the first three:

1. The Story of Language by C. L. Barber
2. The Greek World edited by H. Lloyd-Jones
3. The Decipherment of Linear B by John Chadwick

Indeed, I read the Chadwick book and enjoyed it. I have yet to find a well-written book about language evolution (although I liked [2]John McWorter's lectures on the subject) so I look forward to the Barber book.

More people should write books like this; the underlying idea is very good. I found one important gap in Flynn's categories of books (Science and Early History, American History, America Broods, The Human Condition 1, ...): Books That Caused Discomfort (and are fun to read). There are not many such books. Robert Moses was intensely discomforted by Robert Caro's The Power Broker. (A recent enjoyable TV series that caused discomfort was [3]The Kennedys.) Lolita was discomforting, far more than Nabokov's other books. First prize in this category goes to The Man Who Would be Queen by Michael Bailey.

---

bjk (2011-06-19 06:11:44)

Adam's Tongue by Derek Bickerton is a very entertaining book on language evolution, or on Bickerton's theory of language evolution.

mike kenny (2011-06-19 06:39:40)

robert wright's 'the moral animal' was almost traumatic to read—it's one of my favorite books. i'd love to read a list of your favorite educational/enjoyable books seth.

vgm (2011-06-19 08:46:36)

Professor: A 'Books that Caused Discomfort' would be a phenomenal! Do you think you could write a post (or maybe a guest post on Tim Ferriss' blog, which I imagine may receive more traffic) asking for recommendations?

dearieme (2011-06-19 12:09:42)

If discomfort is what you want, read James Hogg's *The Confessions of a Justified Sinner*.

Alex Chernavsky (2011-06-19 12:49:17)

"I believe that we should read only those books that bite and sting us. If a book we are reading does not rouse us with a blow to the head, then why read it? Because it will make us happy, you tell me? My God, we would also be happy if we had no books, and the kind of books that make us happy we could, if necessary, write ourselves. What we need are books that affect us like some really grievous misfortune, like the death of one whom we loved more than ourselves, as if we were banished to distant forests, away from everybody, like a suicide; a book must be the ax for the frozen sea within us. That is what I believe." – Franz Kafka, letter to Oskar Pollak, January 27, 1904

Gestion de patrimoine (2011-06-20 04:58:40)

*The Story of Language* by C. L. Barber is great. It's one of the most important piece of my library.

I.S. (2011-06-21 09:16:05)

Hi Seth, "I have yet to find a well-written book about language evolution" Everyone points me to Pinker's books on this topic. I was wondering what you thought of his popular writings?

reader (2011-06-21 14:15:27)

Until the list is put online, here's [1]an edited extract of books 93 through 114.

1. <http://www.odt.co.nz/entertainment/books/142618/edited-extract-torchlight-list?page=0%2C0>

### **Marcia Angell on Psychiatry: A Train Wreck (2011-06-21 22:22)**

Marcia Angell, a former editor of *JAMA*, may be the most prominent critic of drug companies. The most recent two issues of the *New York Review of Books* contain a two-part critique by her of psychiatry. I liked [1]Part 1 because she described the excellent work of Irving Kirsch (*The Emperor's New Drugs*). [2]Part 2, however, is a disaster.

She goes on and on about the evils of the DSMs – the diagnostic manuals of psychiatry. Improving the reliability of diagnosis is playing into the hands of the drug companies, she seems to say. She complains that the number of diagnoses is increasing. Well, yes, all diagnostic systems get larger over time. This is a good thing; if you don't have a name for a problem, it is hard to do cumulative research about it and hard to communicate research results to everyone else. She complains, apparently, that new categories are being added:

There are proposals for entirely new entries, such as "hypersexual disorder," "restless legs syndrome," and "binge eating."

She does not say why this is bad. Maybe she thinks it's obvious. It isn't obvious to me. Diagnostic categories help researchers and doctors and the rest of us communicate. For example, [3]Dennis Mangan's research shows why it is a good idea for the term restless legs syndrome to have an agreed-upon meaning.

She complains that the DSM doesn't have enough "citations":

There are no citations of scientific studies to support its decisions. That is an astonishing omission, because in all medical publications, whether journal articles or textbooks, statements of fact are supposed to be supported by citations of published scientific studies. (There are four separate "sourcebooks" for the current edition of the DSM that present the rationale for some decisions, along with references, but that is not the same thing as specific references.)

Please. This is clueless. A diagnostic manual is a dictionary. It assigns meanings to diagnostic categories. You can make a useful dictionary without "citations of scientific studies". Long before you can do scientific studies about the best way to define dog you can come up with a definition of dog that is better than nothing.

She ends her review with this:

Above all, we should remember the time-honored medical dictum: first, do no harm (*primum non nocere*)

Gag me with a spoon. Time-honored? Doctors – with the support of JAMA, not to mention the rest of the health-care establishment – continually prescribe drugs with bad side effects and high prices and suppress innovative alternatives. (Not only that. [4]My own surgeon recommended a dangerous surgery of no clear value.) How they can claim to do no harm escapes me.

Sure, psychiatry is awful. For a long time psychiatrists rallied around a transparent intellectual fraud (Freud and his offshoots). Now they rally around a less transparent intellectual fraud (neurotransmitter theories of mental illness). Psychotherapists and their wacky theories and no-more-effective treatments are no better so I wouldn't blame the drug companies for the underlying problem. I put the problem like this: Our health care system consists of a very large number of people, many with very large salaries, who must get paid. Being human, they strongly oppose any progress that would reduce their salary or influence or, heaven forbid, eliminate their job. Because of them, many promising lines of research, such as prevention via environmental change or cure via nutrition, are completely or almost completely ignored. This is the fundamental reason Angell's critique is so bad: She is part of the problem. She is very smart, but she's been brainwashed ("*primum non nocere*"!). She utterly ignores the fact that we don't know what causes depression, what causes schizophrenia, what causes autism, and so forth. Only when we learn what causes these and other mental disorders will we be in a good position to improve our mental health.

Analog Eye (2011-06-21 23:50:10)

"She does not say why this is bad. Maybe she thinks it's obvious. It isn't obvious to me." I'd guess she's talking about hypermedicalization of situations that do not really warrant a medical treatment, or at least a treatment with drugs. Maybe she's confusing both of these (e.g. prescribing changes in exercise patterns or diet rather than drugs), but that's the general point I think she's trying to make.

Seth Roberts (2011-06-22 05:49:59)

How can we learn how to treat a problem if we don't have a name for the problem? The term "hypermedicalization" doesn't answer that question.

Alex Chernavsky (2011-06-22 06:22:31)

I think the issue is whether the problem exists in the first place, or whether the DSM contains a bunch of self-serving pseudo-diagnoses that allow the mental-health industry to prescribe harmful "treatments", dis-empower people, and further entrench the *status quo*. See, for example: [1]'Shyness: How Normal Behavior Became a Sickness'

1. <http://online.wsj.com/article/SB119402985846180627.html>

mike kenny (2011-06-22 07:37:15)

regarding increasing diagnoses-why do we even need a formal diagnostic manual? doctor's obviously want to get a handle on what people have, and will use words to express problems, and if they have a set of official diagnoses, then they might be constrained in what they would diagnose. 'it must be one of these diagnoses on this table.' in other words, getting rid of official tables of diagnoses would allow for many more possible diagnoses, and inventions of diagnoses. french is guarded by a body that approves words that are 'officially' french, while english doesn't-which language do you think is going to be more expressive in the long run? two, freud and his disciples seem to be getting bashes too much. where's the appreciative thinking? he seemed to apply the empirical approach to introspection and challenged orthodoxy, trusting his lying eyes over authority, very much in the spirit of self experimentation. his disciples often seemed to do this too, breaking with freud. i think albert ellis was a freudian, and then he went his own way and developed an obviously effective cognitive behavioral approach.

Nancy Lebovitz (2011-06-22 08:00:15)

So far as restless leg syndrome is concerned, I have a friend who's plagued by it- if she doesn't take meds for RLS, she can't get nearly enough sleep. There may be some other solution (I've heard a little good stuff about acupuncture), but meds seem to be legitimate for that one. On the other hand, I can't see why it's filed under psychiatry. It's pretty clearly neurological, with no emotional or cognitive component.

Seth Roberts (2011-06-22 08:19:38)

"the issue is whether the problem exists in the first place" - you are saying that a large fraction of the disorders in the DSM are not problems? Angell doesn't say this. And I don't agree with this. I have never heard this claim made. Even Szasz never said this.

Alex Chernavsky (2011-06-22 09:58:37)

I don't know the fraction of problems vs. non-problems. Recall that homosexuality was apparently a problem prior to 1973 - but then suddenly ceased being a problem. Now, apparently, shyness is a problem worthy of medical attention. Angell's point (or one of them) is that the ever-expanding scope of the DSM is an underhanded attempt by the psychiatric establishment to medicalize (problemetize?) the range of normal human traits and behaviors. I'm not really a big fan of Thomas Szasz, but for whatever it's worth, see this essay about his views on the DSM: <http://www.themoralliberal.com/2010/12/20/the-illegitimacy-of-the-%E2%80%9Cpsychiatric-bible%E2%80%9D/>

Vic (2011-06-22 18:37:07)

"On the other hand, I can't see why it's filed under psychiatry. It's pretty clearly neurological, with no emotional or cognitive component." Not clear at all... lots of seeming "neurological" problems have emotional and cognitive underpinnings, sometimes nonconscious (see Freud, who made acute observations and had some revolutionary insights regarding nonconscious mental activity, even if much of what he said was wrong)

Vic (2011-06-22 18:37:55)

ps Seth, have you ever actually read Freud or are you just going off how he's been represented by others?

Seth Roberts (2011-06-23 21:29:52)  
I have read about 15 books by Freud.

Mark Shulgasser (2011-07-18 14:51:44)  
Part One and Part Two are of a piece. Superficial, or perverse, not to recognize that. Both of them of a piece with her 1995 "The Truth about Drug Companies".

### **Albert Einstein: Out-of-Touch Theorist (2011-06-23 17:41)**

[1]Martin Wolf relays what passes for wisdom:

Albert Einstein is reported to have said that insanity consists of doing the same thing over and over again and expecting different results.

Which, if true, shows that Einstein was a theorist.

Call me insane. Based on many years of data collection, I believe [2]scientific progress has a power-law distribution. You sample from this distribution when you collect data. You collect data again and again – "doing the same thing over and over again". Almost all the data you collect produces little progress; a tiny fraction produces great progress. The secret to scientific progress is doing the same thing over and over – and being wise enough to grasp that the results will vary greatly. (Nassim Taleb understands this.) In the short term, it seems like you are getting nowhere.

I learned this lesson from [3]my sleep research. For ten years I tried various solutions to my problem of early awakening. Nothing worked. All my ideas were wrong. Eventually I got "lucky" but actually I made my own luck by persisting so long.

Once you realize the distribution of progress, you grasp that the secret of success is making the cost per sample as low as possible. Few scientists, in my experience, have figured this out. They prefer expensive experiments because larger grants signal higher status. Won't fancy equipment tell me more? they rationalize. Grant givers, also failing to understand the basic point, are happy to oblige the status-seekers: Much easier to administer one \$200,000 grant than 10 \$20,000 grants. And progress slows to a crawl.

More [4]Rita Mae Brown is a more likely source of this saying than Albert Einstein.

---

Vince (2011-06-23 19:40:58)  
It depends what you mean by "the same thing." Does repeatedly collecting data about a problem while trying various solutions count as doing the same thing? I'd say no - the various solutions that you're trying are different things that you're doing, and

the data that you're collecting are the results which you're checking to see if they've come out different.

Alex Chernavsky (2011-06-23 19:51:39)

Lots of quotes are falsely attributed to Einstein (and Mark Twain, Abraham Lincoln, Samuel Johnson...).

PS (2011-06-23 22:53:03)

I second Vince. I think you're confusing perseverance with "doing the same thing". I don't think Einstein (or whoever else) would've dissed perseverance. That's just anathema to research, and pretty much excellence in any sphere.

dearieme (2011-06-24 04:00:07)

<http://www.telegraph.co.uk/health/8594293/Crash-course-diet-reverses-Type-2-d-iabetes-in-a-week.html>

Seth Roberts (2011-06-24 04:36:37)

What is the difference between perseverance and doing the same thing again and again?

Chung-chieh Shan (2011-06-24 05:37:25)

One difference between perseverance and doing the same thing again and again is that perseverance includes doing slightly different things again and again.

Nancy Lebovitz (2011-06-24 06:55:28)

Would you describe what's required for the focused practice needed for the 10K hours to mastery as perseverance?

Seth Roberts (2011-06-24 07:00:16)

"perseverance includes doing slightly different things again and again." It does? I have never heard that definition of perseverance. Is it in any dictionary?

Seth Roberts (2011-06-24 07:01:32)

Nancy, no, the long practice you need to become good at something is inevitably varied.

Olga (2011-06-24 07:35:34)

I always read this quote if you are doing exactly the same (e.g. collect the same data and do the SAME experiment) then you are insane. For example, in trying to lose weight, trying the same diet (e.g. chocolate-chip cookies), but each time expect to lose weight. This is insanity. I think that the difference here is in the process. The quote says that if you want different results, you need to change something in the process. So to answer this question: "What is the difference between perseverance and doing the same thing again and again?" Perseverance is in the goal (e.g. lose weight, find inner piece, etc.). Doing the same thing again and again - is in the process (trying the same method over and over). It looks like you have shown perseverance without insanity. You have tried different methods to achieve your goal.

Tuck (2011-06-24 10:04:46)

I agree with the others: you're misinterpreting Einstein's quote. To understand how, examine Thomas Edison: "While working on the nickel/iron storage battery, he performed 10,295 failed experiments before achieving success." <http://www.yeartosuccess.com/members/y2s/blog/VIEW/00000021/00000257/Inspiration-from-Thomas-Edison.html> That's 10,295 \*different\* experiments. If he'd performed the same experiment 10,295 times, expecting a different outcome, he would have clearly been insane. Edison was known as the "Godfather of Perseverance".

Seth Roberts (2011-06-24 10:48:27)

Repetition is never exact, in my experience. If Einstein's quote is to mean anything - is to apply anywhere - it must refer to inexact repetition. In the article by Wolf from which I took it, it refers to inexact repetition. But the exact meaning of "repetition" and "perseverance" is a digression. The point of this post is that I learned something from my self-experimentation

(the power-law distribution of progress) that I hadn't known, that makes a difference in what scientists should do, and that I have never heard anyone else say. I did know about Edison ("genius is 99 % perspiration"), but thought of him as an engineer, not a scientist. If the power law distribution of scientific progress is well-known, I would be happy to be corrected.

Michael Whitaker (2011-06-24 11:50:07)

To me the salient point in this post is "the secret of success is making the cost per sample as low as possible". Now that's a great quote, Seth! In my world of web analytics, there is a lot of interest in doing AB testing/controlled experiments. The challenge is to get some successes from time to time, otherwise people will lose interest. And the only way to get there is to do lots of experiments, which is only possible if the implementation of these AB tests is quick and cheap.

twelve (2011-06-24 12:44:30)

Dear Professor- If you take a narrow view of 'doing the same thing over and over again', then Einstein's own statement would define Einstein as insane. After all, it took him 10 years to formulate general relativity after the special case (1905 to 1915) and he spent most of this time thinking and occasionally writing it down. But I think, and I'm sure you agree, what Einstein means is that insanity is attempting the same thing over and over again and expecting different results, all other things being equal. I think Olga is correct when she gives the example of eating chocolate chip cookies. Now things get a little messy for me, so maybe you can help me out: it is certainly true that the statement is impotent if it only applies to noise-free cases, but I think a fair reading would suggest that in cases where noise and variability are low, trying the same thing over and over and expecting different results is foolish. Certainly, it's hard to draw lines here, but I think we would agree that collecting data over a sufficiently long period of time, finding that your approach produces insignificant results, and attempting it again under the same circumstances with no modification, is foolish.

Vic (2011-06-25 09:49:45)

brilliant post

Oliver Mayor (2011-06-26 19:35:11)

Good observation. Would a fair summary be: "Self-experimentation is antifragile; it benefits from volatility rather than suffering because of it"? Perhaps Taleb already includes personal science under "aggressive tinkering/convex bricolage". Ask him next time he's around.

Tom Passin (2011-06-28 12:10:51)

I'm certainly in favor of doing lots of cheap, easy experiments. But I'm not completely convinced that it's always the best thing. Thinking back say 30 or 40 years ago when it was much harder to do lab measurements (in physics labs, for example, especially pre-computer) because the equipment cost a lot, budgets were smaller, and generally speaking it was harder to make measurements, to analyze the results you generally had to think a lot harder before setting up an experiment, and you had to work harder to understand what the results were telling you. The result was you learned more at both ends (before and after) of the measurements. The drawback was that it was harder to discover if you had observed a special case or exception. I'm not sure that this trade off has changed in favorable ways over the years.

Seth Roberts (2011-06-28 16:01:21)

Tom, you seem to be saying that if you slow down research you are forced to think harder and therefore do more productive research. This is exactly what I thought BEFORE I started doing self-experimentation. Before self-experimentation, I believed it was a good idea to think long and hard before doing an experiment. When I started doing more frequent experiments, I came to see that I was completely wrong about this. I made more progress in one month of doing fast "unthinking" "sloppy" experiments than I had in a year of doing careful thoughtful ones. I think your idea that slower is better is an illusion. If you were actually able to compare different speeds of research I predict you would find that faster is better.

Tom Passin (2011-06-28 18:57:35)

That's certainly how I program, and I don't know how I'd be able to do it any other way, not with effectiveness. And it's how I

\*like\* to work in other areas, too. It suits me pretty well. But I'm not convinced it's a one size fits all thing. I'm not exactly saying if you slow down, you will automatically do better work. I was reflecting on when our circumstances or equipment forced us to be slower and more thoughtful. It's not quite the same thing. I think - just based on what I noticed in myself and others - that when it became easier to work quickly, people tended to lose touch with the phenomena (or the world) - sometimes, anyway. It takes a different attitude to make good use of little throwaway steps, and maybe that doesn't work well for everyone or for all areas. But personally, it suits me fine!

Dave Lull (2011-06-25 05:37:27)

For comments on that "crash diet" see Jenny Ruhl's latest blog posting: 'Idiotically Dangerous Diet "Reverses Diabetes" but So Does Moderate Carb Restriction Without Calorie Restriction' [http://diabetesupdate.blogspot.com/2011/06/idiotically-dangerous-diet-reverse s.html](http://diabetesupdate.blogspot.com/2011/06/idiotically-dangerous-diet-reverse-s.html)

Tom (2011-06-29 10:09:13)

Ruhl doesn't really support her assertion that the diet is dangerous. It seems very unlikely to me that it is. I have to believe that we evolved to be extremely well equipped to go a **single week** on sparse food. It seems very believable that it would have a salutary effect after **five or six decades of uninterrupted gorging**. The "KimKins" diet that she throws up is a red herring. Kimkins was the fat, fraudulent, scientifically-illiterate housewife whose low carb, low fat, **high protein** "Kimkins" diet really **was** dangerous as it results in "rabbit starvation": [http://en.wikipedia.org/wiki/Rabbit\\_starvation](http://en.wikipedia.org/wiki/Rabbit_starvation)

### Mercury Damage Revealed by Brain Test (2011-06-26 16:28)

For several years I have been doing simple daily tests to measure my brain function. I got the idea when I noticed that a few capsules of flaxseed oil improved my balance. Flaxseed oil also improved other measures of brain function,

such as digit span. I wasn't surprised I could do better; what was surprising was how easy it was. It revealed a big gap in our understanding of nutrition. I do the daily tests not only to improve brain function but also to improve the rest of my body. I think the brain is like a canary in a coal mine – especially sensitive to bad environments. Learning what environment was best for the brain would suggest what environment is best for the rest of the body. When I started taking an optimal amount of flaxseed oil, my gums turned from red (inflamed) to pink (not inflamed), supporting this assumption.

I tried six or seven mental tests and eventually settled on a test of arithmetic (how fast I could do simple problems such as 5-3). I hoped that now and then my score would change (in either direction, faster or slower) and that these changes would point to new things that control brain function. No one had/has done such a thing. I had no idea if unexpected changes would show up or, if they did, how often. I didn't know what the score changes would look like (their size and shape) nor, of course, what would cause them. Would all of them involve diet? Would all of them make sense in terms of what we already know? (Flaxseed oil makes sense because the brain contains lots of omega-3.)

The first two surprises were these: 1. My score suddenly improved a few days after switching from Chinese flaxseed oil to American flaxseed oil. This made sense: It is easy to destroy omega-3 if flaxseed oil is kept at room temperature. 2. My score suddenly improved when I switched from pig fat to butter. This was counter-intuitive: pig fat is more paleo than butter.

Last fall, [1]there was another surprise: My score greatly improved since the summer. I was much faster than ever before. At first I thought the improvement was due to moving to Beijing. I had moved from Berkeley to Beijing in early September. My Beijing life differed in a thousand ways from my Berkeley life. I had three ideas about which differences might matter. 1. Walnuts. Perhaps I ate more walnuts in Beijing. Walnuts are supposed to be good for brain function. 2. Heat. It was much hotter in Beijing than Berkeley. Maybe that improved brain function. 3. Vitamins. I took less vitamin supplements in Beijing. Maybe they harmed brain function.

I tested these possibilities. 1. I stopped eating walnuts. My arithmetic score did not clearly change. 2. Winter came, it got much colder. The improvement did not go away. 3. I took the same amount of vitamins I'd taken in Berkeley. My arithmetic score didn't change. So all of these ideas were wrong.

Because they were wrong, I considered a fourth possibility: The improvement was due to removal of two mercury amalgam fillings on July 28, 2010. They were replaced with non-amalgam fillings. I'd had them removed for precautionary reasons. I wasn't suffering from any signs of mercury poisoning. Hair tests had repeatedly shown mildly high amounts of mercury in my hair (75th percentile of an unspecified sample). Measurements of the mercury in my breath had come out higher than usual but it was hard to be sure the machine was working correctly.

I looked again at my data. It showed something I hadn't noticed: the improvement started before I went to Beijing. It started very close to July 28. That was good evidence that the mercury explanation was correct. Now the evidence is even stronger. I've returned to Berkeley and thereby made my life quite similar to the situation when my scores were much higher than now. The improvement has remained.

The evidence for causality – removal of mercury amalgam fillings improved my arithmetic score – rests on three things: 1. Four other explanations made incorrect predictions. 2. The improvement, which lasted months, started within a few days of the removal. Long-term improvements (not due to practice) are rare – this is the only one I've noticed. 3. Mercury is known to harm neural function ("mad as a hatter"). As far as I'm concerned, that's plenty.

[2]A long Wikipedia article describes evidence on both sides of the question of whether mercury amalgam fillings cause damage. In 2009, the American Dental Association stated in a press release "the overwhelming weight of scientific evidence supports the safety and efficacy of dental [mercury-containing] amalgam." As recently as 1991, Consumer Reports told readers "if a dentist wants to remove your fillings because they contain mercury, watch your

wallet." (Dental insurance will pay most of the cost of removing my remaining amalgam fillings.) In an essay last revised in 2006, Stephen "Quackwatch" Barrett [3] explained at length why mercury toxicity is a "scam". According to Barrett, "there is overwhelming evidence that amalgam fillings are safe."

[4] Ask your dentist some pointed questions.

---

Mario Iwakura (2011-06-27 03:55:36)

After reading some studies of Jarmila Prochazkova (notably pubmed 16804512, 15349088 and 12743535), I decided to have my 11 amalgams removed. Where I live (Brazil) there are no dentists specialized in safe amalgam removal. Before the extraction, my thyroid antibodies (anti TPO) were decreasing while following a gluten free paleo diet. But somewhat stabilized around 400 UI/ml. Fifteen days after extraction, my tpo jumped to 454, then peaked 505 after 3 months, and then started to decrease. Only after 6 months, it returned to 400. During all this time, I was supplementing with chlorella, cilantro, vitamin c, high dose iodine and selenium. Unfortunately, I started to eat fish (cod) twice a week, and that raised, again, my antibodies. Now, amalgam and fish free, I can say that I'm in the right track to overcome my autoimmune condition.

Steve Wright (2011-06-27 08:35:56)

Hey Seth, did you take any precautionary supplements or steps before or after the removals? The info on how and if to remove amalgams seems way too convoluted, it would be nice to find more successful detailed stories. There just doesn't appear to be any referenced and creditable resources of science plus testimonials. Any thoughts? Thanks for all you do!

Seth Roberts (2011-06-27 10:25:37)

I didn't take any precautionary supplements or steps before or after the removals. Re the absence of "referenced and credible

resources of science plus testimonials". There is credible evidence amalgam fillings are dangerous; that is why they have been banned in several countries. You seem to be focusing on what is missing ("more successful detailed stories") but I suggest you pay more attention to what is present – the evidence implying amalgams are dangerous.

TomGinTX (2011-06-27 13:16:03)

I had read about this a long time ago, but did not want to get my fillings removed because I had read that this could be dangerous too, by releasing more Hg during the removal. And I did not know of a dentist who would remove them anyway. So I was pleasantly surprised a couple of years ago when my dentist told me I needed a filling replaced and he was going to use some kind of space age plastic resin. I asked why, and he said that he thought the Hg amalgam might be unhealthy, and there was finally something that was sturdy enough to use instead.

Jonathan (2011-06-27 14:45:22)

Seth, sorry if this is off-topic, but have you checked whether fish oil has the same positive effects for you (or other people) as the flaxseed oil? I'm wondering whether omega-3 oils are somewhat interchangeable, or whether there's something special about flaxseed oil. Thanks.

JohnN (2011-06-27 16:15:26)

Seth - Have you considered another confounding factor that is living in the new city (Beijing) with the worst air quality - bar none? Additionally, your score is expected to improve over time from repeated cognitive exercise.

Ragout (2011-06-27 18:57:36)

As I understand it, mercury is very persistent in the body. So removing amalgam fillings can't be expected to have an effect on your mercury levels for a long time. Hence, it seems very implausible that removing your fillings had any effect on brain function a few days later.

Erik La Gattuta (2011-06-27 21:19:54)

Hi Seth Do you have a recommendation for a specific hair test? A recommended lab?

Seth Roberts (2011-06-28 06:37:09)

on a friend's recommendation, I use Doctor's Data for hair tests.

Seth Roberts (2011-06-28 06:39:00)

John N, bad air (Beijing) should not make my brain work better. As for "repeated cognitive exercise" I had stopped getting better from practice long before this.

Seth Roberts (2011-06-28 06:40:31)

Jonathan, I tried fish oil once. It gave me a headache, so I've stuck with flaxseed oil. However, other people report the same effects (as I get with flaxseed oil) with fish oil.

Jan (2011-06-28 12:37:51)

Hi Seth, I've been wanting to remove my amalgam fillings for quite some time now. But I haven't found a dentist who had something that I trusted as a safe replacement. Most composites contain either bisphenol A or nanoparticles. And polymerisation of the composites is never 100 %, so there could be stuff leaking into your body, if I've understood well. I'm interested in any info on fillings that seem safe to you!

Seth Roberts (2011-06-28 15:56:13)

Jan, the next time I talk to my dentist I'll find out what filling material he used.

Vic (2011-06-28 21:47:03)

Most likely he used a composite that includes bisphenol A - supposedly the levels that leech from it are minimal and safe, but then that's what they say about mercury amalgams too. On the other hand, maybe bisphenol A is improving your brain function - it's the other thing that changed at the same time as the removal of mercury.

Chris (2011-06-29 02:23:08)

If it's really mercury, then there should also be a measureable effect in individuals with mercury fillings who just eat a lot of coriander/cilantro as that's supposed to chelate the metals out of the body and into the urine..

Jeff M. (2011-07-05 15:10:43)

Seth, Is your dentist a 'regular' dentist or a 'holistic' dentist? Many anti-amalgamists claim there is special training required to safely remove amalgams. How much does it cost to have amalgams replaced? I'm trying to find out if the holistic folks charge significantly more than a regular dentist would, but Google isn't turning up much, because most folks don't like to list costs online.

Jeff M. (2011-07-05 15:29:46)

Also, have you repeated the Doctor's Data hair test before and after the amalgam removal on your new hair growth to compare mercury pre- and post? Thanks, Jeff

Seth Roberts (2011-07-05 21:00:39)

My dentist, Sandor Hites, is a holistic dentist. I recently had 3 fillings replaced. Two of them cost \$260 each; the third cost \$339. I don't know why the price varied. My dental insurance paid 70 %.

Seth Roberts (2011-07-05 21:01:53)

it is too early to tell what has happened to the mercury in my hair as a result of my filling removals. But, yes, I have had the hair test repeated.

Kim (2012-03-08 09:51:41)

I had a mouthful of amalgams (12+) removed last fall at the insistence of my functional medicine doctor, and my autoimmune (Hashimoto's) symptoms are finally improving. My endocrinologist has been fiddling with my medicine for years, but they never helped. I'm a believer.

## **The Medtronic Scandal (2011-06-28 20:39)**

In August 2010, John Farber, a reporter at the Milwaukee Journal Sentinel, wrote [1]an article about how a medical device called Infuse, used for spinal surgeries, "went from revolutionary advance [2002] to public health alert [2008]." Bad side effects were common when Infuse was used, far more common than when it wasn't used. Infuse is a hugely profitable product of Medtronic, the largest medical device company in the United States.

How did the high rate of bad side effects go unnoticed? Farber went on to find that there were unreported conflicts of interest in the journal articles about Infuse. The authors of the articles had received (before and after publication of the articles) large payments from Medtronic, on the order of \$5 million per person. The articles themselves greatly underreported side effects. [2]Moreover,

Evidence has accumulated suggesting that the superior clinical results reported by doctors with financial ties to Medtronic have not been replicated when the device was used by doctors who receive no payments from Medtronic.

[3]A whole issue of The Spine Journal has been devoted to the problem and [4]a Senate committee is investigating.

Thanks to Zachary Hamaker.

Janna (2011-06-28 21:37:04)

Great topic. The company is called Medtronic (no "s"). Feel free to delete this comment.

dearieme (2011-06-29 07:47:42)

When I started reading about statins, the first thing that struck me was the systematic suppression of evidence about side-effects: lies, in other words, but lies of a specific sort.

### **Health Care Stagnation (2011-06-30 18:27)**

In December, the Los Angeles Times reported – very briefly – that from 2007 to 2008, [1]life expectancy in the United States declined by 0.1 year. It should have been the lead story of every newspaper in the country with the largest possible headlines ("LESS LIFE"). Did 9/11 reduce life expectancy this much? Of course not. Did World War II? Not in a visible way – American life expectancy rose during World War II. I can't think any event in the last 100 years that made such a difference to Americans. The decline is even more newsworthy when you realize: 1. It is the continuation of trends. The yearly increase in life expectancy has been dropping for about the last 40 years. 2. Americans spend far more on health care than any other country. Meaning vast resources have been available to translate new discoveries into practice. 3. Americans spend far more on health research than any other country and should be the first to benefit from new discoveries.

Maybe I'm biased (because my research is health-related) but I think this is the biggest event of our time. It is the Industrial Revolution in reverse – progress grinding to a halt. For no obvious reason, just as the Industrial Revolution had no obvious reason. Health researchers have been given billions of dollars to improve our health, the whole system has been given tens of billions of dollars, and the result is ... nothing. Worse than nothing.

No journalist, with the exception of Gary Taubes, seems the least bit aware of this. It is a difficult story to cover, true. But several journalists, such as health writers for The New Yorker (Atul Gawande, Michael Specter, and Jerome Groopman) are perfectly capable of covering it. They haven't. With a few exceptions, they write about progress (e.g., Peter Provonost's checklists). It is like only reporting instances when Dirk Nowitzki missed a free throw. Each instance is true but the big picture they create – he misses all free throws – is profoundly false.

Among academics, the stagnation has received a tiny amount of attention. In [2]a recent paper (gated), two University

of Southern California professors, considering a wider time period, point out that there has been some improvement in how long you live after you get sick, but no improvement in how long you live before getting sick. Here is how the discussion section of their article begins:

There is substantial evidence that we have done little to date [meaning: from the 1960s to the 1990s] to eliminate or delay disease or the physiological changes that are linked to age. For example, the incidence of a first heart attack has remained relatively stable between the 1960s and 1990s and the incidence of some of the most important cancers has been increasing until very recently. Similarly, there have been substantial increases in the incidence of diabetes in the last decades.

Here is my explanation of the paradox of: 1. Enormous and increasing health care costs. 2. Vast amounts spent on research. 3. No better health. Health researchers, such as medical school professors, shape their research to favor expensive treatments, such as expensive drugs. In fact, the best treatments would cost nothing (e.g., the Shangri-La Diet). To make the expensive treatments seem worth studying, they invent utterly false theories and claim to believe them. For an example (research about depression), see *The Emperor's New Drugs* by Irving Kirsch. Because health researchers are forced to worship absurd theories, they are incapable of good research. Absence of good research is why there is no progress. The health care supply chain – everyone between you and the research, such as doctors, nurses, drug company employees, hospital employees, alternative medicine practitioners, [3]medical device makers, and so on – is happy with the situation (useless research) because it ensures that little will change and they will continue to get paid. They are the supposed experts – and remain silent.

It is human nature that everyone in the supply chain remains silent. They are protecting their jobs. But the silence of the journalists is *The Emperor's New Clothes* writ large. To explain why smart journalists fail to notice the stagnation, I think you have to go back to studies of conformity. When everyone you talk to – people in the supply chain – says black = white (i.e., that progress is being made), you say the same thing.

Why is personal science, the main subject of this blog, important? Because [4]it is a way out of this stagnation.

Pippy (2011-06-30 20:37:01)

I think this is possibly the best and most important post you have ever written. A decline in life expectancy in the U.S. is absolutely shameful. I hope the journalists you mentioned sit up and take notice. Lack of integrity in the U.S. health, economic and political systems is a major problem and is causing us to stagnate. Corruption and poverty go hand in hand. Without independent journalists and bloggers shining a very bright light on such conflicts of interest, they will continue to go on unaddressed. Maybe this post will get the ball rolling.

Seth Roberts (2011-06-30 22:06:16)

Thanks, Pippy, that's very nice to hear. I added a new category (health care stagnation) for this post and hope to write about it often.

Sonic Charmer (2011-06-30 22:08:49)

I would like to see a more granular breakout of this life expectancy calculation. Specifically, as it relates to something like: residency status.

Terveydenhuollon stagnaatio | Tutkimusmatka terveyteen (2011-06-30 23:10:31)

[...] Seth Roberts kirjoittaa tärkeästä mutta hyvin vähälle huomiolle jääneestä asiasta: terveydenhuollon jämähtäneestä kehityksestä. Periaatteessahan tiedämme jatkuvasti enemmän ihmiskehosta ja siitä, miten sitä saa hakkeroitua terveempään suuntaan. Mutta miksi tämä ei näy käytännössä? Vuosien 2007 ja 2008 välillä elinaikaodote lyhentyi Yhdysvalloissa 0,1 vuodella. Tuo on loppujen lopuksi aika järkyttävä luku. Miten tuollainen on edes mahdollista nykypäivänä – kun kehitys kiihtyy yhä nopeammaksi ja nopeammaksi? [...]

Jake (2011-07-01 02:35:03)

Excellent. You didn't mention the huge breakthrough in health care-the internet. It allows us to use personal science to give us a disease free life. From my reading of research papers, advances are being made in biochemistry but it is not reaching the medical profession. I am using those advances to bypass the doctors. I would much rather see a biochemist for my illness than a doctor.

Mark Cancellieri (2011-07-01 03:35:23)

Life expectancy as a measure of the quality of a health care system has its limitations. For example, here in the United States, we often get criticized because our life expectancy isn't the highest despite having the highest health care costs, but if you make a simple adjustment for life expectancy by excluding fatal injuries, then suddenly we have the highest life expectancy. Why? Maybe it's because of a greater degree of deaths from car accidents since car ownership is so high in the U.S. Maybe it is because of a high degree of violent deaths. I'm not certain, but it is highly likely to be a demographic issue rather than a issue of not responding effectively to fatal injuries. The United States also faces the challenge of soaring obesity rates (and people who are just overweight and not classified as obese), which is another factor that is a demographic issue and doesn't reflect poorly on the health care system. The obesity rate in the US is far higher than most other nations of the world. The fact that it has been steadily getting worse could be contributing to a stagnating life expectancy. It would probably be preferable to track more precise measures of health care quality. One example might be historical 5-year cancer survival rates. The incidence of cancer in a country is probably fairly closely related to demographics, whereas the survival of cancer is probably somewhat less so. I agree that personal science could go a long way to reducing costs and improving outcomes. I think far too often patients are put on drugs (such as statins) without really tracking the results in any careful way. For example, my mother is on medication for high blood pressure. It would be interesting to track her results without the medication for a month, then with it, and then without it again. This would probably be sacrilegious to both the medical community and my mother though. It's a shame.

Tomas (2011-07-01 04:43:08)

Mark, maybe I misunderstood your second paragraph about obesity being a demographic issue... surely it is, but I tend to view it as a result of the failure of the health care system, not just a standalone factor outside it which contributes to the decrease of life expectancy.

Mark Cancellieri (2011-07-01 04:56:43)

Tomas, How exactly is obesity a result of the failure of the health care system? Should we blame doctors and nurses for the way that we eat or how little we exercise?

Seth Roberts (2011-07-01 04:58:05)

Mark, like Tomas I see obesity as a failure of the health care system. Among other health problems, obesity makes diabetes more likely. "Should we blame doctors and nurses for obesity?" Well, yes, to some extent. Doctors and nurses seem to be satisfied with weight-loss advice that obviously doesn't work. (A typical doctor says "eat less, move more.") If doctors and nurses are brain-dead, as in this case they appear to be, that's a real problem. Either they should shut up ("sorry, Mr. Jones,

your weight is an enormous health problem but I have no idea what to do about it”) or say something sensible.

Mark Cancellieri (2011-07-01 06:57:39)

Seth, Obesity is one area that we will disagree on. Even faced with the prospect of dying, the vast majority of people don't change their behaviors: Change or Die <http://www.fastcompany.com/node/52717/print> Don't get me wrong. There is definitely room for improvement in the health care community's response to obesity. Their understanding of nutrition and exercise is in serious need of updating, but the real challenge is in teaching others how to change their behavior in a sustainable way. I personally don't blame the medical community for not having solved this immensely difficult problem, especially when the medical community has essentially zero control over the behaviors of their patients.

q (2011-07-01 07:47:54)

if i were to guess why, probably just that a higher percentage of children are born into poverty each year and poor people don't live as long. so not health care per se but income distribution. or it could be a statistical artifact of same.

q (2011-07-01 07:51:58)

or (to continue) it could be an artifact of the fact that we are in a big recession and so people are poorer than they were a year or two ago and will be able to afford less health care.

dearieme (2011-07-01 10:53:33)

In Britain we are told that continuous increases in our life expectancy is one of the main reasons that our pension schemes are in financial trouble. As far as I know this is true. Is the decline unique to the USA?

Jonathan (2011-07-01 12:16:04)

Seth, I recommend you Google Bruce Charlton's blog, as well as his "The story of real science", for the very best discussion I've seen of stagnation in both medicine and science in general. The man sees reality on a higher level than most people can.

E. coli (2011-07-01 13:16:23)

Just my opinion: 1. As a commenter above pointed out, life expectancy takes into account deaths resulting from non-medically related issues such as car accidents, crime, and illegal drug use. 2. Incidence of cancer in the United State (and probably in other developed nations) is likely increasing due to changing lifestyle and increasing exposure to risk factors (e.g. chemical products, tanning). 3. It's extremely unlikely that healthcare researchers are deliberately slowing down the progress of medical research to a halt in order to retain their jobs. Are we really worried that making people's lives better will cause reduced funding in health research because we no longer need improvements in healthcare? - only in your wildest dreams. There may be problems with how funding agencies tend to fund the research topics that are "hot" right now and a lot of researchers jump on the bandwagon when they really don't have any innovative ideas. However, I think it's unfathomable that people are intentionally studying problems that have no prospects of improving the quality of life, given that a healthcare researcher's success mostly depends on how much of a positive impact one's research program has on healthcare (duh!).

bjk (2011-07-01 13:31:38)

What if we've just chosen a trade-off between better tasting food and a shorter life expectancy? If somebody gave me the choice between 10000 hamburger-and-milkshake meals and an extra two years of life, I'm not so sure what I'd choose. Years 77-78 don't sound like much fun, and I like hamburgers. We make that same choice every day in small ways, and it is a choice. I don't know that doctors or drug companies are to blame, they're essentially unarmed compared with the appeal of modern conveniences.

Seth Roberts (2011-07-01 15:43:58)

E. coli (is that your real name?), you write "I think it's unfathomable that people are intentionally studying problems that have no prospects of improving the quality of life, given that a healthcare researcher's success mostly depends on how much of a positive impact one's research program has on healthcare (duh!)." There is always a cover story that the research will somehow

improve the quality of life. But compared to what? I am claiming that much different research – e.g., focussed on prevention – would do a much better job. The ability of people to rationalize what they do is quite good. The highest aspiration of a large number of medical school professors is to win a Nobel Prize, not to improve the quality of people's lives. In the short term, they want a big lab and a large grant. You reach that goal by publishing many papers. They would laugh if you said their main motivation was "to improve healthcare".

Nancy Lebovitz (2011-07-01 18:03:08)

"Overweight" people actually live a little longer than "healthy weight" people, and low end obese people are in between. [1][<http://www.healthnewstrack.com/health-news-1606.html>] [2]] Fat people have difficulty getting access to competent medical care– they're at risk of having doctors ignore their symptoms in favor of just telling them to lose weight.

Jack in Davao (2011-07-03 06:18:31)

To which one could add as a further cause of the appalling pace of progress in American biomedical research: the top-down, centrally planned funding monopoly, with a peer review process dominated by established researchers who are deeply invested in (often) failed or unproductive theories and are not about to fund any upstarts proposing ideas that might challenge them, and with politically driven priorities that channel most of the money into whatever are the latest fads. The growth of personal science and web-based information exchange are hopeful signs, but in America the medical gatekeepers remain a serious obstacle to personal experimentation – they keep lab testing, drugs, and devices at best expensive and at worst unavailable without a prescription. Fortunately some Asian countries (including here in the Philippines) take a less paternalistic view, and that, coupled with the incentive to promote medical tourism, may shift the center of gravity of progress to Asia.

Bulldog (2011-07-03 17:41:52)

It's more like reporting that Dirk Nowitzki's free throw rate has decline from 95 % to 94 % after improving for a decade. I think part of the disconnect comes from ideas about economic growth. In the former we don't need growth just to maintain the status quo. If economic growth declines by 0.1 %, America is in a huge amount of trouble. If life expectancy declines by 0.1 %, things are exactly the same as they were yesterday.

Sean Estey (2011-07-03 18:23:40)

Great post. It'll probably take someone you describe as an outsider with insider knowledge to really bring this issue into the public spotlight. As for where these absurd health theories come from in the first place, I believe it stems from the contamination of politics into the research domain. When politicians make it their job to fund science and make public health guidelines, they do so 1) before the science has settled, and often reach incorrect conclusions, then 2) direct research almost exclusively in the direction of confirming rather than falsifying public health recommendations, eliminating the marketplace of competing idea. Science ceases to be science and you reach stagnation.

Nancy Lebovitz (2011-07-03 18:55:10)

What about bad practice? Last I heard, it's hard work to get doctors to wash their hands reliably.

quigley (2011-07-03 20:47:28)

First, disclosure. I'm an MD who spends "vast amounts...on research" as a basic and clinical researcher. Second, where we agree: a. Falling life expectancy is a shame on our society. b. Losing weight means eating less. How you get there and how much royalty you collect off books sales are details. Now where we disagree: Specifically regarding obesity and its consequences, the medical community has pushed decreased food intake and increased exertion to treat one of the leading consequences of obesity, Type 2 diabetes. Patients don't do it. If your diet is so great, the medical community will applaud you, and overweight people will build statues in your honor, just like they did with Atkins...right? An important reason that cancer rates have increased is better detection. Please include this in your discussion. BTW, MD's in medical research make 1/2 what they could in private practice on the whole. No one's in this game just to be paid.

Seth Roberts (2011-07-04 04:26:28)

quigley, you write: "the medical community has pushed decreased food intake and increased exertion to treat one of the leading consequences of obesity, Type 2 diabetes. Patients don't do it." I agree. The medical community has pushed that solution for at least 50 years. And patients don't do it – meaning it is a bad solution. That is a sign of stagnation I don't mention in this post: Ancient solutions that don't work well continue to be promoted.

quigley (2011-07-04 07:19:56)

Dr. Roberts: I've tried to find data that your diet works for SUSTAINED weight reduction in a study that would be applicable to a generalizable population. As you know, temporary weight loss is relatively easy. Sustained weight loss (wt loss > 2 yrs), is hard. If your diet can do it, I'd prescribe it every day.

Alex Chernavsky (2011-07-04 07:59:29)

Quigley, I started the Shangri-La diet on October 22, 2009 when I weighed about 222 lbs. At my lowest point since then, I weighed about 191. I'm currently hovering around 194, for a net loss of about 28 lbs. (I know it's not quite two years.) Here's a quick-and-dirty graph that's current as of July 4, 2011. The solid, darker line is a ten-day moving average. <http://www.astrocyte-design.com/shangri-la-diet/shangri-la.jpg> See also my description of my diet, although this page is a little out of date: <http://www.astrocyte-design.com/shangri-la-diet/index.html>

Bill Cecil (2011-07-04 08:04:33)

According to the report "Life Expectancy in the United States" by the Congressional Research Service, at: <http://aging.senate.gov/crs/aging1.pdf>, since 1910 life expectancy has declined about 20 times-the last time before 2007-08 in 1993. Clearly it is an important event for some of the reasons mentioned but it does seem to happen, luckily, with decreasing frequency over time: 5 times in the 10s; 5 times in the 20s; twice in the 30s; twice in the 40s; once in the 50s; 3 times 60s; once in the 80s; once in the 90s and once in the 2000s. Looks like improvement to me.

Seth Roberts (2011-07-04 11:44:39)

Bill, thank you for bringing that document to my attention. It shows that the 1918 influenza epidemic was by far the biggest disaster in terms of life expectancy in the past 100 years. As you say, life expectancy has declined several other times. The

overall trend is unquestionably a slowing down of the rate of increase. The fact that the overall rate of increase is slowing down at the same time that the number of year-to-year declines is decreasing (as you point out) suggests that improvement in data quality (less random error) is why the number of year-to-year declines is decreasing. As data quality increases, each decline becomes more significant.

Seth Roberts (2011-07-04 12:13:02)

Quigley, in my book I show that my initial use of sugar water and extra-light olive oil (ELOO) led to a weight loss that was sustained at least 5 years. Now I do the diet using butter (nose-clipped) – a healthier calorie source than ELOO or sugar water. In 1990 I weighed 200 pounds. That's when I started trying to lose weight. Making dietary changes that led to my theory and that the theory later explained, including the Shangri-La Diet, I have been well below 200 pounds ever since. I'm now about 170 pounds. That's more than 20 years of sustained weight loss. I think that low-carb diets work, too, but I believe they work for the same reason the Shangri-La Diet works – by reducing the overall strength of smell-calorie associations in your diet, they reduce your setpoint. Before I discovered SLD, I lost about 6 pounds by no longer eating bread. It never came back.

quigley (2011-07-04 20:49:02)

Fine. You provide one anecdote, and Alex provides another. How do you know that if you'd tried something else, your weight loss wouldn't have been better or equal? Anecdotal evidence is the weakest form of evidence of generalizable benefit for an intervention.

Seth Roberts (2011-07-05 03:56:41)

Quigley, the theory behind the Shangri-La Diet explains a range of hard-to-explain observations that come not only from many people but from rats. That is excellent reason to believe that if the theory is true, the phenomena it predicts will be general. You ask: "How do you know that if you'd tried something else, your weight loss wouldn't have been better or equal?" Because I tried many other things. They produced much less weight loss.

Alex Chernavsky (2011-07-05 06:38:49)

My cousin once had a friend who relied a lot on anecdotal evidence, and really bad things ended up happening to the guy.

npm (2011-07-06 06:36:20)

This is seriously misleading. Go here: [http://www.cdc.gov/nchs/data/nvsr/nvsr59/nvsr59\\_04.pdf](http://www.cdc.gov/nchs/data/nvsr/nvsr59/nvsr59_04.pdf) Scroll down to Figure 1, on p.31. You will see that the 2008 increase was a blip in the long-term trend of a steady decades-long decrease in mortality rates. Here's the real story from that figure: Today, we are avoiding over a QUARTER of the deaths that would have occurred if death rates had not changed over the last 30 years. That's freaking amazing. (Yes, that's aggregate and hides shamefully high levels of differential mortality, but still! A QUARTER! And it's not like people were dying like flies in 1980.) Why look at mortality rather than life expectancy? Because life expectancy is a complicated transformation of mortality rates, and even large improvements in mortality don't translate into large increases in life expectancy in low-mortality countries. From <http://www.deathreference.com/Ke-Ma/Life-Expectancy.html>: "Since the middle of the twentieth century, gains in life expectancy have been due more to medical factors that have reduced mortality among older persons. These reductions are harder to achieve than decreases in infant mortality; hence, improvements in life expectancy at birth have slowed down."

Seth Roberts (2011-07-07 03:53:28)

That's very interesting and helpful. I agree that the steady decline in age-adjusted death rates since 1980 does not suggest stagnation. But the usual stagnation claim – "improvements in life expectancy have slowed down" – is not about early in 1980-2009 versus late in 1980-2009 but comparison of much earlier (e.g., 1930-1960) to later (e.g., 1980-2010). The statement "these reductions are harder to achieve" is not an explanation ("hence") of the slowdown but a description of it. The big picture, as far as I can tell with this new data, is what the USC authors described: Over the last 30 years, people are living somewhat longer after they get sick, but they are getting sick at the same age. This makes sense given the overwhelming emphasis of our health care system on keeping symptoms from getting worse relative to prevention of those symptoms. For example, we treat diabetes rather than prevent it. This is a kind of stagnation all by itself: A problem becomes large (e.g., diabetes) but all

you ever do is treat it. Okay, people with diabetes live a bit longer, but progress on prevention remains stagnant at roughly zero.

Bernd Jendrissek (2011-07-09 12:05:38)

"For example, we treat diabetes rather than prevent it." Seth, you remind me of people in my country complaining about high crime rates, pleading, "Somebody should DO SOMETHING!" Without being very specific at all about what "do something" might entail. What would you have the medical community do that satisfies you that they are earnestly working on preventing, say, diabetes? Would you like to see medical practitioners applying to courts to have their patients declared legally incompetent, in order to inter them in starving houses? Hold guns to their patients' heads and MAKE them lose weight? Aren't you just being a bit sore about the fact that the medical community isn't just accepting your assertions that your diet is the silver bullet of weight control? That instead they recommend "eat less, move more" and leave it up to their patient to decide how (or if!) to achieve that, without specifically recommending your diet? Without actual hard evidence that a particular method works, it wouldn't be appropriate for a medical practitioner to be pushing any one method. Asking them to do so under the guise of "It is both cheap and safe" is to propose a sort of dietary Pascal's wager. From a distance your diet looks just like any other fad diet. Without significant investment in time, I cannot determine if your diet works any better than, say, eating only raw meat. I really don't think it's reasonable to hold party A (the doctor) accountable for a recommendation they make (to lose weight - somehow!) that party B (the patient) doesn't follow through with personal research and ACTION. If you're into transactional analysis a la Berne you'll see the problem here.

Seth Roberts (2011-07-09 13:01:50)

"What would you have the medical community do that satisfies you that they are earnestly working on preventing, say, diabetes?" Right now, research money is about 99 % cure (study of possible cures) and 1 % prevention. This is insane. It is wonderful for the people inside the research community and ordinary doctors, who benefit from that allocation. (Doctors benefit because it means more people will need to be cured - by them.) It is horrible for everyone else. When the percentages are reversed (99 % of research money goes to studying how to prevent, 1 % how to cure) I will know they are serious. "Aren't you just being a bit sore about the fact that the medical community isn't just accepting your assertions that your diet is the silver bullet of weight control?" I don't think my diet is the silver bullet of weight control. I do think my diet introduces an entirely new idea into our understanding of weight control and how we handle obesity. I found that something that absolutely should not work according to all prevailing wisdom - including the wisdom of the low-carbers - does work. Rather than "accept [my] assertions" the medical community should test my assertions. But with one exception (Lisa Kaufmann) they haven't. It isn't just diabetes of course. The medical community's record on prevention is terrible. Prevent heart disease by prescribing statins? Just one problem: They don't prevent heart disease. Oops. Prevent depression? Never heard of it. Prevent arthritis? Never heard of it. Prevent cancer? Uh, doctors discourage patients from smoking - a 50-year-old idea.

### Ancient Wisdom: Butter is Brain Food (2011-07-02 05:00)

In Ayurvedic medicine (Indian traditional medicine), ghee, a type of clarified butter, is believed to improve brain function. [1]For example, "Vedic medicine extols the virtues of ghee and dairy for the brain." I found that [2]butter improved how fast I could do arithmetic.

---

john (2011-07-02 18:20:32)

Seth, was kind of butter was it? What are some of your thoughts as to why butter is effective? Have you tried suet or tallow?

Txomin (2011-07-03 05:59:45)

I have tried eating more butter but I have found that it increases my weight dramatically. I have been wondering for a while what your experience and thoughts are on this since you eat huge amounts of it. By the way, thank you for all the effort that you put into this site. It has been a steady source of interesting information.

Seth Roberts (2011-07-03 14:17:23)

When I started eating lots of butter, I lost weight. After several months, I started gaining weight. Then I switched to eating the butter nose-clipped. Then I started losing weight. All this is consistent with the theory behind the Shangri-La Diet, which predicts new foods and foods without smell (which have weak or no smell-calorie associations) cause weight loss compared to familiar foods (which have strong smell-calorie associations). I suggest you eat the butter nose-clipped.

Alex Chernavsky (2011-07-03 19:18:20)

Seth, I've been eating coconut fat nose-clipped, but I can still taste it a little bit when I remove the clip, even if I drink a glass of water first. How sensitive is the system that associates smells with calories?

Txomin (2011-07-03 21:37:38)

Thank you very much, Seth. The smell/calorie connection is news to me. An interesting venue for experimentation.

gwern (2011-07-09 08:06:09)

So, would this be the same ancient wisdom infatuated with heavy metals ([#Safety](https://secure.wikimedia.org/wikipedia/en/wiki/Ayurveda))? Well, I suppose even a stopped clock... /goes back to looking at some numbers for [#melatonin-analysis](http://www.gwern.net/Zeo)

## Unofficial Beer Tasting Winner: Uncommon Brewers (2011-07-03 07:59)

Last night I went to a beer tasting in San Francisco. I didn't taste all the beers but of the 15-odd I did taste the best were by [1]Uncommon Brewers – especially their [2]Siamese Twin ("the floral notes of lemongrass and sharper bite of kaffir lime blend with the deep malt") and [3]Baltic Porter ("whole licorice root and star anise").

Five or six years ago I went to a sake-tasting event in San Francisco called "The Joy of Sake". About 140 sakes. In a few hours I became such a sake connoisseur that the sake I could afford – and used to buy regularly – I now despised. The only sake I now liked was so expensive ( \$80/bottle) that I never bought another bottle of sake.

Jahed (2011-07-03 12:13:20)

Did you go to the Marin Brewing Company's BreastFest as well? Haha, small world if you did. Cheers

Seth Roberts (2011-07-03 14:14:13)

yes, that is where I went.

Kirk (2011-07-04 09:32:41)

Many years ago I decided to buy a fragrance for my wife. Since at the time we didn't have much money, we visited several shops where we smelled at least a hundred fragrances on test strips, plus another dozen or so on the skin (for fragrance changes over time as it interacts with the skin). They all smelled OK, but a few seemed somewhat better than the others. We finally settled upon one. Over the years, as we subsequently visited fragrance shops, I have noticed how much more sensitive I am to smells. My wife says, for a typical unappreciated fragrance, that my eyes wince and my face flattens as I shrink back, and I'll use language to describe it along the lines of, "It's an army of Brazilian ants marching up towards my sinuses, and each ant swings a machete."

James (2011-07-04 19:59:21)

"The only sake I now liked was so expensive ( \$80/bottle) that I never bought another bottle of sake." And you still go to tastings?? It seems like ignorance is bliss here, better to preserve your ability to enjoy cheap things.

Maria Droujkova (2011-07-05 05:40:07)

An assorted link: a blind man who "sees" through echo-location <http://www.mensjournal.com/the-blind-man-who-taught-himself-to-see> Kish is seeking — despite a lack of support from every mainstream blind organization in America — nothing less than a profound reordering of the way the world views blind people, and the way blind people view the world. He's tired of being told that the blind are best served by staying close to home, sticking only to memorized routes, and depending on the unreliable benevolence of the sighted to do anything beyond the most routine of tasks. Kish and a handful of coworkers run a nonprofit organization called World Access for the Blind, headquartered in Kish's home. World Access offers training on how to gracefully interact with one's environment, using echolocation as a primary tool. So far, in the decade it has existed, the organization has introduced more than 500 students to echolocation. Kish is not the first blind person to use echolocation, but he's the only one to meticulously document it, to break it down into its component parts, and to figure out how to teach it.

### Great Delusions: James Watson (2011-07-05 05:00)

[1]In an interview, James D. Watson, co-discovery of the structure of DNA, said

Some day a child is going to sue its parents for being born. They will say, My life is so awful with these terrible genetic defects.

(Quoted by Richard Bentall in Doctoring the Mind.) Watson is implying that genetic defects matter in the big picture of human impairment. They don't. Changes over time in disease incidence, migration studies (in all instances I know of, the disease profile of the migrating group changes to match the place where they live), powerful nutritional effects (e.g., Weston Price) and other evidence of environmental potency show that all major diseases (heart disease, cancer, depression, obesity, plague, tuberculosis, smallpox, etc.) are mostly caused by the environment, in the sense that environmental changes could greatly reduce their incidence. Genes are a distraction. (To say that major diseases are also "caused" by genes in the sense that genes affect environmental potency is to miss the point that we want to reduce the diseases – want to reduce obesity for example – so it is the environmental lever that matters. If a child could eliminate its obesity by changing its environment, it would not sue its parents.) If Watson was unaware of that, okay. But for him to claim the opposite is a great – and I am afraid profoundly self-serving – delusion.

[2]As I blogged, Aaron Blaisdell had a certifiably "genetic" disease. The chromosome involved had been identified. It turned out to be under nutritional control. When he improved his diet, it vanished. Calling it "genetic" seriously distracted from learning how to eliminate it, it turned out. Another example of how "genetic" problems are not what they seem – impossible to change – is provided by lactose intolerance. The rate of lactose intolerance [3]varies greatly from group to group. (I thank Phil Price for the link.) It is rare in Sweden, common in Asia, including China. I assume these differences reflect genetic differences. Yet Beijing supermarkets have aisles full of milk products. How can that be? Because the aisles are full of yogurt. Yogurt bacteria digest the lactose. So lactose intolerance is not a big deal. You can still drink milk, after it has been predigested by bacteria.

[4]The dreams of geneticists.

Cindy (2011-07-05 09:39:54)

Perhaps other context was not included in the above quote but I certainly did not take the quote to mean the diseases of civilization (obesity, atherosclerosis, diabetes, etc.) As a mother of a child with a congenital heart defect, I took it to mean congenital defects. As his grandmother has the exact same heart defect but to a lesser degree, we know it's genetic. He has had two heart surgeries in his life so far and will have more through his life. The treatment for the defect sucks and has cognitive impact. He knows it. We see it. It sucks. While researching the genetic cause of the heart defect, we've engaged in conversations with genetics doctors who've led us to believe that congenital structural defects as well as childhood onset cancers are almost always genetically based (teratogenic agents, notwithstanding.) Parents of children suffering childhood cancers and heart defects know that the cures, while heroic, have life long cognitive effects that are not cured by environmental factors. Chemotherapy and heart-lung bypass have real excitotoxic impact on the rapidly developing pediatric neurons. It sucks. The irretrievable loss of the child's full cognitive potential is heart breaking for a parent. The cost of treating or maintaining the life of human with an impactful genetic defect is great. It has become my goal to discover the genetic defect that causes the heart defect. I want my progeny to have the option to fix this problem. If we can fix the genetic defect but don't, the child

should sue.

Seth Roberts (2011-07-05 10:57:32)

Cindy, thanks for the informative comment. Watson said similar things many times, in contexts where it was clear he believes that genetic diseases are a big contributor to human disability and disease. Based on comments like his, vast amounts of research money have gone to study "the genetic basis" of this or that big health problem – even obesity! Your particular case is an example of what I am talking about. Perhaps I am mistaken, but based on what you have written, neither you nor anyone you talked to seems have understood that a "genetic" congenital defect in a child may be caused by the child's mom's environment, such as her prenatal diet. (I'm not surprised "genetic doctors" would fail to understand it. It would make them less important.) As you may know, there is plenty of evidence that prenatal nutrition can have lifelong effects – e.g., increasing the rate of heart disease. Perhaps those life-long effects are produced by structural changes in the fetus. Due to genetics, some babies will be more susceptible than others to imperfect prenatal nutrition. You can read about this in a book called Mothers, Babies, and Health in Later Life by D. J. B. Barker. Of course the mom's nutrition is a thousand or million times easier to modify than the mom's genes. You might want to consider prenatal-nutrition causality given that you "want [your] progeny to have the option to fix this problem."

Jenny (2011-07-06 10:55:08)

I have a 2 generational example of environment affecting the genetic status. I have enlarged vertebrae in my back - the result of genetic translocation error. My daughter has a gigantic finger - likewise from a translocation error. However, belatedly, we found that we are a family of coeliacs. My own mother developed problems in late age, I was obviously always coeliac (always ill) but not diagnosed till 58. I feel there is a good chance that our poor nutritional systems affected the respective pregnancies. With knowledge and luck, my daughter will not pass on any disability!

### **New Support for Prenatal Ultrasound Cause of Autism (2011-07-06 05:00)**

I have [1]blogged several times about Caroline Rodger's idea that sonograms during pregnancy greatly increase the risk of autism in the fetus. Her idea is supported by several lines of evidence, as she explains in [2]this talk.

[3]A new study provides more evidence. It found a high concordance rate among fraternal twins. In the general population from which the new study was drawn (California), about 1 child in 100 has autism. But if you are an identical twin, and your co-twin has autism spectrum disorder, your chance of having the same diagnosis is about 70 %. The crucial point of the study is that the concordance was also high for fraternal twins: about 40 %. [4]As one commenter put it, this result "puts a spotlight on pregnancy as a time when environmental factors might exert their effects".

[5]Another study found more risk of autism if the mom took an anti-depressant during pregnancy. This supports the idea that a bad prenatal environment causes autism.

Thanks to Paul Sas and Gary Wolf.

---

SB (2011-07-06 08:02:59)

Twins are exposed to the same environmental factors even after pregnancy. They are fed the same foods, go out together, live in the same house, even go to pre-school together. The commentator completely ignores this. These studies just point to the importance of epigenetics, nothing else.

Tomas (2011-07-06 09:02:45)

I guess that ultrasound should remain potentially dangerous until proved safe. More so when the current technology capabilities and accuracy are rather poor, only adding to the prenatal stress and the mother's stress ("Madam, there is a 1 in X probability that your child will have XXX). Meanwhile, Michel Odent is a great source of information on pregnancy and birth-giving <http://www.wombecology.com/maternalemotional.html>

Jonathan (2011-07-06 12:54:37)

It seems to me that the figure for fraternal twins is useless for drawing conclusions about pregnancy unless we also know the figure for siblings gestated apart. Fraternal twins share half the genes, so the 40 % correlation is what you would expect.

Seth Roberts (2011-07-06 18:46:20)

This study did not measure the concordance for siblings gestated apart. I think it's about 10 %.

Death is a star (2011-07-25 23:51:41)

If ultrasounds "cause autism" (per the title of your post), the difference between identical and fraternal twins would be negligible. The difference between 70 % and 40 % only suggests that ultrasounds may exacerbate a predisposition for autism.

## **Causal Reasoning in Science: Don't Dismiss Correlations (2011-07-07 05:00)**

In [1]a paper (and [2]blog post), Andrew Gelman writes:

As a statistician, I was trained to think of randomized experimentation as representing the gold standard of knowledge in the social sciences, and, despite having seen occasional arguments to the contrary, I still hold that view, expressed pithily by Box, Hunter, and Hunter (1978) that "To find out what happens when you change something, it is necessary to change it."

Box, Hunter, and Hunter (1978) (a book called Statistics for Experimenters) is well-regarded by statisticians. Perhaps Box, Hunter, and Hunter, and Andrew, were/are unfamiliar with another quote (modified [3]from Beveridge): "Every-one believes an experiment except the experimenter; no one believes a theory except the theorist."

Box, Hunter, and Hunter were/are theorists, in the sense that they don't do experiments (or even collect data) themselves. And their book has a massive blind spot. It contains 500 pages on how to test ideas and not one page – not one sentence – on how to come up with ideas worth testing. Which is just as important. Had they considered both goals – idea generation and idea testing – they would have written a different book. It would have said much more about graphical data analysis and simple experimental designs, and, I hope, would not have contained the flat statement ("To find out what happens ...") Andrew quotes.

"To find out what happens when you change something, it is necessary to change it." It's not "necessary" because belief in causality, like all belief, is graded: it can take on an infinity of values, from zero ("can't possibly be true") to one ("I'm completely sure"). And belief changes gradually. In my experience, significant (substantially greater than zero) belief in the statement A changes B usually starts with the observation of a correlation between A and B. For example,

I began to believe that one-legged standing would make me sleep better after I slept unusually well one night and realized that the previous day I had stood on one leg (which I almost never do). That correlation made one-legged standing improves sleep more plausible, taking it from near zero to some middle value of belief ("might be true, might not be true") [4]Experiments in which I stood on one leg various amounts pushed my belief in the statement close to one ("sure it's true"). In other words, my journey "to find out what happens" to my sleep when I stood on one leg began with a correlation. Not an experiment. To push belief from high (say, 0.8) to really high (say, 0.99) you do need experiments. But to push belief from low (say, 0.0001) to medium (say, 0.5), you don't need experiments. To fail to understand how beliefs begin, as Box et al. apparently do, is to miss something really important.

Science is about increasing certainty – about learning. You can learn from any observation, as distasteful as that may be to [5]evidence snobs. By saying that experiments are "necessary" to find out something, Box et al. said the opposite of you can learn from any observation. Among shades of gray, they drew a line and said "this side white, that side black".

The Box et al. attitude makes a big difference in practice. It has two effects:

1. Too-complex research designs. Just as researchers undervalue correlations, they undervalue simple experiments. They overdesign. Their experiments (or data collection efforts) cost far more and take much longer than they should. The self-experimentation I've learned so much from, for example, is undervalued. This is one reason I learned so much from it – because it was new.
2. Existing evidence is undervalued, [6]even ignored, because it doesn't meet some standard of purity.

In my experience, both tendencies (too-complex designs, undervaluation of evidence) are very common. In the last ten years, for example, almost every proposed experiment I've learned about has been more complicated than I think wise.

Why did Box, Hunter, and Hunter get it so wrong? I think it gets back to [7]the job/hobby distinction. As I said, Box et al. didn't generate data themselves. They got it from professional researchers – mostly engineers and scientists in academia or industry. Those engineers and scientists have jobs. Their job is to do research. They need regular publications. Hypothesis testing is good for that. You do an experiment to test an idea, you publish the result. Hypothesis generation, on the other hand, is too uncertain. It's rare. It's like tossing a coin, hoping for heads, when the chance of heads is tiny. Ten researchers might work for ten years, tossing coins many times, and generate only one new idea. Perhaps all their work, all that coin tossing, was equally good. But only one researcher came up with the idea. Should only one researcher get credit? Should the rest get fired, for wasting ten years? You see the problem, and so do the researchers themselves. So hypothesis generation is essentially ignored by professionals because they have jobs. They don't go to statisticians asking: How can I better generate ideas? They do ask: How can I better test ideas? So statisticians get a biased view of what matters, do biased research (ignoring idea generation), and write biased books (that don't mention idea generation).

My self-experimentation taught me that the Box et al. view of experimentation (and of science – that it was all about hypothesis testing) was seriously incomplete. It could do so because it was like a hobby. I had no need for publications or other steady output. Over thirty years, I collected a lot of data, did a lot of fast-and-dirty experiments, noticed informative correlations ("accidental observations") many times, and came to see the great importance of correlations in learning about causality.

Sean S (2011-07-07 07:36:46)

It's a great point that the world also needs better theory generation, but you're reviewing a different book when you criticize their focus on experimental design. Was their book a failure since it wasn't *The Soup to Nuts Encyclopedia of the Scientific Method*? Box, Hunter and Hunter were many things, but they were not evidence snobs. When I asked George Box, what he thought about requiring a  $p\text{-value} < 0.05$  to declare a factor "important", he said it was much more important to use your brain than to pass some artificial statistical threshold. It feels like you're stretching your thesis a bit (academics are more interested in earning status through publishing the arcane than doing "useful" work) when you also claim that engineers in industry are only interested in research. Process optimization and problem-solving are decidedly not ivory tower, and most of the industrial examples from BHH's book were real-world problems. Problem: too many defects on the production line? Answer: run a fancy experimental design to impress your colleagues, but still not fix the problem. Good luck in your next job. My reading of the quote about "you need to change something to learn" is not against using induction to generate new theories and it's not saying "correlation is not causation", it's about the simple truth that once you have an idea in your head, the only way to learn about it (get more confidence in your belief), is to test it. How did you learn about one-leg standing in the first place; you had to try it. By my reading the real-world problems they were addressing with their book were: 1) coming up with a theory, assuming it's true, and never testing it (a staple of executives in business) 2) over-reliance on one-factor at a time experiments to generate knowledge in a world where interactions exist. You're painting Box and the Hunters with the brush of the ivory-tower statistician that only believe results with a  $p\text{ value} < 0.05$  from randomized studies when they were quite practical in using experimental design to improve real-world processes. The current efforts of statisticians in experimental design does fit 100 % with your ideas about academia though. The designs get more esoteric, harder to use, and less useful to the engineers working on real-world problems. Since their book completely missed the theory-generation mark, do you have any recommendations of books that cover that topic well?

Seth Roberts (2011-07-07 09:28:38)

I heard Box speak once. One of his examples involved design of a cake mix. Yes, Box et al. is genuinely useful, especially to people who are designing stuff. In the broad sequence of science/engineering, the steps are 0. have no idea. 1. have an idea that might be right. 2. confirm idea. 3. use confirmed idea to do something useful. Box, I gathered, was much more familiar with the end of this sequence (where interactions really matter) than the beginning (where they don't matter at all). If the book had been titled Statistics For Engineers I wouldn't be complaining. Their conventional emphasis on "hypothesis testing" is actually misleading in two ways: it disregards idea generation and it is a poor name for idea development, which much of their book is about. John Tukey's Exploratory Data Analysis is a good guide to data analysis that will help you generate ideas. No one, as far as I know, has ever written at length about how to design research (e.g., experiments) to generate ideas.

Paul (2011-07-08 15:35:07)

Great post. Really insightful point.

Around the Web Meets Cancer, Infections, Cholesterol, and Nitrates | Perfect Health Diet (2011-07-09 10:04:06)

[...] Seth Roberts reminds us of a good quote (modified from Beveridge): "Everyone believes an experiment except the experimenter; no one believes a theory except the theorist." In another post, Seth reports that health in the US as measured by age of disease onset has not improved since the 1960s, life expectancy in the US peaked in 2007 and is now declining, medical care has stagnated, and this should be a big story. [...]

Justin (2011-07-25 12:47:36)

A book is dying to be written on generating ideas, and who better to do it than you, Seth.

John Hunter (2011-08-05 01:16:16)

William Hunter was my father. He did many experiments. George Box did many experiments. You are entitled to your opinions obviously but the claim that they only dealt with other people data is not accurate. It is true they were world renowned experts on experimenting and had many people consult them about their experiments, for help: designing them, analyzing them, what to do next, how to improve the process of experimentation in their organization, etc.. While it seems to be implied in the post that such consultation was a reason to distrust their thoughts on experimentation I hardly think that is a sensible conclusion to draw. Most of those they helped were running experiments in industry, to improve results (not to publish papers). They were and are applied statistician. What experiments need to be done is critical for an applied statistician. What matters is making improvement in real world processes. If you don't run the right experiments, you won't learn things to help you improve. They worked on the problem of where to focus to learn quite a bit. One significant part of there belief was to have those involved in the work do the thinking about what needed to be improved. This isn't tremendously radical today but in the past you had many people that thought "workers" should do what the college graduates in their office at headquarters tell them to do. Here is one of many such example, from [http://williamghunter.net/articles/managing\\_our\\_way\\_to\\_economic\\_success.cfm](http://williamghunter.net/articles/managing_our_way_to_economic_success.cfm) "The key is that employees at all levels must have appropriate technical tools so that they can do the following things: - recognize when a problem has arisen or an opportunity for improvement exists, - collect relevant data, - analyze the situation, - determine whose responsibility it is to take further action, - solve the problem or refer it to someone more appropriate..." I don't have the book in front of me, but doesn't it start with an example on learning where you can use inductive reasoning and from the facts that you see you can draw conclusions and construct a theory that fits the facts. If so, it seems to call into question the idea that they claimed "[the] opposite of you can learn from any observation." is not actually accurate. They understood you can use inductive reasoning to create theories. You then use experiments to test theories. The books is called Statistics for Experimenters, right? Not statistics for drawing conclusions when not doing experiments. When you are experimenting you can test whether beliefs you have are accurate and you can learn about things you try. Smart people can make guesses what will happen and be right. I know the authors would believe those knowledgeable about the system in question are well suited to determine what variables to test. It is that knowledge that will lead to experiments that are likely to be effective. The authors of the book were trying to help those that often failed to learn as much from experiments as they could. Far too many people still don't use the most effective statistical tools when experimenting. They emphasized, consistently, the need for those doing the work to involved in the experiments. The job of statisticians was to help in the cases

where advanced statistical tools and knowledge would be useful. The reason for those who do the work (are familiar with the process) is because they have knowledge to bring to what should be tried in experiments. When I read through *The Scientific Context of Quality Improvement, 1987* by George Box and Soren Bisgaard <http://cqpi.engr.wisc.edu/system/files/r025.pdf> it seems to me it discusses the types of issues you raise: how do we learn without experimenting? I am not sure if it is just me, or if it clearly addresses that issue. Here is another <http://cqpi.engr.wisc.edu/system/files/r172.pdf> *Statistics as a Catalyst to Learning by Scientific Method* by George E. P. Box. Here is another <http://cqpi.engr.wisc.edu/system/files/r179.pdf> *Statistics for Discovery*. There are many other sources, I am sure. They understood the importance of learning as much as you could from available sources. They just also understood the importance of experiments and learning the most you could from experiments. And the book, *Statistics for Experimenters*, was focused on the most effective ways to improve using statistics to learn from experiments. Here is what Box, said in his own words about the objective (and it isn't proving the hypothesis) <http://management.curiouscatblog.net/2009/11/16/highlights-from-recent-george-box-speech/> [too many people ]"can't really get the fact that it's not about proving a theorem, it's about being curious about things. There aren't enough people who will apply [DOE] as a way of finding things out" *Statistics for Experimenters: Design, Innovation, and Discovery* shows that the goal of design of experiments is to learn and refine your experiment based on the knowledge you gain and experiment again. It is a process of discovery. That discovery is useful when it allows you to make improvement in real world outcomes. That is the objective.

Seth Roberts (2011-08-05 05:10:40)

John Hunter, thank you for your comments and links. I'm sorry that I don't have time to revisit the whole subject at length right now and I imagine that anyone reading this can judge for themselves whether I am being fair. A briefer comment on George Box's contribution is this: There are three stages of scientific/engineering inquiry: 1. discovery (finding ideas to take seriously). Above all, this involves discovery of new cause-effect relationships. 2. testing (distinguishing among the ideas created in the first stage). 3. development (using ideas from stage 2 to create useful products). Box was an expert at Stage 3; he seems to have known little about Stage 1. All the detailed examples in his work, including the papers you link to, come from Stage 3. In Stage 3, interactions are what matter most – the main effects were figured out in Stage 2. In Stage 1, interactions are unimportant because the main effects haven't yet been figured out. The best tools for Stage 3 are quite different from the best tools for Stage 1 – which is why *Statistics for Experiments* is so incomplete for anyone who wants to do Stage 1. In contrast, *Exploratory Data Analysis* was heavily focussed on Stage 1. A statistician once said to me that no one actually used Tukey's ideas. It was true that for Stage 2 and especially Stage 3, Tukey's ideas were indeed less useful. Stage 2 and especially Stage 3 are more remunerative than Stage 1 so there are far more people working there, as far as I can tell.

John Hunter (2011-08-08 00:49:26)

Thanks for your reply. I realize you can't try to respond to every person who comments in detail, I just wanted to make some points I think are important. I'm not so sure Box expertise is limited to stage 3, but that is certainly something people can decide. I think the idea that they were disconnected from the real world improvement results is the thing I feel strongly against. They focused precisely on how to improve. They did not care for elegant statistical models that didn't actually result in better results in the real world. And they fought the heavy emphasis on math-statistics that existed and exists - contrasted to applied statistics. They were (in my biased opinion) in the lead for promoting (what is still a minority) statisticians actually working with people on real world improvements as what matters. As part of that they completely understood the systems involved that include generating ideas as a very important component. It is also true they didn't write about that aspect as much. Though they did write about it quite a bit (it seems to me), but it might not be as in your face as the writing on using statistics and experiments to continually improve results. And it is true they had less new knowledge to share with the world in that area I think.

Seth Roberts (2011-08-08 16:28:08)

John Hunter, you are right, to lump Box in with the many many statisticians who had less real-world experience than he did is misleading. By calling him a "theorist" I probably did that. He was a theorist in the sense that the title of his book seemed to imply that it applied to all experimentation, whereas it did not – for example, it said nothing useful about how to do experiments that generate ideas in the Stage 1 of science I describe above. But thank you for writing again to clarify this. The

reason I read Box, Hunter and Hunter in the first place was that it was more applications-oriented and realistic than a dozen other books on the subject.

### **The Willat Effect: Side-by-Side Comparisons Create Connoisseurs (2011-07-08 05:00)**

About ten years ago, while visiting my friend Carl Willat, he presented me with five versions of [1]limoncello (an Italian lemon liqueur) side by side in shot glasses. Two were store-bought, the rest homemade, if I remember correctly. I tried them one by one. I had had limoncello many times but never different versions side by side. It was easy to notice differences between them. Obviously. What surprised me was an hedonic reaction: I thought two of them (with more complex flavors) were wonderful and one (store-bought) was awful. Both reactions (wonderful and awful) were stronger than usual. In a small way, I'd become a connoisseur. After that, I was happy to buy expensive limoncello (e.g., \$26). I no longer bought cheap limoncello ( \$18). I call the hedonic changes produced by side-by-side comparisons the Willat Effect. Carl became a connoisseur of Italian hand-painted tableware due to side by side comparisons. I believe [2]connoisseurs were important in human evolution because they helped support skilled artisans. Our design preference for repeated elements (e.g., wallpaper, textiles) evolved so that we would put similar things side by side.

I mentioned a downside of the Willat Effect [3]a few posts ago:

Five or six years ago I went to a sake-tasting event in San Francisco called "The Joy of Sake". About 140 sakes. In a few hours I became such a sake connoisseur that the sake I could afford – and used to buy regularly – I now despised. The only sake I now liked was so expensive ( \$80/bottle) that I never bought another bottle of sake.

[4]A reader named James Bailey commented:

And you still go to tastings?? It seems like ignorance is bliss here, better to preserve your ability to enjoy cheap things.

Yes, I still go to tastings. The sake tasting was the only one that had that effect. Mostly they have no effect because the samples vary too much. For example, I've been to many wine tastings but haven't become much of a wine connoisseur. The many wines at the tastings were all over the place. If I want to get the effect, I usually have to do it myself: buy several versions of a product and try them side by side. I recently did this for whiskey. When I go back to Beijing maybe I'll do it for some sort of tea.

When I do it myself I control the price range and limit the high end to what I can afford. I didn't buy \$80 whiskeys, for example, although many were available. So the effect makes me enjoy stuff at the upper end of what I'll pay. When I became an assistant professor, I thought it would be fun to enjoy fine art (e.g., paintings) more. I attended several art history classes. They had no effect – I was bored. Side-by-side comparisons, in contrast, actually work and, as Carl illustrated, are easily shared. And they are consumerist and artisanal at the same time.

Alrenous (2011-07-08 07:11:31)

Amusement. I use the Willat Effect to test governments. (It's depressing, I don't recommend it if you don't have to.) Of course the most important connoisseurship is of things you produce. Everyone should do side-by-side comparisons of parenting, for example. I'd like to be a blog connoisseur but it's hard to find directly comparable blog posts by different people.

Kirk (2011-07-08 09:49:36)

I'm not sure that it requires side-by-side comparisons. For example, I remember the day I became a real cook. I used to buy canned chow mein, heat it, and pour it over chow mein noodles which had just come tumbling fresh out of the bag, and we thought that was decent home-cooking. Then, for some reason that day, I decided to taste supper. Really taste by focusing on the flavor. There was an underlying metallic tone, and that's when I realized that I'd never be able to buy canned chow mein again. I have repeated this experience multiple times with different foods, and smells, and music. What puzzles me is why I start caring about certain categories. I don't care about specific plants, for example, although we often visit botanical gardens, and I can easily spend half an hour sniffing roses and irises when they're in bloom. But I'll never write down the names of the plants. On the other hand, I agree that once you start caring about a particular category, the best way to sharpen your selection criteria is via side-by-side comparisons. And for some categories, I can play a game where an uninteresting category becomes interesting for a few hours. It's usually when going to some place which interests somebody else and I'm just tagging along. I ask myself, 'What are the 3 most interesting things here?' or 'What seems to be the most bizarre thing here?' or 'What did somebody else craft that makes me envious and I wish I had that skill?'

RioRico (2011-10-18 12:04:23)

Who is Willat? I think of the Willat-Spadina Witch House, designed and built by Harry Oliver on the Willat Studios cine lot back in the 1920's. I visualized the Willat Effect as side-by-size comparisons of Witch-House architecture. Am I nutz?

ChaTo (2011-10-18 12:38:42)

There are two parts (i) a distaste for the lesser varieties and (ii) a knowledge about what constitutes a good variety. For the first part.- Barry Schwartz in "The paradox of choice" popularized an idea that has been tested experimentally many times: when you compare several options side by side, each of the option's value is decreased. That explains why now for you cheap limoncello fell beyond the level of what you would consider acceptable. For the second part.- The fact that now you learned about what makes differences are between different limoncelli, well, would not be possible without comparing them. All the best, - ChaTo

Andrey Shestakov (2012-01-31 02:48:28)

In the world of programming, it's very possible to achieve this effect by side-by-side comparison of two versions of the same code (differently formatted, with different variable namings etc.). I think it's actually where the desire for clean and beautiful code comes from. Probably, I could derive much more pleasure out of programming if I will always code in a side-by-side setup (or at least look at previous versions often enough). General purpose text editing tool with a possibility like this would be really great for bloggers and other writers, don't you think?

Nick (2012-03-04 10:02:50)

The experience is colored by order. Side by side can also happen in the range of days and is probably easier to practice in the long run.

### Better To Do Than To Think (2011-07-10 05:00)

The most important thing I learned in graduate school – or ever – about research is: Better to do than to think. By do I mean collect data. It is better to do an experiment than to think about doing an experiment, in the sense that you will learn more from an hour spent doing (e.g., doing an experiment) than from an hour thinking about what to do. Because 99 % of what goes on in university classrooms and homework assignments is much closer to thinking than doing, and because professors often say they teach "thinking" ("I teach my students how to think") but never say they teach "doing", you can see this goes against prevailing norms. I first came across this idea in [1]an article by Paul Halmos about teaching mathematics. Halmos put it like this: "The best way to learn is to do." When I put it into practice, it was soon clear he was right.

I have never heard a scientist say this. But I recently heard a story that makes the same point. A friend wrote me:

I met Kary Mullis after high school. I knew that PCR was already taught in some high schools (like mine) and was curious how he discovered it. He said that he had some ideas about how to make the reaction work and discussed them with others, who explained why it wouldn't work. He wasn't insightful enough to understand their explanations so he had to go to the lab and see for himself why it wouldn't work. It turned out it worked.

An example of better to do than to think.

Better to do than to think is not exactly anti-authoritarian but it is close. I was incredibly lucky to learn it from Halmos. It isn't obvious how else I might have learned it. It took me many years to learn Research Lesson #2: Do the smallest easiest thing. And I learned this only because of all my self-experimentation. I started doing self-experimentation because of better to do than to think.

1. <http://www.jstor.org/stable/2319737>

---

Bob (2011-07-10 08:33:50)

The first sentence in the Halmos article you linked is something I pound on constantly with tennis coaches: "The best way to learn is to do; the worst way to teach is to talk."

Dennis Mangan (2011-07-10 13:13:43)

The current number two downloaded paper (it was number one for quite some time) on the SSRN is by an outsider, Mebane Faber. He has a bachelor's degree in, I think, biochemistry, but the paper is in the field of finance, in which he now works. He appears to be self-taught in finance. [http://hq.ssrn.com/rankings/Ranking\\_display.cfm?TRN\\_gID=10&requesttimeout=900](http://hq.ssrn.com/rankings/Ranking_display.cfm?TRN_gID=10&requesttimeout=900)

Erik La Gattuta (2011-07-10 15:00:03)

As an artist, the same thing applies. Your imagination is in your fingers.

Jack in Davao (2011-07-10 17:00:20)

As with Mullis, most of the great discoveries have come from creative people tinkering, often using new tools. Therefore, academic science is organized so that in order to "do", you must first write a grant application (i.e. lots of "thinking" and "writing"), which must be scored by a committee (i.e. a minimal amount of "thinking" and lots of "reading" and "talking"), and then if you're one of the one in ten or so lucky ones who get funded you may finally get a chance for a small amount of "doing" (except it won't really be tinkering since you'll be limited by what you said you were going to do in the application). Hmm – perhaps if we had more committees to "set direction" and tell researchers what subjects they should be "thinking" about . . . that could work . . .

Michael (2011-07-10 18:01:46)

Completely agree. I tutor inmates trying to get their GED in math. The only method I've seen have any success is for them to do tons of problems, and then do even more problems. So when I'm teaching someone how to multiply fractions, I'll spend maybe five minutes showing him the rule for multiplying fractions, and then we spend the rest of the hour just multiplying fractions. The next time we meet, I'll have him do even more problems. I used to try to explain what fractions are, why the rule is the way it is, but I quickly found that was a waste of everyone's time. Thing is, after doing several hundred problems with fractions, most are able to give a pretty good explanation of what fractions are, and why the multiplication rule is what it is.

JeffR (2011-07-10 19:12:49)

Seth, I would disagree with your use of PCR as a supporting example. Let's think about how PCR came to be and the influence of thinking vs doing. PCR was conceived in a theoretical sense by Mullis. He likes to tell the story of figuring out PCR, a thought that came to him while driving in California. It was from "thinking" about this problem not "doing" something. You are right about the importance of Mullis persevering when others told him it wouldn't work, but that is illustrating something closer to perseverance or believing in oneself. Mullis probably would never have figured out PCR if he was pursuing a solution by "doing." I'm not sure what that would even mean in this context but trying various experiments probably wasn't going to lead him to this solution or at least not as fast. In the field of health, with so many opportunities for false positives and negatives, confounding, correlation not being causation, etc I would prefer if people engaged in even more thinking about what they are doing, not less. I think the examples given in the above comments are instructive; teaching tennis, doing art or learning fractions. For those examples I would agree with the quote "the best way to learn is to do." These are very different from attempting to show cause and effect in factors relating to human health. For that, the "doing" can make you better at the techniques, such as collecting data. But while trying to determine truths one can easily be lead astray by not having thought enough.

Seth Roberts (2011-07-10 23:06:00)

JeffR, yes, you need to do a little thinking – I agree with you there. A more subtle version of my "doing-better-than-thinking" point would be about the optimal mix of thinking and doing. It would be that the optimum doing-to-thinking ratio (time spent doing compared to time spent thinking) is a lot more than you probably think or practice. (That is, most people spend far too much time thinking.) But the rest of what you say I disagree with. For example, the notion that "correlation is not causation" is an anti-doing way of looking at correlations. It discourages people from using correlations to come up with testable ideas; testable ideas encourage doing.

Shane (2011-07-11 10:18:18)

It's important also to keep in mind the opportunity costs for various kinds of things under discussion. I love the math problems idea – of course the best mix would be lots and lots of doing, because the cost of doing is cheap and the price for failure is low: if you get a problem wrong, do another one. Simple. Who could argue? Same with a lot of the self-tracking stuff: if an important insight can be had, and the cost of bad experimental design, or confounded data, is low, then who cares? Do the experiment. More data is better. But this is not always the case, and in fact is probably not often the case, at least with respect to the scientific enterprise that Seth likes to kick around. I'm in the process of doing an fMRI study, and I can tell you that a kind of wild west "just do it" mentality is about the best way I can think of to waste a hundred thousand dollars and never ever get the opportunity to do another study. A host of other examples come to mind: launching a satellite; building a house; building a highway, or a shopping center; figuring out what regions around a brain tumor can be resected with the least chance of turning someone into a cauliflower. The "correlation vs. causation" canard is getting kind of tired, too. Yes, the mantra "correlation is not causation" is probably overused and wrongly used. And yes, Seth is right to point out that following correlations can be an incredibly fruitful tool for finding interesting questions. But why can't you be satisfied with making an insightful and reasonable comment without barreling headfirst into a tree? Correlation is not causation; and when the scientific question is subtle, potentially misleading, and expensive to misdiagnose, you damn well better understand why the difference matters. The goal with all of this shouldn't be to get everyone to renounce the distinction between the two (thinking vs. doing, correlation vs. causation) but rather to know when to care about that distinction, and how much.

Seth Roberts (2011-07-13 05:17:59)

Shane, I was talking about research, not building ("building a highway or shopping mall") or brain surgery. With an fMRI experiment, you are forced to spend a lot of time thinking since the cost is so high. "Correlation is \_not \_ causation." That's a truism. Not helpful. In this post I was summarizing my experiences. If you have had an experience that suggested a correlation was overinterpreted, that would be good to know.

Shane (2011-07-13 14:38:22)

"Shane, I was talking about research, not building or brain surgery." Brain surgery is research. Where someone cuts depends on a large body of research. If that research is sloppy, the putative function of some bit of brain may turn out to be rather more important wrt some particular functionality than was thought. "Correlation is \_not \_ causation." That's a truism. Not helpful." Activity, or lack thereof, in anterior temporal lobe correlates nicely with progression of semantic dementia. The same activity also correlates nicely with social processing. So what can you say about social processing based on ATL activation? Not too damn much. What can you say about ATL wrt general semantic processing, the kind lost in SD? Also not too damn much. What you can say, based on these very nice correlations in both cases, is that ATL does something, at some point, during the course of both types of processing, and yet that hasn't stopped a lot of overprediction based on correlation worshipping.

JeffR (2011-07-13 17:29:58)

In public health school, an example they use to teach us that correlation is not necessarily due to causation (to fancy up the expression a bit) is of initial research that indicated coffee was a cause of pancreatic cancer. Additional research lead to the realization that pancreatic cancer is caused by cigarettes and smokers drink coffee more often. It's a little more complicated than that, more available [1]heret.

The Image is in Your Pencil « oxpal blog (2011-07-14 05:09:01)

[...] interesting Blog post at Seth's Blog again – called "Better To Do Than To Think". He applies it there to science: Rather do experiments than spending time thinking of how to [...]

Thomas (2011-07-14 06:56:32)

Erik La Gattuta Says "As an artist, the same thing applies. Your imagination is in your fingers." Exactly my thoughts when I read the post. Either I have the perfect image in my head in the moment I hear the assignment, or there is no other way then to pick up a pencil. I really tried the tough way - sitting half a day around thinking, trying to get an image in my head. But it just doesn't work. Starting to draw does the trick. I nearly suspect humans are just not very good at thinking... Your text just puts it more poetic than I could have said it. Kinda adapted on my page, hope thats ok.

Josh Fisher (2011-07-15 14:39:19)

To me the difference between doing and thinking is the scale. When we think something physical is happening so it could be considered that we are doing something. What concerns me about doing on a larger scale is there is always a reaction of which we are only assuming what the results will be. I do not feel well informed enough to make a decision as to whether or not it is good or bad, it just is. For me I hope all that I do is good, but all I can trust is my gut instinct which has been too conditioned since birth to completely trust. I think the answer lies deeper than we could possibly be aware of, but I've noticed plenty of signs along the way that make we question the expectations I've been following. Its usually when I stop and reflect on past actions. This may reason that no action would be the answer, however with no action I'm assuming we wouldn't exist. This leads me to believe one again there is a balance and its going to vary for every single person at different times.

Nick (2011-07-17 02:28:43)

How ironic (yeah, I know) that the ad on the top-right is "Anything's possible. Keep thinking."

Joe User (2011-07-17 08:05:14)

Do I really have to point out that to think is in the subset of verbs that are to do? My experience has been, for anything sufficiently complicated thinking comes first. I should also point out that there are plenty of studies that suggests that thinking about doing something is as good or better than practicing that thing. Of course, there is some physical practice required for this to work, and maybe that is what the poster is trying to get at. As someone who does \*a lot\* of troubleshooting and is very good at it, I can tell you how I do this one activity where thinkers outperform doers. I get some information about a system that may be broken. I then time thinking about what could cause the symptoms, that is, I simulate the system in my head, and twist and turn knobs until I can see in my head something that might have symptoms similar to the knowledge I already have. Now I have a hypothesis. Now I can test my hypothesis. I gather more data, then I adjust the simulation in my head (occasionally I even get such new information that I actually need to adjust the model in my head of the system I am working on). Now I think some more, running some more simulations until I have a new hypothesis to test. Rinse. Repeat. There's always a trade off here though. Thinking is usually cheap, but it can take you places that could never happen. Doing is usually expensive, but you'll never do something impossible. Thinking prevents you from doing something that won't work. Doing prevents you from thinking about what can't work. Each can save you time and effort. And the ratio changes depending on their relative costs for a given person and a given problem space.

Seth Roberts (2011-07-17 08:54:19)

In this post I am talking about scientific research at the low end of the cost/hour scale. When something is well-understood theoretically, as is usually true in engineering (e.g., electrical engineering), I agree you should use the theory ("thinking") to guide what to do.

steve (2011-07-17 10:08:03)

I think you should set some time for thinking and if you still don't get it, then it's time to start doing it.

Seth Roberts (2011-07-17 12:52:26)

Yeah, that makes sense. I suppose I usually "don't get it".

beagle3 (2011-07-17 23:31:34)

Very relevant: <http://www.brepettis.com/blog/2009/3/3/the-cult-of-done-manifesto.html> (Bre Pettis is a cofounder of the NYC Resistor hackerspace, and of MakerBot Industries) I agree with what you write here, but on the other hand I also keep in mind the adage that "Two years in the lab can save you as much as two weeks in the library!" - there needs to be a balance between the effort spent thinking and the effort spent doing.

Seth Roberts (2011-07-18 08:25:03)

I wouldn't call time spent in the library "thinking". I call that reading. And I have learned plenty of useful things from reading—my reading has led me to many self-experiments that had useful results.

## Phone Hacking and Jane Jacobs (2011-07-13 07:28)

I am fascinated by the British phone hacking scandal. Jane Jacobs has helped me understand it.

Should police officers be paid per arrest? Most people think this is a bad idea, I imagine, but the larger point (what can we learn from this?) isn't clear. In [1]Systems of Survival, Jacobs tried to spell out the larger point. She wrote about two sets of moral rules. One set ("guardian syndrome") applied to warriors, government officials, and religious leaders. It prizes loyalty and obedience, for example. The other set ("commercial syndrome") applied to merchants. It prizes honesty, avoidance of force, and industriousness, for example. The two syndromes correspond to two ways of making a living: taking and trading. The syndromes reached the form they have today because they worked – different jobs need different rules. When people in one sort of work (e.g., guardian) follow the rules of the other, things turn out badly. Ayn Rand glorified the commercial syndrome. When Alan Greenspan, one of her acolytes, became a governor, he did a poor job.

What about journalists? As a journalistic business becomes more powerful, it becomes more guardian-like. A powerful newspaper isn't inherently bad; we want a powerful newspaper to keep other powerful institutions (government, large businesses) in check. Murdoch's News International, of course, has become very powerful. Yet Murdoch newsrooms retained commercial norms, especially an emphasis on selling many copies. Reporters in Murdoch newsrooms were under intense pressure to produce – like policemen paid per arrest. Other journalists, with guardian norms (e.g., at the New York Times), didn't like the commercial norms of Murdoch newspapers. The mixture of commercial values and guardian power led to the phone hacking scandal. Friends of mine blame Murdoch himself – but commercial norms are not unique to Murdoch. The problem is their mixture with great power.

When newspapers are small, they are not powerful, not guardians, and must adopt commercial norms – they must try to sell more copies or they will be crushed. When a small newspaper becomes large and powerful, however, its norms must change to guardian ones or things will turn out badly. This suggests that the phone-hacking scandal happened

because Murdoch became very powerful too fast – too fast for a shift in values to accompany much greater power.

---

Alan (2011-07-13 09:48:21)

Seth, I think you got it exactly backwards. In the past, journalism felt the need to be guardians - they felt a responsibility to the public, which they took seriously. News had to be "fit to print" and all that. This is evidence that the transition \*is\* complete. They are fully commercial enterprises doing whatever it takes to sell a story.

Robin Barooah (2011-07-13 12:09:03)

This is thought provoking, but I'm not sure I see how 'speed of acquiring power' could be the independent variable determining which syndrome emerges. What forces are different if power is acquired slowly? I think that one problem (not of your analysis - of modern business) is a failure to recognize the limits of using price to regulate action. For example the reason it's bad to pay police per-arrest, is that the value of the arrest is determined by information only available much later, and it can be negative so there is no way to discount the price based on quality without looking at the later consequences of each arrest. Paying by arrest quality - i.e. the guilt to innocence ratio creates an even worse incentive; for police to distort the evidence to improve the ratio. Furthermore, there is no disincentive against collusion. A nightmare scenario, yet such a police force might well be very financially successful, especially if paid directly by consumers of its services. Imagine investing in such a business - you put up money for police stations, guns and batons and handcuffs etc. You hire some 'officers', you charge victims for 'bringing perpetrators to justice', and you pay the officers a percentage. The point here is that profit making organizations can be created that have the semblance of other institutions but are devoid of the value those institutions were intended to provide. The belief that we can attach a monetary value to anything we want to promote is simply a delusion. Unfortunately, acknowledging this means recognizing that we have less control than we would like, and leads to political disadvantage compared to those who deny it.

Seth Roberts (2011-07-13 12:30:56)

"in the past journalism felt the need to be guardians". Many journalists still feel this need. Maybe the majority do. If you go back to the very beginning of newspapers, when they had no power at all, I think you will find a more commercial attitude. The term "yellow press" comes from the 1890s and describes a more commercial attitude. It arose during circulation wars. Even by then journalists had become enough guardian-like to condemn such behavior.

Robin Barooah (2011-07-13 15:04:27)

I don't doubt the existence of journalists who want primarily to serve as guardians. I'm just not certain that our system is going to keep allocating enough resources to them to enable them to practice. They are competing against organizations who have a greater flexibility in how they acquire those resources and so are at a disadvantage.

UncleLongHair (2011-07-15 02:46:38)

The era of the "big newspaper" is gone, because the era of the newspaper is gone. Every reader has access to thousands of news outlets every day, all vying for their attention. News doesn't come once a day now, it comes every second. In order to compete in this world, news outlets need a constant stream of splashy short headlines in order to attract "clicks" (see cnn.com). Quality, depth and accuracy of the underlying journalism is a distant tertiary priority. I think the Murdoch scandal is an example of an "old fashioned" newspaper getting more and more desperate to stay competitive and resorting to riskier and riskier tactics to find stories. I am sure they lost all of their what we used to call legit journalists long ago, and were staffed with paparazzi with a short attention span. I hope the New York Times survives because I prefer to read thoughtful, in-depth stories, but I am not sure how they will.

Tom (2011-07-16 00:52:00)

Great post, Seth. I'm not sure it's just 'speed' though - I think it's a matter of generations. Though Rupert Murdoch did inherit his father's firm, he did "cut his teeth" on Fleet Street in the fifties. He absorbed the competitive ethos and retained it sixty years later when he had (arguably) become one of the most powerful people in the world. Most newspapers would have iterated through one or more generations by that point. Harrison Otis, founder of the LA Times, profited greatly from buying up land in the San Fernando Valley while his paper stampeded readers into thinking that L.A. was running out of water (thus driving support of the aquaduct that would turn the Owens valley into a desert.) Subsequent generations of Times owners - notably the Chandler family - were no longer pirates but very much staid guardians. Otis & Mulholland stole the money that the Chandlers would then use to build opera houses.

Glenn (2012-01-04 15:56:02)

Hi Seth, You have made an excellent point in connecting the phone-hacking scandal and Jane Jacobs's systems of survival, however I have interpreted slightly differently. Whilst Jacobs agrees that newspapers have become the guardians of guardians I believe she would interpret the phone-hacking as a form of what she termed 'monstrous hybrids'. Not only did the newspapers break the commercial syndrome precepts of 'respect contracts' and 'be honest' to name a few, but they inadvisedly adopted a precept from the guardian syndrome; 'Deceive for the sake of the task'. Following Jacobs' argument, I believe this picking of the precepts from the different syndromes, which Jacobs and Plato state should never happen, created the 'monstrous hybrid' that is the News of the World phone-hacking. Ironically, this was then reported by other newspapers, adopting the guardian role, aiming to protect the public, all very confusing! Please comment as I am actually writing an essay on this very book as part of my Masters Degree and warmly welcome any criticism or comments you have about what I have said :)

## Percentile Feedback Update (2011-07-17 08:43)

In March I discovered that [2]looking at a graph of my productivity (for the current day, with a percentile attached) was a big help. My "efficiency" – the time spent working that day divided by the time available to work – jumped as soon as the new feedback started (as this graph shows). The percentile score, which I can get at any moment during the day, indicates how my current efficiency score ranks according to scores from previous days within one hour of the same time. For example, a score of 50 at 1 p.m. means that half of the previous days' scores from noon to 2 p.m. were better, half worse. The time available to work starts when I get up. For example, if I got up at 4 a.m., at 6 a.m. there were 2 hours available to work. The measurement period usually stops at dinner time or in the early evening.

This graph shows the results so far. It shows efficiency scores at the end of each day. (Now and then I take a day off.) One interesting fact is I've kept doing it. The data collection isn't automated; I shift to R to collect it, typing "work.start" or "work.stop" or "work.switch" when I start, stop, or switch tasks. This is the third or fourth time I've tried some sort of work tracking system and the first time I have persisted this long. Another interesting fact is the slow improvement, shown by the positive slopes of the fitted lines. Apparently I am slowly developing better work habits.

The behavioral engineering is more complicated than you might think. My daily activities naturally divide into three categories: 1. things I want to do but have to push myself to do. This helps with that, obviously. 2. things I don't want to do a lot of but have to push myself away from (e.g., web surfing). 3. things I want to do and have no trouble doing. But the recording system is binary. What do I do with activities in the third category? Eventually I decided to put the short-duration examples (e.g., standing on one foot, lasts 10 minutes) in the first category (counts as work), keeping the long-duration examples (e.g., walking, might last one hour) in the second category (doesn't count as work).

Before I started this I thought of a dozen reasons why it wouldn't work, but it has. In line with my belief that it is [3]better to do than to think.

Paul (2011-07-17 11:48:32)

Hi, Seth. I have enjoyed your blog for a while but am a first-time commenter. Many thanks for all your insights. (I have especially enjoyed and benefited by your articles on fermented foods.) Your tracking system seems helpful. When doing work that requires creativity or deep insight, however (as I'm sure much of your work does), I would be reluctant to use this sort of tracking system for fear of over-emphasizing quantity of work at the expense of quality. I tend to prefer productivity systems that focus attention on outputs rather than inputs, thereby rewarding efficiency and creativity. Have you found your tracking system to have any adverse effects on the quality of your work or your morale? Have you tried tracking other variables that measure your outputs rather than your inputs?

Seth Roberts (2011-07-17 12:48:18)

I would think that "productivity systems that focus attention on outputs" reward quantity at the expense of quality. For example, how many words you have written at the expense of the quality of those words. They reward efficiency, yes, but I don't see how they reward creativity. One reason I measure time spent (an input) rather than other things (such as outputs) is exactly this issue: to encourage quality over quantity. Maybe I can't produce much output (= words) but at least I get credit for trying. To answer your question about adverse effects, I haven't noticed any change in quality. The system has improved my morale since I am more aware of making progress every day and believe I am using my time more productively (in terms of time spent working).

Paul (2011-07-17 13:47:39)

Thanks for your thoughtful reply, Seth. I agree that a crude measure of output such as # of words written would tend to lower quality, and I was not recommending such a measure. Since you are monitoring yourself, you are free to try more nuanced and more subjective measures of output than raw word counts (as, for example, when you measure the quality of your sleep). I don't know whether you would find such measures as useful as your current measure of efficiency, but they may merit some experiments. :)

carl (2011-07-18 06:08:04)

Seth, a little off topic here, but I'd be curious to know what you think of "brain training" like Lumosity. I would really like to think I could improve my overall mental performance by playing these games every day, and the software (on-line) offers tracking functions to show if improvement is being made.

Seth Roberts (2011-07-18 10:35:52)

carl, I believe you will improve only on tasks similar to the task you practice on.

carl (2011-07-25 06:24:27)

seth, thanks for the reply. that's a good thought. i agree it's probably not a good idea to put too much stock into it. still, i'm going to continue to play them, mostly because I enjoy them and it seems to help refresh the mind on occasion.

## **Worse Than Placebo? Forest Laboratories's Shameful Marketing (2011-07-18 05:00)**

While Forest [Laboratories] applied to the FDA for pediatric use of Celexa [the anti-depressant] and was eventually denied, the company admitted it had marketed the drug to doctors by hiring speakers to tout its benefits for young patients. Forest also admitted it had suppressed the negative results of research in Europe that found Celexa was no more effective in treating depressed children and adolescents than a sugar pill. Fourteen young patients in that study attempted suicide or contemplated suicide, compared with five in the placebo group, court records show.

From [1]this article. Is Forest Laboratories worse than other big drug companies? Probably not. What's horrible is how this sort of thing – suppression of negative results – keeps happening. It suggests that the evaluation of drugs should be taken entirely out of the hands of drug companies.

1. <http://www.irishtimes.com/newspaper/health/2011/0222/1224290501283.html>

Glen Raphael (2011-07-18 13:27:53)

Are there any laws preventing drug companies from pointing out the flaws in the drugs of their competitors? It seems like that would be a natural way to find this sort of thing out. Just like "negative campaign ads" are more informative - and more convincing - than positive ones, you could imagine a drug market in which the drugs that objectively did best were advertised as such (and false claims were investigated by the media and/or the courts as possible fraud). You could even include a standardized URL where all the fine print caveats are listed (instead of scrolling past pages of fine print spoken by a fast-talker) Another thing to consider is that FDA approval is too binary: "approved" or "unapproved". If we made FDA approval optional it seems likely something like Consumer Reports would come about to arbitrate not just whether drugs work but \*how well\* they work. Including ranking drugs against each other to see what the comparative advantage is.

## **The Value of a Diagnosis of Asperger's (2011-07-19 05:00)**

In [1]a recent post I said Marcia Angell was too hard on psychiatric diagnosis. Long before perfection, diagnoses can be useful. For example, Alexandra Carmichael recently found out she has something close to Asperger's Syndrome (note that she has not been diagnosed by a doctor). She explained why:

I feel like at least I'm on the \*path\* to a much smoother life now - whether I'm there or not can be debated. :) Learning about Asperger's has illuminated sensory and social sensitivities that I didn't realize other people \*didn't\* have. It was understandably confusing to live in a world where I thought I was defective because I couldn't do what other people were doing as easily. Knowing that there is a subset of people who experience the world the way I do has been liberating, and seeing how other "aspies" modify their lives and routines to suffer less has helped me make helpful structural changes in my life, too.

For example, right now I am wearing my Bose QC 15 headphones on a flight from Boston to San Francisco, because I know that too much sound in a day can make me incredibly weak the next day. I've arranged to do 90 % of my work by email and chat these days, with the occasional in-person meeting, because I know that my auditory processing is not great for phone calls, and it takes me days to prepare for and recover from a social meeting/event. I say no to most things I get invited to (conferences, dinners, etc),

because I prefer to contribute my thinking/organizing/connecting talents online and reserve social energy for one-on-one time with close friends. I've also become aware that my ability to listen and empathize with people is powerful and something I enjoy, maybe in part because I build such intricate models of everyone I meet, so my purpose in life has become to listen and help where I can. I only wear comfortable clothes, because my mood will suffer terribly if I have jeans or high heels on. I give and receive lots of hugs, because these are very calming for me. I have a very detailed daily routine that I follow, which reduces cognitive load used to consider options every day and feels comfortable for me. I'm much more aware of my weaknesses, especially regarding relationships, and am very careful about communicating clearly and non-violently, making sure I have a good understanding of both my needs and the needs of people around me - so that I can help, or at least not harm them.

So things like this have all come about because of trying on the Asperger's hat for a while, and the increased self-awareness that came with it. After a certain point, you can drop the label and integrate what you've learned into your identity. But for me, having the label for a while was a guide and a relief, helping me realize that it's really ok to be myself.

1. <http://blog.sethroberts.net/2011/06/21/marcia-angell-on-psychiatry/>

---

David Clingingsmith (2011-07-19 09:02:25)

It's quite inspiring to read how knowledge about Asperger's has improved this woman's life. I'm puzzled by your raising it in the context of Angell's views on psychiatric diagnosis, given that Ms. Carmichael seems to have benefited most from the classification of a set of experiences, abilities, and limitations she has as part of a human "type" that allows her to feel at peace with who she is and organize her life according to what works for her. She has not even been diagnosed by a doctor! This speaks much more to the power of making the ideas and findings of research accessible to the public. An important question is whether that research could be produced without the diagnostic apparatus. Probably not if we mean a system of organizing and classifying phenomena, but that's not really at issue in the debate.

Seth Roberts (2011-07-19 09:38:50)

Asperger's is a psychiatric diagnosis. Created in the context of psychiatric diagnosis. "This speaks much more to the power of making the ideas and findings of research accessible to the public." Well, who knows about "more", but yes, it also suggests the value of doing that. Alex's experience required both A (psychiatric diagnosis) and B (making ideas accessible). That B matters doesn't mean A doesn't matter.

## Morning Faces Therapy for Bipolar Disorder: Follow-Up Questions (2011-07-20 05:00)

In May [1]I posted a friend's story about how he used [2]my morning-faces discovery to improve his life. It helped enormously ("It felt like a giant headache was just lifted off me"). I asked him some follow-up questions.

What time of day do you look at your face in a mirror? For how long?

I look at my face in a mirror for an hour starting at about 6:20am (Daylight Saving Time). It doesn't feel weird or vain to me. I usually listen to C-SPAN, Comedy Central, or music during the therapy.

You wrote: "I'm able to enjoy life and relate to others in ways that I never could my entire life." Could you elaborate?

In my letter I said that my initial reaction to the face therapy was that it felt like a giant headache was just lifted off of me. That "headache" was the weight of depression and anxiety on my mind. My whole life I have been burdened by that weight, under its shadow to one degree or another. Another angle on this: Your initial reaction was "I felt great – cheerful and calm, yet full of energy". I am quite certain that before the therapy I was never in that state of mind. But I'm not just talking about typical enjoyment—hearing the music, conversing and laughing, a fine meal, etc. In The Simpsons episode "Barting Over", Homer is twirling slowly high in the air on a skateboard, and a novel idea pops into his head: if he buys two kinds of nuts separately, he can combine them at home to get "mixed nuts". That sensation of weightlessness, with little solutions to little problems just popping up, is new to me. When you add up hundreds of those solutions, you find life itself less burdensome. You make more room for appreciation, gratitude, friendship, and so on. You begin to get an inkling of what a full human life could be.

People "automatically reject the idea", you wrote. What happens?

"That's the most ridiculous thing I've ever heard" was the comment of a woman in the bipolar support group. Some in the group of the if-it-sounds-crazy-enough-I-believe-it persuasion would nod their support. My sister theorized that it was all just meditation (!) and finished by saying, "I get enough faces at work." My dental hygienist was somewhat persuaded by the fact that a newborn can recognize its mother's face within hours of birth. Do you continue to see a psychiatrist and/or a psychologist? If so, are they curious about how well you are doing without meds? If they're not curious, how do they explain it? My psychiatrist and psychotherapist are glad that I'm doing well, but they are not curious about the face therapy, the bright lights, or the fish oil. They are skeptical toward alternative treatments. I gather they think that my improvement is due to remission, or an upswing in the illness's cycle, or the accumulated years of talk therapy. Or they abandon reason altogether, saying, "Whatever works for you." Why do you need to go to bed "early"? What happens if you don't? What makes it difficult or discipline-requiring to go to bed "early"? If I go to bed late, I need to take an hour nap the next day, which is a drag. At 10pm I'm almost never tired enough, plus I usually feel that I haven't accomplished enough for the day. At your suggestion, I am trying to reset my circadian rhythm by getting 2 hours of morning light from approximately 7:30am to 9:30am. What effect does the early morning bright light therapy have? How do you do it (e.g., equipment, time of day)? Why did you start it? As I recall, the lights helped me to wake up early, fairly rested and alert. I started in 1997 at your suggestion with a bank of four GE

F40SP65-ECO tubes, 40 watts each, 48 inches long. I now cover half of the bank to reduce the intensity. I get thirty minutes of exposure starting at about 6:50 am (Daylight Saving Time). In 1997, what made you decide to try the faces? I was primed for the idea that a big change might help. Six months prior, I had made a somewhat beneficial switch to Depakote after taking lithium for 11 years. Also, you claimed that you already had good experimental results with several people, and that Andrew Gelman at Columbia University was impressed with your work. "I hadn't needed Moban since 1999," you write. Why not? From 1999 to 2003, the face therapy was so effective that I didn't need an antipsychotic (e.g. Moban). From 2003 to 2006, when I didn't use the face therapy, I kept certain habits that I had adopted during that therapy: keeping a fairly normal sleep schedule, avoiding fluorescent lights at night, and getting a decent amount of social interaction. With the benefit of hindsight, why do you think it did not keep you out of the hospital in 2003? When I told my psychiatrist in 1999 that I was going to use the face therapy instead of medications, he exclaimed, "That's like taking off a cast and trying to walk right away!" Indeed, for 12 years my mind had been numbed with psychiatric drugs. Although the face therapy was seemingly miraculous, it couldn't restore all that was lost. Yet with little support from others I was trying to "walk": I had the goals of getting a job and a social circle; I had a dream of leading the way for all depressed people. It was unrealistic to expect that I could do much more than crawl through life. By 2003, I needed the hospital because I was in over my head. Why did back pain and stress put you back in the hospital? Why did they lead to a suicide attempt? My mental state deteriorated because of lack of sleep, which in turn was due to back pain and stress. Both back pain and stress are manageable—given enough time and attention. Unfortunately, at the time I was overwhelmed with many new problems and many lingering old problems. I had just moved. The house had far more traffic noise and housemates than I was accustomed to. I didn't have the money or strength to move again; I was falling out with an old friend; my wrists and feet were injured. If I went back to the mental health system, I would be more handicapped than ever. The situation seemed hopeless. Why did publicity related to The Shangri-La Diet make you try this again? I actually thought that Diane Sawyer might call me after saying to herself, "Wow, what else has Professor Roberts discovered?" So I wanted to shape up my mood fast! I assumed that the Shangri-la Diet in its way must be about as great as the face therapy. I didn't suspect that the media would treat your diet like any other—as an offbeat fad. You wrote: "In August of 2010, dissatisfied with my low energy level, I decided to go off medications completely again. What did you do? I had been "stabilized" on 250 mg of Depakote, which is a sedating anti-manic drug, and 20mg of Prozac, which is an antidepressant that can induce mania. About once a month, I got rid of the sedation by skipping the Depakote for a few days. On one occasion, when I tried to skip the Depakote for 9 successive days, I became slightly hypomanic and had trouble sleeping. Over the course of several months, I reduced the Prozac to 10mg, and even to 5mg, but still I couldn't stay off the Depakote for more than about 7 days without problems. You wrote: "Getting off just the two drugs was tricky, because of the difference in half-lives." What was "tricky" about it? I was boxed in by the difference in the drugs' half-lives. Prozac has a plasma half-life of about 10 days, while Depakote has a half-life on the order of only 10 hours. I considered splitting the enteric-coated Depakote, but never did. I decided that the only way out was to stop taking the Prozac, but continue taking the Depakote for 10 days until the Prozac was out of my system. So I tolerated being depressed and sedated until I could stop the Depakote, too.

Peter Silverman (2011-07-21 18:37:30)

I tried a bunch of alternative treatments for my bi-polar after it seemed clear that psychiatric medications weren't helping. When I tried a supplement from Canada for bi-polar, it went away, and I've been six years now with no mania, no depression, and no meds. Of course I don't know for sure the supplement (emPower Plus from truehope.com) was what did the trick, but the timing makes me think so. I've also never met anyone else who tried that supplement.

Seth Roberts (2011-07-22 05:39:46)

Peter Silverman, thanks for your comment. [1]More about EmPower Plus here.

1. [http://www.bpchildresearch.org/dcforum\\_public/DCForumID1/1371.html](http://www.bpchildresearch.org/dcforum_public/DCForumID1/1371.html)

Jeff (2011-07-22 14:33:01)

Seth - I've tried morning faces on several occasions without success. You previously mentioned that exposure to faces in the evening removes the positive impact of morning faces. I can't avoid seeing faces most evenings because I live with someone else. Have you ever known morning faces to work for people who are not living alone?

Seth Roberts (2011-07-22 20:06:44)

Yes, one of my subjects had/has a family. It is long face-to-face contact you need to avoid in the evening. The sort of contact you have in a face to face conversation. Seeing faces in other situations won't have much effect, as far as I can tell. You certainly need to go to bed relatively early (like 10 or 11 pm) and get up relatively early (like 6 pm) for it to work. However, I think you bring up a good point – it isn't easy to avoid face to face contact at night. Perhaps special glasses will be sold that both filter out blue light (which when experience at night can disturb circadian rhythms) and obscure faces.

Jeff (2011-07-23 11:20:30)

Thanks for the feedback and additional information about sleep time, Seth.

Jeff (2011-07-27 15:53:53)

Seth or anyone else - I have a follow up question on blue blocker glasses. I recently purchased a pair, but there are small gaps at the top and bottom of the glasses that would allow some blue light in. Is it essential the lenses completely block out all blue light to obtain the sleep benefit? If so, any suggestions on what to do to correct this problem, hopefully, outside of purchasing a new pair? TIA

Seth Roberts (2011-07-27 16:31:50)

Jeff, my answer to your question is: I doubt it. Whether the glasses will help you sleep I don't know – I don't know enough about you – but I suspect that the small amount of light they let in isn't going to make much difference.

Jeff (2011-07-28 17:41:09)

The blue blocker glasses appear to have the most impact on how quickly a person initially falls asleep based on your earlier posts and information from the Quantified Self conference. Any other sleep benefit(s) these glasses would offer that you know of?

Seth Roberts (2011-07-29 07:41:40)

I believe the blue blocker glasses reduce disruption to an invisible circadian rhythm that controls when we are awake and asleep and controls the morning-faces effect on mood that this post is about. This invisible rhythm creates a "sensitive period" during which the faces have an effect. If the rhythm is disrupted there is no sensitive period.

## **Welcome to the Sausage Factory: Multiple Fraud in a Paxil Study (2011-07-21 05:00)**

Dr. Jay Amsterdam, a professor of psychiatry at the University of Pennsylvania, recently lodged [1]a very interesting complaint against five authors of a 2001 study that compared Paxil to another drug and placebo for treatment of bipolar disorder. The paper reports research paid for by SmithGlaxoKline, the makers of Paxil. For a subgroup of patients, it says, Paxil worked better than the other drug and better than placebo. Paxil supposedly had fewer side effects than the comparison drug. Amsterdam accuses the five academic authors of plagiarism – meaning they put their names on a paper they didn't write (like a student who buys a paper). He also says the paper grossly misrepresents the results

(because the subgroup analysis was completely ad hoc and the side effects description utterly wrong). So if they did write it . . .

The paper has been cited hundreds of times. Given the actual results – Paxil had worse side effects than the other drug, and the subgroup result means little – this is no small matter.

As Spy magazine has said, if you cheat your customers, don't fire anyone. Email included with Amsterdam's complaint suggests he was upset because he was not an author on the paper. Why? Well, the study was done at many sites and there could be only one author per site – according perhaps to SmithGlaxoKline. At Penn, the work (enrolling subjects) was first given to a junior faculty member named Laszlo Gyulai. However, Gyulai couldn't enroll enough subjects. Amsterdam was asked to help and paid for doing so. He ended up enrolling more subjects (12) than Gyulai (7). Yet Gyulai was an author and he was not! This greatly bothered him. He considered it "misappropriation" of his data, said Gyulai had engaged in "the theft and publication of a professor's data", and wanted Gyulai censured. Perhaps Gyulai had considered Amsterdam's non-authorship okay because many professors who contributed subjects were not authors. Whatever the reason, it appears that authorship was determined by the firm that did the ghostwriting, Scientific Therapeutics Information, presumably following orders from SmithGlaxoKline.

I don't know why Amsterdam waited ten years to complain. Since 2001, however, the ghostwriting problem has become much clearer. In 2001, Amsterdam complained to his department chair, Dr. Dwight Evans, about the situation. In 2010, Amsterdam learned that Evans had benefited from ghostwriting. That's how common it was.

There's [2]also this:

POGO [Project on Government Oversight], in a letter to President Obama [related to Amsterdam's complaint], asked that he remove Amy Gutmann, president of the University of Pennsylvania, from her position as chairman of the Presidential Commission for the Study of Bioethical Issues, until the two cases involving Dr. Evans are fully investigated and resolved.

Chairman! Another indication how common and tolerated ghostwriting is. It is as if an obesity expert, appointed head of the most important obesity committee in the country, charged with recommending how to stop the obesity epidemic . . . is fat.

Perhaps British journalistic phone-hacking has been more common than misrepresentation of results by med school professors but the latter, I'm sure, has done more damage.

[3]Attachments to the Amsterdam complaint. [4]Pharmalot weighs in. [5]Some of the accused defend themselves.

AZ (2011-07-21 09:46:31)

I found a case where a public health official outsourced the writing of a report. I checked the properties feature of the document. I googled the listed author and found the name attached to a scientific writing firm abroad. I emailed that person and the person confirmed doing the design for the report. I sat on the information, but I probably could have done something with it when the individual came before the Senate for confirmation to higher office.

JeffR (2011-07-21 18:44:04)

I think your writing on this subject is valuable and I'd love to see it reaching a wide audience.

### **Harvard Psychiatrist Joseph Biederman and Parents: "Should Be Left in a Room Together" (2011-07-22 05:00)**

Joseph Biederman is a professor of psychiatry at Harvard. [1]He recently received a far-too-mild sanction for behavior that included this:

Biederman was then placed in charge of the institute and began a study of 40 children between 4 and 6 years old who were given Risperdal [made by Johnson & Johnson] and Lilly's Zyprexa, another antipsychotic. At the time, Harvard and MGH [Massachusetts General Hospital] rules forbid researchers from running trials with [drugs] if they receive more than \$10,000 from a company that makes the drug.

It was eventually revealed that Biederman had received at least \$1.6 million from drug companies, including far more than \$10,000 from Johnson & Johnson and far more than \$10,000 from Lilly. One comment on the quoted article made the excellent point that bipolar disorder had a usual onset age of onset of 18 years or more and had never been found in young teenagers (e.g., 14-year-olds). Yet Biederman suddenly claimed it appeared in 6-year-olds. In a good expression of how I feel about Biederman's behavior, another comment said he should "be left alone in a room with the parents of the children [he] treated".

1. <http://www.pharmalot.com/2011/07/harvard-docs-disciplined-for-conflicts-of-interest/>

---

Alex Chernavsky (2011-07-22 06:11:11)

Yeah, and I would have put the word "treated" in scare quotes. Joseph Biederman and Charles Nemeroff (among others) should be permanently barred from doing any clinical work and any research.

Seth Roberts (2011-07-22 08:24:26)

Alex, you are too forgiving. Biederman should go to jail.

Ruth (2011-07-22 13:16:56)

I wish I were surprised.

psychotherapy (2011-08-04 19:48:13)

It is very unfortunate that such high caliber professional was involved in such a scheme. Many doctors are "in bed" with pharmaceutical companies and prescribe only medications that are more profitable for them. Unfortunately, it is very common. Thank you for an interesting post.

## Google Yes, Wikipedia Yes, Aaron Swartz No? (2011-07-22 06:00)

We praise Google and Wikipedia for making knowledge more available – consider them two of the best innovations of the last 50 years – but after Aaron Swartz, a friend of mine, apparently tried to do the same thing [1]he was charged with wire and computer fraud and faces up to 35 years in jail and a \$1 million fine.

The prosecutor, U.S. Attorney Carmen Ortiz, made an interesting statement:

Stealing is stealing, whether you use a computer command or a crowbar, and whether you take documents, data or dollars. It is equally harmful to the victim whether you sell what you have stolen or give it away.

In my experience, tautological statements such as "stealing is stealing" or "correlation is not causation" do not bode well for that side of the argument. As Thorstein Veblen might say, the reason for the tautology was the need for it.

Ortiz's statement shows that she, like the rest of us, thinks that what matters is amount of harm. Harm is hard to find here. The only clear harm is that MIT access to JSTOR was shut down for a few days. This is so minor that [2]JSTOR's statement about the case (which includes "it was the government's decision whether to prosecute, not JSTOR's. . . . We [have] no interest in this becoming an ongoing legal matter") doesn't mention it. I don't think many people will agree that this amount of harm justifies the charges that Ortiz has brought.

[3]Sign a petition supporting Aaron.

---

tom (2011-07-25 08:19:58)

Seth, he was trying to take something and knew he did not have permission to take it. Or do you dispute this description of what he did: The indictment (.pdf) accuses Swartz of repeatedly spoofing the MAC address — an identifier that is usually static — of his computer after MIT blocked his computer based on that number. Swartz also allegedly snuck an Acer laptop bought just for the downloading into a closet at MIT in order to get a persistent connection to the network. Swartz allegedly hid his face from surveillance cameras by holding his bike helmet up to his face and looking through the ventilation holes when going in to swap out an external drive used to store the documents. Swartz also allegedly named his guest account "Gary Host," with the nickname "Ghost."

Seth Roberts (2011-07-25 11:23:32)

"Seth, he was trying to take something and knew he did not have permission to take it. Or do you dispute this description of what he did?" What I dispute is that what you just said is all we need to think about when deciding how his actions should be dealt with. There have been many examples of civil disobedience in human history. All of them involved people doing what they did not have "permission" to do. For example, Rosa Parks sat where she did not have permission to sit. I think it is a good idea to think about them when deciding what should happen in this case.

tom (2011-07-29 06:24:27)

Seth, "civil disobedience" usually means intentionally violating a law and intentionally and publicly taking the consequences because you think the law is unjust and should be challenged. That's Rosa Parks. The goal is to testing the law and people's reactions to the case against the person testing it. The civil disobedience you are talking about is different. Swartz didn't want to get caught, he wanted a fait accompli. He wanted the articles irretrievably released. So compared to Rosa Parks, Swartz is not a civil disobedient. You also argue that there was no 'harm' other than the MIT shutdown of JSTOR access. Of course, the actual harm of a failed crime is irrelevant. You need to look at the harm if the person had succeeded. I think you are really saying there would have been no harm to others if Swartz had 'freed' huge chunks of JSTOR because it is unjust for JSTOR to be limited-access. Is that right? It's not exactly the same, but should I free Shangri-La Diet and email it to huge groups of people so I can help thousands of them get healthier? Should I free the archives of high-quality subscription websites giving paleo- health advice?

Seth Roberts (2011-07-29 07:36:32)

"I think you are really saying that there would have been no harm to others if..." No, of course there would have been harm to others – JSTOR employees, for example. Just as Rosa Parks caused harm to many. And of course there are differences between what Rosa Parks did and what Swartz did. I am saying the similarities matter.

tom (2011-07-29 14:54:25)

I feel like you're skipping the key harm: to the journals and people whose works are published through JSTOR. If you say there would be no harm to the publications and no harm to the authors, that's a very big point. Will you step up and say that? You are also ignoring that Swartz didn't choose civil disobedience like Rosa Parks did: He wasn't petitioning for a law to make JSTOR public, he didn't try to get each of the journals in JSTOR to agree with him, he didn't go to Congress, and he didn't try to publish a small number of articles illegally so that he could get caught on purpose and try to test the issues in court and change people's minds. He tried to take everyone's publications–without their consent–and make them all public so that JSTOR was public. You may like what he did, and you may like civil disobedience, but what he did is not civil disobedience. He wasn't trying to start a debate, he was trying to end one.

Seth Roberts (2011-07-29 17:12:18)

"What he did is not civil disobedience." Okay. I am not concerned about whether his actions fit your definition. "Harm to authors". None – they want their work publicized. "Harm to journals" – Unlikely. They too want wide distribution. "He wasn't trying to start a debate, he was trying to end one." Huh? I don't understand how you know what he was trying to do. Of course he could have done a dozen other things. That could be said about anything anyone does to achieve any goal. My point is that what he did and what Rosa Parks did have similarities, which are important. Rosa Parks believed that Negroes should be able to sit where they want on a bus. To help create such a world, she deliberately broke a rule restricting where they can sit. Swartz believed that the journal articles he downloaded should be more widely available. To help create such a world, he deliberately broke a rule restricting access. It's perfectly reasonable that if you want to create a better world, you take steps in that direction, even if some of the steps break rules. Even if what you do differs from what someone else did. Even if what you do isn't exactly "civil disobedience." Tom, your questions about harm to journals and authors, which you call the "key harm", emphasize how little harm Swartz did. The harm to journals and authors is vague or non-existent. Whereas the benefit to the rest of us – had he made the downloaded papers widely available – is obvious.

q (2011-07-23 12:21:20)

> Because of refined screening techniques, autism can be diagnosed at younger and younger ages, getting closer and closer to the birth of the child, indicating that whatever is triggering autism must be affecting the child while still in the womb. what in the devil is he talking about? autism isn't generally diagnosed until people are several YEARS of age. and "advanced screening" is – what exactly? that invalidates his entire argument, as far as i can tell. which is not to say that he is wrong, necessarily, but that he has NO IDEA what he is talking about.

Sean Estey (2011-07-23 12:24:17)

The intervention bias is interesting to me, because unlike other cognitive biases like confirmation bias, it seems to be deliberate and strategically rather than an unconscious, systematic error in thinking. I think many decision makers are smart enough to know that often non-intervention is the best course of action, but micro-management pre-emptively deflects the "you didn't do anything to prevent this!" criticism. Nixon knew well the consequences of price controls in the 70's, yet he invoked them anyway for fear of being accused of not "doing anything" to fix the economy. For this reason I don't blame the decision makers for erring on the side of over-managing. They are simply reacting to the ignorance of the general population, who in my opinion are the people who truly lie at the root of the problem.

dearieme (2011-07-24 03:53:00)

Steven Pinker ... "Marc is a scientist of enormous creativity...": sure is.

Seth Roberts (2011-07-24 04:23:45)

"that invalidates his entire argument". No, I would say he hasn't been clear about what "refined screening techniques" are. They are tests that predict the outcome when a child is tested for autism later in life.

Seth Roberts (2011-07-24 04:25:27)

"They are reacting to the ignorance of the general population." I would say they are taking advantage of the ignorance of the general population. Doctors are paid for intervention; they are paid much less for doing nothing.

Justin (2011-07-24 16:48:42)

Why don't you have a Fitbit, Seth? Mine just became 3x more valuable to me now that I can download the raw data.

Seth Roberts (2011-07-24 18:38:23)

I might get a FitBit, but I am less interested in measuring inputs (e.g., amount walked) than outputs (e.g., sleep). It's the outputs I want to control but don't know how to. Whereas I know how to control the amount I walk. I know roughly how much I've walked without a FitBit.

### **Amy Winehouse, R.I.P. (2011-07-23 11:50)**

Amy Winehouse, my favorite singer, [1]is dead. I'm very sad. She [2]made half my music collection unlistenable because she set such a high standard. I wish you a good journey, Amy.

Melinda (2011-07-23 21:34:04)

I listened to a few of her songs and was very impressed but as time went by I turned away from the train wreck in the making that was her life and didn't follow her. I too am very sad to learn she has died. It reminds me of Janis Joplin. How sad.

### **Flaxseed Oil Cures Bleeding Gums in Three Days (2011-07-24 05:00)**

I am pleased by [1]these results:

After a possibly overzealous dentist told me I need a gum graft [which [2]may cost \$3000], my husband encouraged me to start taking flaxseed oil. A few people online have [3]reported that flaxseed oil dramatically improved their gum health, and we figured it was worth a shot.

My initial dose of flaxseed oil was two tablespoons a day, and my gums stopped bleeding and hurting within three days. This is pretty huge for me, because my gums have been bleeding since I was in junior high. [Emphasis added.] At the same time, I added using a Sonicare toothbrush and flossing a little more vigorously. Considering that I had tried these things in the past without the flaxseed oil and they only made me bleed more, I feel like the flaxseed oil is the difference maker.

I have subsequently reduced my flaxseed oil dose to one tablespoon, which I feel is more appropriate for a woman my size. I haven't gained any weight from the flaxseed oil, which was a bit of a surprise. Taking it in the morning seems to help curb my appetite by at least the 130 calories it consumes.

The online reports she mentions are from this blog. A recap: [4]Because of the Shangri-La Diet, one evening I took four or five flaxseed oil capsules. The next morning, I was surprised to notice that putting on my shoes standing up, which I'd done hundreds of times, was much easier than usual. This suggested that the flaxseed oil had improved

my balance. I started to carefully measure my balance and varied my flaxseed oil intake. My measurements showed that variations in amount of flaxseed oil really did affect my balance. They also suggested the best dose. My balance improved up to a dose of 3 tablespoons/day of flaxseed oil. So the best dose was about 3 tablespoons per day. [5]I blogged about this.

[6]Tyler Cowen, inspired by my results, started taking 2 tablespoons/day. A month later, he no longer needed gum surgery. Knowing nothing about my flaxseed oil intake or Tyler Cowen's results, [7]my dentist told me my gums were in excellent shape, better than ever. [8]My sister's gums showed similar improvement. [9]Tucker Max noticed his gums stopped bleeding after he started taking flaxseed oil. He'd had bleeding gums most of his adult life. Nothing else had helped. He also found [10]training injuries healed faster. [11]When he stopped drinking flaxseed oil, his gums soon got worse. [12]Carl Willat noticed dramatic gum improvement. [13]Joyce Cohen had excellent results (her gums were "in great shape - better than ever"). [14]Tim Beneke and [15]Jack Rusher had similar results. [16]Gary Wolf, on the other hand, didn't like the mental effects. [17]A recent epidemiological study found a weak correlation between inflamed gums and omega-3 intake.

What have I learned? Above all, that such a pattern of results is possible. These results suggest there was/is a big hole in the usual nutritional ideas. Tyler Cowen, me, my sister, etc., were eating a conventionally "good diet" yet there was a lot of room for improvement, both in brain function and overall inflammation level. (I'm sure flaxseed oil heals gums because it reduces inflammation.) And improvement wasn't hard - there was a simple fix. In other words, omega-3 deficiency is very common. The conventional deficiency diseases, such as scurvy and pellagra, were/are rare. They appeared only under extreme conditions with very limited diets (e.g., prison, long sea voyage). Yet just as scurvy and pellagra are easily cured, there is a simple cure for omega-3 deficiency: about 2 tablespoons/day of flaxseed oil. (Perhaps ground flaxseed is an even better source.)

Other facts support the idea of widespread omega-3 deficiency. When gums are very red, and bleed very easily, it's called gingivitis. According to [18]this article, " estimates of the general prevalence of adult gingivitis vary from approximately 50 to 100 %". Heart disease is common. There's plenty of evidence that [19]heart disease is caused by inflammation (gated). For example, it's well-known that [20]inflamed gums correlate with heart disease. Statins may reduce heart disease - to the mild extent they do - [21]because they reduce inflammation.

I also learned that psychology can help improve general health (too much inflammation causes all sorts of problems, as Tucker Max's experience suggests). My background in experimental psychology made it easy for me to measure balance. I also found other mental tests were sensitive to flaxseed oil. These mental tests were like an animal model in the sense that they made helpful experiments (e.g., different doses) much easier. My friend Kenneth Carpenter, in [22]his book about the discovery of Vitamin C (gated), stressed the importance of an animal model of scurvy. Once the best dose of flaxseed oil (for me) was known, it turned out to be easy to take a dose that produced dramatic improvement (in others).

The idea that psychology and self-experimentation can improve overall health is new. I presented my flaxseed oil results at a meeting of the Psychonomic Society a few years ago. After my talk, one member of the audience, a professor of psychology at Illinois State University, angrily complained that my talk was "pop culture" - not even pop psychology - and said I shouldn't have been allowed to speak. He thought I had made elementary mistakes.

[23]Flaxseed oil better than fish oil. [24]Bad results of flaxseed oil.

---

Allen K. (2011-07-24 09:49:00)

I think you've mentioned before, but I can't locate it now – where do you recommend buying flaxseed oil in Berkeley? (Where I am presently.) And was there a kind to get vs. a kind to avoid?

Flaxseed Oil? | Mark's Daily Apple Health and Fitness Forum page (2011-07-24 11:10:36)  
[...] [...]

Seth Roberts (2011-07-24 12:45:28)

I have tried Spectrum, Barleans, and the Whole Food house brand flaxseed oil and noticed no differences between them. I have bought them at Andronico's and Whole Foods.

SM (2011-07-24 13:35:24)

Seth, The overall effect seems substantiated, but the mechanism, not so much. How do you know it's the omega 3? And wouldn't it be pretty easy to test this – just substitute the flaxseed oil for fish oil and see if the effect remains? If anything, the effect should be stronger, since omega 3 from animal sources is shown to be much better assimilated by humans. Also, if it is in fact omega 3 (a big if), I think a much better prescription is to cut down on omega 6 rather than load up on omega 3. Omega 3s are anti-inflammatory only because most people's diets are way too overloaded with omega 6s as a result of our modern industrial diet/food system. Omega 3s just balance out Omega 6s (they work antagonistically), they aren't really anti-inflammatory in and of themselves. Always better to eat a good diet rather than supplement to make up for a deficiency, in my opinion.

SM (2011-07-24 13:40:25)

BTW, just noticed the flax oil vs. fish oil link at the bottom of the post. So I guess that's one data point negating the omega 3 mechanism.

Mike (2011-07-24 15:29:12)

As always, interesting stuff, Seth. What are your thoughts on the low human conversion of ALA to EPA and DHA, and, based on that, fish oil supplementation over flax? Or is there a constituent of flax beyond EPA & DHA that is reducing inflammation?

Seth Roberts (2011-07-24 18:34:28)

Mike, I think that the experiments that have measured conversion rate have not realized there is a large effect of experience: the more you eat a food, the better you get at digesting it. They probably gave ALA to people unfamiliar with it.

Seth Roberts (2011-07-24 18:42:32)

SM, I believe that omega-3 is responsible for several reasons, above all that others have gotten similar results with fish oil. "Better to eat a good diet": It is much easier to vary the dose by varying amount of flaxseed oil. Varying the amount of omega-6 by varying the amount of "good diet" would be hard. Simply reducing the amount of omega-6 will not necessarily increase the amount of omega-3 in the brain. It may be much easier to increase the amount of omega-3 in the brain by increasing the amount in the diet.

Julia (2011-07-25 06:22:45)

Very interesting! My gum health has improved since I've been adding 2 tablespoons of ground flaxseed to my yogurt in the morning. Not to mention my hair and nails are doing exceptionally well.

Seth Roberts (2011-07-25 07:26:43)

Julia, that's very interesting. Could you say more about the improvement in your gums, hair, and nails? When did you start adding 2 tablespoons of ground flaxseed to your yogurt? What caused you to make this change?

Fred Stange DDS (2011-07-29 05:02:13)

I have also seen the benefits of Omega 3 oils in my patient's diet. In 3 different instances I have asked what the difference in their hygiene routine was...nothing, just adding the Omega 3. Of course this will not take the place of brushing and flossing as you see here...our writer began brushing and flossing better as well. The Omega3 reduces the inflammation in the body and thus the gum tissue improves as well. Bleeding gum is the body response to "infectious" bacteria remove the bacteria and the body response will return to less bleeding. Brushing Flossing and Omega3 things will look much better. Your gum graft may be a separate issue as the Omega3 oils will not change bone levels below the gum tissue however this is a separate issue and sounds like you are on a good track!

Daz (2011-07-29 16:04:04)

my last comment did not appear. so this is a test comment. thanks for the post Seth.

Daz (2011-07-29 16:06:13)

Thanks for some very informative articles on Flax. Your post 'flaxseed-oil-vs-fish-oil' was a great brief snapshot for me. Paul Jaminet pointed me over here, after I asked a question on ALA (from Flax oil). Reading your posts has reinforced my recent decision to start back on the flax oil after I quit back in Jan this year (2011). From memory I quit to reduce my Poly intake & after reading some negative comments over at raypeat.com on linseed (flaxseed). Have you tried Chia Oil, its EFA breakdown is very similar to Flax Oil, do you think it would work the same as Flax oil?

Seth Roberts (2011-07-29 17:14:08)

Comments must be approved before they appear.

Seth Roberts (2011-07-29 17:15:19)

I haven't tried Chia Oil. I will look into it. Yeah, if its EFA profile is similar it should have similar effects.

Tana (2011-11-01 07:21:36)

I started taking 2 TB of flax oil daily about four days ago and now my gums are barely bleeding at all after I brush and floss. My gums were red, swollen and would bleed after I brushed and flossed and are now pink and healthy looking. I've had this problem for years and I could not understand why it would keep happening even though I was consistent with my dental routine. I take the berry flavored Barlean's flax oil mainly because it tastes good and so I look forward to taking it- if it was gross I would not be consistent with taking it. Anyhow, thanks for the information! I wish dentists would look into this but they probably won't so I'm glad that you do.

Parviz Edalat (2012-01-13 08:09:38)

That's very attractive. Can you say more concerning the development in your gums, hair, and nails? When did you start adding up 2 tablespoons of land flax-seed to your yogurt? What caused you to create this change?

### **Yogurt and Nuts Correlate With Weight Loss: Why? (2011-07-25 05:00)**

[1]A new longitudinal study finds:

Despite conventional advice to eat less fat, weight loss was greatest among people who ate more yogurt and nuts, including peanut butter, over each four-year period. . . .

That yogurt, among all foods, was most strongly linked to weight loss was the study's most surprising dietary finding, the researchers said. Participants who ate more yogurt [than the average for all participants?] lost an average of 0.82 pound every four years.

Why might this be?

Yogurt and peanut butter are both unusual foods. Yogurt is strange because unflavored yogurt has little or no smell. It tastes good for other reasons: strong sourness, creaminess, and coolness. People are also pushed to eat it not only by how pleasant it is to eat but by the thought that it is good for them. Most foods, in the form that we eat them, have a smell. I explain the yogurt results by saying that yogurt consumption replaced consumption of foods with stronger smells.

Peanut butter is unusual because when I was visiting publishers to sell The Shangri-La Diet, I met a woman who told me she had lost weight simply by eating peanut butter – that is, by adding peanut butter to the rest of her diet, making no other changes. I think she ate about 3 tablespoons per day. This predisposed her to think there might be something to my ideas. No one has ever told me such a story about another food. If peanut butter has a smell, it's really weak. It's pleasant to eat because of fat content and texture. When I was a boy, my mom made me peanut butter sandwiches (no jam) for school lunch. I never came to like them. This implies I never learned a smell-calorie association. The bread must have supplied a strong fast calorie signal so this implies that the peanut butter generated little or no smell signal.

Thanks to Eri Gentry.

---

Glen Raphael (2011-07-25 07:09:52)

If you google "peanut butter diet" you find a lot of recipes that involve adding peanut butter to familiar foods. Mix peanut butter into your oatmeal or your maple syrup or what-have-you. That seems like a form of "crazy spicing" to make your familiar foods taste a little strange. If the peanut taste is dominant it could also make your overall diet seem more bland. I may have to try it and report back.

David (2011-07-25 09:37:34)

I've also noticed an SDL-effect with scrambled eggs and toast or tortilla. No strong smell -> weight loss.

Elisa (2011-07-25 09:56:55)

Eh? Peanut butter is one of the most recognizable smells. It's a strong smell. I think it's the fat. Eating a spoonful of peanut butter is similar to drinking a tablespoon of oil (but much tastier).

Weston (2011-07-25 11:18:18)

I've got to agree with Elisa. I would not categorize peanut butter's smell as "really weak"

Kirk (2011-07-25 13:05:46)

But without the data, it's all speculation. I can just as easily explain the yogurt results as a replacement of 'bad' gut bacteria with 'good' bacteria, which leads to signals by the 'good' bacteria to the brain to ingest more nutritional food and less junk food. Or another explanation: people who eat yogurt generally eat more nutritious food in general than those who don't. Also, most yogurt on the store shelves is flavored and sweetened. That's why I would want to see the data, in detail. The study was supported by grants from the NIH; as a taxpayer, I want that data made available for analysis by others (presuming, of course, that the identity of the participants can be obscured.)

Justus (2011-07-25 13:54:10)

Isn't the real news that 0.82 pounds over four years is pathetic? Would you change your diet if you were told it would help you lose a quarter of a pound a year?

Seth Roberts (2011-07-25 15:28:17)

Kirk, in my experience speculation based on data is where good ideas begin. Where experiments begin. For example, this result might be followed up by an experiment where people deliberately eat yogurt. That would help establish cause and effect. If yogurt really did cause weight loss I would predict that flavored yogurt would cause less weight loss than unflavored yogurt. If that were true it would support my explanation (lack of smell) over yours (replacement of bad gut bacteria) because my explanation would have made a correct prediction. If both flavored and unflavored yogurt produced the same weight loss that would support your explanation over mine.

David (2011-07-26 00:05:11)

Justus: If I were gaining weight and someone said eating some yogurt and nuts (not such a bad thing) would make me stop gaining weight and start losing modest amounts, I'd be interesting. So we'd have to know how the non-yogurt and nut eaters did. Anyway, you can do much better than .82/4 years with SLD techniques.

Kirk (2011-07-26 12:05:35)

That would be an interesting experiment; a group eats plain yogurt, another group eats flavored yogurt. If they ate the yogurt only during an SLD-like eating window, then I agree the plain yogurt folks would probably lose more weight. I don't think SLD would apply if they ate the plain yogurt with other foods. The thing is that this longitudinal theory suggests three theories to

me, and I sympathize with all three theories. The first theory is SLD. I agree that SLD techniques work. Used them myself. As for the impact of SLD on this study, I suspect little impact, unless the data shows that people took extra effort to eat certain foods during an SLD-like eating window. The second theory could be labeled the Paleo eating theory. If I had to make bets on this particular longitudinal study before seeing the detail, this is the theory I would choose as to what influenced the weight loss. I suspect that the people who lost weight shopped the edges of the grocery store . . . they ate fresh fruit, fresh vegetables, meat, fish, eggs, cooked their own food, avoided industrial seed oils and processed foods, ate fewer neolithic grains, and so on; the way of eating as articulated by Robb, Mark, Chris, Kurt, and Paul and Shou-Ching. The final theory, and it's a long shot, is the influence of good bacteria. I'd be tempted to place a 'long bet' on bacteria therapy as an eventual cure for obesity. As for yogurt, the shelves are crowded with flavored yogurt, and my guess is that most people who buy plain yogurt take it home to eat it with their own favorite flavoring . . . cinnamon sugar, honey, maple syrup, or their favorite granola. To me, peanut butter has a strong smell. That would be an interesting experiment for you and your friends . . . a blind smell test, and include peanut butter amongst the candidate foods. Perhaps peanut butter is a bland smell to you. I just ran a (visible) test and found that I could identify the smell of peanut butter when my nose was positioned 4 inches above a open jar.

### **Finding The Source of Migraines (2011-07-25 15:51)**

Please read [1]my story at Boing Boing about how a woman figured out what caused her migraines. I am always interested in cases where people figure out for themselves how to be healthy. If you have a story like that please contact me.

It has generated a lot of comments. Mark Frauenfelder, who posted it, told me he knew it would generate a lot of comments and one of the first would be "anecdotes are not data". He was right. [2]Preventive stupidity in action. It tells you something that scientists teach that "anecdotes are not data", when all major scientific truths, as far as I know, began with a single observation. For example, the discovery of electricity began with a single observation that a dead frog's leg twitched when touched with a scalpel. Why is something so at odds with reality taught and repeated by scientists, whose job is paying attention to reality? My explanation is human nature: How much we enjoy feeling superior.

1. <http://boingboing.net/2011/07/25/finding-the-source-of-migraines-and-fifty-useless-migraine-drugs.html>

2. <http://blog.sethroberts.net/2010/05/12/preventive-stupidity-exists/>

---

some anonymous guy (2011-07-25 18:11:04)

The dismissive comments to your post are infuriating me. It's as if everyone has forgotten, or been brainwashed to forget what science actually is. All they can see now is "science industrial complex" not the actual genuine process. It's so strange to me that the whole system has managed to sort of stamp out the type of independent inventor and discoverer activity that is responsible for the largest advances in medicine – the kinds that existed way before the whole complex was even around. Not only that, but you must have the politically appropriate scientific beliefs (as defined by the complex) at all times otherwise people try to threaten and reject what you say as "not science". Newton spent a large amount of time dabbling in alchemy and trying to decode the bible for hidden messages... but you know, he did some other interesting things too.

Seth Roberts (2011-07-25 19:47:53)

Thanks. I am not yet sure what to learn from all the dismissive comments but I agree there is something importantly bad about them.

JeffR (2011-07-25 20:10:15)

I think "anecdotes are not data" should be thought of as meaning more evidence should be pursued, not that the particular example given is wrong. Sometimes people "discover" a cure for their disease or a way to be healthier and they are in fact mistaken. I'm sure you understand there are lots and lots of people on the internet with wrong ideas about health due to something they think happened to them (an anecdote). In those cases, pursuing more data will reveal the mistaken association. Whereas in this case, pursuing more data could validate what she learned about migraines. Or not, which is of course the key part. How do we ever learn truths about health unless we are willing to go past the single data points.

JeffR (2011-07-25 21:51:29)

And later that very night, I found an example for Seth of someone finding a health solution by personal observation. Caffeine and dementia. <http://www.tinyrevolution.com/mt/archives/003542.html>

Tom (2011-07-25 22:05:16)

*Thanks. I am not yet sure what to learn from all the dismissive comments but I agree there is something importantly bad about them.* You know what I think it is? There is this mindless herd rage, bordering on lethality, at people who *don't know their place*. It's the same impulse that led to hundreds of thousands of people making the most vicious statements about Rebecca Black, the middle-schooler who dared make a music video. People pretended they were enraged by the song, but they were actually enraged because she dared to act like a rock star without having been anointed by the music establishment. The comments on the migraine article are the same phenomenon. They're at a higher reading comprehension level, but its still all about class, and the primitive urge to destroy those who don't cower accordingly.

Seth Roberts (2011-07-25 22:26:56)

In the migraine example, I don't see how Sarah could be "mistaken" about what caused her migraines. She did hundreds of tests.

Michal (2011-07-26 09:42:55)

This article highlights one of the biggest problems with medicine. The girl tried 50 different drugs and they didn't work. The messed up part is that this is a best case scenario. She was forced to figure out the cause of her migraines. If there was a drug that worked it wouldn't have been like an antibiotic. You don't take an antimigraine drug for 2 weeks and then are cured for life. You have to keep taking it and dealing with side effects for the rest of your life. Modern medicine is great at treating symptoms but tends to be poor at finding and treating causes.

Susan (2011-07-26 09:52:52)

After over 20 years of migraines, and after much searching, I finally discovered the reason: aspartame. I never used the sweetener packets, but found aspartame interspersed among the items in my pantry and refrigerator. It's been almost two years now since I've had a migraine. What a relief!

James Lockwood (2011-07-26 18:09:13)

One story of a self-cure would be Jasper Lawrence's. He went to Africa, infected himself with hookworms, cured his asthma, and started a company selling them. <http://www.asthmahookworm.com/> <http://autoimmunetherapies.com/> Another individual who found a self-cure would be that of Gary Rea, who went on the Paleo Diet for a year with amazing results. He is no longer a type II diabetic, his blood pressure has gone from 180/90 to 115/72, he went from 233 lbs. to 160 lbs. and, at 56 years old, his body looks like it did when he was in his 30's. <http://paleoeater.blogspot.com/> <http://www.thepaleodiet.com/>

heffiji (2011-07-27 16:08:48)

As someone who was raised and trained as a scientist and worked for years in medical research, you are spot on. Though there is more to it than just ego, there are also particular issues in science surrounded by a deep cultural well of buttheadedness around a truth being suppressed for some reason. I think of them as f-nords, though it's a bit removed from the original definition. "Things one is not supposed to question or think about", science has them too. Some of it is obviously profit-based upon closer inspection, some of it is weirder, like the "central dogma" of molecular biology, so named by Francis Crick because he was trying to point out that it has absolutely no basis in evidence or sense and was in fact a moronic thing to assume. The named assumption is that information only passes from the DNA to the RNA and there is no means other than completely random mutation combined with successful reproduction to change the DNA. Which of course has been disproven in many ways by now. That one comes in part out of the politicization of science by the communist/capitalist thing, each side tried to warp their science to support their ideology, I heard the story first from a microbiology prof. But my point was, actually thought in science is cluttered up by all sorts of variously motivated PR campaigns against various ideas, old and new, buttheadedness plays into it but there is more going on than that. You are spot-on about the difference between real science and what currently goes on in medicine. My doctor can not look at my problem like a scientist even if he wants to. I can tell him what happens to me and how to test it, and he can probably think of tests I wouldn't even know about, but he/she has to work from a script and within the limits imposed by a whole flock of bureaucracies, none of whom have anything to gain by actually helping me. In the end even if he believes me and wants to help, he won't do the tests that could prove the question because there is no way to bill for it, full stop no appeal. And yes, looking at the anecdotal and even utterly mundane is exactly where a lot of breakthrough science comes from, and from looking at the places where the current assumptions seem to not actually hold true. The problem lies in how it gets chosen what gets researched, and in the way the industry has warped to game the patent laws. Nothing easier than not funding research and using 'lack of evidence for efficacy' as a dismissal. On the subject of medical miracles: the news is full of them, I know, legitimately miraculous and wonderful things. Science fiction become reality, lives saved and greatly improved. But when I go to the doctor with crippling pain, they genuinely have no way to tell the difference between me and some plausible con looking for opiates for a good time, because the state of the art method for determining my level of pain is to ask me how bad, on a scale of one to ten, I think it is. They don't even ask me what personal experiences might have formed my scale, that does vary widely, seems like they should care. The world is full of hustlers who are far more plausible telling a complete fabrication than I am being dead honest, medicine really needs a reality check or three, there is really no excuse. Seriously. They are not really that utterly and completely helpless that they can not come up with one single solitary objective test if they actually tried even a little bit. They have monkeys moving computer cursors with their minds, and do some damn fancy research when trying to improve their ability to sell me things, and they can't do a single chemical or imaging test to find some evidence of genuine pain meaning something is wrong and a closer inspection is in fact warranted? That should not be passing anyone's bullshit detector. Look at your medical care as if it were some other service, are they actually even trying to fix what you really want and need fixed? If I don't sound like a crank yet I will the instant I say "government-backed monopoly", but that is exactly what we have and exactly what the problem is. I don't have a grand plan to fix it, I just have seen some of the ways it is broken. :-)

Seth Roberts (2011-07-28 09:15:37)

You put it well. Especially: 1. "None of whom have anything to gain by actually helping me." 2. "Nothing easier than not funding research and using 'lack of evidence for efficacy' as a dismissal."

## **Billionaire, Genius, and This? (2011-07-25 21:04)**

Nathan Myhrvold is presumably a billionaire. He is regularly called a genius. Yet he is in charge of a business (Intellectual Ventures) that one person, in [1]a great This American Life podcast, compared to the Mafia.

1. <http://www.podtrac.com/pts/redirect.mp3/podcast.thisamericanlife.org/podcast/441.mp3>

---

wcw (2011-07-25 21:18:43)

The only surprise here is that you are surprised.

Seth Roberts (2011-07-25 22:24:49)

wcw, why should I have not been surprised?

Nathan Myers (2011-07-26 01:13:38)

I can answer that. This person learned business at Microsoft, where the most appealing business model in any market was always extortion. He found a business that was inherently extortionate, yet inherently proof against anti-trust law, and is exploiting it with great energy. Were you going to suggest that genius implies ethical behavior? Maybe you should see the movie "Mars Attacks". Or, that everybody's definition of genius is the same? Many people admire "genius" Bill Gates, apparently just because he got lots of money through largely extortionate means. Did Myhrvold ever do anything that benefited society or the species, or is he just clever with applied math problems? There's nothing more wrong with cleverness than with a capacity for hard work. Either way, what matters is what you do with it. Edward Teller had a (probably much better deserved) reputation for genius, yet spent most of his life arranging for a large fraction of his adopted country's wealth to be consumed in constructing and operating weapons of mass destruction.

Darrin Thompson (2011-07-26 07:13:12)

The US patent system is an economic disaster. Patent trolls are this disaster's looters. Their only redeeming purpose in life is that they call attention to the problem that is modern patents. If Nathan Myhrvold is a genius then so is Jeffrey Skilling. IMHO.

Seth Roberts (2011-07-27 09:59:47)

My reasoning is billionaire x genius = better business opportunities than patent troll

Dr W (2011-08-21 09:01:18)

Nathan Myers, funny thing you should mention Teller, Myhrvold's best friend is apparently Lowell Wood, the man who was chief scientist for the US "Star Wars" program and actually did much of the technical work for Edward Teller back in the day!  
<http://www.atmos.washington.edu/bitz/111/readings/drevil.pdf>

## **Phone Hacking and Jane Jacobs (Roberts/Jacobs emails: Part 1 of 3) (2011-07-26 05:00)**

After I wrote about [1]the relation between Jane Jacobs's ideas and the British phone-hacking scandal, I heard from Jim Jacobs, one of her sons. He wrote:

Mary Rowe forwarded your post about News of the World and Systems of Survival. It's an interesting observation. Here's my take on it:

The moral principle we all value most in our news media is 'Be honest'. Even the slightest deviation is viewed with alarm. Among other types of dishonesty, when newspapers get too close to government or filter their presentations through ideology they become worthless, often destructive. This requirement for honesty pervades the work of searching out the news too, just as it does for scientists searching for an understanding of something. (We expect reporters to respect 'off-the-record' confidentialities, for

example.) Together with honesty, the entire commercial moral syndrome fits a newspaper, whatever its size. I won't repeat the list here, but just look at it and see if you don't think every one of the commercial moral principles are considered admirable in a newspaper, right down to 'Be optimistic' - newspapers are frequently criticized for too much doom-and-gloom. Note that there is no moral principle of 'Sell more newspapers': commercial morals don't always lead to financial success. In fact, what Jane dubs 'Monstrous Hybrids' are often the roads to quick, immoral, riches. Media empires frequently drift toward guardian morals, immoral for them, and Murdoch's is no exception. Therein lies their destructiveness, and eventual demise.

I hope this helps.

I replied:

It's great to have your take on this. Here's what I think about the points you raise.

For newspapers the overwhelming value isn't "be honest" but "be accurate". Honesty is saying what you think; accuracy is being accurate in what you say. It's easy to be honest and inaccurate.

I believe that powerful newspapers consider themselves a fourth branch of government, and rightly so. Publication of the Pentagon Papers, for example, had nothing to do with selling more papers; it was all about fulfilling their responsibilities - which included loyalty to readers.

"Shun trading" is a part of newspaper practice in the sense that paying for interviews is thought to be bad. "Respect contracts" is not supposed to apply to them - it is bad for a magazine to strike a deal with a celebrity in order to get their cooperation.

"Be optimistic". Sure, some readers want newspapers to be different, including more optimistic. They want more entertainment listings, for example. They want more stories about celebrities (and Murdoch gave them this). But the people who run powerful papers don't agree. Editorials are usually preachy: this is bad, that is bad. That's not entertaining at all - which is why Us magazine has no editorials - but whoever writes them thinks it is their job to make the world a better place by telling others what to do. When one of Murdoch's lieutenants took over the Wall Street Journal, he said something about other papers being too concerned with their status in the eyes of other journalists (an example of "treasure honor") than selling newspapers. Whereas to NY Times journalists, Murdoch's papers "pandered".

"Respect contracts". I agree with you there.

"Come to voluntary agreements." Newspapers are supposed to be nonviolent, yes. But when they have something important to say - e.g., some dirt to reveal - they are supposed to ignore legal threats. For example, the CBC is now being sued by a nutrition researcher because they aired a negative program about him.

"Deceive for the sake of the task." Journalists do this all the time. For example, a restaurant reviewer will wear a disguise.

"Treasure honor". There is now talk of a Hippocratic oath for journalists.

"Dissent for the sake of the task." I don't see that. I see newspapers with a party line. For example someone was fired from NPR recently for expressing views his bosses didn't agree with.

"Be open to inventiveness and novelty." I don't see this. Perhaps newspapers are no more stagnant than other powerful companies however.

Because newspapers are actually businesses, they do value certain commercial values. But they see themselves as quite different from other businesses. Few people in other businesses are so concerned with "truth" and "the public interest".

I will post Jim's reply tomorrow.

1. <http://blog.sethroberts.net/2011/07/13/phone-hacking-and-jane-jacobs/>

---

Jake (2011-07-26 07:40:31)

Happily for accuracy and honesty in the world, the audience for mainstream media is shrinking every day. In fact they are irrelevant in today's world. Accuracy and honesty takes a leap forward whenever a journalist loses his job. And there is plenty to cheer about with ever increasing layoffs in the media.

### **Phone Hacking and Jane Jacobs (Roberts/Jacobs emails: Part 2 of 3) (2011-07-27 05:00)**

<http://blog.sethroberts.net/2011/07/26/phone-hacking-and-jane-jacobs-robertsj>

acobs-emails-part-1-of-3/ of [1]Jane Jacobs's Systems of Survival and the British phone-hacking scandal continued. Jim wrote:

It's of course important to look at what morals a newspaper is admired for, not what it does, nor what makes it successful. Jane was often frustrated at how people found it difficult to sort out which moral syndrome they belonged in, most often imagining they were 'guardians' when they weren't. She thought in part it was the name 'guardian' that led people astray.

In the sense Jane uses it, 'Be honest' here means do your best to report the truth, or report what you think, but not to pretend one is the other. We don't admire Fox for saying what they think mixed with what they observe, and newspaper editorials are admirable when kept separate from the news.

Opinionated tracts and advertising copy can be fine and honest representations of someone's opinion, but they aren't newspapers. Accuracy as an admirable trait is, like bravery, universal, and thus not useful in distinguishing one moral syndrome from another.

This is going to be long-winded, I'm afraid.

Look at the Commercial list:

Shun force - violence inflicted on reporters is never admired, nor is 'embedding' them in army forces.

Come to voluntary agreements - Armies and government are allowed great latitude in the means they use to get information. Reporters are expected to work with information voluntarily given, and payment to a source for an exclusive interview is considered part of legitimate competition. Hacking phones is not a voluntary agreement. It's considered admirable when used by government to catch criminals, but not when done by a newspaper. Wikileaks is admired for bravely putting out information voluntarily provided to it; the soldier who provided it is rightly despised by the Army (operating under guardian morals).

Be honest - A reporter who augments his story with stuff that might have been true, or chances things like names without telling the reader is considered reprehensible. (But it's fine for a novelist, even an historical novelist.) So are dishonest business dealings of the organization. This is pretty much the same situation for scientists (always governed by the commercial syndrome, as we both know, and used as a drawn-out example in *Systems of Survival*). As Jane points out, scientists need to be honest in their means as well as their ends - no pirated software. Newspapers do dishonest things all the time, but they aren't considered admirable.

Collaborate easily with strangers and aliens - reporters are admired for getting a story from someone they don't know, often in a foreign land and language. A recent Toronto reporter was greatly admired for getting in-depth interviews from Taliban fighters and reporting what was said.

Compete - We admire a reporter who gets the scoop. We don't admire anti-competitive collusion by media empires.

Respect contracts - Confidentiality agreements with sources are contracts as are 'off-the-record' agreements. Newspapers are admired for respecting both, even when this restricts the information that can be provided. Judith Miller was admired for going to jail to 'protect her source's identity' and then despised (and fired from the NY Times) when it turned out she was actually working with Bush to slant the news to support their shared ideology.

Use initiative and enterprise - Any clever way to get a story is admired, as long as it's honest.

Be open to inventiveness and novelty - Newspapers are admired for putting their content online, even if they still haven't figured out how to make any money there. Newspapers are admired for endlessly tinkering with their format, even if they get it wrong trying. Newspapers were admired for being pioneers in new printing technology.

Be efficient - There are many kinds of efficiency, but efficient writing is something newspaper reporters have always been especially admired for, even when it makes for less-fun reading. But honesty and voluntary agreement trump efficiency, always, in commercial morals. Hacking phones may be efficient means, but not admired.

Promote comfort and convenience - A newspaper is admired as a bulwark of everyday civilization and a bastion of consumerism.

Dissent for the sake of the task - News reports that bravely dissent from the government line or from advertisers' vested interests are admired. Crusading journalism is admired as long as it's truthful.

(A reporter too close to his story is considered suspect.) Governments that shut down dissident papers are not admired.

Invest for productive purposes - Newspapers are admired for using their resources in getting their job done. Conrad Black was criticized for using his papers' resources to support his political causes and lavish lifestyle. Likewise Murdoch.

Be industrious - The steady work of putting out a paper every day is admired. A daily paper that can put out a brilliant edition once a week and can't get it together the other days is criticized, and soon slips to being a weekly. Although a paper may happily report flamboyant leisure it shouldn't indulge in it itself.

Be thrifty - No media was ever admired for wasting money, or time. Getting a story may involve expensive travel for example - that's productive investment - but it shouldn't be wasteful or show-off.

Be optimistic - Although much of the news that's important is bad ("No news is good news.") news media are praised for an optimistic outlook, even when pessimism might be more realistic.

Now, go through the guardian list (a little more quickly, I hope):

Shun trading - Media are admired for trading information with each other. Buying and selling information is despised when done by spies (guardian morals) but not when done by the newspapers.

Exert prowess, Show fortitude - Media powerhouses are not admired for using their strength to suppress small independents (as Amazon is now trying) or to control government policy. Media execs who go into public service (Bloomberg) are expected to keep hands-off and are criticized for using their power (and even their money) to support their careers. All these things are commonly done, but they aren't considered admirable.

Be obedient and disciplined & Respect hierarchy & Be loyal - This is what's needed in a government-controlled propaganda paper - always despised. When there's no conflict between loyalty and honesty there's no problem; but when they're in conflict which way should a newspaper go? Honesty is the moral imperative for a newspaper - loyalty is more important to the army it may be writing about. A paper that thinks it's an arm of government is in moral trouble.

Take vengeance - Media competition is considered good and moral - vendettas are not.

Deceive for the sake of the task - A reporter is expected to identify himself before asking questions. When they don't they're criticized. Deceptions (and force) used by paparazzi to get a photo are not admired. Reporters are not admired for tricking each other in competitive zeal. Media companies and their execs are never admired for deceptive business practice (Conrad Black is now in jail). Small innocent deceptions of the reader to give him a better story are considered inappropriate. All of these things are done, of course, and often to good effect - they just aren't good media morals.

Make rich use of leisure, Be ostentatious, Dispense largesse - These are characteristics of media empires, like Murdoch's, and are considered immoral and inappropriate, even when they appear to be harmless. Charity, on the other hand, is one of the universally 'good' morals, for everyone, but often confused with largesse. Papers that promote charities are admired for it.

Be exclusive - In Jane's context, exclusive means avoiding outsiders. The diametrical opposite of

Collaborate easily with strangers and aliens. It won't help a media empire to behave like that, and even the Murdochs' excessive aloofness is criticized as poor form.

Be fatalistic - A newspaper that thinks there's no hope for change, even if there isn't, has given up. Why would you go to all the trouble to find and write the news if you didn't hope it could do some good. Copy that's purely for entertainment value (News of the World?) is considered lightweight, frivolous, dumb. To say it's just to sell newspapers, or just to sell advertising, is cynicism obscuring the point.

Treasure honor - When a newspaper makes a mistake should it protect its honor by hiding the error? It was a huge embarrassment to the NY Times when the NY Review reported that the Times' lead reporter, Miller, had been slanting the news in favor of the invasion of Iraq. The Times was admired for coming clean, its honor badly tarnished.

Seth, all the bad stuff the Murdoch press has done, and been roundly criticized for, and many other deficits - are the result of moral slippages, largely into guardian territory. That some of these help sell papers is beside the point. Lots of immoral things are profitable, although always corrosive. There is no smooth transition from one moral syndrome to the other as an entity grows larger. And mixing syndromes is the moral disaster Jane is most vociferous about, largely because of its insidiousness. As you say, Systems of Survival is helpful in understanding this stuff, but it isn't easy. Jane sometimes regretted having left out too much helpful stuff in the interest of keeping the book short and readable.

Tomorrow I will post our concluding emails.

### **Phone Hacking and Jane Jacobs (Roberts/Jacobs emails: 3 of 3) (2011-07-28 05:00)**

After I posted on [1]the relation between Jane Jacobs's ideas and the British phone-hacking scandal, Jim Jacobs, one of her sons, wrote to me. The first back-and-forth emails in our discussion are [2]here and [3]here. Finally, I wrote:

Thanks for more explanation. You're quite right that exposure of the truth is at the heart of journalism and is utterly counter to what governments want. In this sense good journalism and governments are opposites - or rather opponents. In this sense, also, journalism is inherently populist whereas governments rarely are. Businesses are inherently populist.

On the other hand, journalism is not a standard commercial enterprise. This is why at many publications there is strict separation between advertising (devoted to raising money) and "editorial" (which spends it). They don't want what they print to be affected by commercial considerations. That is utterly different than a conventional business. Powerful newspapers, such as the NY Times, see themselves (rightly) as far more than mere commercial enterprises - which is one reason the NY Times has lost so much money lately. It is one reason the NY Times took so long to get a sports section and why they barely have a gossip

column. I have seen too many "undercover investigations" and "hidden camera" interviews to believe that journalists find anything wrong with deceiving for the sake of the task. They usually identify themselves, true, but so do police officers.

Exclusivity varies with organizational needs. Journalists do mix with everyone to get stories but that's because of what they do; it couldn't be otherwise. Some religions (which are far more guardian than commercial) make a big deal out of missionary work – again, the details of their enterprise demand it. Along the same lines, some businesses try to appear exclusive – the nature of their brand (luxury) demands it.

I agree that journalists trade information and favors with powerful sources. (But think it bad form to pay for interviews.) Whether this is different than governments forming alliances and signing treaties I don't know.

Because journalism is actually a business, there are necessarily some commercial values, such as avoiding waste, being efficient, and so on.

In contrast to trading and rulers, which have been around for many thousands of years, powerful newspapers and powerful journalists are no more than a few hundred years old, if that. So there has been less time to clarify values. But there's a reason they're called the "fourth estate" – two of the other estates being religion and government.

And you've heard the phrase "the pen is mightier than the sword" – implying that the pen and the sword are on the same playing field. I can't imagine anyone saying "the jacket is mightier than the sword" or "the carton of milk is mightier than the sword".

To which Jim replied:

As I mentioned before, Jane had real trouble finding good names for the two syndromes. You can see it in the part of Chapter 2 where she talks about names - first A & B, then heroic is rejected, etc. and finally she ended up with commercial & guardian. She later regretted the choice because these names can be quite misleading. Activities using the commercial syndrome don't need to make money or be 'commercial' - most good science, for example. Activities using the guardian syndrome don't need to be guarding anything - classical music, for example. Writing can be either, depending on its use. Advertising shares much with propaganda writing - deception, ostentation, fortitude, etc. No wonder advertising and journalism need to be kept apart! Too much charitable work will ruin any business' profitability, but it isn't inherently at odds with the moral syndrome. Nor are stupid business decisions.

I agree that journalists do use unscrupulous means to get their information - like hacking phones. It works. It's effective. But it isn't right, and in the end, like all unethical behavior, there'll be a comeuppance. But what's wrong for a journalist is right for a police detective, as Jane explains.

Religions are guardian activities, as you say, and missionary work can be either charity or largesse, or a mix. It's not an aberration that missionaries were traditionally expected to remain aloof from their flocks, just as religious leaders were. Although a luxury goods dealer may sell its goods to royalty, it should itself operate 'commercially', being non-exclusive in its dealings with suppliers, rich foreigners, etc. Journalists get much of their material from government, and to government the selling of information is treason.

Don't expect government to give such activity any blessing! Unlike the breaking of a contract, the breaking of a treaty between governments is considered 'strategic' (the Hitler/Stalin pact, for example). Between governments the aberration is a contract (Alaska purchase, for example).

Journalism may be older than one would guess. Sometimes it's hard to tell after ages of editing and translation. Homer probably wrote propaganda, but Herodotus and Thucydides, although usually thought of as historians, seem much like journalists to me - their values certainly align with those of journalists. And just as the sword and shield can be used to make dinner (paella may have originated as a soldier's meal, prepared on a shield) so may the pen be made to serve both commercial and guardian work - and be mighty in either role.

And there you have it.

## Morning Faces Therapy For Bipolar Disorder: A Story (Part 2: First Two Months) (2011-07-29 05:00)

In the 1990s, I discovered that if I see faces on TV early in the morning, I feel better (happier, more eager, more serene) the next day, but not the same day. Faces Monday morning, for example, make me feel better on Tuesday but not Monday. [1]I studied this effect extensively. The results suggested that a circadian oscillator controls our mood and sleep and needs morning face exposure to work properly. Absence of morning face exposure, this theory says, increases your risk of depression – a view not compatible with the “chemical imbalance” explanation of depression but one supported by [2]the strong association between depression and insomnia.

I told friends about this. One of them had devastating bipolar disorder. As he describes [3]here and [4]here, he got great benefit from looking at faces in the morning. After I posted his account of his experience, a man I’ll call Rex wrote me that he was going to try it. At 29, he was diagnosed with bipolar disorder. At 32, he slit his wrists. He is now 37. Since then he’s been in and out of mental hospitals. Now he lives at home. I wanted to follow his use of morning face therapy “prospectively” – before knowing what would happen. I posted [5]this, about his background, around the time he started.

Treatment details. He began about two months ago. He gets up naturally (no alarm) at about 8 am. He starts watching faces on TV – Squawk on the Street (CNN) – soon after he gets up. He watches for 1-2 hours on a 43-inch high-definition TV; the faces are roughly life-size. He sits 10 feet away.

Mood. Before starting the faces, he was in a depressed mood 5-7 days per month. During those days he had low energy, low motivation, and a bad attitude. The low phases would last a few days, then he’d start feeling better. Now, he says, “my mood is better first thing in the morning. I feel ready to go, turn the TV on, watch something. I feel a little lighter. I no longer feel the early morning doom that I used to feel. I’ve never been a morning person, but I feel that way more now than any time I can remember. I haven’t had any depressed moods since I started the faces. I haven’t had any really adverse or negative emotions. Things are going very smoothly. I have less worries, I feel a more uplifting, upbeat tempo throughout the day. Everything seems better.” (Note: Morning faces likewise shifted me toward being a morning person.)

Medication. He used to take an antidepressant every day (Simbalta, 60 mg/day). Now he takes 30 mg once every 3 to 4 days. He’s tried to stop taking it entirely but gets withdrawal symptoms (headache, nausea) when he does that. Note that he still had 5-7 days/month of depressed moods every month even when taking the antidepressant. In the spring his depression was better so he cut back slowly on the medication.

Sleep. For a long time he has had great difficulty falling asleep. He would lie in bed for an hour without falling asleep. He took sleep medication, usually Lunesta or Ambien, very often. “Lots of times in the past I would give up [after lying in bed a long time] and go watch TV. Or start to read, stay up to 2:30. That’s always been a problem – ever since I was in college. In college, my sleeping schedule went nuts. When I got into the working world, it continued to where I would stay up late and couldn’t sleep.” Since he started the morning faces, his sleep is much better. He usually falls asleep within 20 minutes of lying down, a very noticeable difference. He has taken much less sleep medication – about 20 % of what it was before. (He still takes it when he knows he has to get up early or he feels wired.) At one point, when he took antipsychotics, he did fall asleep quickly “but the side effects were awful,” he said. “Grogginess, foggy head all day. I didn’t have as much mania and depression but I would sleep 11 hours per night and I couldn’t get out of bed in the morning. I couldn’t concentrate. I couldn’t go back to college, because I couldn’t think clearly.”

At the same time he started the faces, he started getting blue light exposure in the morning from a blue light box called the [6]Apollo Health goLITE. He started with 20 minutes of exposure. It did seem to improve his mood and make him feel tired earlier. However, it also made him feel anxious and tense. To try to get rid of this effect, he reduced the exposure: 10 minutes, 5 minutes, 2 minutes. After a week, he stopped using it altogether.

"I'm just ecstatic about the results," he said.

Joseph Dantes (2011-08-06 11:21:37)

As far as I'm concerned, this phenomenon is established fact and you are its discoverer. I still say though that slideshow pics of pretty women on a computer monitor are even better than CNN. Clothed or otherwise. See here for the science: [http://chaosandpain.blogspot.com/2011/07/evil-will-always-triumph-because-goo d.html](http://chaosandpain.blogspot.com/2011/07/evil-will-always-triumph-because-goo-d.html) (Link NSFW) Testosterone... it does a body good. And those gals will put a smile on your face. And motivation in your life. I get the feeling you don't think I'm serious about this but I definitely am. Also, I don't see why a computer screen that's a foot and a half from your face is less effective at delivering sufficiently large facial sizes to your eyeballs than a TV screen that's 10 feet away.

Seth Roberts (2011-08-06 16:13:59)

Joseph Dantes, I varied screen distance. A conversational distance worked best. And life-size faces worked best.

Joseph Dantes (2011-08-07 01:07:18)

Interesting, I guess I'll have to try that then

## Science in Action: Why Energetic? (2011-07-30 05:00)

Last night I slept unusually well, waking up more rested and with more energy than usual. I slept longer than usual: 7.0 hours versus my usual 5.1 hours (median of the previous 20 days). My rating of how rested I felt was 99.2 % (that is, 99.2 % of fully rested); the median of the previous 20 days is 98.8 %. Because the maximum is 100 %, this is really a comparison of 0.8 % (this morning) with 1.2 % (previous mornings); and the comparison is not adjusted for the number of times I stood on one leg to exhaustion, [1]which improves this rating. During the previous 20 days I often stood on one leg to exhaustion six times; yesterday I only did it four times. Above all, I felt more energy in the morning. This was obvious. I have just started to measure this. At 8 am and 9 am, I rate my energy on a 0-100 scale where 50 = neither sluggish nor energetic/energized, 60 = slightly energetic/energized, 70 = somewhat energetic/energized, and 75 = energetic/energized. My ratings this morning were 73 (8 am) and 74 (9 am). The median of my 9 previous ratings is 62. The energy improvement (73/74 vs 62) is why I am curious. I would like to feel this way every morning.

What caused it? I had not exercised the previous day. My room was no darker than usual. My flaxseed oil intake was no different than usual. I had not [2]eaten more pork fat than usual. However, four things had been different than usual:

1. 2 tablespoons of butter at lunch. In addition to my usual 4 tablespoons per day.

2. 0.5-1 tablespoons of butter at bedtime. Again, in addition the usual 4.

3. 1 tablespoon (15 g) coconut butter at bedtime. Part of a longer study of the effect of coconut butter. Gary Taubes suggested this. I had eaten 1 T coconut butter at bedtime 13 previous days. On the first of those 13 days, I had felt a lot more energetic than usual in the morning. On the remaining days, however, the improvement was less clear. I started measuring how energetic I felt in the morning to study this further. Last night was Friday night. On the previous two nights (Wednesday and Thursday) I had not eaten the coconut butter. Maybe absence of coconut butter followed by resumption of coconut butter is the cause.

4. Fresh air and ambient noise. Following a friend's suggestion, I opened one of my bedroom windows.

My first question is whether the improvement is repeatable. If so, I will start to vary these four factors.

1. <http://blog.sethroberts.net/2011/03/22/effect-of-one-legged-standing-on-sleep/>

2. <http://blog.sethroberts.net/2009/10/31/effect-of-animal-fat-on-sleep-more/>

---

Alex Chernavsky (2011-07-30 10:31:51)

Seth, what was Gary Taubes's reasoning to recommend the coconut fat? Also, I'm impressed that you can get to almost 99 % rested on just over 5 hours of sleep. I would need 7 hours or more to get anywhere near that level of restfulness. I know you do one-legged standing, you expose yourself to sunlight in the morning, and you avoid eating until three hours or more after you wake up. Do you have an estimate for the relative effects of those three strategies? Also, Is there anything else you would recommend to improve the efficiency of one's sleep?

dearieme (2011-07-30 10:36:46)

I put toasted coconut into my muesli. This has the advantage that whether or not it does me good, it tastes delicious.

Seth Roberts (2011-07-30 11:29:10)

Gary Taubes reasoning re coconut butter (which isn't the same as coconut oil): It worked for him. one-legged standing: 50 %. morning sunlight: 30 %. avoid early breakfast: 20 %. I believe a diet high in animal fat can greatly sleep. see my experiments on pork fat and sleep.

August (2011-07-30 11:37:00)

It could be simply a function of increased calories, though I have been trying to eat more lately (more butter too) and haven't noticed an increase in energy. I haven't tried coconut butter at night; I've always assumed the MCTs would keep me awake. Good to know. I could certainly use more energy in the morning.

Seth Roberts (2011-07-31 05:44:01)

"increased calories": unlikely. If I eat more butter, I eat less of other foods.

### **"Everyone Agrees: Fresh Food Better." Uh, Not Everyone. (2011-07-31 05:00)**

In [1]a brief Atlantic article about the paleo diet, Alesh Houdek writes:

There is no question that we should eat more fresh and unprocessed foods. . . . The Paleo diet's dictum to eat as fresh as possible is shared universally with all modern sane eating guidelines.

As regular readers of this blog know, I disagree that "fresh is better". Fermented is not just better but necessary. To work best, I think our bodies need substantial daily doses of fermented food or their microbial equivalent. Evolution has shaped us to like sour, umami-flavored, and complex-flavored food so that we will eat more microbe-laden food. More about this in [2]these posts. Pass the[3] umeboshi.

dearieme (2011-07-31 06:53:42)

Beer and bread, then?

dearieme (2011-07-31 06:54:48)

Oops, beer and bread-and-butter? And cheese?

Michal (2011-07-31 07:38:51)

bread is dead after it bakes. Some beers are still alive. it's about the bacteria, they are good for you

q (2011-07-31 18:57:51)

i right now have a raging headache after eating a quart jar of pickles.

dearieme (2011-08-01 06:32:25)

beer, bread-and-butter, cheese, pickles: we call that a ploughman's lunch - favourite pub fare. Eat healthy, eat English!

ce (2011-08-02 08:38:22)

Well, before re Fridgeration, food was fresh for a little bit, then it was fermented/covered in microbes, whether you wanted it to be or not. Meat, fruit, veggies, everything. My family leaves (cooked) animal products out overnight without even thinking about it. People from families who don't do this are afraid of eating a hard boiled egg that's been out of the fridge for a day. Something about stomach pain and vomiting? Anyways, where are the calls to be less of a baby about food spoilage?

Steve G. (2011-08-03 13:09:23)

Seth, Some of these comments raise an interesting question that you might clarify : does the microbial content need to be alive? As one writer points out, bread is made with yeast, but the yeast would be killed in baking. Also, what about pickles: alive or dead (salt or vinegar)? Finally, what about beer? I'm fond (in moderation, mind you) of Belgian traditional brews, which I believe retain active yeast cultures. On the side of the angels? I will say that when ever I down some sour kraut or yogurt--and I am fond of both--I have you to thank for the feeling having made a good health choice while I enjoy the flavor.

Seth Roberts (2011-08-03 14:52:16)

To improve digestion they need to be alive. To improve immune function, probably not. It's hard to measure effectiveness. So I play it safe with several kinds of fermented foods every day.

## Edward Jay Epstein Offer (2011-07-31 07:25)

Edward Jay Epstein, the investigative journalist whom [1]I praise here, [2]offers free copies of his latest books (which include [3]Myths of the Media, [4]Who Killed God's Banker?, and [5]Armand Hammer, The Darker Side, all Amazon Kindles) to those who will write Amazon reviews. I took him up on it. You can reach him at ed at edwardjayepstein.com.

### The Comments on "Finding the Source of Migraines..." (2011-08-02 05:00)

Nowadays, far more than ever before, people can do useful science (collect data, draw conclusions) about their own health. This personal science can produce much better results than expert advice. For example, I found ways to sleep better and raise my mood superior to what sleep and mood experts know. I wonder how others are using this new power. This is why I wrote a story for Boing Boing about [1]a woman (Sarah) who figured out what caused her migraines after conventional doctors failed to help her. She was eventually helped by an expert (a naturopath) but most of the improvement came from self-experimentation showing that cleaning and skin care products caused migraines.

The story got many comments. A surprising number were eerily dismissive. You might think it was a good thing that Sarah got rid of frequent crippling migraines after doctors failed to. Nope: "Anecdotes are not data" (56 likes). The same person also said "data is data". Both are examples of [2]preventive stupidity. "Big Brother loves you," replied Mark Frauenfelder, and I agree. Another surprising comment was "Don't encourage these people" (= people like Sarah). One of the dismissistas came to his senses. "I'd simply like to close with an apology, as on reflection little I've posted here has been useful or expansive," he wrote.

Some comments nicely summed up the main points of the story. "When all you have is a hammer, everything looks like a nail" was a good description of Sarah's conventional doctors. They acted as if their only tool was the ability to write prescriptions – so every problem called for a prescription. When the first 10 drugs didn't work, they tried more drugs. When the first 30 drugs didn't work, they tried more drugs. Surely this is bad medicine, yet, as far as I can tell, that's what they learn to do.

Some comments asked questions it would have helped if I had anticipated. How could Sarah have tried 50 different migraine drugs and 13 different birth control pills in one year? I wasn't puzzled by this but details would have clarified things.

Above all, the comments supported my belief that Sarah's problem was common. Many commenters said they had migraines caused by environmental triggers. Only one said his migraines turned out to be caused by a tumor. In spite of this pattern of causality, the comments also suggested that conventional doctors generally prescribe drugs for migraines. ("They had the prescription typed into the system before I was even finished telling them what was going on.") It's like trying to enter a room by breaking through a wall (prescribing a drug) instead of using the door

(finding the triggers). It's as if all they have is a sledgehammer.

1. <http://boingboing.net/2011/07/25/finding-the-source-of-migraines-and-fifty-useless-migraine-drugs.html>

2. <http://blog.sethroberts.net/2010/05/12/preventive-stupidity-exists/>

---

dearieme (2011-08-02 05:54:26)

"data is data": bollocks. "Data" is plural.

Alex Chernavsky (2011-08-02 06:51:30)

"It's time to admit that data has joined *agenda*, *erotica*, *insignia*, *opera*, and other technically plural Latin and Greek words that have become thoroughly Anglicized as singular nouns, taking singular verbs. No plural form is necessary, and the old singular form, *datum*, can be left to the Romans." <http://www.linztech.com/grammarcentral-topics.htm> #data

Kris (2011-08-02 09:30:56)

There is a certain ingredient in that is common in perfumes and personal care products that triggers migraines for me. I know it as soon as I smell it. My wife has had to throw out new soaps and lotions because of the "smell." Another trigger for me is eating something made of processed carbs first when I am very hungry. Since I cut the wheat and most processed food out of my diet, I rarely get migraines anymore, and when I do they are usually pretty mild compared to the old days. Hardly anyone believes it though, and very few try it. People do not want to change how they are living, even if it is harming them. They prefer a short cut every time (i.e. drugs).

John III (2011-08-02 13:55:38)

Dearieme and Alex, lol. You really get to the heart of the matter.

Pen Pen (2011-08-03 04:08:26)

I recently suffered migraines up to 2 times per week which started in my right temple. I thought I had tried everything - naturopath, chiropractor, regular neck stretches, avoiding common triggers (e.g caffeine, chocolate, red wine etc). After seeing a very clever osteopath, we deduced that looking at the ergonomics of my desk at work was key because it was likely that my right shoulder was getting overworked from using the mouse with my right hand. She also gave me exercises to strengthen my mid back. The thing that made the greatest difference was swapping the mouse to my left hand (which required a few days training) and surprise, surprise, no migraines.

Seth Roberts (2011-08-03 04:47:48)

Fascinating story, Pen Pen.

Ruth @ Ruth's Real Food (2011-08-03 14:09:01)

These reactions have everything to do with psychology and nothing to do with science. A real man/woman of science would at a minimum look at Sarah's story as a fascinating lead that he/she can learn from and study further. A doctor with an ego sees someone going over his/her head and doesn't like it. (I was just going to use "they" "there" but I didn't want to upset the grammar police :) )

Jazi yechezkel zilber (2011-08-05 02:47:57)

The doctros were actually tinkering. They tried all drugs looking fr the effects. The only difrences were More dangerous. Less emthodical (they do not measure methodically the effects daily). And pretending authority and science. This is what a friend

noted to me. That we do many tricks etc. Unconsciously, but do not notice it consciously. PS. What is your new book about?

Ela (2011-08-06 09:47:20)

I have had migraines since I was a child and my 13 yr. old son has had them since he was 8. He was having 2/week with vomiting by age 10. 6 years ago I began suspecting my diet was the primary cause of my migraines. At that point they ruled my life and affected every aspect. Doctors, naturopaths, herbalists, acupuncturist, holistic MD's, biofeedback, and medications did not help much or for long. After going gluten-free for unrelated reasons I noticed a small improvement immediately and thus began my search for an answer in my diet. I now avoid consuming artificial chemicals; all herbs and spices; most fruits and veggies (not all!); anything fermented; and generally avoid all grains. I also avoid strong and artificial scents. Foods that are high in amines, salicylates, and tannins definitely cause headaches for me. If I follow the diet, I have no migraines. My son follows a modified version of my diet and has a migraine less than every month. My best diet consists of meat, salt, butter, (Dr. Mercola at <http://articles.mercola.com/sites/articles/archive/2010/12/07/why-is-butter-better.aspx>) has great info regarding the benefits of butter!), raw milk, egg yolk, cabbage, kale, lettuce, carrots, potatoes, apples, pears, and mango. David Buchholz, MD (Johns Hopkins neurologist) wrote a book, Heal Your Headache: The 123 Program, about the strong connection between headaches and diet and has a good explanation for the difficulty in determining headache triggers. And this sight is great for info on the potentially problematic chemicals in foods <http://failsafediet.wordpress.com/>.

nicole harkin (2011-08-17 21:18:53)

On the topic of the efficacy of drugs, I was wondering if you had read these two New York Review of Books articles: <http://www.nybooks.com/articles/archives/2011/jun/23/epidemic-mental-illness-why/> and <http://www.nybooks.com/articles/archives/2011/jul/14/illusions-of-psychiatry/> A fascinating review of books comparing whether drugs work better than placebos...mostly they don't...

Seth Roberts (2011-08-18 07:18:02)

Yes, I read them and blogged about them: search "Marcia Angell".

## **Personal Science in Japan: Radioactivity Measurements (2011-08-03 05:00)**

Personal science isn't just self-measurement. [1]In Japan:

Kiyoko Okoshi had a simple goal when she spent about \$625 for a dosimeter [that measured radioactivity]: she missed her daughter and grandsons and wanted them to come home. Local officials kept telling her that their remote village was safe, even though it was less than 20 miles from the crippled Fukushima Daiichi nuclear power plant. But her daughter remained dubious, especially since no one from the government had taken radiation readings near their home.

So starting in April, Mrs. Okoshi began using her dosimeter to check nearby forest roads and rice paddies. What she found was startling. Near one sewage ditch, the meter beeped wildly, and the screen read 67 microsieverts per hour, a potentially harmful level. Mrs. Okoshi and a cousin who lives nearby worked up the courage to confront elected officials, who did not respond, confirming their worry that the government was not doing its job.

With her simple yet bold act, Mrs. Okoshi joined the small but growing number of Japanese who have decided to step in as the government fumbles its reaction to the widespread contamination, which leaders acknowledge is much worse than originally announced.

Maybe it is obvious that a woman who wants to see her grandchildren yet keep them safe is far more motivated to find the truth than a local politician or even surveyors hired by the government. Personal scientists who study other

things have the same motivational advantage. As I have said [2]more than once, I care far more about improving my sleep than any professional scientist.

Mrs. Okoshi misses her daughter and grandchildren very much. Her husband recently died and her daughter's family left, afraid of nuclear fallout.

"Our life was so lively when the four boys were running around the mountains in the back of the house," she said.

Personal science channels her emotion in a way that helps everyone around her.

### **My Daily Dose of Flax Seed (2011-08-03 17:00)**

Currently I eat 33 grams (= 45 ml = 3 tablespoons) of flax seed in yogurt twice a day. That's 66 g/day (which contains about 2 tablespoons of flaxseed oil). I grind it for 30 seconds before adding it to the yogurt. I like yogurt with ground flax seed better than yogurt without it, leaving aside the health benefits.

Unlike flaxseed oil, which must be kept cool, flax seed can be stored at room temperature, which makes a huge difference. I discovered that Chinese flaxseed oil was worthless, presumably because it hadn't been kept cool. To bring American flaxseed oil to China was a nightmare – lugging it, trying to keep it cool. Chinese flax seed is fine, and not hard to get in Beijing.

---

Haggus (2011-08-03 20:26:46)

Dr. Roberts, I'm losing out by nuking my flaxseed with water, for 30 seconds to warm it up (not boiling.) Or how about mixing it with water heated to around 80C?

Timothy Beneke (2011-08-03 23:03:26)

I take it that ground flax seed must be kept refrigerated, given that it is sold that way in health food stores. Is that right?

Sophie Ogle (2011-08-04 02:31:18)

What kind of grinder do you use for grinding flaxseed? Is it manual? Electric? Mortar and pestle? Something else?

dearieme (2011-08-04 04:09:01)

I use half a tablespoon in a week's supply of muesli. You seem to be suggesting that that is too little? I store it at (UK) room temperature.

Seth Roberts (2011-08-04 07:16:44)

In China I use a blender. There is an attachment meant for grinding spices. In America I use an immersion blender (Braun) – again, there is an attachment meant for grinding spices. As blenders go, both of these are small.

bjk (2011-08-04 08:02:55)

Doesn't all this flax seed contribute lots of omega-6? And doesn't the absolute level of omega-6 matter?

Seth Roberts (2011-08-04 08:36:17)

"Doesn't all this flax seed contribute lots of omega-6?" No. The reason that the omega-3/omega-6 ratio is very high in flaxseed oil is that the ratio is very high in flax seeds. The oil extraction process does not discriminate between omega-3 and omega-6. It does not selectively remove omega-6.

David (2011-08-06 18:58:21)

I notice that drinking tablespoons of flaxseed oil can be constipating but consuming a similar amount of ground flaxseed causes no problems. I also put it in yogurt, in smoothies, and on salads.

Eric (2011-09-14 15:00:54)

I use a coffee grinder that was \$13 on Amazon and got good reviews. In 20s it turns the seeds into a fine powder. I do, however, wonder about the phytoestrogens in flax. I'm not sure if they matter as these doses.

haig (2011-11-18 14:16:28)

Seth, are you at all concerned with the phytoestrogen content of flaxseeds and the studies that have found a correlation between flaxseed consumption and prostate cancer? I am really interested in the positive results on gum health and reduction of inflammation in general, but have thus far not started taking flaxseed due to my above concerns. Have you or any other males taking daily flaxseed noticed increase in breast size, inflamed prostate, or any other side-effects?

Seth Roberts (2011-11-18 15:35:30)

I haven't noticed any bad effects. I agree that it would be better to have multiple sources of omega-3.

## How Rare My Heart Scan Improvement? (2011-08-04 05:00)

In 2009, I had a heart scan – a three-dimensional X-ray. The scan was used to calculate an Agatston score, a measure of arterial plaque. Higher scores mean a higher risk of heart attack. A few months after that, I discovered that butter improves how fast I do arithmetic.

Because butter was good for my brain, I started eating half a stick of butter (66 g) every day. Surely the butter was improving overall brain function. The effect of butter on the rest of my body I didn't know. However, I thought it was highly unlikely that a food that greatly improves brain function is going to damage the rest of the body. The food you eat, after digestion, goes to the whole body (leaving aside the blood-brain barrier). Every part of the body must have been optimized to work well with the same food.

As I have posted earlier, I had a second heart scan, producing a second Agatston score, about a year after the first one. Amazingly, the second score was better (lower) than the first score. The woman in charge of the testing center said this was very rare – about 1 time in 100. The usual annual increase is about 20 percent.

Now I have gotten more information about the annual rate of change in Agatston scores. The graph above (thanks to Harry Rood) shows data from 40 people who listed their scores at the Track Your Plaque site. It is based on pairs of consecutive scores: it plots change versus level (average?). Because some people provided more than two scores, the data allowed 77 points to be plotted. My two scores were 38 (log 38 = 1.58) and 29 (log 29 = 1.46). So the decrease in log units was 0.12. If you look at the graph, you can see what an outlier this is – as I was told, it really is about 1 in 100.

Here we have the conjunction of two unusual things: 1. Eating half a stick of butter per day. Almost no one eats so much butter. 2. An extremely rare drop in the Agatston score over the same period. A principle of reasoning called Reichenbach's Common Cause Principle says if two rare events might reflect cause and effect, they probably do. You can think of it like this: Lighting doesn't strike twice in one place for two different reasons. Indeed, there is other evidence that high levels of saturated fat cause heart-scan improvement (even though this contradicts everything you've been told). [2]Mozzafarian et al. (2004) found that in postmenopausal women, "a greater saturated fat intake is associated with less progression of coronary atherosclerosis." So it is quite plausible that my butter intake improved my Agatston score.

1. <http://blog.sethroberts.net/wp-content/uploads/2011/06/log-change-in-score-vs-log-score.jpg>

2. <http://www.ajcn.org/content/80/5/1175.full>

---

Chris (2011-08-04 06:42:42)

Do you need to eat half a stick of butter a day to maintain the cognitive benefits? Or do you think that once a deficiency has been corrected you can reduce the dose? Thanks, Chris

Tuck (2011-08-04 07:56:04)

Fascinating result. Dr. Davis might reconsider his anti-butter stance... <http://www.trackyourplaque.com/blog/2010/10/butter-just-because-its-low-carb-doesnt-mean-its-good.html> Of course Peter at Hyperlipid has already explained how Dr. Davis mis-read this... (I'm a big fan of Dr. Davis, but no-one is perfect.)

Seth Roberts (2011-08-04 08:41:33)

You need to eat the butter regularly to maintain the benefits. When the butter goes away, the brain gets worse.

Wilhelm (2011-08-04 11:44:40)

Do you eat the butter mostly as it is or cooked/fried/heated ?

Alex Chernavsky (2011-08-04 12:18:40)

I know that Eri Gentry's "Buttermind" study suggested that coconut oil doesn't have the same positive effect as butter. Aside from flaxseed oil, is there any other plant-based food that may have the same (or similar) beneficial effect as butter?

Paul Winter (2011-08-04 14:21:00)

K2, found in butter. Dr. Davies has a couple of posts on K2 causing a reduction of the arterial plaque.

Aaron Ashmann (2011-08-04 16:30:04)

Seth do you consume a lot of choline? I'm worry that if I eat a primarily vegetarian diet that if I add a lot of butter, I might not be ingesting enough choline to break down the fats. I don't consider taking a supplement to be adequate way of getting the nutrient- any ideas here?

Jonathan Shewchuk (2011-08-04 18:00:40)

While I think saturated fat is probably good for you, I don't see why you're focusing on it for heart scans. My guess for the most likely hypothesis is that the Vitamin K2 in the butter (and maybe the Vitamins D and A too) is regulating your calcium so it goes into your bones instead of into your arteries. Check out these posts on K2 and heart disease: <http://wholehealthsource.blogspot.com/2008/11/can-vitamin-k2-reverse-arterial.html> <http://wholehealthsource.blogspot.com/2008/11/cardiovascular-disease-and-vitamin-k2.html> <http://wholehealthsource.blogspot.com/2008/06/vitamin-k2-menatetrenone-mk-4.html> Of course, the butter-calcium relation could be a many-factored effect, but the fat-soluble vitamins have a lot of evidence behind them. It's not clear to me whether the fat itself is important or just a carrier for the vitamins.

Alex (2011-08-04 21:39:17)

It's "Agatston." I only mention it because it's a search keyword. I love the interesting insights from your blog.

Vic (2011-08-04 22:34:29)

Seth, is the yogurt you eat also full fat?

Aaron (2011-08-05 01:27:43)

Dear Seth - What do you think about the (rather conflicting) research regarding flaxseed consumption and prostate cancer? I assume you are not worried?

Seth Roberts (2011-08-05 04:37:08)  
Thanks for the correction.

Seth Roberts (2011-08-05 04:47:21)  
Aaron, I haven't looked into it much. The benefits of omega-3 are overwhelming. I will eventually compare different sources of omega-3 but haven't yet.

Seth Roberts (2011-08-05 05:04:39)  
yes, the yogurt I eat is full fat.

JohnN (2011-08-07 11:53:10)  
Seth, There are probably more causation than correlation between your consumption of butter and improved brain functions. Have you considered, however, other factors such as K2 (mentioned by other posters), added sodium as electrolyte and brain running on ketone (not uniquely limited to butter)? John PS: is there any positive effect on teeth and dental health as well? The butter fat can break up dental plaque and neutralize the acidic environment created by the bacteria.

The Ancestral Health Symposium | Perfect Health Diet (2011-08-09 17:08:15)  
[...] On Saturday I started with Seth Roberts and Tucker Max. Seth's talk was excellent – the gist can be found in recent blog posts, such as the one on butter reducing his coronary calcium score. [...]

Seth Roberts (2011-08-09 22:53:42)  
JohnN, re correlation or causation. The Genomera experiment, based on my findings, was an ABA design, where A = no butter and B = butter. It found a difference in outcome between A and B supporting causation. Re K2. I haven't noticed a difference in effect between cheap and expensive butters, which I would expect to differ in K2 content. Re added sodium. I got the effect with unsalted butter. I haven't noticed a difference between salted and unsalted butter. Haven't noticed any dental changes. My gums are pink due to flaxseed oil.

Chris (2011-08-11 15:50:10)  
With K being a fat soluble vitamin, I would guess that it is not responsible for the cognitive benefits since, as Seth wrote, you need to eat the butter regularly. I would think that the K would accumulate in the body and the benefits would be maintained for some time after due to the body mobilising its stores. Does cheese provide a similar effect? If not, the differences between cheese and butter might hold clues to the mechanism.

harry (2011-08-14 11:38:16)  
Hi Seth, I'd be a little cautious about concluding that eating a half-stick of butter every day will result in a significant CAC score reduction. Not that I think that the butter is detrimental, I eat a quarter of a stick every day myself, and lots of other saturated fat, a total of about 80 grams of it per day. My caution about concluding that saturated fat reduces CAC score is due to 2 things. First, the fact that my CAC score isn't going down, and second, the large uncertainty in each CAC score measurement, especially at the lower values of total score. Your Agatston score was initially 38 and it changed to 28.8 a year later, if I understand what you have said. That's great, but it's a relatively low level of calcium as these things go. If we look at studies of reproducibility of CAC score where they have taken into account the score uncertainty as a function of score, we see considerable uncertainty. For example, the study "Serial Electron Beam CT Measurements of Coronary Artery Calcium: Has Your Patient's Calcium Score Actually Changed?", by Sevrakov, Bland, and Kondos, 2005, suggests that if the measured CAC score is 40, the 95 % repeatability limits on that value fall between 8.8 and 71 agatston units. Similarly, the 95 % repeatability limits on a score of 30 is between 3 and 57. This is based on a large number of scores repeated serially within a short time. And the other major study of CAC reproducibility is even worse. See "Repeatability Limits for Measurement of Coronary Artery Calcified Plaque with Cardiac CT in the Multi-Ethnic Study of Atherosclerosis, by Chung, McClelland, Katz, Carr and Budoff, 2008; I think we need a lot more tests of the hypothesis that butter, or saturated fat reduces calcium score before we can conclude that the hypothesis is valid. I've been eating a high-fat, high-saturated fat diet for several years, and my CAC score continues to increase (although it may

be slowing down, percentagewise).

Seth Roberts (2011-08-14 18:16:25)

Harry, the graph suggests that a reduction like mine is quite rare – about 1 in 100. That probability calculation includes error of measurement. But I certainly agree that more tests of the hypothesis are needed. Yet it is still meaningful that my results were so different than predicted by conventional wisdom. Conventional wisdom says that butter causes heart disease. My results, to the extent they say anything, point in the opposite direction.

Kelly (2012-02-07 00:26:13)

Thanks Seth...this "improvement" story by eating a half stick of butter a day was truly hilarious. I needed the laugh.

Seth Roberts (2012-02-07 11:37:57)

Kelly, thank you for your sneer.

## **The Evolution of Lactose Tolerance and My Butter Discoveries (2011-08-05 05:00)**

From a BBC documentary called [1]Are We Still Evolving? I learned that after the development of farming there was intense selection in Europe for "lactose tolerance" – meaning the ability to digest lactose as an adult, which requires the enzyme lactase. (The technical name is lactase persistence.) The necessary gene spread rapidly. Now most Europeans have the gene. In Ireland almost everyone has the gene. [2]Mark Thomas, an evolutionary geneticist interviewed on the show, who does [3]research on lactose tolerance, said this:

It's probably the most advantageous characteristic that Europeans have evolved in the last 30,000 years..  
. . The advantage that's been measured is just incredible, absolutely incredible, how big an advantage it was for these early farmers in Europe.

"Why would drinking milk into adulthood be so strongly selected for?" asked Alice Roberts, the presenter. Thomas replied,

Milk has got lots of energy in it, it's very nutrient dense, it's got lots of other goodies, like various vitamins, calcium, and so on. Also, it's a relatively clean fluid, so it's much better than drinking stream water or river water or well water or something like that. Another advantage is if you're growing crops you have a boom and bust in terms of the food supply.

Not a word about butterfat – "lots of energy" is true of all fats. The rapid spread, the "incredible" advantage, suggests that milk supplied something resembling a necessary nutrient. As if everyone had been suffering from scurvy and the new gene allowed them to eat citrus – something like that. Such a gene would spread rapidly.

Does milk supply a necessary nutrient? My results suggest that butter – half a stick (60 g)/day – provides two clear benefits: 1. [4]Better brain function. 2. [5]Less risk of heart disease (probably). As far as I can tell, roughly everyone in America would get these benefits because their diets now lack enough of whatever it is. Both benefits reflect invisible problems. Like everyone else, I had no idea my brain function could be substantially improved and had no idea of my rate of progression (narrowing of arteries) toward atherosclerosis. Only because of unusual tests (the arithmetic test and a "heart scan") did I notice sudden large improvements when I started eating lots of butter – what you'd expected from addition of a missing necessary nutrient. This explains why Thomas and almost everyone else is unaware of these benefits.

Keep in mind that before I started eating butter, I already ate a high-fat low-carbohydrate diet. Yet I wasn't getting enough of something in butter. I already ate lots of pork fat. Perhaps the saturated fat in butter is better digested than the saturated fat in pork. Or perhaps the fat profile is better.

If lactose tolerance is so helpful, why are most Asians lactose intolerant? My work suggests two answers: 1. Yogurt. Long ago, Asians ate lots of yogurt. I know the Mongols did. There are present-day indications of this. The Chinese appreciate the value of yogurt more than Americans. Yogurt is more common in Chinese supermarkets than American ones. Yogurt makers are better and more common in China than Europe and America. Lots of Chinese make their own yogurt; as far as I can tell, home yogurt making is more popular in China than America. You can buy a cheap good yogurt maker many places in Beijing, unlike San Francisco. Yogurt provided butterfat. 2. Pork. The Chinese, of course, eat far more pork than Europeans. Unlike cows, pigs supply a cut with a large amount of fat: pork belly. I found it easy to get plenty of pork belly in China and eat it as the main course. Difficulty getting pork belly in the Bay Area is what pushed me to eat butter. This view predicts that European farmers raised more cows than pigs.

Anyway, to summarize, the great advantage conferred by lactose tolerance suggests the great value of something in milk if you eat a European-farmer-like diet. My work supports this; it suggests the crucial ingredient is butterfat. Which many Americans carefully avoid!

Note: The [6]danger posed by the high level of AGEs (advanced glycation endproducts) in butter I don't know about – but of course this danger has nothing to do with why lactose tolerance was so beneficial. My experience so far (the heart-scan improvement) suggests that that ordinary butter is not "artery-constricting". Presumably AGEs are formed when milk is pasteurized so I would prefer to eat unpasteurized butter.

Valtsu (2011-08-05 06:14:25)

Hello Seth! Chris Masterjohn wrote an article regarding Davis' butter-AGE statement: <http://blog.cholesterol-and-health.com/2010/10/is-butter-high-in-ages.html> BTW, your blog is wonderful!

Michal (2011-08-05 06:36:28)

AGE's in food aren't the same as AGE's in your blood. Just like cholesterol in your diet doesn't lead to cholesterol increases in your blood.

Tomas (2011-08-05 06:40:47)

Seth, the supposed danger of AGEs from butter is based upon degradation of either milk proteins or milk sugar, not sure right now which one. As butter contains little of both, the theory seems to be wrong. I think Stephan Guyenet wrote about the issue recently. AFAIK he thinks that the whole AGE thing is trash

Tomas (2011-08-05 06:41:20)  
ah sorry it was Chris Masterjohn

Max (2011-08-05 06:43:02)

Hi Seth, How do you manage to consume half a stick of butter every day on a low carbohydrate diet? I am on a similar diet; if I weren't I would probably just spread the butter on bread. I enjoy cooking with butter but don't think that alone will get me close to half a stick per day. Thanks, Max

john (2011-08-05 06:44:13)

Seth, Chris Masterjohn has written a good article talking about AGEs and butter, I think somewhat as a response to Dr. Davis' post you linked.

Tuck (2011-08-05 06:55:14)

I mentioned a commentary on Dr. Davis' post in my other comment. I should have looked it up, it wasn't from Peter at Hyperlipid, it was from Chris at the Daily Lipid. It's tough keeping my Lipid sources straight. ;) Here it is: "Is Butter High in AGEs?" <http://blog.cholesterol-and-health.com/2010/10/is-butter-high-in-ages.html> I wouldn't get to stressed about the ill effects of butter. I don't. As far as the advantage to butterfat, it's likely vitamin K2, which was identified by Weston Price as "factor X" that made butter so healthy. Stephen Guyenet has done a bunch of posts on the cardiovascular advantages of K2, and K2 has specifically been shown to prevent arterial calcification in rats (MK4 is K2): <http://content.karger.com/produktedb/produkte.asp?typ=fulltext&file=JVR2003040006531> So keep eating your butter. Btw, as I just started following your blog, I don't know if you've discovered the joys of pastured (grass-fed) butter. It tastes far better, and is available in most Whole Foods I've been to. What makes butter taste better or worse? K2 content. Pastured butter has more.

Darrin Thompson (2011-08-05 07:12:50)

You found an easy way to get unpasteurized butter? Do tell.

Joseph Dantes (2011-08-05 09:37:29)

Have you tested butter against seafood, non-farmed, specifically shellfish? I've noticed an improvement of similar or greater magnitude when I eat shellfish. Perhaps that's the missing nutrient pathway... farming and farm raised animals create deficiencies correctable by seafood or butter. I'd like to test the butter/yogurt hypothesis once I've got my current problems fully corrected. Right now my vitality scores are acceptable but not stupendous.

Kirk (2011-08-05 10:47:54)

Interesting. Things must have changed in China since the 1989 China Study. The authors of that study said about consumption of animal fat (D053 ANIMFAT), "This (6.5 g/day) constitutes a relatively small proportion of total lipid intake (D002:TOTFAT), which averages about 50 g/day." And about milk (D047: MILK) they said, "Milk is almost never consumed in most parts of rural China. The few places where it is consumed are nomadic herding areas." Have you considered whether there is a specific ingredient of butter which has that impact on you? For somebody like me, whose gut dislikes more than a teaspoon of butter per six hours, have you found a good breakdown of the ingredients of butter? The only unique ingredient that I know about is K2, which supposedly pastured butter has in greater quantity than commercial butter. (It seemed to me that my skin improved once I started taking K2, but it's not that I had major skin problems to correct, so it's more of an impression than a measurement.)

Jeff (2011-08-05 11:54:48)

Seth - How did you settle on eating half a stick of butter? Why not more or less?

steve (2011-08-05 12:10:43)

The decrease in your heart scan score may most likely be attributable to variability in score results; the measurements are calculations based on an algorithm and there is variability; the score could have been up or down by 10 %. It can also change from machine to machine. So I would not base your argument so much on a decreased scan score, but upon the

fact it remains unchanged. This alone is quite an accomplishment given plaque can grow by as much as 30 % per year. Great job!

Tom (2011-08-05 13:56:01)

Kirk said: *Interesting. Things must have changed in China since the 1989 China Study. The authors of that study said about consumption of animal fat (D053 ANIMFAT), "This (6.5 g/day) constitutes a relatively small proportion of total lipid intake (D002:TOTFAT), which averages about 50 g/day." And about milk (D047: MILK) they said, "Milk is almost never consumed in most parts of rural China. The few places where it is consumed are nomadic herding areas."* The actual data is not what Campbell pretends it is in his book (which is a pop nutrition book with no peer review, by the same publisher behind *Seven Seasons of Buffy*.) In fact, Campbell played fast and loose with the data from Tuoli county whose Uyghur residents eat a diet that's extremely high in dairy, yet are healthier than the Chinese from counties who don't. Campbell protested being caught out on this by Denise Minger, saying that he was convinced that the residents were "feasting" on the days of data collection, and thus the data for the county was not representative. (He did not explain why only one county would behave this way, while all the others would not.) Anyway, for more on why "The China Study" (speaking of the pop culture book, rather than the dataset) cannot be trusted, read here: <http://rawfoodsos.com/2010/08/06/final-china-study-response-html/> ...and here: <http://rawfoodsos.com/2011/07/31/one-year-later-the-china-study-revisited-and-re-bashed/>

08/06/11 – Super Saturday (2011-08-05 18:02:13)

[...] The Evolution of Lactose Tolerance and My Butter Discoveries - Seth's Blog [...]

kxmoore (2011-08-05 22:48:03)

Seth great blog. I would like to add more butter to my diet but the thought of eating half a stick straight is unappealing. How do you eat your butter?

pacob (2011-08-06 01:43:59)

2. Pork. The Chinese, of course, eat far more pork than Europeans. In fact, this is not true for all European countries. Germany and Spain are the biggest pork meat consumers in the world. Only third place go to China.

Seth Roberts (2011-08-06 06:26:16)

I eat the butter with small pieces of meat – for example, small pieces of roast beef or roast pork.

Seth Roberts (2011-08-06 06:28:37)

Steve, you can see from the graph the average variability. It shows that the decrease in my heart scan score is unlikely to be due to variability. There was no change of machine – both scores were measured on the same machine.

Seth Roberts (2011-08-06 06:29:50)

Jeff, a half a stick was easy. I have tried larger amounts now and then and found them both difficult and producing noticeable improvement.

Seth Roberts (2011-08-06 06:31:23)

Max, as I said in reply to someone else, I eat the butter with small pieces of meat.

Alex Chernavsky (2011-08-06 11:10:13)

Just did some Googling and found out that natto (Japanese fermented soybeans) contain K2. Being a vegan, I won't eat butter, but I'll have to try natto. I understand it's an acquired taste.

Kirk (2011-08-06 11:14:44)

@Tom, I am not quoting from the book titled 'The China Study' by T. Colin Campbell. I have that book checked out from the library right now and about every 20 pages I am tempted to throw it against the wall whenever Campbell proudly points to something as proof of his assumptions, and meanwhile I remember clearly how Taubes or Minger or one of the paleo bloggers

has previously destroyed that argument. I took my information directly from the China Study data. I found the data by chasing the links in Denise Minger's reviews of Campbell's analysis. My assumption is that the data itself is valid, since both Denise Minger and Ned Kock have used it for statistical analysis. The text extracts I used were taken from the PDF titled 'Mono \_Diet \_Survey.pdf' (which, on the CTSU web page, is labeled 'Diet survey intake').

Jeff (2011-08-06 16:52:44)

Seth - If you had no trouble consuming more butter, how much would you eat daily? Also what kind of trouble are you experiencing? I've consumed as much as 1/2 a stick twice a day. It took a few tries for my digestive system to adapt, but now I don't experience any problems. Lastly, where are you finding unpasteurized butter? TIA

Willis Morse (2011-08-07 05:14:16)

Interesting short article from biology writer Robert Dunn on lactose tolerance: <http://www.robrdunn.com/2011/05/the-secret-truth-about-lactose-deficiency/> He says lactose tolerance genes have evolved independently from the European lactose tolerance gene several times in Africa and in other nomadic populations, but they were ignored because none of the genetic databases have much coverage of non-Western populations until one researcher traveled through Africa and did her own genetic sampling. Also, there are African tribes that exhibit lactose tolerance without having any known lactose tolerance gene, raising the possibility of population-wide gut flora adaptations.

Seth Roberts (2011-08-07 11:53:16)

I got some unpasteurized butter from a friend of mine who got it from an Amish farmer. As you say it is very hard to find.

Tom (2011-08-07 14:05:13)

I've had this raw butter from Organic Pastures. It's good, but expensive and hard to find. Note that many of the stores they list on their website as carrying it do not; it's best to call first. For those in Southern California, Co-Opportunity in Santa Monica carries it.

Tom (2011-08-07 14:05:33)

Sorry, forgot the link: [http://www.organicpastures.com/products\\_butter.html](http://www.organicpastures.com/products_butter.html)

Tom (2011-08-07 14:06:02)

last try: [organicpastures.com/products\\_butter.html](http://www.organicpastures.com/products_butter.html)

some anonymous guy (2011-08-07 17:45:03)

Hi Seth, Since butter is just heavy cream whipped, have you tried drinking the appropriate amount of heavy cream, or do you think there is something in the change from one state (liquid) to the other (sort of solid?) that makes it beneficial? I know that as far back as the 1950s, bodybuilders used to use heavy cream as a staple of their diets: [http://www.google.com/search?sourceid=chrome &ie=UTF-8 &q=heavy+cream+bodybuilder+1950s](http://www.google.com/search?sourceid=chrome&ie=UTF-8&q=heavy+cream+bodybuilder+1950s) If you really think about it, bodybuilders have been self-experimenting for their data for some amount of decades now. And their self-experimentation which has yielded significant results, as you might predict, is argued against by establishment figures. As an example, you can still see a lot of dietitians (maybe even the majority) argue that extra protein is not needed if someone engages in a heavy weight lifting program. This advice is mostly rejected by almost everyone involved in a heavy weight lifting program that has seen significant results (which are of course, tracked in a log book, like any good self-experiment).

Seth Roberts (2011-08-07 19:20:22)

I haven't tried just drinking cream. It's a good idea. Easy.

Adria (2011-08-10 11:05:14)

Actually, butter is not simply whipped cream. Butter has the buttermilk (which contains most of the protein that was in the cream) drained off.

## **At the Ancestral Health Symposium (2011-08-06 05:00)**

I am in Los Angeles for the Ancestral Health Symposium. I am giving a talk called "What Foods Make My Brain Work Best?" Readers of this blog won't be surprised: I will talk about flaxseed oil, pork fat, and butter. On Thursday, there was a party at Aaron Blaisdell's house for presenters and volunteers. It was kind of magical to see at the same party Mark Cohen, Gary Taubes, Denise Minger, Mark Sisson, Jimmy Moore, Boyd Eaton, Loren Cordain, Chris Masterjohn, and Tucker Max. Plus others, such as Staffan Lindeberg, whom I didn't manage to meet. More like an historical tableau in a mural or tapestry than an actual event.

There was more meat than any other party I've ever been to. Grilled outside. Mostly steak but also boar and salmon. It was delicious. I wish I knew the name of the grillmaster so I could thank him.

---

David (2011-08-06 18:53:21)

Were the steaks grass finished or corn fed?

Chris Sturdy (2011-08-06 22:36:52)

Hi Seth, His name was Christian, and his last name escapes me at the moment, but he is John Durant's cousin. Nice to meet and chat with you. Cheers, Chris

Seth Roberts (2011-08-07 11:48:58)

David, I didn't ask about the steaks but probably they were grass fed.

Aaron Blaisdell (2011-08-07 18:01:09)

The steaks were grass fed, donated by US Wellness meats. The chef is Christian Page. Richard Nikoley (free the animal blog), Stephan Guyenet (whole health source blog), Dr. BG (animal pharm blog), Emily Deans (evolutionary psychiatry blog), Jamie Scott (that paleo guy blog), John Durant (hunt gather blog), Melissa Mcewan (hunt gather love blog), Don Matesz (primal wisdom blog), Robb Wolf (paleo solution), Mat Lalond (aka the Kraken), and Craig Stanford were there as well.

Chris (2011-08-07 20:06:26)

I think the term is pitmaster rather than grillmaster.

David (2011-08-10 06:59:31)

So all beef is grass fed for a while at least. Grass \_finished\_ beef is quite pricey, so if you were getting that then you had some very generous patrons. When I buy grass finished beef, the poor clerks think they made a mistake when they see the total. David

## The Curious Popularity of "How To Win an Argument With a Meat-Eater" (2011-08-07 05:00)

Denise Minger started her presentation at the Ancestral Health Symposium (titled "How to win an argument with a vegetarian") with a comparison of number of Google hits:

"how to win an argument with a meat-eater": 53,700 hits

"how to win an argument with a vegetarian": 7 hits

Why all this concern with winning arguments? Sure, vegetarians are outnumbered, but shouldn't the results speak for themselves?

Denise went on to make the excellent point that some of the most popular proponents of less meat and low-fat diets, such as Dean Ornish, base their claims on experiments with complex treatments. Group A (no meat, low fat) turns out to be more healthy than Group B (baseline) but the two groups differ in twenty other ways. Group A eats less sugar, gets more exercise, eats less processed food, and so on. But, as Denise said, it must be the vegetarianism.

---

ala lala (2011-08-07 17:58:36)

It's a bit harsh to lump all vegetarians in the low-fat diet camp. A significant percentage of south-asians are vegetarians for cultural reasons rather than healthy reasons. Additionally, many vegetarians may chose the meat free life style for ethical reasons. The hits for "how to win an argument with a meat eater" may in fact be from people that need a list of strong arguments to support their moral choices. As a non vegetarian I enjoy pork belly, chicken liver, bone marrow and other "exotic" animal parts (many cooked in butter). However, I also use arguments from the "how to win an argument with a meat eater" when trying to raise awareness about current un-sustainable and often un-ethical meat producing practices.

Seth Roberts (2011-08-07 19:22:28)

The particular diet gurus, such as Dean Ornish, that Denise discussed did in fact recommend low fat diets. Keep in mind that the Google hit comparison and the inference discussion (what can we learn from an outcome difference between Groups A and B) were separate parts of her talk.

Tomas (2011-08-08 01:39:16)

I understand that some vegetarians might avoid meat for purely ethical reasons. But if you look at their approach from a different angle, you can see that their cause is not that noble - they are just avoiding the responsibility of finding an "ethical" source of meat. That equals hypocrisy in my book.

Forrest (2011-08-08 15:00:43)

Actually, I googled "how to win an argument with a vegetarian" and got over 14,000 hits. But only 4 for "vegan". I think the point still stands, though. To me, the question is this: How many people switched to paleo diets from vege- diets due to health problems, vs. the other way around? When she asked for a show of hands of recovering herbivores, it seemed like it must have been a fifth of the room! Is there even one person that got sick on the paleo diet and stopped eating all meat?

Seth Roberts (2011-08-08 16:20:12)

Re 14,000 hits: Because of Denise's talk. When she googled it, there were 3 hits. By the time I got around to googling it, there were 7 hits. Re the number who switch from vegetarian to paleo versus the other way. Yeah, except vegetarian is many thousand times more popular. Hard to correct for that.

Alex Chernavsky (2011-08-08 18:09:24)

A couple of points: Seven years ago, I switched from an Atkins-type diet to a purely vegan diet. I did it entirely for ethical reasons, after I started working at an animal shelter that houses both domestic pets and farm animals. After spending time with different types of animals and learning about them, I came to the conclusion that all sentient beings have an interest in avoiding suffering and living out their lives. (Of course, this idea is hardly original and is – or ought to be – fairly obvious.) Another point: There is no morally relevant difference between eating *flesh* versus eating *eggs* or *dairy products*. It's all the same, and it all involves suffering and death. In fact, there is probably more suffering in a glass of milk or an egg than there is in a steak. (A single cow produces a lot of meat, and hens and dairy cows typically live under quite horrible conditions.) After I switched from a low-carb diet to a vegan diet, I did gain weight – but I lost it again after doing Seth's Shangri-La diet. Other than the weight gain, I have not noticed any change in my overall physical health or mental status. At some point, I need to do some research to figure out what aspects of the paleo diet might be both healthy and amenable to being veganized.

William S. (2011-08-09 20:34:48)

Vegans and vegetarians define violence down. All farming kills sentient creatures.

Alex Chernavsky (2011-08-10 04:34:22)

@William S. – the issue is with *numbers* of creatures. See, "Least Harm: A Defense of Vegetarianism from Steven Davis's Omnivorous Proposal", by Gaverick Matheny. *JOURNAL OF AGRICULTURAL AND ENVIRONMENTAL ETHICS* Volume 16, Number 5, 505-511. [http://ethik.univie.ac.at/fileadmin/user\\_upload/inst\\_ethik\\_wiss\\_dialog/Matheny\\_G\\_2003\\_Defense\\_of\\_Veg\\_in\\_J\\_Agric\\_Ethics.pdf](http://ethik.univie.ac.at/fileadmin/user_upload/inst_ethik_wiss_dialog/Matheny_G_2003_Defense_of_Veg_in_J_Agric_Ethics.pdf)

David (2011-08-10 06:54:52)

@Tomas: Ethical meat is pretty expensive. It's hard to imagine any but the most affluent buying grass finished beef. Ethical eggs are pretty cheap though.

## Andreas Eenfeldt on the Ancestral Health Symposium (2011-08-07 10:33)

I'm beginning to think Andreas Eenfeldt, a Swedish doctor, gave the very best talk at the just-finished Ancestral Health Symposium. (Which was full of excellent talks.) And I missed it. Well, that's what the Internet is for. His talk was about the spread of paleo ideas in Sweden. Apparently not all establishments are hostile to all new ideas. Someone told me that sales of butter in Sweden have recently increased 40 %.

Eenfeldt has written [1] a great series of posts about the Symposium.

1. <http://www.dietdoctor.com/>

Chris Sturdy (2011-08-07 18:56:55)

I saw his talk and it was great! Almost seemed like he was talking about a different planet since people actually agreed that conventional advice for diet was wrong.

Kim Øyhus (2011-08-08 22:46:46)

The insecticide my parents used in our cabin many years ago was just a couple of atoms different from a neurotoxin developed for warfare, and it was very efficient against insects. But if it is that close to being directly lethal to humans, then it is likely to be damaging to humans, just not obviously so, because they test against that. And then there are all the random chemical reactions happening everywhere, surely changing some the insecticide to variants of the one for killing humans. And then there is the farmer branch of my family tree, with a lot of clearly inherited aquired genetic defects. The farmer who was said to be sloppy with insecticides.

dearieme (2011-08-09 02:45:43)

"a couple of atoms different from a neurotoxin developed for warfare, .... But if it is that close to being directly lethal to humans..": chemistry doesn't work like that. Common salt is just one atom different from a toxic gas and a flammable metal.

Kim Øyhus (2011-08-09 07:01:01)

Example of a nerve toxin similar to an insecticide: Organophosphates are fairly complex poisons, where small differences can give similar properties. Sarin is a potent nerve toxin for humans. <http://en.wikipedia.org/wiki/Sarin> Diisopropyl-fluorophosphate is an insect poison, but to humans it is a medicine. It has a molecule very similar to Sarin, except it has two iso-propane groups instead of one. [http://en.wikipedia.org/wiki/Diisopropyl \\_fluorophosphate](http://en.wikipedia.org/wiki/Diisopropyl_fluorophosphate)

Seth Roberts (2011-08-10 00:39:03)

"Common salt is just one atom different." But common salt has just two atoms – obviously changing 50 % of a molecule will make a huge difference. The pesticides that Kim is talking about have far more than two atoms.

Alrenous (2011-08-10 10:02:39)

I want to see that justice study, except done on judges on a paleo diet or otherwise not sugar-addicted.

## **Top and Bottom Versus Middle: China, Schools, Health? (2011-08-09 05:00)**

[1]My explanation of the Ten Commandments is that someone at the top (Moses) was trying to convince people at the bottom to join him. People at the bottom were being preyed upon. "Thou shalt not steal" meant, to Moses's audience, "no one will steal from you – or at least we, your leaders, will discourage it." At the very beginning of [2]the Code of Hammurabi, another ancient set of rules, it says one purpose of the rules is "so that the strong will not harm the weak".

I keep seeing this pattern – people at or near the top of the hierarchy making common cause with people on the bottom against people in the middle. I was reminded of it by [3]this story:

One anecdote described a Hu Yaobang [top Chinese leader] visit that Mr. Wen arranged with Guizhou Province villagers — secretly, he wrote, because Hu Yaobang did not trust local leaders to let them speak freely.

In the 1960s, the U.S. civil rights movement gained considerable force and accomplishment when the very top of the government (first, President Kennedy and Attorney General Robert Kennedy, later President Johnson) weighed in on the side of the protesters (bottom) against the various state governments (middle).

The practical value of this alignment of forces is illustrated by [4]How to Walk to School, a book about school reform (which I reviewed [5]here). Two mothers of young children, Jacqueline Edelberg and another woman, wanted to improve their neighborhood schools before it was too late for their own children to benefit. On the face of it, this was impossible. But they found common cause with the principal of a local school (Susan Kurland). It goes unmentioned in the book but my impression, reading between the lines, is that the main thing that happened is that the worst teachers were shamed into leaving, above all by parents sitting in their classrooms. The principal alone could do nothing about terrible teachers; the parents alone could do nothing; together they did a lot. I spoke to Edelberg about this and she agreed with me.

I point out this pattern because it works. Judaism (Moses) still exists; people still read the Old Testament. Even more powerfully, all governments have lists of laws (Hammurabi). Jacqueline Edelberg's neighborhood school is much better. The next big revolution in human affairs, I believe, will be health care. The current system, in which people pay vast amounts for drugs that barely work, have awful side effects, and leave intact the root cause (e.g., too little dietary omega-3), will be replaced by a much better system. The much better system will be some version of paleo. As [6]Woody Allen predicted, people will come to believe that butter is health food.

How will it happen? I suspect this pattern will be the driving force. People at the top and people at the bottom will put pressure on people in the middle. Self-experimentation, self-quantification, and personal science (which overlap greatly) are tools of people at the bottom. They cost nothing, they are available to all. When you track (quantify and record) your health problem, and show your doctor, via numbers and graphs, that the drug he prescribed didn't work, that puts pressure on him. When you bring your doctor numbers and graphs that show a paleo solution did work,

that puts even more pressure on him. The point, if it isn't obvious, is that numbers and graphs, based on carefully collected day-after-day data, amplify what one person can do. Not just what they can learn, not just how healthy they can be, but how much they can influence others. And this amplification of influence, which I never discuss, may ultimately be the most important.

Kirk (2011-08-09 11:16:42)

Agreed. I wonder how long it's going to take to change their minds. When I went in for my recent annual, I brought a full-page description of my various exercises, resting heart rate, morning and afternoon BP, morning, one-hour, and two-hour blood glucose readings after a typical meal, supplements, and description of diet (paleo) . . . and his response was to advise me that we all get sick and die. He sees himself as a mechanic, and his virtuous fight is against his penny-pinching administrators , the insurance companies, and Big Pharma. Oh well. I just go in there for the insurance-covered physical, to ask a few questions, and to get the covered blood tests. One book which impressed me this year was *The End of Medicine* by Andy Kessler. I also liked the TED talk by Daniel Kraft: 'Medicine's future? There's an app for that' .

Tom (2011-08-09 13:12:36)

And if you're *really* devious, you can manipulate the lower class into attacking themselves as well. Thus we see the Murdochs and the Koch brothers propagandizing working class evangelicals into voting for people who slash taxes on billionaires – all while collapsing the dollar (a gigantic, invisible tax on the middle and lower classes.) Ted Turner famously said "Christianity is a religion for losers." Boy, did he nail it.

Noumenon (2011-08-12 04:24:56)

In the first link you said, "I predict that someday someone in the American government (top) will realize that a way to greatly improve health care is to empower patients (bottom) against doctors (middle)." My father wants to know where insurance companies fit into this. Are there two middles?

### **Ancestral Health Symposium: Meat versus Fat (2011-08-10 05:00)**

Yesterday I was telling a relative about the Ancestral Health Symposium and I mentioned the emphasis on meat eating – for example, two vendors gave out samples of beef jerky. To most people, I think paleo means eating lots of meat. I told my relative I disagreed with this. I find nothing wonderful about meat protein; I would happily get my protein from plants. I eat meat almost only for the associated fat. Which I can get from butter. A lot of meat I am served, such as in fancy restaurants, strikes me as too low in fat. Yesterday I requested butter at a sushi restaurant. The waitress was unsure if they had some.

Today I see Melissa McEwen [1]said the same thing much better:

It was interesting to observe that [at the Ancestral Health Symposium] among the low-carbers, there seemed to be an epidemic of puffy red skin, particularly in older men. I'm sure the pictures, when they are posted, will make obvious who these people are. The ones who had healthy complexions like the Eades and Nora are those espousing a high-fat diet. It goes very well with some of the anthropological stuff I've been working on showing that almost all cultures that eat meaty diets are doing so because they have access to high-fat game.

1. <http://huntgatherlove.com/content/ancestral-health-symposium-part-1>

---

Ahrand (2011-08-10 06:24:21)

That's why they called it the Ancestral Health Symposium, not (only) about the paleo diet which seems to be mostly 'Atkins for hippies' (the high protein, low carb part). There are notable exceptions, even at the AHS : - Dr. Lynda A. Frassetto from UCSF - Don Matesz from [donmatesz.blogspot.com](http://donmatesz.blogspot.com) Who advocate low protein (to maintain proper PH balance)

Jay (2011-08-10 06:45:48)

Hello Seth, I apologize for not being familiar with you before this, I stumbled in through some AHS links. I'm curious what you personally consider good sources of plant protein? I've tried to do a cursory scan of your blog to find out but I'm coming up empty - I'm sure it's there, I'm just not doing a very good job of tracking it down.

David (2011-08-10 07:01:17)

Seth, you're awesome! First you told me I could lose weight by drinking sugar water, now you tell me I can be smarter by eating sticks of butter. David

Seth Roberts (2011-08-10 09:49:20)

Jay, I have never blogged about good sources of plant protein. I don't know anything you don't know: that we need several different amino acids to make muscle and other proteins and therefore you need protein from several different plant sources if you want it to be well matched to the needs of your body. For example, I've heard that the combination of rice and beans are well-matched, i.e., rice and beans are good complements. Whereas animal protein is already well-matched.

Owen (2011-08-10 13:14:33)

Seth, this is a good point you make and it also ties in to the somewhat misguided anti-vegetarian stance of a lot of the paleo superstars. You don't need to eat meat to get good quality protein and in fact meat is by no means the best source: <http://en.wikipedia.org/wiki/PDCAAS> (Although plant protein comes out looking extremely problematic on that level as well, unless you are willing to consume soy as a bulk food source, which has very well documented problems of its own...) Paleo theory can go on about how milk isn't "paleo" (I'm not entirely sure where they stand with the Maasai these days), but if you can escape that paradigm, dairy (and egg) protein has some excellent qualities to consider: they are higher quality than muscle tissue, generally cheaper, more convenient to prepare and eat when you are busy, may have a less inflammatory amino acid balance than muscle and are much lower in oxidative iron. Egg yolk can, to an extent, function in place of organ meats as a good source of retinol, B-vitamins and cholesterol. In truth though, I am not vegetarian and do enjoy eating all manner of steaks, lamb, offal, game birds, seafood, etc., but I do it with the mindset that it is a sensory treat and not the credo that it is the ideal food for everyone at all times. Though, one thing you can say pretty accurately is that red meat is one of the best sources of dietary zinc.

Vic (2011-08-10 16:50:34)

"The ones who had healthy complexions like the Eades and Nora are those espousing a high-fat diet." uh, the Eades' web sites are called [eatprotein](http://eatprotein.com) and [proteinpower](http://proteinpower.com) - and they don't get their protein from plants!

Lemniscate (2011-08-11 00:37:48)

Some of the meat enthusiasts don't focus enough on organ meat, as this would have comprised a much larger part of the diet of ancestral meat eaters than it does for modern meat eaters. Eating endless bovine muscle meat might be a good way to put on muscle (although whey protein and egg protein would be cheaper), but I doubt it is as healthy as giving good space in the diet to organ and bone based dishes, which tend to be much more nutritious.

Adria (2011-08-11 07:24:54)

@ Vic I think the reason the Eades have that titular focus on protein is due to pressure from their publishers, and because of the public's irrational fear of fat. If you actually look at the content of the diet they recommend, they are by no means suggesting low fat, and actively suggest eating saturated fat. A "high-protein" diet is code for high-fat. Compare that with, for example, Cordain, who has been claiming that hunter-gatherers ate a low-fat diet because wild muscle meat tends to be lean. (He seemed to ignore observations of HGs noting that the fat, brains, marrow, and organ meat are prized, and often eaten first). @ Owen I think a lot of the AHS "big names" have moved away from paleo as historical reenactment and more using it as a guiding principle, a la Kurt Harris or Peter "Hyperlipid" or the Jaminets. Personally, one of the reasons I am so late to the paleo party is that, as someone who studied archaeology, the idea that we can reconstruct details of diet during the paleolithic struck me as extremely silly. If we use it more as a way to generate testable hypotheses about what may or may not be good for us, it becomes a much more interesting idea. For me, anyway.

Owen (2011-08-11 08:13:42)

Adria, definitely agree, especially regarding Peter. His views on protein are very compelling to me: he limits it to around 65g/d (this was in 2008, so I'm not sure if it's still accurate) and so he mentioned that he enjoys "spending" his "allowance" on meat, rather than egg white or milk protein (this is why he uses only yolks and cream for fat, rather than whole egg and milk...) His reasoning... "This comes from Dr Kwasniewski's ideas. The basic plan is to minimise insulinaemia and also metabolic work by the liver. Using the highest quality protein minimises the total amount and also the requirements for amino acid transformation. No point in using more than needed." (<http://high-fat-nutrition.blogspot.com/2008/01/what-do-i-eat-fitday-analysis.html>)

Thomas Seay (2011-08-11 09:45:20)

The problem with the "Paleo" diet is that its very name implies that we KNOW what Paleo man ate AND we SHOULD eat that way. It's a nice name for a fad, because it is simple to grasp and has a "jingle" quality to it like a radio ad. As such, it becomes somewhat difficult for people to get unglued from Paleo dogma. Do we really know what our ancestors ate? Have we stopped evolving? Was what Paleolithic people ate really what is the healthiest for us? Don't we live in a different time and environment (pollution, stress, etc) in which maybe we need to eat differently? I think "Paleo" isn't useful or helpful anymore. It could even be a construct that limits our ability to see better possibilities.

Tyler (2011-08-11 10:55:32)

@Thomas For me, the term "paleo", with regards to what we eat, simply means cutting grains and legumes out of my diet. I think there's very little room for argument as to how that can be a bad move. Beyond that, however, there exists many different opinions. High fat, low fat, dairy or not... That's all evolving. But I think there's merit to that foundation.

08/12/11 - Deadlift + Sprints (2011-08-11 18:01:45)

[...] Meat Vs. Fat - Seth's Blog [...]

David (2011-08-11 20:37:44)

I also wonder if it's even possible to eat the way paleolithic man ate unless you live in the country and can get a lot of calories from game animals. But even those game animals will have eaten a lot of crops planted by man and so might not offer the same nutrition to the cave man wannabe.

## The Beer Archaeologist (2011-08-11 05:00)

Patrick McGovern is a professor of archaeology at the University of Pennsylvania who studies fermented beverages. [1]His work reveals their long history. Just like modern nutritionists, modern archaeologists overlook this:

Many of McGovern's most startling finds stem from other archaeologists' spadework; he brings a fresh perspective to forgotten digs, and his "excavations" are sometimes no more taxing than walking up or down a flight of stairs in his own museum to retrieve a sherd or two. Residues extracted from the drinking set of King Midas—who ruled over Phrygia, an ancient district of Turkey—had languished in storage for 40 years before McGovern found them and went to work. The artifacts contained more than four pounds of organic materials, a treasure—to a biomolecular archaeologist—far more precious than the king's fabled gold.

Beer figures more in his work than wine. I'm not surprised. I'm a beer snob. The best beers at [2]a recent beer tasting were far better than the best wines at similar wine tastings. The upper-class preference for wine over beer may have the same explanation as earlier upper-class preferences for white rice over brown rice (rich Japanese got beriberi more than poor Japanese) and white bread over dark bread. Or it may also have something to do with the fact that cheap beer in America is terrible.

Thanks to [3]Melissa McEwen.

---

Glen Raphael (2011-08-11 06:58:47)

> "I'm a beer snob." That data point might help explain why I couldn't personally reproduce your "complex tastes are better" claim. I recently went to a beer tasting run by a beer snob. There were a couple dozen beers available that were supposed to represent the widest possible variety of types. The problem I had with all of them was that they "tasted like beer". The only thing called "beer" I find somewhat tasty (rather than wince-worthy) is a Belgian Lambic which tastes \*nothing\* like beer - it tends to taste like a strawberry wine cooler. Do you have any suggestions for \*learning\* to like beer? Or to at least tolerate it?

Seth Roberts (2011-08-11 10:21:10)

how to learn to like beer: first you must learn to like the taste of alcohol. That happens just by drinking alcoholic beverages. if you already like the taste of alcohol, I'm puzzled.

dearieme (2011-08-11 13:23:09)

Beer is an acquired taste. People, or at least men, used to acquire it late in adolescence - though I must say that many Brits no longer acquire it and so drink lager instead, largely muck in the style of cheap American beer. If even that is too manly for them then they drink spirits with 'orrible additives.

garymar (2011-08-11 16:40:00)

Beer is the great summer thirst quencher. How good it tastes right now in the northern hemisphere! But I usually stop and switch to wine around mid-September.

BarryBrolley (2011-08-11 18:25:45)

Seth, Seems Matt Lallonde liked your question: <http://robbwolf.com/category/podcasts/> (go to episode 92 19 minutes in) Barry

Glen Raphael (2011-08-11 19:21:32)

I don't much care for the taste of alcohol generally but I like the taste of wine, especially white wine. And can drink some dessert-type liquors. I have no trouble at all drinking wine on social occasions. When you say "The best beers at a recent beer tasting were far better than the best wines at similar wine tastings." - My contrary sense is that all beers taste more-or-less bad - it's a chore to try to finish even \*one\* bottle of (any variety of) beer. Whereas all wines taste...fine. Some taste pretty good. Wines that are considered especially "good" don't taste noticeably better than average. In blind taste testings even experts can't reliably tell the difference between an expensive wine and a cheap one - it's mostly about expectation - so at a restaurant I tend to go with the cheap one. Anyway, put me down as a data point: I like wine over beer because beer reliably tastes terrible, though I've tried "good" beers. (Beer is fine as a food ingredient, just not as a drink.)

Seth Roberts (2011-08-12 07:34:51)

Thanks, Barry. Nice to hear. It's a great podcast.

Owen (2011-08-12 11:52:51)

When people say they don't like beer, I always assume it's the bitterness from the hops that is bothering them. Good American craft beer is usually incredibly hoppy unless they are imitating a European style and using noble hops. And on the other side you have cheap American beer that is bland because it is brewed with a huge proportion of rice and not so great. But I think non-beer drinkers might have the best luck trying a Belgian or English ale that tends towards being malty and spicy or nutty and hides the bitterness and alcohol well. Leffe Blond and Fuller's London Pride are two that might be worth a shot and aren't hard to find. I worry about drinking beer a lot thought, because the hops really are strongly estrogenic: <http://jcem.endojournals.org/content/84/6/2249.abstract> My new interest is to track down some of these traditional Scottish-style ales being brewed by Williams Bros, where in lieu of hops they use either heather or Scots pine to flavor the beer. I've heard they are very unusual and drinkable!

Seth Roberts (2011-08-12 18:58:03)

That's a subtle and helpful take on the whole thing, thanks, Owen. It's true, I don't like bitter beers. I like the spicy, malty, nutty ones.

## **What We Learn From the Better Health of Vegetarians (2011-08-11 17:00)**

Lots of people think it's obvious: vegetarians are healthier than omnivores in Study X. Therefore vegetarianism is healthy. This is such a common line of argument that I draw your attention to [1]Denise Minger's slides for her talk at the Ancestral Health Symposium, which I have [2]already blogged about. The slides make clearer than I did what she said. It's all excellent but the best part is at the beginning where she points out the many confounds in the studies of Dean Ornish, Neal Barnard, Caldwell Esselstyn, and John McDougall. They change many things but - as Denise put it - What caused the benefits? It must be the vegetarianism! Paleo humor.

There are lots of other interesting things in Denise's talk, as you will see, such as the health of religious vegetarians.

1. <http://www.slideshare.net/ancestralhealth/ahs-slidesdenise-minger>
2. <http://blog.sethroberts.net/2011/08/07/the-curious-popularity-of-how-to-win-an-argument-with-a-meat-eater/>

---

Shane (2011-08-11 17:53:17)

Wait, what? Correlation is not causation?

Jon (2011-08-11 22:37:02)

One of the slides is misleading. The exercise comparison was 70 % compared to 80 %. Proper charting says you always start your bar chart at 0, the person that did the chart started at 50 or so. Otherwise, interesting, not a lot of info, just the last slide that gives a website to look at. Will make me look at it a little closer when I do comparisons in the future. BTW, bought your book and have been losing weight. It'll be nice when I get down to my desired "ideal". Maybe then I'll be able to run again without getting injured all the time.

Seth Roberts (2011-08-12 07:27:42)

Shane, the data Denise was talking about (Ornish, etc.) is not correlational – that is, from a survey. It's from experiments. Moreover, one of Denise's slides is about "religious vegetarians" – what we can learn from them. The data in that slide is correlational. I believe that data is helpful. To claim, as Denise did (and I agree), that you can learn something helpful from survey data is roughly the opposite of "correlation is not causation".

### Assorted Links (2011-08-12 05:00)

griff (2011-08-13 14:19:12)

Thanks for pointing out the excellent Vanity Fair article on Germany and finance. Nevertheless, parts of it made me laugh out loud as I had recently seen this via a reddit link. <http://asecular.com/scott/misc/toilet.htm>. Apparently Germans really do like to inspect their fecal matter.

Sam (2011-09-03 13:09:39)

According to a beekeeper the CCD problem is mainly caused by beekeepers themselves: Beekeepers tended to be annoyed by some sticky stuff bees produce and for decades bred bees which produced less of this sticky stuff. Problem is, this sticky stuff (called propolis) is important to bee health and by breeding this out of the bees they made them more susceptible to health problems, which 'assisted' in CCDs.

## More Migraine Headaches Caused by Cleaning Products: From N=1 to N=2 (2011-08-13 05:00)

At Thursday's Quantified Self Silicon Valley Meetup (where I gave a talk called [1]QS + Paleo = ?), Alexandra Carmichael introduced herself with the three words "no", "headache", and "today". About five days earlier, she had started having migraine headaches every day. Before that, she hadn't had a migraine headache in a year. After the headaches began, her husband, having read [2]my Boing Boing story (about a woman whose migraines were mostly from cleaning products), suggested that her headaches might be caused by the [3]Febreze they had just started using. They stopped using it. Because it can linger in carpets, etc., they cleaned their whole apartment with vinegar and baking soda, to get rid of all traces. That's when Alexandra's headaches stopped. When they started using Febreze, one of their daughters became very cranky. After they stopped using it and cleaned their apartment, she returned to her usual self.

Other people have found that Febreze gives them migraines. For example, [4]R. Haeckler:

[Febreze] gives me terrible migraines. . . . Whenever I go to someone's house who uses it I get a headache almost immediately that lasts the rest of the night.

And [5]this woman ("No Febreze EVER. Gives me a headache and makes me dizzy").

This is a good example of why n=1 experimentation is so important. The woman I wrote about for Boing Boing (Sarah) figured out, beyond any doubt, that certain cleaning products caused migraines. Yes, Sarah's results were unusual. They "don't generalize" to most people in the sense that most people don't get migraines from cleaning products. But, as Alexandra's story shows, they were still helpful – they helped Alexandra avoid migraines.

My writing about n=1 experimentation has emphasized learning widely-applicable truths – how to lose weight, sleep better, and so on. But this other use – learn stuff that is true only for you and perhaps a small subset of people (1 %?) – is also important. Sarah's n=1 experimentation doesn't fit in the standard healthcare system. It was not suggested or encouraged by her doctors. No professor or researcher could write a paper about it – it's too small. But it made a difference – first, to herself, now, to Alexandra. The results of n=1 experiments can be spread, however, in the new patient communities, such as the ones at [6]PatientsLikeMe, [7]MedHelp, and [8]CureTogether (started by Alexandra and her husband).

When I submitted for publication [9]my long self-experimentation paper, one of the referees decided he would find out if fructose water would help him lose weight (one of my examples). He discovered that fructose water made his fingers ache – he had a sensitivity to fructose he hadn't known about. In his review, he said that these sorts of individual differences were not an argument against my method but actually favored it: We need n=1 experiments to fully understand human variation in health.

Around the Web; Post-AHS Edition | Perfect Health Diet (2011-08-13 10:48:00)

[...] Roberts reports that cleaning products such as Febreze can cause migraines and cranky mood. Vinegar and baking soda [...]

Bryan (2011-08-13 16:25:17)

Febreeze and most colognes and perfumes have always given me a headache too. (My dad is the same way so perhaps there's a genetic component.) I always avoid them.

q (2011-08-14 05:06:11)

some chemical in Tide makes me unable to sleep if i am around it too much. it's the scent, not the detergent as I often use Unscented Tide (at the very least I don't like cleaning scents whether they are harmful or not) and have no problem with it.

David (2011-08-14 19:34:07)

Strong chemical smells also give me headaches. but I don't think they're migraines (i.e. they're annoying but not debilitating). My daughter had some fresh finger nail polish on the other day and very quickly I had a headache. So the proposition that the smell of certain chemicals trigger migraines in some people sounds quite plausible to me.

Pasta Maker (2011-08-15 12:48:34)

This is interesting. Thinking back, I always have headache when using most of the perfumes, and my friends never believe about my claims that the perfumes are causing me headaches. After reading this, I'm relieved that maybe it is not just my imagination that the perfumes are causing me the headaches.

Dr.Zachar (2011-08-15 15:25:40)

That's interesting. I'm always one to opt for NATURAL cleaning products of the sort. Thanks for the informative post though!

More migraine headaches caused by cleaning products: from N=1 to N=2 | It's like, Really? (2011-08-17 17:21:06)

[...] More Migraine Headaches Caused by Cleaning Products: From N=1 to N=2 [...]

Syngen (2011-08-17 18:53:09)

I would venture that it's the fragrance component of the Febreze that's offensive and probably not the  $\beta$ -cyclodextrin. I'm actually very curious to know if these migraine sufferers react the same way to unscented Febreze? I think the cyclodextrin molecules are too big to get properly airborne? Of course this would require a double blind randomized trial. (I'm a scientist so even with self experimentation I run the control. My doctor made fun of me for doing that last time I had an appointment.) Also, "natural" cleaning products are usually just similar surfactants with some citronellol to make it smell "natural." I'll grant that that I'd rather the citronallol than the artificial scents, but still. The marketing of this stuff drives me bonkers.

E A R (2011-08-17 20:28:44)

I haven't been able to use any scented cleaning products for 30 yrs. For many with these headaches (and other types), inhaling natural peppermint oil eases them. It's cheap. Or you can grow mint in a window box.

Joanna (2011-08-17 22:03:05)

The Febreze / headache case is not an outlier. Here is an example of a WHO meeting in May where Spanish physicians demanded inclusion of multiple chemical sensitivity in the WHO ICD10 code list. <http://www.ei-resource.org/columns/multiple-chemical-sensitivity/world-health-organization-meeting-on-mcs-and-ehs/> What is interesting is the number of people affected – estimated at around a 15 % prevalence worldwide. Then add in the migraine sufferers, asthmatics, people with chronic respiratory conditions... chemical triggers are very common in these illnesses, as well as less obvious illnesses such as chronic fatigue and fibromyalgia. For some reason doctors refrain from informing patients about such common irritants, and most people have no idea of the epidemic happening right in front of them.

More migraine headaches caused by cleaning products: from N=1 to N=2 « News Xazri (2011-08-18 04:23:47)

[...] More Migraine Headaches Caused by Cleaning Products: From N=1 to N=2 [...]

Barry Spencer (2011-08-18 22:50:55)

A trial study involving only one subject can't demonstrate that Febreze causes migraine episodes in some people, because a trial using only one subject can't rule out coincidence. People who blame their migraines on odors are mistaking symptom for cause. Migraine symptoms can include "olfactory aura:" olfactory amplification, olfactory distortion, and even olfactory hallucination. Olfactory aura, like visual aura, often precedes the headache phase. Many migraine patients notice and remember strong or unusual odors right before onset of headache, and mistakenly conclude the odor must have caused or triggered the subsequent headache. The truth is, by the time they noticed the odor, the migraine episode had already been developing for some time. It's not odor → headache but rather odor amplifies headache.

Seth Roberts (2011-08-19 05:26:28)

Barry, in my story about a woman who cured her own migraines, the woman discovered that if she avoided chemicals called artificial fragrances her migraines became less common. Cause and effect was shown beyond doubt. In this case, I think the chances of it being a coincidence are very low.

Rachael (2011-08-23 13:32:47)

It may be that some people have olfactory auras, but I absolutely get headaches, and migraines from artificial, and even some natural fragrances. Every year when the lilacs bloom, hyacinth and lily of the valley too, I have constant headaches. I am not hallucinating flowers, and the life-long consistency of the response is pretty telling. However, it is interesting to me that I can lower my sensitivity in other ways. For years any strong floral scent gave me migraine, but changing my diet, exercising enough but not too much, taking magnesium and B vitamins, etc. have lowered my sensitivity so now only lilac time and stores that sell many scented products give me migraine. Any way, it's hardly n=1, google fragrance migraine trigger and there are thousands of hits. (I use only unscented household products because I also get serious eczema from scented products.)

Asteroid (2011-09-10 08:58:51)

My migraines are without a doubt CAUSED by aerated Chemical cleaning products. Caused. Not amplified. I use natural liquid cleaning products only. I can without a doubt prove this if given a scientific environment. I can't be around any aerated artificial scents either such as junk perfume (and some 'nice' ones) febreze air fresheners etc. The funny thing is, I've found that if I have a bad migraine I usually have a severe sneezing attack at some point. At which time the headache, auras, nausea and blurriness start to dissipate. For the life of me though I can't force myself to sneeze before that though. I wish I could.

Seth, here is another one you'll probably like : <http://blog.jayparkinsonmd.com/post/4024600220/what-happens-to-doctors-who-think-outside-the-box> Via <http://hunter-gatherer.com/>

Erik M Jacobs (2011-08-14 06:34:45)

Unfortunately, the colonic health study does not appear, at first glance, to indicate the specific sources of the foods provided. It is likely that typical factory/industrial foods were provided to the individuals in this study. It would be interesting to see the results of HP/hflc industrial compared to 'primal'/paleo non-industrial hp/hflc.

Tom (2011-08-14 09:52:01)

Seth, The spoiled food link doesn't work.

Kudzu Bob (2011-08-14 16:35:30)

Interesting that taurine may be helpful for eczema. Isn't taurine a sulfur-rich amino acid? If I recall correctly, sulfur—particularly in the form enjoyed by people who bathe in those hot springs that smell like rotten eggs—has long been reputed to promote skin health. Incidentally, on the same thread that you link to, one commenter remarks upon the beneficial properties of MSM lotion for eczema. MSM also contains a lot of sulfur. As for my own eczema, a type that my doctor called "neurodermatitis," I suffered with it for the better part of a decade. Once I finally understood that what goes into my mouth might actually have some bearing on the state of my health, I began to consume both flax oil and fish oil. Within two months my condition had improved to the extent that I no longer needed a dermatologist. I don't miss him, his ineffectual steroid creams, or his bills one bit. I have been eczema-free for several years now. I still take omega-3, in addition to a number of other supplements, and enjoy excellent health.

Tomas (2011-08-15 02:45:18)

## **A Happy Reader Writes: Yogurt, Butter, Flaxseed Oil (2011-08-14 07:42)**

A reader of this blog started taking flaxseed oil, half a stick of butter daily, and yogurt. "This works wonders," he wrote me. "It feels like lubricant to the mind."

---

Ruth @ Ruth's Real Food (2011-08-14 22:47:38)

Seth, what kind of butter and yogurt do you take? Are they made from raw milk?

Seth Roberts (2011-08-15 20:14:43)

Ruth, I have tried many butters and a few milks. I have been unable to detect a difference between cheaper and more expensive butter. Including butter that costs \$10/pound, presumably made from raw milk. I don't make yogurt from raw milk. I make yogurt from DHA enriched organic milk.

Ezer (2011-08-15 21:55:42)

Seth, I started taking 260g of magnesium in form of magnesium glycinate and this works wonders too, my mood improved clearly. Do you supplement magnesium too? It would be interesting to evaluate. Now, I was thinking: maybe flaxseed oil is more effective than fish oil to improve cognitive function, not because ALA conversion to EPA and DHA, but mainly because ALA and EPA conversion uses elongase fatty acids, thus reducing elongase fatty acids available, needed to LA conversion into arachidonic acid, which could increase inflammation. What do you think about it? Very nice blog :)

Ruth @ Ruth's Real Food (2011-08-15 21:56:17)

Interesting. How do you actually ingest such a large quantity of butter? I usually use about a tablespoon and a half to make eggs in the morning, but half a stick is four tablespoons.

Ezer (2011-08-15 22:00:49)

Ruth, my two cents: I ingest 80g of butter with cooked hot sweet potatoes and coffee. this is delicious.

Seth Roberts (2011-08-16 04:41:29)

That magnesium effect is fascinating. I do not take magnesium but I will try it. It's not "elongase fatty acids" but "fatty acids elongase" (an enzyme that elongates fatty acids). Your idea makes sense to me but I cannot judge how plausible it is.

Tom (2011-08-16 06:23:06)

Michael Eades has written that as many as 70 percent of people don't even get the minimum RDA of magnesium: [1]Magnesium and Inflammation

1. <http://www.proteinpower.com/drmike/uncategorized/magnesium-and-inflammation/>

Tom (2011-08-16 06:24:09)

another by Dr. Eades (scroll down to magnesium section): [proteinpower.com/drmike/saturated-fat/tips-tricks-for-starting-or-restarting-low-carb-pt-ii](http://proteinpower.com/drmike/saturated-fat/tips-tricks-for-starting-or-restarting-low-carb-pt-ii)

Shawn (2011-08-26 07:30:18)

Isn't butter & other fats bad for your heart, arteries, veins, etc., despite the fact that it can help you sleep?

Martin (2011-11-21 08:08:49)

Flax seeds two tbsp (around 30 gram), making ground in grinder, mix with appropriate yogurt, that is the way to go I feel awesome after that, lots of energy and awesome mood. But indeed flax seed alone doesn't do that much, Yogurt boosts Flax seed job?

## **Deborah Estrin on Top and Bottom versus Middle (2011-08-15 05:00)**

[1]Deborah Estrin is a computer science professor at UCLA. Commenting on my recent post [2]Top and Bottom versus Middle: Schools, China, Health? she said "amen to that".

I asked her why she agreed. Because she sees the same thing a lot, she said. In particular, performance metrics are often devised by people in the middle, and those metrics tend to serve their interests – and not the interests of everyone else. She gave three examples: 1. Fee for service. Doctors are paid per office visit and per surgery, for example. The bad effects of this are obvious. For example, [3]surgeons are pushed to recommend ill-advised surgeries. 2. Financial instruments, such as derivatives. They were sold to outsiders as ways to reduce risk but we all now know they had the opposite effect. As [4]Michael Lewis puts it, "extremely smart traders inside Wall Street investment banks devise deeply unfair, diabolically complicated bets, and then send their sales forces out to scour the world for some idiot who will take the other side of those bets." 3. Publications. Professors are rated and promoted and to some extent paid based on how many publications they produce. This pushes them toward "safe" projects that are likely to produce a publication within a reasonable time and away from harder, more important problems.

When you measure yourself you can use whatever metric you want – and thereby a metric that serves your interests.

Tim Beneke (2011-08-15 12:08:43)

A friend who recently got her Ph.D. through the Berkeley psych dept describes how in her "professional seminar" a distinguished professor in the dept came and gave a talk and explained how by the time they got their Ph.D.s they needed to have about 7 publications. At least one should be in X journal; another should be in Y journal; the others should be in A, B, and C journals; etc. She loves doing psychological research and exploring ideas, but she found this rather shattering; it took some of the joy out of the process and biases the kinds of research people are willing to do...

### **Absence of Fermented Food From the Thoughts of a Foodie (2011-08-16 05:00)**

A diagnosis of stomach cancer and the need for radical surgery led a writer named Anna Stoessinger to plan [1]a series of meals before surgery. She and her husband care enormously about food:

My husband and I have been known to spend our rent money on the tasting menu at Jean Georges, our savings on caviar or wagyu tartare. We plan our vacations around food — the province of China known for its chicken feet, the village in Turkey that grows the sweetest figs, the town in northwest France with the very best raclette.

Yet in her two-page article she doesn't mention fermented food even once. (Leaving aside a mention of cheese.) Here are some foods she does mention:

- roast duck, crostini and rich fish stews
- roast chicken with leeks
- roadside cheeseburgers, bonito with ginger sauce, hazelnut gelato
- peanut butter and jelly doughnuts, ginger ice cream, sashimi, grilled porterhouse, wild blueberries
- candy
- foie gras and fig torchon
- butter-poached smoked lobster
- passion fruit coulis
- butter-seared scallops
- wild boar terrine and Guinness vegetable soup with rosemary whipped cream
- apple and cinnamon tarte tartin

Of the thousands of fermented foods, eaten daily by people all over the world from time immemorial, nothing. To me, it's like she's had a stroke and has spatial neglect. She is unaware of half the visual field but doesn't notice anything wrong. The absence of fermented foods from her article reflects the larger near-total absence of fermented foods in American restaurants (both high and low), supermarkets, cookbooks, newspapers, and health advice.

I no longer use cookbooks. I rarely use spices. I make the food I cook taste good by adding fermented foods – for example, miso or yogurt or stinky tofu or fermented bean paste. The result is much tastier than almost anything I can get in restaurants (if I say so myself) and no doubt much healthier.

Ms. Stoessinger's article reads like a series of boasts: look how much I know and care about food. I think that's part of the problem: You can't boast about fermented food. It doesn't require expensive skilled preparation to taste delicious. You can't impress guests with fermented food, you just serve it. A bowl of miso soup: big deal. The bacteria made it delicious, not you. So fermented food can't be a high-end product. Nor can it be a low-end mass-produced product because it takes too long to make, is hard to standardize, and is "objectionable" (e.g., stinky tofu). The growth of our modern food economy has pushed it to the margins, with very bad consequences for our health.

1. <http://www.nytimes.com/2011/08/14/opinion/sunday/i-wont-have-the-stomach-for-this.html?pagewanted=all>

---

Andrew (2011-08-16 05:38:57)

Are you sure fermented foods can't be high-end or impressive?! Wine, cheese...? I used to live in Korea, and a restaurant's reputation could be made or ruined by the quality of its various kimchi. The fermented skate is a very special delicacy (like Iceland's Hákarl), and also one of the worst things I've ever tried in my life. I live in Japan now, and in Kyoto especially, the humble pickle has definitely been raised to an art form. Certain mountain villages are as famous for their pickles as certain Turkish ones are for their sweet figs. On a side note, it's always the mountainous regions in Japan and Korea that are famous for their pickled foods. I always assumed this was because the colder winters meant they needed foods to keep, but I've been wondering lately if it's not equally because of limited access to fresh seafood, which fermented foods could compensate for somewhat nutritionally.

mike kenny (2011-08-16 06:12:28)

seth writes: "Nor can it be a low-end mass-produced product because it takes too long to make, is hard to standardize, and is "objectionable" (e.g., stinky tofu). The growth of our modern food economy has pushed it to the margins, with very bad consequences for our health." but don't they?—cheese, pickles, beer, yogurt—all fermented and mass-produced. one thing that really puzzles me is, why would stuff that smells objectionable be good for us, and indeed taste good? very odd—just going on a certain evolutionary logic, wouldn't we be wired to want to avoid stuff that stinks? but then we eat it and like it. very odd. maybe the shortage of food in our ancestral environment made us less picky about smells and we made some happy discoveries.

Tracy (2011-08-16 07:27:57)

I've also been making my food taste good by adding ferments - lamb meatballs, for example, with a sauce made by adding homemade goat yogurt and a squeeze of lemon to the pan juices. Fermented lemonade with a hint of nutmeg, either drunk on its own or transformed into gelatin and served with fermented cream. So, so simple and tasty! A lost art, really... if people understood how easy it is to ferment your own foods, why would they buy sour cream, sauerkraut etc from the store? And as to the mass-produced thing... @mike kenny many foods like pickles that were traditionally fermented are now just pickled, with vinegar etc creating that sour taste we love so much, as opposed to being rammed in a big barrel and left to the whims of bacteria.

aeK (2011-08-16 07:35:11)

Intriguing point, Seth! I spoke (on the NYT site) to her mourning over her perceived benefit of spontaneity and abandon in approaching food. From the list, it seems as if she is going quite a bit for mouth feel. Your assertion that you rarely use spices is interesting, too. I learned how to make yogurt, and eat it almost daily. But I add cocoa power, cayenne, ginger, cinnamon and pumpkin pie spices to it. I also heavily add spices and herbs to protein and vegetable dishes. That seems to add to the satiety factor in my case.

Seth Roberts (2011-08-16 07:37:17)

I am now eating yogurt nose-clipped. Like you, I do add spices to yogurt, such as cardamon, cinnamon, nutmeg, and cocoa, when I eat it without my nose clipped.

Seth Roberts (2011-08-16 07:40:47)

good question, Mike, why would stuff that smells objectionable be good for us? Perhaps a large part of the (mild) aversion is cultural, lack of exposure to strong smells and a belief that bacteria are bad. In ancient times there was plenty of exposure to strong smells and the concept of bacteria didn't exist.

Brian (2011-08-16 07:49:57)

"Ms. Stoessinger's article reads like a series of boasts: look how much I know and care about food. I think that's part of the problem: You can't boast about fermented food." I think you just proved yourself wrong...

dearieme (2011-08-16 10:03:21)

This reminds me of a childhood trade between me, supplying a fermented drink made with liquorice (I can't remember the recipe), and a neighbour, supplying ginger beer made with a "ginger beer plant". I have no idea why these were viewed as childish tastes.

Paul Sherrard (2011-08-16 17:07:40)

Re the "smells bad but good for us" thing: An intriguing point! I feel that our relationship to the smell & flavor of fermented food is complex. The initial reaction—"this is stinky"—can be accounted for as a useful aversion to garbage or rotten food. As humans evolved, an aversion to foodborne bacteria may have been quite useful, e.g. avoiding salmonella could have been more immediately advantageous than cultivating stomach cultures. In my experience, most children can't tell fermented food from rotten food. But we learn: it's normal for adults to have a taste for wine, veined cheese, pickles, etc. I love gorgonzola cheese, and absolutely hated it when I was a kid, but I can still understand exactly why it smells like garbage to someone without a taste for it. Isn't it possible that the mechanisms that tell us "this is bad; don't eat it" can be retrained when it's to our advantage. They can be taught to "make exceptions." Other instincts can be modified: for instance, contact lens wearers have trained themselves to suppress their blinking instinct when they're putting in their lenses. They "make an exception," but leave the blinking instinct otherwise intact.

Dr.Zachar (2011-08-16 21:35:41)

Nothing like the natural process of fermentation to liven up the taste buds! I've actually had some experience with this recently at a local Indian place. It was some kind of fermented peanut, can't remember it for the life of me though.

et (2011-08-18 10:50:34)

Food spoilage bacteria are harmless Anastacia Marx de Salcedo of Slate explains the difference between spoilage bacteria and pathogenic bacteria. It turns out the the bacteria that stinks and makes food look disgusting is harmless, but the bacteria that makes you sick "provide no sensory clues as to their presence in food." <http://boingboing.net/2011/08/10/food-spoilage-bacteria-are-harmless.html>

## Many Supplements Taken Together Reduce Depression/Dysthymia (2011-08-17 05:00)

At the recent Quantified Self Meetup in Mountain View, Fenn Lipkowitz told me that he had started taking a long list of supplements and now felt much better. At last week's QS Silicon Valley Meetup, he gave a talk about it. The graph above shows "wellness" ratings before and after the change. Here's what the scale numbers mean:

- 3 = "i'm hurting, i just want to crawl under my blanket and suffer for a few hours."
- 4 = "today sucks, i think i'll hide and eat some chocolate and read manga."
- 5 = "well, i'm here and dont have any excuses, so i guess i'll go do something."
- 6 = "bright eyed and bushy tailed, ready to go do some work"
- 7 = "why am i writing in my log, i should be out dancing!"
- 8 = "holy shit, tearing it up, backflipping over ninjas and juggling fire"

He describes the improvement like this:

Things seem really easy now that were serious barriers before. I now sleep 4-6 hours a night instead of 12, and bounce out of bed. I no longer have high dance inertia, I can just start dancing on demand. I can type 143 works per minute vs my maximum of 92 wpm a month ago.

Every morning he takes:

- vinpocetine 10mg
- vitamin-d 125ug
- fish-oil 1g
- piracetam 1600mg
- alpha-gpc 300mg
- choline-bitartrate 500mg
- dmae 260mg
- boswellia 300mg
- curcumin 300mg
- cordyceps-extract 1.2g
- aloha-cordyceps 525mg
- coq10 30mg

- ginkgo-extract 60mg
- tryptophan 500mg
- Flintstones multivitamin B-complex

Here are his explanations for some of these:

vinpocetine - vasodilator derived from periwinkle plant. enhances focus, seems to improve long range vision, seems to cause your eyes to fixate more steadily on what you're looking at, less saccades.

piracetam - increases communication between two halves of brain; the effects of this vary by person depending on which half of their brain is in control. for me it makes interpersonal relations become more clear, easier to cooperate and understand the motivations and intentions of others. also uses up choline at a faster rate, which is why i also take

alpha-gpc - a high bioavailability form of choline precursor, which is in the form that cells usually generate when they're self-scavenging in choline-depletion state. it doesn't go into rebuilding the cell walls, but is used for synthesis of acetylcholine, a neurotransmitter involved in memory and muscle control.

choline-bitartrate - choline is transformed into phosphatidyl choline in order to (re)build cell membranes. this is low oral availability (doesn't cross blood/brain barrier easily?) but super cheap and tastes good. i have a theory that alzheimers is caused mostly by long-term choline deficiency.

dmae - another choline precursor? aka "deanol" and has been shown to increase the life-span of mice by 50 %, possibly through the mechanism of clearing out lipofuscin deposits. cheap, tastes good.

boswellia - no idea, it's in the curcumin pills; somewhat aromatic and pungent, like tea tree oil or piperazine.

curcumin - this is straight up turmeric extract. antioxidant and various other bodily health effects.

cordyceps extract - zombie ant brain fungus. look up images of it online, it's sick. it makes you want to climb up to the top leaf in a tree, clamp your mandibles, and explode spores everywhere. well, not really. but it improves oxygenation, energy, and will kill a viral infection in one day. the extract is prepared by rapidly growing a lot of cordyceps mycelia in a warm fermenter and spray drying the liquid that comes off. this is highly unnatural environment

aloha cordyceps - aloha pharmaceuticals saw the explosion in "farmed" cordyceps and decided it wasn't natural enough or something, so they recreated the mushroom's natural environment of tibetan steppes. they grow it up fast and then let it sit for months in the dark in refrigerators with low oxygen. they claim that their process increases the number of good chemicals (cordycepin, uracil, based on HPLC analysis) and reduces the gross things. i can confirm it tastes/smells much better than swanson brand cordyceps extract. i started taking regular cordyceps extract first and can confirm it works as advertised, but maybe aloha is better, so i take that too. i have a friend taking only aloha cordyceps so we'll see what happens.

[1]More here.

---

David (2011-08-17 06:01:58)

The "Flintstones multivitamin B-complex" is a nice touch.

Alex Chernavsky (2011-08-17 06:31:58)

When you look at clinical trials for depression, you find that no matter *what* treatment you try, everything seems to work. (And when I say "treatment", I don't mean just pills – I mean stuff like exercise, meditation, etc.). The important thing seems to be do *something* to address the problem, as opposed to just lying in bed or whatever. So I'm not surprised that Fenn's elaborate regimen had an effect. The more-interesting question is *why* it worked. The graph is also curious for the amount of variability that he experiences. Note the data points toward the far-right side. I wonder what's going on there.

Glen Raphael (2011-08-17 09:52:44)

Alex: One possible explanation for the fact that almost anything you try "works" to treat depression is simple regression toward the mean. Assuming your depression level has cyclical and/or random variable components to it, you are likely to seek professional help when you are in or have just been through an \*unusually bad\* period. Sample a random period some time later and through chance alone it'll tend to be better than that, regardless of what potions the witch doctor prescribed. Therefore, you'll think the potions worked. If you're \*really\* depressed, you might not have the energy to go see someone. So if you get up and try something, that's already a symptom that you're recovering.

CK (2011-08-17 11:12:56)

Alex, The far right side of the graph is explained if you click the link.

BenB (2011-08-17 12:14:14)

His website links to a quite wonderful 1981 paper by Allen Neuringer on self experimentation, including many of his own and his student's self-experiments. One of these was inspired by Neuringer taking Judy Masee's Dance 110 class at Reed College.

???? (2011-08-17 19:36:22)

That seems a lot of stuff to take on everyday.... is that really needed, too many pills isnt it ?

justsomeguy (2011-08-19 06:24:30)

Interesting list. 2 quick thoughts ... I'm "justsomeguy", but I thought Tryptophan was illegal in US ? Thought that's why folks take GABA or 5-htp as an alternative to boost Serotonin. B-complex very important, but suspect Flintstones brand includes a sweetener that ain't so healthy.

Great links for the weekend! (2011-11-11 14:05:56)

[...] up of someone else's experiment, taking a long list of supplements which seemed to succeed in reducing depression. I found it interesting because Chris and I have ended up with a long list of supplements to try [...]

## My Self-Tracking Wish List (2011-08-18 05:00)

Right now I am tracking 6 things:

1. Sleep. I use a stopwatch and Zeo.
2. Weight. I use three expensive scales.
3. [1]Blood glucose (fasting). I use Abbott's Freestyle Lite system. I get the blood by pricking my forearm; it's painless.
4. Brain function. I use an [2]arithmetic test.
5. Morning energy. I rate my energy on a 0-100 scale at 8 am and 9 am.
6. Productivity. I use the [3]percentile feedback system I've described.

I keep crude measures of my workouts (on scraps of paper). Two more things I want to track:

1. Inflammation. I would like to measure the redness of my gums. This is possible (take photo, measure redness), but hard.
2. The effects of fermented foods, especially their effect on my immune system. I believe fermented foods differ greatly in potency but I am unable to do any quantification.

1. <http://blog.sethroberts.net/2010/07/18/fasting-blood-sugar-reduced-by-walking/>
2. <http://blog.sethroberts.net/2010/08/13/arithmetic-and-butter/>
3. <http://blog.sethroberts.net/2011/05/01/percentile-feedback-and-productivity/>

---

Tomas (2011-08-18 06:11:26)

I can imagine that tracking the effects of fermented foods would require some kind of intestine content sampling for the quality and quantity of gut flora.

gwern (2011-08-18 08:14:28)

As far as inflammation goes, you might look into whether you could get personal or trial or otherwise informally supplied tests like <http://chronopause.com/index.php/2011/07/14/supar-power-a-rapid-inexpensive-highly-accurate-method-of-predicting-all-cause-and-disease-specific-mortality/>

Metodo Dukan (2011-08-18 15:45:13)

Mine is very similar... ;-)

David (2011-08-18 22:08:32)

Why three scales instead of on very good one?

Seth Roberts (2011-08-19 05:21:03)

I have three scales rather than one because if I have one scale and it breaks I am in bad shape. This once happened. If something changes, I want to make sure it's because I've changed rather than the scale.

Jazi yechezkel zilber (2011-08-19 13:33:04)

High sensitivity CRP (c-reactive protein) gauges overall inflammation.

Jazi yechezkel zilber (2011-08-20 01:00:36)

There is research showing crp being a reliable marker for cardiovascular health

Jazi yechezkel zilber (2011-08-20 02:03:32)

Acid - base balance Easy to test at home even multiple times a day, with saliva or urin. It is balanced in ancestral lifestyle. But highy acid today. Reviews on ancestral vs. Modern habits hold that modern people have chronic low level acidosis, causing bad health It is an independent predictor of mortality. (reference in next comment) Tests strips are cheap. Saliva and urn. Phion is one brand. Or search ph balabce strips. I can help It is also easy to trick by supplemeting with potassium bicarbonate.

Jazi yechezkel zilber (2011-08-20 02:06:33)

<http://archinte.ama-assn.org/cgi/reprint/164/14/1546.pdf> Uric Acid Level as a Risk Factor for Cardiovascular and All-Cause Mortality in Middle-aged Men A Prospective Cohort Study

Jazi yechezkel zilber (2011-08-24 12:17:10)

Glucose levels after (identical) meals. A central predictor of prediabetes illnesses <http://munews.missouri.edu/news-releases-/2011/0823-mu-study-links-inactivity-with-risk-factors-for-type-2-diabetes/>

Jamie Morrison (2011-08-29 17:43:44)

"I keep crude measures of my workouts (on scraps of paper)"... If you have an iPhone/iPad check out My Session Plan in the app store... It was designed to get rid of the scraps of paper and record times and reps. I use Overtraining Monitor in the app store to track resting heart rate and weight.

## **Flaxseed Oil Reduces Healing Time (2011-08-19 05:00)**

A few days ago, Dominic Andriacchi, a 25-year-old law student living near Detroit, told me that he mentioned some of my self-experimentation ([1]my discovery that postponing breakfast reduced insomnia) in an Amazon ebook ([2]Law School Livin') he'd just published. He added that something he read in this blog really helped him:

Thank you for introducing me to flaxseed oil. Recently, I re-injured my back (a injury that occurred during college football). While I've never seen a doctor for the injury, I did a little internet searching and figured that I had herniated a disk in my lower back. I also had pain in my leg due to, I presume, pressure on the sciatic nerve from the herniated disk.

He re-injured his back pulling a small tree uphill.

Usually, it takes at least a week for the pain to go away. I have trouble sitting, walking, and so forth. That day, because I [had] read [3]the post of Tucker Max's ankle injury and flaxseed oil, I immediately upped my flaxseed oil to a total of 15 1000mg capsules. The next day, there was nearly no pain at all. I could bend over and touch my toes with only the slightest pain. The day after that, I was back to normal.

Later he added some details:

I took 15 capsules of flaxseed oil [the day of the injury] to see what would happen. There was no immediate benefit that I felt that day, but the next day it was great. Even sitting or the slightest bending can cause a lot of pain, but I was able to bend over and nearly touch my toes. I took another 10 capsules that day as well. The day after that, I was completely pain free. I took more flaxseed oil capsules even though I was experiencing no pain at all. I expected the pain to come back, but it didn't. From then on, I would just take my normal two flaxseed oil capsules [per day]. I was spacing them out, 5 at a time in between meals.

---

Michal (2011-08-19 06:06:02)

I find all the effects that you see from flax seed oil very interesting (high in ALA). There is no evidence that ALA gets converted to DHA or EPA in any significant amounts (doesn't mean it doesn't, however that is my hypothesis). I've read something by Dr Eades that suggests overall eicosanoid production is decreased by ALA. I do wonder about the effects of flax seed oil and how it differs from fish oil.

Aaron (halotek) (2011-08-19 07:23:41)

I also find it interesting that flax oil could have such fast effects – I would figure it would take some time for the benefits to accrue because of how fatty acids incorporate. Maybe there is some type of other anti-inflammatory compound in flax oil? Also, what about people who have problems with flax oil? When I take any I seem to be jumping off walls and start to feel real tired – almost like I have taken a stimulant – and it disrupts my night sleep too. DHA supplements do not have this effect with me so I know something else is going on with the flax.

john (2011-08-19 08:38:24)

I was wondering the same as Michal. What would happen if one tried fish oil instead?

Michal (2011-08-19 09:30:15)

I thought about this some more. There were trials done that showed human synthesis of dha from ala is minimal. Dr. Roberts is under the impression that this is because it was in people that are not used to ALA. With repeated exposure the body gets better at turning it into dha. Unless I'm mistaken, Dr Roberts saw immediate benefits from flax oil. There was no delay while the body was getting better at conversion. This leads me to the conclusion that ALA is beneficial in its own way.

Kevin (2011-08-19 09:33:47)

I have had a similar experience with Salmon oil. A few years ago I started taking it on the advice of my doctor to help lower my cholesterol levels, and I found after a few weeks that my chronic knee pain was significantly reduced. I had made no other changes to my diet or routine that would account for the change.

Joanna (2011-08-19 11:29:26)

I have read that conversion of the alpha-linolenic acid in flax oil into EPA and DHA is dependent (among other things) on genetic factors and your nutrient status. I've been a vegetarian for 20 years (well fed, I thought!), and eaten flax oil regularly the last 5 of those. After reading that DHA composes 60 % of your brain (Mark Hyman Ultramind Solution and other places), I thought I would try an actual DHA supplement. I have had frequent (often incapacitating) swelling-type headaches for years, difficulty thinking, some general inflammation, and the regular feeling that my brain is a little on fire, and sometimes terribly on fire. So – algal DHA, 100 mg capsules. As soon as I started taking these, I experienced a greatly increased ability to think clearly, and a gentle cooling in the region of my brain. There is actually a striking difference for me between before taking a pill, and the

hours after taking one. This is one supplement where an effect is obvious for me. I started taking fish oil instead of the algal DHA so I could get 'more' DHA, but oddly the effect wasn't as pronounced. I don't understand why that would be (and I think I am going to try a different fish oil). However, my baseline neural discomfort is also much improved since April (start of DHA supplementation), so it is harder to compare. I find self-experimentation involving my brain a bit complicated. Anyhow, I think that this is an example of DHA providing a benefit where flax oil failed, even in a long-term flax user, at least in the nervous system where DHA is the critical substance.

Michal (2011-08-19 12:07:55)

I don't see why fish oil would be much different from algal dha. Maybe one has more dha?

Joanna (2011-08-22 09:51:12)

The algal DHA is just DHA (and less – 100 mg), whereas a serving of that cod liver oil should have had more DHA (it didn't give the breakdown, and claimed it varies), but also would have had other omega-3's (EPA and 7 others?), and also could have had impurities, despite the labelling. It also had significant vitamins A,D,E,K, I think. So it's a very different product than straight DHA. It made me feel syrupy. This site inspires me to quantify more of my experiences (with results of supplements, for example), but I don't yet grasp how to quantify some things, like the sticky, syrupy feeling that that fish oil gave me. Higher amounts of DHA (like more than one algal DHA capsule) still feels great. And I went and bought a new type of fish oil this weekend (550mg DHA per serving), and I also feel very good after taking it – enough so that I think about it frequently and can't wait to take it again.

joseph (2011-08-24 15:24:32)

I started eating Flaxseed for the first time this week, i took monday about 2 TBS then increased it today to 9 TSP i didnt have a TBS... interesting in the morning i felt better then usual but late afternoon i become very tired almost eyes clsoing, anyone any ideas why? is it cuased by falxseed? or somthing else? but it seems a new occurance to me as in the past i had many tiring dayes just grumpy, now i start the day better but then i feel really tired... any suggestions? btw im using ground flax took it with a soup...

Eric (2011-08-31 14:24:24)

I would like to reiterate the comments and questions about the difference between flax and fish oil. Anecdotes here and on PaleoHacks suggest that flax has unique effects. But nobody seems to have any ideas about why this might be the case. You (SR) seem to think that flax is unique and perhaps better, but to my knowledge you've never elaborated on this. Even if it's speculative, I'd like to hear what your current thoughts are on their differences. Have you experimented with fish oil?

Seth Roberts (2011-08-31 14:29:25)

Because the short-chain omega-3 in flaxseed oil must be converted to long-chain omega-3 (DHA) to be useful in the brain, flaxseed oil is like a delayed release source of DHA. Fish oil is like an all-at-once source of DHA. That's one theory.

Eric (2011-09-12 18:03:17)

Do you think that the phytoestrogen content of flax are a concern? Dose probably matters, so, fwiw, I've been consuming two tablespoons of ground flax seed a day.

## More About the Migraine Story Comments (2011-08-20 05:00)

[1]My post at Boing Boing about a woman who figured out the sources of her migraines attracted lots of comments, some of them [2]preventive stupidity (e.g., "anecdotes are not evidence"). I asked the subject of the story what she thought of it. Here's what she said:

I feel that many people entirely missed the point when reading the original article. I wasn't trying to com-

municate that a) all doctors are evil/drug-pushing/uncaring or b) my 'natural' solution would magically cure everyone. I have to admit, I'm a little tired of both sides of that old 'Real Science vs. Natural Healing' argument anyway. In my case, at least, both extremes are obvious oversimplifications of years of my life that were a very trying, difficult struggle for me.

I am quite aware that the number of drugs I had been tried on was absurd (and layering them as was done: some to 'prevent', some to treat as needed, etc, definitely did not help. How can you distinguish what works? You can't). The armful of drugs to "try until one works" left me dumbfounded for that very reason. At the same time, without the help of a doctor (who happened to be a naturopath, but that is beside the point) who was willing to take a look at my data and listen and apply what she knew, I'd never have reached the stable, much healthier point I'm at now. She hit on a pattern that made a significant difference. One that I wouldn't have known how to help had I even seen it, because I'm not a doctor.

I believe the take-away message from my story ought to be simply: take charge of your health. I'm also well-aware that this isn't a new message.

Nevertheless, if you have migraines, there's only one person who wants them solved more than anyone else in the world, and that's you. So tracking, I believe, is necessary.

As for my self-experimenting on removing harsh chemicals: so what? It made (and continues to make) a significant difference for me. Perhaps it is placebo, perhaps it's a sensitivity. I have to say, the allegations that 'spreading lies about how cleaners cause migraines cause doctors to have to clean up the mess' strike me as particularly amusing because, with a touch of further digging, one quickly realises that switching to a fragrance-free, SLS-free, paraben-free cleaner isn't exactly the kind of thing that lands people in the hospital.

I don't care to argue about so-called natural living. Annie B. Bond's story (and if I'm tooting horns for anyone, it's her) and contributions to various websites made me start to wonder about the things I took for granted in the world around me and their impact on my health. If reading my story gave someone else a moment's pause to consider what had changed in their environment along with the return or start of a health issue, well. I'm the first to admit that correlation is not causation. The science isn't "perfect": you don't live in a lab. To my mind, that's poor reason to give up before trying. It's a terrible reason to give up before even considering. Critical thinking about your life, habits, environment, health, and how they intersect is not wasted thinking.

In any case, I have to admit, the only thing that surprised me is how willing people are to get into the arguments. I've commented on the natural-vs.-real-science bit above; the anecdotes-don't-make-good-research theme is really an equally old and equally tedious argument to have with someone (my current faculty still tries to balance on the qualitative vs. quantitative data debate). For those who care, then, I hope they can come to consider this a piece of a much larger, multivariate puzzle of "everyone's health". Migraine sufferers, as far as I know, don't have a "patients-like-me" site dedicated to them. Even if you get nothing else out of a story, you should get a sense of community. Other people are also going through what you're going through- whatever the cause, whatever the outcome.

[3]One person helped by the Boing Boing story. [4]My comment on the comments.

---

Elizabeth Molin (2011-08-20 08:14:06)

There is actually a site for migraine sufferers to track their headaches and possible triggers. They give a list of standard triggers, to which you can make as many of your own additions as you like. You then fill in a daily questionnaire, which takes only a minute after you get on to it. [mymigrainejournal.com](http://mymigrainejournal.com)

### **Tucker Max on Writing and the Importance of Understanding How You Differ (2011-08-21 06:47)**

I recently heard Tucker Max speak about writing books. He said he had succeeded because he told the truth about himself – including the unpleasant stuff. Most people don't. That, plus an ability to make it entertaining, was what he could do that other people couldn't. He was saying that "being yourself" – more precisely, building on how you are different – was the only good place to start. Imitating other people is not a good place to start. Jane Jacobs said the same thing about how cities should develop. She said it was pointless to try to imitate other cities – to imitate them by building a stadium or convention center, for example. Each city should figure out what its unique strengths are – what makes Springfield Springfield – and build on them. Amplify them.

I was pleased to hear Tucker's remarks because I never hear such stuff said publicly (or privately), except from Jane Jacobs. When I was at Berkeley, now and then I'd tell other professors: It's a mistake to treat all students in a class the same (by giving them the same assignments, the same tests, etc.). They're not all the same. They differ greatly. A lot is lost by treating them all alike – a lot of self-esteem, for instance. My colleagues didn't like hearing this. It was convenient to treat all students the same. And it was status-boosting. My fellow professors worked in a system where the dimension used to gauge success was something they were good at. The notion that there were many other useful ways to excel was undermining. If there is only one measure of success and I am #1 on that measure, I am #1 period. If there are thirty measures of success, all equally valid, and I am #1 on only one of them, my superiority is less clear.

Tucker's presence at the Ancestral Health Symposium was criticized. Here is an email that the organizers (who include me) received:

One thing neither I nor my attendee friends can explain: Tucker Max as a speaker? Really? His claim to fame is having rough sex with drunk girls and then writing about it. I'm pretty sure the majority of his speaking gigs take place at bars and frat houses. From his own website:

"I get excessively drunk at inappropriate times, disregard social norms, indulge every whim, ignore the consequences of my actions, mock idiots and posers, sleep with more women than is safe or reasonable, and just generally act like a raging dickhead."

If you have a chance, could someone please explain this choice of speaker? I'd love to support this conference in the future, and I'm all for challenging social norms, but not those that have to do with basic respect for other people.

I replied:

I wanted Tucker Max to come and went so far as to give up half my presentation time to allow him to speak.

Why did I want him to speak? Because he is a big supporter of paleo, because he had something fresh to say, because he would say it well (and he did), and because he is deeply respected by an audience it is crucial to reach – college students. Sure, some things he writes offend some people. I don't think that means he doesn't have something helpful to say.

I don't think college students respect him so much because he writes about getting raging drunk, etc. I think they respect him because he speaks the truth about subjects where most people don't speak the truth.

The connection between "being yourself" and speaking the truth about difficult subjects is simple: Being yourself inevitably involves being different and being different inevitably involves some people scorning you. As Tucker said things that caused people to scorn him. As some people scorn my self-experimentation. In a society where being yourself isn't valued enough, the fear of scorn wins, people self-censor, and, as in the above email, they censor others. Everyone's loss.

The effect of an educational lifetime of being treated the same – from kindergarten thru college – is that the notion that you are different and have something unique to add becomes less and less plausible to you. Because it becomes implausible, that possibility doesn't enter into your calculations about what to do with your life – in particular, what job to choose. You begin to think that success = imitation of successful people, when that is misleading. Imitate successful people like you, yes, but most people aren't like you. I chatted with Tucker after his talk. He said it isn't enough to be different, you have to act on it, become better and better at exercising your unique talent. I agree. In a better world, you would do this starting young, like 10, and slowly become better so that by the time you needed to make a living you would have substantial skill. But our educational system, by treating everyone the same, or nearly the same, discourages this.

---

Nancy Lebovitz (2011-08-21 08:11:03)

<http://www.ribbonfarm.com/2011/08/19/the-calculus-of-grit/#more-2701> This is an extensive piece about building mastery of a field that didn't exist until you developed it. Googling turned up a little. <http://dbcs.typepad.com/lifeatwork/2010/05/build-your-strengths-rather-than-fix-your-weaknesses.html> <http://www.amazon.com/Discover-Your-Strengths-Marcus-Buckingham/dp/0743201140>

David Perch (2011-08-21 11:38:51)

Wow, what a great post... It moved me because it really resonates with my personal experience. Thank you.

Maxy (2011-08-21 17:08:58)

It's ok you guys! I degrade and humiliate women, and have profited handsomely from it, but I don't pretend I'm not degrading women. Telling the truth makes it ok. I'm an ideal choice for speaking at your conference.

Tom (2011-08-21 17:31:14)

Holy cow. One of the best pieces of writing I've ever read.

Robbo (2011-08-21 23:23:12)

When I was hiring people into my team, while sifting CVs, one of the criteria I used was 'Does this one have something special about themselves?'. In building a team it is much better to have individuals with different strengths than to have a group who are all average at everything. If college doesn't get this, it's college that is wrong.

Jill (2011-08-22 05:47:04)

"...the notion that you are different and have something unique to add becomes less and less plausible to you. Because it becomes implausible, that possibility doesn't enter into your calculations about what to do with your life — in particular, what job to choose." This is so true. Growing up, I always wanted to be a writer, but there was this idea that so few writers are able to make a living at it... what makes me think I could be one of them? Instead, I ended up going into a field (software designer - i.e., programmer) where "success" is practically guaranteed.

Jscott (2011-08-22 15:00:53)

Fear is central to most discussions dealing with anything ancestral. Thought provoking post, Seth. Robert Greene's book, The 50th law deals with the issue of fear and highlights another figure that is not popular with the pressed and polite crowd. Fantastic book that made me cringe a bit. Odd thing about not exposing who we are is that it creates the very anxiety (of not wanting to be found out) we are trying to avoid. A prison of sorts. One that we have constructed. Thanks for the reminder.

Seth Roberts (2011-08-22 23:12:40)

Maxy, here is one response to Tucker Max's talk at AHS: <http://hunter-gatherer.com/blog/2011-ancestral-health-symposium-awards>

Olga (2011-08-23 09:08:56)

Interesting, would you find a man bragging on beating his wife/child as "he speaks the truth about subjects where most people don't speak the truth"?

Jscott (2011-08-23 15:14:40)

"Olga" You have links for the accusations? (TM is not married with children)

Jscott (2011-08-23 15:16:02)

Related: [http://www.huffingtonpost.com/cent/keep-moving—flow\\_b\\_380221.html](http://www.huffingtonpost.com/cent/keep-moving—flow_b_380221.html) "Every individual we come across in life is unique, with his or her own energy, desires and history. But wanting more control over people, our first impulse is generally to try to push them into conforming to our moods and ideas, into acting in ways that are familiar and comfortable to us. "

Olga (2011-08-23 16:04:49)

Jscott: I'm sorry if it is sounded like an accusation. No, it was an example. The guy is bragging of being an asshole. I gave an example of a different type of asshole, bragging and being honest about it. I don't see big difference between the two: both being honest.

Jscott (2011-08-23 17:04:02)

I understand ya Olga. Wanna dive deeper? What can you share that is scary? Something that is disappointing to the mainstream, offensive, or embarrassing? The asshole is just a category. Some people can benefit. It matters not to me. I might need your category of honesty. One that OTHER people might find offensive and "wrong." But it might help me and 100 others. Anything to share? I will show you mine if you show me yours.

Adam (2011-08-23 17:07:21)

Seth: Q: Is there a transcript of his talk? BTW, couldn't help thinking of this routine by Bill Cosby: I said to a guy, "Tell me, what is it about cocaine that makes it so wonderful," and he said, "Because it intensifies your personality." I said, "Yes, but what if you're an asshole?"

Tom (2011-08-24 01:02:14)

I am so bored by the "Olgas" of the world and their blithering hatred of anything male. And I am disgusted that these liars have cowed 99 % of our society with their moronic, libelous shrieking. And I am delighted that the AHS is in the 1 %. It makes sense that AHS would be. But God damn, it's a delightful surprise, nonetheless. And even though most of the people blogging about TM have written about being "surprised" about his acquitting himself well – I think they're lying, too. Even John Durant – he's LYING. I think Durant KNEW Tucker Max would take his AHS slot seriously and KNEW Max would do a good job. But Durant is PRETENDING that this surprised him – because for Durant to acknowledge that he expected an intelligent, interesting talk from TM might cause others to think that Durant holds the "wrong" opinion about TM in other areas. Lying is so fucking endemic in our culture that people don't even know when they're lying any more.

Shawn (2011-08-24 05:11:12)

I'm a little surprised that you choose to write about Max, because whenever you do so, you elevate the status of that goofball.

Olga (2011-08-24 07:07:06)

Jscott: I am not really following your thoughts here. Why is honesty associated with offensive and 'wrong'? I would agree that admitting that one is wrong is honesty. But I don't see it here. Bragging of insulting other people is not. Using other people for advantages of one person without regard for other people feelings is not. Again, an asshole is just an asshole. There is nothing really heroic about it. Tom: I do not have blithering hatred of anything male. An asshole can be a female. It is just a category. I just don't see anything heroic to be proud to be an asshole. On some level, it simply assumes that everybody around is an asshole - just uncertain about it. However, I do wonder why you consider somebody's bragging of using, humiliating, and degrading other people as highest standard of honesty. Or is this so difficult for you to accept that women are human too?

anna (2011-08-24 07:09:31)

I think this blog post misses the point entirely. Written from a male, privileged perspective, its easy (but disappointing) to see why. Max is consistently celebrated as a, bold, ballsy, writer who isn't afraid to speak truth. Fine. But, I think it's dangerous to ignore his content. How he treats women, how they (at times) allow themselves to be treated, and how he takes advantage of them (or situations) when they're intoxicated - isn't bold, new and different. It's actually cowardly, old and extremely common. A majority (not all) of women are deeply offended and emotionally affected by his writing. Personally, I think exploring "why" is far more interesting than Tucker Max himself. There's nothing, at all, new about him.

Jscott (2011-08-24 11:45:49)

"Olga" It seems that T.Max might be blinding you from Seth's point. You do not like that he is not contrite and that he is elevated because of his antics. Fine. The highest form of honesty comes when dealing with myself. The inner world. You are associating things with me I did not say. So, fine Tucker has been a bad bad boy. Now what? We could have been talking about individuality and fear and why so many of us stay in the middle of the back instead of doing something great or at least something real. This, at least for me, started once I was able to express myself without protection of anonymity. To be able to take criticism and to deal with me while leaving the judgement of the world at large alone. You know, a Buddhist or Gandhi type of thing. Awake to awaken others or be the change you want to see in the world blah blah. Now, back to fear and individuality...

Jscott (2011-08-24 12:18:55)

"Olga" It seems that T.Max might be blinding you from Seth's point. You do not like that Max is not contrite and that he is elevated because of his antics. Fine. The highest form of honesty comes when dealing with myself. The inner world. You are associating things with me I did not say. So, fine Tucker has been a bad bad boy. Now what? We could have been talking about individuality and fear and why so many of us stay in the middle of the pack instead of doing something great or at least something real. This, at least for me, started once I was able to express myself without protection of anonymity. To be able to take criticism and to deal with me while leaving the judgement of the world at large alone. You know, a Buddhist or Gandhi type of thing. Awake to awaken others or be the change you want to see in the world blah blah. Now, back to fear and individuality...

Olga (2011-08-24 12:34:29)

Jscott: You are right, I have deviated from the bigger point in this discussion about individuality and Seth's remarks on the importance of being different and unique. I got caught up in the example of an individual instead of the main point itself because I do not think that it is a good example. I disagree with Seth that the speaker is being respected for telling the truth. I think that it is exactly because of his drunken stories. Trying to change the world to be a better place, Gandhi style, takes courage and guts. Being a proud asshole, praised for 'individuality', does not. There is not much individuality in being an asshole. Being individual is much more than that. And by the way, both Buddhist philosophers and Gandhi emphasized not using other people. I guess I got diverted because I really like the main about individuality, but I do not like the example lacking it.

Tom (2011-08-26 01:04:03)

You got diverted because you only like individuality that conforms to your beliefs. ie, you despise individuality. TM outrages you because he gets how irrelevant non-individuals like you are and acts according to it. That courage, plus hard work and tremendous intelligence, have given him more of a platform than you'll ever have. Despite (actually because of) the fact that you only ever say the "right" things. You flatter yourself that you're striking a blow for something. But you're just being predictable, common and snotty. Even after a talk universally regarded as one of the most interesting at AHS, you're lobbying for him to be silenced in the future. That makes you the asshole. Parrotting PC contempt counts for nothing. Multiply you by ten million, the product is still nothing.

q (2011-08-28 15:59:13)

i don't see why womanizing and acting like an asshole is a mark of individualism. in the society i was brought up in, it's just a sign of lack of respect for other people. can someone enlighten me in this? for instance, can you tell me, does he like women that match society's ideal sense of beauty or does he make up his own mind about this?

andrew (2011-09-01 09:17:05)

If you have to ask you'll never know

## Sulfites in Wine May Cause Bad Dreams (2011-08-23 05:00)

Eric Stroud, [1]a web and marketing consultant, thought it would be nice to have a glass of wine an hour before bed-time. Wine is healthy, right?

But after seven or so nights of this, he began to have unpleasant dreams of a sort he'd never had before. They became more and more visceral, nightmarish, and anxiety-drenched. This continued four or five nights. Then he stopped drinking the wine. The bad dreams went away in one or two days. Something similar happened to one of his cousins.

He believes the bad dreams were due to the sulfites in wine. When he drank sulfite-free wine, he felt fine.

1. <http://www.70b3.com/>

---

Ben B (2011-08-29 11:15:40)

I've not experienced this with wine, but I certainly have with magnesium supplementation: 500mg before bed will reliably give me-not nightmares exactly-but intense, 'visceral' and disturbing dreams.

Louis (2011-08-29 12:16:42)

Supposedly all wine has naturally occurring sulfites. When a bottle of wine indicates that no sulfites are added, it doesn't necessarily mean that it is sulfite-free. Perhaps the form which is artificially added to wine is more harmful than the naturally occurring one? Or maybe it's a matter of quantity?

Ray Sawhill (2011-09-03 00:32:23)

I had to give up drinking red wine because it was causing bad dreams. Quite reliably, a glass or two of red wine in the evening would lead to really awful, hyper-emotional dreams, often about suicide. Given that in the daytime I'm one of the world's cheeriest and most appreciative people, this clearly wasn't right, and it clearly wasn't me. Gave up the red wine, the bad dreams (at least those bad dreams) went away. White wine and spirits don't bother me similarly. I've run into other people who've had similar problems with red wine, god knows the term "red-head" (for being bothered by red wine) is pretty common.

Bill (2011-09-12 19:41:59)

Might this also have to do with the fact that red wine contains some mycotoxins from the fermentation process? I have noticed that since starting anti-fungal herbs and medication (Diflucan) I have had a strange nightmare almost every night.

Great links for the weekend! (2011-09-22 13:02:38)

[...] Eric Stroud realised that drinking wine gives him bad dreams and thinks it is due to the sulphites in the wine. What do you [...]

mbtuna (2012-01-26 10:14:18)

Drinking either Red or White wine has been giving me horrible, terrifying nightmares! After being up all last night, and then reading this blog... I'm giving up wine for good! It's not worth it!

Nick (2012-03-04 10:41:15)

I drink red wine before bed on a regular occasion as part of my night time prep ritual. Not controlling variables I do believe I remember my dreams more and overall experience more lucid dreams, but I can't relate to having more nightmares.

## Morning Faces Therapy For Depression and Bipolar Disorder: Resources (2011-08-23 07:02)

In 1995, I found that if I see faces in the morning, I feel better the next day. If I see faces Monday morning, I feel better on Tuesday. Here is information about this discovery and related material.

### Discovery

- [1]Self-experimentation as a source of new ideas: Examples from sleep, mood, health, and weight. Example 2 of this paper describes the discovery.

### Related Results

- [2]A 'sticky" interhemispheric switch in bipolar disorder? by John Pettigrew, an Australian neuroscientist. He argues that bipolar disorder may be caused by a sluggish internal oscillator that is overly prone to stay in a high or low state.
- The connection between depression and circadian rhythms is reviewed in [3]this 2007 article.
- [4]Van Gogh Defense Project: Rationale. Mood tracking to prevent manic episodes.

### Applications

- A friend of mine tried it in 1997. He still does it. [5]These posts tell what happened. [6]Here is what he's learned.
- [7]A man who started doing it in 2006.

### Sources of Faces

- [8]Bloggingheads TV. This site contains many videos of hour-long conversations with two people look at the camera – perfect. On a large monitor, the picture size can be adjusted until they are life-size.
- [9]An animated face. Pretty but slightly creepy.
- [10]Life-size faces on YouTube.
- [11]Big Think. Many interviews with experts.

### Other Resources

## **The Rules of the Tunnel by Ned Zeman (2011-08-24 15:05)**

I loved Ned Zeman's new book [1]The Rules of the Tunnel, which I read during a long plane flight. Not only does it combine three of my favorite subjects – high-end magazines, bipolar disorder, and the crappiness of modern psychiatry – but it's very well-written and revealing. I haven't enjoyed a book so much in a long time.

Zeman once wrote for Spy, as did I. Long ago, I met him at a Spy party. I suppose I could have gotten a free copy of his book but I bought it. I wanted something great to read on the plane.

1. <http://therulesofthetunnel.com/>

---

Peter Silverman (2011-08-26 13:17:27)

My bi-polar symptoms went away a few month after I started taking a supplement from Canada for bi-polar (emPower Plus from Truehope.com.) This was six years ago, and I discontinued Lithium et. al. six months later. I don't know for sure of course,

if the supplement was what did the trick, but I keep hoping it lasts, I haven't had any severe mood swings in the six years, the psychiatrist was skeptical, said maybe the bi-polar "spun itself out." My wife said: My husband's back!"

### **Morning Faces Therapy Page (2011-08-24 18:16)**

If you want to find out about using morning faces to improve your mood, go to [1]this page, to which I will be slowly adding links. If you have suggestions about what to include, please leave a comment or email me. The page is meant to be an easy way to learn more.

peter (2011-08-28 11:05:22)

another reason to be bare footed on ground is "grounding"; it's suppose to drain the build up of electro-magnetic frequency build up in one's body. whatever the precise mechanism, i found that i have considerably more stamina since standing in my bare feet at least 20 minutes a day. i do a form of qi gong; one of the stances/postures is embracing horse, which you're suppose to do/hold for 20 minutes; before i started grounding i was limited to 10-12 minutes until i was exhausted; i now can do the complete 20 minutes with no problem.

Todd (2011-08-29 11:04:43)

The Lieberman interview is great. I especially agree with his statement that "We think that one reason runners crash into the ground is because the shoe makes it possible to hit the ground hard." Thinking that cushioned shoes PREVENT injuries is a consequence of the mindset that fails to look at how complex adaptive systems (like human beings) actually respond to stress. In case after case, measures intended to buffer us from hardship and stress end up hurting us. Edward Tenner's excellent book "Why Things Bite Back" is a grand tour of how the law of unintended consequences applies when such "preventive" measures are unwittingly attempted. Barefoot running is often justified on evolutionary or "paleo" principles, but I think a far more powerful explanatory principle is that of hormesis, the application of controlled stress to elicit an adaptive response that builds long term strength or capacity. I wrote about how this applies specifically in the case of barefoot running mechanics in this post: <http://gettingstronger.org/2010/03/the-paradox-of-barefoot-running/> Todd

Jarno Virtanen (2011-09-10 23:54:34)

### **Alexandra Carmichael Almost Eliminates Headaches (2011-08-29 20:32)**

In [1]this post, Alexandra Carmichael describes how she recently figured out what caused most of her headaches. She had suffered from frequent headaches for twenty years. One source was dairy. She confirmed this source when eating 1/4 stick of butter gave her a splitting headache. Another source was gluten. She got the idea that gluten might matter from the [2]CureTogether list of migraine treatments. A final source turned out to be Febreze, as I mentioned in [3]an earlier post.

You might marvel that conventional healthcare (e.g., doctors, the [4]Mayo Clinic website, and so on) was no help. Or you might not. In the case of [5]the woman I wrote about for Boing Boing, her conventional doctors actively got in the way of helping her find the source of her migraines. Alexandra takes ibuprofen for her headaches. So conventional healthcare (in this case, the makers of ibuprofen) has managed to profit from every one of her headaches but hasn't done one useful thing to prevent them. A nasty state of affairs (provide expensive relief of symptoms, ignore prevention and underlying causes, thus ensuring that people continue to get sick and need relief) that is repeated a thousand places in our healthcare system (e.g., in depression, cancer, etc.).

At the First QS Conference, I gave a talk that included the following equation:

progress = resources\*knowledge\*time\*freedom\*motivation

I used this equation to explain why mainstream medicine was stagnating, but personal science was not. Personal scientists (individuals trying to improve their own health) seem tiny and insignificant compared to medical school professors with million-dollar grants and large labs. But the visible superiority of medical school professors – they have far more resources and knowledge than personal scientists, not to mention more prestige – masks an enormous hidden inferiority: Personal scientists have far more time, freedom, and motivation than medical school professors. And personal scientists are rapidly gaining more resources and knowledge. This is why, in terms of progress, they are catching up to and surpassing mainstream healthcare.

Alexandra's story illustrates the pattern. In this case, personal science made progress (it eliminated most of her headaches), mainstream healthcare did not (it eliminated none of them). And the success of personal science depended on increases in resources and increases in knowledge. A new resource that helped Alexandra was a DailyBurn iPhone app that helped her track what she ate. From those records she noticed a curious pattern: that changes in how much dairy she ate caused trouble. Two new sources of knowledge also helped her. The accumulation of knowledge at CureTogether led to her to suspect gluten was one of her triggers. And my story in Boing Boing led to her to suspect that Febreze and other cleaning products were triggers.

## **The Continued Existence of Acne Reveals the Perverse Incentives of Modern Medicine (2011-08-31 05:00)**

[1]Yesterday I wrote how [2]Alexandra Carmichael's headache story illustrated a large and awful truth about modern healthcare: It happily provides expensive relief of symptoms while ignoring investigation of underlying causes. If we understood underlying causes (e.g., causes of migraines), prevention would be easy. Let people get sick so that we can make money from them. There should be a name for this scam. In law enforcement, it's called entrapment.

Sensible prevention research would start small. Not by trying to prevent breast cancer, or heart disease, or something like that: They take many years to develop and therefore are hard to study. Sensible prevention research would focus on things that are easy to measure and happen soon after their causative agents. One example is migraines. Migraines happen hours after exposure. The fact that Chemical X causes migraines means it is likely that Chemical X is bad for us, even if it doesn't cause migraines in everyone. This is the canary-in-a-coal-mine idea. Migraines are the canary.

Acne is another canary. Acne is easy to measure. Figuring out how to prevent it would be a good way to begin prevention research. To prevent acne would be to take the first steps toward preventing many more diseases. A high-school student could do ground-breaking research – research that would improve the lives of hundreds of millions of people – about how to prevent acne but somehow this never happens. In spite of this possibility, grand-prize-winning high-school science projects, from the most brilliant students in the whole country, are always about trivia.

[3]A just-published review in The Lancet reveals once again the unfortunate perspective of medical school professors. The abstract ends with this:

New research is needed into the therapeutic comparative effectiveness and safety of the many products available, and to better understand the natural history, subtypes, and triggers of acne.

Actually, finding out what causes acne is all that's needed.

To figure out what causes acne (and thereby how to prevent it) three things are necessary: (a) study of environmental causes, such as diet, (b) starting with  $n=1$ , and (c) willingness to test many ideas that might be wrong (because it's far from obvious how to prevent acne). All three of these things are exactly what the current healthcare research system opposes. It opposes prevention research because drug companies don't fund it. It opposes  $n=1$  studies because they are small and cheap, which is low-status. To do such a study would be like driving a Corolla. It opposes studies that could take indefinitely long because such studies are bad for a researcher's career. Researchers need a steady stream of publications.

High school students, who aren't worried about status or number of publications, could make a real contribution here. You don't need fancy equipment to measure acne.

Thanks to Michael Constans.

Valtsu (2011-08-31 06:10:29)

Re causes of acne, You might find this  $n=1$  experiment interesting! <http://www.acne.org/messageboard/Zinc-Zinc-Regimen-Adul-t243340.html> Here are some real studies with nice results: <http://www.lipidworld.com/content/7/1/36> <http://www.ncbi.nlm.nih.gov/pubmed/16871775> <http://www.ncbi.nlm.nih.gov/pubmed/20666829>

Acnefreenow (2011-08-31 11:33:38)

Systemic Inflammation is the primary cause of acne. It causes the tissue around pores to swell up, blocking the pores, which causes oil, etc. to build up, and bacteria to be trapped inside and swell up, resulting in infection. Anything that reduces such inflammation reduces acne. Eating a non-inflammatory diet such as one that excludes refined flours and sugars, helps for example. If you want to convince yourself, conduct your own  $N=1$  experiment by reading up on non-inflammatory nutrition, cut out flours and sugars, and you'll see a massive difference in two weeks.

Seth Roberts (2011-08-31 14:31:01)

"Systemic Inflammation is the primary cause of acne." what is your evidence for this? A student I know cut way down on sugar to test this theory. It helped, but did not make a "massive difference".

Nancy Lebovitz (2011-08-31 15:43:22)

Nitpick: I know someone who gets migraine a few days after eating seafood, so it's not always hours. Still, your general point stands.

Acnefreeenow (2011-08-31 16:19:02)

Seth, Evidence 1: acne-free primitive peoples that go from paleo diets to modern inflammation-promoting diets achieve acne incident rates the same as people in the developed world Evidence 2: at age 44, I have found that like clockwork, when I go off a good paleo/anti-inflammatory lifestyle too far, I still get acne coming back like a teenager, every time, but virtually never when I stay on track I'm not surprised your student didn't see much effect from just reducing sugar. I would recommend they read up on which foods and supplements promote and reduce systemic inflammation, and make whatever changes make sense to them for a full two weeks. At a minimum, I would expect they would need to eliminate ALL sugars and flours for a full two weeks to cool down the body's cytokine levels and other markers of inflammation.

Acnefreeenow (2011-08-31 16:36:30)

The reason I suggest people look at all factors that go in to an anti-inflammatory lifestyle, and not just, say, reduce sugar, is that if your student is unaware that their bad oral hygiene, for example, is an even bigger source of inflammation than their diet, then dietary changes may not be enough. That being said, a good paleo diet plus things like plenty of flax seed oil can go a long way towards reducing orally caused inflammation even if the patient is not a regular brusher/flosser. Other lifestyle factors, like exercise, can also help reduce inflammation. Self-experimentation is the only way to determine what will work for oneself.

MikeW (2011-08-31 17:23:25)

Well, I'll agree with the end of the previous comment, "self-experimentation is the only way to determine what will work". I challenged my acne-prone skin with a load of sugar that would horrify any paleo follower: 3 pounds of jelly bellies over the course of a week. (No lie - I find JB's incredibly addictive.) Result: my skin was perfectly clear, so clear I joked to myself that I had found a cure. Yet one handful of dried blueberries with citric acid added, or so-called fruit snacks (also with citric acid), I immediately feel a tingling in my mouth, a little heat on my face, and within a day I have a few pimples. So in my case I think it's local inflammation, not systemic. I don't know why I have such a reaction to added citric acid - something to do with the mold or yeast they use to produce it industrially I guess. I know there are many good reasons to avoid sugar, but in my experience acne isn't one of them.

bjk (2011-08-31 19:57:56)

I tried many different approaches, this is what worked. First, cut out all omega-6 from diet. Especially soybean oil, but also nuts, peanut butter, olive oil, and some other stuff you wouldn't expect to have it (I know, because I'll eat a large amount (lots of peanut butter, for instance) and then get acne). Second, FCLO daily, not the unfermented kind, that didn't work at all. I like the FCLO with the vitamin K etc etc, don't know if that works better than just plain FCLO. Third, daily benzoyl peroxide regime adds to the effectiveness. I know all of this works because when I don't follow the regime, I get acne. When I do, no acne. My skin also feels much softer and cooler.

john (2011-08-31 20:56:55)

I haven't eaten any junk in about a year, but I still have very mild acne. I eat starches and fruits, but I'm relatively low carb. I do eat high calorie though, as I've never seemed to gain body fat, so that might be a factor. I'm skeptical of the idea that we simply need to do enough "anti-inflammatory" things, as I eat quite a lot of n-3s from fish and have tried flaxseed oil (didn't notice anything) and get a decent amount of sun. I do eat significant amounts of dairy and a coffee every other day, so maybe that'd be a good place to start.

Brent (2011-09-01 00:24:57)

I thought this problem was definitively solved in 2006 with Professor Cordain's book, The Dietary Cure for Acne. <http://www.amazon.com/Dietary-Cure-Ph-D-Loren-Cordain/dp/0978510917-B>

Seth Roberts (2011-09-01 03:19:58)

Brent, this long discussion suggests a different cause of acne than the ones theorized by Cordain: <http://www.acne.org/messageboard/Zinc-Zinc-Regimen-Adul-t243340.html>

bjk (2011-09-01 06:27:09)

"I'm skeptical of the idea that we simply need to do enough "anti-inflammatory" things, as I eat quite a lot of n-3s from fish and have tried flaxseed oil (didn't notice anything) and get a decent amount of sun." I found flaxseed oil didn't work. It has high omega-3:omega-6 ratio, but the absolute level of omega-6 is too high. That's my experience, not saying I could pass an exam on the difference, but lowering the absolute level has made a noticeable difference on my skin.

Jeff (2011-09-01 17:30:54)

As a high school student myself, I experience firsthand the poor environment most of my peers live in and see the possibility of what could be. However, I do not feel I could "do groundbreaking research." Cooperation would be hard, if not impossible, to come by. To be honest with you, the majority of my peers could care less about their health. I can not even bring up my dietary opinions in casual conversations with some of my peers because they simply do not want to hear that their two-Gatorade-a-day habit could be detrimental to their health. I'm ashamed to admit this, but this close-minded, apathetic attitude has led me to keep my mouth shut when discussions of health and diet do happen to arise. I would love to make a contribution, but have no idea where to start. No mother would allow some teenager to be guiding her child's nutritional habits. Additionally, who would listen to a teenager? We are stereotyped as immature and irresponsible as it is, therefore have no credibility, even if one did have sound data pointing to a sound conclusion. -Jeff

Seth Roberts (2011-09-01 18:15:55)

Jeff, you can study yourself, if you have acne.

Maria Schröder (2011-09-28 08:25:19)

Hello all ! I am new to forums that discuss Acne and other skin imperfections. I have been suffering for many years and sometimes almost given up on mingling with other people because of my looks. I can never talk to anyone unless I feel that the person is looking at my ugly blackheads, whiteheads and scars. I write to day because I am stuck. I heard last week of a new formula that was so powerful that a person with my skin problems would get rid off the acne in just 2 or 3 months and could stay acne free by using the formula once a month. But the person that told me this had forgotten where this formula was obtained from. The only thing she remembered was "wonderful scandinavia". Has anyone of you people heard about this fomula ? I really would appreciate the info if this is as good as the story was. Maria Schröder maria@myndabankinn.is

Maria (2011-10-03 17:44:02)

I had the worst cystic acne you ever saw from the time I was 16 until age 27. It was hard for me to even look at myself in the mirror. Like most people facing that I went from doctor to doctor and tried every medication available but nothing really helped much. Then In starting taking Accutane and everything changed. In a couple of weeks the cysts were gone and when I finished taking all the prescribed pills the cysts were gone and never came back. I know that Accutane won't prevent or cure acne but it sure delivered the knockout punch to my cystic acne.

Ted (2012-01-22 01:37:37)

My acne cleared up after I had been taking lots of fish oil (6 grams) every day for 5 months. After a couple of years, though, I noticed that the fish oil, while improving my skin and initially my mood, was starting to make me feel sluggish and depressed. So I cut way down on fish oil (half a gram a day) and instead eliminated as much omega-6 from my diet as I possibly could. My skin remained clear and I stopped feeling sluggish and depressed. (Off-topic, but when I cut gluten out of my diet, my lifelong

dandruff disappeared within a couple of weeks and has never returned.)

Nancy Lebovitz (2011-09-02 12:42:43)

I listened to the Tucker Max piece. He didn't sound deliberately offensive- just kind of nervous. If you've been following his career, has he been taking a more reasonable tone after he'd been doing MMA for a while. He talked about how MMA was good for him psychologically as well as physically.

### Van Gogh Defense Project: Rationale (2011-09-01 18:19)

A colleague I'll call John has decided to start tracking his mood for a long period of time (years). He explains why:

A few years ago, after a severe manic attack, I was diagnosed with bipolar disorder. The attack was preceded by an intense period of stress, then two weeks of elevated mood, increased social activity (hanging out and meeting people), and racing thoughts (hypomania). Then I skipped a few nights of sleep, wandered down roads in the middle of the night, and eventually became psychotic, in that I could no longer distinguish between reality and imagination. I was chased by cops on several occasions, and was involuntarily committed to the mental health wing of a hospital for a month. It put a massive dent in my life.

Family, medicine, and time helped me recover. Being out of control like that was fun only for the first two weeks. Having my life turned upside down was not fun either. As I recovered I became increasingly interested in finding ways to prevent a relapse. One doctor said: You have a vulnerability. You need to protect yourself. I agreed.

Looking back on the experience, I realized there was a rise in odd behaviors two weeks before I started to skip nights of sleep and fell into psychosis. There was an even longer buildup of stress, anxiety, and fear in the months before the mania hit. During the last two weeks before the mania, my behavior was different from what is normal for me. I felt

elated and had a sense of general "breakthrough". I suddenly felt no fear and anxiety. I felt on top of the world. I was constantly taking notes because ideas and thoughts were running through my head. I scheduled meetings and social activities almost constantly throughout these two weeks and shared my experiences as my new self. As I started to sleep less and skip nights of sleep, others later told me I seemed agitated and down.

Maybe it is possible to catch these early warning signs and take counter measures before they worsen into mania or depression. This is why I have started to track my behavior starting with mood and sleep. If I can get a baseline of my behavior and know what is 'normal' for me, it will be easier to notice when I am outside my normal range. I can alert myself or be alerted by others around me who are monitoring me. Long-term records of mood will also help me experiment to see which things influence my mood. This may give me more control over my mood.

Mood tracking might be a good idea for anyone to do, but it may be especially helpful for people with a bipolar diagnosis. Everyone has mood variation. For bipolars, however, mood swings can be more extreme (in both directions, up and down) , have far worse consequences (psychosis on one end and suicide on the other), change more rapidly, and be more vulnerable to environmental triggers like stress. The good news is that the first changes in mood can happen hours or days before more extreme changes. This gives people a chance to take countermeasures to prevent more extreme states.

The project name refers to the fact that Van Gogh had bipolar disorder.

---

Tim Beneke (2011-09-02 11:31:50)

I want to thank Seth's colleague "John" for articulating and sharing this. I am not bipolar, but I do have relatively mild manic tendencies, and I am very vulnerable to serious depression and work hard to find ways to avoid/avert it, with reasonable success the last decade or so. I periodically rediscover how important good circadian rhythms are in protecting me from depression – getting up and getting sunlight early in the morning makes a big difference. (A realization I owe to Seth.) Reading "John's" account is helpful. It's a real challenge to maintain some objectivity about one's moods and the factors that may be influencing them; it requires real work – and work that one should not try to do entirely alone. The help and feedback of loved ones, colleagues, etc. is important. And gaining valid causal knowledge of what is influencing your mood is crucial – I find it regrettable that the therapeutic establishment that I sought help from for many years had little valid knowledge. They mostly wanted me to revisit the "repressed" emotions of my childhood – that road led only to more suffering and was mostly a waste of time. My impression is that many people of my baby boomer generation are learning to become managers of their moods, weight, sleep, energy, relationships, etc.... Thanks again, "John".

Minhaj (2011-09-04 06:01:23)

Thanks! That is a very clear description of what you went through. I love the name Van Gogh Defense Project. As you you have experienced with intensity what some of us go have only felt at a mild level, I think this is inspiring. After reading this I want to track my mood because this is very relevant and its about self awareness. I think getting to know ourselves better is the dream and goal of a philosopher/Writer and having years of data can really help improve my life.

**Workplace of the Future: The Chair (2011-09-03 05:00)**

[1]

Standing desks are becoming popular. From [2]a WSJ article:

A growing number of workers at Google Inc., Facebook Inc. and other employers are trading in their sit-down desks for standing ones, saying they feel more comfortable and energized. They also are motivated by medical reports saying that sitting for too long leads to increased health risks.

I started standing while working fifteen years ago, after I found that [3]I slept better if I stood a lot. I got a standing desk. (Parts at Ikea \$100.) I made what was apparently [4]the first treadmill desk. But since then I learned a lot and my preferences changed. I never went back to a conventional desk, but I found that a standing desk wasn't optimal. Here's what I learned:

1. Standing a lot is not all good. Standing in one place for a long time is psychologically difficult. If I stood for more than 8 hours or so, my feet started to hurt. Yet I needed at least 8 hours of standing to get the sleep benefits. I also found epidemiology that suggested that if you stand a lot, your blood puddles in your legs, with bad effects. Above all, standing in one place is distracting, probably because it is inherently unpleasant. I find it much easier to write in the lounge-like position I describe below.

2. Walking a lot is bad. I work perhaps 8 hours per day. No way would I walk that much. The main use of my treadmill desk was standing, not walking. There was also a noise problem. Occupants of adjacent office complained.

3. Walking a little is good. If I walk about 20 minutes per hour, I found I can work really long periods of time—without stimulants. I have also found that walking makes my brain work better. The measure I used to detect this improvement was arithmetic speed but I'm sure it applies to all sorts of thinking.

4. [5]One-legged standing can produce the sleep benefits of normal standing. The benefits of better sleep are huge. After I started sleeping better, mainly because of standing a lot, [6]I stopped getting obvious colds. I also felt more energetic during the day.

When you put these together it is easy to grasp that the best workplace will not involve, as its main component, a standing desk.

Nowadays I mix lounge-like sitting (there is no one word for it) and walking. By "lounge-like sitting" I mean I sit in

such a way that I lean back somewhat (so that some of my weight is on my back) and my knees are both bent and supported. The chair pictured above is the closest piece of furniture I could find designed for this. The goal of such a piece of furniture is to make the surface area (i.e., skin) supporting you as wide as possible so that the maximum pressure is minimized. A normal chair does a terrible job of this, but even the chair in the picture is not ideal: (a) It should have armrests. (b) It should have adjustable weights so that the angle at which it reclines can be set to the best position. How much walking I do depends on the time of day. During the day, when I feel restless, I might walk on a treadmill 20 minutes per hour. In the early morning and evening I don't walk at all.

It's fascinating there's no word for an action I spend many hours every day performing and that perhaps a billion people would do many hours per day if they could. (At least a billion people have jobs where they must sit in ordinary chairs.) What I do is roughly a billion times more comfortable. Given the size of the market and the size of the benefit, it is equally fascinating that you cannot buy anywhere the proper furniture for doing this. [7]The company that made the chair in the picture seems to have stopped making it. This should give pause to anyone who thinks that any or all of (a) free markets, (b) governments, or (c) academic/pure research can produce all the products we need to live a healthy happy life.

Charles (2011-09-03 07:25:46)

For the same reason I got a "Zero-gravity Chair." (You can Google it.) They are expensive, but have all the features you discuss. Highly recommend it! I've had mine for five years and love it. I have it in my office and use it as you suggest.

Charles (2011-09-03 07:27:03)

<http://www.relaxtheback.com/recliners/zero-gravity.html> I didn't know if your filter would allow the link.

Shawn (2011-09-03 08:07:41)

When I lounge-like sit I simply lean back in my chair and put my legs on the desk. I can obtain the same position you describe. I've been doing this naturally for quite some time; it just feels right, most likely because it helps even-out blood flow throughout the body. (Usually the part of the knee down to the feet goes on the desk.) It's easy for me to reposition myself because sometimes I like to sit normally as well.

Leslie (2011-09-03 08:48:40)

Some researchers did a study where they put people in an MRI, seated at either a 70, 90, or 135 degree angle, and came to the conclusion that leaning back in your chair is better for you... <http://news.bbc.co.uk/2/hi/6187080.stm>

sawfoot (2011-09-03 10:33:07)

You can get garden lounge chairs "zero gravity" style pretty cheaply ( \$50) which would seem to fit the bill.

Kirk (2011-09-03 10:44:23)

Several months ago I switched over to standing at my computer. My sleep has been much better since. (There is one other change that I made at that time, so I'm not positive it's the standing, but I think it is.) This change to standing at the computer replaced about 3 hours of sitting with 3 hours of standing. As for a chair that leans back with legs supported, I have one of those, the Lazboy Forte Reclina-Rocker. Not standard cubicle equipment. (I work from home so I can get away with it.) I have two problems with extended sessions in the recliner: (1) I get sleepy and (2) it hurts my lower back when I read. Mostly I use it for short naps, light reading, or when I have to sleep while keeping the head elevated, such as when suffering nasal congestion. I think the better approach involves sitting straight. If I remember correctly, Esther Gokhale in '8 Steps to a Pain-Free Back' recommends this approach to sitting. Another expert on posture whom I respect, Professor Cheng Man-ching, said, "The back of the chair is for hanging your coat." Wolfe Lowenthal explained that meant you should not lean back in your chair.

et (2011-09-03 11:21:41)

Couldn't this be summed up as: Variation is better than static?

Kevin Miller (2011-09-03 12:11:15)

I've been using a standing desk for about a year and have discovered something my physician friend says is well known among people who have to stand all day - that being able to have one foot higher than the other makes a big difference. This is implemented in a few different ways - the desk I made uses a Geekdesk, which has a horizontal bar conveniently place for leaning a foot against, I've also used a small rubbermaid stool, and most recently I've been standing on a partly inflated Bosu ball (which helps me work on my balance). I also have a table I sit at when I'm meeting with students and a comfortable chair with footrest that I can sit in if I'm just reading a long paper, and I do move back and forth among these locations. The big advantage I find in standing is that it makes it easier for me to pace around or to take short walks; the minor gravity well of sitting in a chair seems to inhibit some of that activity. But I note that if I end up sitting all day I'm a bit stiff at the end, and I don't have that experience with my standing desk.

Kim Øyhus (2011-09-03 12:28:32)

I used the chair you are looking for, for two decades: <http://artdco.net/wp-content/uploads/49877b0f8eccd.jpg>  
[http://www.opsvik.no/index.asp?page=works\\_11002\\_balans\\_Duo\\_anim](http://www.opsvik.no/index.asp?page=works_11002_balans_Duo_anim) It even got a prize for being the best office chair, so they discontinued it. Nagging them to make new ones got me nowhere, and the one I had was completely worn out and repaired many times, so I bought one of designer Opsvik's newer chairs, which is not nearly as good.

Perfect Health Diet » Around the Web; Labor Day Edition (2011-09-03 15:28:16)

[...] Seth Roberts, who pioneered the treadmill desk, is on to the next big thing: the lounge-office. [...]

Ren (2011-09-04 21:01:20)

Professor i am a thu student. i want to be a Postgraduate in THU Psychology.and when i came to the thu Psychology website to learn something and see your website then i clicked to here. I write my wordpress blog about my thinking life in chinese here:<http://rene1989.web-126.com/> it seems that you have difficulty in chinese.it is a pity that you will not read my blogs. I ADORE YOU ,YOU ARE NOT ONLY A SERIOUS PRO, BUT ONE LIKE TO SHARE YOUR IDEAS

bc (2011-09-05 11:52:37)

That chair pictured above looks to be inspired by the Le Corbusier chaise lounge, although the one above looks like it rocks and the LC doesn't, although you can slide it to different angles. You can certainly still buy the Le Corbusier chair.

gesher (2011-09-05 15:28:47)

Nowadays I mix lounge-like sitting (there is no one word for it) and walking. ... It's fascinating there's no word for an action I

spend many hours every day performing [...] You mean reclining?

Seth Roberts (2011-09-05 15:43:20)

"You mean reclining"? No, I don't. My knees are bent & supported. Reclining does not imply that.

Noumenon (2011-09-06 01:48:32)

I spent a long time in the La-Z-boy store shopping for a "computer recliner" that would have a mouse pad holder instead of a right armrest. I did find some half-recliners but eventually came up empty. Don't people want to surf from a recliner? I suppose you use a laptop.

Seth Roberts (2011-09-06 13:11:09)

yes, I use a laptop.

Jennifer Eloff (2011-09-04 13:34:59)

Just thought I'd comment. Thanks for the link to my blog post (not one I am particularly proud of, but it makes a point). You have a popular blog because my stats went through the roof. That was fun!! Have a nice day. :)

James A Donald (2011-09-04 14:51:35)

The five trillion was not stolen by the banksters. Check all that spam in your inbox. Along with the ads for real viagra, fake viagra, and viagra manufactured in violation of patents, you will see offers of no money down loans. A very large number of people, most of them Hispanic, many of them with no job or legal income, purchased million dollar houses no money down,

and never made a payment on them. If the price went up, they intended to flip them for a profit. If the price went down, they intended to live in it rent free indefinitely. And who is responsible for the bright idea of lending to such people? You will find the answer at [http://www2.fdic.gov/crapes/2007/32069\\_071001.pdf](http://www2.fdic.gov/crapes/2007/32069_071001.pdf)

UncleLongHair (2011-09-05 08:44:12)

Where does this 2.2 trillion figure come from? I think it is completely fabricated. The CEO of Wells Fargo was recently paid \$21 million in a year. That is a lot, maybe too much and excessive, but it would take 22 thousand pay packages this size to add up to 2.2 trillion over 5 years, and only a handful of execs are paid like this. What exactly constitutes a "banker", are they including hedge funds and investment banks like Goldman Sachs? Maybe they are including all of the rank and file bank employees - suggesting that bank tellers are overpaid? I think some fact checking is in order before accepting this argument.

Paul Sherrard (2011-09-06 13:00:00)

"OMG we gave trillions of \$ \$ \$ to the banks? Michelle Malkin never told me!" The federal government bought up trillions' worth of worthless toxic assets from the banks. <http://sanders.senate.gov/newsroom/news/?id=9e2a4ea8-6e73-4be2-a753-62060dcbb3c3>: They have NOT SPENT ONE DIME in aid for defaulting homeowners. Hispanic or not. Furthermore, the homes were foreclosed on. They represent assets RETURNED to the banks. This is not too hard to figure out. The people who bought homes they couldn't afford and are now out on the street? No, they're not the ones who took our money and ran.

Paul Sherrard (2011-09-06 13:05:44)

Anyway, I think it's important that Taleb's larger point be stressed: the call for widespread divestment in banks that enrich their employees at public expense.

Joseph Moroco (2011-09-08 08:29:20)

Love all the chocolate is good for us articles, but really wish someone would lie to me and say there is scientific proof that it is "milk" chocolate that benefits me.

## **Poor Replication Rate in Psychiatric Genetics Research (2011-09-05 13:29)**

With the ability to measure individual genes has come interest in learning what they do. Perhaps Person X is depressed and Person Y is not depressed because Person X's genes differ from Person Y's. A whole generation of psychiatry researchers now believes this is plausible. There are "general reasons to expect that GxEs [gene by environment interactions] are common," says [1] a new review paper in the American Journal of Psychiatry. By "common" they mean large enough and common enough to do research about.

I don't agree with this conclusion. Sure, twin studies show that genes matter for psychiatric diagnoses. Identical twins are more likely to be concordant (= have the same diagnosis) than fraternal twins, for example. But this is a very long way from indicating that single genes matter. Twins results are entirely consistent with the possibility that a large number of genes each matter a little. If this is true - and I find it far more plausible, when it comes to psychiatry, than the single-gene idea - then searching for one gene that does this or that is a waste of time. Individual genes are too weak. To do psychiatric gene research you have to dismiss or ignore the many-tiny-effects possibility, because if true it would mean what you are doing is bound to fail. The new review paper I mentioned ignores it.

The new review paper surveys all of the research papers about GxEs during the first decade of research (2000-2009) in this area - about 100 papers. It asks (a) if initial findings have been repeatable and (b) how much we should trust the repetition attempts. To answer the first question, they found that only a third (10 of 37) of initial findings were repeated when tested a second time. If things were working well, all of the initial findings would have been repeatable. The low replication rate doesn't mean that two-thirds of the initial findings were false. Perhaps the replication attempts were poorly done and all of the initial findings would have held up if they were better done (e.g., larger

samples). Or perhaps the replication attempts were biased toward positive results and none of the initial findings would have held up if they were better done.

The review paper also found that positive replication attempts had much smaller samples (median sample size about 150) than negative replication attempts (median sample size about 380). This suggests that the negative replication attempts are more trustworthy than the positive ones. The true replication rate is probably lower than one-third.

The findings, in other words, support my initial belief that the whole field is a waste of time. Amusingly, the authors of the review (one at Harvard, the other at the University of Colorado) conclude the opposite. Here's what they say:

This review should not be taken as a call for skepticism about the G×E field in psychiatry. . . . True progress in understanding G×Es in psychiatry requires investigators, reviewers, and editors to agree on standards that will increase certainty in reported results. By doing so, the second decade of G×E research in psychiatry can live up to the promises made by the first.

Of course their findings support skepticism about G×E research. This isn't slanting your conclusions to be more convenient, this is bending them backwards. And failure to mention the many-tiny-effects possibility, a plausible explanation for all the results they describe, is another sign that this area of research is not to be trusted.

Alex Chernavsky (2011-09-05 19:45:05)

Speaking of concordance studies in identical twins, see: [1]"The Fallacy of the 50 % Concordance Rate for Schizophrenia in Identical Twins"

1. <http://human-nature.com/nibbs/03/joseph.html>

Sam (2011-09-06 01:23:19)

Twin studies usually forget that even twins grew in the same womb, got the same nutrients and stimulants there and therefore share a very important part of growing (up) even if they are separated at birth. The time in the womb is the foundation for everything that follows. Of course people with the same foundation will have similarities. Gerald Hüther has published very good information about this.

Seth Roberts (2011-09-06 13:25:05)

Sam, that's why I pointed to differences between fraternal twins and identical twins.

Perfect Health Diet » Around the Web; 9/11 Remembrance and Brain Injury Recovery Edition (2011-09-10 11:53:44)

[...] Other times, research proceeds busily in a hopeless direction. For instance, genes are densely networked, and so no one gene has a big effect; observed effects may be mostly noise. Seth Roberts argues that reported gene-environment interactions may all be invalid. [...]

## Anil Potti, Ranjit Chandra, and Reducing Scientific Fraud (2011-09-07 05:00)

[1]An account of the genomics scandal at Duke University has appeared in Significance (a journal sponsored by British and American statistical societies). The scandal caused the end of a clinical trial – it had been based on fraudulent data – and the resignation of assistant professor Anil Potti, who had among other things falsified his resume.

It reminded me of [2]the Ranjit Chandra case. Similarities: 1. The published results could not be reconstructed from data. In Chandra's case, some of the results were statistically impossible. In the Potti case, two statisticians were unable to go from raw data they were given to the published results. 2. Outsiders important. Saul Sternberg and I, who are psychology professors, not nutrition professors, wrote an article that drew attention to what Chandra had done and caused retraction of one of his papers. As far as I could tell, at least a few nutrition professors had believed for many years that Chandra made up data. In Potti's case, the deception was revealed by two statisticians. Perhaps Chandra and Potti both believed (a) hardly anyone will notice and (b) if anyone notices, they won't do anything. 3. Incidental fabrication. In one paper, Chandra said that everyone asked to be in the study agreed to participate. The study involved having blood drawn many times. Potti claimed to be something similar to a Rhodes Scholar. 4. Found innocent. Years before Sternberg and I got involved, Chandra had been accused by his research assistant, a nurse. A Memorial University committee found him innocent of her accusations – at least, her accusations were not upheld. Chandra then sued the nurse. In the Potti case, a Duke University committee looked into the case and found no serious wrongdoing. A clinical trial based on the Potti results, which had been stopped, was resumed.

Factor 2 (outsiders important) is no surprise to readers of this blog, although the new account doesn't mention it. But Factors 1 (reconstruction impossible) and 3 (incidental fabrication) mean that the fabrication should have been relatively easy to confirm. Yet Factor 4 seems to suggest it was hard to confirm. Factor 4 – in spite of Factors 1 and 3 – implies there is something mysterious and important going on here, more mysterious and interesting than someone lying. But I cannot say what.

The Significance article, which is by Darrel Ince, a professor of computing at the Open University, includes several suggestions for improving the system. I fail to see why they will help and they have significant costs. One of them is to put the original data and software in an independent repository. I think this would make things worse. People would continue to fake research; now, they would now also fake raw data, in addition to the graphs and tables needed for publication. In the past, thinking they wouldn't be caught, fakers would either (a) not make up the raw data (Chandra) or (b) do so carelessly (Potti). Their overconfidence was key to catching them.

My suggestion along these lines is a requirement that researchers make available upon request the raw data and any original software. They store it themselves, in other words. If they fail to fulfill outside requests for these materials within one month, this will be grounds for immediate retraction of the paper. Without something like this, a store-it-yourself requirement means little. I once requested the raw data for a paper that had appeared in a journal that had a make-data-available policy. The authors refused my request. The editor did nothing. As A. W. Montford makes clear in [3]The Hockey Stick Illusion, we would all be better off if Michael Mann and other authors had simply handed over the raw data behind their "hockey stick" temperature graphs when requested rather than fight a long string of FOIA battles (and [4]mull over what emails to delete).

John (2011-09-07 05:53:20)

As I understand it, the Duke case was not about fraudulent data but sloppy data analysis. Some may feel that "sloppy" is being too generous and that there was fraud in the analysis. But I don't believe anyone is questioning the data itself, only the analysis.

Jun Zhai (2011-09-07 09:41:08)

Anil Potti did avoid share his raw data from his bioinformation and statistician colleagues. They've been suspecting fishy data handling way before the scandal outbreak. He made Joe Nevins believe he did better job analyzing their data than statisticians can.

Mike H (2011-09-07 11:32:34)

I like this idea. Assumedly competing "data banks" would arise, that would offer to store the data and fulfill requests for a fee.

Seth Roberts (2011-09-07 12:59:59)

John, you're right, I have not heard the data "questioned" – just the whole analysis, which could be said to include more than the data. On the other hand, you are the first person I've heard say that perhaps Potti was merely sloppy – that is, made honest mistakes. The whole picture doesn't support that conclusion. There were too many problems, for one thing. And the effect of all the supposed sloppiness was far too favorable for the sloppy person.

Alrenous (2011-09-07 15:27:39)

Factor 4 does prove that the oversight committees are incompetent at oversight. They're either not using the obvious metrics or invalidly explaining away negative results. As always, I distrust official pronouncements unless I have specific evidence to confirm them. Historically, such committees have been rubber-stamp providers, used as political gatekeepers. For example, if these scientists and committees were Chinese, everyone would just assume it was all political. In this case, we have specific evidence that they are similar to the historical norm. Fact is, unravelling the support for the corrupt institution is highly complex. (That's why they're the historical norm.) For example, having the entire voting public well-versed in history would do it - it would be well known they're usually 100 % political - but that's impossible. In any case, the perverse incentives have to be disrupted, and these particular perverse incentives are due to system-wide perverse incentives. Though, eventually it will go away on its own. Rubber-stamp enough fraudulent studies, and even the thickest observer will realize the scientists aren't reliable.

Parvathi (2011-09-07 18:29:46)

Both researchers are Indians. Indians cheat a lot.

horace (2011-09-07 19:27:36)

Your are missing the most important part of the story, what happened to the nurse ? Was she punished ? If so the most important lesson that we can draw is that if you see scientific misconduct on the part of a superior, keep your mouth shut.

{ Brown Pundits } » Three Links (2011-09-07 21:42:57)

[...] Seth Roberts, of "Shangri-La Diet" fame, beats the Anil Potti drum after a year of silence. Medscape reports that yet another Potti paper has [...]

Seth Roberts (2011-09-08 03:14:18)

"was the nurse punished?" As I said she was sued. That is punishment, for sure.

John (2011-09-08 10:53:32)

I followed the Potti story more closely at the beginning than now. My colleagues were the ones who tried and failed to reproduce the analysis. At first it looked like incompetence. Now more people are suggesting fraud. It's sobering to realize how difficult it was to get anyone to acknowledge there was a problem here. Baggerly and Coombes had to be very persistent in their criticism before people started to pay attention. Eventually it became a scandal, but it would not have been if they had given up after, say, a year.

Seth Roberts (2011-09-08 23:00:13)

"At first it looked like incompetence." At first it was interpreted as incompetence, I suppose, only because that was the more charitable and safer interpretation. It was not a likely explanation. Incompetence turns great raw data into bad surface data. Never the opposite. Potti had great surface data.

John (2011-09-09 14:56:03)

I believe you're arguing that the probability of a positive result given an error is small. And I agree. Mistakes usually don't help your case. But consider the opposite probability, the probability of an error given a positive result. Suppose you're working in an area where positive results are few and far between. What is the probability that a promising result resulted from a bungled analysis? Possibly high. If nearly every result is truly negative, the positive ones that catch our attention are likely to be in error. There could be an effect analogous to stochastic resonance.

John (2011-09-10 03:38:40)

Here's a new article about the Potti case from The Economist that was just posted. <http://www.economist.com/node/21528593>  
Here's my favorite line from the article: "I find it ironic that we have been yelling for three years about the science, which has the potential to be very damaging to patients, but that was not what has started things rolling." Bad science didn't bring Potti down, padding his resume did.

Seth Roberts (2011-09-10 04:57:22)

Thanks for the link, John. Excellent article. My favorite line is: Dr. Nevins "could not explain why he had not detected the problems even when alerted to anomalies." In other words, Nevins did not understand the research in a paper that he co-authored.

John (2011-09-10 11:56:23)

Your comment about Nevins reminds me of someone – I forget who, I may have seen it on Andrew Gelman's blog – who blamed problems with his article on a graduate student who had not been listed as a co-author. In other words, "I get the credit and my peons take the blame." What a deal!

### **Acupuncture Critic Misses Big Points (2011-09-09 12:11)**

Recently the Guardian ran [1]an article by David Colquhoun, a professor of pharmacology at University College London, complaining about peer review. His complaints were innocuous; what was interesting was his example. How bad is peer review? he said. Look what gets published! He pointed to [2]a study of the efficacy of acupuncture and included graphs of the results. "It's obvious at a glance that acupuncture has at best a tiny and erratic effect on any of the outcomes that were measured," he wrote.

Except it wasn't. There were four graphs. Each had two lines – one labelled "acupuncture," the other labelled "control". You might think to assess the effect of acupuncture you compare the two lines. That wasn't true. The labels were

misleading. The "acupuncture" group got acupuncture early in the experiment; the "control" group got acupuncture late in the experiment. Better names would have been early treatment and late treatment. You could not allow for this "at a glance". It was too complicated. With this design, if acupuncture were effective the difference between the two lines should be "erratic".

The paper's data analysis is poor. To judge the efficacy of acupuncture, their main comparison used only the data from the first 26 weeks. They could have used data from all 52 weeks. That is, they ignored half of their data when trying to answer their main question. Colquhoun could have criticized that, but he didn't.

Colquhoun's criticism was so harsh and shallow, apparently he is biased against acupuncture. But there are two big things few pharmacology professors appear to know. One is how to stimulate the immune system. This should be central in pharmacology, but it isn't. Half of why I think fermented foods are so important is that I think they stimulate the immune system. (The other half is they improve digestion.) There are plenty of less common ways to do this. The phenomenon of hormesis suggests that small doses of all sorts of poisons, including radiation, stimulate repair systems. The evidence behind the hygiene hypothesis suggests that dirt improves the immune systems of children. Bee stings have been used to treat arthritis. And so on. In this context, sticking needles into someone, which puts a small amount of bacteria into their blood, is not absurd. Acupuncture also allowed patients to share their symptoms, the value of which [3]Jon Cousins has emphasized.

The other big thing Colquhoun doesn't seem to know is the absurdity of the chemical imbalance theory of depression. Speaking of ridiculous, that's ridiculous. Which plays a larger role in modern medicine – antidepressants or acupuncture? If you want criticize peer review, criticize the chemical imbalance theory. It is as if peer reviewers have been saying, yes, the earth really is flat for fifty years. Perhaps this is ending. During a talk that Robert Whitaker gave at the Massachusetts General Hospital in January, he was [4]told by doctors there that the chemical-imbalance theory was an "outdated model".

Thanks to Dave Lull and Gary Wolf.

gwern (2011-09-09 13:47:47)

> In this context, sticking needles into someone, which puts a small amount of bacteria into their blood, is not absurd. In the vast acupuncture literature, no particular importance has been noted about breaking the skin barrier... eg. <http://www.sciencedaily.com/releases/2008/12/081201082353.htm> > 109 received traditional acupuncture, with needles penetrating the skin in particular points. According to ancient Chinese tradition, the needle is twisted until a certain 'needle sensation' arises. The other 106 patients received a simulated acupuncture instead, with a telescopic, blunt placebo needle that merely touches the skin. The acupuncture was performed by physiotherapists two or three times a week throughout the five-week radiation period. > > Afterwards 95 percent of the patients in both groups felt that the acupuncture treatment had helped relieve nausea, and 67 percent had experienced other positive effects such as improved sleep, brighter mood, and less pain.

Seth Roberts (2011-09-10 04:59:58)

Thanks, Gwern. I agree, that argues against the little-bit-of-bacteria explanation.

The Way to Healthy Living - Page 5 (2011-09-10 09:35:50)

[...] repeats his interventions he can be certain what is causing what. You may also be interested in his article on Acupuncture There is too much sloppy science around and too much telling of stories that have little basis in [...]

gwern (2011-09-10 14:20:16)

Another anti-bacteria point that occurred to me this morning. The usual way acupuncture trials are blinded are by sticking in needles in places which \*aren't\* the special chi meridians or whatever hogwash that particular acupuncture claims. Presumably both the meridians and random points near meridians are equally unclean, and so studies should never show a difference beyond random noise and bias if the bacteria point were true (both 'control' and experimental groups being equally contaminated); but acupuncture is still a live issue, so...

David Colquhoun (2011-09-12 11:01:25)

Well, you may have written a book about diet, but I have written a textbook on statistics. If you want to get mathematical I'll take happy to take you on, You really shouldn't invent things. I have never from its start thought much of the "serotonin hypothesis". As it happens I'm talking tomorrow to clinicians about, among other things, that downfall of SSRIs, once the whole evidence emerged (and incidentally, the downfall with them of St John's Wort, which every herbalist boasted is as good as SSRIs. Talking of made up theories, the corniest of all has to be "stimulating the immune system". There is, and never has been, any evidence that it happens -it is the eternal mantra of every quack who is trying to sell you their own brand of implausible therapy. Incidentally, it is considered polite to spell authors' names correctly. Gamma minus

Seth Roberts (2011-09-12 14:28:01)

Prof. Colquhoun, I have fixed the spelling of your name, thanks for the correction. As for the rest of your comment, I am glad you never took the "serotonin hypothesis" seriously. Because antidepressants are far more important than acupuncture, that theory would have been a far more interesting target of criticism than an acupuncture experiment. You say that stimulating the immune system is the "eternal mantra of every quack". And I say that few pharmacology professors know how to stimulate the immune system. We seem to agree here. If you would like evidence that the immune system can be stimulated, you should study the many connections between better sleep and better health. I am sure that sleep stimulates the immune system. If you would like to see evidence of immune stimulation by something like drugs, check out studies of the effects of probiotics on health. Finally, as for statistics, I believe that your criticism of the acupuncture graphs was misleading and you failed to point out a really big blunder in the acupuncture paper – ignoring half of their data when answering their biggest question. But perhaps we agree here too. You say peer reviewers make big mistakes. I say you – who surely review many papers – made big mistakes. You see the similarity of our positions, I hope. It seemed to me that the pot was calling the kettle black.

## **Great TV: Downton Abbey, Switched At Birth, Suits (2011-09-10 23:41)**

Everyone knows Mad Men, The Good Wife, and Glee – especially Mad Men – are great TV. If you read about TV, you have read about them – especially Mad Men – endlessly. Not everyone knows that Downton Abbey [1](second season trailer), Switched At Birth, and Suits are also great TV.

Downton Abbey is great because Julian Fellowes, who also wrote Snobs and Gosford Park, is a great writer. The plot is good, the details are good. I'd read or watch anything he does. (After I wrote this post I came across [2]this interview with Fellowes – apparently the NY Times saw the same gap in coverage as I did.)

Switched At Birth is great because to a perfectly good idea for a TV show (two girls are switched at birth, a fact discovered when they are teenagers) was added – by management, not the originators of the show – an excellent

idea: one of the girls is deaf. This adds an attractive layer of complexity and novelty (deaf teenage life).

Suits appears formulaic: lawyer show, buddy show, cartoon villain, romantic plot connecting the episodes, every episode, the good guys win cleverly. But perhaps the formula, whatever it is, is really well-executed because I enjoy every episode and don't feel dirty afterwards.

1. [http://www.youtube.com/watch?v=xpoSSLeX60Q&feature=player\\_embedded](http://www.youtube.com/watch?v=xpoSSLeX60Q&feature=player_embedded)

2. <http://www.nytimes.com/2011/09/11/magazine/julian-fellowes-the-creator-of-downton-abbey.html?pagewanted=all>

---

dearieme (2011-09-11 07:29:05)

Downton Abbey bears one resemblance to Pride and Prejudice: everything turns on an "entail" in a will.

TomGinTX (2011-09-11 09:29:08)

I like the shows on USA Network, but \_Suits\_ is at the bottom of the list. I like Psych, Burn Notice, and White Collar much better.

Stephen M (Ethesis) (2011-09-11 15:37:14)

Now I have to watch some television again. ;)

Eric (2011-09-12 17:55:35)

Other good shows that are overlooked: Luther, Zen, Louie, The Hour, The Killing, and Friday Night Dinner.

dearieme (2011-09-13 07:32:31)

Yes, I liked "Zen" too. Unfortunately they decided not to make any more.

emily (2011-09-13 15:56:51)

so are u saying there is a book series on the tv series switched at birth

Seth Roberts (2011-09-14 02:55:28)

no there is no book series based on the switched at birth tv series.

Alrenous (2011-09-14 10:27:36)

That pretty much rules out me thinking that I'm liking TV more because, as I grow up, they address my demographic better. I wonder if it's a permanent upswing in quality or just a cyclical trend. Because good lord TV was awful when I was growing up. It's nice that I don't watch Glee because it isn't my kind of show, not because it is utter dreck. Appreciation and respect are way better than the alternative, contempt. Suits, on the other hand, sounds like exactly my kind of show. Kings is cancelled now, but when I was growing up I was constantly wondering why they didn't make exactly that kind of show. I think they flubbed the plot in episode 9; otherwise stellar in every detail. I don't know a single other show where I actually cared enough about the plot to tell if they screwed it up or not.

Seth Roberts (2011-09-14 11:24:32)  
Alrenous, you mean "episode 9" of Suits?

Alrenous (2011-09-16 12:56:24)

Your mention of good television, including Suits, reminded me of Kings. Kings screwed up the plot in episode 9. Suits is now on my list of things to watch.

erica (2011-11-27 09:21:52)

I like Switched at Birth personally. Also, I want to be an actor, especially ON Switched at Birth. The problems are: I only have slight acting experience I am not, and don't desire to be on a AFTRA contract thingy And I wouldn't be able to start until towards the end of 2012 And the way I would be on the show, is (I have ideas for it but don't know what to do with them accept for dream...) : Ty comes back, and bay and Ty get back together, Bay gets Pregnant. Emmitt and Daphne get together, but Emmitt slowly "drifts away" from Daphne, because of his new friendship with a little younger girl, that newly goes to their Deaf school. who was from NY. But this girl he becomes friends with, also happens have to been adopted by the Kennish family, and she becomes Bay and Daphne and Tobye's little sister, (13-15 yrs played by me). The girl is deaf, (isn't a deaf actor) but is still learning sign (the character and the actor) because she recently has gone deaf. (not the actor, the actor is hearing, playing a deaf character, both the actor (me) and the character are still learning sign language) so Emmitt and this girl, (me) (I don't know what her name should be) become really close friends like Emmitt and Daphne were, and the whole friendship between \_ \_ \_ \_ \_ Kennish and Emmitt is a secret because you know Bay and Daphne would flip and stuff. And from there they can do what they want with the story... The thing is, if they were to use any part of my idea, they have to use me. But that's never going to happen. But I dream. The reason why I like this idea for the show is because i feel like its just going... I think this would really twist it up, especially give it a spice. But I don't know if it would work because the second season isn't out yet, but whatever.....

---

Martin (2011-09-12 04:55:10)

Seth, I like your blog as it addresses self-experimentation, what I do not understand however is why you persistently are trying to discredit AGW as a theory. Not only that, but you use evidence against it that is flimsy at best and has been

debunked in the (very recent) past. <http://blogs.discovermagazine.com/badastronomy/2011/08/31/no-a-new-study-does-not-show-cosmic-rays-are-connected-to-global-warming/>

Seth Roberts (2011-09-12 16:17:03)

Martin, the post to which you link (at Bad Astronomy) is right that several newspapers badly misinterpreted the study. But the poster at Bad Astronomy misses a much more important point: That (a) we don't know if cosmic rays influence climate and (b) therefore the models on which all AGW claims are based could easily be wrong. Those models assume no cosmic ray influence – but we don't know that. The models are going out on a limb. They could easily be wrong. They have never been shown to predict correctly. There is no good reason to believe them. I am saying that AGW claims are overstated because they are based on models that could easily be wrong. I am "denying" that the evidence for AGW is as strong as AGW proponents say.

Alrenous (2011-09-14 10:01:04)

I thought stroke researchers didn't claim to understand stroke. I was clearly wrong, thanks Seth.

Todd (2011-09-14 20:44:16)

Seth, I think that the cosmic ray theory of Svensmark, though not proven is quite credible. The post at "Bad Scientist" leaves out some key results regarding how pions (cosmic ray analogues) did in fact generate nucleating clusters that could seed clouds. Together with earlier work of Svensmark, and studies correlating ice ages with the Earth's travel through the oscillating spiral arms of the Milky Way galaxy, there are the elements of a consistent explanatory theory. The best overall account of the theory is given in Calder's book "The Chilling Stars". There is also an excellent series on YouTube, reviewing all the supporting data: [http://www.youtube.com/watch?v=n1qGOUiRa\\_c0](http://www.youtube.com/watch?v=n1qGOUiRa_c0) By contrast, there are three key observations which render the AGW theory of global warming untenable: 1. The "correlation" between atmospheric CO2 levels and global temperatures are extremely good, but with one problem: the rise and fall in CO2 actually lags the rise and fall and temperature by about 800 years. This proves that rising CO2 is a consequence, not a cause of temperature, and hence cannot be the major forcing issue. The same is true of methane, another "greenhouse" gas. The lag is better explained by the outgassing of CO2 from the oceans as they warm, and resolubilization as they cool – with the lag explained by the very large solubility capacity of the oceans. AGW advocates have tried to "explain" this, but their explanation has been debunked: <http://www.sciencebits.com/IceCoreTruth> <http://motls.blogspot.com/2007/04/co2-lags-temperature-how-alarmists.html> 2. Water vapor is a far more potent "greenhouse gas" than carbon dioxide, and is present at far higher levels, yet water vapor (in the form of clouds) is typically left out of climate models because clouds are too difficult to model. (This is one of the points that Svensmark's cosmic ray theory may fill in). <http://www.theweatherprediction.com/habyhints/155/> 3. Warming on other planets correlates well with that on Earth, and with solar irradiance. Certainly, that can't be explained by an anthropogenic effect, and it is hard to find any alternate explanation that solar effects: Neptune: <http://www.worldclimaterreport.com/index.php/2007/05/08/neptune-news/> Mars: <http://news.nationalgeographic.com/news/2007/02/070228-mars-warming.html> So the cosmic ray theory may not yet be proven, but it is at least as credible as the AGW/CO2 theory, which itself has many holes in it. And Svensmark has faced incredible ostracism from the entrenched peer-reviewed publications. Whether you agree or not, it is an amazing demonstration of the lack of freedom in contemporary science, which is largely a result of the system of government funding and peer review. Stay tuned. There will be more to come out of the CLOUD study at CERN.

Todd (2011-09-14 21:04:01)

Seth, As further points to my above comment, I think these discussions of the Nature article on the CERN results by Nir Shaviv and Nigel Calder are instructive: <http://motls.blogspot.com/2011/08/nir-shaviv-cloud-is-clearing.html> <http://calderup.wordpress.com/2011/08/24/cern-experiment-confirms-cosmic-ray-action/> Shaviv came to the cosmic ray theory independently of Svensmark, from his background as a cosmoclimatologist. The fact that completely different, orthogonal types of data support the cosmic ray theory is itself quite striking. It's all documented here. Take a look at Figure 2 and try to explain it away! [http://stephenschneider.stanford.edu/Publications/PDF\\_Papers/shaviv-veizer-03.pdf](http://stephenschneider.stanford.edu/Publications/PDF_Papers/shaviv-veizer-03.pdf)

Tom Fid (2011-09-15 08:04:37)

Whether we do or don't know that cosmic rays influence climate, we do know that there's been no trend in cosmic rays since

the 50s, so they don't have any explanatory power for observed recent temperature trends. Also, it's quite false to claim that models haven't predicted correctly. Observed temperature corresponds rather well with predictions by Budyko in the 60s, Charney et al in the 70s, Hansen in the 80s, 1990 IPCC report, etc. Also, models have predicted several phenomena that were only later verified through observations, including tropospheric temperature trend where observations turned out to be wrong due to UAH processing errors. There are still many gaps, but compare the performance of mainstream models to alternatives, for example the hypothesis that cosmic rays drive climate and climate sensitivity is otherwise very low, like Lindzen's preferred  $0.5C/2xCO_2$ . Rewind to 1970 or so, and backcast future global temps with that model, and you'll find that you're pretty far out on the low tails of the likelihood. You'll also have a very hard time explaining natural variability and ocean heat accumulation with strong negative feedback on temps. The models also assume no influence of pirates, angels and aliens - and we can never be sure that those don't matter either. But there are endless sources of possible systematic error in every endeavor. The fact that mainstream climate models, from simple energy balances to GCMs, have withstood investigation of a long list of those errors without major changes to their central conclusion speaks in their favor.

Seth Roberts (2011-09-15 15:39:17)

Tom, I am unable to find support for your statement that "Observed temperature corresponds rather well with predictions by Budyko in the 60s, Charney et al in the 70s, Hansen in the 80s, 1990 IPCC report, etc." Could you tell me where I can find the predictions by Budyko (not Budyko) and Charney et al? My phrase "the models have not predicted correctly" is short for "the models have not predicted global temperature in a way that increases belief in them." It is no great success for a model when it predicts the continuation of a trend - e.g., continuation of a linear increase in temperature. The models may predict all sorts of things correctly without being able to predict global temperature correctly. (Maybe this is what you mean by "there are still many gaps".) If they can't predict global temperature, they can't be used to argue that humans have had or will have a big effect on global temperature. That's what I am saying here, in short hand: The models can't be trusted. Without being able to trust the models, reason to believe AGW disappears.

Marc Drops (2011-09-15 23:48:38)

Nice discovery that marijuana oil can help prevent skin cancer. I have too many of those worthless plants growing around my yard. Now they have a real purpose.

Tom Fid (2011-09-16 09:58:19)

Budyko wrote a lot, and unfortunately I haven't figured out where to get it all, but one discussion of CO<sub>2</sub> and aerosol effects is in Tellus (1977), 29, 193-204, "On present-day climatic changes". A related and well-known, extremely simple model is in "The effect of solar radiation variations on the climate of the earth", Tellus 1969. Note that in both articles, the temperature data on which Budyko relies does not show a clear long-term warming trend, so he is not merely extrapolating. Trend extrapolation is a lousy null forecast anyway, because it's impossible for any length of time, and lacks physical justification. A plausible null forecast really needs some kind of mean reversion or stationarity built in to be plausible, especially if your position is "we know nothing." It's a bit of a dodge to say that "models may predict all sorts of things correctly without being able to predict global temperature correctly" as if they were predicting the price of chocolate. Many of the things that they're reproducing reasonably well are features of global temps, e.g. seasonal and latitudinal patterns, response to volcanic eruptions. A single time series is a weak test of a model. Physics also matters. Getting things right, other than global temps, provides a lot of information that you can't get out of temps alone, in part because the inputs to the model (forcing) are uncertain. By your metric, (not predicted correctly = predicted continued trend), it would be impossible to validate any that one would naively expect to continue, which is pretty silly. (Especially so if competing alternatives, like cosmic rays, fail to show a long term trend.) Charney = [http://www.atmos.ucla.edu/brianpm/download/charney\\_report.pdf](http://www.atmos.ucla.edu/brianpm/download/charney_report.pdf) - not a model, but does put bounds on climate sensitivity (3 +/- 1.5 C). You can plug that into an early energy balance model, like Schneider, S. H. & Thompson, S. L. (1981) J. Geophys. Res. 86, 3135-3147, for retrospective tests. There are quite a few interesting early works collected in <http://www.amazon.com/Warming-Papers-David-Archer/dp/1405196173>

Seth Roberts (2011-09-16 16:19:33)

Thanks, Tom. This is from the Charney report:

Our confidence in our conclusion that a doubling of [atmospheric] CO<sub>2</sub> will eventually result in significant tem-

perature increases and other climate changes is based on the fact that the results of the radiative-convective and heat-balance model studies can be understood in purely physical terms and are verified by the more complex GCMs.

That does not increase my belief in those GCMs. Not even a tiny bit.

Tom Fid (2011-09-16 18:32:14)

From what you've said so far, you're not convinced by correct predictions of time series data, replication of other phenomena or physical grounding of model structure. That would seem to rule out all possible lines of evidence by which one would compare models in a non-experimental field. On the other hand, you're willing to entertain a nontrivial probability that cosmic rays drive observed temperatures, in spite of flimsy evidence for the mechanism and lack of a trend coincident with temperature. It seems like you're applying an inconsistent burden of proof. If you really don't believe models (or just GCMs?), what's your null model for climate over the century?

Seth Roberts (2011-09-16 23:24:29)

Tom, I will be convinced of the value of GCMs when they correctly and persuasively predict global temperatures. Simple as that. Persuasive = the prediction was a priori unlikely. It is not enough to make correct predictions. A model only gains belief when it correctly makes predictions that seem unlikely a priori. This is why I came to believe my own model of weight control: It predicted that sugar water could cause weight loss. This was highly counterintuitive – practically everyone thought sugar is fattening. That the prediction was counterintuitive is what made the fact that it turned out to be true persuasive. If GCMs did a good job of predicting global temperature, and did so without assuming anything about cosmic rays, no smart person would be looking into cosmic rays as a possible big influence. That smart people are doing so should tell you something.

Tom Fid (2011-09-17 09:09:51)

By your metric, it seems impossible to validate a model of any system that generates 'a priori likely' behavior. That's a problem, because you're defining 'likely' ex post. If you look at the data available to Budyko, Manabe & Wetherald, and others predicting warming in the 70s, they were coming off a 3-decade period of level or declining temperature, and expecting an end to the interglacial at some point. So how was a positive trend a priori likely? That's why I was trying to nail down your null model or forecast. I doubt that there's a plausible choice, trained to pre-1970 data, that makes observed warming likely. You still haven't pointed out a specific flaw in GCM temperature replication that would motivate a smart person to look for alternatives. The AR4 ensemble fits history pretty well. Admittedly that's a weak test - but then you have to get into validating the physics. 'Smart' is not the only motive. Regardless of what you think of the models, you'd have to be a bit naive to not notice a cottage industry in exploring even silly alternatives for ideological and financial gain.

Todd (2011-09-18 20:56:51)

@Tom, You write: "Whether we do or don't know that cosmic rays influence climate, we do know that there's been no trend in cosmic rays since the 50s, so they don't have any explanatory power for observed recent temperature trends." That's an old claim by Lockwood and Frolich that was rebutted convincingly by Svensmark in this 2007 paper: <http://icecap.us/images/uploads/SvensmarkPaper.pdf>

Todd (2011-09-18 21:52:25)

Recent empirical calculations by Roy Spencer- showing how the last decade of global radiative energy balance has changed with variations in cosmic ray activity-have converted him from a skeptic of Svensmark's cosmic ray theory to a believer: <http://wattsupwiththat.com/2011/05/20/indirect-solar-forcing-of-climate-by-galactic-cosmic-rays-an-observational-estimate/>

Tom Fid (2011-09-19 08:12:56)

The link's not working at the moment, but I assume this is the Cosmoclimatology paper. The CLIMAX data (red in Fig 5), also found elsewhere, actually confirms 'no trend since the 50s.' Also, since the amplitude of the cycle in cosmic rays is large relative to the trend (Svensmark Fig 5), where's 11-year spectral line in temperature? If the net solar/cosmic forcing trend was negative

over the last decade, as Spencer concludes, and that's responsible for level temperatures and ocean heat, then wouldn't a solar/cosmic explanation require a strong positive trend to explain warming from '70-'00? (Bearing in mind that temperature is the integral of forcing and feedbacks, not merely correlated, of course.)

"UM officials had serious concerns about Nemeroff's history of ethical blunders...": blunders? That's not the mot juste, surely?

### Why is Health Care So Expensive? (2011-09-16 16:54)

Because health care costs have been increasing faster than other costs for a long time. Everyone knows that. But why is that happening? Not so clear. [1]This excellent article (via [2]Marginal Revolution) says that health care is not subject to the same pressures as industries where costs have come down. Off-shore manufacturing is one such pressure. For example, a cell phone used in California can easily be made in China. In contrast, the health care a person in California is likely to want (e.g., X-rays, check-ups) must be supplied locally.

Let me suggest other reasons:

1. A large fraction of medical school professors are co-opted by industry. They get lots of money from health care companies. The companies have no interest in cutting costs. They fund research by medical school professors for exactly one reason: to sell more product.
2. The average medical school professor has little idea how to do research. Recently I mentioned a study in which

they threw away half of their data. An article about the Potti scandal revealed that Potti's main co-author, Dr. Nevins, essentially confessed [3]he didn't understand the research in the papers he had co-authored with Potti. As far as I can tell, medical school professors usually know so little statistics they cannot analyze the data from the studies they do. If you don't understand how to do research, innovation will be difficult.

But I think the bigger and less obvious reasons are these:

3. The health-care supply chain is long. Some medical school professors can innovate – Peter Provonost, for example. But they face a special problem: the enormous health-care supply chain. It includes doctors, nurses, hospital workers, drug company employees, health insurance employees, medical equipment manufacturers, alternative medicine practitioners, psychotherapists, X-ray techs, health food store employees, and on and on. No other industry is like this. No one in the supply chain can innovate, yet all of them can block innovation. Everyone in the health-care supply chain must be paid. They care enormously about being paid. They hate to take a pay cut. Any innovation – unless it increases the cost of health care – threatens their paycheck. So there is a huge bias in favor of change that increases cost and a huge bias against change that decreases costs.

4. Let them get sick. If a man is not afraid, you cannot sell him protection. This is why protection rackets have two parts: (a) threat followed by (b) offer of (expensive) protection. Modern health care workers understand a similar truth: If a person is not sick, you cannot sell him (expensive) health care. Modern health care workers do not actively make people sick, they let a dysfunctional research system do that. (E.g., cluelessness about how to stimulate the immune system.) Then they pounce – and the money starts to flow. Once the money starts flowing, political power builds up. In a sane world, schools of public health, which care about prevention, would receive vastly more money than medical schools, which ignore prevention. In fact, the opposite is true.

This is why personal science will be so important: It is a way around our massively-dysfunctional health-care system – dysfunctional, that is, for everyone outside it.

Zetji (2011-09-16 22:11:32)

I work in health care, and the main reason for outrageous profit margins is because health care is heavily subsidized and supported by the government: about a third of the work force works for the state now, and their benefits are 400 % times those of the private sector, which usually includes the most expensive health care plans. The government gets them because, hey, it's other peoples money, so they can just spend more by raising taxes or firing up the printing presses. The government also mandates coverage in many cases such as medicare and medicaid, and heavily encourages companies to provide insurance. With so many people covered doctors can fill their practice with only insured patients. At which point no market controls exist, and the sensible thing to do is just make up as high of charges as you want. Sure, the insure companies could try and police the doctors, but it's easier to just raise premiums. The really high margins plans are the ones held by the government anyway, and they have bottomless pockets since, as I said before, they can just steal money from the public through taxation or inflation. Just screw over the taxpayers and everyone in the private sector. Why do we health care practitioners charge so much? Because we can and there are no market forces to stop us, no incentives

to not gouge. Insurance also acts as a moat, insulating bad practice and keeping competition away, because patients will be reluctant to seek alternative treatment that they have to pay out of pocket when they can see their doctor and have the insurance cover it. As an example of price inflation: a 90 minute massages market price around where I live is about \$90. When charged to the government though as manual therapy and neuromuscular reeducation I've seen the same treatments get paid out for over 300 % more. Elites will use their position at the top to manipulate the laws and the social structure to accrue benefits to themselves at the expense of others. The solution would be to restore a real market economy to health care. Ban all automatic health insurance; no government plans, no employee plans; the only health insurance should be that which individuals buy of their own will from the private market. If doctors could no longer depend on having practices full of insurances patients subsidized by the government prices would come crashing down to reasonable market level.

Seth Roberts (2011-09-16 23:29:42)

Zetji, I agree with your analysis. I just think it is incomplete. All the downward pressure on prices in the world will not produce innovation. Our current system is based on an inherently expensive idea (first, let people get sick).

iamreddave (2011-09-17 00:11:32)

There is the Hanson theory that healthcare is expensive for the same reason engagement rings are. the purpose of healthcare is not to make people better but to show how much we care "our ancestors showed loyalty by taking care of sick allies, and that, for such signals, how much one spends matters more than how effective is the care, and commonly-observed clues of quality matter more than private clues. So today we spend enough to distinguish ourselves from people who don't care as much as we do, and we pay little attention to private clues about the health effectiveness of medicine" <http://www.cato-unbound.org/2007/09/10/robin-hanson/cut-medicine-in-half/>

dearieme (2011-09-17 04:41:56)

Long ago I had a tenuous connection with medical research. A statistician told me that medics would rather be taught Statistics by a fellow medic than by any statistician. At most they'd learn a few, probably misunderstood, statistical recipes.

aretae (2011-09-17 10:16:17)

Seth, Great answer...wrong question. Medical care is expensive for 2 main and 1 subsidiary reason. 1. Supply restriction. An emt can do 50 % of the useful work of a doc...with 6 months training. India has 4 year degree doctors. FDA limits drug entry massively and patent law limits supply of existing drugs. High regulation. 2. First dollar insurance as encouraged by US tax law...as compared to Singaporean catastrophic insurance with HSAs. Subsidiary: Unclear benefits. Given other people's money (lack of alignment between beneficiary, payer & decider roles)...the incentive to find what works is weak.

Paul Sherrard (2011-09-17 13:37:42)

Zetji says: "the main reason for outrageous profit margins is because health care is heavily subsidized and supported by the government." If that's true, why do so many countries where health care is FULLY subsidized by the government have such affordable health care compared to us? If the solution is to "restore a real market economy," why do the countries with the least exposure to market forces consistently provide the best care for the most people? I think it's worth at least entertaining the idea that obscene profit margins are driven by a capitalist (i.e., profit-taking) system. I dunno. Just a thought.

Seth Roberts (2011-09-17 13:39:23)

Arætae, an ounce of prevention isn't just worth a pound of cure, it costs a thousand times less. There is a "supply restriction" on prevention. Eliminating it - figuring out how to prevent major diseases - would reduce health care costs by a huge factor. People would die eventually, yes, but they would contribute more to other people's health (via taxes and caring for children) and have more money to spend on their own health (due to savings) before doing so. What is the "wrong question" I have asked?

Matt McCandless (2011-09-18 11:42:34)

Paul, I always have to respond to comments such as yours. One of the greatest fallacies of our current healthcare debate is the assumption that our current health care system resembles anything close to a free-market. Our current National Healthcare

System differs from it's foreign counterparts only in it's inability to offer universal access. It is subject to the same absurd barriers to entry that have stifled progress in everything from food costs to energy efficiency. The system is SO massive and convoluted that it really knocks me on my face when people such as yourself assert such claims. The counter question to yours now is given that free markets have worked so well at effectively distributing everything from diapers to cellphone. Making life changing technology available to even the poorest sections of the planet. Why are people so afraid to let our most valuable resources, food and healthcare, be controlled by those same mechanisms.

Paul Sherrard (2011-09-18 13:50:59)

Matt McCandless: "The system is SO massive and convoluted that it really knocks me on my face when people such as yourself assert such claims." In fact I made no claim of any kind anywhere in my post. I posed a couple of questions, then offered the opinion that a particular idea—the idea that profit-taking itself could be the culprit—was worth considering. However, your claim—"Our current National Healthcare System differs from it's foreign counterparts only in it's inability to offer universal access"—is not a factual statement. Our current system differs dramatically from its foreign counterparts in that it is (1) overpriced and (2) grossly inefficient in every area EXCEPT that of delivering profits to investors in the insurance and drug industries as well as the beneficiaries of profiteering hospitals and HMOs (their ostensible for- or non-profit status notwithstanding).

Matt McCandless (2011-09-18 17:36:05)

Excuse me, I assumed your last statement, "I think it's worth at least entertaining the idea that obscene profit margins are driven by a capitalist (i.e., profit-taking) system. I dunno. Just a thought.", as a passive assertion. I am still not convinced I was wrong but I will give you the benefit of the doubt. Given my new interpretation of your statement I would say, No, it is not worth considering. To offer something up as a culprit in a crime assumes that that something exists. In this case there is not Capitalist Health System to scape goat. Capitalism implies choice, our current system offers none. Everything from diagnosis to acceptable treatments to prevention are dictated by a series of committees and enforced under the penalty of law. What we have in America much more closely resembles socialism than capitalism and that was my point. It is the underdog nature of you comment that really prompted me to comment though. As if no one as yet thought profits could be at the core of the current crisis. When in reality you would be hard press to find a New York Times article that does not cite capitalism as the main culprit of our current situation. Why target capitalism you might ask? Because it is the only real threat to their current monopoly. Regulation, socialization, these are things that can be manipulated through politics. Free choice and open competition cannot.

Matt McCandless (2011-09-18 17:53:59)

On a separate note though, it is hard not to notice that the three areas that The Atlantic cites as becoming more expensive, "beds, meds, and higher-ed" are the three most regulated areas of our economy. So I guess where Seth might say this is because they are not open to the same types of innovation that other areas such as electronics may be open to. I would say we to not see those types of innovation in those fields because our economy is not open to them.

Paul Sherrard (2011-09-19 07:12:31)

Matt McCandless: "Capitalism implies choice"—how so? You could say it rewards innovation, but (1) that doesn't mean "choice" is implicit and (2) it rewards it via buyout, i.e. assimilation, and tends toward the "Mac & PC" duopolistic parody of choice that lies at the end of the capitalist road in every sector. The triumph of the capitalist has always involved the elimination of real choice. This has always been true, from Big Auto tearing up trolley tracks to Big Pharma writing the health care bill. What you see as anti-business regulation actually benefits big business, and the important point is that someone's pockets are lined in the process. Someone is getting rich off the status quo. And I would venture to suspect that you've been trained not to view that someone as a Capitalist, although he is the quintessential Capitalist; he is the very definition of a Capitalist. The objectivist-libertarian-Austrian ideology talks up a storm about "capitalism" while hardly whispering a word about Capital. But it is Capital that frantically seeks returns even when it has all the money; it is Capital that bribes politicians to create huge barriers to entry; it was Capital that wrote Romneycare and Obamacare and it will be Capital that thwarts any of your efforts at a return to small-market logic, or at least any meaningful elements thereof. "[Y]ou would be hard press to find a New York Times article that does not cite capitalism as the main culprit of our current situation." If you can find, and link to,

a Times article that actually asks "cui bono," as I did, I'll be greatly surprised. (What you don't seem to grasp is that I wasn't attacking "free choice and open competition"; I was asking "cui bono.") Matt says: "What we have in America much more closely resembles socialism than capitalism and that was my point." And my point was this: If that were true, it would follow that countries that more fully embrace a Socialist model would have even worse problems. And instead the opposite is the case. In case after case after case.

Matt McCandless (2011-09-19 16:04:45)

In order to reward innovation there must be a choice? Or else it is just giving things to people. It is natural in any competitive process that you will eventually whittle down to two or three choices. No one is going to buy the fifth best operating system, it is a feature not a flaw. Market share does not insulate firms from competition or restrict choice. I believe it is you who has been trained, to see any move toward ones best interest as necessarily destructive or immoral. Your "Quintessential Capitalist" is not necessarily a capitalist at all, in reality he could be a pacifist, he could be an anarchist, he could even be a baker. What you have described is an immoral human being and he can just as easily fit into one mold as the next. I believe that most socialist healthcare systems, to the extent that they have worked, have done so by successfully pitting the medical establishment against it's political overlords. A politician may be elected in a single payer system based on his ability to control healthcare costs by directly intervening in the market, and because he is subject only to his constituency he is free to pursue those ends. In America we still retain a belief that we have a free healthcare market and in the past have not generally voted for politicians who claimed they would directly intrude into healthcare the way a European Politician might. It is hostile to our fantasy. In this system it is the medical establishment that comes out as the big winner as they are able to secure all of the monopolistic powers befitting a social enterprise without any of the downward pressure from their political counterparts. You can see how in this best of both worlds scenario it is the people who lose. A step either direction on the spectrum of choice would most likely result in a much more optimal outcome for the average consumer. But when in doubt most libertarians will repeat the mantra, "freedom is it's own end". I think the problem with anti-capital arguments is the belief that capital is only present in a capitalist society. The question for an economy is not whether or not capital should or should not exist or make returns, but rather, who should get those returns and how much should those returns be. In any socialist system there is still "capital" but instead of being allocated through a system of prices, it is allocated through a system of bureaucrats. Ideas are not priced according to their market value but rather their political appeal. This is in stark contrast to true capitalism where ideas are disseminated, not based on their appeal to a political faction, but rather by their ability to satisfy the needs of enough individuals to secure a return on the initial investment. I would argue that contemporary capitalism implies the lack of an over arching control structure, and that it is that structure, not the capital that it controls that defines socialism. So in closing, yes, it is humans ever present quest for capital return that lures them to lobby politicians for handouts, but it is a societies susceptibility to those efforts that places it somewhere on the spectrum of Capitalist/Socialist. I think George Will said it best in his interview on econotalk, as the state attains a greater and greater ability to influence the profitability of enterprise it follows naturally that enterprise will spend a greater and greater amount of time trying to influence the state. I guess I would leave up to you to decide how to best address that problem.

Paul Sherrard (2011-09-19 16:37:31)

No offense, but as I am already familiar with the libertarian catechism to the extent that it bores me to tears, I'll just cut to the part that's relevant to the current discussion: "In this system it is the medical establishment that comes out as the big winner as they are able to secure all of the monopolistic powers befitting a social enterprise without any of the downward pressure from their political counterparts." Interesting. Who, specifically, within "the medical establishment" is "the big winner"?

Tuesday miscellany — The Endeavour (2011-09-20 07:41:36)

[...] Why is health care so expensive? An immune system trained to kill cancer [...]

Justin (2011-09-20 09:25:22)

Paul asks "Who, specifically, within "the medical establishment" is "the big winner"?" Answer: Everyone who has a stake in the supply chain. This includes "doctors, nurses, hospital workers, drug company employees, health insurance employees, medical equipment manufacturers, alternative medicine practitioners, psychotherapists, X-ray techs, health food store employees, and

on and on", academic professors and researchers, union leaders, hospital and clinic administrators, and even [currently in our system setup] politicians and beaurecrats. So, who are the losers? Everyone else, particularly the tax payer and patient (customer). To head off the discussion that many of the winners also fall into the losers group... I'll pay 20 % more for my industry services and in fact cheer on cost/price increases if that means I get a 50 % raise myself!

Alex (2011-09-20 09:56:25)

Maybe average consumer shopping in the insurance marketplace needs more transparency and product education? If you wouldn't sign a mortgage without checking your credit report, why do some many people pay for insurance policies without verifying their medical report? In fact, many consumers and even many insurance agents are unaware that Humana, UnitedHealth Group, Aetna (AET), Blue Cross plans, and other insurance giants have ready access to applicants' prescription histories. An investigation in 2008 by the Federal Trade Commission found that the two companies supplying these pharmacy profiles—MedPoint and IntelliScript—violated federal law for years by keeping the system hidden from consumers. The FTC has now required disclosure of personal medical and prescription files. MedPoint and IntelliScript say they are now fully complying with the FTC's order. Yet, 2/3 of all health insurers are using prescription data—not only to deny coverage to individuals and families but also to charge some customers higher premiums or exclude certain medical conditions from policies, according to agents and others in the industry. Some carriers are also using the data to charge small employers higher group rates. Separately, some 20 % of life insurance companies are relying on prescription histories when reviewing applications, according to experts in that business. <https://www.annualmedicalreport.com/prescription-analytics-corporate-database-s-track-whats-in-your-medicine-cabinet/> Unfortunately, failing to check your medical report can be costly; errors or omissions within individual medical report files can cause applicants to be rejected outright, pay higher policy premiums, or suffer outright rescission of coverage! For example, the Consumer Reports Health Blog discusses how insurance can be denied because a medical coding error in your medical report file in the MIB Group Inc. databases. <http://blogs.consumerreports.org/health/2008/08/denied-insuranc.html> Few people realize the MIB Group has a file on them. Like the credit-reporting agencies, MIB monitors virtually every aspect of a person's health care. When someone applies for individual health-care coverage, the application is routinely run through MIB's huge database of health and medical information. Insurers effectively use the MIB data for health-insurance applicants like they use motor-vehicle administration records for auto-insurance applicants, adjusting premiums or even denying coverage based wholly or in part on what is in a person's MIB file. All health insurance applicants and policyholders should request an annual copy of their "medical report" files from the three major specialty nationwide consumer reporting agencies to ensure they aren't overpaying for insurance or in danger of policy rejection or rescission for reported pre-existing conditions.

Matt McCandless (2011-09-20 10:34:53)

While I would never claim to understand the issue entirely. It would seem that the "Big Winners" would actually be a conglomerate of, (in no particular order) 1. Medical Lobbyists, who are able to secure a nice paycheck by greasing wheels of the establishment and help their own accent into it's ranks. 2. Doctors, who are able to charge substantially inflated prices due to the protected nature of their field and there access to consumers who have no real choice in service or price thanks to "Cost Control Mechanisms". The icing on the cake and where all social ideas eventually break down is that they are not spending their own money so there is no incentive to make a good decision. 3. Politicians, who are able to secure donations and support by giving the whole process the federal stamp of approval. 4. Regulatory agencies such as the FDA, who are able to intervene in markets and hence enjoy a level of power that should exist no where in a free society. 5. Insurance Companies, who, while potentially paying more in benefits, are able to recoup that cost by creating barriers to entry that would not be possible without the explicit support of all other players. I am sure we could think of more but I think the point is clear, this is not a capitalist system, in any honest interpretation of the word.

Paul Sherrard (2011-09-20 13:11:15)

OK, this is what I find astonishing. I see this again and again, yet it never fails to amaze me. Every single champion of "capitalism" on the Internet is the same: they have utterly NO IDEA, not a CLUE, how capitalism actually works. They can analyze a profiteering situation and not even wonder where the profits go. They can witness skyrocketing prices and a simultaneous boom in the wealth of the investing class without ever connecting the dots. They can even refer to lobbyists and bribed

politicians without, apparently, wondering on whose behalf the lobbyists lobby and from whose largesse the pols are bribed. Matt, who do you think pays the lobbyists? Who do you think benefits from the status quo enough to take the trouble to "contribute" to so many key candidates' war chests? I'll give you a hint: it's not doctors. Doctors haven't prospered as medical costs have risen out of control. On the contrary, their incomes have declined. <http://www.marketwatch.com/story/primary-care-doctors-income-drop-may-lead-to-shortage-study> As for the FDA, its budget and staff has been steadily cut since the Reagan administration. I don't see how it could be construed as a "winner." Maybe it "wins" every time it approves a drug that's actually harmful, because Merck or whoever pays them off? But then that's a case of Merck's investors (i.e., Capitalists) greasing the necessary wheels en route to massive profits. Over the past few decades we've had a boom in private hospitals and private HMOs. At the same time, reports of profiteering by "non-profit" hospitals are rampant and some have undergone restructuring efforts administered by investment banks. Over the same period, pharmaceutical co.s have become the most widely held stocks on the NYSE, and insurance companies have reported record profits. AND costs are rising uncontrollably, while doctors' pay declines. The writing is on the wall. Big investors are making out like bandits. Or, to use old fashioned terminology, Labor's pay declines while Capital pockets record profits. And contrary to your assertion, this is exactly what Capitalism is. It's just not how Capitalism has been (mis)represented to you.

aretae (2011-10-03 14:39:34)

Responding finally... Supply restriction prevents the folks who could make money by selling the prevention from doing so...and especially for advertising the results (See: baby aspirin + Heart Disease). Who is allowed to make money from prevention? Not many, as the FDA is now cracking down on supplement manufacturers? First Dollar insurance + sick days insulates consumers from the immediate costs of their health behavior. The incentives to solve the health problem are broken...so it's not being solved. As far as I've seen, every industry that gets the incentives right, even in medicine (plastic surgery, lasik, etc.), has hugely decreased and still decreasing costs. As to wrong questions: I think you answered the question of how the medical industry responded to massive levels of protectionism...not the question of why the costs are high. I'd look at Kaiser Health Care, or Singapore or Germany before concluding that the problem is insufficient prevention..

josey jasen (2011-10-05 05:59:03)

I just stumbled upon your blog and wanted to say that I have really enjoyed browsing your blog posts. In any case I'll be subscribing to your feed and I hope you write again soon!

Carl (2011-11-05 18:20:31)

on the 90's the minimum wage was \$ 4.25/hour, a full coverage individual health insurance policy \$ 75.00 (I mean full without so many co-pays) 2011 the minimum wage is \$ 7.50/hour, a (full coverage?) individual health insurance policy is = over \$ 700.00 the difference is that the suppliers, equipment's etc are manufacturer in China for a "fraction" of the cost... It's getting very close to the point that lots of people will going to drop their health insurance plans and if the USA think that a crisis exist, wait until we got on this point to see what a massive destruction for good means. The government need to step up and act right now to audit and cut the health insurance plans costs in at least 50 %.

## How to Start a Talk (2011-09-17 16:22)

[1]A recent talk at the London School of Economics by Carne Ross, author of a book called *The Leaderless Revolution: How ordinary people will take power and change politics in the 21st century*, began with this:

I was preparing the talk this afternoon at my beloved cousin's, where I'm staying. 'cause I don't live in London anymore. She said, "How are you, Carne, how are you doing?" I said, "I'm a bit nervous, to be honest." She said, "Don't worry, Carne, I've heard lots of bad talks at the LSE."

---

Katy (2011-09-18 13:07:41)

Wow- that talk was extremely inspiring! I wish his new book was available over here, I'd love to read it. Maybe when my current TBR list is a bit shorter, I'll go ahead and order it from amazonUK.

### **First, Let Them Get Sick (2011-09-18 20:58)**

In *Cities and the Wealth of Nations*, Jane Jacobs tells how, in the 1920s, one of her aunts moved to an isolated North Carolina village to, among other things, have a church built. The aunt suggested to the villagers that the church be built out of the large stones in a nearby river. The villagers scoffed: Impossible. They had not just forgotten how to build with stone, they had forgotten it was possible.

A similar forgetting has taken place among influential Western intellectuals – the people whose words you read every day. [1]Recently I wrote about why health care is so expensive. One reason is that the central principle of our health care is not the meaningless advertising slogan promoted by doctors ("first, do no harm") but rather the entirely nasty first, let them get sick. Let people get sick. Then we (doctors, etc.) can make money from them. This is actually how the system works.

It is no surprise that doctors and others within the health care system take the first, let them get sick approach. It is wholly in their self-interest. It is how they get paid. If nobody got Disease X, specialists in Disease X would go out of business. What is interesting is that outsiders take the first, let them get sick attitude for granted. It is not at all in their self-interest, just as it was not at all in the self-interest of the Carolina villagers to think building with stones impossible.

An example of an outsider taking first, let them get sick for granted is [2]a recent article in the *London Review of Books* by John Meeks, an excellent writer (except for this blind spot). The article is about the commercialization of the National Health System. Much of it is about hip replacements. How modern hip replacements were invented. Their inventor, John Charnley. How a hospital that specialized in hip replacements (the Cheshire and Merseyside NHS Treatment Centre) went out of business. And so on. Nothing, not one word, is said about the possibility of prevention. About figuring out why people come to need hip replacements and how they might change their lives so that they don't. Sure, a surgeon (John Charnley) is unlikely to think or say or do anything about prevention. That's not his job. But John Meeks, the author of the article, is outside the system. He is perfectly capable of grasping the possibility of prevention and the parasitic nature of a system that ignores it. Long ago, people understood that prevention was possible. As Weston Price documents, for example, isolated Swiss villagers knew they needed small amounts of seafood to stay healthy. But Meeks – and those whom he listens to and reads – have forgotten.

---

1. <http://blog.sethroberts.net/2011/09/16/why-is-health-care-so-expensive/>

2. <http://www.lrb.co.uk/v33/n18/james-meek/its-already-happened>

dearieme (2011-09-19 03:00:10)

And yet when politicians talk about saving money by spending more on prevention and less on cure, I assume that the "prevention" will be some puritanical doctrine for which no good evidence exists. After all, for decades the buggers told us not to eat egg yolks.

dearieme (2011-09-19 03:00:34)

Nor, come to think of it, butter.

q (2011-09-19 04:40:29)

i guess you're right. doctors would never ever tell someone to stop smoking, for example, and more perversely lung cancer rates have been skyrocketing in the USA because neither physicians nor public health officials have any attempt to convince people to stop smoking.

dearieme (2011-09-19 06:38:16)

But smoking is the past - the only really substantial mass killer identified successfully by more-or-less modern epidemiology. (And even then it's worth noting that the original discovery of the perils of smoking was rejected by doctors on the grounds that it was Nazi science.) Since then doctorly lecturing has been regularly based on weak or absent evidence. Or it amounts to a feeble repetition of the stuff your mother told you - "Go out and play, dear" - or, as I say, erroneous countermanding of your mother's excellent advice to eat up your egg. Dim-witted nagging is not the same thing as prevention.

JPB (2011-09-19 08:07:28)

Very true, but until that message gets out to the masses, it will be more of the same. My former doctor was convinced I would drop dead very soon because I declined to take a statin. He also said there was no way to correct lipid numbers with diet. Wasn't even willing to give me some time to see if it would work!

Seth Roberts (2011-09-19 09:36:21)

"Doctors would never ever tell someone to stop smoking, for example." yeah, "for example". Except that (a) it is almost the only example and (b) everyone already knows smoking is unhealthy and (c) giving such preventive advice is a very small fraction (0.1 %?) of what doctors spend their time on and (d) this advice is 50 years old - that is, stale. The other example of what a doctor might do to prevent disease I can think of is telling patients to lose weight. As if (a) the patient didn't realize he/she was fat and (b) the notion that they should lose weight was a new idea. If you went to a doctor and all they did was tell you to stop smoking and lose weight you might wonder if they were an imposter - if they went to medical school. You would certainly resent paying \$100 or whatever for such blindingly-obvious advice.

jeff borsato (2011-09-19 10:06:45)

I think it is difficult to quantify how many illnesses or diseases are directly the result of poor lifestyle or risky behavior. It is equally difficult to paint the health care industry with the same brush because it is so varied from state to state let alone from nation to nation. Doctors do not have a vested financial interest in the basic health and safety of people while they are healthy. Car companies have a financial interest in making cars safer to avoid excessive litigation, but doctors are only called in when people require their services. Should doctors be paragons of public health and safety? Should they like priests of old preach to the masses the evils of certain risky behaviors? Im not so sure, and in Canada there exist layer upon layer of prevention and safety positions staffed by doctors and nurses to preach that same message to the people. The assumption your argument appears to rest up is that sending a message of prevention will be received and put into practice and what line should this message not cross? If these strategies worked, let us compare mortality/accident rates for nations with varying levels of spending on prevention/health and safety type outreach among medical professionals to qualify that sentiment. Medical professionals are not without their own disagreements and moral dilemmas, asking a doctor to invest himself in prevention could result in varying messages, some smacking of a morality not shared by all and not scientific in nature. This would simply give rise to a sort of propaganda unit of central control to provide the message doctors "ought" to give, which in itself presents a host of problems. A carpenter should not beyond a moral inclination be expected to learn about sustainable tree planting to

work with wood. With the amount of training for a doctor just to treat the sick, we might make best use of their time doing just that. Prevention is a messy tangle of morals and science when we move beyond the very basic messages. Doctors preach already to patients to stop smoking or loose weight, but many simply refuse to listen because there is little or no incentive to do so. The message is not the problem, human nature is.

David (2011-09-19 16:41:52)

The reason doctors make an exception to the "no prevention" rule for smoking and losing weight is simple: they know from experience that almost no one can or does follow that particular advice.

Alrenous (2011-09-19 17:04:03)

Tabacco chewing was considered a [1]filthy habit at least as long ago as 1870, and I hope you'll excuse me for concluding that cigarettes would have acquired the moniker instantly, by association. Especially as it in fact smells bad. Fifty years old is too young by a factor of nearly three.

1. [http://books.google.ca/books?id=issHAQAAMAAJ&pg=PA703&lpg=PA703&dq=%22filthy+habit%22+etymology&source=bl&ots=whVNxA-ZrU&sig=UqJe81Ylf6Ht0kRFz9rn7AbKN38&hl=en&ei=add3ToKyK6jl0QGk74nqCw&sa=X&oi=book\\_result&ct=result&resnum=6&ved=0CDsQ6AEwBQ#v=onepage&q=filthy&f=false](http://books.google.ca/books?id=issHAQAAMAAJ&pg=PA703&lpg=PA703&dq=%22filthy+habit%22+etymology&source=bl&ots=whVNxA-ZrU&sig=UqJe81Ylf6Ht0kRFz9rn7AbKN38&hl=en&ei=add3ToKyK6jl0QGk74nqCw&sa=X&oi=book_result&ct=result&resnum=6&ved=0CDsQ6AEwBQ#v=onepage&q=filthy&f=false)

WCB (2011-09-19 18:12:33)

Seth, I'm a regular reader and really appreciate your blog. Re your above piece, I have often thought that a better term than disease "prevention" would be to coin the term "disease avoidance." That's because it seems the term "prevention" in this context has been corrupted to refer to the marketing and delivery of more and more medical services such as annual physicals and regular medical testing,. The resulting doctor prescriptions of pharmaceuticals for high blood pressure, "high cholestrerol" and "treatment" of numerous other "conditions" are of course intended to be prescribed for the remainder of the patient's life and need to be constantly monitored by the service provider. More visits, more services, more income for you-know-who. With regard to the example of prescription of drugs for many of the typically diagnosed "conditions," it is clear that most of these don't actually cure any condition in anybody; but they sure pad the income statements of the drug manufacturers year after year. The result is that the system is well on its way to bankrupting Medicare and Medicaid. I've also arrived at the view that many of these conditions (especially type 2 diabetes which is now rampant) are almost always the result of a bad nutritional lifestyle, not genetics. So in the end, the system seeks to market a type of "prevention" that puts money in the pockets of medical care professionals, hospitals and pharma companies, but hardly ever prevents illness and doesn't cure anybody. I suppose all of this has become the driver of a terribly corrupt and unsustainable "let them get sick" medical system. BTW, while I'm in rant mode, we should all stop using the misleading term "health care" system since the system has evolved to a point where the "health" of the individual has become largely irrelevant. It's now just about churning profit.

Seth Roberts (2011-09-19 18:46:11)

yes, WCB, that's a good point. Our health care system is happy to do "prevention" so long as it is expensive – e.g., statins. The quality of this prevention is indicated by the finding that statins don't seem to help people who haven't had a heart attack.

JeffR (2011-09-20 01:38:38)

A question for Seth. What are the prevention strategies that you think doctors should be sharing with their patients? Bear in mind doctors are going to be hesitant to share health advice without a strong base of evidence.

Nancy Lebovitz (2011-09-20 04:45:32)

One possibility for prevention of joint problems– Feldenkrais method is a system of gentle movements done attentively so that people can recover varied, well-coordinated movement.

Seth Roberts (2011-09-20 06:10:20)

Jeff, I think doctors are helpless. They can only repeat what they are told. There is a lack of prevention research. That's where a better health care system would start: with more prevention research. Nancy, I suspect a lot of hip replacement is due to

inflammation, which would be prevented by sufficient omega-3.

WCB (2011-09-20 12:34:15)

@Nancy: In addition to Seth's comment (about omega-3 supplementation being helpful in preventing joint problems), I would like to mention the work of Dr. William Davis regarding the problems of inflammation, arthritis, celiac disease (and many other serious issues) caused by consumption of grains, particularly wheat. In case you aren't familiar with Dr. Davis, he is a practicing cardiologist in Milwaukee and offers a lot of useful info on his Heart Scan blog. Dr. Davis also recently published his book entitled "Wheat Belly" which is newly listed in the NY Times book review as number 5 on the best seller list for its category. It looks like Dr. Davis is really onto something when it comes to sound ideas for prevention (or avoidance, as I prefer to think of it) of a number of common diseases, all based on his clinical experience with numerous patients and research he has done on the subject. WCB

Rajiv Mehta (2011-09-20 16:02:22)

Seth, your critique is right in line with a couple of books I read recently: "Over-Diagnosed" by Dr Gilbert Welch, and "Worried Sick" by Dr Nortin Hadler. Both point out that a great deal of today's medical practices, especially the purportedly "preventive" stuff, is unproven, and worse is making us sicker. I reviewed the books on my blog (<http://bit.ly/opoqAl>).

Seth Roberts (2011-09-20 16:54:57)

Rajiv, thanks for drawing my attention to Over-Diagnosed. It sounds good.

JPB (2011-09-21 07:55:37)

Also, "Selling Sickness"

dearieme (2011-09-19 14:35:47)

Dear God, so of three suspects, two were driven to their deaths and a third had to be handed a huge sum in compensation for FBI actions. Add this yarn to Waco and I am left wondering whether Federal government agencies have carte blanche to misbehave.

Property of the State (2011-09-19 17:06:11)

"I am left wondering whether Federal government agencies have carte blanche to misbehave." Sovereign Immunity. a.k.a The King is above the law. Thus it always was. Thus it always will be.

Alrenous (2011-09-19 17:16:46)

That protein thing is hilarious. "Well, we have a computationally intractable problem." "Obviously, the solution is to give it to regular people to solve." And then it works. "Hi, I'd like to buy the 'human' peripheral for my computer. I bought some software it was a pre-req for without realizing..."

Alex Chernavsky (2011-09-20 09:13:22)

Somehow, that protein-folding article reminded me of that case in 2005, whereby someone discovered that it's trivially easy to open those fancy, expensive Kryptonite bike locks: <http://www.wired.com/culture/lifestyle/news/2004/09/64987> You can pick the locks without any special training, using just a plastic pen cap. Or, you *could* do it, before the company re-designed the locks.

Nancy Lebovitz (2011-09-20 13:24:17)

[1]I Heard the Sirens Scream is about 9/11 and the anthrax attacks. I've only heard the NPR interview with her, but she seems generally reasonable, and believes that Al Qaeda was behind the anthrax.

1. [http://www.amazon.com/HEARD-SIRENS-SCREAM-Americans-ebook/dp/B005DFHYQK/ref=sr\\_1\\_1?ie=UTF8&qid=1316549909&sr=8-1](http://www.amazon.com/HEARD-SIRENS-SCREAM-Americans-ebook/dp/B005DFHYQK/ref=sr_1_1?ie=UTF8&qid=1316549909&sr=8-1)

Seth Roberts (2011-09-20 16:07:23)

I Heard the Sirens Scream is by Laurie Garrett. Her most famous book is The Coming Plague (1995). Which hasn't yet come.

Vic (2011-09-20 20:48:34)

I don't know why you insist on continuing to wallow in ignorance along with E. J. Epstein with respect to the anthrax investigation when I have posted here on your past posts about the guy at [anthraxinvestigation.com](http://anthraxinvestigation.com)... he's spent the last 10 years of his life doing almost nothing but follow every single detail of this case and makes it unambiguously clear that the FBI got the right man on this one. He also specifically debunks Epstein's crackpot nonsense...

Nancy Lebovitz (2011-09-22 10:06:22)

Interesting point about Laurie Garrett. Did she say anything about when she expected a new plague?

Seth Roberts (2011-09-23 16:51:39)

Nancy, I forget the details of her prediction.

## First Day of Class 2011 (2011-09-20 05:00)

Yesterday was the first day of one of my Tsinghua classes. It has about 25 students. I asked each of them to say their favorite book in English. Several were mentioned twice: Pride and Prejudice (mentioned three times), Harry Potter, Catcher in the Rye, The Little Prince, and – this surprised me – The Secret. The last student to answer this question said her favorite book was Lolita. The class oohed. Last year a student said his favorite book was Ulysses. I said my favorite book was [1]Cities and the Wealth of Nations. (A close second is [2]Totto-Chan.)

I said the class would have three underlying principles: (a) Every student is different. (b) [3]The best way to learn is to do. (c) Reading group. Two years ago, a Tsinghua engineering student started a reading group to read some famous Chinese book. He put a sign-up sheet in the library. The idea spread and now there are maybe ten reading groups, which meet weekly. It's a alternative and successful educational system, they must be doing something right. To try to learn from their success, I am going to imitate their most obvious feature, which is a presentation about the

week's reading. For the coming week I asked for volunteers to give 5-minute presentations about the reading assignment. I said that if you gave a presentation, you wouldn't have to do the regular homework assignment (commenting on the reading) for two weeks. Three students volunteered. After class, as I was leaving, one of the volunteers came up to me. She wanted to do the homework anyway, she said. She had volunteered to do a presentation "to exercise my bravery".

1. <http://www.portifex.com/BSPages/Cities&Wealth.htm>
2. <http://www.arvindguptatoys.com/arvindgupta/Tottochan.pdf>
3. <http://courses.csail.mit.edu/6.042/fall11/The%20Best%20Way%20to%20Learn.pdf>

---

Tom (2011-09-21 06:00:26)

Seth, the "exercise my bravery" thing reminded me of an interesting article in the NY Times which I thought you'd like: <http://nytimes.com/2011/09/18/magazine/what-if-the-secret-to-success-is-failure.html>

Karen (2011-09-24 02:22:29)

Hi Seth!! I'm one of the volunteer..... I'm now dealing with my comments and presentation and finding everything available to help my work so that my performance on Monday won't ruin your enthusiasm of reading group:)

Karen (2011-09-24 02:24:20)

Oh! sorry!! I mean READING GROUP .....

Karen (2011-09-24 02:25:49)

And honestly speaking, I find your paper quite interesting!

Thussy (2011-09-28 03:39:10)

Professor Roberts, What time/place does your class meet at Tsinghua?

Seth Roberts (2011-09-28 16:48:40)

My Frontiers of Psychology class meets Monday 3:20 pm in Teaching Building 6, Section A, Room 113. My R class meets Tuesday 3:20 pm in Teaching Building 3, Section 3, Room 3109. You are welcome to attend.

## **Arthritis Relief From Flaxseed Oil (2011-09-20 23:24)**

From [1]the Shangri-La Diet forums:

I have just been doing the flaxseed oil for a few days and I am experiencing a dramatic decrease of my arthritis pain! It is a wonderful benefit. . . . My doctor friend who told me about the SLD told me that the flaxseed oil would help my arthritis as well, but I never expected anything this dramatic or quick!

[2]A friend of mine noticed something similar: his sore back stopped hurting shortly after he started taking flaxseed oil. If he skipped a day or so, the pain returned. Update: Reminded of this, he said, "I had forgotten all about that. When people ask me how my back is I tell them it never bothers me anymore since I stopped going to the gym."

Update 2: At first the arthritis sufferer took 4 1200-mg capsules 3 times/day – that is, 12 capsules per day. Then she increased her dosage to 6 capsules 3 times/day (= 18 capsules/day).

Update 3. " Yesterday, I was off to work and could not find my oil capsules. I didn't have time to look for them, so I resigned myself to doing sugar water during the day. . . . I did notice a small but significant worsening of the pain in my knees. When I got home, I found the capsules, and began taking them again. By the time I woke up this morning, I noted that my knees are again feeling better."

1. <http://boards.sethroberts.net/index.php?topic=8179.0>

2. <http://blog.sethroberts.net/2008/10/28/advances-in-the-shangri-la-diet/>

---

BLJ (2011-09-21 02:07:34)

I'll chime in here as well. I began taking the oil about a month ago to see if it could improve my gum health. Instead I have noticed considerable improvement in some pain in my back and somewhat arthritic hip. Still working on the gums.

Adam (2011-09-21 05:01:42)

Hey Seth, I'm also living in China (Shanghai, to be exact) and I've been having a hard time finding flaxseed. I've looked at all the local pharmacies and TCM stores. Can't find it anywhere. Any hints?

Seth Roberts (2011-09-21 12:59:09)

Adam, I get my flax seed from LohaoCity, which sells organic food. I used to get it at Carrefour. There is no branch of LohaoCity in Shanghai but there are several Carrefours. The flax seed I get has a label printed with LohaoCity and [www.lohaocity.com](http://www.lohaocity.com) so LohaoCity might ship it to you from the nearest store.

## Assorted Links (2011-09-22 05:00)

- [1]Lard chic. "“I might have a cold,” she says. “Eat this, then,” I say, proffering a piece of hot toast with a thin, transparent slice of cured pork fat.”
- Skeptical Science is a blog devoted to rebutting every argument offered by AGW skeptics like me. [2]Bishop Hill points out that after two comments were critical of a post about Antarctic ice, the post was rewritten. Rather than point out the rewriting, replies were added to the critical comments saying that the commenters hadn't read the post ("read and reread the post above").
- [3]Nobel Laureates Behaving Badly. "In his Nobel Prize Lecture of December 12, 1946, Hermann J. Muller argued that the dose-response for radiation-induced germ cell mutations was linear and that there was “no escape from the conclusion that there is no threshold [below which radiation is harmless]”. However, assessment of correspondence between Muller and Curt Stern 1 month prior to his Nobel Prize Lecture reveals that Muller knew the results and implications of a recently completed study at the University of Rochester under the direction of Stern, which directly contradicted his Nobel Prize Lecture.” This is related to radiation hormesis – the observation that low doses of radiation are beneficial. Airport screening may be making people healthier.

Michal (2011-09-22 07:31:41)

I just eat fatty cured meats straight without anything, you can taste them much better that way.

Stephen M (Ethesis) (2011-09-27 15:57:16)

[http://en.wikipedia.org/wiki/Hockey\\_stick\\_controversy#Mann\\_et\\_al.\\_2008\\_and\\_2009\\_fyi](http://en.wikipedia.org/wiki/Hockey_stick_controversy#Mann_et_al._2008_and_2009_fyi)

Glen Raphael (2011-10-07 22:12:10)

Stephen: why do you think that wikipedia ref is relevant or particularly informative? Have you looked into the issues re: Mann 2009? McIntyre pretty clearly had the better end of that debate, Mann's dismissive response notwithstanding.

## **Why Antidepressants Barely Work (2011-09-25 00:16)**

When antidepressants are compared to placebos, they do only slightly better. This is not a problem for psychiatrists. People get better, they can charge money for access – that's what matters. The rest of us, who would benefit from a better understanding of depression, do not feel bad because we have no idea what we are missing. But the puzzle of weak effectiveness remains. If the theory used to justify the antidepressants is correct, shouldn't they work better? If the theory is totally wrong, why do they work at all?

John Horgan, a science writer, [1]commented about this recently:

I first took a close look at treatments for mental illness 15 years ago while researching an article for Scientific American. At the time, sales of a new class of antidepressants, selective serotonin reuptake inhibitors, or SSRI's, were booming. The first SSRI, Prozac, had quickly become the most widely prescribed drug in the world. Many psychiatrists, notably Peter D. Kramer, author of the best seller Listening to Prozac, touted SSRI's as a revolutionary advance in the treatment of mental illness. Prozac, Kramer said in a phrase that I hope now haunts him, could make patients "better than well."

Clinical trials told a different story. SSRI's are no more effective than two older classes of antidepressants, tricyclics and monoamine oxidase inhibitors. What was even more surprising to me—given the rave reviews Prozac had received from Kramer and others—was that antidepressants as a whole were not

more effective than so-called talking cures, whether cognitive behavioral therapy or even old-fashioned Freudian psychoanalysis. . . . Psychiatry has made disturbingly little progress since the heyday of Freudian theory.

To psychiatrists, psychiatry has made great progress since Freud. First, it is much easier to prescribe a pill than listen to a patient talk for 50 minutes. Second, the new pseudoscience of serotonin deficiency is far more respectable (more "scientific") than the old pseudoscience of psychoanalysis (ego, id, super-ego, repression, etc.). It is harder for other doctors to make fun of psychiatrists.

But Horgan was not thinking like a psychiatrist. He was thinking like the rest of us. From that point of view, he should not have been "disturbed" by "little progress". Antidepressants will never work well. Poor effectiveness is inherent in the situation. Antidepressants must do two things: (a) people must get better and (b) psychiatrists must make a living. Those are different goals ("misaligned incentives") and they conflict.

Suppose a repairman comes to fix your dryer. One part is broken. The repairman orders a replacement and installs it. Your dryer now works fine. Because you could not diagnose the problem nor fix it, the repairman continues to be necessary. Suppose, on the other hand, the repairman can not replace the broken part. He must do something else. Maybe use duct tape. In this situation, the repair cannot possibly work well. Whatever he does can be better than nothing, but it cannot be a good repair

That is the situation of psychiatrists. I'm sure depression is due to the wrong environment. My work suggests [2]we need to see faces in the morning for our mood-controlling system to work properly. Jon Cousins' work suggests [3]we need to believe others care about us. Those are two possibilities. Psychiatrists cannot fix the environment. The pieces of the environment we need to be healthy must have been abundant during the Stone Age. This means they must be cheap. Psychiatrists cannot supply things that are cheap and abundant. If that's what they did, they couldn't make a living. This means they can only supply something that is not what is missing. Like a repairman who cannot replace a broken part, they are stuck with second-rate solutions. This is the fundamental reason that all mainstream treatments for depression, whether talk or drug, have roughly the same effectiveness – and none of them work very well.

Thanks to James Lucoff.

dearieme (2011-09-25 01:08:18)

To what extent can the faces of pets do in place of human morning faces?

Alex Chernavsky (2011-09-25 06:38:50)

Interesting post, but I think that antidepressants are worse than placebos in one crucial way. Antidepressants are known to cause long-term changes in synaptic function. Evidence exists that those changes may be harmful and may actually **cause** depression (or at least exacerbate it). The main thesis of Robert Whitaker's recent book, [1]*Anatomy of an Epidemic*, is that

the widespread use of antidepressants (and other psychiatric drugs) is causing an epidemic of mental illness. For a shorter treatment, see: [2]Now Antidepressant-Induced Chronic Depression Has a Name: Tardive Dysphoria.

1. <http://www.amazon.com/Anatomy-Epidemic-Bullets-Psychiatric-Astonishing/dp/0307452425/>

q (2011-09-25 17:11:37)

ok, so new yorkers who get up early and ride the subway into work should suffer from depression very infrequently?

Seth Roberts (2011-09-25 22:27:44)

the morning faces need to be face to face - what you see when you are having a conversation. That doesn't happen on the NYC subway.

Tom (2011-09-25 23:03:39)

Reminds me of a problem the Xacto corporation was having a few decades back. They were successful company, but profits were modest. They would sell a customer a handheld knife and a pack of refill blades, but that was it. Xacto called in a consultant to advise them on what to do to grow. The consultant told them to make the blades out of softer steel. Profits exploded, since the blades now needed constant replacement. (Previously, they lasted until one happened to break, which might take months.) Progress.

Jazi yechezkel zilber (2011-09-26 00:51:55)

Dearieme, Why not try for facing your dog for an hour every morning and record the results? All of us here will be highly interested in it. Seth, Therapies that work a tiny bit abound. (every change in whatever parameters of body, mind, environment should have. \*some\* effect). Basically the only plus of antidepressants is that they have huge clinical trials and have the aura of science. Otherwise, I bet there are very many things that have a tiny effect on almost any complex illness

LisaW (2011-09-26 01:39:40)

My normal but unhappy brother in law was put on a cocktail of anti depressants and has now developed bipolar disorder, so they very well may make things worse. I think that talking therapies could be a route to helping an individual change their environment, as this can often involve hard choices.

Jazi yechezkel zilber (2011-09-26 04:27:11)

Talkig therapies work. But most of the effect is in the very act of coming to talk and the talking. Methods of talk therapy do not matter much. When compared to "placebo" (i cannot remember how they managed to fix a placebo to. Tlk theraoy) there are claims that it gives similar results. I am fully supporting using the placebo effect (somehow medicine ignores its strong effect, maybe not much money to make from. Or the delusion at we need "something real"). Anyway, placebo is superior, as it does not contain harmful chemicals. One only needs to make the psychological staging as strong as possible. (the more professional looking, aura etc. The stronger the placebo effect)

David Perch (2011-09-26 08:01:29)

I am an avid reader of this blog and totally respect and admire Mr. Roberts' sometimes unconventional way of looking at things. But I have to say I was disappointed in the one-sidedness of this article (and the comments on it so far). These opinions do not seem to come from people with personal experience with depression and/or anti-depressants. Why be so judgemental about something you know nothing about? Try to believe me when I say that when you are in the midst of a depression (which is NOT the same as 'being in a bad mood') and you suddenly feel the clouds lifting you will KNOW it is because of the pills you have been taking, not the result of the placebo effect. Especially if you, like many others, have tried different drugs before you found one that works.

Alex Chernavsky (2011-09-26 10:17:11)

David – a couple of things: First, I have some experience with antidepressants. From 1995 to 1998, I worked on the team that managed the antidepressant Zoloft (generic name: sertraline; known as Lustral in the UK and in some other countries). Second, I don't think that introspection is a reliable method to distinguish placebo effects from true drug effects. See, for example, [1] this article, which starts with the story of a person who participated in a clinical trial for an antidepressant. The woman's response to the treatment was so profound that she was *astonished* to find out that she had actually been enrolled in the placebo arm of the study. I've included the first few paragraphs below.

Janis Schonfeld recalls the events that started her on her recovery from 30 years of depression with snapshot clarity: the newspaper ad she saw in 1997 seeking subjects for an antidepressant study; the chair she was sitting in when she called UCLA's Neuropsychiatric Institute; the window she was looking out of when she first spoke with Michelle Abrams, the research nurse who shepherded her through the trial. She remembers being both nervous and hopeful when she arrived at the institute, and a little uncomfortable when a technician put gel on her head, attached a nylon cap shot through with electrodes, and recorded her brain activity for 45 minutes. But most of all she remembers getting the bottle of her new pills in a brown paper bag from the hospital pharmacy. "I was so excited," she told me. "I couldn't wait to get started on them." Within a couple of weeks, Schonfeld, then a 46-year-old interior designer, got quickly and dramatically better, able once again to care for herself and her husband and daughter, no longer so convinced of her own worthlessness that she'd consider killing herself. For the next two months, she came back weekly for more interviews and tests and EEGs. And by the end of the study, Schonfeld seemed to be yet another person who owed a nearly miraculous recovery to the new generation of antidepressants – in this case, venlafaxine, better known as Effexor. But during her final visit to the institute, one of the doctors directing the research sat her down to deliver some disturbing news. "He told me I hadn't been taking a medicine at all. I'd been on a placebo. I was totally shocked."

<http://motherjones.com/politics/2003/11/it-prozac-or-placebo>

1. <http://motherjones.com/politics/2003/11/it-prozac-or-placebo>

Joe Montgomery (2011-09-26 10:52:40)

Definitely good analysis there... And I totally respect people who have used SSRI's and had great personal success, but you have to look at the problem from a scientific perspective. And if they don't make sense to all parties when you look at them scientifically, there needs to be a change somewhere. I'm not sure whether that means trying to change public perception, medical practice, or research practices, but something needs to change.

Jazi yechezkel zilber (2011-09-26 11:03:08)

David Perch, I accept the possibility that a specific drug that is compatible to a specific person can work well for depression. The studies of antidepressants use large groups of people, so the personal compatibility is probably nonexistent. In terms of scientific knowledge, however, we have no information. There are no strong effects in the studies, and we cannot take personal experience as proof. Practically speaking, I believe that science aside, what works for a person works. And it is foolish to avoid using a drug that proved highly effective for a person for whatever sophisticated thinking possible. (I would say that Seth would accept this as kind of personal science)

Pablo Stafforini (2011-09-26 11:26:20)

Seth, I am generally in sympathy with the tenor of your article, but I do object to one argument you appear to be making towards the end of your post. You conclude that psychiatry will never succeed in curing depression because (a) depression is due to environmental factors and (b) psychiatry cannot change the environment nor supply the "cheap and abundant" things that were present in the ancestral environment but missing in contemporary society. This is a non-sequitur. Suppose your own hypothesis is correct and depression is caused by a failure to see faces in the morning. The brain would still be implicated in this chain of causality: absence of morning faces will cause certain changes in the brain which would themselves cause people to feel and act depressed. If psychiatrists uncovered the relevant neural mechanisms involved in this process, they could in principle develop agents that mimicked the effect of morning faces in the brain. So it is not true that, because depression is ultimately caused by the environment, it falls outside the scope of psychiatry.

David Perch (2011-09-26 11:37:46)

Jazi, thanks for your comment. You hit on something I have been wondering about. I have never really understood the absolute reliance on clinical trials in these matters. They do not seem to take into account that people can react very differently to the exact same thing. If our individual response to recreational drugs like cannabis and alcohol vary so dramatically why can this not be true for non-recreational drugs? Millions of people use paracetamol/acetaminophen successfully but it has never done a thing for me, for instance. Cannabis makes me very relaxed and in touch with my creative side, it makes plenty of other people tired and paranoid. Why would it be different with something like Prozac? It makes me wonder whether we might be missing out on some wonderful drugs just because they did not work on a large enough percentage of people. I thought one of the major points that Mr. Roberts is making in his work is that absolute scientific proof is less important than finding something that works. I am not sure if anyone will ever prove beyond a shadow of a doubt that standing on one leg to improve sleep really works but in the meantime it seems like a good idea to try it when you are having sleep problems. To clarify: I am not from the US so as a result perhaps not so suspicious of our healthcare system as you guys are of yours. One of the perks of living in what a lot of Americans seem to fear so much: a 'socialist' society.

Joe (2011-09-26 13:24:41)

David, we're not suspicious of our health-care system; we're suspicious of our government. And the more that the government gets involved with our health care, the more suspicious we will become. One man's perk is another man's poison.

Seth Roberts (2011-09-26 13:57:50)

Alex, good quote, thanks. Pablo, you write, "If psychiatrists uncovered the relevant neural mechanisms involved in this process, they could in principle develop agents that mimicked the effect of morning faces in the brain." Think of it like this. Scurvy is due to lack of Vitamin C. But no one is going to make a living by "developing agents that mimic the effect of [Vitamin C]" because Vitamin C is easy to get.

Jazi yechezkel zilber (2011-09-26 18:16:53)

we should device a clinical trial for morning faces therapy. ideally, we need people who handle something (audio) on a computer screen anyway. we assign to two groups one with random visuals etc. the other with faces, and measure depression scales ( in a masked way, to avoid them knowing the idea. like asking various inventories) I am thinking about where we can find a large enough group of people who can get easily subjected to such an experiment.

John (2011-09-26 19:34:49)

Seth, Vitamin C is easy to get now that we can synthesize it cheaply, just like fish/flax seed oil and Vitamin D pills..but human attention in forms that will alleviate depression? Unfortunately that is a commodity too costly in US society for many people, hence the drive to replace therapy with pills. I'm reminded of Emily in Our Town, back from the dead for one day: "Oh Mama, just look at me for one minute as if you really saw...." Did Book TV really work for you? Joe, I'm not sure why you don't trust the government when you trust the highly paid health care administrators who deny people coverage and suck up 40 % of our health care bill. The hospital is the only place where a bandage can cost you \$50 dollars, and you can't bring your own. After being without insurance for almost two years, I'm looking forward to the day when people don't have to "choose" between affording a pain pill and an antibiotic for lack of coverage like the young man in Cincinnati who died. And I work and I pay taxes, thank you. Health care or endless war? I'd like health care, please.

WCB (2011-09-27 10:58:20)

Seth, your suggestion that needing to see faces of others (and to converse with them) in the a.m. is intriguing. It makes sense if we think about the fact that humans are essentially social animals, seek friendships, and crave regular interaction with others. And here's another thought: Why hasn't the issue of widespread vitamin D deficiency been explored more thoroughly? There has been a good deal of writing (and some scientific examination) into the fact that vitamin D deficiency is rampant in modern society (especially in climes where sunlight is weaker). And there is apparently evidence that using light therapy, or raising the individual's blood levels of 25(OH)D through supplementation with vitamin D3, can be effective in treating SAD or other mood disorders. So why hasn't there been more focused scientific inquiry along these lines? Could it be that

advising people to get more exposure to natural sunlight, or otherwise recommending they raise their serum level of vitamin D with supplementation, is just too simple, direct and cheap compared to drugs and psychiatric treatment, which are expensive?

Alex Chernavsky (2011-09-27 12:08:26)

@WCB: Here's my experience with vitamin D deficiency, for whatever it's worth. About four months ago, I had routine bloodwork done. The results showed very low vitamin D levels. Since that time, I started taking D3 supplements, and the latest lab results showed normal levels. I have not noticed any change in my mood (though I was not depressed to begin with).

thehova83 (2011-09-27 13:45:20)

Lots of commenters are dismissing cognitive behavioral therapy. But it has been relatively successful. The CBT method appears to be effective even outside one on one therapy.

WCB (2011-09-27 14:15:44)

@Alex: Thanks for your comment about your experience with D3. I'm guessing that over a longer time frame you will likely realize many other benefits, apart from the subject matter in this string. In any event, it's certainly clear that more research on the topic of finding effective, inexpensive treatments for those who experience depression is needed. But more broadly re vitamin D supplementation, based on the reading and research I've been doing for quite awhile, and my own experience with adding D3 over some four years and continuing, I'll just mention that eliminating the deficiency can have a number of other benefits, including prevention (or avoidance) of things we would all like to avoid. But rather than me going OT reciting the litany of potential benefits and cluttering up Seth's excellent blog, you might be interested in checking out a blog such as that of Dr. William Davis (Heart Scan blog) and the website of the Vitamin D Council. They both provide a lot of useful info, including, inter alia, advice as to the desirable level of serum 25(OH)D for most individuals to realize the full benefits (based, e.g., on Dr. Davis' own clinical experience) which is significantly higher than the conventional view of something like 25-30 ng/ml. Regards, WCB

Jim Purdy (2011-09-28 20:48:32)

As Jazi yechezkel zilber said above "... placebo is superior, as it does not contain harmful chemicals." I am strongly opposed to using "harmful chemicals" (drugs) of any kind for myself. Despite the severe scoldings I get from doctors, I currently use no prescription medicines, no over-the-counter meds (not even aspirin or vitamins), and certainly no alcohol, tobacco or illegal drugs. My resolve may be severely tested this weekend. This Friday, September 30, I am scheduled for some surgery. (If I had my way, it would be done without anesthesia, but the surgeon will not do it without anesthesia.) The surgeon has told me that I will need medication for pain after the surgery, and she plans to prescribe Lortab (hydrocodone). I told her that I would not take hydrocodone, or even fill the prescription. As I told her: "I have only had one hydrocodone pill in my life, and it made me feel so good that I immediately threw the other 17 pills away. As far as I'm concerned, the only thing worse than a drug that makes me feel bad is a drug that makes me feel good, because the feel-good drug is the one that could get me addicted." That screaming you will hear this weekend will be me suffering without pain meds.

Seth Roberts (2011-09-29 13:59:33)

Jim Purdy, I pretty much agree, except I have no problem with alcohol. I tried to get a dental operation done without anesthesia but I lasted about 0.5 seconds. I was able to avoid pain killers after the operation, however. Seth

Alex Chernavsky (2011-09-29 15:15:25)

My father-in-law gets root canals done without any anesthetics. I don't know how he does it. I need a shot of Novocaine just to walk into the waiting room.

Glen Raphael (2011-10-07 21:41:39)

Try to believe me when I say that when you are in the midst of a depression (which is NOT the same as 'being in a bad mood') and you suddenly feel the clouds lifting you will KNOW it is because of the pills you have been taking,

not the result of the placebo effect. Especially if you, like many others, have tried different drugs before you found one that works.

Sorry, but that methodology doesn't work. Assume for the sake of argument that your depression is either environmental, seasonal, or cyclical - something that gets triggered at time T and then sometime much later at time U goes away. What does that look like to somebody who takes pills? You go to the doctor, who prescribes pill A; it doesn't seem to work, so the doctor prescribes pill B which also doesn't seem to work, and so on until time U is achieved. Since time U happens a couple weeks after you've started drug D, you are now utterly convinced drug D is the "one that works". Regression toward the mean explains much of the apparent effect of antidepressants.

### **The Beginning of the End of AGW (2011-09-26 13:46)**

A month ago at a conference I met a journalist who wanted to increase public understanding of science. I said, yeah, it would be good if the public understood science, then they could see how weak the case that humans are seriously warming the planet (anthropogenic global warming, AGW). After I said that, my questions received short answers, haha.

Then there's Gary Trudeau. According to [1]a recent Doonesbury cartoon, I'm not just a moron, I'm a moron:

The scientific case for global warming is overwhelming – and it grows daily. Only a moron would deny it.

But I think the dissent is getting louder. Jeff Jacoby, a columnist for the Boston Globe, [2]recently wrote:

You don't have to look far to see that impeccable scientific standards can go hand-in-hand with skepticism about global warming. Ivar Giaever, a 1973 Nobel laureate in physics, resigned this month as a Fellow of the American Physical Society (APS) to protest the organization's official position that evidence of manmade climate change is "incontrovertible" and cause for alarm.

Giaever, unlike Jacoby, [3]voted for Obama. And there's this, from ScottishSkeptic:

This weekend I was sitting with a group of (unrelated) people I'd known since a child, and the subject of wheat farming and weather forecasts came up and almost without prompting someone else mentioned their dislike of the politicisation at the Met Office, the way the forecasts were always wrong and their suspicion about what we are being told about global warming. And then the rest of the company agreed with them.

None of these people had any financial interest in the subject, they were all educated in science at leading Universities, but they are not only questioning the assertions of global warming, they were actively sceptical.

To say I was shocked was an understatement. In many other ways this is a very pro-environment group.

So maybe there is hope for the ideas that butter is good and breakfast bad, that sugar can cause weight loss, that food is healthier after the expiration date, that faces Monday morning can make you happier on Tuesday, and so on.

1. <http://thinkprogress.org/romm/2011/09/25/328068/great-doonsebury-global-warming-cartoon/>
2. <http://www.jeffjacoby.com/10407/climate-skeptics-dont-deny-science>
3. <http://www.theblaze.com/stories/nobel-prize-winner-resigns-over-an-incontrovertible-stance-on-global-warming/>

---

Steve G. (2011-09-26 15:39:42)

Skepticism is—or should be—the hallmark of science. Unremitting questioning should be the order of the day in science. However, policy and action cannot operate on such standards. You confuse scientific skepticism—almost always a good thing—with rational judgment, which must, in the face of choices, always act in the face of uncertainty. When  $N=1$ , you'd better be sure that you want to run the experiment. We're running an experiment in AGW, and based on the results so far, we'd better think very strongly about stopping the experiment. The experiment is fun—unlimited energy makes all of our lives better by any material measure—but if we don't watch it, we could end up creating a mess for ourselves and future generations. That's what choice is about. BTW, how about an ideological Turing test for you? (E.g. [http://econlog.econlib.org/archives/2011/06/the\\_ideological.html](http://econlog.econlib.org/archives/2011/06/the_ideological.html)). Will you post the strongest possible arguments possible in support of AGW, and based upon that statement, make a set of policy recommendations? After doing so, you can then post what policies you do support and why you've made that choice. Thanks,

B. Compson (2011-09-27 03:27:03)

Seth, I'll bet your opinion on AGW makes many of your Berkeley friends squirm. You're a rebuke to those who would dismiss all AGW skeptics as know-nothing, Fox News-watching tea partiers. If pinned down I would say my degree of belief in AGW is about 68 % and climbing, but I admire your courage and I hope you are correct and "they" are wrong.

Alrenous (2011-09-27 13:19:41)

If they had an actual case they wouldn't need to resort to name calling. If it wasn't politically relevant they wouldn't bother. Follow the money. This has been said before but apparently it bears repeating.

Stephen M (Ethesis) (2011-09-27 15:49:28)

I would think more of AGW believers if they were doing things that fit with what they were espousing. Moving to Canada and moving inland, etc. I need to browse around the internet to see how the hockey stick looks now that we have ten more years of data to add to it.

Nathan Myers (2011-09-28 11:03:21)

Tying the vindication of your butter and breakfast hypotheses to the ultimate repudiation of AGW shows very little confidence in your own ideas. You still have not said whether you don't believe there's persuasive evidence that GW is occurring at all, or whether you don't believe there's any way that human activity can be causing the (manifestly observable) melting of the tundra. The two positions are fundamentally contradictory. Which is it? Even days one, odd days the other?

Tom Fid (2011-09-28 11:54:36)

You still haven't said what your null forecast or model for climate is, or even stated a reasonable burden of proof for non-experimental situations, so that you can never be proven wrong. That doesn't seem very consistent with your experimental approach to other problems, which I admire.

MetaThought (2011-09-28 16:04:11)

@Nathan, it's up to the climate scientists to prove both the assumptions. Disproving either will be sufficient for the anti-AGW people.

Seth Roberts (2011-09-28 16:49:48)

Nathan, I believe that the earth has warmed considerably since the Little Ice Age.

Tom Fid (2011-09-29 13:23:12)

@Stephen Then you should think a lot of the fact that oil companies are placing big bets on oil exploration in the arctic.

Eugene Woodbury (2011-09-29 14:32:18)

Calls for scientific skepticism to yield to the political impulse to act (for the children, for the public good, for the planet, and to keep the money flowing) calls to mind what Bryan Caplan calls the "Activist's fallacy": 1. Something must be done 2. This is something 3. Therefore, this must be done. We know what causes earthquakes, but thankfully no one is seriously proposing a worldwide, trillion-dollar effort to stop continental drift. We do our best to understand it and deal with it. We don't pretend we're powerful enough to stop it. As P.J. O'Rourke points out, "There are 1.3 billion people in China and they all want a Buick." If global warming is caused by burning fossil fuels, nothing can stop it. All the political action in the world will only waste scads of time and money.

Seth Roberts (2011-09-29 16:38:54)

Eugene, I like Bryan's Activist's Fallacy. I suppose it is 90 % fallacy, 10 % reasonable. As I say in my next post, if you don't do anything, you'll learn less than if you do something, even the wrong thing.

MetaThought (2011-09-29 23:04:25)

But are there any signs that we(as a collective) are capable of recognizing that we are doing the wrong thing and changing direction? Doing the wrong thing is a reasonable approach at the individual level, but horribly bad at the State level where mistakes may go unacknowledged for decades.

Mike (2011-10-01 07:25:56)

One less blog for me to read. Your statement that the science is weak on AGW makes me question everything you have written.

## **Spycraft, Personal Science, and Overconfidence in What We Know (2011-09-28 20:21)**

[1]Edward Jay Epstein's newest Kindle book is [2]James Jesus Angleton: Was He Right?. Angleton worked at the CIA most of his career, which spanned the Cold War. He struck some of his colleagues as paranoid: He believed that the CIA could easily contain Russian spies. Colleagues said Oh, no, that couldn't happen. After his death, it turned out he was right (e.g., Aldrich Ames). At one point he warned the CIA director, "an intelligence [agency] is most vulnerable to deception when it considers itself invulnerable to deception."

What interests me is the asymmetry of the mistakes. When it really matters, we overestimate far more than underestimate our understanding. CIA employees' overestimation of their ability to detect deception is a big example. There are innumerable small examples. When people are asked to guess everyday facts (e.g., height of the Empire

State Building) and provide 95 % confidence intervals for their guesses, their intervals are too short, usually much too short (e.g., the correct answer is outside the intervals 20 % of the time). People arrive at destinations more often later than expected than earlier than expected. Projects large and small take longer than expected far more often than shorter than expected. For any one example, there are many possible explanations. But the diversity of examples suggests the common thread is true: We are too sure of what we know.

There are several plausible explanations. One is that it helps groups work together. If people work together toward a single goal, they are more likely to reach that goal and at least learn what happens than if they squabble. Another is the same idea at an individual level. Overconfidence in our beliefs helps us act on them. By acting on them, we learn. Doing nothing teaches less. A third is a mismatch idea: We are overconfident because modern life is more complicated than the Stone-Age world to which evolution adjusted our brains. No one asked Stone-Age people How tall is the Empire State Building? A fourth is that we assume what physicists assume: the distant world follows the same rules as the world close to us. This is a natural assumption, but it's wrong.

Early in Angleton's career, he had a very unpleasant shock: He realized he had been fooled by the Russians in a big way for a long time. This led him to try to understand why he'd been fooled. Early in my scientific career, I too was shocked: Rats in Skinner boxes did not act as expected far more often than I would have thought. I overestimated my understanding of them. In a heavily-controlled heavily-studied situation! I generalized from this. If I couldn't predict the behavior of rats in a Skinner box, I couldn't predict human behavior in ordinary life. My conclusion was data is more precious than we think. In other words, data is underpriced. If a stock is underpriced, you buy as much of it as possible. I tried to collect as much data as possible. Personal science – studying my sleep, my weight, and so on – was a way to gather data at essentially zero cost. And, indeed, the results surprised me far more than I expected. I could act based on the overconfidence effect but I could not remove it from my expectations.

---

Tom (2011-09-28 23:06:11)

I swear, Seth, you're as interesting a thinker as can be found on the net.

Seth Roberts (2011-09-29 07:28:10)

What a nice comment, thanks!

Todd (2011-09-29 10:42:37)

Your essay contains one of the most beautiful statements I've heard in science: "Data is more precious than we think...data is underpriced." As a scientist, I find that some colleagues love to spend time spinning hypotheses and arguing with each other....when it would take less time to go into the lab and run the experiment. So often the data reveal surprises and confound theories. There is just no substitute for quality data.

Tim Beneke (2011-09-29 11:49:38)

I agree. Great provocative post Seth! Don't forget the influence of professional roles and the situations they cast people in, and how this generates overconfidence and the unwillingness to objectively rate the degree of confidence one should have in a prediction, given the relative knowledge available. For example, psychiatry for most of its history has had virtually nothing to offer people suffering mental illness. (It has only a little now.) When we lack knowledge, the void gets filled with theory – vast, rather obscure psychoanalytic theory based upon intuitions, much or most of which, in the light of subsequent evidence, has turned out to be nonsense. But the psychiatrists are faced with desperate patients and their families; they want to have an upper middle class income, like their other medical colleagues and they need to appear authoritative. They can't just say that they have no idea why someone suffers from schizophrenia or manic depression and that they really have no way to treat it. Who would pay them for that? Or look at economists, who cannot perform experiments with history to get causal knowledge and are only recently beginning to rely on psych experiments to see how economic cognition, affect and behavior function. I like Paul Krugman, but he did not know where the economy was headed in 1994, or in 2001, or in 2008; he was fairly clueless. Yet he is very confident that a massive stimulus program will have certain positive effects on the economy. And obviously politics distorts cognition in economics. Or nutrition and the over-authoritization that takes place there. Professionals have a lot of trouble just saying that they don't know much... I don't know how to sort out the effects of economic self interest, situational responses to the strong needs of those they serve, cognitive biases that are just part of the larger culture, and many other things, but it's a mess...

JeffR (2011-09-29 17:10:32)

I'm not sure what to make of the fact that I sometimes think you are overestimating how much you know, Seth.

Seth Roberts (2011-09-30 06:37:58)

JeffR, exactly. If you overestimate what you know, you will underestimate what others know. Maybe that is part of the secret of Wikipedia – taking advantage of that misperception.

Seth Roberts (2011-09-30 22:52:16)

Thanks, Todd. I am puzzled that this idea isn't widespread among laboratory scientists, who – judging by your comment – just like me see that even under highly-controlled highly-studied situations it's still hard to be sure what will happen.

Nancy Lebovitz (2011-10-01 07:28:56)

Seth, you do careful experimentation on yourself, but then you extrapolate the results to everyone.

Seth Roberts (2011-10-01 14:31:37)

Nancy, experimental psychologists have 100 years of data showing that the results from careful studies of individuals (if those individuals weren't specially chosen) extrapolate to many people. I don't extrapolate to "everyone", just many people. And I do it partly because of all that experimental psych data.

Nancy Lebovitz (2011-10-01 16:54:43)

It's sounded to me as though you say things like "everyone should eat more bacteria" rather than, "eating more bacteria may be a good idea for you, here's how to test it".

Seth Roberts (2011-10-01 18:36:53)

Nancy, my ideas about the value of fermented food are based on a wide range of data. very little from me. quite different from my other ideas, most of which involve a lot of data from me (e.g., butter). I am sure that we need fermented food to be healthy just as much as we need Vitamin C. I see no other plausible explanation for the wide range of data. I extrapolate to "everyone" partly because there is no group of people who don't need Vitamin C (or any other vitamin or necessary nutrient, such as iron). That's why I am sure this requirement (plenty of microbes in your diet) is universal. In large part because of the long history of nutrition. That being said, in a tiny number of cases fermented food has had bad effects. This shouldn't interfere with seeing

the big picture.

Scot (2011-10-02 06:36:57)

Seth, See Dan Gilbert's "Stumbling on Happiness" for (a delightful read and) another explanation of why we're so bad at predicting what we will feel in the future. We overpredict how difficult and how satisfying future events will be, because we remember distinctive events, not regular ones. Regular events would be more stable data sources for prediction.

Tom (2011-10-02 09:47:49)

Seth, I'm pretty sure you're aware of him, but just in case, Art Ayers writes in great detail about the importance of ingesting bacteria (and soluble fiber) to promote healthy gut flora: <http://coolinginflammation.blogspot.com/search/label/gut%20flora>

Seth Roberts (2011-10-02 17:33:21)

thanks, great blog. I wasn't aware of it.

## **Two More Shangri-La Diet Success Stories (2011-09-30 22:46)**

From [1]the Shangri-La Diet forums:

I started this process on or around the 3rd week of July. Not sure of the exact date lets say 7-23-11. Weight was 228 lbs, blood pressure maxing out at 160/100. Today (9-30-11) my weight is 195 lbs and the bp is below 120/80.

So in 10 weeks I have dropped 33 lbs about 3.3 pounds a week or half a pound a day. My goal weight is 175. I have done the canola oil twice a day. No breakfast and mixing in salad and fruit for lunch and dinner with 6 ounces of meat, seafood or chicken. Some carbs but not a lot. I have not had any cravings to overeat or to snack on junk food and I just stopped drinking sodas for no reason that I can explain and I don't feel hungry after meals.

People at the gym must think I am sick because I am losing weight and don't do very much. I lift 20 minutes to maintain what I have and ran twice in the past 10 weeks for a total of maybe 3 miles. I have started doing more abs now that you might be able to see them when all the fat is gone.

In 30 years of dieting this is the easiest thing I have ever done. I don't understand why this isn't the number one diet in the world.

Let it not be because I don't blog about it. [2]Someone else, who started at 321 pounds, has lost 67 pounds in 8 months. Graph [3]here.

Rocky (2011-10-03 09:49:12)

I've not done an extensive search of the forums, but I was curious if anyone has tried coconut oil for the preferred oil on the SLD. I lost a bunch of weight back in 2006 trying SLD and I used ELOO and WO. Both of those oils were gross to take and the WO was a bit worse, but I got used to them. Just last week, I bought my first batch of coconut oil (CO) and I ingested it orally. I was shocked that I did not taste anything! I thought it would taste like coconut, but it really didn't have a taste. In fact, when compared to ELOO and WO, CO had even less taste. So I was curious to see if anyone has tried CO for SLD.

Rocky (2011-10-07 07:08:35)

Just as a follow-up from my previous comment ... there is this thread that talks about a few people using CO and having success: [#msg83326](http://boards.sethroberts.net/index.php?topic=6972.msg83326)

## 6.10 October

### **Cheap Safe Remedies: Oatmeal (Cholesterol) & Deep Breathing (Blood Pressure) (2011-10-01 13:44)**

A friend who lives in New York City writes:

The doctor I had when I lived in San Diego believed in always trying the gentlest and simplest remedies before resorting to anything as drastic as drugs or surgery. My cholesterol was high and she suggested I try lowering it by eating oatmeal for breakfast every day, saying it didn't work for everybody but a lot of her patients had been able to avoid going on statins that way. "But I hate oatmeal," I whined, like a sulky child. She said perhaps I would get used to it; wouldn't it be better than being dependent on medications for the rest of my life? So, reluctantly, I bought some Quaker Oats and gave it a try. The results were dramatic – my cholesterol numbers were "perfect" the next time I had a blood test. Dr. Yu was right about getting used to oatmeal, too – I actually like it now, and look forward to my daily bowl.

Perhaps inspired by my success with the oatmeal, I also lowered my blood pressure myself, through breathing exercises. A friend who is into alternative medicine had told me about being advised by several of her alternative-medicine practitioners to try lowering her blood pressure in that way, so when mine was high, I just googled about lowering it until I found [1]a site that offered free demo clips of a kind of breathing exercise geared to music – you can choose whether classical or new age. As it said on the site, they don't work for everybody, and most people have to do them for twenty minutes daily for a couple of weeks before the benefits begin showing up at all, but some lucky folks see an immediate and drastic drop in blood pressure the first time they try. I turned out to be one of the lucky ones. For months, I did the breathing exercises daily, cued to inhale and exhale by their demo tapes, and my blood pressure stayed down. Eventually i even sprang for the CD set they were selling on the site, just because I got sick of hearing those same melodies on the free demo clips over and over. Now I've internalized the rhythms so I don't need any music at all to cue me, and I can do the exercises anywhere, while doing other things, and my blood pressure has remained low. I do notice that if I ever neglect the exercises,

when my life gets busy and I just forget to do them, it starts creeping up again – which is good incentive to keep them up. Basically, the exercises just consist of inhaling to a slow count of 8 and exhaling to a slow count of 16, and doing that for about 20 minutes every day. My blood pressure was around 160/90 before I started the exercises. Now it's 120/80, just as it should be.

I also find the breathing exercises very soothing, in general. When I'm upset about something like, say, being stuck on a slow bus that is crawling through traffic while I'm in danger of being late to something and am surrounded by screeching children, I find that doing those exercises enables me to be reasonably serene and philosophical instead of miserable and angry and anxious.

Notice that by measuring her blood pressure regularly my friend (a) learned how to control it and (b) collected excellent evidence that breathing exercises help. Because individuals can easily collect such evidence – my friend did so by being lazy – a good response to "where's the double-blind randomized trial?" is [2]Mark Frauenfelder's: [3]Big Brother loves you.

Vic (2011-10-01 22:52:29)

sounds like she might have had white-coat hypertension...

Jazi yechezkel zilber (2011-10-02 05:20:21)

Here is another advantage of personal science. The huge amount of things that can be tested. I am now reminded in the sheer number of possible relaxation techniques. Making. Formal research on these is a formidable task. But just hundred anxious persons can test thousands of relaxation tricks! I am excited by the possibilities. And here is an idea. Can self experimentation be orchestrated? In principle one. Can coordinate for many people to systematically test whatever. Can be done in many flavors, but the cost effectiveness is high

Jazi yechezkel zilber (2011-10-02 05:21:31)

Ps. I had very good experience with oatmeal for my health. I ate it daily and it was very good for me, until I stopped from other reasons

Seth Roberts (2011-10-02 07:26:46)

Vic, mostly she measured her blood pressure herself. No white coats involved.

Pablo Stafforini (2011-10-02 11:04:22)

Seth, can you or your friend provide the name or address of the site that offers the free demo clips of breathing exercises described in the post? Thanks.

Seth Roberts (2011-10-02 16:51:11)

Pablo, here is the link: <http://www.control-your-blood-pressure.com/>

JPB (2011-10-03 09:00:48)

As far as the oatmeal, your friend should also consider the effect it has on her blood sugar. Check out Dr. William Davis on The Heart Scan Blog for this topic.

### **Flaxseed in Various Units. (2011-10-03 12:59)**

I eat 66 grams of flaxseed per day. (I eat it with yogurt in two batches. For each batch, I weigh out 33 g of whole flaxseeds then grind them.) Not everyone has a scale, so I found that 100 ml of whole flaxseed weighs about 64 grams. Assuming 1 tablespoon = 15 ml, that's 6.9 tablespoons/day whole flaxseed. If you are interested in weight/volume conversion, that's 9.5 g of whole flaxseed = 1 tablespoon. I checked this using two different volume spoons and a scale that matches another scale.

[1]This website says there are 15.02 g of whole flaxseed in a tablespoon. I am measuring brown flaxseeds. Perhaps their golden flaxseeds are smaller and therefore more dense. The overprecision suggests this shouldn't be trusted.

[2]This website says there 14.17 g of "dry" flaxseed in a tablespoon. Again with the overprecision.

According to [3]this website, there are 7.5 g of whole flaxseed in a tablespoon.

1. <http://www.ellies-whole-grains.com/how-many-grams-of-flaxseed-in-a-tablespoon.html>
2. [http://wiki.answers.com/Q/How\\_many\\_grams\\_in\\_a\\_tablespoon\\_of\\_dry\\_flax\\_seed](http://wiki.answers.com/Q/How_many_grams_in_a_tablespoon_of_dry_flax_seed)
3. [http://wiki.answers.com/Q/How\\_many\\_grams\\_of\\_flaxseed\\_in\\_one\\_tespoon](http://wiki.answers.com/Q/How_many_grams_of_flaxseed_in_one_tespoon)

---

aretae (2011-10-03 14:21:53)

And in what form? powdered, whole, ?? Do you have thoughts/opinions/data about what forms are valuable?

Tom Passin (2011-10-03 15:35:41)

Today I weighed out a bit over 3 tablespoons of whole flax seeds, and they weighed 31 g. I don't know what kind of flax (I got them at Whole Foods Market).

Seth Roberts (2011-10-03 18:34:42)

Aretae, I eat my flaxseed ground. I have revised the post. Thanks, Tom, that agrees with my measurements. There are two main kinds of flax seed: brown and golden. Whole Foods usually has golden, in my experience.

Alex Chernavsky (2011-10-03 20:32:32)

Do the brown and golden varieties differ in terms of efficacy?

Outis (2011-10-03 22:08:06)

I would suffer from constipation if I consumed that much flaxseed (ground or in a corresponding amount of oil).

dearieme (2011-10-04 02:14:16)

I have just weighed one level tablespoon (British) of brown linseed (= your "flaxseed"). 14 g.

dearieme (2011-10-04 02:16:52)

"convertalot" reports: Not all tablespoons are the same. The Australian tablespoon is 20 ml; the British tablespoon is 17.7 ml. In most Canadian recipes the tablespoon is 15 ml while the American tablespoon is actually 14.2 ml.

Seth Roberts (2011-10-04 07:19:35)

curious

Bill Moran (2011-10-04 07:32:17)

Seth, one question: Why do you weigh your flax seed? I buy and eat Whole Foods organic flax seed (golden is prettier, but I think brown has more oil) every morning and the health benefits are self evident. But it only costs 25-30 dollars for a 25 Pound bag, and it takes Months for me to go through a bag. (I put it on top of raw organic rolled oats, and top it with orange juice, like cereal, but without the dairy products.)

Seth Roberts (2011-10-04 08:36:56)

I weigh it because weight works better than volume for measurement purposes. For example, it is easier to produce 27 grams than 2.7 tablespoons. I want to know how much I eat each day so that I can study the effect of varying the amount and so that I can get an optimal amount.

## **More News about Liberation Therapy (2011-10-03 13:38)**

An Italian surgeon, Paolo Zamboni, claimed that he found low blood flow from the brain in 100 % of patients with multiple sclerosis (MS). He began by studying his wife.

[1]A new study supports the connection:

The Canadian researchers analyzed eight studies from Italy, Germany, Jordan and the U.S. that involved 664 MS patients in total. The studies looked at how frequently CCSVI [chronic cerebrospinal venous insufficiency] was found in people with MS compared to healthy people or those with other neurological disorders such as Parkinson's disease.

One of the studies — Zamboni's — found CCSVI in 100 per cent of people with MS, and zero per cent of people without the disease. Other studies found the vein abnormalities in people who didn't have MS.

Overall, when the results were combined, people with MS were 13.5 times more likely to have CCSVI. Even when the study by Zamboni — which generated the excitement about CCSVI — was removed, the syndrome was 3.7 times more common in people with MS.

Thanks to Anne Weiss.

## The 2011 Nobel Prize in Medicine (2011-10-04 08:26)

To rehabilitate his reputation, Alfred Nobel, in his will, established the Nobel Prizes, the crucial element of which was that they honor the most useful research. Nobel wanted to be associated with good works. This has become a considerable problem for the committee that awards the Physiology and Medicine prize because, if you haven't noticed, the most prestigious research – the stuff done at great expense in gleaming new laboratories – isn't useful. The uselessness of high-prestige academic research was emphasized by Thorstein Veblen in *The Theory of the Leisure Class*. Unfortunately Nobel died shortly before it was published.

For a long time, the Nobel prize-winning research in Medicine hasn't provided significant help with major health problems (depression, obesity, diabetes, cancer, stroke, heart disease, etc.). Sometimes it has been a tiny bit helpful. Most often the prize-winning research has been, at the time of the award, no clear help at all. This is one of those years. The press release announcing the 2011 prize tries to hide this important truth. Here is the "what use is it?" section of [1]this year's press release:

From fundamental research to medical use

The discoveries that are awarded the 2011 Nobel Prize have provided novel insights into the activation and regulation of our immune system. They have made possible the development of new methods for preventing and treating disease, for instance with improved vaccines against infections and in attempts to stimulate the immune system to attack tumors. These discoveries also help us understand why the immune system can attack our own tissues, thus providing clues for novel treatment of inflammatory diseases.

"They have made possible the development of new methods for preventing and treating disease." False (and, uh, just a wee bit grandiose). Such development was already possible. Note what isn't said: "They led to new methods for preventing and treating disease."

"Improved vaccines against infections." I have heard nothing about this, in spite of the plural (vaccines rather than vaccine). In any case, this is faint praise because the improvement might be a small percentage. If you know whether this claim is true, please leave a comment. Again note what isn't said: "New vaccines". According to [2]this article, the work led to a vaccine against prostate cancer. (With no noticeable benefit so far.) Does the press release writer think prostate cancer is infectious?

"Attempts to stimulate the immune system to attack tumors." Attempts? As in failed attempts? Apparently.

The final sentence ("These discoveries also help us understand . . . ") is out of place. The section is about actually helping people ("medical use") not ivory-tower stuff like "providing clues". Whoever wrote this is like a student with not enough to say trying to meet a teacher's minimum word count.

There you have it. The practical value of the research awarded the most prestigious prize in the world – a prize that [3]Alfred Nobel's will said should be given to "those who, during the preceding year, shall have conferred the greatest benefit on mankind."

To make your immune system work better, I am sure there are two simple, practical and powerful ways of doing so: [4]deepen your sleep and eat fermented foods.

---

wcb (2011-10-04 10:52:53)

Seth, thanks for these observations which, unfortunately, appear to be quite accurate. Sad to say that, based on all I have learned and personally experienced in the last decade or so, I have to suspect that most of what passes for "high-prestige academic research" in the medical / health arena is sponsored (i.e. largely paid for) by pharmaceutical companies and other commercial interests. So I suppose no one should be surprised that, unless and until the research is being done by individuals whose independence has not been compromised, a true benefit to mankind is much less likely. Whatever happened to integrity in academia and government?

dearieme (2011-10-04 16:27:04)

The difference between Applied Science and Pure Science lies in the motives of those pursuing them. The motives in Pure Science are pure; they are the purely selfish attempt to advance the interests of the researchers. Those interests vary: sometimes they may be dominated by the desire to satisfy intellectual curiosity; more often, I suspect, they are dominated by the desire for career advancement. Given this structure of motivations, it follows that all Applied Science research institutions are at permanent risk of being taken over by Pure Science. Put simply, someone whose motives are mixed, including the desire to do some good for society, must expect to lose in competition against someone whose motives are entirely selfish.

Seth Roberts (2011-10-04 19:41:52)

dearime, yes, I think that is what is happening. If you want to do research that helps people, you must pay a considerable price, especially in prestige. Outsiders fail to understand this, so there is no pressure to change.

John W (2011-10-05 06:02:08)

I can't even begin to express how angry this butter tax makes me. Let people make their own goddamn decisions about their health. Perhaps my anger stems from the fear that such a thing will happen here (US) soon too - or worse my pastured Irish butter may one day be illegal! Better buy a cow.

Tomas (2011-10-06 07:48:53)

so it has come into effect Something is rotten in the state of Denmark and it's margarine not butter which goes sour

### **Morning Faces Therapy: Personal Account (2011-10-06 05:00)**

Five years ago I heard from someone that he had been successfully using my discovery that seeing faces in the morning improved my mood the next day. Recently I asked him to write about his experiences with it. Here's what he wrote:

I'm a male professional in my 30s and have had mild to moderate depression since my early teens. I am a considerable rationalist and skeptic, so when I read about Seth's morning faces therapy in [1]a New York Times article about 5 years ago, my first thought was to doubt its effectiveness. But it was so easy and simple to try, with nothing to lose, that I gave it a shot. To my surprise, it really worked, and the change was quite noticeable.

I do 30-40 minutes of faces therapy every morning, starting around 7:00, 7:15, but the timing moves around a bit based on my schedule or sometimes for experimentation purposes. My first few years I used videos of actual faces (some of the recommendations that I found on Seth's blog and others that I found on my own). Over time it's become harder to find quality videos of sufficient length and compelling interest, and I now more often use a mirror. The effect, for me, usually lags by a day or two. So if I haven't been doing faces for a while and I'm depressed then it takes a couple of day or so to get back to where I should be, and similarly when I stop the faces therapy it takes a few days or so for the depression to return.

While the therapy itself is simple, getting up on time and doing it every single morning has proven more difficult than expected. Even when I do it for several weeks in a row with no break, at some point the tiredness and weariness inevitably kicks in, whether because I was up late several nights in a row and am too tired to get up early, or because I'm traveling, or for other reasons.

Proof the therapy works is that I'm still carrying on five years after discovering it! When I stop for more than a few days, the resultant drop in mood inevitably brings me back.

As an aside, I sometimes spend time in the evening or morning doing other depression exercises, such as writing a gratitude list (google "count your blessings exercise") or doing meditation/self-hypnosis. In the spirit of self-experimentation, I am currently seeing whether I can get the equivalent effect I get from the faces, by doing these other therapies in morning sunlight at the same early hour as I do the faces therapy. Full results are not yet in.

[2]More about morning faces therapy.

---

Beth@WeightMaven (2011-10-06 12:03:34)

I've been using Flickr slideshows for what I call "assisted meditation" ... I started out viewing nature shows, but found that looking at smiling faces was more uplifting. Especially when it's babies! [http://www.flickr.com/groups/baby\\_love/pool/show/](http://www.flickr.com/groups/baby_love/pool/show/)

Rex (2011-10-06 16:52:56)

Seth has profiled me on this blog. I have been on anti-depressants continuously over the last 8 years. Most recently I have been taking Cymbalta. I finally weened myself off it during the summer, after experiencing nasty withdrawals. Morning faces has been the one major change in my daily routine. I began in late Spring and have not experienced any depression except for the usual sad stuff we all deal with. I have had some mania, which tends to hit me in late summer. I seem to get quicker benefits from morning faces than others, but also feel more down days when I do not stick to the plan. I do not want to stop what I'm doing, but am sure there will come a time when I go without morning faces for an extended time. Then I will have a better idea of the benefits I am getting using Seth's theory.

Jeff (2011-10-06 17:56:05)

Seth - Your original research paper mentions the need to avoid fluorescent lights in the evening because they mess with the circadian rhythm. I assume that's also the same reason for the recommended consistent sleep schedule of around 10 p.m. - 11 p.m. to 6 a.m. - 7 a.m. Is there a certain point in the evening when one should avoid fluorescent lights (e.g., 2 hours before bed)? I'm asking because my job requires me to attend some evening meetings that have fluorescent lights. It might negatively impact my job security if I start wearing blue blocker glasses to these work functions. :)

Seth Roberts (2011-10-06 18:59:33)

Jeff, I try to avoid fluorescent lights after the sun goes down. I'm sure their damaging effect gets worse the later you are exposed to them - I can't say more than that. Before 7 pm I don't worry much. Seth

Jeff (2011-10-08 09:46:10)

Seth - Thanks for the info. I live in the midwest where nightfall happens as early as 5 p.m. in the middle of winter. My sleep time remains fairly consistent. Does your suggested 7 p.m. fluorescent light time frame hold true under these circumstances as well?

Seth Roberts (2011-10-09 01:44:34)

Jeff, I don't know, sorry. Nowadays when I am exposed to fluorescent lights after dark I wear blue-blocker glasses. I still try to avoid fluorescent lights after dark but sometimes they are unavoidable. I worry much less about them now so long as I am wearing my blue-blocker glasses.

Donald (2012-04-06 01:37:32)

This is very interesting and I may well try it. These are some random points I'd make: - It might be useful to combine a SAD light above the computer while looking at vlogs, particularly if the people are talking supportively about mood disorders. I even wonder if people who record vlogs could be given instructions in how to make their posts useful for this technique, i.e. looking directly at the camera, filling the frame. - I'm reminded of psychology research where 2 groups of employers told staff they were changing the temperature (or some other variable) by 1 degree to increase productivity and this resulted in higher productivity whether or not the temperature became higher or lower; i.e. taking any steps whatsoever to produce an outcome may be enough to get the result. - This therapy takes a lot of commitment so may encourage strong mindfulness which may be the cause of improvement. I wonder if this level of commitment would produce a result

regardless of the goal, i.e. spend an hour every morning on a demanding technique and you will lose weight as you are creating a strong commitment to weight loss. - As well as using faces other changes have been incorporated: light therapy, early sleeping, early rising, consistent sleep and wake times (?). I suppose I'm still skeptical, however only a few years ago even light therapy raised eyebrows. Seth: When I discovered the effect, I found that lots of details mattered (e.g., face distance). If the effect was due simply to making a big commitment, or changing something, these details shouldn't have mattered.

## **Appetite Suppression from the Shangri-La Diet (2011-10-07 05:00)**

[1]This person has been doing the Shangri-La Diet (SLD) for two weeks:

The appetite suppression is now strong. Yesterday I went to dinner at one of my favorite Mexican restaurants. Ordered my favorite meal there. I could only eat about 1/3 of my favorite dish and a few chips and salsa. . . . That is nothing short of amazing. The best part is: it satisfied me. I would normally eat the whole meal and not be satisfied, I would be able to eat more. I wouldn't normally eat more, but I could eat more. Not this time. Didn't want more.

He eats about 700 calories/day nose-clipped - that's his version of the diet. Before he started the diet he was gaining 10 pounds every year. When he started SLD, he weighed 250 pounds at 5 feet 10 inches tall (BMI = 36).

If I were to write The Shangri-La Diet all over again I would emphasize nose-clipping. You can easily eat lots of smell-free yet healthy calories nose-clipped and get great appetite suppression, as in this case. That's one reason the book is short. I wanted to get the idea out in the world soon, so other people could help improve it. That's what happened. Nose-clipping was someone else's idea (Gary Skaleski, 2006), not mine. It was a better application of my theory and early findings (e.g., sugar water causes weight loss) than I was capable of. Now, thanks to the Internet, I can find out what happens when people do the new improved version.

---

Michal (2011-10-07 08:02:46)

I've tried this diet and lost a few pounds but not very many. It was weird in that I sort of felt hungry but I didn't necessarily want to eat. I hear about weight loss all the time, but that only tells a limited part of the story. What body fat percentage have people gotten down with with SLD?

Meegs (2011-10-07 15:13:33)

I have been doing this diet the past few months, and it's amazing to me. For years I have never been able to lose those pesky last 10-15 pounds I need to lose, and as of today I've lost 7 pounds. It started slow, but after a month or two I noticed the weight steadily start to come off. Also, I find I can adjust the amount of oil I take to adjust my appetite. If I'm eating too much and getting cravings, I take more oil. If I'm eating too little, I take less. Another benefit- it's made it easy to switch to a "paleo-style" diet that limits processed foods, and I don't crave the old foods. But I don't think the paleo diet would work for me without the oil. Seth, I think it's an amazing discovery, I just wish I had found your book earlier!

Meegs (2011-10-07 15:19:25)

Michal, I would recommend you keep up the diet. That's exactly how I felt for the first month or two- still kinda hungry. But then the effects really kicked in and the hunger was gone. Now I feel in control of what I want to eat.

Tom (2011-10-09 13:18:31)

*Another benefit- it's made it easy to switch to a "paleo-style" diet that limits processed foods, and I don't crave the old foods. But I don't think the paleo diet would work for me without the oil.* This is what I've found, as well – drinking oil suppresses overall hunger, true, but it also shifts the foods I desire. If I'm not drinking oil, I want a blast of carbs before bed. On the oil, I may get hungry late at night, but I want a bit of protein instead. That's been one of the key benefits of Shangri-La for me – it makes it possible for me to remain compliant with LCHF/Paleo. (This experience is also why I don't take Stephan Guyanet's Unified Theory of Palatability seriously.)

Seth Roberts (2011-10-09 17:43:39)

Tom, that's an interesting comment:

(This experience is also why I don't take Stephan Guyanet's Unified Theory of Palatability seriously.)

Could you explain it? The difference between Stephan's theory and mine, as far as I can tell, is that his theory says that anything that makes food more pleasant raises the set point. Whereas I say only flavor-calorie associations (which make food taste better) raise the set point. I find that unlikely – why should salting one's food raise the set point? How much pleasure we derive from salt is determined by how much we are salt-deficient. Which seems to me unrelated to fat storage. Anyway that is related to your criticism but not the same. I would like to understand your criticism better.

Tom (2011-10-09 20:18:44)

Hi, Seth, My point is probably more basic than the question you're asking. But I'm simply thinking that my ingesting oil clearly did nothing to change any quality *inherent* in the carbs that I invariably crave on days when I'm not drinking oil. Yet oil-drinking drives their *perceived* 'palatability/food reward' to zero. The effect is clear and 100 % repeatable for me. On no-oil days I *always* want carby cookies or crackers, with milk, before bed. On oil days I *sometimes* want meat (or eggs), with water, before bed...but *never* carbs. (I'm wondering if there's only one 'set point' – perhaps there are different ones for different classes of nutrients?)

Meegs (2011-10-10 18:39:15)

Isn't the oil itself sort of a bland food? It has calories with zero taste. This tricks the body into lowering the setpoint. Perhaps that's how it is compatible with Guyanet's theory of palatability.

Tom (2011-10-10 22:50:29)

Yet I still get hungry, Meegs. But the food I desire shifts. One food gets more palatable, another gets less palatable, because oil was consumed hours earlier? That makes no sense to me. I read the comments on WHS and people seem to be tying themselves in knots to make Stephan's theory work. But...why? I hope it's not because Stephan is supposedly "nicer" than Gary Taubes. (At this point, I hardly think he is. And who cares? I just want to know what to eat to get healthier.)

Tom (2011-10-10 23:03:47)

Sorry for following-on to my own post, but I just saw J.Stanton's comment over at Hyperlipid, which expresses my feelings about Stephan's current tangent better than I ever could: *"When one starts with a conclusion and works backwards, it is often necessary to skip over, gloss, conflate, or otherwise befuddle the explanations of the parts that don't support the predetermined endpoint.* source: <http://high-fat-nutrition.blogspot.com/2011/10/adipocyte-insulin-resistance.html>

Meegs (2011-10-11 07:35:20)

Tom, I guess I have a different experience with the oil. When I take it, my hunger goes away. I simply stop thinking about food. And yet, even if I have taken the oil, if I go to a restaurant and start eating something highly rewarding (chips, dessert, etc.) I

find it difficult to stop. This isn't the case with protein. If I eat a couple of eggs, I'm satisfied.

johnny (2011-10-11 14:14:09)

Hi Seth: Correct me if I'm wrong but I interpreted your statement "He eats about 700 calories/day nose-clipped — that's his version of the diet" to mean the person ate food nose-clipped, yet got the same results as if he/she had taken oil or sugar water without a nose clip. Is this correct? Please clarify.

Seth Roberts (2011-10-11 14:22:20)

johnny, your interpretation is correct.

Tim (2011-10-15 07:54:47)

Diet Soda - I believe the prevailing theory is that diet soda tends to increase appetite, resulting in the person eating more calories, gaining more weight over time. I'm doing intermittent fasting (not eating during work, until about 6 PM in the evening). I have no problem fasting during the day, but I get by by drinking obscene amounts of diet soda. I've recently read about your Shangri-La diet and started implementing those concepts into what I am already doing. My guess is that diet soda is ultimately bad for weight loss, but it would seem that drinking diet soda without ingesting calories close to the time I drink the soda (during my fast) would support flavor/calorie disassociation. I'm guessing it doesn't work as my appetite has not decreased at all, but I would like your take on what the difference is between that and doing calories with no flavor, if any.

Seth Roberts (2011-10-15 14:16:09)

Ingesting flavor w/ no calories (such as diet soda) can be helpful, I believe if –you would have otherwise drunk/eaten something fattening (such as regular Coke) –it reduces a craving for flavor. when I started ingesting lots of calories without flavor (the Shangri-La Diet) I started to crave flavor. So the calories without flavor helped me do SLD. I hope that answers your question. To put it briefly: Flavor w/o calories by itself does nothing. But it will help you do SLD (calories w/o flavor).

Matt (2011-10-26 07:19:38)

Seth, after listening to your podcast on Jimmy Moore I have been thinking more about SLD and I have a couple of theories/observations that have been bubbling around for a couple of days - wondering your thoughts. 1. Often, I lose weight when I have a cold. I had always attributed that to a boosted metabolism, but now I'm considering the change in smell that occurs when I'm congested. 2. Smokers weigh less than non-smokers, and crave sweets when they quit. This is perfectly consistent with what you wrote above about calorie-free flavor. 3. Often I drink sugar water at work, because it's convenient when I travel to different offices - sugar is easy to come by at the coffee station. Am I sabotaged if someone put a big pile of brownies in the kitchen? Should I avoid drinking the sugar water in the kitchen, or should I wait at least an hour before or after SMELLING the brownies before drinking the sugar water?

Seth Roberts (2011-10-26 13:16:08)

Are you sabotaged by brownies that you smell but don't eat? No, I think smells not from your food don't matter.

John (2012-02-06 10:35:40)

Is salt a flavor or a taste? My nephew posed the question in response to your defining the difference between you and Stephan "I think that if you add salt to white rice that white rice becomes more palatable" That led me to ask is salt a flavor or a taste. Sugar is a taste and my assumption is that salt would be similar. You said: Whereas I say only flavor-calorie associations (which make food taste better) raise the set point. I find that unlikely — why should salting one's food raise the set point? How much pleasure we derive from salt is determined by how much we are salt-deficient. Which seems to me unrelated to fat storage. Anyway that is related to your criticism but not the same. I would like to understand your criticism better.

Seth Roberts (2012-02-06 17:50:06)

Salt is a taste. My theory says that smell is what matters. Salt has no smell. Just as sugar has no smell.

Nick (2012-03-04 10:37:16)

Hi Seth, I really like you blog, podcasts and the concept of this book. I didn't like the implementation, but tried another variation with similar effects. Eating as much as possible novel foods and spacing repeat foods apart when I didn't have access to a novel food. Originally I thought I'd run out of novel foods but that hasn't happened nor do I think it will happen anymore. Same weight management effect but also up regulating senses of smell and taste. My appetite hasn't changed however and remains healthy. Overall I had a good experience with this approach and must say that it's given more reason to enjoy life. A few drawbacks is that it also polarized me giving me more favorites but also dislikes. Some smells now practically send me running

### Assorted Links (2011-10-08 05:00)

- The Shangri-La Diet: still [1]too good to be true. It was my dream – and maybe every scientist's dream – to discover something (a) useful and (b) counter-intuitive, the more surprising the better. It did not occur to me that (a) and (b) conflict. I think that more surprising discoveries are eventually more useful (as logic suggests), but it takes much longer.
- Marisa Tomei [2]wants to play Jane Jacobs. "I love that she saved Greenwich Village." When she does, perhaps Robert Caro will post the unpublished Jane Jacobs chapter of The Power Broker.
- [3]Symposium on The Death and Life of Great American Cities by Jane Jacobs.
- Did you know that Mindy Kaling's [4]amusing article in this week's New Yorker is [5]an excerpt from a forthcoming book? Neither did I. Likewise, the recent Murakami story [6]Town of Cats was from a forthcoming book. The New Yorker, unlike other magazines, never identifies book excerpts. This is unfortunate because doing so would help both writers (sell books) and readers (find books to read). For more criticism of The New Yorker, see the great book [7]Gone: The Last Days of The New Yorker by Renata Adler.

Thanks to Dave Lull.

Alrenous (2011-10-08 11:03:54)

A: So are you saying most with the job title 'scientist' aren't scientists, or are you saying Veblen was wrong? I think it is very, very significant that most of the time voters are considered to want quick, easy fixes yet if you offer a quick, easy fix that actually works, they'll reject it. (Principle: life is usually not easy, and for good reason. But it can't be hard all the time - sometimes the simple and easy is effective.) My housemate is trying to lose weight. I've told him about Shangri-La. His behaviour is better explained by the theory that he's not dieting to lose weight, but dieting to prove to himself he's a worthwhile person because he has the self-control to starve himself, and the weight is just one possible objective metric. This is especially ironic when we go out to eat and he has three times what I have. I couldn't eat that much if I wanted to. What I'd do if I had weight issues would be to just try it. It takes what, like a few weeks, at most? And a few days, usually? How does one go about simultaneously

*actually* wanting to lose weight and not just trying it?

q (2011-10-08 14:14:32)

i'm quite glad that greenwich village was saved, but of course you understand that 95 % of its current residents are extremely wealthy and live there mostly as a show of their high status. there is essentially no 'community' there any more of the form that was there in jj's time. (i don't think it's her fault, and i don't know what to do about it if anything, but i don't think she would be particularly happy with the way things are now if she came back today.)

Seth Roberts (2011-10-09 01:53:04)

Alrenous, that's a good point about Veblen being wrong. I think scientists have many goals. In practice, they choose prestige (attached more to useless research than useful research, as Veblen said) over usefulness. They want to be useful, but in practice a desire for prestige is more powerful.

Alrenous (2011-10-10 06:10:18)

So scientists are scientists, but not so you would notice? It's always weird for me when I see people accepting an insider's status hierarchy. Why doesn't every non-scientist laugh at useless science? How is it at all in their interest to support it?

## **Fermented Foods In Gladiator (2011-10-09 04:38)**

From the movie Gladiator:

Slave Trader 1 These slaves are rotten.

Slave Trader 2 It all adds to the flavor.

A big reason I believe we need to eat fermented foods to be healthy is that they taste so good.

---

Alex Chernavsky (2011-10-10 16:54:41)

After I began reading Seth's blog a couple of years ago, I started experimenting with fermented foods. It's fun. I make kombucha on a regular basis, and I usually let it undergo a second fermentation. I add a couple of ounces of fruit juice to a 16-ounce glass bottle, top it off with kombucha, and then close the lid tightly. Within a couple of days, the kombucha is nicely carbonated. You have to be careful, though, to use juice without any preservatives – otherwise, it doesn't work. I've also made lacto-fermented salsa and fermented jalapeño slices. I tried making kim chee once, but it had a pretty nasty flavor to it, so I threw it away. Anyway, making your own fermented food is fun, and it tastes good (usually).

## **Let Them Get Sick (running) (2011-10-09 05:00)**

I [1]wrote recently about how our health care system resembles a protection racket. In a protection racket, you or someone else threatens people so that you can make money protecting them. Modern health care, especially in America, ignores prevention. It says let them get sick. Let the general public get sick so that we (health care providers) can

make money treating them.

The profitability of let them get sick is illustrated by some numbers in [2]Run Barefoot Run Healthy, a new book by Ashish Mukharji (who gave me a copy). Ashish has run several marathons. Before he started running barefoot, running caused all sorts of problems. To deal with them was costly:

- Two or three pairs of orthotics (a type of insole): \$200- \$300 each.
- One MRI, for what turned out to be ITBS (Iliotibial Band Syndrome, a thigh injury): around \$1,000.
- Twenty or more deep-tissue massage treatments for ITBS: around \$80 each.
- Corns removed (twice): \$500 per treatment.
- Twenty or more sessions of physical therapy for ITBS and Achilles tendonitis: \$100- \$250 per session.
- Several visits to orthopedists and podiatrists: \$150 per visit.
- Cortisone injection for plantar fasciitis: \$200.

Since he started barefoot running (3 years and 2 marathons ago), he has incurred no (zero) running-injury expenses. Interviews with other barefoot runners convince him this is typical. Long ago a runner friend of mine told me everyone who runs eventually hurts themselves. The truth of this was confirmed many times by runners I met after she said this. Now it appears she was right because all the runners she and I knew wore shoes.

I started barefoot running/walking on my treadmill a year ago. I have never had running injuries (probably because I walk – uphill fast – much more than run). Going barefoot saved time. During the first few months, I got four or five cuts (actually, splits) on the sides of my feet. The skin was split by downward pressure. The cuts made ordinary walking (in shoes) a little unpleasant. I did nothing about them. They healed and have not recurred.

A better health care system would have discovered the damage caused by running shoes long ago. We are lucky to live when personal scientists such as Ashish can figure out the truth themselves and tell others.

1. <http://blog.sethroberts.net/2011/09/18/first-let-them-get-sick/>

2. <http://www.amazon.com/Run-Barefoot-Healthy-Less-Runners/dp/0983035407>

---

Tuck (2011-10-09 15:04:08)

"A better health care system would have discovered the damage caused by running shoes long ago." It did. In 1912. Somewhat shakes your faith in humanity, science, and the notion of "progress" to realize that all this was known and forgotten 100 years ago. "The Soldier's Foot and the Military Shoe" [http://books.google.com/books?id=frFJAAAAIAAJ&printsec=frontcover&source=gbs\\_ge\\_summary\\_r&cad=0#v=onepage&q&f=false](http://books.google.com/books?id=frFJAAAAIAAJ&printsec=frontcover&source=gbs_ge_summary_r&cad=0#v=onepage&q&f=false) We shod millions of Americans in "barefoot-style" shoes, and then forgot all about it. Oops.

Steven Sashen (2011-10-09 16:13:09)

I switched to barefoot 2 years ago after I heard it could cure my various running injuries. Well, within a month they were all gone and haven't come back. And, as a sprinter, going 2 years without an injury is unheard of. Geek that I am, I started

making high-tech huaraches (so I could be almost barefoot all the time, and still get into restaurants ;-)). That turned into [www.invisibleshoe.com](http://www.invisibleshoe.com) and I'm thrilled to say we've now helped over 10,000 people make the transition. I'm also happy to report that last year I decided to see how long I could make it into the Colorado winter before I wanted to put on shoes.... next thing I knew, it was Spring! ;-)

Michal (2011-10-09 16:56:15)  
or just stop running all together.

Evelyn Majidi (2011-10-09 20:44:52)  
Stopping in a local physical therapy office I saw a bulletin board advising patients about future amateur athletic events, some of which were quite dangerous to life and limb. Drumming up future business no doubt.

Alrenous (2011-10-10 06:20:26)  
Tuck, it doesn't shake my faith too much, as A: I already know that kind of thing happens and B: there's a fairly good explanation. We have forgotten, but before the industrial revolution people feared nature because it had much more power in their lives than they did. And didn't particularly care to use that power for good, obviously. Thick soles were probably psychologically motivated by wanting to reject this dangerous 'nature' stuff. To us it's obvious that we can't design a better shoe-ground interface than nature did. (At least, not for a while yet.) To them it was just as obvious, but they were too invested to accept it. In 1912, the culture hadn't yet forgotten its fear and hatred of nature. Even though nature had already been conquered, these feelings take a while to subside in cultures, just like feelings take a while to subside in individuals. The whole 'nature is good' thing is really new and was, as far as I'm aware, spurred by the whole radioactive consumer goods debacle. Before that, the emotional affect of 'all-natural' was held by the words 'artificial' and 'synthetic,' which you can check by looking at period advertisements. Subsequent events with pesticides etc. have played into confirmation bias.

Unshod Ashish (2011-10-10 09:46:42)  
Sadly, individual hospital chains within the US healthcare system (possibly excepting Kaiser) appear to have no incentive to improve their patients' health or reduce injuries - quite the opposite. To podiatrists, just the mention of barefoot running is a red flag waving in front of their face, as they see all business disappearing. I need to get my book in front of decision-makers at Kaiser.

Jazi zilber (2011-10-10 11:09:37)  
They say running injuries increased 70 % since the introduction of running shoes in 1972

SPalmer (2011-10-11 06:08:09)  
There are inexpensive biofeedback insoles like Barefoot Science that will help promote a strengthening of the foot. It is a wierd arrangement. The parent company encourages people to be barefoot and strengthen their feet the most natural way possible, but if you need to wear shoes, for running or anything, then you use their insoles to combat the negative atrophying effects of the shoe. The stronger healthier foot makes the transisition to be being barefoot faster and safer, and yes, it also would show huge cost reduction benefits to the helath care system

Virgil (2011-10-11 06:28:24)  
I would not blame the medical system for the above problems, but the shoe manufacturers. Given that plantar fasciitis and ITBS are pretty nasty problems which, left untreated will result in excruciating pain and inability to walk, I'd say the medical system here did a pretty good job - it diagnosed and treated the patient. If the patient then continued with the damaging behavior (running in regular shoes), that's not the medical establishment's fault. Expecting the medical establishment to be fully aware of problems with running shoes, when hundreds of millions of people use them every day without issue, is also unreasonable. I know your blog is usually biased (sometimes correctly) against the medical-industrial-complex, but in this case I think the rage is mis-directed. The shoe manufacturers should be the target.

Seth Roberts (2011-10-11 06:56:16)

Virgil, you write: "The shoe manufacturers should be the target." Hmm. They are not going to voluntarily stop making shoes. Therefore they cannot take seriously the idea that barefoot running is best. In contrast, medical school professors (and by extension doctors ,who repeat what med school professors say) can take seriously that idea. Nothing stops them from learning how to prevent, not just how to cure. The medical system did a bad job here because it focused on the symptoms and ignored the cause of the symptoms.

Seth Roberts (2011-10-11 07:01:02)

That's an interesting way to make money from barefoot running.

Alex Chernavsky (2011-10-12 09:40:13)

The *New York Times* recently had a short article about barefoot running: <http://well.blogs.nytimes.com/2011/09/30/are-barefoot-shoes-really-better/> The comments are interesting, too.

Stephen M (Ethesis) (2011-10-12 17:19:44)

You know, when I used to train in Judo and Karate, I remember having trouble running, so I never jogged (using jogging shoes) but when they made us run some laps as part of the workouts (barefoot), I never had trouble. I never really thought about it then. Jogging shoes = foot problems. No shoes, no problems. On the other hand, I do have shoes I walk in that give me no trouble at all.

michelle@healthylifetoolkit.com (2011-12-09 08:40:30)

Hey Seth. Great post! This is only one of the many ways the health care industry fails us. And one I hadn't considered. The band-aid approach (throw a pill at it) rather than address the underlying cause of an issue is the norm. As a nurse, I see this all too often and find it very frustrating. Glad to see a post on the subject.

reycroxas (2012-03-08 04:03:22)

I have been running barefoot for almost ten months now. And from my experience, it is more comfortable to do. Hence, less injury. Seth is right, shoe manufacturers will not stop making shoes because they make a lot of profit. In order for us to prevent such injuries, we must be wise on what decisions we make.

## **New Source of Omega-3? (2011-10-09 13:28)**

I used to get my omega-3 from flaxseed oil. Then I encountered problems with the flaxseed oil going bad, in the sense of losing potency. (It did not smell bad.) I switched to flax seeds, which I grind and eat with yogurt. This is more difficult than drinking flaxseed oil.

From Peter Spero I have learned of a possible new source of omega-3: camelina oil. Camelina oil, unlike flaxseed oil, [1]contains high levels of anti-oxidants, which protect it from going bad. Camelina is [2]cheap to grow and can be grown where other crops cannot.

1. [http://en.wikipedia.org/wiki/Camelina\\_sativa](http://en.wikipedia.org/wiki/Camelina_sativa)

2. <http://www.hort.purdue.edu/newcrop/proceedings1993/v2-314.html>

Tuck (2011-10-09 14:59:24)

Have you looked into macadamia nuts and chia seeds as sources? Have you looked into the issues converting vegetable sources of n-3 into human-usable sources? Why do you prefer vegetable sources? (I eat macadamia nuts and fatty fish regularly, as well as pastured meats. I no longer feel it necessary to supplement; I was craving n-3s early on in my dietary experiment.)

Jahed (2011-10-09 17:41:52)

Why not something like this? <http://www.bodybuilding.com/store/asc/se a.html> It contains a high EPA/DHA amount per dose and it comes with green tea extract added, presumably to stave off oxidation. The only problem I could foresee is that the fish oil could go bad, and given that it has a lemon scent/taste, it could be difficult to detect whether or not you are imbibing rancid fish oil.

wr (2011-10-09 17:46:41)

Seconding the chia seeds. Any thoughts on those?

Seth Roberts (2011-10-09 17:52:00)

Why do I prefer vegetable sources? Because fish oil gave me a headache. I have nothing against other sources but the vegetable sources have had clear benefits: better balance, better gums, better arithmetic speed, etc. So if those "issues" are about low convertability, the statements are wrong in my case. Plenty of short chain omega-3 is converted to long-chain omega-3. By getting a large amount of omega-3 from flax seeds I can more easily vary the dosage and thereby find out the best dose. I have never – before or after I started consuming lots of flaxseed oil or flax seed – found myself craving omega-3. I don't know what that feels like.

Seth Roberts (2011-10-09 18:02:40)

Chia seeds: I am happy to try them. Flax seeds are much easier to get.

Seth Roberts (2011-10-09 18:04:52)

Why not a product that I must order over the internet? Because flax seeds are available at nearby supermarkets. And probably cost much less.

Peter (2011-10-09 18:08:49)

Seth, I wonder whether a burr grinder would work with flaxseed. I have a Capresso Infinity which I use for coffee. The advantage would be you could just leave a bunch of seed in the hopper, and calibrate the timer so that you could dial the amount you want without having to measure out anything.

Seth Roberts (2011-10-09 22:36:34)

Peter, it is easy to measure out 33 g of flax seeds. It is sort of fun: I see how many iterations it takes, sort of like strokes in golf. Now I can usually hit 33 g with 3 iterations or less.

T (2011-10-09 23:08:31)

I can't find a source to buy this at. Any ideas?

chris (2011-10-10 08:53:40)

I'd look into shiso (aka perilla) oil as well. It has about the same omega 3 content as flax seed oil with less odor...it's easy to find in Japan so it might be easier to get in China than good flax seed oil.

threepipeproblem (2011-10-11 08:26:29)

I have seen plans for simple oil presses for home use. Perhaps you could develop a micro-oil press to press the flax seeds when you want oil. I don't know, maybe it would be too involved.

ajb (2011-10-11 13:11:00)

FWIW, I actually find grinding flax seeds easier than using flax seed oil.

Tyler (2011-10-12 12:07:01)

Seth, What are your thoughts on the estrogen content of flax? I remember reading that flax is about three times higher in estrogen than soy. This is the main reason I have been supplementing with fish oil while consuming mostly ruminant meat.

James A Donald (2011-10-12 20:24:36)

I soak and rinse flax seeds for a couple of days, then grind them up, then mix in some flour, then cook them into pancakes. It is a lot of work, but I think I get a better result - my blood pressure has dropped, and I run without my knees complaining.

Oliver Mayor (2011-10-13 21:34:14)

I finally looked up the Omega-III content for both. Flaxseed seems to be nearly 1.5 as dense as ALA as chia; I'm impressed. I'll still take chia, though, even considering how much it costs (five times as much) because I like taking chia. Taking flaxseed is much less convenient for my habits. Flaxseed and flaxseed meal doesn't mix well with the kind of foods I like eating and can eat. I'd love to mix it with yogurt like Seth does but food allergies stop me. Despite my present very large fermented food intake, cow's milk derivatives, including homemade yogurt and kefir, still trigger my food allergies and cause me to get sick a few days later (ear infections, cold, flu, etc.) It's amusing that consuming milk products is pretty much the \*only\* thing that can get me sick these days, thanks to homemade kimchi and kombucha.

ajb (2011-10-14 07:24:10)

"Flaxseed and flaxseed meal doesn't mix well with the kind of foods I like eating and can eat." You can just add some water to ground flaxseed, which makes it into something like oatmeal. Then, you can add whatever you want to that for flavouring (applesauce, cinnamon, blueberry sauce, and so on).

Evelyn Majidi (2011-11-29 21:55:16)

Based on this suggestion, I ordered camelina oil from the good farmers in Saskatchewan and began taking it using the same dose (3T/day) that I had been taking of flaxseed oil for relief of psoriasis and lichen planus. Unfortunately, the slow but sure improvement I had been experiencing over the past year with flaxseed oil stopped immediately and after a week my skin and mouth began to deteriorate. After using about 1/4 of a bottle of the new oil I went back to flaxseed and am delighted to report that I am now having good results with it. Since both of my conditions wax and wane without any reason identified by medical science I cannot state that it was simply the flaxseed oil that has led to this success. Based on my experience, however, I intend to continue taking the oil regularly and I recommend that others with either psoriasis or lichen planus try it. For me, two tablespoons a day were not enough, I needed three tablespoons of the oil to see a change. I don't think it advisable to take capsules, you'd need to take too many of them to equal 3T of oil.

Seth Roberts (2011-11-30 14:29:38)

thanks, Evelyn, that's very useful information.

## **Edward Jay Epstein on Homeland (2011-10-10 05:00)**

A new series on Showtime called Homeland is about a CIA agent (played by Claire Danes) who believes that a newly-released American prisoner of war may have been "turned" during his years in Iraqi captivity. In the first episode, she tries to find evidence to support her belief. Judging by that episode, it is very good.

I told [1]Edward Jay Epstein about it - [2]his book on James Angleton centers on CIA infiltration by "moles". He commented:

What is interesting here is the schism between the fictional world and real world of counterespionage. In the former, it is an issue of "who". Find the guilty man and arrest or kill him. In the real world, the issue is vulnerability. The bureaucracy has two choices: admit its methods are vulnerable to penetration and paralyze the organization, or deem the search for a mole to be paranoia and sick think. That latter course is what happens in the real world, alas. Some fiction writers understand this: Graham Greene in *Human Factor* and Le Carre in *Smiley's People*.

Yes. If you go back in time, I predict you will find that the term kill the messenger arose at the same time as powerful organizations. I have a theory: Only people who derive power from their placement in big organizations want to kill the messenger (who says the organization assumes something not true). In other situations, bad news is less threatening. In health care, outside ideas are met by insiders, such as doctors, with where's the double-blind placebo-controlled study? As Epstein says, the dismissiveness is partly motivated by fear: fear that something is wrong with their system and its values.

1. <http://www.edwardjayepstein.com/>

2. [http://www.amazon.com/James-Jesus-Angleton-Original-ebook/dp/B005LPE5SC/ref=ase\\_sethrobertand-20](http://www.amazon.com/James-Jesus-Angleton-Original-ebook/dp/B005LPE5SC/ref=ase_sethrobertand-20)

---

Tim Beneke (2011-10-10 08:53:25)

FYI: The lore on killing the messenger goes back to the Greeks at least; I'm struck by how often I encounter the phenomenon when I offer people psychological or scientific findings that do not please them - they get mad at me... From Wiki: [http://en.wikipedia.org/wiki/Shooting\\_the\\_messenger](http://en.wikipedia.org/wiki/Shooting_the_messenger) Plutarch's *Lives* has this line: "The first messenger that gave notice of Lucullus's coming was so far from pleasing Tigranes that he had his head cut off for his pains; and no man daring to bring further information, without any intelligence at all, Tigranes sat while war was already blazing around him, giving ear only to those who flattered him..."[5]

Alrenous (2011-10-10 11:00:42)

Ironically, assuming that the organization isn't vulnerable absolutely guarantees it will be compromised.

Nathan Myers (2011-10-11 22:04:57)

Powerful organizations predate written language and even agriculture by thousands of years. They were religions, of course. Respect for facts was never their strong suit. "Where's the double-blind controlled trial?" is a good question, years after it should have been done, published, and acted on. But we are constrained to depend on admitted monopolists to perform those few that are done.

## **Grandmother Knows Best About Crohn's Disease (2011-10-10 15:06)**

On Boing Boing [1]a post by me tell about a man who cured himself of Crohn's Disease mainly by following what is called The Specific Carbohydrate Diet. He got the idea from his grandmother, who heard about it on the radio. The diet is about eighty years old. The version he used appeared in a book published in 1994 - 17 years ago. Still no clinical trial.

As I've said, if you have managed to cure yourself of a serious medical condition please let me know. I would like to learn from your experience and help others learn from it.

1. <http://boingboing.net/2011/10/10/seth-roberts-grandmother-knows-best-about-crohns-disease.html>

---

Jay (2011-10-10 20:20:53)

Great post. If it is indeed effective, I wonder how translates to those without Crohn's, or perhaps people with Celiac, etc.

Anne (2011-10-10 22:43:28)

Hi Seth, I had Crohn's for ten years and I was on Prednisone for ten years, in the end i told the doctors that I wanted the large intestine cut out and they did, my small intestine was made into a j-pouch and I began to get my life back. I no longer have the symptoms of the disease but now have adrenal problems from being on Prednisone for ten years. Six months ago I was given antibiotics for an acne break out. After seven days I began to experience much of the same symptoms as I had when I had the disease, i did lots of 'google research' and determined that it was Colistrium Difficile as the symptoms were very much like that of a corkscrew burrowing into my intestine. I knew that if I didn't stop it soon I would be back in hospital. I took probiotics and a rice based protein supplemental powder which has a lot of fibre in it. It stopped within a day of taking these things. I took the probiotics for 2 weeks and then stopped and within 2 days I got the same pain. I started probiotics again only this time I took the ones with Saccharomyces boulardii in it, because it fights against spore producing bacteria. I then had Sauerkraut which is a fermented food. The symptoms were gone within a day of doing this and I have not had them since. I also take Colloidal Silver which kills off any infection that I have. I found out that I was allergic to wheat and dairy and that it was making me sneeze and break out. Once i stopped eating it, my body then began to create a die off effect of the bad bacteria and I broke out even more, lasted a couple of months and then it just stopped. If you take Colloidal Silver, probiotics, you go through what is called a 'die off' reaction and your body acts as if it has the flu. This is normal because it is getting rid of all the bad bacteria. I thought that you might be interested in my story :)

Felix (2011-10-11 02:21:18)

Hi, i suffered for a long time from migraine (megrim?) and nothing did help. I did take heavy pain medicamentation and later triptans. These started to work in the beginning, but they weren't a real cure. so what did me help with this problem? Getting fired from my job! The moment someone told me, that i needed to go, the headache was gone, never to return. I do not blame my doctor for this, since she suspected, that it was a psychological problem. Greetings Felix PS: I read in some of your posts month ago, that you wanted to improve your sleep by opening a window at night. This is interesting because i had some problems with sleeping and what helped me was reducing noise (moving to another place) and minimizing light. Sometimes i sleep with ear plugs and a sleep mask. Since i started this i need aprox. 1 hour less of sleep every night.

Tomm (2011-10-11 03:25:14)

It was mentioned on the wikipedia page, but perhaps you missed it: there is a 100 person clinical trial that was started earlier this year at Rush in Chicago. <http://www.rush.edu/rumc/page-1298328953440.html> Also, thanks for mentioning that the Wikipedia article was imperiled in your article - I went and fixed up the article so it's no longer in any danger of getting deleted.

Christina (2011-10-11 06:42:45)

I had a number of health problems that doctors insisted on treating individually - I couldn't keep food down, had ulcers, anxiety, joint pain, kidney infections....I was told repeatedly that it was IBS and nothing could be done about it and/or that it was just stress and that I needed to "relax." After ten years of starving and being in pain (I'm 5'5" and weighed 98lbs. I was paranoid about eating in public for fear of throwing up as a few bites would trigger me to throw up) an acupuncturist suggested food allergies and I persued cures myself and realized I most likely had Celiac Disease. I went back the the gastroentinelogist who had "cured" my ulcers and he claimed I didn't have the disease based on my lab results from 5 years prior but if eating a gluten free diet made me feel better then to stick with it. When I started getting panic attacks after a

nasty kidney infection/stone my doctor wrote me off when I questioned dietary changes and blamed the antibiotics. She immediately wanted to stick me on Xanax. I self diagnosed and started playing around with a yeast free diet and never filled the subscription. Eventually I started working with a holistic chiropractor who has listened to me, supported my experiments, and given me dietary advice. He convinced me to without telling me to return to meat after twenty years as a vegetarian, got me off sugar (although that is a work in progress), and all grains - not just gluten based ones. I'm not 100 % better, but I am doing so well compared to just a year ago. I know more about nutrition then ever and can "hear' changes in my body - like recognizing when food has something in it that I'm hypersensitive to after a few bites (and knowing how to combat and problems that might result). I too went on glutamine, probiotics, and B12. Through diet I've corrected a lot of problems with my liver, kidneys, intestines (and GI tract), anemia, etc. My thinking is clearer, I don't feel so strung out, no more panic attacks, more energy, no joint pain. I just wish someone had listened and been able to advise me sooner - ten years is way to long to wait.

Seth Roberts (2011-10-11 07:01:56)

Tomm, thanks for saving the Wikipedia article.

CJ (2011-10-11 10:19:53)

I'm a biochemist; I have Crohn's disease. I started the SCD the day I was diagnosed, now almost 4 years ago. The Boingboing discussion is very discouraging. Within 2 weeks, my diarrhea had stopped. Within 2 months, the bleeding had stopped. Within 3 months, I was up 13 pounds, after losing 1 pound/week for almost 9 months. Within 6 months, I was back to arduous caving trips. Within a year, my blood values were all within norms, except for folate. (That pesky folate.) About that time, I converted to a generally low-carb, grain-free diet, a combination of what Lutz (Life Without Bread) and Gottschall (Breaking the Vicious Cycle) had to say. And I felt even better. Today, I'm fine; I suffer not at all, unless I stray from the diet, in which case I suffer severe pain and discomfort. It must be noted my diagnosis is absolute; the doctor is beyond reproach, and in a phone conversation with the attending pathologist, it's clearly Crohn's and the differentials don't match at all. Since my diagnosis, I have read >10,000 pages of books and primary literature on the subject- now adding "Colon and Rectal Surgery" (933 pages) for good measure. Also read Crohn's original books, including his autobiography, the original Crohn, Ginzburg, and Oppenheimer paper, etc. Everything I can read. Anyway, doing great. Also note Leo Galland studied the SCD, and found it worked very well. [http://www.mdheal.org/crohn %27s.htm](http://www.mdheal.org/crohn%27s.htm) "All 20 patients demonstrated a decrease in symptoms and reduction in medication use. Six patients have entered complete clinical remission, discontinued all medication, and maintained remission for five to 80 months." As it is, I think I know what causes Crohn's; I'm writing a book on the subject, but I don't have a publisher. It's a combination of technical literature and "popular" writing, so I don't expect it to sell well. Most Crohnies don't seem to want anything more than pills and surgery. Y'all take care, and if I could offer one tidbit: for those that wish to try dietary control, consider an all-meat diet. Check out the Dirty Carnivore forums.

Henry Zhu (2011-10-11 10:57:29)

Hey Seth, I have had many problems since I was a child. Asthma, eczema, allergies, etc. In high school I fractured my hip but wasn't able to recover to normal. I wasn't diagnosed with anything in particular because no one was really able to know what happened, why it happened, and what the problem was other than I had back problems. They say the hip/back was inflamed, gave me pain pills, and told me to come back if anything got worse (some sort of arthritis/back stiffening). If that would have happened I probably would of had to do surgery. My whole time I had been taking various medicines and things for all my ailments. I also tried a lot of alternative methods. Nothing really 'worked' and satisfied me. However, this past year and summer I learned about a method of self-healing in China and it really helped me. Its called Yixingtianxia. The two main methods are called la-jin and pai-da. They have a pretty bad English website at <http://www.yixingtianxia.com/newpage/en/index.html>. Its catching on pretty fast in China, so I'm not sure if you have heard of it. I was probably one of the few (and youngest) people to go there from the US to do a workshop there. I've written pretty extensively on the subject on a blog I made to talk about my experiences with disease/alternative medicine. I plan to continue to update my status and my thoughts there at [eltacodelmente.wordpress.com](http://eltacodelmente.wordpress.com). I would extremely glad to talk to you about my experience and happy to talk with you about the subject. I can only say that my life has truly been changed through my diseases. I feel like a totally different person not relying on the medicine to 'treat' my pain. Because I've been so greatly helped it only seems right to try and tell other people about what I've been through and what I've experienced. Its all pretty new to me but I feel eager to learn. I guess this passion comes from the personal connection to my life. I just stumbled upon your article yesterday and I feel it really in

alignment with what I've been thinking about lately. Thanks a lot!

Elisa (2011-10-11 14:27:08)

Scads of commenters saying that we can't trust dietary treatments until we do double-blind studies. Uh, guys? You can't do a double-blind study with FOOD! Double-blind studies work for drug trials because placebos and real pills look alike. A carb-free diet doesn't look like a carby one. Seriously, do these people not know what "double-blind" means?

CJ (2011-10-11 14:34:37)

Elisa- while true that double-blind studies are not possible, here's one for you: to deny that diets work in Crohn's disease would be to deny tens- probably hundreds- of controlled studies done on enteral nutrition (EN) and total parenteral nutrition (TPN). Very few medical professionals experienced with IBD would challenge that EN and TPN are effective at inducing and maintaining remission; most studies put the efficacy of EN and TPN at somewhere around 60-70 %. See Oppenheimer's excellent (and well-referenced) "Beat Crohn's!" for more information on the subject. So- if "food in a can" (EN) or a needle-fed diet (TPN) control IBD, what is the mechanism? Note (from Oppenheimer's book) that they are roughly equivalent in terms of efficacy, so it is not a matter of "bowel rest" (as provided by TPN). Instead, close examination of the ingredients of many brands- including Modulen IBD by Nestle- shows they are all depleted in starch and complex carbohydrates. This is extremely important: it's the starch and the polymeric carbs (probably even disaccharides, including sucrose and lactose) that cause the problems. Monosaccharides are absorbed very "high" in the digestive tract- before they get to the part of the intestines in which the bacterial/yeast dysbiosis is occurring. The SCD/Gottschall/BTVC is simply a fork-and-plate version of EN and TPN. It is also important to note that all enteral diets are devoid of wheat, barley, rye, and oats; most have some small amount of cornstarch or rice starch as a texturizing agent.

Elisa (2011-10-11 14:47:48)

Actually, that gives me an idea - maybe you \*could\* do a double-blind study with food if all the food was administered in some kind of liquid form....

CJ (2011-10-11 15:12:27)

Nasogastric tube.

Elisa (2011-10-11 16:40:03)

Of course, the bulk of our "knowledge" about diet and nutrition with regards to health is based on very shaky extrapolation. Nobody has done double-blind studies to test the long-term effects of salt, saturated fat, cholesterol, etc. in the human diet, but doctors keep on advocating that we reduce our intake anyway. The reason we don't do double-blind studies of diets is because diets don't require FDA approval.

Nathan Myers (2011-10-12 00:27:23)

\*\*\*\*\*- 21Perhaps these are too pedestrian, but I discovered that the tiny blisters I got on the backs of my hands and neck only showed up when I eat cranberries, and that the sloughing skin in my nose, and bleeding sinuses, recur only when I eat onions or garlic. I mention these just because I have not found a physician who can name the symptoms. To -

Nathan Myers (2011-10-12 00:30:43)

... To expect sensible treatment, or even advice, is too much to ask when there is no name for the apparent condition.

Jazi yechezkel zilber (2011-10-12 10:04:14)

Used versions of the diet mentioned are almost priced as new. Evidence for the book desirability. Most books especially that old can be found for very cheap prices. [http://www.bookfinder.com/search/?ac=sl&st=sl&ref=bf\\_s2\\_a1\\_t1\\_1&q=qUDpzW5kRtTQqI3uJN0,dBk1jd8\\_3311505934\\_1:39:215&bq=author%3Delaine%2520gloria%2520gottschall%26title%3Dbreaking%2520the%2520vicious%2520cycle%2520intestinal%2520health%2520through%2520diet](http://www.bookfinder.com/search/?ac=sl&st=sl&ref=bf_s2_a1_t1_1&q=qUDpzW5kRtTQqI3uJN0,dBk1jd8_3311505934_1:39:215&bq=author%3Delaine%2520gloria%2520gottschall%26title%3Dbreaking%2520the%2520vicious%2520cycle%2520intestinal%2520health%2520through%2520diet) I have a very sensitive stomach, with chanigng stuff. But food is \*obviously\* a strong cause in the stomach. It is obvious to the blind. Mqny healthy people i know have a clear experience of food affecting the stomach. Denying that, is like saying that day is night. BTW,

i am now browsing the SCD food list, and see that bananas are allowed only when ripe with black points. I know from my stomach experience, that i can eat bananas only when fully ripe. So she was clearly on something.

Missy (2011-10-12 19:59:01)

I've had IBS for ever (since I was 4). Never once did a doctor look at my diet. Really? You're a doctor and you can't, or are being paid off not to, connect the dots between what a patient eats and them having severe diarrhea 20 minutes after each meal? Bitch, please.

Jazi yechezkel zilber (2011-10-13 07:17:40)

Here are detailed records of SCD and all measures for chron's. This lady measured it in many ways! <http://thescdexperiment.com/results/> Seth, This book is a guy who got his academic degrees by optimizing food and diet. He states that he is not smart, but hugely improved brain by a variety of food tricks. He tried everything he says. He is very well versed in the literature (a thousand references!) <http://www.amazon.com/How-to-Become-Smarter-ebook/dp/B0032JT11K>

Christina (2011-10-13 08:42:49)

After reading this (and the boing boing article) and talking to more and more people with digestive and GI related illnesses - I started a little survey (informal) to see what the responses of accurate doctor diagnosis and support is with regards to diet changes. Not sure how I'll publish the results yet, but I am surprised at how many people without these health issues think self-diagnosis is wrong or that seeing a few doctors before someone figures it out is an exception rather than the rule. Would love for this to spread to get a more accurate idea of what people's experiences really are. <http://www.surveymonkey.com/s/XNQKKDF>

Thomas Seay (2011-10-13 11:59:29)

I don't know what constitutes "serious" ailment to your mind, but I had a very severe case of heartburn/acid reflux about 5 years ago. I couldn't sleep well and was in pain most of the time. Eating became misery. At first I tried the acid blockers the doctors recommended, but that stopped working over time. Finally I found out about Dr. Jonathon Wright MD and his suggestion that acid reflux is actually caused by too little digestive acid. I started taking Hydrochloric Acid per his suggestion with every meal. In addition to his suggestion, I took mass quantities of probiotics and also took Mastic Gum. I was better within a few days and completely cured within two weeks.

Seth Roberts (2011-10-13 15:01:27)

thanks, Jazi. Those are both very interesting links.

Jazi yechezkel zilber (2011-10-14 18:02:44)

Logical blindness against SCD In [http://en.wikipedia.org/wiki/Specific\\_Carbohydrate\\_Diet#Criticism](http://en.wikipedia.org/wiki/Specific_Carbohydrate_Diet#Criticism) A doctor says: in my experience, for every patient I see who tried the diet and it worked, there are three to four others who tried it and it didn't work" He practically says that it works for \*some\* people. Yet, if it does not work for all, it does not count. (rationally, if it heals 20 % of sufferers it is a wonderful gamble to try!) Which is again the cognitive illusion that personal solutions are uninteresting and he needs a solution that works for all. I see it as stemming from wanting a "good solution" rather than a practical solution. Looking for a story. A diet that works for some is not a "solution" just a patch. As usual, normal people want to be healthy, and care zilch on whether it helps \*everyone\* PS. The blog is not loading much of the time recently. No idea why

Perfect Health Diet » Around the Web; The Case of the Killer Vitamins (2011-10-15 13:30:00)

[...] Seth Roberts points out that the Specific Carbohydrate Diet has been curing Crohn's for 80 years, but still no clinical trial. [...]

Seth Roberts (2011-10-15 21:39:20)

Jazi, good point. The accepted drug "solutions" don't work for everyone either. As you say, he is just biased against SCD. The same doctor also said (quoted in that wikipedia article), "We're not ruling out the possibility that it works, but you need more than a few successes to establish proof." There are more than a "few" successes.

Christina (2011-10-17 07:22:20)

There are two reasons dietary healing only works for "some" One is that changing your diet - especially when it means cutting out food you love - is difficult. It's easy to cheat and results are rarely instant so it becomes easy to fall back into bad habits, and out of guilt use a white lie or two to justify your habit. The other is that not all people attempting dietary changes are getting good advice, or the right advice. I was treated for ulcers with pills and told to stay away from nightshades temporarily....turns out I had Celiac Disease which was causing the ulcers. Pills and that particular diet were a temporary fix destined to fail. Until there are controlled studies (and better diagnosis) diets will always only work for a small sampling of patients. In the survey I set-up (<http://www.surveymonkey.com/s/XNQKKDF> - still a small sampling) 85 % had to self-diagnose after visiting 1-6 doctors to figure out what was going on. And they also had to bring up the idea of dietary changes as a method for healing.

### **Public Speaking Advice From My Students (2011-10-12 05:00)**

In the Frontiers of Psychology class I teach at Tsinghua (Monday 3:20-4:55, Teaching Building 6, Room A113, visitors welcome) , the students will give several presentations each class period. So I decided to assemble a list of advice. I came up with Items 1-3, the students came up with the rest.

1. Give a presentation that you would like to hear. Don't worry about following a formula.
2. Make your points by telling stories. Don't just say "X is true". Tell a story that will make your listeners think that X is true.
3. Stay within the allotted time (e.g., 5 minutes). In real life – presentations at scientific conferences, for example – most presentations are too long. Listeners rarely like this. They think the speaker is selfish. If one person speaks too long, this usually means that other speakers will have less time to speak.
4. Don't read your talk.
5. Use simple, spoken English. Don't speak fast
6. Smile and use body language to connect with the audience.
7. Pause before the most important points.
8. Ask questions to attract attention.
9. Show the big structure of your talk.
10. When telling a story, don't go far from the point of the story (e.g., with unnecessary details)

To me, the most interesting item is #8 (ask questions). For example, instead of saying "Let us begin" I can say "Shall we begin?" Which is certainly an improvement over coughing, which is what one student said was the usual way officials began talks.

For example, which phrasing works better?

Why does question-asking work? I asked my students.

I asked my students why question-asking works.

The first way ("Why does") grabs my attention more than the second ("I asked"). I did ask my students why it works.

One said that when you hear a question you automatically try to answer it. I cannot do better than that. I suppose we notice questions much like we notice loud noises.

---

Txomin (2011-10-12 05:24:05)

I have forgotten how many times I've seen a presenter struggle (and waste everyone's time) because they figure they would be able to improvise. Even those few people that are good at it amount to little more than entertainers. Write a good paper and learn to read aloud well.

Alex Chernavsky (2011-10-12 07:32:57)

If you are using a microphone, a computer & projector, or other audiovisual equipment, spend some time in advance to make sure that everything works properly. I can't tell you the number of times I've seen speakers struggling with their PowerPoint presentation. The most amusing instance was a lecture given by the Chief Technology Officer of a Fortune 500 company. Members of the audience actually ran up on stage to help troubleshoot the equipment, but it was all to no avail. The PowerPoint presentation still wouldn't work. Also, make sure that you are prepared to give a version of your talk without any additional equipment at all, in case of power failure or some such thing.

dearieme (2011-10-12 15:38:29)

#4 is wrong. It should read: 1. Don't you bloody dare to read your talk. to which I would add And don't you bloody dare to read out your powerpoint slides either.

Stephen M (Ethesis) (2011-10-12 17:21:29)

Even if you are an excellent improviser, the kind that wins competitions, you do better if you don't. No matter how good you are, you can improve what you do by not taking more time than you are scheduled for, and a little less (and taking questions or sharing it with other presenters) goes a long way.

Åse (2011-10-13 10:46:21)

I can kind of see #4. (And, I sure as hell don't read lectures, and try to eliminate most writing from my power points these days), but, when I started out, stage fright petrified me. Rather chockingly so the first time. And, when I had to do my first longer presentation when I started grad school, my adviser suggested that I would write it out, write it in a spoken voice, and if I freaked, I could just read it. Which is what I did. And what I did for my first lecture. And, then, rather quickly actually, my stage fright disappeared, my written lecture was more a security blanket, and eventually that stopped too (because who has time to write out an entire talk or lecture, when you don't need it). So, I do suggest writing it out to read for people who are like me and petrified with stage fright. Because actually saying something up there and making it to the end is better than not being able to do anything.

Txomin (2011-10-17 01:47:35)

That's the point, really. The people that do well without reading are those that know the material so thoroughly that, essentially, are reading it directly out of their minds. Anyone that lectures regularly gets to that point eventually. Nonetheless, the only way to be densely informative (and not to waste other people's time) is to sacrifice resources invested in the creation of an illusion of mastery (look Ma', no hands!) and, rather, invest everything into getting the information through with eloquence and clarity. WRITE IT. Memorize if you feel you've gotta dazzle too, but WRITE IT.

Ian Ross (2011-10-18 04:36:02)

One other thing: PRACTICE! When you start out, get as much practice as you can giving talks in non-threatening environments.

And then, always practice the talk you're going to give to an empty room, and maybe once, to friends or colleagues. For conference talks, I usually figure an hour of practice time: 4 times through for a 15-minute talk, 5 times for a 12-minute talk, and so on. Short talks are hard to get right. You need that practice. And so many people give bad bad bad talks that you can really stand out if you're a little more on the ball.

Unshod Ashish (2011-10-18 09:26:10)

I think they missed the most important point: never address a "group." Address individuals within that group, one at a time. At each instant, look at the person you are addressing in that instant. This both: - Helps conquer anxiety - we all know how to talk to one person. - Gives your presentation the conversational flow that the audience wants. Also will pass on this insight I read just a few minutes ago: "In my freshmen psych class, they said that, as a general rule, well-prepared people will perform better when they have an audience, and those who are not well-prepared will do worse."

### **Make Yourself Healthy (Boing Boing posts) (2011-10-12 19:33)**

I have written several [1]Boing Boing posts about people with serious health problems who figured out how to cure themselves.

1. [2]Restless Legs Syndrome (title: Restless Legs Syndrome, Niacin, and Web Search). Co-written with Gary Wolf. Dennis Mangan figured out that his mother, who had Restless Legs Syndrome, might have a niacin deficiency.
2. [3]Frequent Migraines (title: Finding the Source of Migraines – and Fifty Useless Migraine Drugs). A woman greatly reduced her migraines by avoiding household cleaning products. [4]Alexandra Carmichael benefited from this story.
3. [5]Crohn's Disease (title: Grandmother Knows Best About Crohn's Disease). Reid Kimball greatly reduced his symptoms by following the Specific Carbohydrate Diet.
4. [6]Should your child have a tonsillectomy? (title: Tonsillectomy Confidential: doctors ignore polio epidemics and high school biology). After her doctor recommended that her son have a tonsillectomy, a woman, looking into research about them, learned they have little benefit. Your tonsils are part of your immune system and cutting them off because you have too many infections makes as much sense as cutting out part of the brain because you have memory problems.
5. [7]Gluten intolerance (title: Daughter Knows Best About Kidney Disease and Gluten Intolerance). A daughter figures out that her mother's kidney problems may be due to gluten intolerance.
6. [8]Acne (title: Searching For the Cause of Acne). Martha Rotter used a process of elimination to find out that cow dairy was causing her acne.

## Nobel Prize Report Card: Economics (2011-10-13 05:00)

The Nobel Prizes awarded each year resemble a kind of report card where each prize-worthy discipline (Physics, Chemistry, etc.) gets a grade that depends on the prize-winning research. If the prize-winning research is useful and surprising, the grade is high. If not the grade is low. More generally, at least to me, the intellectual history of the prize winners sheds light on the whole profession. Perhaps some biologists were unaware of the behavior of Eric Kandel described in [1]Explorers of the Black Box when he was awarded the biology prize. Kandel, I hasten to add, is an unusual case.

Thomas Sargent is one of the winners of this year's Economics prize. In 2007, he gave [2]a graduation speech at Berkeley to economics majors (via [3]Marginal Revolution). In the speech, Sargent called economics "organized common sense". He went on to list 12 common-sense ideas, such as "Individuals and communities face trade-offs" and "governments and voters respond to incentives" that economists believe. The reasons for their belief weren't stated.

When I started as a professor (at Berkeley) I did many experiments with rats and, to my annoyance, discovered an inconvenient truth: I understood rats less well than I thought. Even in a heavily-controlled heavily-studied situation (Skinner box), my rats often did not do what I expected. My common sense was often wrong, in other words. This experience made me considerably more skeptical of other people's "common sense".

To me, and I think to most scientists, science begins with common sense. Experimental psychology certainly does. I used common sense to design my experiments. Had I not done those experiments, I would not have learned that my common sense was wrong. So relying on common sense was helpful – as a place to start. As a way to begin to understand. You begin with common-sense ideas and you test them. That common sense is often wrong is a theme of Freakonomics, in agreement with my experience. Yet Sargent seemed content (he called economics "our beautiful subject") to end with common sense, perhaps tidied up.

This is really unfortunate because economics, beautiful or not, is so important. If you ignore data, the answer to every hard question is the same: the most powerful people are right. That way lies stagnation (problems build up unsolved because powerful people prefer the status quo) and collapse (when the problems become overwhelming). Alan Greenspan's faith-based belief in free markets and the 2008 financial crisis – after Sargent's speech – is an example. In 2009, Sargent's speech might have been less well-received.

The most powerful people are right — The Endeavour (2011-10-13 06:56:22)

[...] Seth Roberts: If you ignore data, the answer to every hard question is the same: the most powerful people are [...]

Scott P. (2011-10-13 07:24:33)

I would only disagree in calling out Alan Greenspan. Though he doesn't get away scot-free, it is more the corrupting influences of government intervention in the housing market and the elimination of moral hazards by that same government that created the financial crisis of 2008 more so than free markets. I place more blame on Barney Frank than I do Alan Greenspan though Greenspan doesn't come away unscathed. Your observations regarding Sargent and his commencement speech are sad. It is

why I disdain consensus science.

James (2011-10-13 07:52:53)

You should be happier about co-winner Chris Sims, all of his work involved looking at data and/or coming up with new ways to look at data.

Tom (2011-10-13 08:48:59)

Is there a difference between common sense and confirmation bias?

George (2011-10-13 09:07:05)

Wow. You learned all you needed to know in order to judge an entire discipline from a *graduation speech*?! If you had bothered to read Sargent's work before judging it you would have seen that he won the Nobel for research showing that what people used to think was common sense (particular fiscal and monetary policy) is actually wrong. Your post (cf. para 3) rests on the unstated assumption that common sense = naive expectations. Sargent's work (on "rational expectations"), on the other hand, specifically argues that this assumption isn't true, so it seems sort of silly to criticize him for making it.

Alex Chernavsky (2011-10-13 09:42:49)

I know Seth blogged about this already, but I'm reminded of "The Truth Wears Off", an article that appeared in the *New Yorker* last December. Here's an excerpt:

In the late nineteen-nineties, John Crabbe, a neuroscientist at the Oregon Health and Science University, conducted an experiment that showed how unknowable chance events can skew tests of replicability. He performed a series of experiments on mouse behavior in three different science labs: in Albany, New York; Edmonton, Alberta; and Portland, Oregon. Before he conducted the experiments, he tried to standardize every variable he could think of. The same strains of mice were used in each lab, shipped on the same day from the same supplier. The animals were raised in the same kind of enclosure, with the same brand of sawdust bedding. They had been exposed to the same amount of incandescent light, were living with the same number of littermates, and were fed the exact same type of chow pellets. When the mice were handled, it was with the same kind of surgical glove, and when they were tested it was on the same equipment, at the same time in the morning. The premise of this test of replicability, of course, is that each of the labs should have generated the same pattern of results. "If any set of experiments should have passed the test, it should have been ours," Crabbe says. "But that's not the way it turned out." In one experiment, Crabbe injected a particular strain of mouse with cocaine. In Portland the mice given the drug moved, on average, six hundred centimetres more than they normally did; in Albany they moved seven hundred and one additional centimetres. But in the Edmonton lab they moved more than five thousand additional centimetres. Similar deviations were observed in a test of anxiety. Furthermore, these inconsistencies didn't follow any detectable pattern. In Portland one strain of mouse proved most anxious, while in Albany another strain won that distinction. The disturbing implication of the Crabbe study is that a lot of extraordinary scientific data are nothing but noise.

Full text: [http://www.neurofly.com/NeuroSeminar\\_files/2011-2.pdf](http://www.neurofly.com/NeuroSeminar_files/2011-2.pdf)

dearieme (2011-10-13 12:38:45)

1) You really ought to acknowledge that the Economics "Nobel" is a rather a pretendy prize - it's not in the old boy's will: all part of the Economists' Physics envy. 2) "If the prize-winning research is useful and surprising...": the science panels seem happily to give prizes for work that has yet to show any "benefit" as the will insists they should. Just another example, I suppose, of institutionalised science operating in bad faith.

Seth Roberts (2011-10-13 14:12:36)

George, I'm not "judging Sargent's work" I'm commenting on a graduation speech. As for Sargent's serious work, here is one paper: <http://www.mpls.frb.org/research/QR/QR531.pdf> Supposedly important. It was linked to in a Washington Post article about why Sargent won the Nobel Prize. Perhaps this paper illustrates what you mean by "showing" that common sense is wrong. Please note the absence of data. In particular, the absence of data and comparison with prediction. To me this instance

of Sargent's work "shows" nothing except theoretical overconfidence. What if, ten years from now, someone tests predictions from Sargent's theory and it turns out that those predictions are wrong? Then you might be less sure than you are now about what Sargent has "shown".

Seth Roberts (2011-10-13 14:24:44)

Thanks, Alex. To me, that example supports my point. Crabbe believed that he was likely to have controlled all the important factors but he was wrong. His common sense was wrong. He tested it, which is good. I don't agree with the author's conclusion here ("a lot of extraordinary scientific data are nothing but noise"). I would say the Crabbe data suggests that a lot of data are less generalizable than we might think. But that data is an improvement on common sense – which is to say it is not "noise". In essence my conclusion is exactly the opposite of the author's (the author is Jonah Lehrer). The Crabbe example shows how important all data is and how we should never ignore it.

Seth Roberts (2011-10-13 14:49:11)

James, that's right, I am much happier with Sims.

Seth Roberts (2011-10-13 15:08:01)

Tom, you ask "Is there a difference between common sense and confirmation bias?" Yes. Common sense is a set of beliefs that we have great faith in and that are widely shared. Confirmation bias is a scientific strategy that tends to set up tests so that they confirm the beliefs we start with. I think you're right that there's a connection: confirmation bias leads us to be overconfident about our common sense. (Whether that is why we are overconfident in our common sense I don't know but it is plausible.)

Jan Madsen (2011-10-13 21:27:57)

Common sense this: If Alan Greenspan had a "faith-based belief in free markets" why did he champion government intervention?

Seth Roberts (2011-10-14 00:47:04)

Jon, perhaps I was unclear. Greenspan was against government regulation of financial markets.

Seth Roberts (2011-10-14 00:53:35)

dearime, that the Nobel Prize is so often given for useless work, contrary to Nobel's instructions, to me shows the power of the forces (especially the desire to project status) that Veblen wrote about in Theory of the Leisure Class. You project status by being useless. Powerful people can afford to be. When a rich person "wastes" their money I have no objection. When a scientist or whole discipline wastes their power to improve human life, it is a tragedy.

Jan Madsen (2011-10-14 12:46:55)

No, you were quite clear. Yes, he was against government regulation of financial markets - in the 1960s and 70s. As chairman of the Fed, however, he was by definition, in body, mind, soul, to the bone, in every way imaginable, very much FOR government intervention of financial markets. His reputation as a free marketeer is simply wrong, wrong, wrong as well as being and insult to both pro and anti interventionists. But I doubt we'll agree on that... Instead, let me finish by saying I really enjoy your work. Thanx!

Roger Sweeny (2011-10-22 10:53:31)

I wouldn't go as far as Jan Madsen but finance is an industry with lots and lots of government regulations. Perhaps in his heart of hearts Greenspan opposed these. However, he made almost no effort to "deregulate" any aspect of the industry when he was Federal Reserve chairman—no speeches, no lobbying Congress, no Fed "studies." He did oppose most new regulation but that is a different thing. He may have felt that finance was about as good an example of "mixed economy" "regulated markets" as you were likely to get. Of course, he was wrong. But we still don't know exactly what changes will make things better how. Dodd-Frank, on balance, is probably doing more harm than good (I count as harm the increased business for lawyers and lobbyist; many in Congress may disagree).

## Jane Jacobs and Amazon.com (2011-10-14 05:00)

How did air-breathing evolve? In [1]The Nature of Economies (p. 87), Jane Jacobs uses it to illustrate the developmental pattern she calls "bifurcation" (air-breathing isn't a refinement of water-breathing). She speculates on how it started:

Lungfish had both gills and a primitive lung, suggesting that their habitat was swampland. The earliest to take to dry land may have inhabited swamps subject to severe droughts or perhaps they were escaping fearsomely-jawed predators who couldn't follow them to dry land.

According to Steve Yegge's already-famous [2]"psst, Googlers" memo, something much like this was why Amazon started selling web computing services, which wasn't a refinement of their earlier business (selling books, toys, etc.):

Amazon was a product company too, so it took an out-of-band force to make Bezos understand the need for a platform. That force was their evaporating margins; he was cornered and had to think of a way out. But all he had was a bunch of engineers and all these computers... if only they could be monetized somehow... you can see how he arrived at AWS [Amazon Web Services], in hindsight.

People say necessity is the mother of invention. That isn't even close to true. Trial and error is the mother of true, profound invention. The Bezos story, and Jacobs's generalization of it, suggest what is actually true: necessity is the mother of development. Necessity pushes people to use, and thereby develop, inventions they had ignored.

[3]Chapter 1 of The Nature of Economies.

- [1]Reclamations. Essays by University of California students about the harm done by student loans. Via [2]Boing Boing. Being taught "how to think" (as many college professors claim they do because the details of their class are obviously useless) is fine when it's a choice. (I support the study of esoteric seemingly-useless stuff - when it's a choice.) When it's required (to get a decent job) and very expensive (due to tuition), there's a problem.
- [3]The Cobblestone Conservative: How Jane Jacobs saved New York City's soul.
- [4]Robin Hanson surveys his students. "[Their] opinions [about "random policy questions"] strongly tend to support the status quo - mostly whatever is, is assumed good." Same thing at Berkeley. Most of my students, for better or worse, were very conformist. My conclusion, which I imagine Robin agrees with, is that the reasons

we give for our beliefs have roughly zero correlation with the actual reasons and shouldn't be taken seriously (e.g., argued with). Professors who claim to teach their students "how to think" (e.g., lines of argument) are shutting their eyes to what Robin shows is right in front of them: the lack of importance of "thinking" in the determination of belief.

Alrenous (2011-10-15 09:28:46)

I need a name for the set of standard causes of belief. This post caused me to google it up - it's called ethnoepistemology. It's undeniable that science-type reason is only a few percent of ethnoepistemology. The rationalizations generated when you ask students about their opinions are neither for justifying those opinions nor very often for spreading them. I'm not sure what they're for.

Seth Roberts (2011-10-15 21:14:27)

that's a good point about the rarity of science as the reason for our beliefs. So when science - science that actually worked - came into the world, a new (and to some extent higher-prestige) way of forming beliefs, it was predictable that people would continue to use the old ways of producing belief but claim they were using the new way - for example, Scientology, much of evidence-based medicine, much of the AGW argument.

Jill (2011-10-17 09:54:18)

I'm currently dealing with the change in the online federal student loan servicer website (kept getting errors and such last week when trying to access my information, and now find out that the switch apparently involved losing the autopay I've had set up for years and have a past-due amount because it didn't do the auto-pay last week - meanwhile, the customer service phone number has a message that states that it can't be reached "right now - try calling back later"), so the Reclamations essays are definitely striking a chord today.

### **Inside Chinese Higher Education: A Hidden Strength (2011-10-16 05:00)**

China has hundreds of colleges. Tsinghua and Beijing University are at the top (top tier), followed by perhaps 20 colleges considered second-tier. A friend of mine attends a third-tier school. In all of her classes, class consists of the professor reading the textbook. Word for word. (Which, by the way, doesn't happen at Tsinghua, I checked.)

Perhaps you grimace. I think this is a great thing. It means students can easily skip class - any sensible person would. Being able to skip class frees them to do internships, visit the National Museum, explore the off-campus world however they want. My friend took advantage of this to do three internships. At Berkeley I told students to take as few

classes as possible and take as many internships as possible. I taught a class called Psychology and the Real World whose sole purpose was to help students learn off campus. When I was a freshman at Caltech, the school had an unintentionally similar feature: all freshman grades were pass/fail. This made it much easier to skip class, which I did most of the time. Even better than the Chinese system, I no longer had to study much. I used my abundant free time to explore my own interests, which included reading Veblen and Freud. I taught psychology to under-privileged eighth-graders. The freedom provided by pass/fail grading allowed me to explore my own interests and started me on the path to becoming an experimental psychologist. I am not kidding: this is a great hidden strength of Chinese higher education.

By the same twisted logic am I glad that American colleges are [1]becoming insufferably expensive – because then fewer people will attend them? Not yet. I think most American high school students think not attending college is dangerous. Reading the textbook at home and doing an internship isn't dangerous.

### **Willat Effect Experiments With Tea (2011-10-17 05:00)**

[1]The Willat Effect is the hedonic change caused by side-by-side comparison of similar things. Your hedonic response to the things compared (e.g., two or more dark chocolates) expands in both directions. The "better" things become more pleasant and the "worse" things become less pleasant. In my experience, it's a big change, easy to notice.

I discovered the Willat Effect when my friend Carl Willat offered me five different limoncellos side by side. Knowing that he likes it, his friends had given them to him. Perhaps three were homemade, two store-bought. I'd had plenty of limoncello before that, but always one version at a time. Within seconds of tasting the five versions side by side, I came to like two of them (with more complex flavors) more than the rest. One or two of them I started to dislike. When you put two similar things next to each other, of course you see their differences more clearly. What's impressive is the hedonic change.

The Willat Effect supports [2]my ideas about human evolution because it pushes people toward connoisseurship. (I predict it won't occur with animals.) The fact that repeating elements are found in so many decorating schemes and patterns meant to be pretty (e.g., wallpapers, textile patterns, rugs, choreography) suggests that we get pleasure from putting similar things side by side – the very state that produces the Willat Effect. According to my theory of human evolution, connoisseurship evolved because it created demand for hard-to-make goods, which helped the most skilled artisans make a living. Carl's limoncello tasting made me a mini-connoisseur of limoncello. I started buying it much more often and bought more expensive brands, thus helping the best limoncello makers make a living. Connoisseurs turn surplus into innovation by giving the most skilled artisans more time and freedom to innovate.

Does the Willat Effect have practical value? Could it improve my life? Recently I decided to see if it could make me a green tea connoisseur. Ever since I discovered the Shangri-La Diet (calories without smell), I'd been

drinking tea (smell without calories) almost daily but I was no connoisseur. Nor had I done many side-by-side comparisons. At home, I had always made one cup at a time.

In Beijing, where I am now, I can easily buy many green teas. I got three identical tea pots (SAMA SAG-08) and three cheap green teas. I drink tea every morning. Instead of brewing one pot, I started making two or three pots at the same time and comparing the results. I compared different teas and the same tea brewed different lengths of time (Carl's idea).

I've been doing this about two weeks. The results so far:

1. The cheapest tea became undrinkable. I decided to never buy it again and not to drink the rest of my purchase. I will use it for kombucha. Two of the three teas cost about twice the cheapest one. After a few side by side comparisons I liked the more expensive ones considerably more than the cheaper one. The two more expensive ones cost about the same but, weirdly, I liked the one that cost (slightly) more a little better than the one that cost less. (Tea is sold in bulk with no packaging or branding so the price I pay is closely related to what the grower was paid. The buyers taste it and decide what it's worth.)
2. I decided to infuse the tea leaves only once. (Usual practice is to infuse green tea two or more times.) The quality of later infusions was too low, I decided. Before this, I had found second and later infusions had been acceptable.

The Willat Effect is working, in other words. After a decade of drinking tea, my practices suddenly changed. I will buy different teas and brew them differently. I will spend a lot more per cup since (a) each cup will require fresh tea, (b) I won't buy the cheapest tea, and (c) I have become far more interested in green tea, partly because each cup tastes better, partly because I am curious if more expensive varieties taste better. When I bought the three varieties I have now I didn't bother to learn their names; I identified them by price. In the future I will learn the names.

To get the Willat Effect, the things being compared must be quite similar. For example, comparing green tea with black tea does nothing. I have learned a methodological lesson: That tea is a great medium for studying this not only because it's cheap but also because you can easily get similar tasting teas by brewing the same tea different lengths of time. I haven't yet tried different water temperatures but that too might work.

I have done similar things before. I bought several versions of orange marmalade, did side-by-side tastings, and indeed became an orange marmalade connoisseur. After that I bought only expensive versions. After a few side-by-side comparisons of cheese that included expensive cheeses, I stopped buying cheap cheese. You could say I am still an orange marmalade and cheese connoisseur but this has no effect on my current life. Because I avoid sugar, I don't eat orange marmalade. Because of all the butter I eat, I rarely eat cheese. My budding green tea connoisseurship, however, is making a difference because I drink tea every day.

[3]My posts about human evolution.

David Scrimshaw (2011-10-17 06:27:07)

I get two take-aways from this. 1) If I want to consume more of something that I don't really enjoy, I should do side-by-side taste tests of different versions to find the better tasting version and develop a taste for it. 2) If I enjoy an inexpensive product, I should avoid side-by-side taste tests so that I do not develop an aversion to the inexpensive version.

Seth Roberts (2011-10-17 06:33:47)

David, yeah, that's correct. I used to enjoy green tea less than black tea. Now I like it more. The bigger point is that here is a faucet of pleasure and here is how to open it. Something that produced a tiny amount of pleasure per day or whatever can now produce pleasure at a much greater rate. Sure, it will cost you but it will feel worth it and you will feel good about the whole thing.

dearieme (2011-10-17 06:51:48)

For God's sake don't try this with wine - it will cost you a packet.

gwern (2011-10-17 07:39:32)

To me, the interesting question is Scrimshaw's. Is one really better off deliberately engaging the Willat effect? You say you are happier but... I think we'd all agree that it would be a bad idea to engage the Willat effect for everything (no one but a millionaire can afford to be a connoisseur in their tea, their milk, their bread, their computer and computer chair, their house, their car, their book etc etc.), which implies that there's some point at which the Willat effect would make one \*worse\* off. Where is that?

Zach (2011-10-17 08:35:23)

As an aside, I'm pretty sure the Willat effect exists in at least some animals. My parent's dog is certainly picky when it comes to dog food (though I suppose that could be a matter of the different types of food being categorically different), and some fruit trees will be picked bare by birds and other critters while others in the same orchard go relatively unscathed.

Robin Barooah (2011-10-17 09:49:30)

I think this is a pretty interesting effect. I've experienced it for myself at coffee and wine tastings. I wonder how much it is related to context as opposed to an absolute scale of what is 'better'. When you set up a side by side comparison there are a few implications: 1. A grading is implied. 2. If you aren't alone, you risk social standing by not being able to identify the 'best'. 3. Costs are already sunk. It seems to me that these are the circumstances of a game that would naturally lead one to seek specific criteria for choosing the 'best'. Perhaps other games are possible. Here are couple of examples from my own experience: I regard myself as something of a coffee connoisseur. In the past I've spent more than \$100 on a single pound of coffee, and pre-ordered specific auction lots prior to harvest. I've tried almost all methods of coffee brewing. Occasionally I buy a coffee by mail order that sounds good by the description, but turns out to be a long way from my tastes - to the point of unpleasantness. When that happens, I have learned to start tweaking the brewing method, temperature, contact time, amount of coffee, grind, etc. to try to get the best out of the specific coffee - it regard it as a challenge. Sometimes I will experiment with blending. I've found that this approach leads me to suspend judgement and focus much more on the distinct qualities of the 'bad' coffee. Through the process, the bad coffee turns into a coffee that I understand, and can like because it has a place in my mental map. It can become something I would choose again for the contrast it provides to the supposedly better coffees. The point here is that by playing a different game, I am able to extend my preferences along more than one dimension of good/bad. Similarly with wine - I've had the opportunity to compare some pretty expensive wines on occasion, but even one bottle of the really good stuff would be out of my price range. So for the wine I drink at home, I think of experiences of drinking table wine at lunch time in the South of France.

Robin Barooah (2011-10-17 09:55:04)

(sorry - tapped post prematurely) ...and so I have tried to find the 'best' cheap french table wine to fit the context I am imagining - which for me turns out to be a \$6 côtes du rhone. More expensive wines have different connotations for me - and although I like them, I don't particularly want to drink them every day. Once again, my point is that by playing a different game, I am able to derive a great deal of pleasure using different criteria to grade what I consume. So my question is - how much of the perceived quality is built into the structure of the game and the context in which you play it, and how much is inherent in the

product?

CJB (2011-10-17 10:00:35)

Seth, I find the Willat effect fascinating, and I feel like I can confirm it from personal experience with beer. I do have a follow up question with Seth – what about the so-called experienced quality affect with price? [http://media.caltech.edu/press\\_releases/13091](http://media.caltech.edu/press_releases/13091) Wouldn't you want to blind yourself to the cost of items to make sure this wasn't having an effect on perceived quality?

CJB (2011-10-17 10:03:52)

As for others concern about cost, keep in mind the additional utility/pleasure experienced the more often you use the product (basically unless you use something very infrequently you should see payback quickly.) If you are buying a lot of something, perhaps you should test it out to see if you like something else better, because you may be spending more money on something you don't like as much...

Tim Ozenne (2011-10-17 10:41:49)

You say the Willat Effect isn't helpful in the choice between, say, green and black tea. How does one know when two items are near enough to make the side-by-side comparison useful. I am thinking specifically of various beers. As you know, there are lots of beer "styles." Would I want to use Willat within a style or would it also apply across styles? Or, all red wines, or only among cabernet sauvignons? (I assume no value in comparing a chardonnay to merlot. )

Alex Chernavsky (2011-10-17 11:05:41)

I'm surprised that more-expensive products consistently taste better than cheaper ones. I wonder if this effect would hold up under blind conditions. See, for example, this study that appeared in the *Journal of Wine Economics*: [1]Do More Expensive Wines Taste Better? Evidence from a Large Sample of Blind Tastings (The answer seems to be, "No, they don't".)

1. [http://www.wine-economics.org/journal/content/Volume3/number1/Full%20Texts/01\\_wine%20economics\\_Robin%20Goldstein\\_vol%203\\_1.pdf](http://www.wine-economics.org/journal/content/Volume3/number1/Full%20Texts/01_wine%20economics_Robin%20Goldstein_vol%203_1.pdf)

Tom (2011-10-17 15:53:04)

There's a huge Willat effect with sushi.

Kirk (2011-10-17 17:25:59)

I predict there is a normal distribution of people susceptible to the Willat Effect. In other words, a few people in a group could participate in tastings day after day and still not be able to discern a difference. Another small group of people are born with this capability; many times they become great cooks (whether in the restaurant business or simply renowned among family and friends). These people can read a cookbook and start wincing at ridiculous combinations, because they have stored flavors in memory. That's why they can instantly tell you if a particular item they're tasting right now is best in class to anything they've tasted before. Most people are in the middle and can be influenced by the Willat Effect, yet usually aren't, unless they get caught up in a social event with somebody who has enthusiastically put together a tasting.

wcw (2011-10-17 22:10:45)

Sometimes, you discover the cheaper offering is better. File under, El Farolito is better than Chipotle.

Stirner (2011-10-17 23:56:02)

I would second that the cheaper offerings can be identified as better. I have done several blind taste tests of Vodkas, and have consistently found that humble Gordon's Vodka tastes cleaner than top flight brands like Grey Goose, and Ketel One. How is this possible? First, I guess the power of marketing. Second, apparently the Vodka industry is in large part supplied by bulk distillers that provide pure vodka to liquor brands. They all put their spin on the final taste, but since the starter material is basically tasteless, it's more feasible for a low end product to carry through the tastelessness.

Jonathon Barton (2011-10-18 00:01:30)

Seth, Here's the flaw I see in your plan. It has been established for quite some time that, in a rigorous scientific taste test, a person will choose the wine in the glass that they are \*told\* is the most expensive - even when the wine, in reality, came out of the exact same bottle. So, it doesn't surprise me that you self-selected the most expensive item as being the best. In order for you to apply the same rigor and validate the Willat Effect, you need to have someone else purchase three kinds of tea on at least two separate occasions: - One occasion where they do not tell you which tea is which. You must select the best tea, and then it will be revealed which tea is at which price point. - A separate occasion where they tell you which one is which, but lie to you about it...giving you the cheap tea, and telling you that it's actually the expensive tea. The Willat Effect is only valid if the taste differences among the teas is sufficient for you to pick out the best one consistently, and more importantly \*blindly\*.

Tim in SF (2011-10-18 10:58:03)

You lost me at "I predict it won't occur with animals." It's already happened with animals. It's happened with us.

Swetch (2011-10-18 11:06:22)

Saw the link to this on Boing-Boing (prepare for the deluge) - and I find this all very fascinating (certainly more so then the work I should be doing). Two comments from me: 1. Hedonic? Ouch - even recognizing the root, I had to look that one up to be sure. 2. I work in snow-ski development, and we exploit this effect when we test product on-snow, to help testers differentiate between a group of very similar models. 5 skis in a group, 5 skiers - we each take ONE run on a pair of skis and then switch to a new pair, eventually looping back taking two runs on the pair of skis that were skied 1st. Any good skier can adjust their technique to accommodate most skis, but by switching every run, you get a good "1st impression" of the ski. And even intermediate skiers that are convinced they won't be able to feel differences are surprised that they DO feel significant differences between similar skis when tested in this way. And with on-snow testing, this process has the added benefit of making the test go quickly - useful for battling the effects of muscle fatigue & changing snow conditions. (BTW - ideally, these are blind tests with all skis sporting the same graphic).

RasmusF (2011-10-18 11:12:35)

Fwiw, whenever I've done blind tests of wine (more than once, less than five times and typically with 3-4 different wines) I've almost always done a reverse ranking by price. Roughly, I've ranked the sweeter, less complex wines as better tasting than the more tart, complex wines. I don't really enjoy wine, spirits or beer all that much though.

Jordan (2011-10-18 11:28:43)

I used to sell televisions and this effect is staggering. In the electronics store- side by side you can see the difference. but once you get the television home nobody notices those differences. Maybe not the cheapest TV, but the \$5K version vs the \$2500 doesn't hardly make a difference (once you're not in the store anymore) If you haven't watched this TED lecture, much of it relates to this exact effect you're talking about here. [http://www.ted.com/talks/benjamin\\_wallace\\_on\\_the\\_price\\_of\\_happiness.html](http://www.ted.com/talks/benjamin_wallace_on_the_price_of_happiness.html) a couple things, #1 Never disclose the prices of what you're comparing for accurate results. #2 Just pretending something is worth more will convince you it's better

Jim Z (2011-10-18 12:00:40)

Maybe I missed something but I really think this would have to be done on a blind testing basis. Or are you saying that the Willat effect really is just people having a tendency to try to be snobbish when they think they can get away with it, calling it intellectual curiosity.

Sally Van Eycke (2011-10-18 13:40:22)

So you've inspired me to do a BLIND study of this with various Rums. I'm part of a drinking club and if I do it right, I can get at least 50 people to test on!

Gnu (2011-10-18 14:33:11)

It does happen in animals. We have two cats at home. We feed them dry food and wet food. The cats notify us that they are hungry by waiting until we're in the kitchen, then whining pathetically until we fill their bowls. Note that the whining only happens when we're in the kitchen, and only before we've fed them - once they stop being hungry, they are content. Up until a few months ago, we only fed them organic dry food of a particular brand. They ate it happily. One week we ran out, and got the generic (non-organic) stuff from the corner store, and they loved it. Since then, when we give them the organic food, they sniff it, and keep whining for the "good stuff". Eventually, one of two things will happen - they get hungry enough to eat the organic food, or my wife will break down and give them the non-organic. They clearly have a preference, in that they will go hungry rather than eat the inferior substitute. Before they knew there was a better alternative, though, they ate it without complaints. About a month ago, we ran into the same situation with the wet food, and yeah, they now do the exact same thing with the wet food.

Bryan (2011-10-18 14:35:28)

Here I have confirmed a finding of my own. Use the cheapest tea you can find for making kombucha. Off topic sure, but kombucha is mentioned in the article.

wangston (2011-10-18 14:45:15)

As many others have noted, it really needs to be a double-blind if you want to exclude price as a factor. CLB and others note that price matters a lot - and I think the study that CLB quoted makes it clear that this is NOT unconscious snobbery or social climbing - price is actually a flavor - it is perceived as taste at the sensory level. More expensive things taste better because rarity is delicious. The point in excluding price as a factor is not because it obscures reality (it *is* reality), but because you are stingy and cheap and want to minimize expenses :) Since all taste is arbitrary anyway, you could go all the way and cultivate an appreciation of cheap flavors.

Seth Roberts (2011-10-18 18:25:40)

Bryan, yeah, cheap tea is fine for kombucha. I have noticed this.

Jennifer (2011-10-18 18:53:30)

@Gnu - it was Meow Mix, wasn't it? At my house, and at my friend's it's the same situation. Once they tasted the Meow Mix they didn't want anything else, much to our dismay.

JR in WV (2011-10-19 08:51:34)

I agree that finding that the most expensive brand of foodstuff is always best reveals a built-in bias. Taste testing must be blind as to brand and comparative price to eliminate this bias. Anecdotally, while spending time in Santa Fe, New Mexico, USA we visited various "Southwest" restaurants for lunch and dinner. The best one was away from tourist districts in a blue-collar neighborhood, serving a wide variety of authentic central-American foods from various cultures. It was neither fancy nor expensive, but the food was well prepared, the recipes were widely varied, the ingredients were top quality and fresh, wonderful. Can't remember the name, couldn't find it now without a lot of driving around that part of town, but it was really popular with the local folks.

Nick (2011-10-20 05:37:00)

I would like to point out that your intention was originally to maximize pleasure, but your results indicate you minimized pleasure derived from at least one tea. It sounds like you used to be happy with any old green tea, but now you've limited the range of acceptable teas by nurturing a disgust for some of them. It is only compounding the problem that the ones you do still enjoy (and would have enjoyed regardless) are more difficult to access. To think, you could have been content with the cheap stuff if you'd never compared. At least you have derived pleasure from the experiment!

Word of the Day - The Willat Effect | Les Jones (2011-10-20 05:37:56)

[...] [...]

Alex Chernavsky (2011-10-20 06:34:56)

@JR in WV: I had a different experience. The worst Mexican restaurants I ever encountered were in Mexico. Maybe they were more authentic... I dunno. But the food was not good.

Seth Roberts (2011-10-20 06:47:03)

Nick, I have vastly increased the pleasure I get from tea. I just spend more money to get it. It is easy to get more expensive teas and I can afford them. It's true, it could go the other way if I couldn't afford the expensive stuff I liked.

marmolillo (2011-10-20 13:44:11)

Another reference: As blueberries go, the wild variety ("lowbush") are the rock stars. The cultivated kind ("highbush") can be planted anywhere, and grow in huge fields in places like New Jersey and Michigan. You're as likely to find either topping your cereal. Sometimes you've got these big, fat berries bobbing in your milk, and other times you'll have tiny bold nuggets on your spoon. Do a taste test someday. The cultivated ones are watery and mealy compared to the tiny wild ones—intense bursts of candy-like fruit. Once you notice the difference, you will never buy the fat ones again.

Maria Droujkova (@MariaDroujkova) (2011-10-21 05:12:34)

I quoted your post in application to mathematics education: <http://www.naturalmath.com/blog/example-spaces-hedonic/> Apparently, there are some delicious complexities there. Check out this quote from a study: "Surprisingly, induction proved from spacing, even though massing apparently created a sense of fluent learning: Participants rated massing as more effective than spacing, even after their own test performance had demonstrated the opposite."

Seth Roberts (2011-10-21 13:52:44)

Thanks, Maria. I think of using the Willat Effect to teach young children science. It is fun to make the comparisons, the results aren't obvious (e.g., how long to brew tea), and the comparisons are tiny experiments. It is mini-science.

Maria Droujkova (@MariaDroujkova) (2011-10-21 17:08:10)

There are classic (in math ed circles) experiments where kids determine which of the mixes of orange juice and water will taste more like orange juice (for example, 1:2 vs. 3:4). The classic study is done on paper, presented as symbols or diagrams, which is sort of funny, in a sad way. In the math club, we once played with making simple shakes out of milk, honey and cocoa. That was a lot of fun, and good math. Please blog if you work with kids on tea experiments - I'd like to know how it works.

Brian J. (2011-11-05 05:31:56)

Just a quick note: it seems like you're working with a taste-level instance of a broader phenomenon discussed by epistemologists: we need to see contrasts in order to see similarities. If I have a very dark blue pair of pants, I'll tend to see them as black if I wear them with a white shirt. But, if I lay out the dark blue pants against a black shirt, I'll see it as blue. Same, even with the color black itself. When I lay out blue-black against red-black against green-black, I can see the differences against each other. But, if I take one at a time and put them against white, it will be harder to see. Same with the color white!

Seth Roberts (2011-11-05 13:47:14)

Brian, that's very interesting. You write, "if I lay out the dark blue pants against a black shirt, I'll see it as blue". That sounds like an instance of seeing similarities (dark color) brings out differences (blue vs. black). Not needing to see differences in order to see similarities (which is also true). An instance of that is comparing blue-black to white brings out the similarity between blue-black and red-black (both are dark).

Jim (2011-12-01 08:11:04)

Interesting concept to apply on the spiritual level as well. Do we get used to certain thought processes that are higher in nature and therefore spoil us into keeping to those processes, therefore making us better people?

Zans (2011-12-20 15:34:23)

That sounds like an interesting observation. I wonder what's the best way of making use of it? Developing a liking for tea is good if you want to drink more tea, but at this point in my life I don't see how I would benefit from developing connoisseurship for wine, movies, or other trivial things. However, there can be certain qualities that would be very useful to develop. Developing a connoisseurship for clothing (something that most women acquire naturally through shopping) could allow one to rise in society faster. A connoisseurship in writing could allow one to become a better writer. The same could be said about speeches and any type of art or crafts. You could argue that developing a good taste in a field is necessary to advance in it (eg you need to be a connoisseur of indie films to make good indie films). But what other hidden willat effects could one exploit? Could you become a connoisseur of productivity? A connoisseur of conversations? Why not see if you could compare two days of your life to each other? In theory you could compare any two things so long as you had them side by side and were mindful of the differences. There's so much potential here, where would you even start?

Seth Roberts (2011-12-20 16:54:03)

The same could be said about speeches and any type of art or crafts. You could argue that developing a good taste in a field is necessary to advance in it (eg you need to be a connoisseur of indie films to make good indie films).

Yes, good point. A friend of mine suggested that musicians be trained by being exposed to side-by-side versions of the same piece. His underlying idea was the same as yours. I like your generalization of it.

Mark Milley (2012-02-21 08:40:04)

Do you believe this study counters your hypothesis? If not, how do you feel they are integrated?  
<http://www.npr.org/blogs/thesalt/2012/02/14/146874769/why-the-best-chocolate-is-the-one-you-eat-last>

Nick (2012-03-04 10:22:27)

Usually when I cook, I often ask for feedback from my wife and or other guests and compare their experiences. I try to elicit as much description as possible and try to force comparisons with past memorable shared dishes. I make small changes each time I cook mostly with substitutions and not volumes. I usually see much more changes than they do, but I also miss some observations. In a tapas I made recently my wife and her father tasted a sardine like flavor independently and without the others awareness. I didn't include any sardines but did use fish roe. Was there a genetic connection? I didn't taste sardines either. I am a foodie but forcing them to make comparisons on a regular basis has made them foodies as well. I find with non foodies in general mixing multiple brands of the same thing usually gets the response of "it's better than usual". For example mixed rice, and mixed coffee brews.

## More About The Willat Effect (2011-10-18 19:21)

[1]The Willat Effect is the hedonic change produced by side-by-side comparisons of similar products – for example, two green teas. It happens in seconds: Suddenly the differences matter more. Some versions become more pleasant, other versions less pleasant. I first noticed it with limoncello that my friend Carl Willat offered me. Here are some reactions to [2]my recent post about it:

1. [3]A Facebook comment from a friend of Carl's:

I too can confirm the existence of The Willat Effect. Example: I'll look at a coat that feels and looks great, see the price and say I can't afford this. Then I'll try another on and it's close to the first but not quite but it's also 300 dollars less. I opt for the first, spending more. Carl's taught me to never settle for second best. And he doesn't make a bad limoncello either.

Yes to both. I recently went bike shopping in Beijing. I asked a Chinese friend who makes the best bikes: Giant, she said. A Taiwanese company. I found a Giant store. I chose the model I wanted. I test-drove it. Fine, except the seat was too short. This could not be fixed, they said. I didn't like any other Giant model. I would have to buy a different make of bike. There were other bike stores nearby, all with cheaper bikes. (Giant bikes cost about 40 % more than the next most costly.) I tested a few. The cheaper bikes were clearly worse than the Giant bike: less smooth ride. Too bad for me. I chose one to buy. The problem of too-short seat remained, but the seller said he could fix it. He brought out a longer neck that could be attached to a seat. I bought the longer neck, took it to the Giant store, and got my first-choice bike. I am especially pleased how smoothly it rides. In the Giant store (franchise), there was no bargaining – the sticker price was the actual price – and the employees were standoffish. In the other stores (non-franchise), you could bargain and the employees were friendly. [4]This talk mentions the very smooth ride of a very expensive car.

2. [5]A Boing Boing post about this linked to [6]a side-by-side comparison of expensive cameras – that is, a side-by-side comparison of the pictures they take. As [7]David Scrimshaw commented, this sh\*\* is dangerous. It could make me dissatisfied with what was previously (and in other ways still is) perfectly acceptable.

3. I compared black tea steeped for 3 minutes with the same tea steeped for 5 minutes. I tasted them side by side. I have been drinking black tea for 10 years. For the first time I noticed that the 5-minute tea had a strong bitter note unnoticeable in the 3-minute tea. People had told me that if you steep black tea too long it becomes bitter. I thought they meant if you steep it for 8 minutes it becomes bitter. I routinely steeped black tea 5 minutes. I told someone about this and he said rinse the tea first. This made no sense (experienced tea drinkers rinse certain green teas, not black teas) but I tried it. I found that ten seconds of rinsing (add water, wait 10 seconds, discard water) didn't eliminate the bitterness. There was no clear difference between rinsed and unrinsed tea.

4. I agree with commenters who said I should taste my tea "blind" – not knowing the price. That's a good idea. During a tea-tasting tour of Beijing (which did not include side-by-side comparisons of similar teas and had little effect on my green tea consumption), I learned that at the wholesale level green tea leaves are priced lot by lot. The buyer tastes tea made from the tea leaves for sale and offers a price. If I notice a correlation for green tea between cost and how much I like it, it presumably reflects this earlier process. As far as I can tell in Beijing there is no advertising for different varieties of green tea. Tea stores usually sell it in bulk in identical bins. No packaging, no boasts or claims.

5. Does the effect happen because I knew the teas cost different prices? I doubt it. During the first example, with limoncello, I had no idea of the prices. The homemade limoncellos, which were not identified, had no price. I have noticed the effect [8]with YouTube videos (different covers of one song), which are free. I have done side-by-side tastings of cheeses, wines, etc., that varied greatly in price countless times. No Willat Effect, presumably because they weren't similar enough (e.g., the two wines came from different lines of grapes). But I agree it would be nice to eliminate the effect of price differences.

6. [9]Wangston commented: "More expensive things taste better because rarity is delicious." There is certainly pressure to say expensive things taste better. You/we are supposed to think that. Millions of advertisers would like us to think that. Surely the phrase the finer things in life came from an ad. Maybe ads are where the pressure comes from. In my experience, without side-by-side comparisons more expensive things usually do not taste better. For example, I have never done side-by-side comparisons of wine. And expensive wines ( \$30/bottle) taste no better than much cheaper wines ( \$10/bottle). Before I did side-by-side cheese tastings, \$30/pound cheese tasted no better than \$10/pound cheese. After side-by-side cheese tastings, only then did I notice and care about the difference. I started to pay much more for cheese. I wish I could make the cheap stuff taste better but every time (tea, cheese, orange marmalade, sake) the expensive stuff turns out to be what tastes better. Contradicting the "rational actor" assumption of economists.

7. [10]Robin Barooah commented that with experience you form a mental map of the product space. He is "something of a coffee connoisseur" and has a mental map of the coffee space. This has allowed him to enjoy less-than-the-best

coffees because they have their place and he enjoys brewing them in different ways. My limited experience entirely supports this. I have never gone far with these close comparisons. I am not a connoisseur of anything. But from my mere two weeks of close tea comparisons I feel the beginnings of a mental map. I hope, as Robin says, it will allow me to enjoy tea I can afford. In Beijing, the most expensive tea is insanely expensive – like \$1000/pound.

dearieme (2011-10-19 04:39:13)

We've just done a gin test, in the form of G & T with a slice of lime: Gordon's vs Beefeater vs Bombay Sapphire vs Adnam's First Rate. Conclusion: We do like G & T. The choice of gin is secondary, but perhaps the Bombay Sapphire edged it. Maybe we'll compare tonics some day.

Elizabeth Molin (2011-10-19 06:12:35)

A couple of years ago we were lucky enough to be invited to a Bordeaux wine dinner (my favorite wine at that time), featuring wines that STARTED at \$85/bottle. I discovered that it would be foolish for me to spend (allowing that I could) over \$250 a bottle, because my palate could not distinguish between the wines above that price level. Up to \$250, I could taste differences; the one I liked best was not the most expensive, but close. This experiment (if I can call it that) left me with new ideas about professional wine tasters: can they REALLY tell the difference? I'm skeptical, but if they can, they have my profound respect.

David (2011-10-19 06:22:00)

I have long known of this effect, but I hadn't framed it quite this way. I have a good memory for taste, so I am able to imagine foods side by side even if sampled at different times. I have long tried to avoid even a taste of premium foodstuffs when offered to me, if I know that I will not be able to afford them after the free taste. I was happy with my cheap tea, chocolate, cheese, etc., until I tried the better versions. Now I am forced to compromise either my eating pleasure or my budget on the things where I didn't resist the taste. Now I know what my problem is called! One example where I have actually been successful to a small extent is tea. I don't order the samples of the super premium teas from my tea catalog. I could afford the sample but not the bulk, and I know that having had the sample I would probably be less satisfied with my merely premium tea.

Matt B (2011-10-19 08:48:51)

Paul Jaminet, a tea connoisseur over at Perfect Health Diet is particularly concerned about toxins in Chinese (vice Taiwanese and Japanese) teas. <http://perfecthealthdiet.com/?p=2101> Somewhere on his blog I recall seeing that he or his wife Shou-Ching

steeps tea for a minute, then discards that water and steeps again, since any toxins in the tea would be present on the surface, and that would serve to eliminate much of them.

Duncan (2011-10-19 10:14:36)

YouTube videos are free, but the reputation (assuming you have any knowledge of this) or appearance of the artist(s), the quality of the video, etc., may affect your perception of the quality of the renditions.

Jeffery Fields (2011-10-19 12:42:52)

I too have difficulty in deciphering the quality of wines. I think I may also do a type of blind tasting to understand the difference of woody, fruity, etc....Jim

marmolillo (2011-10-19 14:01:49)

A wine of 30 \$ bottle it is not expensive wine. In wine is probably where it is more difficult to appreciate the extraordinary quality of a expensive one (300 \$ and much more). Usually they are not better tasting, just unique in flavour.

Jim (2011-10-19 17:12:25)

When I was in high school, I had this experience with stereo equipment. My stereo system was great until I heard my friend's older brother's high-end stereo system. Then mine sounded like an AM radio.

Paul Sherrard (2011-10-20 14:34:03)

Seth, a question: Why are your comparisons always evaluative instead of merely descriptive? In other words, why do the differences between things always lead to the conclusion that one is BETTER than the other? I like bitter lager when it's cold out and smooth lager when it's hot. High-acidity, light-bodied coffee when I'm taking my time over it; full-bodied coffee when I'm knocking one back fast on my way to the subway. And sometimes one is just in the mood for different things. I think a side-by-side comparison has its uses, but if it's used strictly to decide "what's better" then (I suspect) a certain type of thing will always "win"—the type of thing with immediately obvious virtues, that wears its charm on the surface, as it were. The instinct to rank everything from best to worst tends to make complex things dull, in my opinion. If I may make a pretty big digression, I always feel this way when the Winter Olympics are on and the poor figure skaters have to go through hell. Figure skating is simply a far more complex thing than ski jumping or racing, and the attempt to rank performances in defiance of this fact reduces world class athletes to quivering choke machines every time.

Paul Sherrard (2011-10-20 14:36:04)

("ski jumping" above refers to distance jumping, not freestyle.)

Seth Roberts (2011-10-20 15:17:09)

Paul, you ask "Why are your comparisons always evaluative instead of merely descriptive?" It isn't "instead of"; it's "in addition to". In my experience, side-by-side comparisons increase both: I am more conscious of the differences between two things (e.g., two teas or the same tea brewed two different ways) and I care about the difference more. Why is there is a change in desirability (one of the things being compared becomes more desirable, i.e., "better") not just better knowledge of the differences? My evolutionary explanation is: So that the experience will cause action. You pay more for the "better" one or become more likely to buy it. You compare X and Y side by side, X becomes more pleasant, you buy more X. Resources flow to the makers of X. That's the evolutionary point. In the bigger economy, not just trading, I agree with you. For example, professors often rank their students based on how smart they are. Smarter being a synonym for "better". Not a good idea. As you say, a lot is lost by such a narrow descriptive system.

Jazi yechezkel zilber (2011-10-20 18:50:17)

There is reserach showing that when people see pictures of beautiful models their satisfaction and commitment to present partner declines.

Paul Sherrard (2011-10-21 07:40:23)

Thanks for elaborating! One further question: Is the "better" item always more expensive, and is the more expensive one always "better"?

Seth Roberts (2011-10-21 14:02:56)

Paul, the answers to your questions are no and no. When I brew tea, variations in brewing time and whether I wash the tea or not have made clear differences. The tea – and its price – remain the same. So far with green tea, I have only tried three varieties and within that tiny sample, yes, the more expensive is better. But there are so many green teas and some are so expensive I am sure that there is a price above which the more expensive teas are not noticeably better. In the big world of tea (not just green tea), my favorite teas have not been expensive. However, that was before I started learning from these side-by-side comparisons.

Paul Sherrard (2011-10-22 10:56:27)

This blog is so great. Thanks Seth!

Memphis Boot Camp (2012-02-03 00:22:26)

In my experience, without side-by-side comparisons more expensive things usually do not taste better. I have a good memory for taste, so I am able to imagine foods side by side even if sampled at different times. I have long tried to avoid even a taste of premium foodstuffs when offered to me, if I know that I will not be able to afford them after the free taste.

### **Crazy-Spicing Coke Machine (2011-10-20 07:05)**

Has someone been reading *The Shangri-La Diet* (2006)? In 2009, the Coca-Cola Company [1] began offering new Coke machines ([2]Coca-Cola Freestyle) that are close to what I proposed in the last chapter. They produce great diversity of flavor because you can mix many different flavors. Your soft drink, with or without sugar, can be different each time.

According to [3] this curiously-worded article, they did not get the idea from me:

The self-serve fountains – which represent a complete departure from anything The Coca-Cola Company has offered previously – were in development for more than four years prior to launching in 2010.

In *The Shangri-La Diet*, I proposed adding random flavoring to your food so that it tastes different each time. Someone named this crazy spicing. Nose-clipping is much easier but less socially-acceptable.

Thanks to Phil Alexander.

1. <http://www.popsci.com/scitech/article/2009-07/coca-cola-freestyle-most-advanced-soda-fountain-ever>

2. <http://www.coca-colafreestyle.com/>

3. <http://www.marketwatch.com/story/del-taco-tests-coca-cola-freestyler-new-touch-screen-fountain-in-12-locations-throughout-southern-california-2011-10-17>

Meegs (2011-10-20 10:51:48)

You can do this at home with sodastream as well.

Alex Chernavsky (2011-10-20 12:56:06)

Seth, do you have a sense of how much (or how little) extra spice you need to add in order to fool your system? So if I eat a bowl of plain oatmeal every day, is it enough to top it with a sprinkle of random herb/spice from the pantry, or do I really need to spice the hell out of it to get the desired effect?

James A Donald (2011-10-20 13:40:25)

I tried fairly strong spicing with random garlic, ginger, and chili. That, I think, should be strong enough for anyone, but did not seem to work. Maybe one needs a wider variety of spices.

Nancy Lebovitz (2011-10-20 14:42:09)

I suspect there's individual variation- I'm moderately inclined to seek out new flavors, and they don't make me eat less.

Seth Roberts (2011-10-20 15:28:09)

James, when I've done crazy spicing I used about six or seven spice blends (so that I wasn't already familiar with them) and randomly put two of them on my food. Alex, you need to add enough spice so that it gains a "ehh" (what is this?) taste. Hedonically neutral. "Is this food?" you should wonder. "It doesn't taste like any food I've had before."

Erica (2011-10-20 17:05:25)

I don't understand how Coke has "just" come up with this. I mean didn't everyone do this as a child. They were called Suicides... you mix any and all of the pops available in the fountain. This was in the late 80's early 90's and everyone I knew did this. :)

BlueMorrissey (2011-10-20 18:13:30)

Ha, we called them Graveyards when I was a kid in the 80's.

Alex Chernavsky (2011-10-20 19:23:42)

In college, it was called "purple Jesus punch". Everyone was required to come to the party with a bottle of some random alcoholic beverage. All the bottles were dumped into a big plastic garbage can. When you drank the punch, your face turned purple, and you said, "Jesus!".

Nancy Lebovitz (2011-10-21 09:08:50)

I think you'd be amazed at how fast I can go from hedonically neutral to "hey, that's kind of interesting". Admittedly, my recent experience was with food which had been deliberately flavored in a Korean restaurant, but one of the side dishes definitely make a fast transition from weird to pleasant.

## **Beijing Earthquake (2011-10-21 05:00)**

Last week an earthquake centered in Russia was strong enough to be noticed in Beijing. A friend of mine, a designer for Sony Ericsson, was on the 22nd floor of a 27-floor building. She felt the building sway. Everyone rushed downstairs. She was the only one carrying a laptop. Her colleagues told her she was stupid: The company owns that laptop.

dearieme (2011-10-21 07:48:23)

Long ago I knew a Postdoctoral Fellow, one of the small number who had then been let out of Red China to work/study in the West. Once he'd got the hang of things he confided to me that he'd learned the expression "civic responsibility" as a good summary of what no Chinese took seriously: they cared only for self and family. I was astonished at his courage, or foolhardiness, in saying as much to a near-stranger. (We also had an interesting conversation in the wake of his first visit to the British Museum. "Were the civilisations of Egypt and Mesopotamia as old as the museum said?" "Yes." "Then I have been lied to.")

Jack (2011-10-22 22:34:47)

I would like to know how he had been lied to. What was his country telling him of ancient civilizations?

dearieme (2011-10-23 03:59:17)

He didn't elaborate much, apart from checking with me that he understood correctly that the British did not consider themselves the descendants of the ancient Egyptians, Sumerians and whatnot. But that he'd been taught that China pretty much predated everyone at everything was presumably the gist of it - whatever it was, it left him unhappy at the history he'd been taught.

dearieme (2011-10-23 04:02:26)

Come to think of it, there must be plenty of Chinese in their mid-sixties who could, if they wished, explain why he might have been upset. My evidence is restricted to the remarks by one clever, serious-minded, reflective but perhaps naive scientist.

### Assorted Links (2011-10-22 05:55)

- [1]Interview with me on Jimmy Moore's Livin' La Vida Locarb
- [2]This article about natto helped its author win [3]a prize for best newspaper food column
- [4]great QS talk about self-measurement by John Sumser. "It all started when I quit smoking. Bad idea. Since I quit smoking in 2004, every quarter for 7 years it has rained shit on me."
- In [5]a QS talk, I compare the Quantified Self movement and the paleo movement.
- [6]Chinese high-school students in America: Not what was promised. Lack of "rigor" has benefits, as [7]I have blogged: "Dismayed by the school's [poor] college placement record, Chen considered transferring. Instead, he began to enjoy himself. Because his courses were undemanding, he had time for friends and outside interests. He took four Advanced Placement tests on his own. "I've developed my personality a lot," Chen said. "Everything turned out for the best."
- If you read The China Study by T. Colin Campbell, a pro-vegetarian book, you may remember the big role played by some casein experiments with rats. Rats that ate a low-casein (= low animal-protein) diet were supposedly in better health than rats that ate a high-casein (= high animal-protein) diet. In [8]this article Chris Masterjohn shows how misleading that was. "One thing is certain: low-protein diets depressed normal growth, increased the susceptibility to many toxins, killed toxin-exposed animals earlier, induced fatty liver, and increased the development of pre-cancerous lesions when fed during the initiation period of chemical carcinogenesis."

Thanks to Janet Chang.

Mark (2011-10-27 05:58:29)

For more on how misleading the China Study is, you should really check out Denise Minger's analysis. <http://rawfoodsos.com/the-china-study/>

Seth Roberts (2011-10-27 14:23:13)

Mark, good point. When I read The China Study, I was more impressed by the rat experiment data than by the survey data (from China).

## **Bipolar Disorder: Good Results With Blue-Blocker Glasses (2011-10-23 05:00)**

At the Shangri-La Diet forums, [1]Anima writes:

I have been diagnosed with ADHD and Bipolar II disorder. I am also a Non-24, a chronic circadian rhythm disorder where one's body thinks a day is longer than 24 hours. . . .I've been using amber safety glasses (around \$3 in the hunting section of the sporting goods store) for [2]dark therapy. I put them on 3 hours before I want to go to sleep. They block blue light, allowing dark therapy without the dark. I also wear an eye mask while I sleep. The glasses make me look like a big weirdo, but they really work. It's easier to get to sleep, and they prevent hypomania (the milder form of mania that people with Bipolar II experience) better than any medication I have tried. It makes sense that almost anyone could benefit from them, because our ancestors were not exposed to blue light after dark.

She makes many other interesting observations, such as how she kept her cat from waking her up too early.

I don't have trouble falling asleep but this makes me wonder what effect blue-blocker glasses would have if I wore them regularly at night. Nowadays I carry them in my backpack in case I have to be exposed to fluorescent light at night, such as on the subway. Even though I avoid fluorescent light at night, I still get blue light at night from my laptop screen. I have thought it is too weak to matter because using [3]f.lux (which reddens the screen at night) made no clear difference. I can test this idea again by wearing blue-blocker glasses. I have been using a Zeo to measure my sleep, which may help me notice changes.

At Genomera, Michael Nagle and Eri Gentry are doing [4]a study of the effect of blue-blocker glasses on sleep.

---

Joseph Buchignani (2011-10-23 06:20:08)

Hey Seth, F.lux sucks. It's too weak, and there's no way to fix it. I use redshift on Linux, which is quite powerful and actually does make a difference. When I switch from redshift to F.lux on my Windows PC, my eyes hurt. I think it definitely makes a difference.

Seth Roberts (2011-10-23 07:12:54)

okay, Joseph, you've convinced me to try wearing blue-blocker glasses after 9 pm.

Valtsu (2011-10-23 13:06:53)

Hello Seth! Have you heard about this Finnish product: <http://www.valkee.com/uk/> ? They report that in one study, subjects achieved a huge symptom relief rate with that product. However, the study report hasn't been published yet. "In Valkee's CE medical device certification clinical trial, 92 % of severely depressed seasonal affective disorder (also known as 'winter blues') patients experienced total symptoms relief in 4 weeks with 8-12 minutes of bright light via ear canal [8]." The product costs a huge amount of money here in Finland. Almost two hundred euros. Hmm... I think that I should possibly try blue blockers. Are all eyeglasses with orange lenses sufficient to block the melatonin-suppressing effect of my computer screen?

Tom (2011-10-23 22:23:15)

*The product costs a huge amount of money here in Finland. Almost two hundred euros.* Why not make your own? It appears to be nothing but two high intensity LEDs and a rechargeable battery.

Stephen M (Ethesis) (2011-10-24 19:35:48)

Ok, I've got to know how she kept the cat under control. ...

Stephen M (Ethesis) (2011-10-24 19:37:02)

Other than moving his supper time. Guess I have to close off the feed the critter on demand system we use now.

Nansen (2011-10-25 13:46:52)

Seth, have you changed your belief that *incandescent* light at night is harmless (with respect to circadian rhythms)?

Seth Roberts (2011-10-25 14:35:51)

I still believe incandescent light is harmless.

Joseph Buchignani (2011-10-27 08:42:52)

After just having been woken up by a stupid blue cell phone screen, I feel even more certain about the effects. Good luck with your experiment.

Steve Mayall (2012-03-20 12:56:41)

Incandescent light will certainly affect your circadian rhythm. In fact any light source which contains a blue component will suppress melatonin production. This is due to the ganglion cells in our eyes. They are sensitive to blue light as they connect to the pineal gland. Blue light can travel through our eyelids and when it hits the ganglion cells, melatonin is suppressed and we become alert. When it's dark, melatonin production increases and we feel sleepy. You can place yourself in 'virtual darkness' by wearing blue blocking glasses. I tried a number of different pairs of sunglasses without much success and ended up making my own very cheaply. If you want to try them, google rodsnconesdotnet. I'd be grateful if people could tell me how they get on with them. Best of luck Steve

## Even More About The Willat Effect (2011-10-24 05:00)

I have had tea daily for the last ten years, ever since I discovered the Shangri-La Diet. A few weeks ago, I [1]started doing side-by-side comparisons of similar teas or the same tea prepared two ways (e.g., different brewing times). Would [2]the Willat Effect make me a tea connoisseur?

Since then I have done at least one side-by-side comparison every day. It's almost as easy as making an ordinary cup of tea and a lot more fun. These comparisons have taught me more about tea preparation than the previous ten years. I've learned:

1. The black tea I have (an Earl-Grey variant) tastes better when brewed for 3.5 minutes than 4.0 minutes.
2. The black tea tastes better when I use 1.5 grams of tea than when I use 2.0 grams of tea. (After starting these comparisons, I bought [3]a scale for weighing tea.)
3. One of the green teas I have tastes better when "rinsed" for 30 seconds before brewing 1 minute than when simply brewed for 1 minute. In China, this preference (rinse green tea before brewing) is common. I was reminded of it by [4]this comment and [5]Paul Jaminet's post about tea. Black tea is different, as [6]I noted earlier.
4. I have a caffeine-free tea blend called [7]Choco Late made of cacao husks, vanilla, and rooibos. The package says brew 5 minutes. Which is nonsense. It tastes better (fuller, more rounded) when brewed 30 minutes than when brewed 15 minutes. (I've noticed the same thing with caffeine-free chai blends. Enormous brewing times, like 60 minutes, produce much better results than short times.)
5. My most interesting discovery is when I brew Choco Late for 30 minutes it tastes so good I no longer want to sweeten it. It is pleasant enough already and sweetness would distract from the complexity, fullness, and slight bitterness. (At first I wrote "lovely complexity, fullness ...") I was shocked when I noticed this. It has never happened before.

[8]This tea-selling website mentions the Willat Effect under the heading "Do you want to be a tea connoisseur?" I hope this means the idea will spread among the fancy-food community. They have a lot to gain from better understanding of how to make people connoisseurs. Many times I have asked people in that community what makes someone a connoisseur? The usual answer is education. In my case, Willat-Effect comparisons (side-by-side comparisons of similar teas) were far more powerful than reading about tea, drinking a variety of teas, going on tea tours, going to ordinary tea tastings (where you taste a wide range of teas), and talking about tea with experts. I have been to five or six Fancy Food Shows and have visited thousands of booths. Exactly one booth offered side-by-side comparisons of similar products. It was their product made with and without a special ingredient.

Willat-Effect comparisons are mini-science. They aren't quantitative but they include three other things central to science: 1. Close comparisons. This is the essence of experimentation. 2. You don't know the answer. 3. You care about the answer.

---

Scott P. (2011-10-24 11:33:17)

I wonder if the rinsing is actually blunting the harshness of hot water versus doing any kind of actual rinsing? Did you rinse then let dry or at least reach room temperature again?

dearieme (2011-10-24 12:58:15)

Does it matter whether the water is hard or soft?

Jonathan Shewchuk (2011-10-25 00:09:35)

Thanks for these observations; I'll have to buy a scale and start experimenting. How do you brew the Choco Late for 30 minutes without it losing too much heat? Do you brew it in a saucepan on the stove?

Oskar Pearson (2011-10-25 01:18:02)

Hi Stray thought: My impression is that some cultures (eg: Italian) make it culturally acceptable to share dishes at the table, as their meals often consist of platters which contain numerous types of meat, cheese, bread, pickles, and so forth. I think this would thus lead to a culture-wide connoisseur effect... which is what we have in Italy, with huge numbers of specialist cheeses, wines, and so forth. Of course this is difficult to prove, but it might be quite nice to create a micro-culture of sharing food with friends and see if people become "more foodie" over time. :) Oskar

Seth Roberts (2011-10-25 12:42:15)

Oskar, yeah, maybe so. I haven't noticed the effect from eating different kinds of salami, though. It has to be two types of prosciutto, or two types of mortadella, etc.

Seth Roberts (2011-10-25 12:45:40)

Jonathan, I don't heat the Choco Late while brewing; that might be a good idea. I have brewed chai for 80 minutes keeping it warm in a microwave by using a temperature probe.

Seth Roberts (2011-10-25 12:50:18)

Scott, I just "rinse" (= soak, wait, discard hot water) and then immediately add more water.

Kirk (2011-10-25 14:55:35)

Reminds me of this quest for the perfect omelet: <http://www.gilttaste.com/stories/699-chasing-perfection> .

Ludovic Gallant (2011-12-25 20:22:36)

An interesting experiment you could try is brewing the same tea, in the same conditions (water, temperature, time) but in different teapots (by example ceramic, yixing (clay), kyusos and gaiwan). You will notice some interesting differences in the taste. PS: The water temperature makes a huge difference, make sure you never use boiling water on green or white teas. Use a 75 degrees water on Japanese green teas and white teas and a 85 degrees water on Chinese green tea.

## The Curious Case of Richard Muller (2011-10-25 05:00)

About fifteen years ago I had lunch with Richard Muller, a Berkeley professor of physics, at the Berkeley Faculty Club. He told me his theory that the "miracles" that the Bible says Jesus performed, such as changing water into wine, were magic tricks. He was writing [1]a novel about it, he said. He also said he had submitted to Science a new theory of climate change based on [2]Milankovitch cycles (cycles of changes in the Earth's distance and tilt relative to the sun). The editor liked it; the problem was getting it past the reviewers. [3]This press release shows the editor succeeded. So Muller was nice enough or curious enough to have lunch with a stranger (me) who could not possibly help him and was/is creative about big questions. He is now retired. He's had great career success, including a MacArthur Fellowship (in 1982). He's won a teaching award. A talented and decent person. (Steve McIntyre, [4]whose comment I read after I wrote this, also says good things about Muller: "one of the few people in this field I regard as a friend.")

Two years ago he started the Berkeley Earth Surface Temperature Project, devoted to improving the climate record. Fine. In March [5]I liked a talk he gave about climate change. Fine. Now he has done something astonishing. In [6]a recent Wall Street Journal article titled "The Case Against Global-Warming Skepticism" he took "skepticism about global warming" to be skepticism that the Earth has warmed recently. In it, he describes several problems with surface temperature measurements. Then he says:

Without good answers to all these complaints, global-warming skepticism seems sensible. But now let me explain why you should not be a skeptic, at least not any longer.

The vast majority of skeptics, including me, believe the Earth has warmed substantially since the Little Ice Age. That's not the issue. Here's the issue: We are skeptical that we understand why it has warmed and in particular skeptical that humans have caused recent warming. A big difference. Muller has ignored the obvious: what skeptics actually think.

Muller's view of "global warming skepticism" is so strange let me state what might be obvious. For me, and many others, there are three issues: 1. Can we trust climate models? I say no: They have never been shown to be good predictors of what they are being used to predict. The physics of clouds isn't simple or well-understood. 2. Is it unusually hot now? I say no: The Medieval Warm Period was roughly as hot or hotter. 3. Has recent warming been unusually fast? (Which is what Michael Mann's discredited Hockey Stick seemed to show.) I say no. Over the past 200 years, the temperature has increased as fast or faster at least twice. Muller's new data doesn't address any of these concerns. Whether surface temperatures are higher now than in 1950 (which is what Muller's new data shows more conclusively than before) is not a big issue.

Why did Muller misrepresent so badly what skeptics say? I don't know. Maybe he wanted to make his results seem more important than they are. Maybe he has never met a skeptic. I truly don't know. Lots of famous scientists (e.g., James Watson) have said what I consider wacky things about unverifiable stuff. But there is nothing vague or unverifiable about this. It is as if Muller had said Shanghai is the capital of China.

James Fallows, whose work I like, [7]has taken Muller seriously. Paul Krugman [8]has taken Muller seriously. Marc Morano, who runs Climate Depot, has [9]responded at length and created [10]a special Muller page. In March, Morano points out, he (Morano) complained about exactly the same thing from Muller: "Who denies that warming has taken place?" Yes. Morano links to many scientists who are displeased by what Muller has done. [11]One says, "It is not true that the Berkeley group has found relevant evidence for the core questions in the AGW debate." Yes. "Doubts about the validity of the surface temperature record constitute something like 1 % of the issues that climate skeptics as a community have ever raised." Yes.

Muller's error interests me because I can't explain it. Perhaps it illustrates how unwittingly we shape reality, as shown

in [12] a famous split-brain anecdote:

The split-brain patient had to point with his two hands at pictures of two objects corresponding to two images that he had seen on the divided screen (one with each of his two separated hemispheres). The patient's left hand [pointed] at the card with a picture of a snow shovel, because the right hemisphere, which controls this hand, [had] seen the projected image of a winter scene. [The left hemisphere had seen a picture of a chicken. When asked why he chose a shovel, the patient said (via the left hemisphere, which controls speech):] you use a shovel to clean out the chicken house.

Split-brain patients do not have more mental tricks than the rest of us. Surely we all do this. My question is: When?

Thanks to Tim Beneke.

---

Alex Chernavsky (2011-10-25 06:35:24)

Why not invite Muller to another lunch meeting, where you can ask him these questions in person?

Lemniscate (2011-10-25 07:31:27)

It's partially the protean meaning of "global warming". Does it mean simply an increase in the global mean temperature? Does it mean anthropogenic (and perhaps catastrophic) global warming? People tend to use whichever meaning serves their propaganda and publicity purposes best, even if it is deeply misleading.

Scott P. (2011-10-25 07:40:40)

What you have described is exactly what has frustrated me regarding this issue for nearly a decade.

JohnG (2011-10-25 08:32:43)

Thanks for continuing to bring lucid reasoning to this debate!

john (2011-10-25 09:22:08)

What is the wacky James Watson stuff?

Seth Roberts (2011-10-25 12:37:00)

Wacky James Watson stuff: fat people are happier than thin people. <http://www.rense.com/general2/fathappy.htm>.

Tom Fid (2011-10-25 14:03:59)

Your historic perspective may be a little thin on the question of whether any skeptics deny that any increase in temperature is occurring. I've seen a great many such claims. Here's one high profile version: August 27, 2010 (D'Aleo & Watts): SUMMARY FOR POLICY MAKERS 1. Instrumental temperature data for the pre-satellite era (1850-1980) have been so widely, systematically, and uni-directionally tampered with that it cannot be credibly asserted there has been any significant "global warming" in the 20th century. [http://scienceandpublicpolicy.org/originals/policy\\_driven\\_deception.html](http://scienceandpublicpolicy.org/originals/policy_driven_deception.html) As Lemniscale points out, the term "global warming" is ambiguous here too, but a read of the paper leaves no doubt that the authors were claiming exaggeration of the long term instrumental temperature trend.

Seth Roberts (2011-10-25 14:38:07)

Yes a small part of the overall skeptic "movement" is about the temperature record. I think it is obvious there has been plenty of warming since the Little Ice Age so I consider that a minor point.

Drewski (2011-10-25 15:32:01)

What Muller has conclusively shown is that climate scientists ARE rigorous in their work and that there is no "fudging". He has put to bed – once and for all – the ridiculous notion of a world-wide conspiracy amongst climate scientists. That is one very important hurdle now crossed.

Seth Roberts (2011-10-25 15:49:16)

Drewski, I am not saying Muller's work is unimportant. I am saying: why does he so badly misrepresent the position of skeptics? As for "world-wide conspiracy" I believe a substantial number of climate scientists (all over the world) have vastly overstated how certain we can be that humans have caused significant global warming. In this sense they have not been rigorous. I would not use the word conspiracy here but whatever word is used, Muller's new data does not change my opinion about that.

Drewski (2011-10-25 15:57:14)

Seth, you know and I know that there is a sizable percentage of skeptics who believe that the whole climate change issue is a scam encouraged and even manipulated by climate scientists out for money or control or both. It has been a distracting influence on the entire debate. Now, hopefully, that nonsense can be put in the dustbin and we can move on to more germane and important matters. Agreed?

Jonathan (2011-10-25 17:29:20)

In your list of issues, I'm surprised you left out "4. Would global warming be bad for us?" This strikes me as the least-discussed but most vulnerable of the four issues. Have there been arguments against the evidence that life flourished, and food was more plentiful, during previous warming periods?

Thomas (2011-10-25 19:26:03)

Seth Roberts said "I think it is obvious there has been plenty of warming since the Little Ice Age so I consider that a minor point." Just because you think it's obvious, doesn't mean everyone does. Just turn on Fox-News on a day of cold weather, and they will scream "where is the global warming those scientists invented". I've seen full books on the issue that deny the ice-record - or claim that weather stations are merely too close to volcanoes. Drewski said: "Now, hopefully, that nonsense can be put in the dustbin and we can move on..." Wouldn't it be nice if the world would work that way.

Christopher Meyer (2011-10-25 22:12:43)

Request: Can you write about your position on ocean acidification (or attach a link in the comments if you've already done so and I missed it)? I respect your opinion quite a lot, so I've been paying attention to what you write about Global Warming, and am trying to keep an open-mind on it. However, even if you were entirely correct that carbon pollution has not led to

an increase in temperature, that would not affect my opinion that we need to take drastic measures to reduce our carbon pollution. I feel that ocean acidification is the knock-down argument that carbon pollution is having devastating effects. Carbonic acid dissolves calcium carbonate, which is the substance of which shell-life and corals are comprised. Carbonic acid levels are steadily rising, and if they continue to do so shells will grow weak and brittle, which in turn will create an ecological catastrophe. Perhaps the reason we're not seeing as much of a temperature increase as expected is because the carbon is being removed from the atmosphere and absorbed into the ocean. But that doesn't make carbon pollution any less of a problem.

Ashish (2011-10-25 23:28:10)

The top hit for a Google search for: Fox News "global warming" includes this quote: "The planet isn't heating up, in other words." Based on my reading of the newspapers, I'd say that most (US Republican-voting) skeptics of global warming do deny the existence of global warming or any climate change. And yes, they also deny that we have anything to do with it. Because when "1000 year weather catastrophes" roll around year after year, they can just blame gay people.

dearieme (2011-10-26 07:35:05)

I find it entirely plausible that there's been global warming - like many people, I expect, I compare my experiences with my parents' in my part of the world: the notion of warming is consistent with that comparison. But ever since I first looked into Global Warming I've been baffled by the incompetence and, in my view, dishonesty displayed in even so apparently simple a task at trying to calculate a graph of mean land surface temperature versus time, with a decent stab at representing the degree of uncertainty involved. I can't say whether Muller has achieved this either - for a start, I suspect him of having used surface "measurements" that are not measurements at all, having been pre-fudged. Anyway, I'll have to wait for his stuff to be published and then, if I can summon the effort, have a look at it. I have already seen a couple of criticisms that argue that he hasn't remotely achieved what I referred to as "a decent stab at representing the degree of uncertainty involved".

Drewski (2011-10-26 17:30:34)

dearieme says that Muller's measurements may have been "pre-fudged" - and the beat goes on.

dearieme (2011-10-27 06:04:24)

As I understand it (and I'm open to correction) Muller used the usual land surface data, which is undoubtedly pre-fudged, or as the climate scientists like to put it, "adjusted". (Surely no-one denies that it's been "adjusted" - the adjusters boast of their efforts.) So I am still left in the preposterous situation that I find it entirely plausible that the world has warmed since, for example, my parents' childhoods in the 1920s, but I cannot gauge how much it has warmed because no-one has managed to publish a graph that uses un-fudged data, and includes a decent estimate of the uncertainties in the results. This is, I have to say, scandalous. Millions upon millions have been spent, and still there's nothing competent and trustworthy. Why the climate scientists behave like such berks I don't know - do they believe that the warming is so small and uncertain that they need to lie about it? Is doing a decent statistical analysis beyond their intellectual level?

Drewski (2011-10-27 08:13:31)

dearieme, the whole point of the BEST study was to revisit the RAW data with complete openness and to make this data available to any and everyone who wishes to crunch the numbers themselves. BEST used new methodology, a world-class team of climate scientists and statisticians (including the famed skeptic Judith Curry) and looked specifically into areas (such as UHI) that other skeptics deemed to be ignored by NASA, NOAA and HadCRU. BEST also increased the sampling by 5 fold (39,000+ stations) and compiled 1.2 billion (with a 'B') data points. Statistically speaking, getting 4 independent temperature reconstructions (5, if you want to count Anthony Watts' Surface station study) to be so closely aligned based on false data would be like flipping a coin and getting "heads" five hundred times in a row. Your use of the terms "pre-fudged" and "un-fudged" is nothing more than gobbledygook.

dearieme (2011-10-27 11:18:26)

And the representation of uncertainty?

dearieme (2011-10-27 12:22:20)

Here's Matt Briggs on the uncertainty. "BEST's estimates of uncertainty are too narrow. That is, BEST is too sure of themselves. By how much they are uncertain, there is disagreement. There is strong evidence that their certainty is off by at least a factor of two. That is, BEST should at least double its uncertainty, which means we should have even less confidence in what happened in the past. Which means we are still unsure—we may always be unsure—exactly what the temperature was prior to about 1940. We may be sure what it was at a few individual land stations, but we will probably remain unsure what the temperature was averaged over all land surfaces. This is likely a case of scientific tough luck. If only our ancestors had thought to measure temperature most assiduously, we wouldn't be in this boat." For Doug Keenan's view, there's this <http://www.informath.org/apprise/a5700.htm> As for our other differences, I suppose I'll just have to wait until the papers are published and read them and the criticisms that will presumably appear. I'll be particularly interested in Steve McIntyre's, who obviously has no animus towards Muller but is properly sceptical of any data analysis put before him.

Drewski (2011-10-27 21:45:54)

Before I comment on the uncertainties or error bars, lets agree that climate scientists involved in temperature reconstructions are above reproach and that they are both honourable and scrupulous in their work. Agreed?

dearieme (2011-10-28 05:36:28)

Don't be daft.

Drewski (2011-10-28 08:42:32)

Don't be disingenuous and pretend you want a proper discussion. You have just been presented with a 5th temperature reconstruction that so closely matches the other 4 that it would be next to impossible for any of them to have been "fudged", "pre-fudged" or "un-fudged" – statistically speaking of course. Therefore, you must either trust the data and how it was collected or you don't trust statistics. Which is it? You have not even a hint of a shred of a whiff of impropriety by any scientist involved with temperature stations and yet you choose to continue the charade. You, my dearieme, have an agenda and honesty doesn't enter in to it.

dearieme (2011-10-28 09:44:01)

Of course I have an effing "agenda". I think the climate scientists are largely a bunch of duds who made silly, hubristic claims in the early days and since then that many of them have been dishonest as a way of defending their positions. But that's not the point here. This is the one bit of the whole field that the Global Warming hysterics and the sceptics needn't disagree on, namely that it has (probably) got warmer. My complaint is specific: they still haven't been able to produce a convincing curve of mean surface temperature accompanied by a decent stab at its uncertainty. What the hell's the point speculating about the cause of the warming, or predicting its future course, if you can't even provide a trustworthy account of its history? It's an extraordinary failure.

Drewski (2011-10-28 10:35:30)

Moving the goal posts I see. The conversation is not about the ramifications of global warming but about about temperature reconstructions from recording stations of which there have now been 4 (5 with the American focused Surface Station study by Watts). Because they all closely align means that there is an almost statistical impossibility that any one of them could have been fudged, pre-fudged or double fudged. This logically implies that the data from NOAA, NASA, HadCRU and BEST was collected in a professional and rigorous manner. If you can't you admit that then we have nothing to talk about.

### **"We are Heroes, They are Villains": My Brilliant Students (2011-10-26 05:00)**

At Tsinghua University, which is like a Chinese MIT, I am teaching a small class (25 students) called Frontiers of Psychology. It is required of freshmen psychology majors. There are a few students from other majors. So many of my students do brilliant work that it is hard to keep track. For example, two classes ago I started having presentations (short

talks related to the reading). In the very first one, a student talked about her dysmenorrhea and self-experimentation to stop it. Later, during a discussion of how to give a talk, another (female) student said, "I could not have given such a talk." "That's a compliment, right?" I said. "I don't know," she said. Which is only to say what a radical and stunning talk it was.

For this week's class I assigned several readings, from which students chose one. [1]The shortest and most popular paper, by Joshua Knobe, a Yale professor of philosophy, was about judgments of intentionality. Knobe showed subjects various scenarios and asked them whether the side effects of a action described in the scenario should be considered intentional or not. Changing one word had a big effect. Knobe concluded that we tend to see bad side effects as intentional, good side effects as unintentional. I assigned it because the effect of changing one word was large and I liked the source of data ("Subjects were 78 people spending time in a Manhattan public park").

Here is one student's comment:

When I was in primary school, we had a very kind English teacher who was quite close to me. After she left school, she sent some photos to me and I found it a great honor to deliver them to my classmates. Later on, a math teacher got married and she gave another pupil some sweets to deliver the class. I felt unpleasant since not every student could get a sweet. I thought it unjust.

However, in both cases, photos and sweets, there weren't enough for the whole class. The only difference was who passed them out. When I did, the main issue I cared about was "I'm the one to deliver them"; in the other case, "Why can't everyone get one?"

She titled her comment "We are the Heroes, They are the Villains". Her point was that Knobe's results could be explained by the idea that we slant our judgments of others and ourselves to make them look worse and us look better – an explanation that Knobe didn't consider.

Knobe isn't the only one who didn't think of it. Other students proposed other plausible explanations. But I think the "we are heroes" explanation is quite plausible because three other students made the same point in other ways. One of them repeated a story from a test preparation book:

A teacher had a student do ten math problems on the board. Then she asked another student to describe what he saw. "Two of the answers are wrong," he said. "What about the eight correct answers?" said the teacher.

Not a true story but surely based on actual events. Another student told of the time her teacher had made her push her fellow students to exercise for an half-hour per day. The students complained to her about their loss of time. Later, however, her class had finished first in a physical competition – much better than usual. Her classmates did not give her any credit for this.

To emphasize how unobvious this idea is, here is [2]what two professors make of Knobe's results:

This asymmetry in responses between the 'harm' and 'help' scenarios, now known as the Knobe effect, provides a direct challenge to the idea of a one-way flow of judgments from the factual or non-moral domain to the moral sphere. 'These data show that the process is actually much more complex,' argues Knobe.

My students disagree. Their proposed explanations, such as the "we are heroes" idea, were not "much more complex".

I believe they have noticed a broad truth about human nature that has escaped many psychologists, not just Knobe. In [3]this excerpt from his new book, my former colleague Danny Kahneman describes what he calls "the illusion of validity": personality judgments were considered more predictive than they actually were by the people who made them. Could this be another example of "we are heroes"? The "we are heroes" idea also explains the Lake Wobegone Effect: Most people consider themselves above average. The technical name for this is [4]illusory superiority. The Wikipedia article about illusory superiority does not mention the Knobe Effect and vice-versa. In this important aspect of human nature, professors (including me) have had trouble seeing that the trees make a forest.

SB (2011-10-26 06:16:52)

This reminds me of the book "Mistakes were made, but not by me". [http://www.amazon.com/Mistakes-Were-Made-But-Not/dp/0156033909/ref=sr\\_1\\_1?s=books&ie=UTF8&qid=1319634975&sr=1-1](http://www.amazon.com/Mistakes-Were-Made-But-Not/dp/0156033909/ref=sr_1_1?s=books&ie=UTF8&qid=1319634975&sr=1-1)

dearieme (2011-10-26 07:22:40)

I suppose there must be several ways of pronouncing Knobe.

Tom (2011-10-26 10:02:36)

It's fascinating that the concept wouldn't occur to psychologists. Is it too obvious to be worthy of their notice? To me, the insight is almost a truism. "Where you stand depends on where you sit." ? Nelson Mandela It may be a corollary of your idea that academics disdain simple, high-benefit research in favor of complex research of little use: Perhaps they also disdain simple, actionable conclusions in favor of complex, useless ones.

Scott P. (2011-10-26 10:16:26)

I have often thought that if we all know someone we believe to be "crazy" then surely some of us are that someone to someone else.

Åse (2011-10-26 10:20:33)

This is interesting (that it has not been noticed), because ingroup-outgroup (and how you talk about and deal with them) is very standard fare in social psychology, as is, what is called, the fundamental attribution error (which is not necessarily group based, but suggests that you give environmental excuses for yourself, and dispositional for others).

Seth Roberts (2011-10-26 13:12:43)

"Is it too obvious to be worthy of their notice?" I don't think it's obvious at all. After it is pointed out it may sound obvious. My students came up with other possible explanations of Knobe's results. Meaning the "we are heroes" explanation wasn't obvious to them.

Seth Roberts (2011-10-26 13:20:16)

SB, yeah, that book is a good source about this sort of stuff. I haven't read it but the title and range of topics covered are saying something like this is a big part of human nature.

Alex Chernavsky (2011-10-26 13:40:35)

*Mistakes Were Made (But Not by Me)* is truly excellent. I only wish I could force all my co-workers, relatives, and friends to read it, so that they might see themselves as they really are. Heh.

Nancy Lebovitz (2011-10-26 20:20:32)

So, what did she try to stop her dysmenorrhea? Did any of it work?

Seth Roberts (2011-10-27 14:24:33)

Nancy, she tried exercise and eating fruit, if I remember correctly. I forget the results, I'll ask her.

Perfect Health Diet » Around the Web; Snowy Halloween Edition (2011-10-29 15:49:15)

[...] "We are Heroes, They are Villains": a must-read tribute to his students from Seth Roberts. Also, Seth tells us that bees make more honey with kombucha. I wonder how much they would make if given other fermented beverages? [...]

jojo1490 (2012-03-16 01:15:28)

I never thought of it that way....But your students have a point, different decisions and different outlook always affect how we interpret any event that happens to us. Be it intentionally or not. We always find it hard to blame ourselves, because we always think we are right. It's really hard to look at it another way.

## **Kombucha For Bees, Man, and Woman (2011-10-27 05:00)**

Dennis Murrell calls himself a "natural beekeeper". This is one reason [1]he sprayed kombucha on his bees:

In the early spring, I grade my hives strong, average, below average, weak. This year, I sprayed the below average hives with a slightly diluted, about 30 %, solution of overly ripe kombucha. It was probably about 3 weeks old. The spraying was done incidentally, without any planning, etc., just to watch the first reaction of the bees. After spraying, the below average hives were left alone, without any more manipulation or observations. . . . Ten weeks later, I popped the covers off the below average hives and found they had a full super of honey, while all the others, even those with larger bee populations had none. I was quite surprised to say the least! And I'd had forgotten about the incidental kombucha spraying until looking at my notes a week later.

Wow. Does this presage a honey surplus? As other beekeepers follow his example? He sprayed kombucha on his bees partly because [2]he himself had found it so beneficial:

I began drinking about a cup a day. . . . I'd been afflicted with a skin ailment since my youth [psoriasis?]. There's no known cure. Modern medicine can relieve the symptoms. But the drugs used have more long term side effects that are worse than any benefits. Well, within 24 hours [of drinking kombucha], the itching associated with the irritated skin disappeared. Within three days, the slight swelling associated with the irritated skin also disappeared. Within a month, 99 % of the irritated areas disappeared. During that time, I lost joint pain that had plagued me for a decade, commercial beekeeping is rough on the back and joints. I regained full movement in my right shoulder. And a sense of wellness replaced whatever

biologically stressed out condition I thought was normal. Once you're over 50, some of the things lost along the way become more apparent. Hair texture, intestinal fortitude, urinary function, energy level, and sexual prowess all decrease. And weight increases. Using kombucha, a probiotic, has reversed my losses to that of a man 10 to 15 years younger. And I've lost some weight. Before using it, I felt old. After using it, I feel alive. . . . My wife, a nurse, was more than skeptical, she thought I'd poison myself with that ugly looking concoction. But when she saw my results, she tried it. Within a month, her joint pain completely disappeared, allowing her to get up off her knees without help or pain. And her hair has returned to the luster and thickness it had when she was in her 30's.

I gained a few pounds when I moved from Berkeley to Beijing in August. Until I read this, it hadn't occurred to me that it might be due to kombucha deprivation. (It took three weeks to brew kombucha in Beijing. I have not seen it for sale in Beijing [3]even in Western-style health food stores!) To me, the most interesting change he describes is better hair texture. Perhaps it reflects better digestion. I can't see why better immune function would improve your hair.

Thanks to Steve Hansen.

3. <http://kombuchatea.wordpress.com/faq/#comment-304>

---

Maria Droujkova (@MariaDroujkova) (2011-10-27 07:38:50)

Here is a hypothesis. The hair texture probably depends on the same mechanisms that cause reduction in joint pain. Short-term hair changes depend on the excretions from the scalp. Conditioners attempt to substitute for the healthy scalp oils, but of course it's not as natural-looking as what the body can produce. So, when the body works better with its fats, that includes the substances that "oil" joints and substances that "oil" the hair.

Joseph Buchignani (2011-10-27 08:44:24)

The two things I can safely eat are starches (potatoes and rice) and lean meat. Fat is definitely out, even small amounts of it. So I think kombucha is impossible for me, even if it didn't trigger lactose intolerance. What can I ferment? How do I do it?

Joseph Buchignani (2011-10-27 08:49:29)

Oh wait... kombucha isn't milk based. Now I definitely will try it.

Alex Chernavsky (2011-10-27 09:15:59)

I've been drinking kombucha daily for about two years. I haven't noticed any health improvements – but then again, I was pretty healthy to begin with. My wife also drinks it daily, or almost-daily. She has a history of chronic indigestion, bloating, and related digestive problems. She's tried all sorts of drugs, both prescription and over-the-counter, without any success. Probiotics have not helped, either. Drinking kombucha is moderately helpful to her. The digestive problems continue but in abated form. When she misses drinking kombucha for a day or two, she notices a distinct worsening of her symptoms.

Seth Roberts (2011-10-27 13:55:47)

Maria, no doubt kombucha increases digestion of many nutrients. If one of those nutrients is omega-3, that would reduce joint pain. But I suspect kombucha reduces joint pain for the same reason bee stings (and perhaps acupuncture) are effective: introducing antigens reduces inflammation. The better hair, on the other hand, I'd guess is due to better digestion.

Tim Deagan (2011-10-27 15:44:30)

I LOVE kombucha. However, I also love good data and good science. The article Kombucha: The Manchurian Mushroom My Adventures with "The Blob" by Paul Stamets Updated July 1995 Originally published in Mushroom, The Journal, Winter 1994-95 Available at <http://www.fungi.com/info/articles/blob.html> Is amazing reading for anyone who'd like to understand the contents and challenges with repeatable kombucha. Don't get me wrong, I drink kombucha on a regular basis, but I've become much more aware of the underlying issues with it after reading this article. P.S. I found this through the amazing Wild Fermentation site (<http://www.wildfermentation.com/index.php>), another fan of live foods!

Great links for the weekend! (2011-11-25 14:04:56)

[...] I'd not come across it before and then Seth Roberts wrote a post about a guy who used it to great effect on his bees and then, with similarly impressive effects on himself and his wife. All I can find [...]

kombu (2012-02-13 15:40:41)

where did you manage to find kombucha in beijing? although i know how to say it in chinese, none of the people around me seems to know where i could find some. Thanks!!

Seth Roberts (2012-02-13 18:04:34)

I have found kombucha nowhere in Beijing. I brought some mother from America.

kombu (2012-02-13 23:55:02)

any chance you're still in beijing and we can buy you a mother?

### No Cheap Remedies: A Guiding Principle of Modern Health Care (2011-10-29 05:00)

[1]I blogged earlier that a guiding principle of our health care system is first, let them get sick. Show no interest in prevention or environmental causes, thus ensuring that people will get sick and become desperate for remedies, which you (health care provider) can charge lots of money for. An example of the disinterest in prevention is that schools of public health, which do considerable prevention research, get a tiny fraction (1 %?) of the money spent on medical

schools, which never do prevention research. As they say, an ounce of prevention is worth a pound of cure – and the government and other powerful players invest exactly the opposite of what this common-sense wisdom implies. You know the term war profiteering. Modern health care is sick profiteering.

It is profiteering, not ignorance, because another guiding principle of modern health care is no cheap remedies. Along with zero interest in prevention, there is zero interest in cheap remedies, such as dietary ones. Doctors usually prescribe drugs or surgery. Both are expensive. Surely doctors are intelligent, but this principle makes them look stupid: They ignore or dismiss cheap remedies, no matter what. At Boing Boing I wrote about two examples. [2]Sarah suffered from frequent migraines. Her doctors wanted to try one drug after another and do expensive tests. No matter how useless the tests and drugs – Sarah tried 30 drugs – her doctors acted unaware of other possibilities, such as looking for environmental triggers. [3]Reid Kimball, who had Crohn's Disease, found a diet that worked. He told a UCSF doctor how well it worked. I don't think you can manage Crohn's with diet, said the doctor. As if he hadn't understood what Reid had said.

[4]My self-experimentation is a reaction to this state of affairs. It is a way to test cheap remedies. I started self-experimentation about sleep (I woke up too early) because I knew a doctor would simply prescribe a drug. I didn't want to take a drug for the rest of my life. You cannot easily do self-experimentation on prevention (e.g., compare how many colds you get with Regimen A versus Regimen B) but, no surprise, there is great overlap between cheap remedies and prevention. I found various cheap safe ways to sleep better – and [5]I stopped getting colds. Not only does omega-3 make my brain work better, it [6]prevents gum disease. I eat butter to make my brain work better, and [7]I suspect it prevents heart attacks. What's that? Someone told you butter is evil? That's another consequence of our deeply messed-up health care system: When the people at the center of the system, the ones with the most power and prestige, promote twisted self-serving ideas (e.g., Harvard psychiatry professor Joseph Biederman and his advocacy of giving powerful drugs to six-year-olds), these ideas spread outward to everyone else, who believe and repeat them. I was no different. When my self-experimentation starting reaching conclusions utterly different than what I'd been told (e.g., I found that [8]breakfast is bad and sugar can cause weight loss, I was stunned. I'd heard a thousand times that breakfast is good and sugar is fattening.

[9]Gatekeeper syndrome.

dearieme (2011-10-29 07:03:43)

I don't know whether breakfast is bad, but I suspect that large glasses of fruit juice at breakfast time might not be a good idea for everyone. Anyway, can "breakfast is bad" possibly be right for everyone, and irrespective of what they eat for breakfast?

jpb (2011-10-29 07:48:12)

Very good post, Seth! I wrote a guest post for KevinMD on the problems with the pharmaceutical industry. I did a lot of research and wrote a serious piece which outlined the abuses of the industry and ways to make it better. Kevin declined to publish it without giving any reason. I think that the medical industry as a whole does not want to make any changes that will cause anyone to earn less money. They certainly do not want a healthy population!

Alex Chernavsky (2011-10-29 08:01:59)

@jpb – why not post your essay here (or post a link to it, if it's long)?

Seth Roberts (2011-10-29 12:53:36)

"Can 'breakfast is bad' possibly be right for everyone?" Yes. Assuming that everyone has 24-hour access to food. The phenomenon I uncovered (anticipatory awakening) is merely an example in humans of something that has been found in a wide range of other mammals – for example, rats. Rats become more active at the time of day food is available. The phenomenon occurs with protein, fat, and carbohydrate sources of calories. If you eat a breakfast with no calories, you can avoid the problem I uncovered. I drink calorie-free tea early in the morning.

Ashish (2011-10-29 14:38:53)

I don't think the guiding principle you mention need be absolute. As an advocate of barefoot (less to buy) running, I'm trying to identify groups with a financial incentive in prevention - they do exist. Those who sell drugs and devices, or provide healthcare, generally don't benefit from providing prevention. Long-term insurers, on the other hand, do. Kaiser has many "cradle-to-grave" clients, so benefits from cost-effective prevention. I'm in contact with them. The US military does as well - they don't want their soldiers to get injured on duty, and they provide lifetime health care, so are on the hook to pay for long-term health issues. I'm meeting them as well. Who else?

Tom (2011-10-29 15:11:16)

The ultimate expression of this may be converting common nutrients into patentable forms: [1]Lead to Gold: Transforming Nutritional Supplements into Medications

1. <http://www.trackyourplaque.com/blog/2009/01/lead-to-gold-the-alchemy-of-transforming-nutritional-supplement-to-medication.html>

Seth Roberts (2011-10-29 15:37:17)

Ashish, yeah, absolutely. The practical implication of what I am saying is simple: Empower those who benefit from prevention and cheap remedies. Which is everyone outside the current system, plus a few groups inside it, such as insurers.

Seth Roberts (2011-10-29 15:42:28)

I agree with Alex. Post it here or post a link to it.

TomGinTX (2011-10-29 17:55:32)

Seth, can you explain further about breakfast being bad for everyone? I eat breakfast regularly, but I do not wake up early.

LemmusLemmus (2011-10-29 23:10:04)

What TomGinTX said.

Seth Roberts (2011-10-29 23:41:36)

You eat breakfast and don't wake up early? If you stop eating breakfast (or delay it by three hours) you might wake up more rested. (The effect of eating breakfast takes about a week to go away.) Again, research about anticipatory activity – the diversity of animals in which it's been observed – implies that what I found is true for everyone. There are thousands of examples where something like this (observed in a wide range of animals and a few humans) has turned out to be true for all humans. I don't know of a single exception. Another way to think about it is to consider the correlation between the DNA of

one human and the DNA of another human. Very very high.

Digby (2011-10-30 03:11:08)

I have reservations about your breakfast ideas, and serious problems with sugar as we get it the majority of diets–yours excepted. I was just rereading an Upton Sinclair article from the 1920s, he was also a famous self-experimenter, and his comments about the medical professionals as mainly interested in keeping their profession from financial loss due to simple, low- or no-cost remedies mirrors your own. So little had changed.

jpb (2011-10-30 08:27:13)

1. I would be happy to send my article if I had an email address. Where do I find it on your site? 2. Not so sure about the breakfast being bad for all. I think it has something to do with what you eat and how long after awakening.

Seth Roberts (2011-10-30 12:52:26)

Digby, could you provide a link or reference to the article by Sinclair that you mention?

Seth Roberts (2011-10-30 12:55:26)

jpb, could you post your article as a comment? or as several comments? To contact me see "Contact Seth" on the right side of this blog.

Seth Roberts (2011-10-30 13:15:57)

jpb, you can simply post your article as one or more comments. You can find my email address under Contact.

TomGinTX (2011-10-30 14:17:31)

Seth, I will give no-breakfast a try eventually. I just started eating food while pinching my nose shut. I want to see how that works before experimenting with something else.

jpb (2011-10-31 12:03:38)

I needed to do some more editing but will send this evening.

Paul Sherrard (2011-10-31 17:48:17)

Re the "breakfast is bad" thing: I eat breakfast, but don't wake up too early. Is there another reason to stop eating breakfast?

Seth Roberts (2011-11-02 03:20:46)

"Is there another reason to stop eating breakfast?" Yes, you might wake up feeling more rested.

Mike Ellwood (2011-11-02 08:03:23)

FWIW, the "no breakfast" approach would contradict Dr Jack Kruse's idea of a "Leptin Fix", part of which involves eating a breakfast including at least 50 grammes of protein within half an hour of waking. Of course, not everyone has a leptin issue that needs fixing.

## **E-Cat Passes Test (2011-10-30 05:00)**

[1]Andrea Rossi, an Italian inventor, has constructed a version of [2]his E-Cat invention – a new source of energy – that produces 1 gigawatt/hour. [3]A test to verify this claim satisfied an unknown customer, who bought the device. This is easily the most impressive physics/chemistry news of my lifetime. It remains to be determined how long the device can run on a given amount of fuel (supposedly the fuel is cheap), but the evidence that a new source of energy has been found is much better (in my eyes) than anything else I have ever heard. The (previous) evidence for cold

fusion, for example, never came anywhere close to this. (More I learned more after writing this and no longer take E-Cat seriously. For details see end of post.)

The recent BBC documentary Shock and Awe: The Story of Electricity (great, by the way) tells of one big misleading demonstration: Edison's demonstration of direct current near Wall Street. As everyone knows, the world uses alternating current, not direct current. But Edison's demonstration was far less astonishing than Rossi's. Edison's misleading demonstration was no engineering miracle. It was just costly. Again and again, the documentary tells of inventions and demonstrations that appeared miraculous (the battery, wireless transmission) based on the common knowledge of the time. They turned out to predict the future.

[4]According to Wikipedia, Rossi has a doctorate from Kensington University, California, [5]a diploma mill. His nonsense-doctorate is in chemical engineering. His discovery is not chemical engineering. But who better than me to ignore this? My doctoral degree, although real, came from research on animal learning, which is quite different than weight control, mood, sleep, nutrition, all the stuff I claim to have learned new things about. And now I am commenting on physics! What I have learned from my experience of science is that major discoveries require knowledge and freedom – freedom to try a thousand things. It appears that Rossi – who wasn't a professor at a major university, worrying about his next grant – had both.

More Stop the presses! Having read [6]this and [7]this (thanks, expedient), I have much greater doubts about Rossi's claims and would not have written this post had I read them earlier.

1. [http://en.wikipedia.org/wiki/Andrea\\_Rossi\\_%28entrepreneur%29](http://en.wikipedia.org/wiki/Andrea_Rossi_%28entrepreneur%29)

3. [http://www.nyteknik.se/nyheter/energi\\_miljo/energi/article3303682.ece](http://www.nyteknik.se/nyheter/energi_miljo/energi/article3303682.ece)
4. [http://en.wikipedia.org/wiki/Andrea\\_Rossi\\_%28entrepreneur%29](http://en.wikipedia.org/wiki/Andrea_Rossi_%28entrepreneur%29)
5. [http://articles.latimes.com/1996-04-23/local/me-61657\\_1\\_kensington-university](http://articles.latimes.com/1996-04-23/local/me-61657_1_kensington-university)
6. <http://blog.newenergytimes.com/2011/10/30/noble-aspirations-are-not-enough/>
7. <http://blog.newenergytimes.com/2011/10/28/energy-catalzyer-extraordinary-scams-require-extraordinary-claims/>

---

expedient (2011-10-30 06:00:17)

Steady on there. Steven Krivit, the most prominent LENR advocate/journalist these days, soured on Rossi with a vengeance some months ago <http://newenergytimes.com/v2/news/2011/37/NET370.shtml> and reports some odd things about this latest news too: <http://blog.newenergytimes.com/2011/10/30/noble-aspirations-are-not-enough/>.

jon k (2011-10-30 06:28:57)

Your blog posted excited me greatly. Unfortunately, after doing a bit of reading, I am pretty sure Rossi's device is a scam. Several reasons, but this Quote from Wiki is a good start: As Ny Teknik reports, Peter Ekström, lecturer at the Department of Nuclear Physics at Lund University in Sweden, concluded, "I am convinced that the whole story is one big scam, and that it will be revealed in less than one year." [34][24] He cites the unlikelihood of a chemical reaction being strong enough to overcome the Coulomb barrier, the lack of gamma rays, the lack of explanation for the origin of the extra energy, the lack of the expected

radioactivity after fusing a proton with  $^{58}\text{Ni}$ , the unexplained occurrence of 11 % iron in the spent fuel, the 10 % copper in the spent fuel strangely having the same isotopic ratios as natural copper, and the lack of any unstable copper isotope in the spent fuel as if the reactor only produced stable isotopes.[34] He later added in New Energy Times that the steam velocity in a videotaped test appears to be way too low for the reported energy production, and that some liquid water might be exiting the system via the drainage tube.[35]

Michael (2011-10-30 07:29:01)

The very act of getting a diploma from a diploma mill is a red flag.

gwern (2011-10-30 07:51:52)

What probability do you give Rossi not being a fraud?

James Babcock (2011-10-30 08:22:40)

Endorsing this scam seriously damages your credibility. If there were something useful here, its creator would either avoid talking it up to the press, or would provide details. The only reason for not discussing details would be if he knew that someone would take those details and use them to write up an explanation of why the idea won't work. As for what the actual mechanism is, it could be any exothermic chemical reaction. But, in order for it to actually be useful, it would have to use inputs that can be gathered in quantity from nature, without using more energy to mine/refine them than is produced in the reaction. If this isn't a scam, then it's almost certainly a confused person who's failed to grasp this point, and used a chemical input without knowing how much energy it took to gather or produce in the first place. As for academic credentials, I think it makes sense to look at it from a Bayesian perspective: how likely is it that a piece of research is good, conditional on its author having a relevant degree, an irrelevant degree, no degree, or a fake degree? This depends on the amounts of valid and invalid research produced by each group. Your point that the good-to-bad research ratio isn't significantly better for people with relevant degrees than for people with an irrelevant degree or no degree is well taken. The existence of good research by people without relevant degrees is explained by people wanting to do research but not wanting to pay the high cost of getting one. But a fake degree is something else entirely, because someone who just wanted to do research wouldn't bother; they'd rather be uncredentialed. Which makes having a fake degree strong evidence against someone being credible, in a way that lacking a degree isn't.

Bob (2011-10-30 11:39:08)

Very, very high probability of fraud: <http://motls.blogspot.com/2011/10/wuwt-f-orbes-wired-keep-on-pushing-cold.html> #more

Igor Carron (2011-10-30 12:34:39)

Seth, When reading the summary I noticed a mention that the device was still hooked up to the grid with the assurance that no electricity was going through the cables. Why, oh why, would somebody trying to convince some customer of the validity of their claim allow any type of doubt to remain by leaving a cable hooked up to this machine is beyond me... And a red flag. Cheers, Igor

Seth Roberts (2011-10-30 12:50:14)

After reading the Krivit post (from expedient) my estimated probability that this is real went way way down – from about 20 % (when I wrote this post) to about 1 %.

dearieme (2011-10-30 16:48:52)

"that produces 1 gigawatt/hour": dear God, scam or not, that's tosh.

Alrenous (2011-10-31 04:50:39)

Don't forget the point is to assess things on their merits, not on their credibility. I find this a useful test case to separate out merits from red herrings, by comparing it to biological heresies. They're similar in that they're both not what Scientists would expect, but can also be reliably tested on the cheap, for the first-hand observers. (They're like NP-complete: deriving them is hard but checking the solution is easy.)

## Brain Surprise! Why Did I Do So Well? (2011-10-31 05:00)

For the last four years or so I have daily measured how well my brain is working by means of balance measurements and mental tests. For three years I have used a test of simple arithmetic (e.g,  $7 * 8$ ,  $2 + 5$ ). I try to answer as fast as possible. I take faster answers to indicate a better-functioning brain.

Yesterday my score was much better than usual. This shows what happened.

[1]

My usual average is about 550 msec or more; my score yesterday was 525 msec. An unexplained improvement of 25 msec.

What caused the improvement? I came up with a list of ways that yesterday was much different than usual, that is, was an outlier in other ways. These are possible causes. From more to less plausible:

1. I had 33 g extra flaxseed last night. (By mistake. I'm not sure about this.)
2. The test came at the perfect time after I had my afternoon yogurt with 33 g flaxseed. When I took flaxseed oil (now I eat ground flaxseed), it was clear that there was a short-term improvement for a few hours.
3. Many afternoons I eat 33 g ground flaxseed with yogurt. Yesterday I ground the afternoon flaxseed an unusually long time, making made the omega-3 more digestible.
4. I did kettlebells swings and a kettlebell walk about 2 hours before the test. These exercises are not new but usually I do them on different days. Yesterday was the first time I've done them on the same day. I'm sure ordinary walking improves performance for perhaps 30 minutes after I stop walking.
5. I had duck and miso soup a half-hour before the test. Almost never eat this.

6. I had a fermented egg ("thousand-year-old egg") at noon. I rarely eat them.

7. I had peanuts with my yogurt and ground flaxseed. Peanuts alone seem to have no effect. Perhaps something in the peanuts improves digestion of the omega-3 in the flaxseed.

8. I started watching faces at 7 am that morning instead of 6:30 am or earlier.

Here are eight ideas to test. Perhaps one or two will turn out to be important. Perhaps none will.

After I made this list, I read student papers. The assignment was to comment on a research article. One of the articles was about the effect of holding a warm versus cold coffee cup. Holding a warm coffee cup makes you act "warmer," said the article. Commenting on this, a student said she thought it was ridiculous until she remembered going to the barber. She sees the person who washes her hair (in warm water) as friendly, the barber as cold. Maybe this is due to the warm water used to wash her hair, she noted. This made me realize another unusual feature of yesterday: I had washed my hair in warm water longer than usual. I think I did it at least 30 minutes before the arithmetic test but I'm not sure. In any case, here is another idea to test. [2] I found earlier that cold showers slowed down my arithmetic speed.

This illustrates a big advantage of personal science (science done for personal gain) over professional science (science done because it's your job): The random variation in my life may suggest plausible new ideas. As far as I can tell, professional scientists have learned almost nothing about practical ways to make your brain work better. You can find many lists of "brain food" on the internet. Inevitably the evidence is weak. I'd be surprised if any of them helped more than a tiny amount (in my test, a few msec). The real brain foods, in my experience, are butter and omega-3. Perhaps my tests will merely confirm the value of omega-3 (Explanations 1-3). But perhaps not (Explanations 4-8 and head heating).

Maria Droujkova (@MariaDroujkova) (2011-10-31 06:17:08)

I sometimes suggest to my math students they hold their hands under hot water for a while. This is a folk remedy against headaches, but it also helps you relax (that's the reason I suggest it - math anxiety) and seems to have an effect on blood pressure. It would be interesting to try it as an intervention. What is frustrating to me, as an instructional designer, is that changing curriculum often has smaller effects compared to physiological interventions like food, or sitting on an exercise ball rather than a chair. Argh!

ajb (2011-10-31 08:16:37)

Butter in specific, or cream in general?

Thomas Johnson (2011-10-31 12:12:47)

Seth, I have a question about your test. I think that the one at Genomera is identical to the one you use, correct? If so, my understanding is that the test does not count incorrect answers when calculating average speed. So if you answer 8 questions correctly before you answer 32 questions right, you use only the response time for those 32 questions to determine your brain function. But what if a faster speed sometimes indicates poorer brain functioning? For example, let's say that you're getting many "hard" questions (e.g., "13-7") wrong, so your results are biased towards easy questions (e.g., "8-8"). Even if your brain

is functioning poorly, you will be very fast at those easy questions. So because of this sampling bias, your test may actually give backwards results in some cases. I also use the genomera test, so I'm curious about your thoughts on this.

Brian (2011-10-31 12:39:02)

I use the 20-question quiz (addition, subtraction, and multiplication) from the Brain Tuner Lite iPhone app. The quiz involves pressing either a "right" button or a separate "wrong" button to say whether a given simple math equation is wrong or right. Since the app adds five second penalties for each wrong answer, it would seem to avoid the problem @Thomas describes. I perform several tests in succession to measure my cognitive functioning so that I can avoid the problem of an unusually easy batch of questions suggesting improved cognitive function. For example, following the addition of bulletproof coffee to my diet and 20 minutes of dual n-back training to my daily routine, I decreased my speed from an average of just over 600 msec/problem to an average of under 575 msec/problem. Interestingly enough, this increase happened notwithstanding 30 minutes daily of icepacks on the back of my neck and on my trapezis prior to bed (for weight loss purposes as described by Tim Ferriss).

Seth Roberts (2011-10-31 14:50:54)

Ajb, I have not varied the amount of cream I consume. I drink a little bit of cream during the day. I suppose butter and cream will have the same effect, but I have not tested that idea. At first I would use only one brand of butter but now I am sure that many brands produce the benefit.

Seth Roberts (2011-10-31 15:00:40)

Thomas, the Genomera test is very similar to mine, yes. And, yes, I count only correct answers. About the possibility of bias: 1. Variation in error rates is a problem, yes. But I have found wide variation in error rate to be uncorrelated with average speed. There is no clear speed-accuracy tradeoff. 2. I correct for difficulty. Before averaging across trials, the score on every trial (in msec) is adjusted by the difficulty of that trial. Suppose the trial was  $7+3$ . If  $7+3$  is on average 50 msec slower than average, the score on a  $7+3$  trial has 50 msec subtracted before I average over trials. Because of this adjustment, it is no help to get the hard questions wrong so that your score will be based only on easy questions.

jon k (2011-10-31 19:59:25)

I would have thought that this was within the normal variation for this kind of test. Some factors that maybe you didn't think of/account for: hours of sleep the previous night, time the test was taken (in hours after waking, and hour of day), time spent doing analytical things (research, writing, reading) the day before, time spent socializing the day before. Also, do you have a link for the software to run this test? I'd be interested in tracking my own results.

Tom (2011-10-31 23:23:46)

Seth, off-topic, but along the lines of one of your interests: "The New Einsteins Will Be Scientists Who Share From cancer to cosmology, researchers could race ahead by working together—online and in the open" [http://online.wsj.com/article/SB10001424-052970204644504576653573191370088.htm?mod=googlenews\\_wsj](http://online.wsj.com/article/SB10001424-052970204644504576653573191370088.htm?mod=googlenews_wsj)

O/T but I thought that this might interest you. [http://www.dutchnews.nl/news/archives/2011/10/tilburg\\_professor\\_faked\\_data\\_i.php](http://www.dutchnews.nl/news/archives/2011/10/tilburg_professor_faked_data_i.php) (H/T Naked Capitalism)

Jazi yechezkel zilber (2011-11-02 19:40:04)

Two variations on flaxseed and yogurt 1) i noticed that the ground seeds are dry when mixed with yogurt. I usually out them first in a little water, and then add yogurt. 2) if left in water for ten or five minutes, it gets a whole different texture and feels different. May chAnge avilability and digestion Now, I noticed that long grinding makes the ground very hot. With probably effects. Ps. When i eat flaxseed and yogurt at night i sleep very. Well. Such a sweet wake up that I rarely had.

---

Erica (2011-11-01 15:40:55)

I love Earth Clinic. I do have a question about Kombucha. I've only seen it at Whole Foods even tried it a couple times. I was wondering if you think that Kombucha is good enough. When I googled it I found people making their own and was wondering if you make your own or buy it somewhere? Do you think if I just bought it at whole foods it would be just as good as making it? Also, how much should I drink a day would you suggest? The bottles from WF are pretty large.. like at least 20oz I think.

Seth Roberts (2011-11-02 03:17:54)

yes, Whole Foods kombucha is good enough. I prefer to make my own, partly because it tastes better and partly because it's much cheaper (the ingredients are practically free) and more convenient. Try half a bottle per day. That might be enough to notice benefits.

Åse (2011-11-04 01:20:42)

Seth, I'd really like to hear your thoughts about the Stapel case. I've been talking to a lot of people both at my work, on google+ and on facebook. One thing that keeps turning up are questions about how to make science more robust (well, that is my take on the discussions about open source data, publication of direct replication), perhaps not to prevent fraud, because there will always be the temptation for some to cheat, but to limit the damage. I always appreciate what you have to say (whether or not I agree), and I know you have been involved with detecting fraud.

Seth Roberts (2011-11-04 02:30:18)

Given that Stapel supposedly faked so many papers, I would like to know if the numbers in his papers pass that distribution-of-first-digit test that has been used to detect accounting fraud. If he made them up, they should fail that test, whereas the same sort of digits from a random sample of similar papers should pass that test. That would be a way to learn to detect fraud in the future. My experience with fraud detection suggests that fraudulent data is pretty easy to notice. A good exercise would be to ask for this or that paper: How can we test whether the data in this paper are real? Perhaps now that journals are more likely to require raw data, that first-digit test can be more sensitive since it can be done on the raw data. It would be interesting to give grad students (or someone else) five papers, one by Stapel, with names removed. Five similar papers. Then ask them which is most likely to be faked. I also wonder what other researchers in his area thought of his research before the fraud was detected. Now too late to find out, I suppose.

Åse (2011-11-05 00:37:29)

Thanks Seth And, yes, it is too late, but, for what it is worth, I can give you my n=1 experience from having attempted to adapt one of Stapel's paradigms. And a kind of filtered current impression. I'm kind of peripheral when it comes to the field. I'm interested in emotion, and I was interested in modeling emotion (from a kind of dynamical systems perspective), so I ended up accepted into a joint PhD at IU [Indiana University?] where I did a lot of cog sci/math psych classes as well as social cognition. They were very accepting of my somewhat unusual position. I'm still very peripheral for various reasons. Stapel visited during my first couple of years (so this is late 90's). He gave a talk, things surrounding the talk have by now become short propositions mostly in my memory. A couple of things stand out (it will be relevant). He had done work showing that the Ebbinghaus illusion is influenced by social categories. Instead of using the regular circles, they had used line drawings which in some instances depicted people of different social status (they also used trucks). Rich Shiffrin was incredulous. Not, as I recall, in a "fake data" way, but more in a "must be a fluke" way. But the result of the visit was that my adviser, Paula Niedenthal, thought we could adapt this paradigm for investigating our interests which was how emotional state influences perception of emotional stimuli. Her former grad student got stimuli put together at his lab, and I did the actual running of subjects. We did two versions of it, and nothing panned out, which was unremarkable. I had just run 5 studies based on a promising pilot, and nothing panned out. I think all of us have experienced that (I keep thinking about your comment on your experience with rats and data). Also, we are very familiar with results that make us incredulous and are hard to replicate, etc. At the time the priming work from Bargh was something people wondered about. I've done some work on that (we tried to tease out whether the effects we see from felt emotion were from emotion or from the priming of emotion concepts which also comes with the feeling). That was 10 versions of studies, that eventually got published (and conclusion is that it is the emotion, not the priming). I was reading Stapel's paper about the Ebbinghaus work, and at that time none of it struck me as fishy. I still don't know if this was one of the papers where he faked data, I'm now simply assuming it. But I must say I was quite shocked when I heard that he had been fabricating data for a long long long time, possibly because I had done that work. I'm reading a lot of discussions about this (and I'm working on initiating a discussion at my university where I want to focus on how to make the science more robust – more to lessen the impact of the inevitable cheaters than to catch them out). Some of those that are in the middle of the field are (understandably) very defensive. Some discuss ideas about how to prevent this from happening again. Some talk about whether this is a failure of the process or not (I'm reminded of the book Plastic Fantastic). One person claims that Stapel's work wasn't that big of a deal. More flash than theory advancement. Hard to make something out of it, considering that there are myriad reasons why someone would think that now. The anecdote I told is my only encounter with his work, so take it for what it is worth.

## **Can Vitamin D Replace Sunlight? A Stunning Discovery (2011-11-02 05:00)**

[1]Primal Girl is a stay-at-home mom. I met her at the Ancestral Health Symposium. Her sleep was bad. I made recommendations. One of them was to get an hour of sunlight soon after you wake up. She can't do that – too busy being a mom. So she decided to take Vitamin D early in the morning. After all, sunlight exposure produces Vitamin D.  
[2]Here's what happened:

One day as I was taking my supplements, I was thinking about how many units of Vitamin D your skin produces in 30 minutes of sun (20,000 I believe). I looked aghast at the 10,000 units of Vitamin D I was taking. It was 7 o'clock at night! I was essentially giving my body 15 minutes worth of bright sunlight energy. No wonder I was waking up in the middle of the night! I was telling my body that it wasn't really time for bed, it was still the middle of the day. I wondered what would happen if I only took my Vitamin D first thing in the morning. It wouldn't be an hour naked in the sun, but 15 minutes is better than nothing. That night I slept like shit. Worse than normal.

I usually took my supplements mid-afternoon. I vowed to take them first thing every morning. If I forgot, I would not take the Vitamin D at all that day. I tried it the next day and that night I slept like a rock. And the next night. And the next. Days I forgot and skipped the D3, I still slept great. That was the only change I made to my lifestyle and my sleep issues completely resolved. [emphasis added]

OMG! Double OMG! Like Primal Girl, I have never heard anything like this. Even I am stunned that such a simple safe easy change could have such a positive effect. (Taking Vitamin D at sunrise is a lot easier than standing on one leg four times!) I've read lots about circadian rhythms. Many studies showed that a drug would be much more powerful at certain times of day. Most of these studies were with rats. It never occurred to me that the time you take a vitamin could matter so much.

1. <http://www.primalgirl.com/>

2. <http://www.primalgirl.com/2011/11/01/nprimalgirl-sleep-issues-vitamin-d/>

---

Matt (2011-11-02 05:41:09)

I had heard of this somewhere as well, and I too don't take Vitamin D later in the day - if I forget my vitamins one morning/early afternoon then I skip the D that day. I've always tried to take my magnesium at bedtime. <http://www.nutritionalmagnesium.org/articles/insomnia/309-how-magnesium-helps-you-sleep.html>

JG (2011-11-02 05:50:13)

Chrissake man, this is so embarrassing to read early in the am - this is a revelation? With a study of ONE person? My VAST experience with D3 (many more years than "Busy Primal Momz", whatevs) does not support this theory. There...does that make you think twice about making broad generalizations? I cannot believe that this passes as science in your version of self-quantification. Where is the testing before jumping to conclusions? I know this is your blog and you're free to publish what you want, but I've seen less and less self-editing from you and more pruning to fit the message...and everything you write seems to be framed as some MASSIVE REVELATION that required your genius and eye to solve it - further positioning yourself vs. the mainstream, etc. It's clear to me that, while it's cool to rail against mainstream researchers, you have not spent any time in the lab or actually talking with QS peers and bouncing these ideas off of them. This stuff - this STUNNING REVELATION - is old weak sauce. This is not so far removed from what actual doctors know. Seriously, this is medicine 101. It's so obvious that I can't believe this is a revelation to you. HEY, DO YOU THINK THERE WILL BE SOME EFFECT IF YOU TAKE MELATONIN IN THE MORNING...of course! Let's see if you don't fall asleep! Same with Magnesium Citrate - see how long you can go without feeling sleepy. I dare you to take Melatonin and Magnesium today with your yoghurt...and when you wake up eight hours later, perhaps you can write another post about another stunning timing revelation! TRIPLE OMG! D3 is TECHNICALLY a hormone...just like MELATONIN. OF COURSE timing is everything when it comes to HORMONES. I think you're really stretching the scope of discoveries here. Please, kind sir, as an admirer of yours, I ask that you get yourself an editor. Or bounce these ideas off a REAL PRACTITIONER before you go declaring some discoveries as though you're in Mendel's company. TALK TO MORE PEOPLE. You are big and respected enough now to have to face the heat for half-digested posts.

john (2011-11-02 06:39:32)

Nephropal has mentioned this before.

Tim Beneke (2011-11-02 08:10:54)

Fascinating. I've been recently trying to reset my circadian rhythms by getting more morning sunlight. I'll add some morning Vitamin D to the mix and see what happens.... It sounds unlikely that it's just "placebo" - the effect seems pretty striking...

dearieme (2011-11-02 09:19:16)

If you breakfast on smoked salmon and scrambled eggs, or on kipper, would you get some of this effect?

gwern (2011-11-02 09:20:00)

Hm, interesting. I always take my vitamin D with my other capped pills, which include caffeine and sulbutiamine so I never take them after 7 PM. I also never noticed any effects on my sleep when I got fresh supplies on vitamin D. (I probably don't care enough to test this with my Zeo and see whether taking vitamin D right before bedtime makes a difference, though - bad sleep is nasty.)

jpb (2011-11-02 09:24:00)

That is a amazing! I never thought about the effects of taking D3 at night. I have been doing that for a long time and it always takes me hours to fall asleep. I will try the new schedule today and see how things go tonight!

Joseph Buchignani (2011-11-02 10:00:30)

You the man, Seth! And she's the woman! Thanks for the awesome tip. Never liked melatonin. This is much better. Call Tim Ferriss. He'll give you a guest post or something. He NEEDS this.

Chuck Currie (2011-11-02 10:24:46)

I always take my D3 5000 (along with 400 mg magnesium citrate) right before going to bed, but only if I don't get a good dose of natural sun exposure during the day. I have no problems with sleep either way. I sleep at least 8 hours with maybe one bathroom break and wake naturally - no alarms. I've also found that I become drowsy and fall asleep earlier if have more carbs with dinner (potato/sweet potato/rice) or a small bowl of ice cream for dessert (usually an hour or two after dinner). I have also postponed my first meal of the day for about 3 to 4 hours after awakening. I have found that I awaken later than I did when I ate 1 hour after awakening. I only eat two meals a day - usually bacon & eggs with a little sweet potato/plantain/or berries for breakfast and meat and veggies for dinner. I also have two or three glasses of cold tea with heavy cream though out the day. Plus 1/4 stick of butter and two tbls of flax oil, some souerkraut and/or kombucha. Just for reference, I'm 65, male and have been practicing a paleo/primal life style for a year and a half. I know this is a long comment on D3, but I think context is important.

Aaron Blaisdell (2011-11-02 11:37:58)

Like John, I also read about this on Neohropal blog. That's why for the past couple of years I have been taking it in the morning with my coffee.

Seth Roberts (2011-11-02 13:13:26)

"this is a revelation?" To me, yes. "required my genius...to solve it"? My contribution to this was minimal. The notion that morning sunlight might help you sleep is pretty obvious. "This is not so far removed from what actual doctors know. . . . It's so obvious." I have never heard a sleep doctor (or any doctor except Nephropal) say this. Many things that are "obvious" are wrong. The [1]Wikipedia entry for Vitamin D says nothing about time of day effects.

1. [http://en.wikipedia.org/wiki/Vitamin\\_D](http://en.wikipedia.org/wiki/Vitamin_D)

Greg Biggers (2011-11-02 13:16:16)

This is a provocative and probably helpful observation! I would love to see some people turn it into a group study over at Genomera. We (or Seth, for that matter) can help you with study design if you wish.

Seth Roberts (2011-11-02 13:27:52)

Thanks, Aaron & John. Gotta start reading Nephropal. However, there are important differences between what Nephropal said and what Paleogirl says. I will discuss this in tomorrow's post.

Seth Roberts (2011-11-02 13:29:19)

"If you breakfast on .. " No, they have little or no Vitamin D.

Rachael (2011-11-02 13:58:01)

Other supplements that will keep you up if you take them at bed time are B vitamins, and calcium. Magnesium at bed time will help you sleep. I suspect everyone has varying levels reaction to supplements, perhaps if one is replete in vit D one responds to it less?

Jazi yechezkel zilber (2011-11-02 16:22:08)

This book discusses the effects of time of time on ANYTHING! Drugs sex all you can dream of [http://www.amazon.com/Body-Clock-Guide-Better-Health/dp/0805056629/ref=sr\\_1\\_14?s=books&ie=UTF8&qid=1320275979&sr=1-14](http://www.amazon.com/Body-Clock-Guide-Better-Health/dp/0805056629/ref=sr_1_14?s=books&ie=UTF8&qid=1320275979&sr=1-14) I gained a lot from it. Because, I learned that what matters is not the exact time you wake up, but the rythm. So I started sleeping late and waking late an exact timing, which wass good.

Jazi yechezkel zilber (2011-11-02 16:35:21)

Btw, in another book of the author [http://www.amazon.com/Bodyrhythms-Chrono-biology-Performance-Lynne-Lamberg/dp/0595147852/ref=sr\\_1\\_4?s=books&ie=UTF8&qid=1320276492&sr=1-4](http://www.amazon.com/Bodyrhythms-Chrono-biology-Performance-Lynne-Lamberg/dp/0595147852/ref=sr_1_4?s=books&ie=UTF8&qid=1320276492&sr=1-4) See the chapter rythms and depression, where she says - like you - that rythm disruption and depression are ddeeply linked

Seth Roberts (2011-11-02 16:41:51)

Jazi, you have convinced me I should have titled the post Can Vitamin D Replace Sunlight? A Stunning Discovery.

Jim Purdy (2011-11-02 19:55:55)

Seth, I hope you'll forgive me for asking a very off-topic question, but at least it's about self-experimentation, sort of. I am a binge eater with type 2 diabetes, but I refuse to take any medications of any kind, not even over the counter stuff like aspirin or vitamins. (My doctors call me everything from "non-compliant" to "crazy and suicidal.") And I really struggle to get my blood sugar readings out of the stratosphere. However, something happened today that really surprised me. This morning, my blood sugar was very high (I don't want to admit how high, but it was high). And then I went on a binge, eating 30 (yeah, 30!) fast food chicken wings deep-fried in peanut oil. I checked my blood sugar several times over the next 9 hours, and my blood sugar plummeted rapidly, just as if I had taken a huge dose of insulin. Does that make any sense to you? Could chicken wings - and/or peanut oil - help control diabetes? I'm thinking about buying a bunch of plain chicken wings and microwaving them, without any oil or other ingredients. A chicken-wing binge diet for diabetes? Will I die tomorrow?

Jim Purdy (2011-11-02 19:59:23)

oops ... I think I mis-typed my email address in a comment a moment ago. The correct address is [jimpurdy1943@yahoo.com](mailto:jimpurdy1943@yahoo.com)

Seth Roberts (2011-11-03 03:36:03)

Jim, I'm afraid I have no insight about your plummeted blood sugar. I suggest seeing if you can repeat the original observation before trying to figure out what caused it. If you manage to figure anything out about the cause, please let me know.

Jim Purdy (2011-11-03 05:50:56)

Seth, I will repeat my chicken-and-peanut-oil binges ... I mean experiment ... in the name of good science. But at least one of my lacto-vegetarian sons reads your blog, so I may get a severe scolding from them (and my doctors) about my super-binges. I hope you appreciate my big sacrifice here for science. Of course, I am familiar with the Atkins Diet, and how it should have a minimal effect on blood sugar. However, my blood sugar numbers yesterday seemed to go far beyond any Atkins Diet effect that I would

have expected. The numbers, seem amazing to me, considering that I take no medications. About 1145 am yesterday, I ate the first batch of 15 chicken wings, deep-fried in peanut oil. I didn't record the other times that I ate chicken wings, but I did eat a second batch of 15 several hours later, and a third batch of 15 another few hours later. I don't know if it's relevant, but I had a can of Diet Coke with each batch of 15 wings. Yesterday, 1010 am (before any chicken wings): 347 blood sugar 1225 pm (after 15 wings): 263 350 pm: 213 650 pm 210 1005 pm: 164 (down 200 in 12 hours. despite 45 deep-fried chicken wings, and no meds) Today, 130 am: 245 (the wing effect fading?) Today, 325 am: 261. Then I drank 8 ounces of apple juice. Today, 720 am: 256 I've never seen changes of this magnitude before without medications. I will do this again, keeping more detailed records ... unless I die of a heart attack first. To do it right, I should eat the same wings deep-fried in peanut oil, but I think I'll just microwave them, with no oil or anything else. Maybe it's the peanut oil and not the chicken? I hope my cardiologists never see this. My doctors already call me crazy and suicidal because I won't take any of their drugs. Incidentally, I asked Jenny at Diabetes Update about this same experience yesterday, and she replied with some real skepticism [1]here. I will repeat this to see what happens.

1. <http://diabetesupdate.blogspot.com/2011/10/normal-blood-sugars-in-pregnancy.html>

Seth Roberts (2011-11-03 06:35:16)

If someone is scolding you about binging once or five times on deep fried chicken wings they are missing the point. I believe a much bigger problem for you is your very high blood sugar score. If you can find a way to get them way down (and keep them down) you will be helping yourself immensely. You might also want to try large amounts of walking. Perhaps tolerable amounts of walking will reduce your blood sugar substantially. I found that was true.

John W (2011-11-03 08:06:35)

Just to clarify, the D3 you take as a supplement (25-dihydroxy-vitamin D3) is NOT a technically hormone, it is a prohormone. The hormone form (1,25-dihydroxy-vitamin D3) is made from the prohormone form and is tightly regulated. Furthermore, the prohormone has a half-life of a couple of weeks. So it is, in fact, a little surprising that the dose timing can have such an effect. By the way, I noticed this myself a couple years ago - I never take vitamin D in the evening, so n>1.

Nancy Lebovitz (2011-11-03 08:45:06)

Jim, just to check- did you do a significant amount of walking before your blood sugar went down? From what I've heard, doing a lot of mild exercise can make a big difference.

nile (2011-11-03 09:25:15)

Mr. Purdy- In addition to walking, as Seth suggested, you might try, depending on your tolerance for exercise, HIIT or High Intensity Interval Training. A fair amount of research has been done on this in the last 10 years or so. Just go to pubmed (<http://www.ncbi.nlm.nih.gov/pubmed>) and you can search for HIIT studies. About 10 minutes per day of exercise above your aerobic capacity will help a lot. I think it will have the same effect as large amounts of walking. A good protocol to start is "P.A.C.E." by Dr. Al Sears. The book is poorly written but the protocol works fine. Out of shape, unconditioned individuals can use this method to get started. Start slowly and work up to 10 minutes. I think you will find your cravings for carbs and sweets will diminish with exercise - either long walking or HIIT. I hope you can get your blood sugar down. Good luck.

Jim Purdy (2011-11-03 10:19:21)

I hope Seth doesn't get upset with me for going off topic with his blog, but I really appreciate everybody's input. And, actually, I only gave a very short version of my situation. Here are a few more details: 1. THE LEG THAT HAD TO BE AMPUTATED - BUT I REFUSED In early 2010, doctors told me that my right foot had a very bad diabetic ulcer, and that the leg had to be amputated. Being non-compliant, I did not have the amputation, and I went to work on exercise, especially walking up stairs. RESULT: I still have my leg, and it has healed just fine. 2. THE HEART ATTACK THAT WAS MOMENTS AWAY AND REQUIRED QUADRUPLE BYPASSES - BUT I REFUSED In the summer of 2010, cardiologists rushed me straight to a heart hospital because they said I needed emergency quadruple bypasses for had badly blocked coronary arteries and that I could die of a heart attack at any moment. I did not have the bypasses, and I relied on exercise and diet changes. RESULT: I exercise regularly now, and I no longer have any chest pains at all. 3. THE KIDNEYS THAT WERE FAILING AND WOULD SOON NEED DIALYSIS - BUT NOW THEY ARE FINE For a few years, doctors have said my kidneys were failing and that I would eventually need dialysis unless I too lots of BigPharma chemicals. I felt that the chemicals would actually be more of a burden on my kidneys and

liver, and I didn't take any of them. RESULT: On my most recent lab work, my kidneys are just fine. 4. MY ONLY REMAINING BIG HEALTH ISSUE – MY HIGH DIABETIC BLOOD SUGARS Since all my other health issues have improved greatly with lifestyle changes, I am fully confident that the right lifestyle adjustments can control my diabetes. Interestingly, when I asked for advice from Seth Roberts and Jenny Ruhl (of Diabetes Update), they gave me very different responses. Seth recommended exercise, which is indeed what I am working on now in a brand-new exercise room in my apartment building. Jenny had only one suggestion: insulin. I 'm going to go with Seth over Jenny. Exercise has worked for our evolutionary ancestors for many millions of years, but BigPharma's injected insulin has only been around since 1921. I'll take my chances with millions of years of evolution, over 90 years of BigPharma lab products. Sorry for the distraction, Seth, but I really appreciate the input here.

Seth Roberts (2011-11-03 16:05:26)

#1-3 are great and powerful stories, Jim. I am very pleased to have them on this blog.

Matt B (2011-11-04 11:42:20)

@Jim, have you written the very long versions of your stories yet? #2, "cardiologists ...said I needed emergency quadruple bypasses for had badly blocked coronary arteries and that I could die of a heart attack at any moment" is a common refrain that could use some alternate thought.

grace (2011-11-04 19:52:21)

Hi Seth! It is my personal experience as well as observations that vitamin D in the evening disrupts awakening or sleep for some, so I generally always take it < 12-3pm unless I am sick (in which case if I am coming down with a cold, it doesn't matter and I sleep well despite the timing of the dosage). Is this story from Tara at <http://primalgirl.wordpress.com/?> The link above didn't work right for me? Jim Purdy, Awesome story and biohacking! Do you check your BGs frequently (20, 40, 60, 120 min after meals and fasting)? Protein/amino acids and their timing make profound changes on hormones, growth hormone, sex hormones, insulin/glucagon and leptin. Sounds like to me that you have lingering insulin resistance issues. Do the food cravings persist despite eating 50 grams protein in the AM + 15-30 grams carbs in the morning? Have you considered the value of 5HTP or L-tryptophan in the morning for cravings? Often these are deficient with leaky gut/intestinal permeability. Would love to hear your progress. G

Seth Roberts (2011-11-05 01:58:35)

Yes, this story is from Tara at [primalgirl.wordpress.com](http://primalgirl.wordpress.com).

Perfect Health Diet » Around the Web; Wise Traditions & CrossFit NYC Pre-Talk Edition (2011-11-05 17:44:04)

[...] Seth Roberts reports "a stunning discovery": it's better to take vitamin D in the morning. [...]

Dan (2011-11-05 20:10:17)

Vit D, when produced on the skin, is absorbed over a period of days. Hard to square that with this anecdote.

Seth Roberts (2011-11-05 21:28:34)

Dan, several others have reported that Vitamin D at night causes sleep problems. Which supports the idea that it really does affect circadian rhythms. No matter how slowly it is absorbed.

Harpoirseoul (2011-11-10 22:45:35)

Hi Seth, Thank you for your interesting blog. Myself, before going to bed I take Magnesium, and Vitamin B12. I personally find it helps me sleep well. BTW, any thoughts on sulfure? Just wondering.

Seth Roberts (2011-11-11 00:03:35)

I don't know what sulfure is, sorry.

Erin (2011-11-20 14:37:34)

Jim, I'm confused as to if you've made huge lifestyle changes before and gotten miraculous results through them why you still can't kick the binge eating! You should check out Tim Ferris' book 4-Hour Body. His plan is very close to a paleolithic diet, but with very low glycemic index foods, and will lower your blood sugar - and you can still eat wings, just not fried in peanut oil! I think that book would be a good one for you because there is one set binge day a week. Check out the book by Eric Braverman, The Edge Effect. There's a test in there for your neurotransmitter balance. Supplementing certain amino acids can help balance your brain chemistry and help curb your desire to eat compulsively.

Don't take Vitamin D at night | Aquatic Ape Diet (2011-11-25 09:51:47)

Henk Poley (2011-11-26 03:28:59)

View [1]this lecture by Stasha Gominak, where she explains her findings about vitamin D (and B12) in relation to sleep.

1. <http://drgominak.com/lecture>

Seth Roberts (2011-11-26 04:07:04)

Thanks, Henk. A fascinating and informative lecture. Curiously she says nothing about the time of day one takes Vitamin D.

Joseph Buchignani (2011-11-26 04:27:18)

Dan, the chemical mechanism for absorption of Vit-D from skin is different than ingested Vit-D. See the Mayo clinic vitamin D page.

jscott (2011-12-06 13:59:32)

I've been having massive insomnia, but it has been sporadic...or so I thought. Within the past month there have been 5 cases of insomnia. Onset of sleep has varied. Waking time has remained constant. D3 late at night (one hour prior bed) has been the only tracked variable that I have to point to and test. The D3 dosage has also been varied. I have yet to test but found it interesting to say the least.

Seth Roberts (2011-12-06 16:01:22)

[...] an ongoing look at the effects of Vitamin D3 supplementation and its role on sleep. A month ago I blogged about a "stunning discovery": Primal Girl's sleep got much better when she took Vitamin D3 in the early morning instead of [...]

jeanine (2012-02-27 23:13:32)

Jim Purdy, I was diagnosed with gestational diabetes. I tested my blood sugar levels constantly during the day and I found that beans of any sort (chili, refried, etc.) always dramatically lowered my blood sugar levels. Just an fyi.

Pennyjeans (2012-03-16 21:31:45)

Is anyone here a bit concerned that no one has heard from this person Jim Purdy since November 3rd and his last post was that he would continue eating 50 fried chicken wings a day and tell how that worked out for his glucose levels...?

## Vitamin D, Sunlight, and Sleep: More (2011-11-03 05:00)

In the comments on [1]yesterday's post ("Can Vitamin D Replace Sunlight? A Stunning Discovery"), two commenters (John and Aaron Blaisdell) noted that Nephropal had said something similar. They're right. Here's [2]what Nephropal said in 2009:

Vitamin D taken at night causes insomnia. This is a complaint of a few of my patients. Moreover, when they switch to morning dosing, the insomnia subsides. Thus, Vitamin D should be taken in the morning.

That's a great observation, but not the same as Primal Girl's. Here is [3]her observation, shortened for clarity:

I usually took my supplements mid-afternoon. I vowed to take them first thing every morning. I tried it the next day and that night I slept like a rock. And the next night. And the next.

The two observations support each other. Both support the idea that the timing of Vitamin D matters. But there are also big differences. Paleo Girl had been taking her Vitamin D in mid-afternoon, not at night. She shifted to first thing in the morning, which is more specific than morning. I changed the title of yesterday's title to make clearer what is new here: the idea that Vitamin D can substitute for sunlight.

Lots of things cause insomnia if you take them in the evening. Caffeine and other stimulants, for example. [4]A comment on yesterday's post said that B vitamins and calcium cause insomnia if taken in the evening. This is why Nephropal's observation, although very important, is not a stunning surprise. You stop taking X in the evening, your sleep improves – I won't be astonished, no matter what X is.

Vitamin D is not a stimulant or is at best a mild stimulant. Taking Vitamin D in the afternoon should not cause trouble sleeping. Yet Primal Girl had trouble sleeping. And she was getting little morning sunlight. It is a real insight that first-thing-in-the-morning Vitamin D could have the same effect as first-thing-in-the-morning sunlight – in other words, could substitute for missing sunlight. Against all odds, the results supported this idea.

[5]One commenter on yesterday's post said Primal Girl's results were both unproven and obvious. Vitamin D is technically a hormone! Melatonin is a hormone, said the comment. I have not heard anyone propose taking melatonin first thing in the morning to improve sleep. It is standard to take melatonin in the evening. The accepted view among circadian rhythm researchers is that sunlight produces its effects on circadian rhythms via nerves, not blood. For example, hundreds of experiments have found that destroying the suprachiasmatic nucleus of rats destroys their circadian rhythms. The suprachiasmatic nucleus receives neural input from the eyes – that's why these lesions were first made (by Irv Zucker, a Berkeley colleague of mine).

Lots of people think Vitamin D improves sleep. That's not new. Here's what one of them said, in a post promisingly titled "[6]When is the best time to take your Vitamin D supplement?":

In an effort to boost absorption of vitamin D, individuals were asked to take their vitamin D supplements with the largest meal of the day. After 2-3 months, vitamin D levels were checked again. At the end of the study period, vitamin D levels had risen to an average of 47.2 ng/ml (118 nmol/l) – an average increase in vitamin D levels of about 57 per cent. . . It seems sensible, I think, for individuals who are currently supplementing with vitamin D to take this with their largest evening meal.

---

Joseph Buchignani (2011-11-03 07:27:51)  
Haters gon hate, Seth. Great defense.

Elizabeth Molin (2011-11-03 08:27:21)  
This is off-topic (I apologize), but are you familiar with this: <http://www.badsience.net/2011/10/new-edition-of-testing-treatments-best-lay-text-on-evidence-based-medicine/>

Confused (2011-11-03 09:19:53)

I'm a little confused. I understand the claim to be: Vitamin D first thing in the morning helps you sleep better at night. Now here's the sequence of events as I see it: 1. Primalgirl has been sleeping poorly 2. She was and had been taking Vitamin D3 for a while 3. At night. 4. She then started taking it first thing in the morning 5. Starts sleeping like a rock BUT, crucially, she also says: "Days I forgot and skipped the D3, I still slept great." So it sounds like the Vitamin D at night was interfering with her sleep, and now it's been taken away and hence no more interference. If the D3 in the morning was actually helping her sleep better (than baseline) then she should sleep poorly (less better) on the days she skips it. Or am I missing something?

Seth Roberts (2011-11-03 15:58:38)

"Am I missing something?" Yes. She usually took the Vitamin D in mid afternoon, not night. Unlikely that she slept poorly because her afternoon Vitamin D was interfering with her sleep. It might be true that although she usually took her Vitamin D in the afternoon, perhaps once/week she took it in the evening and that was enough to keep her from getting a high-amplitude (= powerful) circadian rhythm in her sleep/wake oscillator. An oscillator doesn't require constant (e.g., daily) input to work properly. You don't have to push a swing every oscillation to make it keep swinging in a big arc. A few pushes at the right time can have a powerful and long lasting effect. A few pushes at the wrong time can be very damaging. So perhaps she was damaging her sleep every night by once/week taking her Vitamin D at night. And once she started doing the right thing (taking her Vitamin D at a favorable time, morning, rather than a neutral time, afternoon) everything started working great.

gwern (2011-11-03 17:02:22)

I could definitely believe the B vitamin thing. Sulbutiamine is a version of B vitamin thiamine, and I definitely noticed it messing with my sleep: <http://www.gwern.net/Nootropics#sulbutiamine>

Seth Roberts (2011-11-03 19:00:55)

no, not familiar, thanks. I downloaded it. It is full of attitudes that I think make progress more difficult (e.g., the idea that some evidence should be ignored). Maybe I will blog about it.

Confused (2011-11-03 20:33:29)

@Seth That's a great answer, thank you.

MetaThought (2011-11-05 00:55:55)

Seth, IIRC your first self-experiment was to test if animal fats promote sleep. I found a plausible explanation for that one. Oleamide is found in animal fats as well as Olive oil. It promotes sleep and has a hypnotic effect: <http://www.ncbi.nlm.nih.gov/pubmed/11681856>

Seth Roberts (2011-11-05 02:00:29)

MetaThought, thanks for the link. You are correct that I have studied the connection between animal fat (pork fat) and sleep. My first self-experiment of any consequence was about acne.

Perfect Health Diet » Around the Web; Wise Traditions & CrossFit NYC Pre-Talk Edition (2011-11-05 17:44:20)

[...] Seth Roberts says that sunlight works "via nerve, not blood." [...]

Daz (2011-11-05 19:42:22)

Thanks for the post Seth. I've linked to it & to the Nephropal one in response to a recent question on Vit D posted over at PaleoHacks. <http://paleohacks.com/questions/74996/when-and-what-is-best-supplement-for-vit-d>

donat (2011-11-06 05:08:37)

lunchtime might be best? J Bone Miner Res. 2010 Apr;25(4):928-30. Taking vitamin D with the largest meal improves absorption and results in higher serum levels of 25-hydroxyvitamin D. Mulligan GB, Licata A. "Many patients treated for vitamin D deficiency fail to achieve an adequate serum level of 25-hydroxyvitamin D [25(OH)D] despite high doses of ergo- or cholecalciferol." "Thus it is concluded that taking vitamin D with the largest meal improves absorption and results in about a 50 % increase in serum levels of 25(OH)D levels achieved." PMID: 20200983

Seth Roberts (2011-11-06 05:20:32)

donat, what about sleep? Percent absorbed is not a big deal – no need to maximize it. If you want more Vitamin D in your blood you need only take more Vitamin D. It isn't expensive.

donat (2011-11-06 06:10:13)

ouch, sorry. I was reacting to your earlier post where this aspect was not yet remarked on. The point was simply that one needs to be aware that dosage might be timing/food dependent.

cel (2011-12-01 14:17:36)

Seth, I recently found your book on Amazon while searching for a book to help me improve my sleep . . . just ordered it and can't wait to start reading it. Very interested to know the principles laid out in the book and will definitely try the diet. Re: vitamin D, i am taking vit D3 with my first meal of the day but when too busy it's not until noon I get to do it . . . I am wondering if taking it first thing in the morning mean taking it on an empty stomach. Since I can't eat until around 11-12 noon I wanted to know if it is safe to take Vit D or any other supplement on an empty stomach. Thank you.

Seth Roberts (2011-12-01 14:27:48)

I wanted to know if it is safe to take Vit D or any other supplement on an empty stomach. I have taken Vitamin D on an empty stomach many times with no problems.

Sleeper (2012-01-11 10:52:50)

this entire exchange surprised me because i started taking 5000 IU of vitamin d before bed and slept 10 hours both nights since, so i expected to find people saying it helped them sleep by taking it before bed

Seth Roberts (2012-01-11 14:10:45)

## **Flaxseed Oil Heals Bleeding Gums, Again (2011-11-04 05:00)**

In response to [1]this post, which went up three months ago, [2]a reader named Tara has just written:

I started taking 2 TB of flax oil daily about four days ago and now my gums are barely bleeding at all after I brush and floss. My gums were red, swollen and would bleed after I brushed and flossed and are now pink and healthy looking.

I've had this problem for years and I could not understand why it would keep happening even though I was consistent with my dental routine. I take the berry flavored Barlean's flax oil mainly because it tastes good and so I look forward to taking it- if it was gross I would not be consistent with taking it.

Anyhow, thanks for the information! I wish dentists would look into this but they probably won't so I'm glad that you do.

I agree about the Barlean's, by the way. Their [3]Omega Swirl flaxseed oil does taste good. The Omega Swirl webpage does not list healthy gums as one of its benefits. Instead it lists a bunch of benefits, such as "Heart Health" that are nearly impossible to verify.

Someone recently told me something fascinating about flaxseed oil: It made it much easier to kneel on the floor. Before he started taking it, his knees would hurt after a few seconds. Now they don't. I don't remember my knees hurting quickly but I consume 66 g/day of ground flaxseed (= about 2 T flaxseed oil) and can kneel without pain for minutes.

The tiny fact reflected in Tara's comment – an easily-available supplement (flaxseed oil) quickly cures a common problem (bleeding gums) but hardly anyone knows this – is a devastating comment on our health care system.

1. Dentists haven't managed to figure this out. Flaxseed oil is not an obscure supplement. Dentists are not making money giving people much worse advice ("floss regularly").

2. Nutrition professors haven't managed to figure this out. Omega-3 is not an obscure nutrient. Nevertheless, the [4]2010 USDA Dietary Guidelines says omega-3 fats are "essential" but says nothing about how much you need. Inflammation is believed to be the cause of many diseases, including heart disease. By getting this one thing (minimum omega-3 intake you need to be healthy) right, the USDA could do a world of good. Instead they tell people to eat less animal fat ("consume less than 10 percent of calories from saturated fatty acids").

To be fair, professional researchers are starting to figure this out. [5]A 2010 study of 9000 people found that "participants in the middle and upper third for omega-3 fatty acid consumption were between 23 percent and 30 percent

less likely to have gum disease than those who consumed the least amount of omega-3 fatty acids." With the right dose, I believe gum disease becomes 100 % less likely. But at least they noticed a connection.

Tuck (2011-11-04 07:50:56)

Interesting. I've also noticed that gum bleeding has decreased almost to nothing since fixing my diet by eliminating wheat and seed oils. I never take flax seed oil, however, although I do eat a lot of fish and macadamia nuts (which are another source of vegetable-omega-3 oils). And lots of pastured meat.

Rashad (2011-11-04 08:52:08)

To be fair, I think in most people brushing and flossing DOES reduce bleeding gums, at least that is true for me. When I'm lazy about flossing, I get bleeding gums, when I start doing it regularly, about a week later my gums stop bleeding. So part of the problem is that I think many dentists view the problem as "solved".

Leslie (2011-11-04 09:01:45)

Hi Seth, I'm wondering if you have tried comparing flax seeds to chia seeds? And do you get much omega 3 from other sources, like fatty fish?

Tim Beneke (2011-11-04 09:10:19)

Once again, add me to the list of people who find that 2-3 tablespoons of flax seed oil a day improves both my gums and joint pain. I suffer intermittent knee, hip and now shoulder joint pain and find after doing a few days on and then a few days off consuming the flax seed oil that there is substantially less pain when I take it. And yes bending down and picking something up is a much less painful experience when I've been doing the oil. I don't like the taste of the oil and don't want to, since I also use it as weak-tasting calories in my weight loss efforts. I swallow it quickly in water with my tongue outside (under) the glass and immediately drink some strong green tea afterwards to mask the taste. It is work to do this, but well worth it... Onwards with more self experimentation! Pooling the efforts of even a small number of self experimenters, we seem to be able to come up with a lot of solutions to problems that high falutin scientists are blind to.

Seth Roberts (2011-11-04 15:38:15)

Thanks, Tim, those observations are very helpful. As you say.

Seth Roberts (2011-11-04 15:43:19)

Leslie, I have not compared flax seeds to chia seeds. Flax seeds are much easier to get. When I'm in Beijing, I rarely eat fatty fish. I first discovered that flaxseed oil (just a few capsules) improved my balance when I was in Berkeley. At the time I ate fatty fish (salmon) regularly, once or twice/week. My initial observation was that a relatively small amount (by my current standards) of flaxseed oil noticeably improved my balance (measured by how easily I could put on my shoes while standing). Eating fatty fish (or anything else) had never done that.

Seth Roberts (2011-11-04 15:45:03)

Rashad, that's a good point. I found the same thing as you: if I flossed enough, my gums stopped bleeding. However, I don't think flossing changed them from red (inflamed) to pink (not inflamed).

Alex Chernavsky (2011-11-06 08:37:36)

Tim, with regard to your procedure for taking flax oil: I take about four tablespoons – straight – every day around noon, as part of my Shangri-La diet regimen. I do not make much effort to mask the taste. Sometimes I chase the oil with water, but I don't always do it, if I'm busy. Still works for me.

David (2011-11-06 11:26:40)

Seth, I agree regarding flossing. I am a regular flosser who never had bleeding gums, yet I did have inflammation which manifested itself in the form of periodontal pockets. I was told the pockets were the result of genetic bone loss. As I posted previously on your blog, I significantly shrunk these pockets between visits to the dentist (6 months) by drinking flaxseed oil. On a different topic, I'm wondering how (if) you reconcile the ideas of people like Chris Masterjohn who believe that the degeneration of PUFA is what drives atherosclerosis. I know flaxseed oil helps my gums, and I have a hunch it may help with my degenerating lumbar disc, but I am concerned about the seemingly contradictory effect on my vascular system. Thoughts?

Seth Roberts (2011-11-06 13:13:04)

"I know flaxseed oil helps my gums, and I have a hunch it may help with my degenerating lumbar disc, but I am concerned about the seemingly contradictory effect on my vascular system." My advice: go with what you can see ("helps my gums"), don't worry about untested theories. I like Chris's work but I doubt he has convincing evidence of that theory.

Jon K (2011-11-07 07:30:13)

Hi, I tried posting a question before and it appears to have not gone through. so I'll try again. Have you noticed any increase in hair loss/thinning as you changed your omega 3 consumption? There appear to be several people (40+) who posted on a hair loss blog with the observation that increased flax/fish oil produced significant hair loss/thinning. Several of the comments were from women, which I found interesting. Less clear was the effect of ground flax seed, which contains lignans, vs flax oil. Some claimed it thickened hair, others that it thinned. Since you've used both methods for a long period, I'm wondering if you could give your observations. Also, anecdotally, there appears to be a link between turmeric intake and an increase in hair loss. What is it with anti-inflammatories that could potentially have this side effect? (the fourth google hit for "flax seed hair loss" contains a blog post where most of the comments I'm referring to come from, though they appear in many other places across the web)

Seth Roberts (2011-11-07 14:28:55)

"Have you noticed any increase in hair loss/thinning as you changed your omega 3 consumption?" No I haven't. Why anti-inflammatories should increase hair loss – if they do – I have no idea. One of my students is measuring hair loss. He is also working on a study about inflammation. Perhaps he will be interested in studying this.

Sade (2011-11-07 17:59:15)

Interestingly, the ophthalmology industry seems to be catching on to the importance of Omega-3's. I'm not sure what they have to do with eye health, but at my doctor's office it is the only "medicine" that he advertises on his walls.

Dan (2011-11-08 00:55:05)

Have you heard of Oil Pulling for dental hygiene? It involves pulling/swishing 1 teaspoon of sesame seed through your teeth first thing in the morning. Just google "oil pulling" and you will find links.

Kevin (2012-01-10 20:26:45)

This is an interesting, yet positive, reaction to taking flaxseed oil. I've always known flaxseed oil was an excellent plant-source of omega 3 fatty acids and their anti-inflammatory effects. I wonder if these effects would occur if you took an omega 3 fish oil or

other sources of omega 3 fatty acids? Nevertheless, I definitely agree with the use of omega 3 supplements; our bodies cannot make these essential fats so it's very important we get these healthy fats in our diets.

### **Ten Reasons To Distrust Drug Companies (2011-11-05 05:00)**

A reader of this blog who wants to be identified as Doctor's Daughter wrote the following editorial and submitted it to [1]KevinMD, which turned it down. KevinMD is aimed at doctors. One recent article ("[2]Why 99 % of health care should be angry") said this: "The real top earners in health care, however, are not physicians, but executives of big corporations, non-profit and especially for profit." Here is what Doctor's Daughter wrote:

(On Kevin MD's website there was a recent piece entitled "How Can Pharma Earn the Trust of Patients?" which was submitted by Richard Meyer, the executive director of Online Strategic Solutions, which develops strategies for companies that engage in direct-to-consumer marketing. . . I feel compelled to offer a different viewpoint, focused on pharma's actual business practices.)

Far too many pharmaceutical companies have:

1. Spent more money on marketing than on honest research and development.
2. Set exorbitant prices for drugs. For example, they have engaged in price-gouging for cancer drugs, with many costing more than \$50,000 annually.
3. Tried to medicalize almost everything and, quelle surprise, they have a pill for that! Few of these drugs do anything to cure the condition; they just alleviate the symptoms.
4. Undermined the independence of guideline panels by making sure that the panels are filled with pharma friendly researchers and clinicians.
5. Unduly influenced the judgment of physicians and tried to undermine their integrity with gifts and cash.
6. Prevented lower-priced generics from coming on the market with "pay to delay" agreements and by other means.
7. Chosen profits over safety (remember the Heparin scandal?).
8. Designed studies that only report the supposed benefit of a particular drug and suppress information about adverse effects.
9. Exercised undue influence over panels that review the efficacy and safety of drugs.
10. Have continued to spend billions on advertising by saturating prime-time TV with Direct-To-Consumer ads to "Ask your doctor..."

With these kinds of abusive practices, should anybody trust these guys?

A reasonable list of complaints.

1. <http://www.kevinmd.com/>

2. <http://www.kevinmd.com/blog/2011/10/99-percent-health-care-angry.html>

---

Jim Purdy (2011-11-05 05:48:32)

Great list! I especially like # 3, and of course BigPharma doesn't stop once they create a scary name for a previously unrecognized disease, or even after they lobby the FDA to approve their new drug for their new made-up disease. They then go to work lobbying the FDA to change the guidelines, so that many more millions of people will get prescriptions for the new drugs to treat the new diseases. Why doesn't the FDA ever de-classify any of these fictional diseases?

WFA (2011-11-05 07:28:59)

Whether it's intentional or unconscious, the numbing repetition of TV commercials suggests to me an additional tactic. It isn't just the drug being promoted, it's the disease. How many people might even succumb to some condition repeatedly 'plugged' as common? There's also the "Ask your Doctor if X-drug is right for you!" which affirms the Doc as an authority figure, garners appointments for him, and presumably produces celebrity ("as seen on TV") prescriptions, when doing nothing might be a better option. (Truth in advertising: "Nothing works better than \_ \_ \_.") And now there's that grey-haired retiree on our screens, getting down with his motorcycle on the salt flats. Sure, 60 may be the new 50 (or some such), and so-called 'active lifestyles' are becoming more common. But having seen these sorts of commercials, how many now on Medicare ("Free!") will take the commercial dare and engage in high risk activities? Dumping his bike at Bonneville could land the guy in just the hospital which shot the commercial! I don't think all the above is necessarily intentional. But why would it not happen?

Glen Raphael (2011-11-05 08:43:18)

#1 and #10 aren't reasonable. If and when drug companies have a drug that actually can make people's lives better, how the potential customers supposed to know about it if the companies don't advertise? It's entirely conceivable that spending lots of money - even billions of dollars - on advertising might both (a) make the drugs being advertised cheaper and/or better, and (b) make customers better off. Ad spending does not conflict with the ability to spend on "honest research and development" nor is there any logical reason it would be better to spend more on R & D than on ads. A well-designed ad campaign "pays for itself", bringing in more than enough extra revenue to cover the cost of the campaign. Which means the company that runs good ads has \*more\* money to spend on R & D (or other appropriate expenses) than they would have without running the ads. Speaking as a consumer, I'm glad companies run direct-to-consumer ads, but I wish the companies were legally allowed to tell me exactly what the product does and that I was legally allowed to go buy it in stores without going through a doctor.

Tom (2011-11-05 11:23:17)

Glen, ad spending aimed at non-physicians by pharmaceutical companies used to be illegal, for good reason in my opinion. I think your points are optimistic to the point of Pollyannaism. Once stocked with right-wing justices, the Court gave corporations - "people" who exist solely as a *legal fiction* - the same free speech rights that actual citizens have. Hence the billions of dollars spent medicalizing children with too much spunk. And don't get me started on the symbiosis between Big Medicine's voracious diabetes/dialysis complex and endless supply of human chum created by Archer/Daniels/Midland-General Foods-Nabisco-Coca Cola etc etc etc. You might think that the fact that fake people can out-shout folks like Seth a billion to one has raised the level of discourse in America and improved the lives of non-imaginary citizens. I'd sooner believe in unicorns.

wcb (2011-11-05 15:56:52)

Tom makes the excellent point that direct-to-consumer ads used to be illegal in this country, like they still are in most other countries including Europe and Canada. A good case can be made that the FDA (or Congress) should revisit this issue in the USA. After all, there's a big difference (or should be) between, say, consumer ads for fashion wear or lipstick and the marketing of prescription drugs that are costly to begin with and may very well cause adverse effects requiring even more expensive

medical interventions. No wonder government programs such as Medicare and Medicaid are going broke. None of this means that pharma companies couldn't cheaply publish objective information about their products (say on their websites) as long as they eliminated the hype and fully disclosed the potential adverse effects. And if they stopped all consumer TV advertising and direct marketing to doctors, imagine how much less expensive some truly useful medicines could be. But perhaps Congress has become too far over-lobbied and compromised by campaign contributions (from you-know-who) to have the backbone and common sense to prohibit TV advertising of prescription drugs. If that turns out to be the case, then maybe the IRS should take the initiative to begin disallowing pharma companies' deduction of these costs as "ordinary and necessary" business expenses on their tax returns. In light of experience, I suggest the prevailing view should be that direct-to-consumer advertising of drugs, although it has most unfortunately become ordinary, should in no way be necessary; and most certainly is not good public policy.

Glen Raphael (2011-11-07 07:17:16)

The "right of corporations to speak" is just the right of \*people\* to speak through corporations. The ACLU is a corporation. Amnesty International is a corporation. Prior to that ruling, the government had effectively banned large swaths of \*political speech\* - exactly the sort of speech the constitution was meant to protect. That ruling makes it easier for people to get the word out, in any direction. The answer to bad speech is more speech, not laws that make whole categories of speech illegal. "Ask your doctor" ads are a second-best solution. The real problem here is that doctors have the prescription monopoly. If pharmacists could sell you drugs without a doctor's prescription (as is done in Mexico), the doctors would have less power \*and\* customers would have more ability to get medicine cheaply when they need it. We should make \*all\* drugs "over the counter", make FDA approval voluntary, and let companies market freely to consumers. Competition would then drive down the cost and improve the effectiveness of drugs. The reason we see so little innovation and such high costs in medicine today is that everything medicine-related has to go through the FDA \*and\* through doctors; there is no opportunity for a tiny startup that comes up with some new treatment that \*might\* help people with some rare disease to start selling it on a small scale and grow organically until lots of people see the benefit or until it gets outcompeted by some better solution. The fact that you have to spend billions of dollars satisfying the FDA \*and\* more billions marketing to the doctors, effectively turning doctors into your sales force, makes real innovation rare and denies effective help to anybody whose disease only affects a few people. Real innovation has risks associated with it. We \*need\* innovation, so we need to accept some level of risk. Trying to eliminate all risk in advance is the riskiest course of all.

Seth Roberts (2011-11-07 14:43:10)

Glen, giving corporations "free speech" amounts to giving defenders of the status quo more power. I think they have enough power already. Yes, FDA regulation and the need for prescriptions reduce drug company innovation. I agree. But drug companies themselves reduce innovation. They reduce the search for non-drug solutions. Which I for one have found enormously helpful. In the case of diagnostic devices, I agree completely. FDA approval impedes innovation, with no significant benefits.

Glen Raphael (2011-11-07 21:01:09)

With regard to "free speech", incumbents in congress get their 98 % reelection rate in large part because they already have power, goodies to auction off and name recognition. Incumbents don't \*need\* big contributions to win; challengers to the status quo do. If we decontrolled "political speech" and let anybody contribute however much they want to any candidate, we'd see better candidates. Right now we have this weird situation where if you're rich you can spend as much as you want on your \*own\* campaign but only a trivial amount on somebody else's. As a result, we tend to get a lot of rich nitwits running for office even when \*they themselves\* know they aren't the best man for the job. Under freedom, a really good candidate would only have to win over \*one\* crazy billionaire - say, Ross Perot - in order to get a seat at the table. Under regulation, we instead get Ross \*actually running\*, which isn't good for anybody. :-) I agree that the status quo reduces the search for non-drug solutions. But it also reduces the search for improved with-drug solutions. We're free to do n=1 experiments with light and vitamins and flax-seed oil but we're not free to do n=1 experiments with, say, Prozac. Or, heck, LSD. We mostly learn new things about prescription drugs through big, official, slow, expensive experiments, and trying to learn more about controlled drugs can actually get patients sent to prison. That seems like a wasted opportunity all around - drugs that \*actually work well\* - either for prevention or for cure - would be a godsend and we don't really have enough of them.

Txomin (2011-11-08 00:09:27)

Sure. The ugly side of pharmaceutical companies is... ugly. But it is also true that none of us have any fear whatsoever of many diseases that not long ago were deadly. Where is the reasonable middle ground?

andrew (2011-11-08 11:31:44)

Seth if you ended drug marketing wouldn't that make patients more dependent on doctors for information?

Seth Roberts (2011-11-08 12:16:23)

Andrew, the answer to your question ("if you ended drug marketing wouldn't that make patients more dependent on doctors for information?") is yes. But patients have other sources of information (on the Internet) less biased than their doctor (or should I say: even their doctor?). Sources of information who surely haven't accepted gifts and free samples from drug company representatives.

### **Testing Treatments: Nine Questions For the Authors (2011-11-06 05:00)**

From [1]this comment (thanks, [2]Elizabeth Molin) I learned of a British book called Testing Treatments ([3]pdf), whose second edition has just come out. Its goal is to make readers more sophisticated consumers of medical research. To help them distinguish "good" science from "bad" science. Ben Goldacre, the Bad Science columnist, [4]fulsomely praises it ("I genuinely, truly, cannot recommend this awesome book highly enough for its clarity, depth, and humanity"). He wrote a foreword. The main text is by Imogen Evans (medical journalist), Hazel Thornton (writer), Iain Chalmers (medical researcher), and Paul Glaziou (medical researcher, editor of Journal of Evidence-Based Medicine).

To me, as I've said, medical research is almost entirely bad. Almost all medical researchers accept two remarkable rules: (a) [5]first, let them get sick and (b) [6]no cheap remedies. These rules severely limit what is studied. In terms of useful progress, the price of these limits has been enormous: near total enfeeblement. For many years the Nobel Prize in Medicine has documented the continuing failure of medical researchers all over the world to make significant progress on all major health problems, including depression, heart disease, obesity, cancer, diabetes, stroke, and so on. It is consistent with their level of understanding that some people associated with medicine would write a book about how to do something (good science) the whole field manifestly can't do. Testing Treatments isn't just a fat person writing a book about how to lose weight, it's the author failing to notice he's fat.

In case the lesson of the Nobel Prizes isn't clear, here are some questions for the authors:

1. Why no chapter on prevention research? To fail to discuss prevention, which should be at least half of health care, at length is like writing a book using only half the letters of the alphabet. The authors appear unaware they have done so.
2. Why are practically all common medical treatments expensive?
3. Why should some data be ignored ("clear rules are followed, describing where to look for evidence, what evidence can be included")? The "systematic reviews" that Goldacre praises here (p. 12) may ignore 95 % of available data.
4. The book says: "Patients with life-threatening conditions can be desperate to try anything, including untested 'treatments'. But it is far better for them to consider enrolling in a suitable clinical trial in which a new treatment is being compared with the current best treatment." Really? Perhaps an ancient treatment (to authors, untested) would

be better. Why are there never clinical trials that compare current treatments (e.g., drugs) to ancient treatments? The ancient treatments, unlike the current ones, have passed the test of time. (The authors appear unaware of this test.) Why is the comparison always one relatively new treatment versus another even newer treatment?

5. Why does all the research you discuss center on reducing symptoms rather than discovering underlying causes? Isn't the latter vastly more helpful than the former?

6. In a discussion of how to treat arthritis (pp. 170-172), why no mention of omega-3? Many people (with [7]good reason, including [8]this) consider omega-3 anti-inflammatory. Isn't inflammation a major source of disease?

7. Why is there nothing about how to make your immune system work better? Why is this topic absent from the examples? The immune system is mentioned only once ("Bacterial infections, such as pneumonia, which are associated with the children's weakened immune system, are a common cause of death [in children with AIDS]").

8. Care to defend what you say about "ghostwriting" (where med school professors are the stated authors of papers they didn't write)? You say ghostwriting is when "a professional writer writes text that is officially credited to someone else" (p. 124). Officially credited? Please explain. You also say "ghostwritten material appears in academic publications too – and with potentially worrying consequences" (p. 124). Potentially worrying consequences? You're not sure?

9. Have you ever discovered a useful treatment? No such discoveries are described in "About the Authors" nor does the main text contain examples. If not, why do you think you know how? If you're just repeating what others have said, why do you think your teachers are capable of useful discovery? The authors dedicate the book to someone "who encouraged us repeatedly to challenge authority." Did you ever ask your teachers for evidence that evidence-based medicine is an improvement?

The sad irony of *Testing Treatments* is that it glorifies evidence-based medicine. According to that line of thinking, doctors should ask for evidence of effectiveness. They should not simply prescribe the conventional treatment. In a meta sense, the authors of *Testing Treatments* have made exactly the mistake that evidence-based medicine was supposed to fix: Failure to look at evidence. They have failed to see abundant evidence (e.g., the Nobel Prizes) that, better or not, evidence-based medicine is little use.

Above all, the authors of *Testing Treatments* and the architects of evidence-based medicine have failed to ask: How do new ideas begin? How can we encourage them? Healthy science is more than hypothesis testing; it includes hypothesis generation – and therefore includes methods for doing so. What are those methods? By denigrating and ignoring and telling others to ignore what they call "low-quality evidence" (e.g., case studies), the architects of evidence-based medicine have stifled the growth of new ideas. Ordinary doctors cannot do double-blind clinical trials. Yet they can gather data. They can write case reports. They can do  $n=1$  experiments. They can do  $n=8$  experiments ("case series"). There are millions of ordinary doctors, some very smart and creative (e.g., [9]Jack Kruse). They are potentially a great source of new ideas about how to improve health. By denigrating what ordinary doctors can do (the evidence they can collect) – not to mention what the rest of us can do – and by failing to understand innovation, the architects of evidence-based medicine have made a bad situation (the two rules I mentioned earlier) even worse. They have further reduced the ability of the whole field to innovate, to find practical solutions to common problems.

Evidence-based medicine is religion-like in its emphasis on hierarchy (grades of evidence) and rule-following. In the design of religions, these features made sense (to the designers). You want unquestioning obedience (followers must not question leaders) and you want the focus to be on procedure (rules and rituals) rather than concrete results. Like many religions, evidence-based medicine draws lines (on this side "good", on that side "bad") where no lines actually exist. Such line-drawing helps religious leaders because it allows their followers to feel superior to someone (to people outside their religion). When it comes to science, however, these features make things worse.

Good ideas can come from anybody, high or low in the hierarchy, on either side of any line. And every scientist comes to realize, if they didn't already know, that you can't do good science simply by following rules. It is harder than that. You have to pay close attention to what happens and be flexible. Evidence-based medicine is the opposite of flexible. "[10]There is considerable intellectual tyranny in the name of science," said Richard Feynman.

Testing Treatments has plenty of stories. Here I agree with the authors – good stories. It's the rest of the book that shows their misunderstanding. I would replace the book's many pages of advice and sermonizing with a few simple words: [11]Ask your doctor for the evidence behind their treatment recommendation. He or she may not want to tell you. Insist. Don't settle for vague banalities ("It's good to catch these things early"). Don't worry about being "difficult". You won't find this advice anywhere in Testing Treatments. If I wanted to help patients, I would find out what happens when it is followed.

More Two of the authors respond in the comments. And I comment on their response.

Lemniscate (2011-11-06 06:04:02)

Evidence-based medicine has a good name. Who doesn't want their medical treatments to be based on evidence? In practice, however, it means medicine deemed by a certain group of experts to be supported by evidence. It's an attempt to create a knowledge monopoly, in the same way that the IPCC attempts to act as a monopoly on climate change knowledge. All monopolies suppress innovation and are often captured or created by special interests – government, academia and corporations. I would suggest knowledge monopolies are often even more damaging than production monopolies, because they deeply affect the entire web of knowledge that they are integrated in to with wide-ranging consequences.

wcb (2011-11-06 10:03:07)

Seth, excellent review and commentary on this topic. I would offer the additional thoughts that, among the things neglected or overlooked by conventional medical research (whether "evidenced-based" or not) is anything having to do with diet/nutrition. I give you mucho credit for addressing these matters on your blog. Along these lines, if more physicians (and our fellow citizens) would but remove their heads from their butts on such issues, I dare say there could be a dramatically positive effect on public health. More focus on nutritional issues would go a long way in advancing prevention for many common diseases and (the way I prefer to look at it), would help people become proactive on their own in avoidance of same. Of course we would also have to change the incentives in a medical care system that is so driven by profit and conflicts of interest. The other reality that would have to be overcome within the medical industry, to foster much less costly prevention (or avoidance) of disease, is the current system that allows issues of diet/nutrition to default to government agencies that have been captured by those whom

they are supposed to regulate (the USDA comes to mind) or trade groups such as the American Diabetes Association that get their financial support from pharma and packaged food companies. Talk about conflict of interest! At the risk of sounding like a pitchman (which I'm not), I would also like to suggest we at least become aware of the work of some doctors (still largely in the minority) who are already practicing (real) preventive medicine. In this case, I'm specifically referring to William Davis, a cardiologist in Milwaukee. His blog is available to anyone with access to the Internet, but he has now also published a book, "Wheat Belly," that contains actual case studies from his medical practice, as well as end notes citing the supporting, scientific sources. Anyone interested in getting a better idea of what it's about can simply go on Amazon.com and check out the reviews. I might add that the book has been on the NY Times best seller list, within its category, off and on for several weeks, and can probably now be found in many public libraries.

Alrenous (2011-11-06 10:12:44)

Ironically and tragically, I heard about the solution when I was a kid. I remember it being about traditional Chinese doctors, though I never verified the story. Pay a doc when you're healthy. When you get sick, stop paying until you get better. You get what you pay for. If you pay for treatment, you get treatment. If you pay for health, you get health.

Seth Roberts (2011-11-06 13:09:30)

"You get what you pay for...if you pay for health, you get health." – Exactly. When doctors are paid for health, I believe we will see a vast improvement.

Tom (2011-11-06 17:02:04)

Seth, Your point is so important, and I think it's worth doing whatever it takes to call attention to how the entire medical establishment is designed to reward the lowest ROI research. How about creating an annual award to draw more news coverage? Why don't you create the **Roberts Prize**, for each year's *highest ROI* health advance?

Seth Roberts (2011-11-06 17:48:31)

That's an interesting idea, Tom. I will think about it. It is certainly a way to publicize the problem.

Seth Roberts (2011-11-06 17:54:47)

Lemniscate, I like your comment very much. I think the term knowledge monopoly, which I haven't heard before, brilliantly describes the problem. I especially like these parts of your comment:

Evidence-based medicine has a good name. Who doesn't want their medical treatments to be based on evidence? .  
. It's an attempt to create a knowledge monopoly, . . . All monopolies suppress innovation and are often captured or created by special interests

You have put the problem very well and I hope that someday people who support evidence-based medicine will address it.

Lemniscate (2011-11-07 11:39:38)

I got the term from Richar Tol's paper "Regulating Knowledge Monopolies: The Case of the IPCC." via Judy Curry. I don't think his solution to regulate knowledge monopolies is that good; the regulator is just as likely to be captured or created by special interests. However, the idea that (effective) knowledge monopolies have bad effects is important. The idea of one super-authoritative technocratic body seems to have some intuitive appeal to many, including "evidence-based medicine" advocates.

Elizabeth Molin (2011-11-10 12:17:06)

This post and the discussion got me thinking, and I wanted to post a comment on a peripherally related idea. When I drafted it, however, it turned out to be much too long for a comment, so I've posted it myself: <http://www.elizabethmolin.com/?p=261>

Seth Roberts (2011-11-10 14:37:39)

Elisabeth, thanks for the link. The post is titled "What should we ask the doctor?" If you ever ask your doctor for evidence, I hope you will write about what happens. I will post it in my blog if you send it to me or link to it if you post it in your blog.

Elizabeth Molin (2011-11-11 11:26:39)

My husband is the one with the (slightly) elevated cholesterol. I hated that our doctor put him on statins, so I did a lot of research (much of it with the help of your blog), and gave him a bunch of links to relevant studies and information to present to her. Her response: "I didn't know that. Thank you. You probably shouldn't be on statins." So now he isn't. Needless to say, I love our doctor!

Seth Roberts (2011-11-11 12:37:42)

Elisabeth, thanks for explaining that. To say you love your doctor because she changed her mind when told about evidence she should have known (statins are dangerous and expensive) is quite a comment on doctor behavior. What if your husband had asked your doctor "what's the evidence behind your recommendation?" Do you have any idea what would have happened?

Paul Glasziou & Iain Chalmers (2011-11-11 15:14:53)

Testing Treatments: nine answers to Seth Roberts' nine questions for the authors The questions raised in Seth Roberts' review of our book reveal a number of misunderstandings about it. The aim of our book is to improve awareness of the need to test treatments properly – old or new – through fair tests of the impact of treatments in patients, on outcomes that matter to them. It was not our intention to provide an overview of the effects of past and present treatments. That information is available from a multitude of other sources. Interested readers can assess our book for themselves: the full text is FREE - a downloadable pdf from [www.testingtreatments.org](http://www.testingtreatments.org). Here are some brief answers to the nine questions posed by Seth Roberts. 1. Why no chapter on prevention research? The book is primarily about testing treatments and interventions for secondary prevention; but it does not exclude prevention. We discuss screening in detail and several preventive interventions, for example, putting babies to sleep on their backs or sides. 2. Why are practically all common medical treatments expensive? We refer to loads of inexpensive common treatments in the book, including citrus fruits, folic acid, vitamin B12, insulin, lumpectomy, aspirin, caffeine, magnesium sulphate, saline, tranexamic acid, streptokinase, co-trimoxazole, diuretics, morphine, mother's kiss, propranolol, steroids, and zidovudine. 3. Why should some data be ignored? We don't suggest ignoring data, but do recommend gathering it all, then sifting the stronger from the weaker evidence – that is the central process of a systematic review. You write in your comment that "medical research is almost entirely bad"; so it should come as no surprise to you that systematic reviews "may ignore 95 % of available data". 4. Why are there never clinical trials that compare current treatments (e.g., drugs) to ancient treatments? The ancient treatments, unlike the current ones, have passed the test of time. We are not sure what qualifies as an 'ancient treatment', but bloodletting and purging were certainly "ancient" and they passed the 'test of time' for over a millennium. Most people believe now that these ancient treatments do more harm than good. All treatments, ancient and modern, need to be subjected to fair tests. Why is the comparison always one relatively new treatment versus another even newer treatment? Would that that were the case! The power of the pharmaceutical industry and the equipment manufacturers has meant that comparative effectiveness studies are all too rare. 5. Why does all the research you discuss center on reducing symptoms rather than discovering underlying causes? We include many examples of treatments aimed at causes, including citrus fruits, folic acid, vitamin B12, and insulin. 6. In a discussion of how to treat arthritis, why no mention of omega-3? Our book is about methods for testing treatments. It is not intended to cover all options for all conditions, and no conceivable book could do that. However a search for trials and systematic reviews of omega-3 for osteoarthritis suggests we have not overlooked convincing evidence. 7. Why is there nothing about how to make your immune system work better? Our response to your question 6 applies. 8. Care to defend what you say about "ghostwriting"? We wrote ghost-writing is "... when a professional writer writes text that is officially credited to someone else. Sometimes the pharmaceutical industry employs communication companies to prepare articles which, unsurprisingly, cast the industry's product in a favourable light." Some of us have been lobbying for transparency in doing and reporting research for over a quarter of a century. 9. Have you ever discovered a useful treatment? Our book was about testing treatments, not inventing treatments. Though we have contributed to the discovery of useful treatments, we're not inclined to indulge in self-promotion.

Seth Roberts (2011-11-11 16:39:35)

Thank you for responding to my questions. That is generous of you. I will discuss your answers at length later but let me make some simple points right now. 1. "We don't suggest ignoring data," you write. Yet you praised "systematic reviews," which do exactly that: exclude large fractions of relevant research. My opinion of medical research is irrelevant to the question of whether you advocate ignoring data. 2. "Our book was about testing treatments, not inventing treatments," Inventing treatments includes testing treatments. The big point of my comments on your book was that what you advocate suppresses innovation. It does so because it denigrates (and, in systematic reviews, ignores) the cheap small-scale studies (i.e., tests) important in the beginning of an idea. 3. "However a search for trials and systematic reviews of omega-3 for osteoarthritis suggests we have not overlooked convincing evidence." Apparently (your use of "convincing") you have decided that some evidence doesn't count. Yet omega-3 is, compared to other treatment options you include, very cheap, very easy to get and take, and very safe. I suspect those considerations (price, availability, ease of treatment, safety) did not enter into your judgement of the evidence. You seem to have simply looked at how convincing the studies were. (This is what evidence-based medicine preaches over and over.) Perhaps if you considered those factors, you would value the studies you now dismiss more highly. You should take those considerations into account. I think I speak for every person in the world outside medicine and health care when I say that. 4. One of my questions was this: "Did you ever ask your teachers for evidence that evidence-based medicine is an improvement?" You seem to have ignored it. The research you praise has its place. The research you denigrate also has its place – at least, I think so. That is why I ask: What is the evidence that evidence-based medicine has made things better? 5. The large point of my questions, to repeat myself, was that the preferences and values shown in your book suppress innovation because they denigrate the work needed in the beginning. You denigrate the cheap obviously-imperfect tests needed to find good ideas worth testing in more expensive ways. You have not addressed this point.

Lemniscate (2011-11-12 08:52:05)

I think the difference in attitude between Seth and the authors can be partially explained by differing emphases on type I and type II errors. "Evidence-based" medicine puts far more emphasis on type I errors at the expense of type II errors. Not caring about type II errors is bad for innovation and expense. There may be lots of safe and cheap potential treatments one could try. If you're worried about making a type I error then you might not try a treatment that actually works, committing a type II error. Which type of error you should try and avoid depends on the treatment being considered – cost, potential risks, etc. – and trying to fit all assessments of treatment efficacy in to one methodology is a mistake.

## **The Verb "To Google" (2011-11-06 17:38)**

I visited Google New York a few years ago. In conversation, an engineer used the verb to google – just like everyone else. Slightly amusing. Today I used the verb to google in an email. Gmail told me it was misspelled! Google is okay but google is not in their dictionary. Too modest!

Mike deCock (2011-11-06 18:39:57)

There is a wiki entry explaining Google's dislike of using the word as a verb: [http://en.wikipedia.org/wiki/Google \\_ %28verb %29](http://en.wikipedia.org/wiki/Google_%28verb%29) "Fearing the genericizing and potential loss of its trademark, Google has discouraged use of the word as a verb, particularly when used as a synonym for general web searching" Perhaps Google is getting too big for its own good. Maybe more of us should start using Yahoo and Bing for our googling. :)

Tom (2011-11-06 20:09:28)

Not modesty...they can lose their trademark if they can't show that they actively protect it by correcting misuse. Aspirin is an example of a lost trademark. "Frigidaire" is a mark that is still alive in the U.S. but has been lost in France. Kleenex and Xerox are marks that would be lost if their companies couldn't show concerted effort to prevent it.

Ashish (2011-11-07 18:13:45)

As others have pointed out, genericization is a standard worry for big companies. As a marketing manager of consumer technology products, I've sat through long lectures from our lawyers about what usages are and are not permitted. I'm actually surprised that Google (the company) hasn't cracked down on "to google" a lot more.

Nathan Myers (2011-11-08 23:23:48)

American trademark law, as I understand it, does not protect verbs. Therefore, you and everyone else are welcome to google generically in lower case – even using Bing if you are not feeling especially pedantic or loyal. It's unlikely that "bing" will ever be a verb. MS should be so lucky.

Seth Roberts (2011-11-09 00:58:31)

Interesting. Clearly there is an incentive for lawyers to be overcautious. I wonder if anyone at Google ever checks what lawyers tell them.

Nancy Lebovitz (2011-11-07 17:43:09)

Stapel reminds me of Bernie Madoff, which I suppose isn't surprising. A big fraud by an individual requires clever social engineering. If someone is arrogant or dismissive when asked for their sources of information, be careful!

### **A Great Idea From Nassim Taleb: End Banker Bonuses (2011-11-08 05:00)**

This is the best response to the 2008 financial crisis I have seen: [1]An op-ed by Nassim Taleb that says end banker bonuses. They encourage risk-taking with other people's money.

Separation of risk-taking from consequences (you gamble, if you lose, other people pay) is an ancient problem. The Chinese government would be wise to take a page from Hammurabi's code, which Taleb quotes:

If a builder builds a house for a man and does not make its construction firm, and the house which he has built collapses and causes the death of the owner of the house, that builder shall be put to death.

During the Szechuan earthquake, hundreds of schoolchildren died when their schools collapsed. Surrounding buildings did not collapse. It turned out the schools were badly built. No builder was punished, much less put to death.

At the end of his op-ed, Taleb puts it very clearly and simply: "bonuses and bailouts should never mix".

Thanks to Dave Lull.

More Large areas of medicine consist of the doctor or someone else gambling with your health.

An especially clear example is surgery. Surgeon are paid per operation. The more operations they do, the more money they make. If an operation kills you, the surgeon is still paid. No penalty for a bad outcome. Wonderful for the surgeon, terrible for the rest of us. The more corrupt the surgeon, the more surgery they will recommend. Taleb's idea suggests that surgeons pay a fine if a patient dies. The size of fines a surgeon would be willing to pay for bad outcomes would be helpful information for patients, who must decide what to do.

Drugs and medical devices are more subtle examples. You pay upfront for the drug or device, which are always expensive. They often have bad side effects, for which, of course, you pay. The drug company or device maker loses nothing. Wonderful for them, bad for the rest of us.

---

1. [http://www.nytimes.com/2011/11/08/opinion/end-bonuses-for-bankers.html?\\_r=2](http://www.nytimes.com/2011/11/08/opinion/end-bonuses-for-bankers.html?_r=2)

Jim Purdy (2011-11-08 09:26:28)

No banker bonuses? Seth! Is that you in the tent next to me at the Occupy protest camp?

dearieme (2011-11-09 02:15:54)

Combine your ideas. Let apprentice surgeons develop their skills by practising on bankers!

Seth Roberts (2011-11-09 03:02:25)

dearime, yeah. I would be happy to introduce them. Gambler With Other People's Money, meet Gambler With Other People's Lives.

Daniel (2011-11-10 14:21:39)

Charging surgeons a fee when a patient dies doesn't necessarily fix the problem. The problem is simply that the agent (in this case, the surgeon) is incentivized by something other than matching the patient's intentions, and the system should try to be realigned to make that less the case. A bigger problem that I think of in this case is - if a surgeon is paid per operation, how is a surgeon supposed to tell you that surgery may not be a good idea?

Seth Roberts (2011-11-10 15:12:12)

If surgeons paid a fine when a patient died, they would be less likely to recommend surgery. A surgeon who lost more in fines than he gained in payments would quit doing surgery. Those are two ways in which the fines I propose would improve matters.

Seth Roberts (2011-11-11 13:31:07)

Daniel, thanks for explaining your reasoning. What is your proposal for improving the situation? "Paying for good decisions" strikes me as too vague to be practical. The domain of "good decisions" can be anything. A surgeon would say if a patient survives, that shows the surgeon made "good decisions" during surgery. If a surgeon fails to give patient nutritional advice, is that a good decision, a bad decision, or no decision? If a primary care doctor fails to give nutritional advice, same question.

## **The Willat Effect: More Consequences (2011-11-09 05:00)**

A month ago I bought three identical tea pots [1]to compare tea side by side. I hoped to take advantage of[2] the Willat Effect (side-by-side comparisons create connoisseurs) to become a tea connoisseur.

It worked. Side-by-side tea comparisons are fun, easy, and have taught me a lot. When I drink tea I notice more and like it more. I do about three comparisons per day. I blogged about the first results [3]here. The most useful idea about these comparisons came from Carl Willat himself: Compare the same tea brewed differently (e.g., different amounts of tea, different brewing times, different water temperatures). Most of my comparisons vary amount of tea or brewing time.

These many comparisons have had several effects:

1. Yeah, I'm a snob. No more cheap tea. Yeah, I'm more nerdy about it.
2. I bought a scale ([4]Camry EHA901, \$12 in America) with a precision of 0.01 gram. No more heaping teaspoons. Mostly I use 1.5 grams of tea with about 170 ml water. For dense tea, 1.5 grams is roughly 1 teaspoon. Standard-size teabags contain about 2 g of tea.
3. Much different brewing times than recommended. The black tea I have now is Ahmad Tea English Tea No. 1 (in spite of the name, not expensive). The tin says "infuse 4-6 minutes." I used to brew it (and all black tea) 5 minutes, now I prefer less than 3 minutes. I found that 2.75 minutes is better than 3 minutes. Around 3 minutes it starts getting

bitter – I never noticed! Another example is [5]American Tea Room's Choco Late, which contains cacao husks, vanilla, and rooibos. The package says brew 5 minutes. I prefer 30 minutes – 30 minutes tastes better than 20 minutes, I have found several times.

4. To make the comparisons as sensitive as possible I want to start with equal tea pots, so I need to clean them well after each use. This became boring. I could eliminate cleaning by using tea bags. I bought ordinary-size empty tea bags. Side-by-side comparisons (same tea, bagged versus loose) showed they made the flavor much worse. Too bad I'd bought 200. I bought much larger tea bags to use as liners rather than bags. That worked fine – no cleaning needed, taste just as good. However, they are too large, so I shorten them. The concept of a disposable tea liner (instead of tea bag) [6]seems to be new. I cannot [7]find any for sale. My connoisseurship has not only caused me to spend much more on tea, it has made me want an interesting new product. Tea pot makers could sell liners specially designed for their pots. Continuing revenue, like razor blades.

5. I stopped adding artificial sweetener (e.g., Splenda) to black tea. Now I prefer it without sweetener. I continue to add cream to black tea. This is the most surprising and intriguing change. Maybe sweetness is a distraction from the complexity of the flavor (which I now notice more and derive more pleasure from), but creaminess is not. I imagine the same thing is behind [8]Richard Stallman's "If it is tea I really like, I like it without milk and sugar." And maybe the same thing is behind all sorts of artistic expression that strike outsiders as harsh and unpleasant. A few years ago I went to a [9]BAM (Brooklyn Academy of Music) concert and was stunned how unpleasant it was. Yet the composer (who performed it) surely enjoyed it.

Regular readers know I think [10]connoisseurship evolved because it increased technological innovation. My experience so far supports this. Thanks to the Willat Effect, I am more of a connoisseur. As a result of this change, I am spending more on high-end artisanal goods (expensive tea) and precision manufacturing (precision scale) and I want a new product (disposable tea liners).

People think of connoisseurs as having higher standards. The word connoisseur seems to mean exactly that. In some obvious ways, they do. Yet the sweetener change (I no longer want sweetener) is in a way a lowering of standards. Sweetness is pleasant. I no longer require, or even want, my tea to be sweet. As far as I can tell, something like this is true throughout the arts. Connoisseurs make unusual demands, yes, but in some ways they are easier to please than non-connoisseurs. Indie films are less pleasant than mainstream films. Yet film connoisseurs like them more. To most people, indie films are also much cheaper and more experimental than mainstream films. By supporting them – by preferring them – film connoisseurs are supporting innovation. The connoisseurs have lowered their standards for film in the sense that they can enjoy cheaper films. A friend of mine attends the San Francisco International Film Festival each year. He enjoys it. I wouldn't. The SF film festival films don't cost much, yet they have a certain innovative quality. (I'm not a film connoisseur, I barely understand it.) The source of pleasure has shifted from conventional sources (plot, music, dialogue, gorgeous actors, sets, and landscapes) to something else, perhaps novelty and complexity.

Rashad (2011-11-09 09:15:46)

Great post! As to the lack of disposable filters, I think it is because there are so many with removable, reusable filters that are almost as easy to use. For example: <http://www.enjoyingtea.com/anjasttewifi.html> [http://teaguys.com/buy\\_tea\\_accessories.htm](http://teaguys.com/buy_tea_accessories.htm) <http://www.amazon.com/Glass-Teapot-w-Filter-42oz/dp/B0052AXO74>

Lemniscate (2011-11-09 09:36:25)

Have you thought about using a tea infuser? I've found the large ball tea infusers to be best, although I've not done a side-by-side comparison. They should be a lot easier to clean than teapots, but they don't need constant replacement like tea bags.

Kirk (2011-11-09 10:56:52)

I switched from paper filters to Finum Goldton tea filters, shortly after the Finum filters were written up on Cool Tools. The Finum filters make a good cup of tea and clean easily. Agreed about cream in black tea. I discovered that cream is better about five years ago. Cream is better than half-and-half, half-and-half is better than milk, milk is better than plain black tea. Several months ago I started transitioning from sweetened coffee and tea to unsweetened, mostly from a nutritional point of view (under the theory that if the brain perceives sweet, the body actually should be digesting incoming glucose). I'm halfway between preferring sweet to unsweetened. In my case, it's a matter of retraining, not preference. I keep a spreadsheet of my ratings of black teas which I have ordered over the years from Upton Tea. My current top 2 favorites are ta30 and zk16. You almost have me convinced me to start measuring and timing during tea preparation.

David (2011-11-09 11:34:29)

Very interesting. Are you brewing the Choco Late at a constant 185 degrees for 30 minutes?

Seth Roberts (2011-11-09 14:07:22)

"Are [I] brewing the Choco Late at a constant 185 degrees for 30 minutes?" No. The water cools. Maybe I could get better results if I kept the water hot but that would be difficult. I have done that with a microwave and temperature probe – brewed chai at constant temperature for 80 minutes. I still remember how great it tasted. It just took too long.

Seth Roberts (2011-11-09 14:18:33)

"Have you thought about using a tea infuser?" Good suggestion, I will try it. For many years, that's what I did. It bothers me to have tea in my waste water (from rinsing the infuser) but now that I think about it that's silly.

Seth Roberts (2011-11-09 14:22:06)

Rashad, thanks for taking the trouble to provide these links.

Seth Roberts (2011-11-09 14:37:03)

Kirk, that's great info! Upton Tea's a30 tea costs \$11 for 125 g, which at 3 g/serving (for me, a serving consists of the same tea made 2 ways) is \$0.26/serving. Their zk16 costs \$7 for 125 g. Shipping (USA domestic) is \$4.

q (2011-11-09 17:46:40)

just wait, you go down this road, and you'll find yourself buying a \$100 scale

Jazi yechezkel zilber (2011-11-10 01:38:06)

I drink only mint tea. I always noticed 1) exactly one minute is great. 15 more seconds makes it ugly. Not nice in stomach, and not tasty. I also noticed a huge difference between brands. It was hard to believe, but it was too clear to neglect. 2) i used sweeteners. 2.1) only one sweetener ( a mixture of aspartam and saccharine) was good in my sensitive stomach. I would run to other stores to find it and gather an inventory. 2.2) it was exactly half a ball of sweetener that was great. No more. No less.... I thoughts i am crazy or fantasizing. But i knew i am right It comes together with many other things that I gave up my eyes because there was no theory, and common opinion were not accepting my eyes. No more blindness! What I See Is What I Believe

Kirk (2011-11-10 10:53:31)

@Jazi Several months ago I started drinking peppermint tea after supper. I agree with your observation that there's a huge difference between brands. I'm about ready to throw out one brand because the tea tastes stale. Also, I hadn't thought about brewing for just one minute; I'll give it a test tonight. @Seth Another advantage to Upton's is that you can order samples for about a dollar each. That's what I did in my first several orders, several dozen samples in each order, and then did a bake-off between them. The smart thing I did at the time was to start a spreadsheet to track my ratings and reactions.

Daniel (2011-11-10 14:14:41)

Hi Seth, I have not been as diligent and methodical as you. However, I have meandered my way into being very bitchy about how my tea is prepared from experimentation and toying around. 1) Like you mentioned with black tea, I have consistently, across all forms of tea or tisanes, preferred less steeping than is suggested, and this is one of the most important factors as to whether the tea is tolerable (to me). 2) Whenever possible, I make tea in french presses so the leaves have plenty of room to move around. When the tea is finished steeping, I transfer the tea to another vessel. I also have a single cup+infuser for traveling, and spent a while finding a brand with an infuser I liked (holes were small enough to accomodate tisanes with small leaves, infuser was almost the entire size of the cup - FORLIFE). As my main, I use a double-walled steel french press to preserve the temperature during steeping. 3) I pour the tea into either small cups (3.5oz) or halfway into larger cups (6oz) so that I can finish the cup while the tea is at a temperature I like. Rest is stored in a thermos. 4) Bagged tea is always terrible, unless it is luxury (fancy infusers, whole leaves) bagged tea where the prices are ridiculous. Fortunately, quality loose tea is very competitively priced to cheap bagged tea. I still have many questions and curiosities and things I'll hope to figure out. For example, the samovar method of tea is common in some cultures and makes some delicious tea, at least black tea, but involves oversteeping and then diluting this oversteeped tea with hot water. Does the temperature of the water matter? Does giving a short pre-soak in cold water help? Does storing or serving the tea in metal vs. glass vs. ceramic matter? Steeping in cast iron vs. clay vs. glass ? My conclusion has been similar to yours - figuring these things out may not necessarily be the right way, but they're the right way for me and gives me pleasure when I'm enjoying my hobby later. The only frustrating thing is, like you mentioned with the liners, you realize you want a product to solve your problem that doesn't exist yet.

Seth Roberts (2011-11-10 14:28:29)

Daniel, I like your definition of connoisseur: "bitchy about how X is prepared." Two things I didn't mention in my post that are related to what you say: 1. I now prefer black tea to green (at the same price). Black has a more complex flavor than green. Now that I make black tea in a way that minimizes the bitterness and drink black tea without cream or sweetener (the same way I drink green tea), that's quite clear. 2. Room temperature tea is fine. The complexity of flavor is clearer at room temperature than other temperatures.

Elizabeth Molin (2011-11-13 08:38:45)

With reference to the Willat effect and your theories of human evolution, do you think connoisseurship and an aesthetic appreciation of "beauty" (or deliciousness, or repeated patterns, or whatever) are evolutionarily beneficial? Do they contribute to the survival of the fittest in some way? I can see that things that taste better might also be more beneficial to one's health, but I can't get any further in my thinking about this.

Seth Roberts (2011-11-13 13:51:31)

Elizabeth, I think connoisseurship was evolutionarily beneficial because it increased innovation. It increased innovation because it made it easier to make a living as a highly-skilled artisan. People with such jobs produce more technological innovation than people with other jobs. Basically connoisseurship raised their salary. Our enjoyment of beautiful objects, and willingness to pay more for them than similar but less attractive objects (e.g., decorated cup versus undecorated cup) likewise increased technological innovation. It caused innovation in decoration, which was a stepping stone to innovation in obviously useful stuff (e.g., better weapons).

Jazi yechezkel zilber (2011-11-13 23:33:19)

Tea making. More parameters. Steering or not? (i.e. letting the tea in gently, and later pulling it out without much movement) Pouring hot water on the tea packet, or easing the tea bag gently into the cup? Water temperature (there are claims that say 90 degrees celsius is better. (can be handled with thermometer

Elizabeth Molin (2011-11-14 07:20:04)

Seth, I understand your discussion of connoisseurship, and it sounds intuitively compelling to me. My question is, where does "our enjoyment of beautiful objects" come in? How did that originate? What is its evolutionary benefit? I just can't seem to come up with a reason why someone with an appreciation of beauty would have an evolutionary advantage over someone without.

ajb (2011-11-14 09:42:52)

"My question is, where does "our enjoyment of beautiful objects" come in? How did that originate? What is its evolutionary benefit? " Beauty seems like a pretty basic 'moving towards' valuation. So, we want to be around or look at things that are beautiful, and presumably these things tend to be good for us. When it comes to art, it seems more like we're recreating the experience of natural patterns or events ...

Elizabeth Molin (2011-11-14 11:56:31)

I'm not explaining myself well. "We want to be around or look at things that are beautiful." Where did the idea of "beauty" come from? Do primates have a sense of beauty? How big a leap is it from "tasty" or "comfortable" (and therefore pleasing) to AESTHETICALLY pleasing? And what evolutionary purpose does an aesthetic appreciation of something (that may not be tasty or comfortable or even useful) serve?

Seth Roberts (2011-11-14 19:55:43)

Elizabeth, I suppose our sense of beauty started with mate assessment. Our distant ancestors, including primates, preferred more symmetrical less damaged mates. But in humans this sort of assessment, at least applied to objects, has gotten much more complicated and powerful, I believe. In other words, whether something (not somebody) is beautiful or not plays a much bigger part in our lives than it does in the life of any (other) animal. The evolutionary purpose of this great expansion of a sense of beauty happened because it caused resources to be given to highly-skilled artisans – the ones who can make the most beautiful things. These resources increased technological innovation. Here I'm talking about visual beauty. I believe our appreciation of auditory "beauty" (music) came about because it caused the same thing: resources going to those who could make the best-sounding instruments. Who were the most skilled artisans, etc. Perhaps the word "beauty" (what might be called the idea) was invented to describe the more attractive objects. Since many animals choose mates based on appearance, it isn't clear what it means to say the idea of beauty was "invented". It's like asking who invented hunger.

Allen K. (2011-11-14 23:08:36)

This film connoisseur is a good example of your observation that connoisseurs are less demanding of conventional perfection: [http://www.slate.com/blogs/browbeat/2011/11/11/william\\_monahan\\_picks\\_his\\_favorite\\_british\\_crime\\_films.html](http://www.slate.com/blogs/browbeat/2011/11/11/william_monahan_picks_his_favorite_british_crime_films.html) After the dogs of memory had had a few days to hunt around, I realized that I'd heard this observation some 30 years ago at an AAAS talk by computer game designer Chris Crawford. He talked about candy, comic books, and computer

games. In the first two cases, one expects that a small child will grow out of a predilection for simple confections and wish to experience more complicated flavors (spicy!) and may eventually become a gourmand, who eats some things that really taste \_bad\_. Crawford was largely expressing a hope that the level of connoisseurship and sophistication we see in cuisine and literature might come someday to computer games. [http://en.wikipedia.org/wiki/Gossip\\_\(computer\\_game\)](http://en.wikipedia.org/wiki/Gossip_(computer_game))

Kirk (2011-11-16 20:15:40)

Tonight I tried a new box of peppermint tea. I brewed just from this new tea, without a comparison cup which would have been brewed using my current favorite boxed peppermint tea. I think of it as a tasting where the comparison is done in memory. (I think it's valid but not as good as having them both available in real time.) I found myself describing this tea as 'fresh, has two sharp edges, a smooth mint flavor, fades well'. Which, I agree, sounds annoyingly like those wine snobs. Which made me curious as to whether you record impressions during your black tea tastings ('malty', 'bitter', 'rich'), or if you are interested solely in the winner? And if you capture impressions, have you noticed any patterns, or whether one way to describe is better than another?

Seth Roberts (2011-11-16 23:55:55)

I don't write down impressions, but I remember them. Smooth is better than rough, not bitter is better than bitter. Full is better than sharp or jagged. Perhaps what I call full other people would call rich. You're certainly right that I notice more than which tastes better: I can always say why (e.g., "A tastes fuller than B").

Stone Glasgow (2012-02-26 10:37:02)

This is a great way to adjust/perfect recipes, too. It works because our brains judge everything relatively, even colors. And it's why we respond to anchor pricing (was \$159, now only \$99!). To humans, characteristics are always based on direct comparisons.

## Assorted Links (2011-11-10 05:00)

- [1]Super-old Ashkenazi Jews. Did they live to be more than a hundred "in spite of" their "bad habits" (eating steak & pork chops, smoking, refusal of Lipitor) or because of those habits? Small amounts of smoking could easily be beneficial due to (or illustrating) hormesis.
- Does Hollywood have a sense of humor? In the new movie about noted anti-Communist J. Edgar Hoover, Hoover's love interest is played by Armie Hammer, grandson of Armand Hammer, who worked for the Soviet Union as a money launderer. Edward Jay Epstein writes about Hammer and the Soviet Union in [2]this excellent Kindle book.
- An advantage of ebooks, not yet realized, is easy updates. When the book is improved – for example, mistakes fixed – you get a new copy. In [3]an even better Kindle book, Epstein writes about the diamond industry. The vast difference between the purchase price of a diamond and its resale value may be the advertising industry's greatest achievement. Recent events caused Epstein to add a new chapter. The book was easy for Epstein to update but unfortunately earlier purchasers did not get the new version.
- Michel Cabanac, who did some of the research behind the Shangri-La Diet, has written [4]a book about his life's work: how we self-regulate via pleasure. During a meal, for example, exactly the same food becomes less pleasant. When it becomes unpleasant, we stop eating. When we are hot, cold water is more pleasant than when we are cold. The secret to weight loss, Cabanac realized, is making exactly the same food less pleasant – an insight few weight-loss writers understand.

Joseph Buchignani (2011-11-10 05:43:56)

You've no idea on smoking. It goes far, far beyond hormesis. Google for the anonymous author "Nightlight". He posts on lots of forums, including forces.org and longecity. I started smoking - \*handrolled\* cigarettes only - based on his arguments. Industrially processed cigs are about like eating McDonald's. Yes, meat is good for you. No, McDonald's patties aren't.

Jim Purdy (2011-11-10 06:51:58)

Seth, when it comes to pathologically compulsive binge eaters, I think there is a fatal flaw in this statement from your post above: "During a meal, for example, exactly the same food becomes less pleasant." For a sometimes binge eater like me, there's no loss of pleasure at any point while I'm eating a massive meal of one of my favorite binge foods, whether the food is dozens of Krispy Kreme donuts or dozens of deep-fried chicken wings. Many years ago, my binge eating was so bad that there were a few times when I ate until my stomach was full, and yet I continued eating while the food starting filling up my esophagus, and I would quit only when the very next bite of food would have blocked my airway and killed me. Literally. Fortunately, I finally figured out that I just can't do that any more, but only because another problem started to develop even before airway obstruction: a few years ago, huge meals started giving me terrible chest pains that made me go to emergency rooms for what I thought were heart attacks. According to EKGs in the emergency rooms, those episodes were not heart attacks, but perhaps something more like a hiatal hernia. Those chest pains finally made me stop eating massive meals. As a result, my weight has been dropping, and several of my health problems have improved. And, actually, I think that it's not all bad to continue to enjoy the same food, as long as the food is healthful. If only I could just keep enjoying a big meal of nothing but lettuce and celery... I am moving in that direction. I have been taking your advice to self-experiment and to monitor and record what I eat, and how my blood sugar responds (<http://thepancreasfiles.blogspot.com/>). I'm finding that some of my favorite foods actually seem to sharply lower my diabetic blood sugars. Maybe I'm just re-discovering the Atkins Diet. I was startled several years ago that a week on a very strict Atkins or low-carb diet would lower my blood pressure, my blood sugar, my LDL cholesterol, my pulse, and my weight.

dearieme (2011-11-10 08:25:51)

Ashkenazi Jews eating pork chops? Very "bad habits".

Tom (2011-11-10 09:05:59)

What's wrong with McDonald's patties?

dilys (2011-11-10 10:16:24)

Thanks for the heads-up on Cabanac. My own weight-loss discovery was making "safe"/filling (lots of shredded raw or steamed vegetables) foods \*more\* pleasurable, by mixing them with teaspoon-quantities of highly flavored rich desirable food. Thus, via satiety, "unsafe" foods became less appealing at the point of choice. The Follow-Your-Pleasure approach, when the pleasure has been tweaked for effectiveness, has been the great practical discovery of my life, along with a related tactic of gentle-but-relentless minutely-incremental change of behaviors with no drama around occasional minor regression. Cabanac's insights also help account for the folly of deciding prematurely what one wants, since in many realms the needs and wants in the moment are more pertinent, and may be more wholesome, than the mind's reach into the future. One diet writer talks about the hazards of the thought, "I'm-a gonna want some-a that [for dessert]." The semi-abstract pursuit of pleasure, while undervaluing its immediacy as a feedback principle, IMO occurs at some peril to our well-being.

Seth Roberts (2011-11-10 15:36:03)

"It goes far beyond hormesis"? What do you mean? Hormesis can be powerful. Nightlight goes off the rails when he blames "big pharma" for anti-smoking science. Ernest Wynder, one of the pioneers, was a medical student. But yeah, there is plenty of reason to think a modest amount of smoking is good for you.

Nancy Lebovitz (2011-11-11 04:25:56)

From what I've read in *The Longevity Project* maintaining social relationships is important to longevity, but it isn't usually on the list of good habits.

Joseph Buchignani (2011-11-11 08:52:08)

If you've read Nightlight, you know everything I'm getting at. By beyond hormesis, I mean that it has positive first order effects through biological pathways that aren't related to poisons.

Seth Roberts (2011-11-11 12:27:47)

Joseph, thanks for explaining that. I have a book called *The Health Effects of Tobacco*.

Peter (2011-11-12 16:32:52)

My wife recently conducted an unintended self-experiment on less pleasant food. I eat gluten-free, and we recently found that our six-year old daughter is also gluten intolerant. As a result, my wife, who is above her desired weight, decided to cook gluten-free meals for the whole family. She found that when she used rice noodles in lasagna and mac and cheese, two of her favorite meals, she could only eat about half of her former portion size and then the food became unappealing, bordering on repellant. The effect has also been noticeable with other meals, such as spaghetti made with rice noodles and pizza baked with a gluten-free crust.

rps (2011-11-12 21:31:21)

The idea that very light smoking is healthy because of hormesis is plausible, if unproven, but the problem with light smoking is that virtually all smokers end up smoking 10-30 or so cigarettes/day within several years. In my entire life I've known hundreds of smokers, and only two people who managed to consistently smoke just a few cigarettes/day for extended periods of time. There are lots of ways to get hormesis that aren't addictive and don't end up titrating themselves to harmful levels. I came across nightlight on a forum several years ago. I can't remember the details, but I do recall that he argued that evidence against smoking is worthless because it's epidemiological, and then he argued in favor of smoking based on epidemiological evidence. [1]Bozo bit set to TRUE.

1. <http://c2.com/cgi/wiki/SetTheBozoBit>

Jazi yechezkel zilber (2011-11-13 04:26:43)

Fifth infouence book ordered. Thanks. Waiting. I have evidence that stoping to smoke can damage the lungs and cause lung cancer. It is only the formidable load of writing a "paper" that proibits me from making my case formal.....

---

charlie (2011-11-11 06:28:58)

The point about medical tests is valid. However, in terms of cost control, you're going to wrack up 75 % of the costs in the last six months of life. A few tests or MRI are wasteful – but they aren't what is driving the medical costs. Most doctors aren't healers. They are guardians of death. One big exception is psychiatrists, and like dentists, they should be excluded from most medical plans.

Tim Ozenne (2011-11-12 08:01:29)

Not a reply on your posting, but did you see Panel Urges Cholesterol Testing for Kids in WSJ 11/12/11? Yikes.

wr (2011-11-12 09:59:38)

The popularity of a diet has nothing to do with its efficacy, and if one were to look at correlations, it's almost certainly an inverse relationship. Who would know this better than you! And anyway, most of the vegans I know consider it an ethical diet, with any health benefits/risks of secondary importance. I'm a vegetarian myself. I find the paleo diet very interesting and believe may be the most healthy for humans. But I also believe that animal suffering matters, so I do my best to approximate it without the meat.

jscott (2011-11-13 15:50:23)

(Off topic...kinda) Have you looked into Reams Biological Theory of Ionization? Specifically with a homebase offshooting from Challen Waychoff and Matt Stone? It seems it would be an interesting study as there are specific measurements to test against.(?) I am skeptical (perhaps because of my own bias) because of naturopathy influences.

Seth Roberts (2011-11-13 18:50:56)

I have heard just a little about the Reams theory. Don't know what to make of it. If there are data about its effectiveness, that would be interesting.

Alex Chernavsky (2011-11-13 20:25:49)

@wr: I used to be a vegetarian, until I started looking into the egg and dairy industries. If your concern is with animal suffering, you'd be better off giving up eggs and dairy and continuing to eat flesh. There is more suffering in an egg or a glass of milk than there is in a steak. Better just to go vegan.

danimal (2012-01-06 14:20:49)

Seth, As for Reams, I think it's mostly anecdotal as far as the human data go, but if you read up on it or read Matt Stone's posts on it while he was interning there, you'll see that it's probably some of the most profound anecdotal data. I don't think it's the ultimate solution, but having just a few of these measurable quantities like saliva and urine PH and salts and sugars and making thousands of these comparisons and tests over time has produced some fantastic results. RBTI for humans is based off of RBTI for agriculture and I think the data is more established there. At least the anecdotal evidence is also just as amazing as people report the tastiest foods of their lives incorporating this methodology.

## Testing Treatments: The Authors Respond (2011-11-12 05:00)

In a [1]previous post I criticized the book Testing Treatments. Two of the authors, Paul Glasziou and Iain Chalmers, [2]have responded. I have [3]replied to their response. They did not respond to the main point of my post, which is that the preferences and values of their book – called evidence-based medicine – hinder innovation.

Sure, care about evidence. Of course. But don't be an [4]evidence snob.

4. <http://blog.sethroberts.net/2008/06/08/evidence-snobs/>

---

Elizabeth Molin (2011-11-12 11:08:34)

To continue our discussion: I have had dealings with superior, arrogant doctors, and doctors who didn't give a damn, and doctors who were sadists (OB/GYN seems to attract those, both male and female). I am very glad to now have a doctor who actually listens, who can admit she's wrong, and who is willing to learn. The statin episode happened before I was well enough informed to suggest that my husband ask for evidence; I would be pushier now. I think our doctor, like most of them, is battling patient expectations. She was delighted (and surprised) that my husband was perfectly willing to make dietary and life-style changes. I think many patients come in demanding Celebrex or Lipitor or whatever was advertised on TV last night. I think many more feel that the doctor is not doing his/her job if they don't come away with at least one prescription. At one point our doctor advised me to "take Tylenol or Advil," and I told her I would not, because of the side effects; if I needed an anti-inflammatory or an OTC painkiller I preferred aspirin. She answered at once that of course I was absolutely right; aspirin is much better! But most people nowadays think it's old-fashioned or has been superseded somehow. So she doesn't suggest it. I guess doctors too get tired of doing the King Canute thing. I'm just glad that I can challenge ours and have a thoughtful, reasoned discussion of what matters to me.

Seth Roberts (2011-11-13 02:23:24)

That's very interesting about how your doctor said "you're perfectly right" about the aspirin. She sounds conflict adverse.

### **"Setting Students on Fire" at Universities: An Alternative (2011-11-12 20:22)**

The first paragraph of [1]an article by Anthony Grafton called "Our Universities: Why Are They Failing?" contains this:

At every level of the system, dedicated professors are setting students on fire with enthusiasm for everything from the structure of crystals to the structure of poems.

Grafton means this as praise, of course: Wow, these professors are doing a great job! I disagree. I think there are a million things in the world to be enthusiastic about – the structure of crystals and the structure of poems are two examples, no better or worse than the rest. I also think it is fundamentally foolish for a professor to try to make every student in his or her class as enthusiastic about X as the professor happens to be. It is foolish because it ignores human variability, which is great along these lines. (I think diversity of interest and enthusiasm is large because [2]such diversity helps produce diverse economies.) It would be much better for the students if the professor were to help them develop their own unique enthusiasms.

I suspect Grafton has never considered this possibility. In discussions at Berkeley that I attended about how to be a good teacher, including special seminars, it never came up. Yet I taught a class at Berkeley (Psychology and the Real World) where I did just that: I allowed students to do volunteer work off-campus about almost anything they wanted. They chose the work, not me.

1. <http://www.nybooks.com/articles/archives/2011/nov/24/our-universities-why-are-they-failing/>
2. <http://sethroberts.net/articles/2011-04-08%20How%20Economics%20Shaped%20Human%20Nature.pdf>

---

dearieme (2011-11-13 05:46:21)

Your thoughts on this are commendably measured: my first response was to sneer with derision at such silly purple prose.

Jazi yechezkel zilber (2011-11-14 00:11:51)

"getting students excited" feels fake. If you need to artificially get people enthusiastic, it means there is nothing to be excited about

### **Danny Kahneman's Decision Making (2011-11-13 05:00)**

[1]A lovely article by Michael Lewis about Daniel ("Danny") Kahneman, my former Berkeley colleague, emphasizes his indecision whether to write a popular book about his work. Should I or shouldn't I? He doesn't like what he's written so far. Finally he decides to pay some experts for their opinion:

He called a young psychologist he knew well and asked him to find four experts in the field of judgment and decision-making, and offer them \$2,000 each to read his book and tell him if he should quit writing it. "I wanted to know, basically, whether it would destroy my reputation," he says. He wanted his reviewers to remain anonymous, so they might trash his book without fear of retribution. The endlessly self-questioning author was now paying people to write nasty reviews of his work. The reviews came in, but they were glowing.

Uh, why would anonymous experts trash his book? They gain in two ways from having it published: 1. It draws attention to their field, making them more important. 2. They can use it as a textbook. I love that Michael Bailey wrote [2]The Man Who Would Be Queen ([3]pdf). It allows me to assign my students a book I admire.

I think Danny has raised two great questions here:

1. How can we set up a situation so that others will tell us the truth (= what they actually think)?
2. How can we tell if we've succeeded – if they've told the truth?

The answers aren't obvious, at least to me. The best answer I can give to Question 1 (what situation?) is write a blog. I take positive and negative comments to be what their authors actually think. Variations on Question 1 are common. [4]Robin Hanson's blog is about how bias distorts what we say and do. [5]Hot or Not provides truthful answers to how attractive you are. [6]CureTogether tries to get truthful answers about health care. The best answer I can give to Question 2 (how to assess) is do a test. Wear something ugly. Do your friends say you look great in it? Why do I think the comments on my blog are truthful? Well, [7]my recent post about E-Cat was poorly-informed (unintentionally).

The comments quickly and overwhelmingly said so. That supports my belief. In contrast to Question 1, Question 2 is rare.

The last time I talked to Danny was in the 90s. I was thinking of writing a book based on my introductory psychology lectures. I wrote a sample chapter based on my possessiveness lecture. The center of that lecture was the endowment effect (we value what we possess much more than the same thing when we do not possess it). Danny had written about it and loss aversion is part of prospect theory. By then Danny was at Princeton. I spoke to him on the phone. Does the endowment effect affect your everyday life? Does it affect what you do? I asked. He thought about it. No, he said. Or at least he couldn't think of examples. In contrast, Richard Thaler chatted happily about the everyday implications.

One everyday sign of the endowment effect is a car in front of a big garage. The car isn't in the garage because the garage is full of "junk". Another is garage sales (also called yard sales). Such sales are held when the clutter becomes unbearable. They illustrate the everyday relevance of the effect. My point isn't that Danny was unobservant, it's the difference between his answer and Thaler's. There is definitely room for two answers to my question. Humans are traders. We specialize and trade. This is central to economic life. Early papers about the endowment effect (I haven't looked at recent papers) didn't notice the problem/puzzle. How can we both (a) hold on to stuff tightly (= the endowment effect, loss aversion) and (b) trade easily? [8]John List noticed.

My friend [9]Michel Cabanac, whose research was behind the Shangri-La Diet, has criticized Danny. In [10]a book (p. 140), Michel wrote:

At a lecture in Jerusalem on January 19, 2001, he [Danny] was kind enough to inform the audience that the recent reorientation of his research toward what he calls "experienced utility," which he acknowledged to be a synonym of pleasure, had been inspired by my 1993 lecture at Princeton University and by previous readings of my publications on pleasure.

In an email he elaborated:

However the "lecture" [at Princeton] was a only an invited seminar in his laboratory with an audience limited to him and his team. If I remember well, he reimbursed my travel and housing expenses. Yet, the Jerusalem mentioning of my contributions was only verbal [i.e., spoken], as I failed and still fail to find reference to Cabanac in his publications.

Michel's whole research career has centered on the idea that pleasure guides our actions, including "cognitive" ones. Faced with an arithmetic problem ( $2 + 7 = ?$ ), for example, some answers will seem more pleasant than others. ( $2 + 7 = 9$  is more pleasant than  $2 + 7 = 10$ , not just more familiar.) He has especially stressed that changes in pleasure – the same events become more or less pleasant – help us self-regulate. We stop eating when food becomes unpleasant, for example. The food stays the same, we change. No one has understood the role of pleasure – which is at the center of all human decision making – better than Michel.

When I get a copy of Danny's new book, *Thinking Fast and Slow*, I will be curious to see what he says about the endowment effect, loss aversion, and Michel Cabanac.

More [11]Via scrbd, I have found that Danny's new book does reference Michel – see p. 488. And, in a chapter about the endowment effect, I found this: "Knetsch, Thaler, and I set out to design an experiment that would highlight the contrast between goods that are held for use and for exchange." He goes on to discuss List's research. I am unable to find anything like the phrase "the contrast between goods that are held for use and for exchange" in

[12]the paper that the three of them wrote about the effect. Jack Knetsch began to study the effect because different ways of trying to establish the value of the environment (e.g., clean water) produced enormously different answers. The endowment-effect chapter is weak on everyday examples – nothing about garage sales – but does include an unsourced quote: "She didn't care which of the two offices she would get, but a day after the announcement was made, she was no longer willing to trade. Endowment effect!"

Thanks to Dave Lull, who suggested online searching.

M (2011-11-14 07:48:50)

You say that writing a blog is one way to get others to tell you the truth. Unfortunately, I don't think it necessarily works this way. A blogger can be wrong on an issue and simply attract comments from others who have the same wrong view, eventually driving out those who have other views. I suspect this happens a lot in the world, leading to "echo chamber" blogs. In fact, I think this has happened in the case of one major issue that you write about on your blog. (I think you are right on many other issues, though!)

John (2011-11-14 11:40:03)

M: Your comment might be more useful if you'd tell us what you think that one major issue is, and also why you think Seth is wrong about it. Don't let us languish in ignorance!

Seth Roberts (2011-11-14 13:33:12)

M, you write "A blogger can be wrong on an issue and simply attract comments from others who have the same wrong view." By "the truth" I don't mean objective truth – I mean it in the sense of what a person really thinks. Whether they like what you've written, whether they like what you're wearing. Truth in the sense of "tell the truth" (versus lie). People may have what you think is "the wrong view" but when they post comments stating that view or agreeing with that wrong view, they are telling the truth, as I am using the word. That said, I agree with John Harper, what's the "one issue" that I write about where I have the wrong view and people just echo me? My guess is man-made climate change.

## Seth Roberts Interview With Pictures (2011-11-14 05:00)

[1] This sidebar appeared in an article about self-tracking (only for subscribers) by James Kennedy, who works at [2]The Future Laboratory in London. The top photo is at a market near my apartment. Below that are photos of my sleep records, my morning-faces setup, my butter, and my kombucha brewing jars. Back then I was comparing three amounts of sugar (each jar a different amount). Now I'm comparing green tea/black tea ratios.

1. <http://blog.sethroberts.net/wp-content/uploads/2011/11/SQ-4.jpg>
2. <http://www.thefuturelaboratory.com/>

TD (2011-11-14 09:59:26)

Another contribution that I think you've made is the realization of how decidedly low-tech *\*real\** progress can be. I like the emphasis on paper, wood, real food...other than the screens, all simple tools. No watch. Good man. You look 38 or 48 in that picture.

Seth Roberts (2011-11-14 14:31:12)

Thanks, TD. Yes, my research is rather low-tech. It was lowest-tech in the very beginning, when I did an experiment on my acne. I just counted pimples every morning and wrote down the number. No computer, not even to analyze the data. After that, however, two recent inventions have been really helpful: 1. Personal computer, so I don't have to bring the data to my office. 2. Photocopier. So I can easily consult journal articles. Berkeley has a service where for a few dollars you can get a journal article copied and put in your mailbox. I was a big user. A lot of treatments I've tested have a basis in the scientific literature, which is much more accessible now. For example, I tried looking at faces on TV in the morning because of a photocopied scientific article I read. I was able to look at all sorts of different faces on TV because of VCRs – long ago, a big new thing.

Nancy Lebovitz (2011-11-14 17:30:25)

<http://www.thisamericanlife.org/radio-archives/episode/450/so-crazy-it-just-might-work?act=1> Off-topic, but I think it counts as an example of the roadblocks conventional science puts in the way of research that might be very useful.

Seth Roberts (2011-11-14 18:42:41)

Nancy, I thought the same thing after I listened to that episode.

by (2011-11-15 13:18:33)

Always wanted to get a glimpse into the appearance of daily life of Seth Roberts. I enjoyed this post.

Parker Bohn (2011-11-15 16:26:06)

I make kombucha with 100 % grape juice. It tastes better, and it seems to have the same relaxing effect. It does seem trickier to get it to the right degree of 'doneness', however.

Seth Roberts (2011-11-15 18:37:22)

Parker, that's fascinating. Could you elaborate on what you mean by "it's more difficult to get it to the right degree of doneness"?

Tom (2011-11-15 21:29:35)

*I make kombucha with 100 % grape juice. It tastes better, and it seems to have the same relaxing effect. Isn't that wine?*

Alex Chernavsky (2011-11-15 22:06:56)

I make kombucha the regular way and then bottle it with a couple of ounces of fruit juice. I use empty bottles from GT Dave's kombucha. With the cap tightly sealed and the bottles stored at room temperature, the result is a nicely carbonated beverage within a day or two. I usually use apple cider for the juice, but I've also used juice from grapes, acai berries, mangoes, black currants, and whatever other stuff I can find in the health food section.

Seth Roberts (2011-11-16 01:47:22)

Wine or not, I have gotten apple juice and grape juice to see what happens when I put kombucha culture in them.

Sara (2011-11-19 01:10:40)

That's very interesting about the morning faces thing - obviously old science now, but I'd not heard of it. When I got back from overseas after visiting my niece, I went into a real depression (jetlag always does this to me anyway, but combined with missing her it was pretty grim). I started watching Deutsche Welle in the mornings just because it reminded me of being with my family and it was always the news program. After a few days I was feeling really good, better than usual. I also work and study from home and spend a lot of time alone (but I'm busy so I don't really feel lonely). I stopped doing the morning TV thing

and have slumped a bit so I'll give it another try. What I thought you might find interesting is that I am a beginner at German and don't understand much of what I hear on Deutsche Welle, so I'd say, if it works, it is the 'face', and maybe the sound but not the influence of recognisable language.

Seth Roberts (2011-11-19 04:20:57)

Sara, I think the sound of voices reduces how lonely we feel. I don't the voices need to be speaking a recognizable language. It's a quite different effect than the effect of seeing faces. For one thing, voices make you feel better right away (within minutes of hearing the voices). With the faces effect, you don't feel better until the next day.

### **Chinese Medicine As Now Practiced (2011-11-15 05:00)**

In America, I often hear praise for "Chinese Medicine". By this they mean Traditional Chinese Medicine, which includes acupuncture and techniques that harness hormesis. I tend to agree. Medicine as now practiced in China is a different story.

Last night, I had dinner with some of my students. I asked them what their parents thought of their decision to major in psychology. One of them had a surprising answer. Her mom was happy that she was majoring in psychology because among the required courses was a human anatomy and physiology class. If her daughter took this class, her mom believed, it would be harder for doctors to cheat us.

Chinese doctors "cheating" patients is a big problem, in other words. They prescribe drugs that don't work, said my student, and perform useless surgeries. Little different than Western medicine, except perhaps the drugs are less dangerous. Just as in Western medicine, drug reps try to bribe doctors to request their drugs. Unlike Western medicine, doctors steal the drugs of hospitalized patients, my student said, which they then sell. After a friend of mine was badly burned, she had (wisely) turned down the recommendation of a skin transplant. This angered her doctor, who would have made money from the operation. Later, when he changed her bandages, he did so roughly, which was very painful. Revenge.

"Don't see the doctors at Tsinghua hospital [the campus hospital]," said my student. She had had a bad experience. She had gotten injured and gone to the hospital. She had had to wait half an hour to see a doctor; who had taken a mere 30 seconds to prescribe a cream that did almost nothing. That evening I watched The Poseidon Adventure. A doctor visits a sick woman in bed in her cabin. After a long wait, he gives her cursory treatment.

HUSBAND (to doctor) Hold it, hold it. You mean to tell me we had to wait all this time just for you to come in here and kiss her off with a couple of pills and some crap about staying in bed? How do you know she's just seasick? Look at her! It could be something else! You didn't even examine her.

Same complaint.

---

Jim Purdy (2011-11-15 08:07:34)

If you get sick, will you go to the campus hospital? I enjoyed the Poseidon adventure. Did you watch the original 1972 Poseidon Adventure with Hackman and Borgnine, or the remake? Did you have any difficulty getting it in China? And how did you like it?

Shawn (2011-11-15 08:08:35)

I like setups like the Mayo clinic where doctors are paid a straight competitive salary. Private practice & medicine do not go together.

Tim Beneke (2011-11-15 10:09:49)

A pretty horrifying picture of Chinese doctors! Is this just a reflection of mass corruption among Chinese authorities? Did you post research finding that more than half of Tsinghua professors fabricate or falsify data? One point: My understanding is that the experiments with "sham" acupuncture where you don't actually let the needles enter the skin but the person feels a bit of pinching finally offered a control. The research strongly shows that whatever is giving the (rather small) positive effects of acupuncture, it's not the needles puncturing the skin, since sham acupuncture got effects as good as the real thing. It is clear that people get some relaxation from acupuncture, most likely an endorphin rush from the needles, and that this can be taken away by an endorphin blocker, Naltrexone.

Chris U (2011-11-15 11:17:53)

Seth, What you seem to be describing is Western-style medicine being practiced in China. Usually when referring to 'Chinese medicine' one means 'Traditional' Chinese medicine (TCM) which is the use of herbs, acupuncture, tuina massage and moxibustion, but primarily herbs. Chinese herbal medicine has been developed over more than 2000 years and is an awesome form of medicine when practiced by a qualified practitioner. My understanding is that although herbalism is practiced in some hospitals, the primary mode of health care in China is the Western style allopathic medicine and that TCM is a struggling if not dying modality. I'm not surprised that your story paints a poor picture of the Chinese medical 'system'. I hope that readers don't associate this negatively with TCM.

Seth Roberts (2011-11-15 13:10:05)

Chris, that's a good point – distinguishing TCM from what I describe. I have changed the post to reflect it.

Seth Roberts (2011-11-15 13:19:36)

Tim, I do not remember posting "research finding that more than half of Tsinghua professors fabricate or falsify data." On the other hand, the same student who told me about bad Chinese doctors has two university professors as parents. Her parents told her not to become a professor because of the "darkness" of Chinese academia. The big problem, said her parents, was what you say: fabrication and falsification of data, including plagiarism. A recent paper by John Ioannidis and a Chinese co-author likewise suggested a large problem with data fabrication among papers from China.

Adam (2011-11-17 18:15:40)

I have had some experience with the medical system here in China. I work in a small international hospital in Shanghai which is clean and modern, but quite expensive. The standards we follow are often much higher than the standards imposed by the Chinese govt. On vacation in Yellow Mountain (Huang Shan / ??) my girlfriend came down with pneumonia. We ended up going to a local, Chinese hospital. The doctor told her she would have to stay overnight in the hospital for 14 days while getting IV antibiotics. As a pharmacist trained in the US, I knew this was absolutely not true. In the US, she could easily receive oral antibiotics and be treated on an outpatient basis. Due to the language barrier, I had a hard time communicating this to the doctor, but the doctor apparently said something to the effect of, the drugs in China are not the same as the drugs in the US, we have to use IV here. I don't believe this at all. I asked one of my co-workers, who is also a pharmacist and whose mother works for a local hospital in Shanghai. She said doctors will try to get any patients they can to stay overnight in the hospital and to get IV fluids and/or antibiotics, because they make "grey money". I'm not sure exactly what she meant by that, but it sounds to me like a case of doctors' greed influencing their treatment of patients, leading them to choose unnecessary and inconvenient treatments over equally effective and convenient ones. Staying overnight in a Chinese hospital is about the last thing anyone would want to do. Many of the patients are not well educated and will spit on the floor and smoke in the beds right next to you. In the hospital we visited, there were people vomiting into trashcans and no cleaning service to tidy it up afterward. I witnessed an old man pull his IV out by accident and get blood all over the floor. It was there for at least 2 hours. I never saw anyone come to clean it up. We ended up gritting our teeth and coming in once a day for about 10 days to get IV

antibiotics. We eventually managed to purchase some oral antibiotics (without a prescription) at a local pharmacy outside the hospital. My girlfriend's pneumonia cleared up and we haven't had any problems since.

Seth Roberts (2011-11-17 19:12:24)

Thanks, Adam. Your account of your experience is very helpful.

### **Dr. Eileen Consorti and Patient Power (2011-11-16 05:00)**

My alternative to Testing Treatments (199 pages), [1]I said recently, is three words: Ask for evidence. Ask your doctor for evidence that their recommendation (drugs, surgery, etc.) is better than other possibilities. A few years ago, I asked Dr. Eileen Consorti, a Berkeley surgeon, for evidence that the surgery she recommended (for a hernia I couldn't detect) was a good idea. Surgery is dangerous, I said. What about doing nothing?

To reread what I'd written about this ([2]here and [3]here), I googled her. I learned she has [4]a blog. It contains only one post (June 21, 2011). That post is only seven words long. I also learned she has two very similar websites ([5]here and [6]here). Both use her full name and title where most people would use she. Perhaps I caused the blog and websites.

Here's what happened:

1. In 2008, during a routine physical, my primary-care doctor finds that I have a hernia, so small I hadn't noticed it. He says I should see Dr. Consorti. Do I need surgery for something so small? I ask. Ask her, he says.
2. Dr. Consorti examines my hernia. She recommends surgery (that she would perform). Why? I ask. It could get worse, she says.
3. Eventually I realize that's a poor reason. Anything can get worse. Influenced by [7]Robin Hanson, I speak to Dr. Consorti: Surgery is dangerous. What about doing nothing? Is there evidence that the surgery you recommend is beneficial? Dr. Consorti says, yes, there is evidence supporting her recommendation. She says I can find it (studies that compared surgery and no surgery) via Google.
4. I try to find the evidence. I use Google and PubMed. I can't find it. My mom, who used to be a medical librarian at UC San Francisco, is an expert at this. She has done thousands of medical searches. She too cannot find any studies supporting Dr. Consorti's recommendation. Moreover, she finds an in-progress study that compares surgery for my problem with doing nothing. Apparently some researchers think doing nothing may be better than surgery.
5. I tell Dr. Consorti that my mom and I couldn't find the studies she said exist. Dr. Consorti says she will find them. She will let me know when she's found them and make copies. I can pick them up at her office.
6. Months pass. I call her office twice. No response.
7. In August 2008, [8]I blog about Dr. Consorti's continuing failure to produce the studies she seemed sure existed.
8. [9]A reader named kirk points out "[10]what looks like a relevant hernia study". It concludes: "Watchful waiting is an acceptable option for men with minimally symptomatic inguinal hernias. Delaying surgical repair until symptoms increase is safe." This argues against Dr. Consorti's recommendation. No one points out studies supporting

her recommendation.

9. Two weeks after my post, [11]someone who appears to be Dr. Consorti replies. She's busy. She has 30 new patients with cancer. She terms my question "scientific curiosity". She says "I will call you once I clear my desk and do my own literature search."

10. More than a year passes. In 2010, I receive a call from Dr. Consorti's office. An assistant asks me to remove [12]my blog post about her failure to provide the studies. Why? I ask. It makes her look bad, he says. He says nothing about inaccuracy. I say I would be happy to amend what I wrote to include whatever Dr. Consorti wants to say about it. The assistant asks if I have any "further questions" for her. No, I say. The conversation ends.

11. A little later, I realize I do have a question. In 2008, during the conversation when I asked Dr. Consorti for evidence, I had said surgery is dangerous. In response, she had said no one had died during any of her surgeries. By 2010, I realized that such an answer was seriously incomplete. Many bad things can happen during surgery. Death is only one bad outcome. How likely were other bad outcomes? Dr. Consorti hadn't said. She knew about these other bad effects much better than I did, yet, in a discussion of the safety of surgery, she hadn't mentioned them. By not mentioning them, she made surgery sound safer than it actually is. Why had she not mentioned them? That's my question. I call Dr. Consorti's office and reach the person who had called me. I ask my question. [13]As I wrote ,

He tried to answer it. I said I wanted to know Dr. Consorti's answer. Wait a moment, he said. He came back to the phone. He had spoken to "the doctor", he said. She wasn't interested in "further dialogue". She would contact a lawyer, he told me.

I haven't heard from her since then.

This story illustrates a big change. As recently as twenty years ago, the doctor-patient balance of power was heavily weighted toward the doctor, in the sense that the doctor exerted considerable influence on the patient (e.g., to have surgery). One reason, [14]Robin Hanson has emphasized, is human nature: The more fearful we are, the more we trust. Patients are often fearful. Another reason for the power imbalance was information imbalance. The doctor knew a lot about the problem (had encountered many examples, had read a lot about it). The patient, on the other hand, knew almost nothing and could not easily learn more.

During the last twenty years, of course, this has changed dramatically. Patients can easily learn a great deal about any health problem. Google, PubMed, on-line forums, [15]MedHelp, [16]CureTogether, and so on. The story of Dr. Consorti and me illustrates what a difference the new access to information can make.

Personal science (science done to help yourself) has two sides. One is: collect data. My self-experimentation is an example. To improve my health, I gathered data about myself. It worked. My skin improved, [17]I lost weight, slept better, improved my mood, and so on. The other side is: use data already collected. That's what I did here. My search for data (including my mom's search) showed that data already in existence (including the absence of evidence supporting surgery) contradicted Dr. Consorti's recommendation. My search was not biased against her recommendation. I didn't care whether she was right or wrong. I just wanted what was best for me. [18]As Feynman said, science is the opposite of trusting experts – including doctors. My first glimpse of the power of self-experimentation was when it showed me that one of the two medicines my dermatologist had prescribed didn't work.

Overtreatment is an enormous problem in America. [19]Overtreated by Shannon Brownlee and [20]Overdiagnosed by H. Gilbert Welch, Lisa Schwartzl and Steve Woloshin are recent books about it. Overtreatment could easily be why [21]Americans pay far more for health care than people in any other country yet die earlier than people in many countries. A large fraction of our health care may do more harm than good. A common view is that the incentives are

wrong. As [22]one commenter put it, pay for treatment, you get treatment. The solution, according to this view, is to change the incentives. That's a good idea but will not happen soon. I believe overtreatment can be reduced now. You can (a) ask for evidence (as I did) and (b) search for evidence (as I did). The difference in lifespan between America and other countries suggests this might add years to your life.

I would like to find out what happens when people ask for evidence and/or search for evidence. Please send me your stories or post them in the comments.

More Two days after I posted this, Dr. Consorti replied to this post and the earlier one with essentially the same comment, which is [23]here.

Jim Purdy (2011-11-16 07:02:59)

What about doctors who refuse to accept the evidence from patients sitting right in front of them? I was amazed a few years ago when a very highly regarded medical specialist actually told me that it would be malpractice for him to pay attention to his patients. He said he had to treat patients according to national guidelines, even if his patients said the treatments weren't working.

Brian (2011-11-16 07:10:09)

A little over two years ago, I was "depressed". My psychiatrist wanted to prescribe an SNRI. I related, once again, my poor experience with an SSRI and asked for evidence that an SNRI would be any more effective. He said there was evidence that SSRIs worked. I pointed out the 2004 meta-analysis that showed no meaningful difference between SSRIs and place-

bos. Then I asked whether there was any better evidence for SNRIs. Since he wasn't able to provide any, I told him that since we know that extremely low Vitamin D blood levels, poor diet, no exercise, and no social life can cause depression, (all things I had at the time), we'll try fixing those things first and then resort to drugs if that fails. It did not fail and I quit seeing him.

Rachael (2011-11-16 07:24:31)

I want to thank you for posting this and re-posting it now. Around the time you were having those experiences my son's pediatrician recommended a tonsillectomy for recurring strep. The Ear Nose and Throat specialist also said it would help. I searched pub med and found research that suggested most children who receive a tonsillectomy have one fewer strep infection in the following year than those that don't. The time, expense, and risk of surgery vs. one strep infection, hmmm, not a tough choice. I don't believe that either doctor was motivated by any thing other than a desire to help my son, but their education pre-dated the meta-analysis I had read, and their training was in conflict with more recent research. No doctor can be as motivated to stay current as someone who will be directly impacted by the decisions. I think it should be standard procedure to e-mail patients the top ten search returns relating to any suggested treatment and discuss those studies before taking action. Government funding to remove pay-walls to all government supported research wouldn't be a bad idea either.

dearieme (2011-11-16 08:34:56)

Here's a question that I asked that, rather unexpectedly, stumped a specialist. "Your coronary arteries are normal" he said. "Ah", I said "do you mean 'normal' as in 'desirable' or 'normal' as in 'average'?"

Tom (2011-11-16 09:38:20)

You did cause those websites, and there are tons more than the ones you mentioned. She's hired a firm to do online 'reputation repair.' It's a big business, very expensive, and it doesn't really work. The company she hired told her that they can push your posts about her off the first page, yet you're still #2 for searches about her. But it's a good business, as people in her position will pay anything.

PJ (2011-11-16 09:40:45)

About five years ago, I had been hospitalized when I simply couldn't breathe anymore, following what I called 'chronic recurring bronchitis' and my body apparently called 'chronic lung infection from reaction to gluten'. After getting out of the hospital, carting around an oxygen tank until the little alveoli in my lungs regrew etc., I went to see the Respiratory Specialist that had been assigned me. Now, he was a handsome guy, very charming as well, seemed very knowledgeable. He prescribed me three kinds of inhalers. "What specifically do these do to prevent the severe asthma?" I asked. He frowned at me in surprise. "Well they {yada yada, make it so you can breathe better }" he says. "But isn't that kind of after the fact?" I say. "I mean, at that point the problem's already in place. Do they do something toward preventing the problem in the first place?" "No," he says. "That is not curable." "So these are ONLY for symptoms," I insist on understanding. "Right," he says. Ok. I had no health insurance and they were a good chunk of extra single-mom budget but hey, you'd be surprised how selfish one is about being able to breathe. Time passes. My cardiologist-assigned me also in the hospital for an event that actually was just about days of steroid, pain and stress combined, I don't actually have a heart problem aside from enlargement from obesity - prescribes me the PPLP low-carb book. After reading it, I decide to do a trial. Just a trial. Without realizing the association at the time of course, I didn't just drop carbs, I dropped gluten. (Back then, LC bread, tortillas, bake mix, etc. didn't much exist-fortunately!) 3 weeks later my "severe asthma" has vanished. My "severe allergies" are gone. My "severe OMFG I'm gonna die" nightly acid reflux is gone. And a lot of less extreme things. I had a follow up appointment, and with shining eyes I told him of this miracle. I thought he'd be as excited about it as I was. So I made a mistake (or not). "Doc," I say, "You're a specialist in this stuff. I wonder if this could help other people. Have you not seen a change in eating affect respiratory problems?" "So you aren't taking the medication I prescribed?" he answers instead. "I - uh - well no of course not, not anymore. You told me they were for symptoms. I don't have any symptoms anymore!" "It's not appropriate for you to be my patient if you can't follow medication direction," he says, looking at me as if I have just confessed to secretly being Evil in some truly egregious way. I was still saying, "but - but - " when he left the room. The nurse finished that appointment and told me not to bother making another. I left feeling like the really smart handsome charismatic guy had told me I sucked, and feeling like I'd done something bad and got caught in it. And then I thought: what am I talking about?! This is the best thing that ever happened to me!! He's an idiot! That's just the way it is I

guess. I mean this wasn't even about surgery or something major, it was nothing more than expensive inhalers for symptoms I no longer had any of at all. Yet still the doctor was bizarrely... what's the word. Resistant? I might add I used to study with a doc who worked in psychoneuroimmunology (a long word that in his case mostly meant using stuff like biofeedback). He had cases where people had carpal tunnel and were about to have surgery that would forever remove their ability to use their hand (which they already couldn't), leaving them a sort of minimal claw effect. He would talk them into putting off the surgery and working with him using biofeedback and hypnosis, and they would go back to their docs showing him hands that worked again. (It's a muscle stressed induced displacement so there isn't any reason why this can't be reversed.) The doctors would be angry. The patients were always bewildered. I think there is some control psychology in play with a lot of medical professionals. They have a hammer. They see you as a nail. They don't really care or want to know what better tools might be applied. PJ

Shawn (2011-11-16 09:58:48)

Doctors aren't always right, that's for sure. While it's good that people have more access to information now than ever before, a lot of people simply are not capable of looking up that information. A lot of old people or mentally challenged people do not know how to use the internet and are not able to read complex studies and understand their implications. The best argument of socialized health care is that the incentives are more properly aligned. My mom was misdiagnosed with epilepsy (I was about 7 years old at the time). She was told she had a petit mal seizures (after supposedly experiencing one on front of her mother) and was put on anti-seizure medications, including depakote. This drug caused her brain to shrink, memory & emotional problems, coarsening of the features, depression, and sleep problems (she would fall asleep during the day at random times). She was kept on all those meds because her "blood levels" supposedly were not where they were "supposed" to be at. 18 years later after talking with a doctor at the Mayo who said she did not need to be on all those medications she cut back until she was not taking any and never had a seizure. She described them as being in a "cloud all those years;" all those years she felt miserable. After she got off them she felt a 1000x better. She ended up getting pancreatic cancer and died from that. We don't know if all the drugs contributed/caused that they could have.

Jim (2011-11-16 10:09:30)

I think many doctors would say they are too busy to look for or provide the type of research you were asking for. I think Dr. Consorti's mistake was when she told you there were plenty of studies on point. In retrospect, she should have just said "I don't know of any such studies. Practicing medicine is part science, part art. Research can't always help, and doctors often have to go with standard practice, gut instincts and experience." You may not have been satisfied with her answer, but at least she would have put the issue to bed instead of prolonging it by having to try to save face each time you followed up.

Alex Chernavsky (2011-11-16 11:03:35)

This kind of stuff isn't limited to doctors. About fifteen years ago, I had conducted some complicated financial transactions during the year, so I hired a tax specialist to prepare my income tax return. He made a big mistake that would have cost me thousands of dollars, had I not spotted it on the draft. When I pointed out his mistake, he initially refused to acknowledge it. Eventually, he admitted that he was wrong. The sad truth of the matter is that you can't trust anyone to be competent, and you always have to do your own homework on matters of any importance.

Jim Purdy (2011-11-16 11:47:15)

PJ's story is very powerful, and all too common. I propose a zero-based "Rick Perry Rule" for health care. In a recent Republican presidential debate, Rick Perry said his foreign aid budget would start at zero, and every country wanting foreign aid would have to justify every dollar. I'm not a Rick Perry fan by any stretch of the imagination, but I wish the government and insurance companies would start all health care budgets at zero, and require at least a little bit of evidence for every treatment, every drug, every device, and every surgery. I suspect that thousands of lives would be saved, millions of lives would be improved, and billions of dollars would be saved, if America were taken off 90 percent of all drugs and surgeries, and doctors were required (and re-trained) to work with patients on lifestyle changes. When I try to talk with most doctors about lifestyle, they look like I'm speaking in Klingon. All they want to do is print out prescriptions and move on to the next patient every 5 minutes.

Jay (2011-11-16 13:35:55)

I think a major reason why doctors are so disapproving of patients experimenting with their own solutions is the fact that they mostly only get to see the results when it doesn't work. Patient A and Patient B go off the reservation and decide to try something different than what the doctor thinks is the way to fix their problem. Patient A manages to figure something out and doesn't visit the doctor anymore since the problem has resolved itself. Patient B doesn't manage to figure something out, or makes things worse with their self-experimentation. Patient B then goes to the doctor, tells him\* of the self-experimentation and the doctor thinks "People who aren't listening to me are really fouling themselves up – the problem is that they are not listening to me." This is repeatedly reinforced. The doctor never gets to see patient A. The doctor sees all the downside, and none of the upside – given the data he is receiving, his viewpoint makes sense, but the data is self-selected and skewed. \*or her

Seth Roberts (2011-11-16 14:02:40)

Jim Purdy, you wrote: "it would be malpractice for him to pay attention to his patients. He said he had to treat patients according to national guidelines, even if his patients said the treatments weren't working." Wow. I am also amazed. That doctors aren't trained to have a more reasonable response when treatments don't work.

Lisa Wainer (2011-11-16 14:07:07)

Hi Seth, Your interaction with this doctor is a really illustrative example of something I have experienced multiple times, having suffered from a serious health condition (Crohn's disease) and self-experimented my way off all medications and avoided of surgery for 20 years. In my view it is a rare to find a doctor who is a thinker, and they are certainly not trained/encouraged to be thinkers. I just wanted to mention a couple of books I read a while ago that you may be interested in (you may know of them) that sound like they are related to the books you mention here. The first is Medical Nemesis by Ivan Illich - a short book noted as a medical classic. I think he first coined the word 'iatrogenic' to mean disease caused by medical intervention. The other one is The Death of Humane Medicine by Petr Skrabanek (available as pdf online) which rallies against 'healthism' and state based health promotion. It is a little harsh on alternative medicine (it was written some time ago) but it is quite a read.

Seth Roberts (2011-11-16 14:20:31)

"I think Dr. Consorti's mistake was when she told you there were plenty of studies on point." I think that when she discovered my blog post, which apparently bothered her, she should have done the search, told me the result, and asked me to amend the post. [More After I wrote that, she did so – see above] "Many doctors would say they are too busy to look for or provide the type of research you were asking for." I agree. One doctor said this in the comments on a previous post. Keep in mind that Dr. Consorti would be paid a considerable amount of money for doing the operation she had recommended.

threepipeproblem (2011-11-16 14:39:58)

Thank you for having the courage to call out someone who acts more like a high priestess than a woman of science. My suspicion is that most doctors are more like priests than scientists.

Seth Roberts (2011-11-16 15:08:24)

"My suspicion is that most doctors are more like priests than scientists." Yeah, that's a good question: What fraction of what doctors do is priest-like, and what fraction scientist-like?

Seth Roberts (2011-11-16 15:11:45)

I just found the introduction chapter of Medical Nemesis online which can be downloaded here: [http://www.digitallibrary.kcci.com.pk/bitstream/32417747/155/1/MedicalNemesis Introduction.pdf](http://www.digitallibrary.kcci.com.pk/bitstream/32417747/155/1/MedicalNemesis%20Introduction.pdf)

Carlson (2011-11-17 09:23:06)

New to your blog, but your thinking parallels what my wife and I have been figuring out over the last few years. One of the things that bothers me about "Obamacare" or any 'one size fits all' healthcare 'fix' is the idea that the current healthcare system is too reliant on pharmacological and surgical solutions. We've known many people who are too quick to seek solutions to their health problems via surgery or drugs. Surgeries ARE dangerous and drugs almost always have side effects. The benefits of surgery and or prescription drugs need to be seriously weighed against the downside (not to mention the ongoing expense).

Grundle (2011-11-17 14:02:53)

Many of you are quick to excoriate doctors while discounting the bewildering amount of knowledge they have to keep track of. Classifying doctors as "non-thinkers" is disingenuous and untrue. The biggest problem I see with doctors is either arrogance or greed. When either of those two get in the way it clouds their ability to provide the best care to patients. An arrogant doctor obviously won't listen to a patient because he "knows better". It is easy to see how someone's view can become so jaundiced when they have to sacrifice four grueling years to medical school and another four to residency. I imagine that many doctors resent a patient who really doesn't know anything, but what they read from some article. In truth, I think the cases where self-diagnosis and self-treatment are successful happen to be the minority. Remember that the body is so complicated that we still don't completely understand how it works. Just understanding cellular metabolism is a challenge. That is only a small percentage of the entire corpus of knowledge a doctor is expected to master. The second case is the greedy doctor that is only in it for the money. This is how I see the physician in this article. She probably knows that the condition is minor, but the accepted approach is always surgery and that means she gets paid to perform that surgery. Every surgery is a paycheck and if someone is greedy enough they will line as many up as possible without worrying about monitoring the condition to see if it gets worse. There is a third type of doctor that is there for their patients. They listen to what the patient says and strive to provide the best care possible. I have met many of these doctors, and although they are not infallible, they constantly work to make sure they are giving the best and most up to date care possible. My point is that if you have questions and your doctor cannot answer them satisfactorily then find a physician who will take the time to sit down and answer your questions, and tell you why his approach may be better. In every profession there are idiots who will make the entire group look bad, however shunning the entire group because of those idiots is not an adequate response either.

Seth Roberts (2011-11-17 14:55:58)

Grundle, is what you say here based on something that happened to you? Or something that you saw? I would like to present a balanced view of doctors. I agree with you that my experience is not the whole story.

David Harmon (2011-11-17 19:42:47)

I'd say there's an even bigger factor than arrogance involved, which is interference from the health insurance companies. A doctor who doesn't toe their line can be dropped from coverage, which for most types, basically puts them out of business. Naturally, this will get worse with ObamaCare's mandatory insurance.... "It's very difficult to make a man see something, when his salary depends on his not seeing it"....

Lisa Wainer (2011-11-18 03:30:49)

Grundle, I have met a lot of doctors in my capacity as a sick person and a few as a healthy person. I have yet to meet one who is happy to accept that my self-experimentation has made me healthy. Some even find it hard to believe that I actually am healthy - i.e. refusing to believe my experience and wanting to do expensive, invasive medical tests to 'check' that what they are seeing with their own clinical judgement is true. That is what I mean by not being able to think. But that is only my experience. This is not to say that I have not met nice doctors or doctors who genuinely care about their patients. Being caring and nice and wanting to do the right thing does not necessarily result in effective treatment (although it can be extremely helpful and supportive) - especially if a doctor does not listen to the patient and think for themselves. I often think of this as an agency problem. Doctors in the UK don't work for the patient - they work for the NHS. But similarly, the doctor that Seth encountered has also lost her agency. She doesn't understand that she should be working for her patient (as her patient pays her directly) and the reverse of personal recommendation happened to her - which risks her livelihood (evidenced by how much spent on reputation repair). Her extra bad luck that her patient had an influential blog.

Alex Chernavsky (2011-11-18 08:50:27)

There are a couple of funny things about this. If Dr. Consorti had just admitted her mistake and eaten a little crow, she probably could have avoided the whole issue. Instead, she has to spend a lot of money to hire a firm to restore her on-line reputation. The other funny thing is that I wonder whether her "reputation consultants" actually know what they're doing. Note to Dr. Consorti: You'd be better off using hyphens in the URLs to separate your names: i.e., instead of eileenconsorti.wordpress.com use eileen-consorti.wordpress.com. Similarly, use eileen-consorti-md.com instead of eileenconsortimd.com. If you use hyphens, search engines will treat the names as separate words. (No charge for my advice.)

Nansen (2011-11-20 17:36:50)

Why didn't you ask for a second opinion? I had two hernia repairs in Berkeley, by two surgeons, and both made it very clear that watchful waiting was an option. (One repair was in 1998, so it wasn't a matter of the doctor needing new research.) I'm not discounting the value of what you're saying, but in this case you might have saved a lot of effort by just doing what many patients commonly do already.

Seth Roberts (2011-11-21 14:47:25)

Why didn't you ask for a second opinion? I had two hernia repairs in Berkeley, by two surgeons, and both made it very clear that watchful waiting was an option. Because a literature search established there was no good reason for the surgery. That was more conclusive than anything a doctor could say. It was also much easier to search the literature (and ask my mom to do so) in the comfort of my apartment than travel to a doctor's office, wait, etc.

Grundle (2011-11-23 09:44:45)

@Seth - Sorry to wait so long to get back to this. I am not sure this is based on anything specific. To be fair, I do a lot of volunteering at a free medical clinic as an interpreter which gives me an advantageous viewpoint of seeing both the viewpoint of the doctors and the patients. Since I effectively become the path of communication between them it is a perfect vantage point to be able to observe and make conclusions on what is happening. Because it is a volunteer clinic run in association with a medical school there are also students learning there, so I get to see the entire gamut of attitudes from the doctor's perspective and since it is a general clinic it is like playing the lottery on knowing what kind of malady the patient will have. @David Harmon brought up a good point when he mentioned doctor's toeing the line with respect to insurance. The fact is, it is even more convoluted than that, because they also have to be aware of swindlers/hypochondriacs who want to get a quick fix of pain killers etc. Doctors have to be on the lookout for not only physical illness but mental illness and respond accordingly. If they work in a hospital they are also required to treat anybody that comes in regardless of their Insurance status. That is a fact. @Seth I think your reaction was correct in your case. You had knowledge of research and asked her to respond to it, which she could not. I do not think that she acted in an ethical manner and as such I would be leery in seeing a doctor of that caliber. Like anything, the relationship between a doctor and patient is predicated on trust and when a physician breaks that bond there really is no way for them to provide adequate care for that patient. @Lisa Wagner - I do not know a doctor that would be happy with self-experimentation either. I know tons of doctors that would be willing to take your ideas into account, sit down with you and try to come up with a plan to tackle the issues. Basically when you throw the doctors advice away for your own self-experimentation you are saying that you know more than they do, which from the perspective of human biology and the scientific approach of treating human illness you are way behind, but I am sure they are lacking in your knowledge of self-awareness. Self-experimentation without guidance is dangerous. As for the issue of "invasive" procedures, I also agree with you that many times this isn't the best approach, but once again doctors have been bound by legal issues. They are basically required to rule out a number of things based on the symptoms, and this precedent has been established due to any number of malpractice lawsuits that have been filed over the years. It is really a no-win for the doctors if you think about it. At least that is how it is here in the US, I can't speak for the UK.

Seth Roberts (2011-11-23 15:02:40)

Grundle, thank you for your helpful reply. Here is what is to me the most interesting part:

I do not know a doctor that would be happy with self-experimentation either. . . .Self-experimentation without

guidance is dangerous.

This is a fascinating state of affairs. What if a teacher said they were unhappy if a student learned on his/her own? Learning without guidance is dangerous, the teacher might say. If doctors knew 100 % of the relevant info, then there would indeed be no need for self-experimentation. You would just follow the doctor's orders. But what if doctors knew only 10 % of the relevant info? Or less? Which is not to be critical of doctors. They are merely the part of the health care system that has the most contact with the rest of us. It is deep inside the system that ignorance is dressed up as wisdom.

Grundle (2011-11-30 08:39:57)

Seth, I understand what you are saying, but I think you are taking too lightly the complexity of the human organism. I don't view self-experimentation on the human body as a simple research project, because there can be some very real and even fatal consequences. I have no problem with learning, and I think it should be encouraged, but let us take your example and expand it. If you were learning about efficient synthesis of Nitro Glycerin, or Serin gas would you go off and try to experimentally come up with a solution or would you seek guidance from already established knowledge before tackling it? One misstep in either of those scenarios could bring disaster. This is where I have a problem with the over prescription of medications in this country. I think doctors are too quick to prescribe when many drugs are going to have an impact on the balance of the overall organism. At the root of everything, we are really just a giant set of complex chemical reactions, but they feed off each other with feedback mechanisms and "on off switches" based on which enzymes become activated and inactivated. Throwing a drug or chemical into that mix will upset the balance. The self-experimentation I would advocate is common sense and good health that can be obtained through a good diet and regular exercise. Of course I could be overthinking your definition of self experimentation. I suppose I should read more of your blog now ^^

## Is Health Data Ever Harmful? (2011-11-17 05:00)

In [1] yesterday's post I described how searching the medical literature helped me avoid a dangerous surgery with no obvious benefit. The surgeon I consulted, who recommended the surgery, said that published evidence backed her up. I could not find that evidence, however. Others found evidence that contradicted her recommendation.

Among the comments on that post were similar stories: Searching/reading the medical literature had been helpful. Learning what had happened (in research studies) was better than relying on an expert (a doctor). Here is an example:

A little over two years ago, I was “depressed”. My psychiatrist wanted to prescribe an SNRI [serotonin-norepinephrine reuptake inhibitor]. I related, once again, my poor experience with an SSRI and asked for evidence that an SNRI would be any more effective. He said there was evidence that SSRIs [selective serotonin reuptake inhibitors] worked. I pointed out the 2004 meta-analysis that showed no meaningful difference between SSRIs and placebos. Then I asked whether there was any better evidence for SNRIs. Since he wasn’t able to provide any, I told him that since we know that extremely low Vitamin D blood levels, poor diet, no exercise, and no social life can cause depression (all things I had at the time), I’ll try fixing those things first and then resort to drugs if that fails. It did not fail and I quit seeing him.

None of the stories in the comments described the opposite outcome: Knowing the data made things worse.

Are there exceptions? Is it always helpful (or at least not harmful) to know what happened (i.e., know research outcomes)? Has anyone reading this had an experience where knowing health research data was harmful?

1. <http://blog.sethroberts.net/2011/11/16/dr-eileen-consorti-and-patient-power/>

---

Alex Chernavsky (2011-11-17 05:37:20)

Well, there’s the issue of [1]cyberchondria:

Cyberchondria (or cyberchondriasis) refers to the unfounded escalation of concerns about common symptomology based on review of search results and literature online.[1][2] Articles in popular media position cyberchondria anywhere from temporary neurotic excess to adjunct hypochondria. Cyberchondria is a growing concern among many healthcare practitioners as patients can now research any and all symptoms of a rare disease, illness or condition, and manifest a state of medical anxiety.

1. <http://en.wikipedia.org/wiki/Cyberchondria>

Joseph Buchignani (2011-11-17 05:44:52)

I can’t cite peer reviewed studies that harmed me, but certainly amateur medical science has slowed me in my progress towards a personal cure, because it was so convincing, yet wrong. During my search for a cure for my dietary issues, I tried and discarded IBS theory, then extended IBS theory (SCD and FODMAPS et al), then paleo diet, then non-conventional paleo, then ketogenic diets, then Aquatic Ape theory, before finally arriving at a diet of 1. white rice and 2. ultra lean seafood, including shrimp, lean fish, and scallops Other influential models included food reward theory, various elimination diet theories, etc. Each paradigm cost me a great deal of time to finally falsify and reject, and clouded a clear interpretation of the evidence staring me in the face. The apparent persuasiveness made me spend much more time and be much more meticulous in my falsification than I needed to be. After each model finally inarguably failed me, I felt betrayed and angry. I eventually adopted a solution that fit no known models. Had I pursued a strict data-driven approach, I might’ve found a solution much faster. Or maybe not. The paradigms were all useful in interpreting and constructing the final theory. I think it is very difficult to see data for what it is when we have persuasive, compelling paradigms suggesting incorrect interpretations and approaches. The solution would be to conduct more rigorous and analytical and intelligent experimentation. Unfortunately this was not possible for me, because strict elimination diets are difficult to adhere to, especially when sick, and often don’t provide sufficient food reward or even sufficient basic nutrition. I guess the major lesson I take away from this is that one should always focus on interpreting your own data properly, and never fall into the cognitive trap of assuming that a model must be correct simply because there is no better model available. But that’s very, very hard to do. I think the vast majority of medical studies don’t even rise to the

level of amateur health models, because they are poorly constructed and therefore suggest false or useless paradigms. The only health info I truly value at this point is rigorous self-experimentation. Everything else is merely for purposes of theoretical suggestion and inspiration. And it's a good thing to try things you "know" won't work, and compare the results to things you "know" should work, to see whether one significantly outperforms the other. That's a rapid way to test a model's validity, instead of testing every possible permutation before junking it.

q (2011-11-17 05:54:34)

well, there's the story, i don't know how accurate it is, that steve jobs died much earlier because he chose a dietary therapy over a surgical one. was that a decision driven by data in any way?

Seth Roberts (2011-11-17 06:21:47)

Thanks, Alex. I consider diagnostic categories theory, not data.

Seth Roberts (2011-11-17 06:24:56)

Joseph, I agree that theories can be harmful. Since the SCD diet has helped many people with IBS (cases where it helped are data, not theory), I don't see why it was a bad idea to try it.

Adam StJames (2011-11-17 06:44:19)

About 12 years ago, my Dr. prescribed Lipitor for high cholesterol. After some research, I decided that there was more risk than benefit and I refused. After many weeks of arguing with him, I told him that if he didn't stop, I'd change doctors. He grudgingly told me that there is a diet that "sometimes" works. He prescribed, then, a very high fat diet. Lots of animal fat, fatty meat, butter, avocados, cream, things like that. Within six months, I lost 40 lbs. and my cholesterol was back into the normal range. That easy. And free.

Jim Purdy (2011-11-17 07:10:14)

For me, the funding sources of the published data are all important. For example, there are many dozens, if not hundreds, of published studies extolling the health virtues of California walnuts. All the studies are paid for by the California Walnut Board. If walnuts are so great, why do they need heavy research and advertising subsidies from the industry? That's just for an inexpensive commodity like walnuts. When it comes to BigPharma or BigSurgery, the billions of dollars involved inevitably distort the studies and their conclusions. As far as I'm concerned all funded studies need to be held to an extremely high standard. Or ignored. But there is one source of data that I consider the gold standard: self-experimentation. I trust my body to tell me when something is working, or not. And my body has told me repeatedly that it does not like BigPharma chemicals, while it does like simple paleolithic foods. Self-experimentation! Hmmm ... who is the Berkeley professor who has written extensively about self-experimentation? :) Maybe the government should find him and make him the head of the FDA.

by (2011-11-17 09:58:49)

re: J.Buchignani's frustration: Maybe the emotion of having put so much work into testing a theory and having it fail, is necessary to solidifying your will to stick to a white rice and lean seafood diet for the rest of your life. Pain seems to be a necessary precursor to lasting habit change, in anything.

Ashish (2011-11-17 11:53:24)

It seems to me that any time your specific health situation/need turns out to be the opposite of the usual case, knowing the "health data" would be harmful. But that's really Monday-morning quarterbacking, isn't it?

Scott P. (2011-11-17 13:26:32)

My only thought is that information can be paralyzing either through volume or being unable to establish information's validity especially in light of contradictory information, which there is a lot of on any given subject.

Seth Roberts (2011-11-17 14:47:57)

Any time your specific health situation/need turns out to be the opposite of the usual case, knowing the "health data" would be harmful. But that's really Monday-morning quarterbacking, isn't it? Sort of. It's not a convincing argument for ignorance, I think we agree.

David Harmon (2011-11-17 19:52:57)

The big problem with self-research is that it's not always obvious which articles are (1) peer-reviewed medical science, (2) alt-med craziness, or (3) paid shills for drug companies (or for that matter, alt-med companies). It is possible to learn enough to tell the difference, but it's not necessarily easy – and some of the ringers feature deception and pressure tactics at cult-like levels. The Mercury Mafia is a good example there – they not only denigrate the vaccines that have turned so many deadly diseases into rarities, but promote dangerous chelation therapies which have already outright killed several children. But if you disagree with them, they'll tell you you're endangering your child.

Joseph Buchignani (2011-11-20 23:04:03)

I've just learned that my needs are unique due to Accutane side effects. I've been diving deep into that community. It's an interesting example that has some bearing. The data showed it could cure acne quick and permanently. The initial clinical trials didn't show THAT bad side effects, I guess. Unfortunately due to its mechanism of shortening telomeres for rapidly dividing cells, the damage shows up years later. So they put it on the market and a ton of people got delayed poisoning. Also, due to the way that studies are done, it's very hard to establish causation for compensation, because the general nature of the mechanism creates widely different effects in people, that are often hard to diagnose. And the delayed and gradual nature of onset makes causation even more difficult to establish in the legal sense. So, the way we collect health data in official studies created this disaster by its formal structure - the link between Accutane and curing acne was easy to establish, while the link between subsequent damage was much more vague, easy to miss if you put on the typical "evidence-driven medicine" blinders.

Joseph Buchignani (2011-11-21 00:29:48)

By the way, kombucha and apple cider vinegar both failed for me, and now I know why - it's the same reason I can't digest fat. Accutane can impair bile production. So I need a non-acidic fermented food. Would yoghurt qualify? And, if anyone has clues on reversing epigenetic damage, especially to telomere lengths, I'm all ears.

Aileen Kennedy (2011-11-24 21:22:23)

Really interesting. What I wondered when I read this was why the commenter, knowing that those were all issues that might contribute to his/her depression, did not take those steps before seeing a doctor. Why wait until you are sitting in the doctor's office before deciding to address them? I agree that such issues should be explored by a doctor first, before medication is suggested, but I was just puzzled by the attitude.

Vince (2011-11-18 09:30:08)

Where does Ridley get his 2-4 degree number from? It sounds like he might be referring to [1]this set of projections, but Hansen only predicted about a 0.7 degree C increase (in Scenario B, which was based on the emissions assumptions that turned out to be closest to what happened) and the actual warming has been about 3/4 of that.

1. <http://www.skepticalscience.com/Hansen-1988-prediction-basic.htm>

Jim Purdy (2011-11-18 11:58:26)

Seth, your Google search for "first let them get sick" has uncovered a nasty truth about the internet and its supposed billions of pages: Actually, the internet is a virtual Potemkin Village, and there really are only 87 pages in the whole internet.

charlie (2011-11-19 09:05:53)

Ridley's argument is filled with straw men. The BEST series puts forward a good argument there has been warming. I agree the historical record is a bad joke, and the models are so augmented to be near meaningless. That being said, he [Ridley] is attacking the straw men, not the bigger problems. We are in a propaganda war, and truth is always the victim. A broad based carbon tax makes a lot of sense. Moving us away from coal and crude oil is a good thing. And frankly, we need the revenue. But any carbon tax that would STOP global warming would also end life as we know it (ie \$20 for a gallon of gas)

Seth Roberts (2011-11-19 12:44:17)

Charlie, that's an interesting comment. When you say "we need the revenue" you seem to be saying you work for the government. But perhaps I am misunderstanding. I agree that taxing the status quo in order to develop alternatives makes sense. On the other hand, there seems to be plenty of innovation related to alternative energy and energy saving ("negawatts") without such a tax.

D (2011-11-19 16:46:33)

"Ridley's argument is filled with straw men." How so?

Thomas (2011-11-20 03:17:29)

Hansens projections seem to me astonishingly good (see Vince's link). Considering how hard it is to predict future events, having just a slight overestimation over 25 years is praiseworthy. Either way, what is your point right now? You said in a recent post that nobody would even contest that there is global warming. Additionally I find it sad that you only ever cite sources that support your point. What about all the studies and findings that say the situation is much worse than projected? How about the fact that Chinese scientists just recently alarmed that their glaciers are melting - their 14 weather stations at 4000 meter height showed a rise since 1961 of 1.73 degree celsius. It's a rare event that Chinese scientists are even allowed to alarm their population. Another recent report says that considering the actual rising use of fossil fuel will make the politically agreed goal of 2 degree rise of temperature until 2100 impossible to reach - the situation will be much worse. I think you're creating yourself a tunnel vision.

charlie (2011-11-21 07:00:54)

Revenue is going to go up. Sorry, Seth. Since you are now a US creditor in China, you should worry about that. We're paying taxes so we the Chinese can waste money on education. How to do that: income tax, sales/GST tax, or a carbon tax. In most countries, income/GST taxes are pretty maxed out. In the US, there is some room for increase, and room for a sub 5 % national GST. Taxing carbon (or energy use) solves problems of the GST or income tax approach. Again, from the revenue side, easy to do. The problem for global warming types is that increase isn't going to stop global warming.

Kirk (2011-11-21 18:04:18)

@Vince, See this article in the Miami News from June 11, 1986: [news.google.com/newspapers?nid=71XFh8zZwT8C&dat=19860611&printsec=frontpage](http://news.google.com/newspapers?nid=71XFh8zZwT8C&dat=19860611&printsec=frontpage) or [astheysawit.com/15389-1986-meteorology.html](http://astheysawit.com/15389-1986-meteorology.html)

Ashish (2011-11-24 23:28:37)

I suspect the Google "bug" is just Google removing redundancies, but I'm forwarding this to a friend who works in the relevant group there.

Vince (2011-11-26 14:46:41)

Thanks for the links, Kirk. But I'd like to see Hansen's actual words or figures, rather than a one-sentence paraphrase by a reporter. Reporters sometimes get things wrong, or leave out unstated assumptions - I'd look to Hansen's published work or public testimony to see what he thought, rather than to a brief newspaper piece. For instance, maybe the high end of that 2-4 degree range is based on Hansen's Scenario A from my link, which assumed that future emissions would be much higher than they actually turned out to be. Hansen's temperature projections were conditional on assumptions about future emissions; since emissions turned out to be much less than that model assumed, it's not a problem with the model if temperatures also turn out to be much less. One thing that the newspaper articles do make clear is that the 2-4 degree estimate was in degrees Fahrenheit, not Celsius. Since the actual amount of warming since the mid 1980s has been about 1 degree F (0.5 degrees C), I don't see how Ridley gets his claim that actual warming is only a tenth of the projection, unless he's taking the high end of the range and mixing up Fahrenheit and Celsius (and thus comparing the actual warming to an "expected" 4 degree C increase). Warming has been about half of the low end of the range given in the newspaper article (1 degree F when the newspaper reports 2-4 degrees F).

Kirk (2011-11-29 12:39:31)

@Vince, If that testimony was inaccurately quoted, then has Dr. Hansen disputed the reportage? I was not able to find such a denial. Is the actual testimony available? I looked around for a while, and it seems like it might be stored in some government library, but I don't have the resources to research further. Since the public newspaper record from that time reports that Dr. Hansen testified there would be an increase of 2 to 4 degrees, I think the burden to prove that reporting was inaccurate is now yours. Good luck. If you look at the WoodForTrees Temperature Index, which is the Mean of HADCRUT3VGL, GISTEMP, UAH and RSS, offset to UAH/RSS baseline (-0.0975K), available at [www.woodfortrees.org](http://www.woodfortrees.org), you will see that the mean (in C) for 1988 was -0.03, and the mean for 2011 (for the first ten months) was 0.12, which is a difference of 0.15 C. If we take a guess at a world average temperature as 56.3 F, and then add 2 degrees and 4 degrees to that temperature, we get the following

temperatures in C: 13.50, 14.61, and 15.72. The difference between the base temperature and the increased temperatures, in C, is 1.11 and 2.22, respectively. Ten times the value 0.15 is definitely between those two. Ridley said in his speech, "Remember Jim Hansen of NASA told us in 1988 to expect 2–4 degrees in 25 years. We are experiencing about one-tenth of that. We are below even the zero-emission path expected by the IPCC in 1990."

## **Evidence-Based Medicine Versus Innovation (2011-11-19 05:00)**

In [1]this interview, a doctor who does research on biofilms named Randall Wolcott makes the same point [2]I made about Testing Treatments – that evidence-based medicine, as now practiced, suppresses innovation:

I take it you [meaning the interviewer] are familiar with evidence-based medicine? It's the increasingly accepted approach for making clinical decisions about how to treat a patient. Basically, doctors are trained to make a decision based on the most current evidence derived from research. But what such thinking boils down to [in practice – theory is different] is that I am supposed to do the same thing that has always been done – to treat my patient in the conventional manner – just because it's become the most popular approach. However, when it comes to chronic wound biofilms, we are in the midst of a crisis – what has been done and is accepted as the standard treatment doesn't work and doesn't meet the needs of the patient.

Thus, evidence-based medicine totally regulates against innovation. Essentially doctors suffer if they step away from mainstream thinking. Sure, there are charlatans out there who are trying to sell us treatments that don't work, but there are many good therapies that are not used because they are unconventional. It is only by considering new treatment options that we can progress.

Right on. He goes on to say that he is unwilling to do a double-blind clinical trial in which some patients do not receive his new therapy because "we know we've got the methods to save most of their limbs" from amputation.

Almost all scientific and intellectual history (and much serious journalism) is about how things begin. How ideas began and spread, how inventions are invented. If you write about Steve Jobs, for example, that's your real subject. How things fail to begin – how good ideas are killed off – is at least as important, but much harder to write about. This is why [3]Tyler Cowen's *The Great Stagnation* is such an important book. It says nothing about the killing-off processes, but at least it describes the stagnation they have caused. Stagnation should scare us. As Jane Jacobs often said, if it lasts long enough, it causes collapse.

Thanks to Heidi.

Jim Purdy (2011-11-19 22:50:14)

The Wolcott interview you cited has profound implications for diabetics. This statement was particularly meaningful to me: "... a small cut or sore can become infected, and flare into a limb- or life-threatening condition in as little as three days. These wounds are so difficult to heal that most of medicine considers them a lost cause and treats them with amputation." In early 2010, I was hospitalized while numerous physicians and surgeons said that my right foot had a massive

diabetic ulcer and that my leg needed to be amputated immediately or I would die. That didn't sound to me like a great idea, and I left the hospital after 6 days, even though the doctors said I would be back within a few days in much worse shape, if I didn't die first. It took many months, but my leg healed just fine. Over millions of years, our bodies have evolved awesome defenses against illness, but doctors give up too quickly and perform many unnecessary life-changing leg amputations.

Thomas (2011-11-20 02:44:12)

I'm sure I'm just missing something here. Didn't you just the other day request that doctors always provide you data with evidence that their treatment works?

Seth Roberts (2011-11-20 03:15:16)

Didn't you just the other day request that doctors always provide you data with evidence that their treatment works? Not quite. I said it was always a good idea to ask for data. If the doctor has no data, fine, now you know. If the doctor has anecdotal data, fine, now you know. The problem with evidence-based medicine is not the emphasis on evidence, it is the emphasis on being an evidence snob. Asking for evidence, to be perfectly clear, is not the same as being an evidence snob.

Grundle (2011-11-30 08:45:06)

Risk versus reward – what doctor is going to risk a hefty malpractice suit and losing their medical license to step out of the norm? There ARE places where this can happen. There are research hospitals trying to pioneer new treatments every day, but because of heavy government regulation there is a lengthy process they go through before their new treatments are allowed to be used.

Mark (2011-12-09 14:05:08)

Seth- Avid reader of your blog (and your book). Just saw this article about a treating physician potentially conflicted due to business relationships with pharma: [http://www.minnpost.com/healthblog/2011/12/09/33717/how\\_u\\_student\\_with\\_ms\\_came\\_to\\_doubt\\_her\\_neurologists\\_motives?utm\\_source=MinnPost-RSS&utm\\_medium=feed&utm\\_campaign=Feed%3A+minnpost-region+%28MinnPost+-+MinnPost.com%3A+Region%29#108-33717](http://www.minnpost.com/healthblog/2011/12/09/33717/how_u_student_with_ms_came_to_doubt_her_neurologists_motives?utm_source=MinnPost-RSS&utm_medium=feed&utm_campaign=Feed%3A+minnpost-region+%28MinnPost+-+MinnPost.com%3A+Region%29#108-33717).

Elaine (2012-01-11 21:11:21)

Evidence-based medicine is an improvement if you compare it not to innovation, but to doing the same thing that has always been done even when that practice does not actually work that well. That is usually what evidence-based medicine is compared to, and that is where the push for evidence-based medicine is coming from. It's not the practitioners pioneering new treatments who are viewed as a problem here, so much as the medical "wisdom" that is unstintingly followed, even when it turns out that it's not so wise after all.

## **Fruit Juice Kombucha (2011-11-20 05:00)**

A reader of this blog named Heidi noticed the discussion of "kombucha" made by fermenting fruit juice with a kombucha culture (SCOBY) [1] started by Parker Bohn. She wrote as follows:

I read somewhere on the internet that kombucha was traditionally brewed with rosehips and elderberries. Since then I've been combining tea (either green, black, or raspberry leaf) with several kinds of wild fruit and making some absolutely amazing kombucha! (Before then I experimented with lots of different herbal kombuchas with different medicinal properties.) Black current, rosehips, elderberries, sumac berries, autumn olive berries, black cherries, and raspberries all made excellent kombucha. The best results seemed to be from tea combined with two different fruits, one tart and the other with a unique flavor. I also tried wild grape juice and hawthorn fruits but wasn't as happy with the results, though the kombucha was still good. Also the SCOBY grows thicker with the tea and fruit combos.

I still used the same amounts of sugar and tea that I had been using, but I was using tart wild fruits that weren't as sweet as store brought juice. My brew of tea, wild fruits, and sugar was a lot stronger and more flavorful than the weak tea and sugar combo that most people use. I would have two or more people sample the results. Different people would have different favorites, but everyone agreed that the fruit and tea combos were the best kombucha they'd ever had.

I also created herbal kombuchas to target different health issues that people had. For example I made a kombucha with wormwood and other parasite killing herbs. After awhile, I pushed it too far with the herbs though, and the SCOBY stopped fermenting well and started to mold. I was able to nurse it back to life though. Certain herbs work much better than others.

Perhaps a mixture roughly half tea and sugar, half fruit juice will work best. At least, that's where I'll start exploring these possibilities. I may never go back to traditional kombucha. Because they are more complex, I can easily believe these newfangled brews taste better. It's interesting they aren't available commercially. Flavored kombucha drinks in stores are kombucha with small amounts of fruit juice added at the end.

1. <http://blog.sethroberts.net/2011/11/14/seth-roberts-interview-with-pictures/#comment-932638>

---

Alex Chernavsky (2011-11-20 06:45:15)

Seth, can you ask Heidi for more-specific instructions? It's not clear whether she includes whole fruit/berries with the tea, mashes it the fruit first, squeezes juice out of it, etc. I'd like to have enough detail to reproduce her kombucha myself.

Seth Roberts (2011-11-20 07:09:44)

okay, I'll ask for more details.

John Eels (2011-11-20 15:21:10)

You might be interested in this drink: <http://www.carpediem.com/en/products/kombucha>

Tom (2011-11-20 16:37:14)

I'm wondering if some of the health benefits attributed to wine may not have more to do with the fact that it's a fermented beverage.

Seth Roberts (2011-11-20 17:19:45)

John, yes, it sounds like they ferment the fruit juice for a long time. The product I said didn't exist.

Heidi 555 (2011-11-21 08:25:33)

Alex, I processed the fruit in different ways depending on what it was and the form that I had it in. For example with the sumac, I steeped the fresh berries in the fridge for 1-4 days. With wild grapes and autumn olive berries I blended the fresh fruit and poured off the liquid. The rosehips and elderberries that I had had been dried, so I steeped them in hot water. The black current and raspberries were part of a green tea blend. The black cherries I cooked, but if I could find a simple way to remove the pits, I would process them differently. If possible I tried not to heat the fruit to preserve the vitamin C. In general I processed the fruit separate from the tea and sugar and then mixed them both together at room temperature. Occasionally, I steeped dried fruit with the tea and then strained it all off. My kombucha brew would be stronger than the weak tea and sugar that is typically recommended. Different fruits combined better with different kinds of tea. I always made two different blends at a time, plus I saved a few bottles from a previous batch. So I did a lot of direct comparisons, and as Seth would say

I became a kombucha snob or connoisseur. I stockpiled a lot of kombucha in my fridge and stopped brewing it for the winter. The kombucha SCOBY can just rest dormant for a long time. I gather most of my own fruits. So it was a labor intensive process. But I have lots of new ideas and combinations that I want to try next year. I would be curious to hear what combos other people discover to be exceptionally good.

Seth Roberts (2011-11-21 14:41:58)

Thanks, Heidi. The way you combine fruit and tea to make kombucha reminds me of the lambic beers I like so much. They involve two fermentations: beer and fruit juice. Also the way I got good results from using three fermented sources of flavor in soups: e.g., miso, fermented black bean sauce, and stinky tofu.

Alex Chernavsky (2011-11-21 15:39:10)

Heidi, thanks for the additional information.

Heidi 555 (2011-11-21 17:27:48)

You are both welcome. I look forward to hearing about your results.

charlie (2011-11-21 07:07:39)

rule of thumb: women goes into a doctor complaining about a thryoid issue. Give her a reference to a psychologist. True about 75 % of GI complaints as well. If there's not blood in the toliet, you dont' need a doctor.

Jim Purdy (2011-11-21 09:10:23)

Megan McArdle asked: "Will evidence-based medicine push us even more towards looking at numbers rather than listening to patients?" "Listening to patients?" Now that's a concept that I haven't seen practiced by many doctors. They all seem to be spend my allotted 3-minute visit typing out expensive prescriptions that their computers tell them that my insurance will cover. Meanwhile, they ignore me sitting there telling them that I don't want any drugs for lifestyle-caused issues like cholesterol, blood pressure, and blood sugar, and that I only want lifestyle advice. Forget evidence-based medicine, I'm ready to try shoe-based medicine. Maybe I could get a doctor's attention if I whack them over the head with a shoe.

Alrenous (2011-11-21 12:30:04)

There's a good reason you go with the objective tests, though. If you have a bunch of thyroid symptoms but normal thyroid levels, most of the time it's because someone's made a mistake somewhere and your thyroid's fine. That said, in this case the House solution is perfect. Give 'em thyroid stuff and see if they improve. Unlike say, chemo, hormones tend not to have the capacity to cause permanent damage. May as well just try it and see.

Seth Roberts (2011-11-21 14:37:46)

Megan McArdle asked: "Will evidence-based medicine push us even more towards looking at numbers rather than listening to patients?" Maybe we should call it evidence-rationalized medicine.

Seth Roberts (2011-11-21 14:59:37)

rule of thumb: women goes into a doctor complaining about a thryoid issue. Give her a reference to a psychologist. and you know this because...?

Sam (2011-11-22 13:38:58)

Just a note on the butter article: according to Wikipedia, kombucha contains butyric acid. [http://en.wikipedia.org/wiki/Butyric\\_acid](http://en.wikipedia.org/wiki/Butyric_acid) #Biosynthesis

Pieter (2011-11-23 05:16:02)

I think the link about the butter should go to Stephan Guyenet himself at <http://wholehealthsource.blogspot.com/20-09/12/butyric-acid-ancient-controller-of.html>, and not to a site that just copies other blogs.

## **"Allergic to the Practical": Law Schools Imitating Academia (2011-11-22 05:00)**

Thorstein Veblen might have gloated that [1]this 2011 article – about the uselessness of law schools and legal scholarship – so thoroughly supports what he wrote in a book published in 1899 (see the last chapter of [2]The Theory of the Leisure Class). Why are law schools useless? Because law professors feel compelled to imitate the rest of academia, which glorifies uselessness:

"Law school has a kind of intellectual inferiority complex, and it's built into the idea of law school itself," says W. Bradley Wendel of the Cornell University Law School, a professor who has written about landing a law school teaching job. "People who teach at law school are part of a profession and part of a university. So we're always worried that other parts of the academy are going to look down on us and say: 'You're just a trade school, like those schools that advertise on late-night TV. You don't write dissertations. You

don't write articles that nobody reads.' And the response of law school professors is to say: 'That's not true. We do all of that. We're scholars [i.e., useless], just like you.' "

Yeah. As I've said, there's a reason for the term ivory tower. And seemingly useless research has value. Glorifying useless research has the useful result of diversifying research, causing a wider range of research directions to be explored. Many of my highly-useful self-experimental findings started or received a big boost from apparently useless research.

The pendulum can swing too far, however, and it has. A large fraction of health researchers, especially medical school researchers, have spent their entire careers refusing to admit, at least in public, the uselessness of what they do. Biology professors have some justification for useless research; medical school professors have none, especially given all the public money they get. Like law professors, they prefer prestige and conformity. The rest of us pay an enormous price for their self-satisfaction ("I'm scientific!" they tell themselves) and peace of mind. The price we pay is stagnation in the understanding of health. Like clockwork, every year the Nobel Prize in Medicine is given to research that has done nothing or very close to nothing to improve our health. And every year, like clockwork, science journalists (all of them!) fail to notice this. If someone can write the article I just quoted about law schools, why can't even one science journalist write the same thing about medical schools – where it matters far more? What's their excuse?

1. <http://www.nytimes.com/2011/11/20/business/after-law-school-associates-learn-to-be-lawyers.html?ref=general&src=me&pagewanted=all>

---

Jazi yechezkel zilber (2011-11-22 10:19:54)

I observed that most lawyers are worse than useless. They cite the law with zero practical acumen. What one needs is knowing the procedure. How the judges think, etc. In a way, judges even smirk at naive lawyers that cite with full earnest the texts with no clue about what is actually going on. The surprise of the many totally clueless lawyers around, lies partly in that these lawyers studies for years how to be stupid. That is to be covered head to toe in textual thinking, while it simply does not work like this.

Alex Chernavsky (2011-11-22 14:03:58)

See also this article about the useless research conducted at business schools: "[1]Is Research in the Ivory Tower 'Fuzzy, Irrelevant, Pretentious'?" The article is actually from 1990, but I doubt that things have changed much since then. Here's a short sample from the article:

[Dean Richard R. ] West, a well-published academic himself, was shocked. Six years later, he's still amazed by what he considers the overemphasis placed on scholarly research at most business schools. After spending some time over the weekend with a recent issue of the *Journal of Strategic Management*, West found only one article, on corporate entrepreneurship, of any interest. "It's often crap," he says of academic writing in learned journals. "They say nothing in these articles, and they say it in a pretentious way. If I wasn't the dean of this school [NYU], I'd be writing a book on the bankruptcy of American management education."

1. <http://chernavsky.dreamhosters.com/b-schools/>

Tom (2011-11-22 17:35:25)

*If someone can write the article I just quoted about law schools, why can't even one science journalist write the same thing about medical schools — where it matters far more? What's their excuse?* Probably because the science journalists suffer from the same phenomenon. (Although science journalists are, if anything, *more* pathetic, as they are only groupies of the

useless.) Gary Taubes is one of the few who hasn't fallen into this trap. By focusing on things that are actually **useful** (such as "Why do people who eat as they 'should' get fat?"), he both earned huge amounts of opprobrium and turned the science world upside down. This is about rock music, but it encapsulates the phenomenon: [theonion.com/articles/history-of-rock-written-by-the-losers,736/](http://theonion.com/articles/history-of-rock-written-by-the-losers,736/)

Alex Chernavsky (2011-11-22 21:30:33)

Robert Whitaker is in the same vein as Gary Taubes. Whitaker does an outstanding job at pointing out the pseudoscience that's prevalent in psychopharmacology. See, [1]*Anatomy of an Epidemic: Magic Bullets, Psychiatric Drugs, and the Astonishing Rise of Mental Illness in America*. [2]John Horgan is a good journalist, as well.

2. <http://www.johnhorgan.org/>

Toyinulye (2011-11-22 22:18:04)

Hey Seth, I am longtime reader and lurker of your blog. I have a burning question for you and that is; why are white males in aggregate not attracted to black women?? I am a slim (5'4 120pounds, 21 years old) African woman. People tell me that I am attractive and that I favor Naomi Campbell. I attract all sorts of men but never white males. Even the liberal white males don't approach me. I tend to wear my hair in a long afro hair style do you think this can be apart of the problem. Do yo suggest that I seek out older white men?? Please let me know. Sorry for all of the questions.

Seth Roberts (2011-11-22 23:14:12)

Probably because the science journalists suffer from the same phenomenon. Well, part of the problem, as everyone acknowledges, is that science journalists are often liberal-arts majors who have difficulty with science. Whereas Taubes majored in physics. Another problem is that if you write critically about scientists you may have trouble getting them to talk to you. And science journalism requires access. This is a well-known problem throughout journalism.

Seth Roberts (2011-11-22 23:27:03)

why are white males in aggregate not attracted to black women? Someone who doesn't want his name used once explained this to me by saying that black culture was more masculine than white culture, which was in turn more masculine than Asian culture, and that men prefer somewhat more feminine women and women somewhat more masculine men. So black men and white women fit together better than white men and black women; and white men and Asian women fit together better than white women and Asian men.

Toyinulye (2011-11-22 23:39:03)

Seth, Thank you so much for your speedy reply. How can I attract white males? Or is it a lost cause?

Txomin (2011-11-23 03:17:26)

As long as the editors and reviewers of academic journals continue to ignore their responsibilities, useless research is the most we can aspire to. I belong to an editorial board and the fight for quality/standards has only gotten crueller over the years.

Seth Roberts (2011-11-23 03:50:12)

How can I attract white males? Or is it a lost cause? I think the man behind Norton Utilities, who is white, has a wife who is black. You could examine how they got together.

Jim Purdy (2011-11-23 04:41:32)

Re Toyinulye's question about white males and black females, I wonder what to make of the secret relationship of Tom Jefferson and Sally Hemings. He was the author of the Declaration of Independence and President of the USA, but he also was a slave owner, making him a very bad example by today's standards. I think that a lot of black women understandably don't trust white men because of their historically bad treatment by white men. Unfortunately, we white men have had a pretty horrible history with lots of women and non-white males.

Jazi yechezkel zilber (2011-11-23 17:06:52)

Seth, Bang on about white men and asian women. I always felt that this match is a win win situation. Both sides are happier than with their respective mates

Grundle (2011-11-30 09:16:30)

I disagree with you strongly on the uselessness of Nobel Prize winners in Medicine. Let us take a look at a few :) 1996 - "the specificity of the cell mediated immune defence" Knowledge of this has given us a new understanding of how to treat viruses and it is also related to the rejection of transplants which, with this new knowledge, has allowed us to reduce the incidence of rejection. I would say this is a significant discovery. 1997 - "discovery of Prions - a new biological principle of infection" This showed us an entirely new branch of infectious disease. Remember "Mad Cow Disease"? It is a prion infection. With this new knowledge we now can combat another subclass of illnesses that we didn't even know about before. This is a significant discovery. 1998 - "for their discoveries concerning nitric oxide as a signalling molecule in the cardiovascular system" - You got me here, I don't know how this one is significant. If I were to guess I would think it would have applications in treating lung maladies such as emphysema 1999 - "for the discovery that proteins have intrinsic signals that govern their transport and localization in the cell" With this new knowledge we can now design gene therapies using these signals to our advantage. Since the signals and the proteins construction are all tied to a specific set of genes. This knowledge brings us a step closer to treating genetic illnesses. I would say it is significant. 2000 - "for their discoveries concerning signal transduction in the nervous system" This one cannot be understated in it's importance. It is like discovering an integral part of the human body such as how breathing works. Knowing that the nervous signal works on "signals" is not enough, but knowing the mechanism behind those signals now gives us a more precise knowledge which of course will allow us to be more specific in treatments and diagnosis. This is significant. So far every one of these I have listed, except for the NO2 lung one, I can think of several ways for how it has helped improve our health. I think you made too much of a generic statement there. This is not to say that I agree with everything academia does. I do think there is incredible waste in research institutions, but I don't think all medical researchers are as incompetent as you paint them to be. The one thing I hope never disappears is honest research in the medical community, because the more we know about the human body the closer we can get to providing proper treatment to people who deserve to live long healthy lives

Seth Roberts (2011-11-30 14:43:50)

Grundle, thank you for your comment. I am not saying that all the prize-winning discoveries are completely useless. I am saying that for a long time none of them have helped us with major health problems (= cancer, heart disease, strokes, diabetes, depression, obesity, etc.). Sure, the 1998 award was for a discovery that reduced male impotence - not usually considered a major health problem. 1996: I am unaware of an important shown-to-work new treatment for viruses based on this discovery.. Organ transplant rejection is not a major health problem. 1997: I am unaware of any benefit from the discovery of prions. 1998: I am unaware of any benefit. "brings us closer" is a statement that it has not yet been useful. 2000: "will allow us to be more specific", you write. The useful application to a major health problem, you seem to imply here, hasn't yet happened. And it's been 10 years since the prize.

### Geniuses: Just Like Us! (2011-11-24 05:00)

[1]I've described how smart my students are. Recently I had dinner with some of them.

ME Why did you decide to go to Tsinghua rather than Beida [Beijing University]?

ONE OF MY MOST BRILLIANT STUDENTS There are more boys here.

1. <http://blog.sethroberts.net/2011/10/26/my-brilliant-tsinghua-students/>

---

Sam (2011-11-24 07:55:38)

Which actually is brilliant: probably the most important decision in their life is: with whom do they want to life with, who are your friends, your social network. And the most important of these will be your spouse, obviously. So it matters a lot to go where you have good chances to find a good match.

Alex Chernavsky (2011-11-24 08:30:28)

Yeah, I think one of the best reasons to attend an elite university isn't so much the quality of the education but the network of contacts that you can establish and that you can rely upon to help you during the rest of your life (witness George Bush at Yale [undergrad] and Harvard [grad]). The education itself is probably overpriced.

gwern (2011-11-24 10:38:35)

Quite brilliant: why go where there is an oversupply of your gender?

Sam (2011-11-24 11:39:52)

(of course we all think it's a girl who said this)

Seth Roberts (2011-11-24 13:43:31)

Yes it's a girl who said this. I was less brilliant: I started college at Caltech, 90 % male.

Tom (2011-11-25 10:20:26)

Off-topic, but in line with one of your interests...a Dutch cardiologist and leading researcher of statin drugs (and who is co-author of over 500 papers), has been fired for fabricating data: (registration may be required to view) [www.theheart.org/article/1315171.do](http://www.theheart.org/article/1315171.do)

## Butter and Arithmetic: How Much Butter? (2011-11-25 05:00)

I measure my arithmetic speed (how fast I do simple arithmetic problems, such as  $3+4$ ) daily. I assume it reflects overall brain function. I assume something that improves brain function will make me faster at arithmetic.

[1] Two years ago I discovered that butter – more precisely, substitution of butter for pork fat – made me faster. This raised the question: how much is best? For a long time I ate 60 g of butter (= 4 tablespoons = half a stick) per day. Was that optimal? I couldn't easily eat more but I could easily eat less.

To find out, I did an experiment. At first I continued my usual intake (60 g /day). Then I ate 30 g/day for several days. Finally I returned to 60 g/day. Here are the main results:

[2]

The graph shows that when I switched to 30 g/day, I became slower. When I resumed 60 g/day, I became faster. Comparing the 30 g/day results with the combination of earlier and later 60 g/day results,  $t = 6$ ,  $p = 0.000001$ .

The amount of butter also affected my error rate. Less butter, less errors:

[3]

Comparing the 30 g/day results with the combination of earlier and later 60 g/day results,  $t = 3$ ,  $p = 0.006$ .

The change in error rates raised the possibility that the speed changes were due to movement along a speed-accuracy tradeoff function (rather than to genuine improvement, which would correspond to a shift in the function). To assess this idea, I plotted speed versus accuracy (each point a different day).

[4]

If differences between conditions were due to differences in speed-accuracy tradeoff, then the points for different days should lie along a single downward-sloping line. They don't. They don't lie along a single line. Within conditions, there was no sign of a speed-accuracy tradeoff (the fitted lines do not slope downward). If this is confusing, look at the points with accuracy values in the middle. Even when equated for accuracy, there are differences between the

30 g/day phase and the 60 g/day phases.

What did I learn?

1. How much butter is best. Before these results, I had no reason to think 60 g/day was better than 30 g/day. Now I do.
2. Speed of change. Environmental changes may take months or years to have their full effect. Something that makes your bones stronger may take months or years to be fully effective. Here, however, changes in butter intake seemed to have their full effect within a day. I noticed the same speed of change [5] with pork fat and sleep: How much pork fat I ate during a single day affected my sleep that night (and only that night). With omega-3, the changes were somewhat slower. A day without it made little difference. You can go weeks without Vitamin C before you get scurvy. Because of the speed of the butter change, in the future I can do better balanced experiments that change conditions more often.
3. Better experimental design. An experiment that compares 60 g/day and 0 g/day probably varies many things besides butter consumption (e.g., preparing the butter to eat it). An experiment that compares 60 g/day and 30 g/day is less confounded. When I ate less butter, I ate more of other food. Compared to a 60 g/0 g experiment, this experiment (60 g/30 g) has less variation in other food. Another sort of experiment, neither better nor worse, would vary type of fat rather than amount. For example, replace 30 g of butter with 30 g of olive oil. Because the effect of eliminating 30 g/day of butter was clear, replacement experiments become more interesting – 30 g/day olive oil is more plausible as a sustainable and healthy amount than 60 g/day.
4. Generality. This experiment used cheaper butter and took place in a different context than the original discovery. I discovered the effect of butter using [6]Straus Family Creamery butter. "One of the top premium butters in America, " says its website, quoting Food & Wine magazine This experiment used a cheaper less-lauded butter ([7]Land O'Lakes). Likewise, I discovered the effect in Berkeley. I did this experiment in Beijing. My Beijing life differs in a thousand ways from my Berkeley life.

The results suggest the value of self-experimentation, of course. Self-experimentation made this study much easier. But other things also mattered.

First, reaction-time methodology. In the 1960s my friend and co-author [8]Saul Sternberg, a professor of psychology at the University of Pennsylvania, introduced [9]better-designed reaction-time experiments to study cognition. They turned out to be far more sensitive than the usual methods, which involved measuring percent correct. ([10]Saul's methodological advice about these experiments.)

Second, personal science (science done to help yourself). I benefited from the results. Normal science is part of a job. The [11]self-experimentation described in books was mostly (or entirely) done as part of a job. Before I collected this data, I put considerable work into these measurements. I discovered the effect of butter in an unusual way (measuring myself day after day), I tried a variety of tasks (I started by measuring balance), I refined the data analysis, and so on. Because I benefited personally, this was easy.

Third, technological advances. Twenty years ago this experiment would have been more difficult. I collected this data outside of a lab using cheap equipment (a Thinkpad laptop running Windows XP). I collected and analyzed the data with R (free). A smart high school student could do what I did.

There is more to learn. The [12]outlier in the speed data (one day was unusually fast) means there can be considerable improvement for a reason I don't understand.

---

Bob (2011-11-25 08:20:43)  
Have you tried 90g/day?

Chris (2011-11-25 09:12:28)  
Seth, Very interesting as usual. My interpretation is as follows: Based on the Speed-Accuracy Tradeoff chart I estimate Average time increased from 555 to 570 (60g vs 30g), a 2.7 % decrease in performance. Average accuracy increased from 30 % to 21 %, a 30 % increase in performance. Such a large improvement in accuracy with a minor decrease in speed would lead me to favor the 30g dose over the 60g dose. Am I missing something? Thanks for sharing and inspiring, Chris

Chris (2011-11-25 11:31:54)  
Maybe I should have expressed the accuracy improvement as an increase in correct answers  $9/70 = 13\%$ . 30g still wins IMO.

Seth Roberts (2011-11-25 11:38:15)  
Have you tried 90g/day? Not for very long. It's hard to eat much more than 60 g/day.

Seth Roberts (2011-11-25 11:45:28)  
Such a large improvement in accuracy with a minor decrease in speed would lead me to favor the 30g dose over the 60g dose. Am I missing something? Yes. As I say, when equated for accuracy, I was faster with 60 g/day. Accuracy is malleable. If I were slower I could easily be 100 % accurate.

Tom (2011-11-25 13:36:21)  
Seth, do you think that the effects of the Land o'Lakes butter are just as strong as with the premium (pastured) butter? Do you have any interest in A/B/A testing a premium, grass-fed butter vs. Land o'Lakes? (Which I'm assuming is not butter from pasture-raised cows.)

Andy (2011-11-25 14:35:25)

Hi Seth, Stephen over at whole health source seems to be suggesting that butters healthful properties come from its butyrate content - <http://wholehealthsource.blogspot.com/2009/12/butyric-acid-ancient-controller-of.html> I wonder if it is also responsible for its mind enhancing properties as well. Butyrate supplements are fairly readily available, maybe its time for Butter Mind 3! Let me know what you think. Cheers, Andy

jon k (2011-11-25 15:24:56)

I'm interested in running similar experiments on myself with diet and other inputs (exercise for example). Question: Where do you find a program that records your trials, and are you manually inputting each data point to graph or can that be done automatically?

Seth Roberts (2011-11-25 17:10:22)

I wonder if it is also responsible for its mind enhancing properties as well. Butyrate supplements are fairly readily available, Yeah, I've heard this idea. I plan to test it.

Seth Roberts (2011-11-25 17:20:48)

Question: Where do you find a program that records your trials, and are you manually inputting each data point to graph or can that be done automatically? I wrote the program myself in R. R runs the experiment and plots the data. You can find much of the R code I use in this blog - look under R - but you will need to know some R to use it.

Seth Roberts (2011-11-25 17:22:39)

do you think that the effects of the Land o'Lakes butter are just as strong as with the premium (pastured) butter? Yes. I have switched between expensive and cheaper butters several times and never noticed a difference. Doing yet another test isn't very attractive because there are too many things that are more likely to have an effect, such as sodium butyrate.

Jazi yechezkel zilber (2011-11-25 20:24:36)

The easiest theory is that speed + accuracy is related to underlying arousal. (baseline arousal, potential arousal change). In which case it is hard to know which one is better slower or faster. If you had a composite measure for general health or general brain functioning it would be better? Note the ideas of "how to become smarter" book, he did lots of self experimentation on brain pformance, and found different foods for attention, concentration, socialization etc.

Jazi yechezkel zilber (2011-11-25 20:25:10)

Ps. I am convinced that butter quality matters. I feel it in my stomach immediately.

Seth Roberts (2011-11-26 04:03:38)

The easiest theory is that speed + accuracy is related to underlying arousal. (baseline arousal, potential arousal change). In which case it is hard to know which one is better slower or faster. Increasing arousal does not make one faster at the same level of accuracy. It pushes you down (toward lower accuracy and greater speed) on a speed-accuracy tradeoff function. I observed that more butter made me faster at the same level of accuracy. Contradicting your theory.

Joseph Buchignani (2011-11-26 10:45:51)

For your encore, you should try Ghee. It's easy to make. Using ghee should greatly narrow down what components of butter are producing the effect. <http://paleodietlifestyle.com/paleo-fats/>

Nansen (2011-11-27 18:17:27)

In addition to butter, do you regularly consume oils (that is, when you're not experimenting).

Seth Roberts (2011-11-28 06:40:12)

In addition to butter, do you regularly consume oils (that is, when you're not experimenting). I regularly consume flax seeds, due to their high omega-3 content. The omega-3 is entirely in the oil. Whether flax seeds are a better source of omega-3 than flaxseed oil I don't know.

wcb (2011-11-29 11:34:28)

Seth, I have begun to employ your idea of consuming 1/4 or more stick of butter and have concluded there is great merit to doing this, if for no other reason than that it supplies the body with some healthy saturated fat. It's also a great quick snack when melted in a cup in a microwave oven and topped with some grated parmesan cheese. You can eat it like soup. :-)

Seth Roberts (2011-11-29 14:02:34)

You can eat it like soup You can also put it in tea. In place of milk or cream.

Christian (2011-12-04 19:45:18)

Hello Seth, great discoveries. But, what about the cream? Is it not supposed to be the same type of fat as the butter? As I use to cook with butter and have cream on sauces and coffee this is an important question to know as to define how much milk fat I take during the day and its effects. Thanks;

Greg Harrington (2011-12-05 11:53:36)

Seth, I have had a casual interest in trying this for a while, but I hadn't figured out how to consume that much butter. \*You can eat it like soup.\* ...did the trick! I just "souped" half a stick of regular grocery store butter. I found it to taste \*extremely\* salty-much more so than eating it as a solid. Do you use salted or unsalted butter?

Seth Roberts (2011-12-05 14:45:26)

I use unsalted butter.

Lisa Wainer (2011-12-07 04:46:26)

Hi Seth, Just a note from the other side of the pond. I wondered how you ate 'half a stick' of butter a day as I eat loads of butter but would struggle to eat half a 'stick'. Now that I see the 60g measure it all becomes clear! In the UK a 'stick' of butter is 250g. I often make scrambled eggs with 30-50g butter as a way to get a good dosing per day. I am going to try the melted butter in tea (and hot chocolate) idea and see how it tastes - thanks.

Seth Roberts and Citizen Science « My Year of Data (2011-12-10 21:17:19)

[...] discovered that eating half a stick of butter per day improves his brain function, as measured on a standardized test of simple arithmetic questions that he takes every day. (He [...])

Patti (2012-05-02 09:15:07)

Hi Professor Roberts, I understand you are conducting the butter experiment for cognitive results. I was wondering if you are self reporting any physical changes or noting any trends in blood work completed. Also, in conjunction with the butter what is the quantity of other fats you consume daily? (I am assuming you are still take a couple of tablespoons of ELOO) Thank you for your time.

Patti (2012-05-02 09:32:20)

No need to answer my question - I found answers on other blogs you wrote about butter. Thank you.

## **Climategate 2.0: How To Tell When an Expert Exaggerates (2011-11-26 05:00)**

[1]The newly-released climate scientist emails (called Climategate 2.0) from University of East Anglia (Phil Jones) and elsewhere (Michael Mann and others) show that [2]top climate scientists agree with me. Like me (see [3]my posts on

global warming), they think the evidence that humans have caused dangerous global warming is weaker than claimed. Unfortunately for the rest of us, they kept their doubts to themselves: "I just refused to give an exclusive interview to SPIEGEL because I will not cause damage for climate science."

This is a big reason I have found self-experimentation useful. It showed me that experts exaggerate, that they overstate their certainty. At first I was shocked. My first useful self-experimental results were about acne. I found that one of the two drugs my dermatologist had prescribed didn't work. He hadn't said This might not work. He didn't try to find out if it worked. He appeared surprised (and said "why did you do that?") when I told him it didn't work. Another useful self-experimental result was [4]breakfast caused me to wake up too early. Breakfast is widely praised by dieticians ("the most important meal of the day"). I have never heard a dietician say It could hurt your sleep or even a modest There's a lot we don't know. [5]My discoveries about morning faces and mood are utterly different than what psychiatrists and psychotherapists say about depression.

As anyone paying attention has noticed, it isn't just climate scientists, doctors, dieticians, psychiatrists, and psychotherapists. How can you tell when an expert is exaggerating? His lips move. There are two types of journalism: 1. Trusts experts. 2. Doesn't trust experts. I suggest using colored headlines to make them easy to distinguish: red = trusts experts, green = doesn't trust experts.

dearieme (2011-11-26 05:05:26)

I tended to rate my colleagues partly by how often the words "I don't know" passed their lips. Often = good.

Joseph Buchignani (2011-11-26 05:48:19)

Re depression, I wanted to note that deranging my Circadian by taking Vit-D morning and night produced a severe but brief depressive episode. I also experienced nausea. Back to 100 % mood after shifting to taking Vit-D in the morning only. This was on back to back days.

Joseph Buchignani (2011-11-26 05:52:11)

Connected with this, I believe early breakfast deranges the Circadian, causing a similar effect that is masked by food intake producing an energy/pleasure swell. It seems far more natural to experience a period of morning fasting before satisfying hunger.

Joseph Buchignani (2011-11-26 05:53:27)

This, of course, presupposes a healthy diet. Dietary composition greatly affects fasting dynamics.

Txomin (2011-11-26 08:16:54)

It is even simpler. Anything you cannot independently verify on your own, consider it belief. It will hurt at first. After all, how many of you can design a scientific experiment that demonstrates the Earth is round? Few, if any. The lesson here is that your ignorance does not imply anything regarding the shape of Earth. Your ignorance is only telling you that all you have is belief,

not knowledge. In order to achieve intellectual maturity, it is crucial to acknowledge that different critical mechanisms apply when working with knowledge and beliefs. Those people that apply the same critical methodologies to both scenarios are hopelessly lost and at the mercy of their gullibility.

Why experts exaggerate — The Endeavour (2011-11-26 08:38:42)

[...] Seth Roberts writes this morning: How can you tell when an expert is exaggerating? His lips move. [...]

Glen Raphael (2011-11-26 09:11:22)

That earth's shadow on the moon is round implies the earth is too

Chuck Currie (2011-11-26 09:41:06)

The shadow only implies that the earth is circular, like a ring, but not necessarily round, like a ball. Also, how do you know that the shadow you see on the moon is actually caused by the earth? Isn't this fun?

ARaybould (2011-11-26 16:53:37)

You have picked a bad example to generalize, as there are special circumstances in that case that do not apply to all areas of expertise. Specifically, there is what amounts to a well-funded industry devoted to sowing doubt, confusion and denial over every issue related to anthropogenic climate change, by any means that works. As the science does not indicate doubt of a sufficient degree and scope for their purpose, the workers in this industry have created a bold and impressive array of deceitful techniques, up to and including simply lying. Given this situation, who can blame a scientist for being careful with his doubts, knowing that they will be exaggerated beyond all reason, and that he will have no effective course for redress, as his antagonists have the best possible access to the media - they own a significant part of it?

Seth Roberts (2011-11-26 18:31:14)

there is what amounts to a well-funded industry devoted to sowing doubt, confusion and denial over every issue related to anthropogenic climate change, by any means that works. As far as I know this does not describe Steve McIntyre, who has been the most persuasive critic. He is not an "industry" nor is he "well-funded". Nor do I have any reason to think whoever leaked the Climategate emails is "well-funded". Leaking those emails cost very little. Although you seem to think climate scientists are different from other experts - better, apparently - I can't think of any reason they would be. Nor do you explain why that would be so. I say: Climate scientists are like other experts. I give several examples. You say: (a) There is a well-funded industry sowing doubt, confusion, etc. You give no evidence or examples. (b) Climate scientists, for no stated reason, are better than other experts. My claim strikes me as a lot more plausible.

Josh (2011-11-26 21:04:35)

Your blog is predominantly red, I suppose we know where you stand. Dun nun nun!

Seth Roberts (2011-11-27 00:02:24)

Fortunately the title of my blog is white on red rather than red on white.

ARaybould (2011-11-27 00:38:12)

As this is the only part of my reply that you have taken issue with, I trust we can assume that you agree with my central point: the author you quoted at the end of your first paragraph has reason to be guarded in what he says to certain parties, in order to protect himself from misrepresentations against which he has no effective recourse. There are a couple of reasons for us to assume that you have no disagreement. The first is that the specifics you take issue with make no difference: even if you would not personally regard the opposition to anthropogenic climate change (ACC) as an "industry" and have not noticed that it is well-funded (more on that below), it does not follow that the researcher in question lacks reasonable grounds for worrying about being misrepresented. An example of misrepresentation: Forbes presented Roy Spencer's recent remote-sensing paper as "blow[ing] a gaping hole in 'global warming alarmism'" when the contents of the paper neither claimed nor supported any conclusion remotely so sweeping. Furthermore, no conceivable evidence with regard to Steve McIntyre's personal funding leads to the conclusion that there is no well-funded opposition to ACC claims. When a

senator who is well-funded by the oil industry uses a novelist to address a Senate committee in order to debunk ACC, the only reasonable responses are of astonishment and cynicism. Then there is the way the Fox channel presents the issues, and Forbes, as mentioned above... I'm sure you could deny every case I could find, but that will merely leave us with an unresolvable disagreement to which Steve McIntyre's funding has no relevance, so there is little point in continuing this line. Therefore, one wonders what the paragraph referencing Steve McIntyre is doing in your reply at all. Is it a non-sequitur, not actually referring to the previous paragraph or anything else I wrote, but placed perhaps to give the hasty reader the impression that there is an actual argument there? Perhaps you are trying to exploit the fact that I failed to explicitly state that not all the opposition is well-funded or indifferent to the facts, but if so then your resort to this splitting of hairs reveals the weakness of your case. You demand proof from me over the funding question, one that is not central to the point - a much-used rhetorical ploy. At the same time, I notice that the standard that you set for yourself on the whole issue, in your last sentence, is mere plausibility - something of a mismatch, it seems. Another well-used ploy repeated here is to make claims, about what I have written, which are unsupported by my words. I invite you, and any other reader who is still with us, to examine what I wrote and notice that nowhere do I assign any level of credence to climate scientists, either absolutely or relative to any other expert (the 'special circumstances' are, as should be quite clear, the nature of some of the opposition to ACC, not some special credibility of climate scientists.) Furthermore, even if I were to hold that view, it would have no relevance to my point. This strikes part b) from your last paragraph, leaving us disagreeing as to whether there is a well-funded opposition to mainstream ACC research. I am comfortable with leaving third parties to make up their own minds on this.

Txomin (2011-11-27 00:41:00)

Like I said, there is no need to panic. The shape of the Earth is not dependent on anyone's beliefs. Only the scientific method guarantees factual knowledge and, exclusively, to the extent of its currently accepted paradigms. Belief, in contrast, has no correlation (or need to correlate) with knowledge whatsoever. That is the reason why it is crucial that we learn to distinguish what we know from what we believe and that we develop separate critical mechanisms to deal with these different cognitive phenomena. If we can't, we are dependent on "authority" and "people say" in order to manage our perception of reality... a dangerous proposition as history repeatedly demonstrates.

Seth Roberts (2011-11-27 15:47:33)

That's interesting, thanks. I agree, you didn't say that climate scientists are better than other experts. I should have phrased my comment differently. If by "well-funded industry" you mean Senator Inhofe, Fox News, and Forbes, I agree, they are well-funded. By "well-funded industry" I thought you meant specific to climate science. Perhaps CFACT is well-funded. I have not studied Forbes but, like you, I don't trust Inhofe and I don't trust Fox News. I mentioned McIntyre because, as far as I can tell, he has been by far the most persuasive and effective critic.

Rubashov (2011-11-27 16:18:11)

Seth, A while back when you were ragging on macroeconomists I thought about replying that they do exactly what climate scientists do: generate predictive models of complex systems based on long runs of time series data. And like Climate scientists, they express more certainty than they should. Reading your critique of climate science here, however, makes me think that I underestimated your criticism of macroeconomics.

Andre (2011-11-28 11:50:38)

The only thing I know for sure is that I don't know - too many people are too uncritical.

### **Assorted Links (2011-11-27 05:00)**

- [1]Salem Comes to the National Institutes of Health. Dr. Herbert Needleman is harassed by the lead industry, with the help of two psychology professors.
- [2]Climate scientists "perpetuating rubbish".

- [3]A humorous article in the BMJ that describes evidence-based medicine (EBM) as a religion. "Despite repeated denials by the high priests of EBM that they have founded a new religion, our report provides irrefutable proof that EBM is, indeed, a full-blown religious movement." The article points out one unquestionable benefit of EBM – that some believers "demand that [the drug] industry divulge all of its secret evidence, instead of publishing only the evidence that favours its products." Of course, you need not believe in EBM to want that. One of [4]the responses to the article makes two of the criticisms of EBM [5]I make: 1. Where is the evidence that EBM helps? 2. EBM stifles innovation.
- [6]What really happened to Dominique Strauss-Kahn? Great journalism by Edward Jay Epstein. This piece, like much of Epstein's work, sheds a very harsh light on American mainstream media. They were made fools of by enemies of Strauss-Kahn. Epstein is a freelance journalist. He uncovered something enormously important that all major media outlets – NY Times, Washington Post, The New Yorker, ABC, NBC, CBS (which includes 60 Minutes), the AP, not to mention French news organizations, all with great resources – missed.

---

disgruntledphd (2011-11-27 05:47:50)

On the Strauss-Kahn thing, it was obviously an attempt to destroy his candidacy for the French elections. I thought I was being cynical when talking about that, but perhaps I wasn't being cynical enough.

Jim Purdy (2011-11-27 13:17:28)

Is it April Fools Day? Or is this a "Special Conspiracy Edition" of Seth's Blog? In any case, all these conspiracies make for fascinating reading. Regarding the DSK story, I remember noticing (but not taking seriously) an odd little news story out of France just hours before the DSK hotel incident. The story, which seemed silly at the time, claimed that DSK was soon gong to be the target of a vicious smear campaign. Within a short time, that story didn't seem so silly after all. Re evidence-based medicine, I think the story has great significance. EBM is in fact nothing more than a way to ignore real evidence in the form of real patients. The fact that EBM has spread like a virulent plague is evidence for the idea that medical doctors are the laziest and most gullible of all the world's fools.

Alex Chernavsky (2011-11-27 15:41:50)

I'm not sure about the rest of medicine, but I think that psychiatry needs evidence-based medicine (or something like it). Most psychiatrists believe in the effectiveness of antidepressants (and of other psychiatric drugs), despite the fact that a careful analysis of the evidence suggests that these drugs are largely ineffective and often harmful. So.. if EBM is bad, then what approach do we need to reform psychiatry?

Seth Roberts (2011-11-27 17:37:33)

I'm not sure about the rest of medicine, but I think that psychiatry needs evidence-based medicine (or something like it). Most psychiatrists believe in the effectiveness of antidepressants (and of other psychiatric drugs), despite the fact that a careful analysis of the evidence suggests that these drugs are largely ineffective and often harmful. So.. if EBM is bad, then what approach do we need to reform psychiatry? Whether EBM taken as a whole has been beneficial or not I don't know. I think it has two big effects: 1. Pushing doctors to pay more attention to evidence (helpful). 2. Increasing denigration and dismissal of evidence that doesn't reach some standard of goodness (harmful). Which effect is larger I don't know. Are anti-depressants

worse than what they replaced? I don't know. I don't think psychiatry will make substantial progress until there is better research into the causes of depression and other mental disorders. In contrast to research about symptom relief. Why research into causes is bad I suppose has many answers, among them (a) all the money given to med school professors and others by drug companies (which love reducing symptoms while leaving the source of those symptoms intact, thereby creating a never-ending demand for their product) and (b) the lack of interest in prevention (because prevention is less profitable than cure). That is, all the money and status linked to perpetuating the status quo. I don't blame EBM for that.

## **Vitamin D: More Reason to Take at Sunrise (2011-11-28 05:00)**

[1]I blogged earlier about what I called a "stunning discovery": [2]Primal Girl found her sleep got much better when she started taking Vitamin D first thing in the morning (= soon after she got up) rather than mid-afternoon. This suggested that Vitamin D acts on your circadian system similar to a blast of sunlight. (More evidence and discussion [3]here.) In [4]his blog, Joseph Buchignani reports another experience that supports the idea that you should take Vitamin D first thing in the morning:

I picked up a bottle of Vit-D and Calcium. Dosage of Vit-D per pill was 1.6ud. Per the instructions, I took 1 at morning and 1 at night. I began this regimin on the night of the 24th of November. It's now the night of the 25th of November, and my circadian rhythm is completely fucked. . . . I'm fully awake now (12:30 AM), and I probably took the last dose of Vit-D around 7-8 PM. . . . I woke up with dark eye rings on the morning of the 25th. My energy level did not rise as it should have, but sort of meandered in the middle, before finally tailing off. Stress levels and depression were both elevated. I got little productive done.

Yesterday I started taking Vitamin D first thing in the morning. I took 2000 IU of Vitamin D3 at 8 am. In the afternoon I felt more energetic than usual. The next morning (this morning) I woke up feeling more rested than usual. This also supports Primal Girl's experience.

Let me repeat: first thing in morning. If you wake up before sunrise, take at sunrise (say, 7 am). Sunlight has a considerably different effect on your circadian system at 7 am than 10 am. (Look up circadian phase-response curve and especially the work of [5]Patricia DeCoursey if you want to understand why three hours makes a big difference.) I have two bottles of Vitamin D. Neither mentions time of day. Both say take with meals.

1. <http://blog.sethroberts.net/2011/11/02/it-matters-when-you-take-vitamin-d-a-stunning-discovery/>
2. <http://www.primalgirl.com/2011/11/01/nprimalgirl-sleep-issues-vitamin-d/>

4. <http://www.aquatic-ape-diet.com/blog/2011/11/25/dont-take-vitamin-d-at-night/>
5. <http://www.biol.sc.edu/faculty/decoursey.html>

---

Joseph Buchignani (2011-11-28 07:28:11)

About the take with meals bit - I took 3 on an empty stomach, about 1.8k IU, and didn't eat. About midday I had stomach trouble. I don't know if it was the building up soybean oil from these pills (I'm fat intolerant), or this particular instance of failing to eat with a meal.

Jazi yechezkel zilber (2011-11-28 08:56:52)

If one takes vitamin d3, it stays in circulation for weeks. And what is mainly counting is the blood levels, which are a long term average. Vitamin d2, on the other has a short life (i vaguely rememb 12 hours, but this is a vageu memory. I am sure its something about a day or less). I would be hugely curious to hear if the girl mentioned used D2. Alternatively, the taking of the stuff can have signaling value irrespective of the blood levels and inherent functions

Tyler (2011-11-28 09:27:34)

Do you take it with meals? What about for those of us who don't eat breakfast?

Seth Roberts (2011-11-28 09:35:42)

If one takes vitamin d3, it stays in circulation for weeks. And what is mainly counting is the blood levels, which are a long term average. Something like that. Which is another reason it is so surprising that the time of day you take it matters.

Seth Roberts (2011-11-28 09:36:44)

Do you take it with meals? What about for those of us who don't eat breakfast? No I take it by itself. I don't eat breakfast.

Clay (2011-11-28 11:02:54)

Isn't taking it buy itself useless? (it's fat soluble, correct?)

Jarno Virtanen (2011-11-28 12:05:20)

*"Let me repeat: first thing in morning. If you wake up before sunrise, take at sunrise (say, 7 am). Sunlight has a considerably different effect on your circadian system at 7 am than 10 am."* So let me get this straight: if I typically wake up at 7am and the sun rises at 9am [1], you recommend to take the dose at 9am? [1] That's when it rises in our place at this time of year. In the northern region of our country, the sun doesn't rise at all for couple of months! :-)

Joseph Buchignani (2011-11-28 12:05:23)

After running through today's irritation cycle, it's pretty clear that this was a reaction to soybean oil on an empty stomach ideosyncratic to fat malabsorbers, not a fundamental problem with taking Vit-D on an empty stomach. Given that Seth is taking it without problem in the morning, it looks like taking it without a meal is fine.

by (2011-11-28 12:21:59)

Dr. Roberts, I know you don't eat soon after waking up to prevent early awakening, but why not breakfast in general? When time do you usually go to sleep and get up in general? Actually, I'm curious to hear the answers of others who skip breakfast.

Jarno Virtanen (2011-11-28 12:45:31)

*"Actually, I'm curious to hear the answers of others who skip breakfast."* I usually go to sleep at 10-12pm and wake up at 7-8am. I skip the breakfast completely and eat lunch at around 11am. (I do drink coffee at 9-10am.) I sometimes feel a little bit hungry at around 9am, but that doesn't last for long. At lunch time, however, I'm usually very hungry.

Latha (2011-11-28 13:13:38)

What do you think about halogen lamps?

by (2011-11-28 13:29:58)

Why do you skip it? Not just to relish the feeling of being very hungry I assume.

Robbo (2011-11-28 14:41:49)

Hej Jarno, I was going to ask the same question because I live in Sweden, and in winter we have to go to work etc well before the sun rises, so it was not clear whether to take the Vit D on waking or at sunrise. But I guess a Finn asked the question first. :)

Seth Roberts (2011-11-28 15:19:04)

So let me get this straight: if I typically wake up at 7am and the sun rises at 9am [1], you recommend to take the dose at 9am? No, I do not mean to be that precise. I am trying to say: 1. A few hours can make a big difference, because changing morning light exposure by a few hours can make a big difference. 2. Start with early morning (e.g., 7 am) rather than late morning (e.g., 11 am). And vary when you take by a few hours to assess the effect of a variety of times. It may have no effect at 8 am but a big effect at 6 am.

Seth Roberts (2011-11-28 15:22:37)

What do you think about halogen lamps? I know little about them. What matters is how much energy they have in the blue area of the spectrum. My guess is: more than incandescent but less than fluorescent.

Seth Roberts (2011-11-28 15:27:08)

Why do you skip breakfast? Breakfast causes me to wake up too early in the morning. See this article: [1]<http://escholarship.org/uc/item/2xc2h866>

1. <http://escholarship.org/uc/item/2xc2h866>

by (2011-11-28 18:59:14)

Oh yes, I've read the section on breakfast/early-awakening several times. I was just wondering if you (or others) had found other benefits from skipping breakfast.

Jarno Virtanen (2011-11-28 22:43:12)

I've not found any other particular benefits from skipping breakfast. However, I do not get hungry before lunch time so I guess you could a benefit is that I don't *have* to eat before that.

Jazi yechezkel zilber (2011-11-29 04:25:57)

Jarno, Fasting part of the day is probably very healthy. So skipping breakfast is is a great way to have a long stretch of hours fasted with no special effort. Dinner till lunch is great

Chris Sturdy (2011-11-29 08:08:54)

Vitamin D should be taken with fat, so for those who skip breakfast (Seth) perhaps adding some cream to coffee/tea or a spoonful of coconut oil to accompany the D would be a good plan.

wcb (2011-11-29 11:22:08)

@ Joseph B. who on 11/28 said in part re Vitamin D: "...I don't know if it was building up soybean oil from these pills (I'm fat intolerant)... Joseph, you should not use a capsule of anything that contains soybean oil as the excipient because it is basically a trans fat slurry and, like all trans fats is pro-inflammatory. There are plenty of D3 capsule formulations available that use better fats such as sunflower or safflower oil. Or you can buy the dry tablet version of D3 and just take it with a tablespoon of light olive oil.

David (2011-11-29 23:00:51)

FYI, Jarrow and Nordic Naturals both offer D3 capsules in olive oil.

Gayle (2011-12-19 11:50:46)

Hi, Seth, This link seems to support the morning exposure to vitamin D: <http://thatpaleoguy.com/2011/12/02/sunbathing-and-circadian-rhythms/>

## Duct Tape, the Eurozone, Status-Quo Bias, and Neglect of Innovation (2011-11-29 05:00)

In 1995, I visited my Swedish relatives. We argued about the Euro. They thought it was a good idea, I thought it had a serious weakness.

ME It ties together economies that are different.

MY AUNT It reduces the chance of war in Europe.

You could say we were both right. There have been no wars between Eurozone countries (supporting my aunt) and the Eurozone is now on the verge of breaking apart for exactly the reason I and many others pointed out (supporting me).

Last week a friend said to me that Europe was in worse shape than America. I was unconvinced. I said that I opposed Geithner's "duct-tape solution". It would have been better to let things fall apart and then put them back together in a safer way.

MY FRIEND Duct-tape works.

ME What Geithner did helped those who benefit from the status quo and hurt those who benefit from change. Just like duct tape.

This struck me as utterly banal until I read [1]a one-sided editorial in The Economist:

The consequences of the euro's destruction are so catastrophic that no sensible policymaker could stand by and let it happen. . . . the threat of a disaster . . . can anything be done to avert disaster?

and [2]similar remarks in The New Yorker (James Surowiecki):

The financial crisis in Europe . . . has now entered a potentially disastrous phase.. . . with dire consequences not just for Europe but also for the rest of us. . . . This is that rarest of problems—one that you really can solve just by throwing money at it [= duct tape]

Wait a sec. What if the Eurozone is a bad idea? Like I (and many others) said in 1995? Why perpetuate a bad idea? Why drive further in the wrong direction? Sure, the dissolution will bring temporary trouble ("disaster", "dire consequences"), but that will be a small price to pay for getting rid of a bad idea. Of course the Euro had/has pluses and minuses. Anyone who claimed to know that the pluses outweighed the minuses (or vice-verse) was a fool or [3]an expert. Now we know more. Given that what the nay-sayers said has come to pass, it is reasonable to think that they (or we) were right: The minuses outweigh the pluses.

You have seen the phrase Japan's lost decade a thousand times. You have never seen the phrase Greece's lost decade. But Greeks lost an enormous amount from being able to borrow money for stupid conventional projects at too low a rate. Had loans been less available, they would have been more original (the less debt involved, the easier it is to take risks) and started at a smaller scale. Which I believe would have been a better use of their time and led to more innovation. Both The Economist's editorial writer and Surowiecki have a status-quo "duct-tape" bias without realizing it.

What's important here is not what two writers, however influential their magazines, think or fail to think. It is that they are so sure of themselves. They fail to take seriously an alternative (breakup of the Eurozone would in the long run be a good thing) that has at least as much to recommend it as what they are sure of (the breakup would be a "disaster"). I believe they are so sure of themselves because they have absorbed (and now imitate) the [4]hemineglect of modern economics. The whole field, they haven't noticed, has an enormous status-quo bias in its failure to study innovation. Innovation – how new goods and services are invented and prosper – should be half the field. Let me repeat: A few years ago I picked up an 800-page introductory economics textbook. It had one page (one worthless page) on innovation. In this staggering neglect, it reflected the entire field. The hemineglect of economics professors is just as bad as the hemineglect of epidemiologists (who ignore immune function, study of what makes us better or worse at fighting off microbes) and statisticians (who pay almost no attention to idea generation).

MORE Even Joe Nocera, whom I like, has trouble grasping that the Euro might be a bad idea. "The only thing that should matter is what works," [5]he writes. Not managing to see that the Euro isn't working.

Joseph Buchignani (2011-11-29 06:41:58)

You've been beating the idea generation drum for a while. My blog and twitter feed at [www.aquatic-ape-diet.com](http://www.aquatic-ape-diet.com) is an example of an exo-self geared for max idea generation. The infrastructure behind it isn't fully visible, but is described at [www.cyborgorganize.org](http://www.cyborgorganize.org) It is not just idea generation that counts - it's idea capture, processing, development, and feedback. My system is primarily focused on maximizing individual idea development, whereas you mostly talk about network effects, as far as I've noticed.

Terry O. (2011-11-29 07:46:01)

"James Surowiecki: This is that rarest of problems—one that you really can solve just by throwing money at it " I have borrowed \$x, which I am unable to repay because I chronically spend more than I earn. So if I borrow more that will "solve" things? My 8 year old knows better. Where do they find these "experts"?

Felix (2011-11-29 10:51:41)

Nice article. It's good to see people arguing against "there is no alternative". Interesting also, that people, who profit from the status quo have no shame arguing (threatening) with war. <http://www.zerohedge.com/news/bring-out-your-dead-ubs-quantifies-costs-euro-break-warns-collapse-banking-system-and-civil-war>

David (2011-11-29 13:38:03)

A lot of people have trouble getting their heads around these recurring financial problems, their causes and potential remedies. Obviously a complex system can be viewed in different ways, using various simplified models to try to understand it. Incorrect models do not lead to useful insight. I think the best model is that of a Ponzi scheme. In a Ponzi scheme, you will generally see the scheme operator offer complex-appearing and opaque investment vehicles to the Ponzi investors. The early investors get generous returns, the Ponzi operators pay themselves very well, but at some point the money is gone and all remaining "investors" holdings are worthless. A Ponzi operator can simply sit on the money, like Madoff, or actually make risky

investments with it, claiming to the "investors" that the investments are not as risky as they actually are. In the ongoing banking "crisis", you have seen the investment banks offer complex investment vehicles with great returns for early investors, take a generous cut for themselves, then suddenly, all of the "investments" are worth nothing or next to nothing. The challenge for the investment banks has been to get the governments of the world to purchase, in one way or another, these "investments" and give them large sums of money to keep the scheme running longer. Viewing the events using this model, the remedies to avoid future "banking failures" are simple. Ban all "investment vehicles" except savings accounts, company stocks, bonds, and simple mortgages. Keep the banking reserve requirements robust. In addition, and this is how this links to the Euro discussion, make sure every country has their own currency. Something along these lines was done after the 1929-1933 crisis. It does not look it will happen this time.

Seth Roberts (2011-11-29 13:59:34)

I think the best model is that of a Ponzi scheme. I think your idea is good. Why was Madoff so successful? Because people (investors) were encouraged to be ignorant and passive. To fail to understand. To fail to ask. That was normal. Madoff was not only one who profitted – the whole financial industry profitted. As you say. Yet the reporting about Madoff blamed Madoff (and the SEC). The broader culture (the encouragement of ignorance and passivity – reliance on experts) was never criticized, at least in what I read.

Joseph Buchignani (2011-11-29 15:28:49)

Here's an example of a suppressed innovative idea, and a discussion of why it happens: <http://vault-co.blogspot.com/2011/11/its-magnetic-reversals-stupid.html>

MetaThought (2011-11-29 20:42:18)

Ban all "investment vehicles" except savings accounts, company stocks, bonds, and simple mortgages. That would mean a drastic reduction in the financial sector, which makes up a large chunk of GDP of many developed countries. Of course, the fact that a lot of money is spent on financial services instead of elsewhere (mal-investment!) is ignored.

Aaron Blaisdell (2011-11-30 13:43:31)

"Had loans been less available, they would have been more original (the less debt involved, the easier it is to take risks) and started at a smaller scale. Which I believe would have been a better use of their time and led to more innovation." Seems like the same principle in economics as we've written about for reinforcement learning in rats and pigeons. In regards to duct taping the EU, I'm familiar with the term shotgun wedding, but perhaps we need another term for shotgun anti-divorce.

Rubashov (2011-12-02 11:54:25)

Not only does accepting student diversity help students be all they can be (instead of all that they would be if they were us), it makes grading much more pleasant. In my research methods class, for example, since I switched my final project from "analyze this set of data using the methods I taught you" to an open-ended "Find a question that interests you, gather your own data, answer it, and make a video about your discovery," I've gotten wonderful, creative work. Today I received one video from a bunch of guys who tested whether appliances actually stop bullets like they do in the movies (hint: they don't. None of them will do particularly well on the written final, but they successfully carried out a piece of independent research and discovered something useful about their world on their own. That's worth a lot. BTW, have you tried "contract grading," where you give students a menu of varied assignment choices/styles for them to individually pick from?

Becky Hargrove (2011-12-02 14:28:56)

Hemineglect is a good term and one I had not been familiar with. But it's not just the failure of economists to study innovation. There seems to be a lack of research regarding ways in which the innate drive to succeed might be incorporated into present day economic activities.

Seth Roberts (2011-12-02 17:30:21)

Not only does accepting student diversity help students be all they can be (instead of all that they would be if they were us), it makes grading much more pleasant. In my research methods class, for example, since I switched my final project from “analyze this set of data using the methods I taught you” to an open-ended “Find a question that interests you, gather your own data, answer it, and make a video about your discovery,” I’ve gotten wonderful, creative work. I had the same experience. When I gave students much more choice, the quality of their work went way up. They learned much more, wrote better about what they had done, and made more thoughtful comments about their experience.

## **An Unbiased View of What We Should Eat . . . From a Rat (2011-11-30 05:00)**

[1]

In nature animals must choose a healthy diet based on what tastes good. This doesn’t work for modern humans – lots of people eat poor diets – but why it fails is a mystery. There are many possible reasons. Are the wrong (“unnatural”) foods available (e.g., too much sugar, too little omega-3, not enough fermented food)? Is something besides food causing trouble (e.g., [2]too little exercise, too little attention to food)? Are bad cultural beliefs too powerful (e.g., “low-fat”, desire for thinness)? Is advertising too powerful? Is convenience too powerful? Lab animals are intermediate between animals in nature and modern humans. They are not affected by cultural beliefs, advertising, and convenience (the foods they are offered are equally convenient). Their choice of food may be better than ours.

Nutrition researchers understand the value of studying what lab animals choose to eat. In 1915, the first research paper about “dietary self-selection” was published, followed by [3]hundreds more. The general finding is that in lab-

oratory or research settings, animals choose a relatively healthy diet. There are [4]two variations:

[1.] Cafeteria experiments with chemically defined [= synthesized] diets showed that some of these animals, when offered the separate, purified nutrient components of their usual diet, eat the nutrients in a balance that more or less resynthesizes the original diet and that is often superior to it. [2.] Other animals eat two or more natural foods in proportions that yield a more favorable balance of nutrients than will any one of these foods alone.

Both findings imply that housing an animal in a lab does not destroy the mechanism that tells it what to eat.

Which is why I was fascinated to recently learn what Mr. T (pictured above), the pet rat of [5]Alexandra Harney, the author of *The China Price*, and her husband, liked to eat. It wasn't obvious. "We tried so many foods with him and always thought it made a powerful statement that even a wild rat turned his nose up at potato chips," says Alexandra. "He hated most processed food. He also hated carrots, though." Here are his top three foods:

1. pate
2. salmon sashimi
3. scrambled eggs

Pate = protein, animal fat, complex flavors (which in nature would have been supplied by microbe-rich, i.e., fermented, food). Salmon sashimi = protein, omega=3. Scrambled eggs = ??

He liked beer in moderation, but not yogurt. "Owners of domestic rats say they love yogurt," says Alexandra, "but Mr T only liked it briefly and then hated it, even lunging to bite a friend who brought him some. [Curious.] He loved cheese, stored bread for future consumption (but almost never ate it). Loved pesto sauce and coconut." Note the absence of fruits and vegetables. Alexandra and her husband have no nutritional theories that I am aware of. They did not shape this list to make some point.

For me the message is: Why scrambled eggs? I too like eggs and eat them regularly and cannot explain why.

More Alex Tabarrok's [6]Thanksgiving post shows the connection between libertarian ideas (economies work better when more choice is allowed) and dietary self-selection.

dearieme (2011-11-30 05:13:25)

Scrambled eggs with smoked salmon makes a fine breakfast, though I must say I do prefer a kipper.

Jan (2011-11-30 05:13:33)

Eggs = high quality proteins?

Elizabeth Molin (2011-11-30 07:00:03)

The importance of dietary cholesterol?

Valtsu (2011-11-30 08:44:46)

Eggs... Choline? Sulfur?

Rashad (2011-11-30 09:55:56)

Well, an egg contains all the essential nutrients to turn a single celled embryo into a living breathing baby chick. Seems logical that they would be healthy.

Elisa (2011-11-30 10:57:25)

Eggs are the same as salmon – protein and omega 3.

by (2011-11-30 11:13:24)

Real support for paleo and low-carb. "Stored bread but never ate it." Ha.

Jeff (2011-11-30 12:36:48)

Interesting. You might want to look at Stephan Guyenet's recent posts. The studies he mentions suggests that rats will undergo(hot, cold, foot shocks, etc.) near torture while ignoring their rat chow. Was the situation different here?

Evelyn Majidi (2011-11-30 16:55:49)

Scrambled eggs are a mixture of fat and protein, same as the rat's two other favorite dishes. Now, if he preferred scrambled eggs to fried eggs, for example, that would be a conundrum. Was that the case? Saving the bread shows that he knows that bread will remain edible even though it is stale, while foods rich in protein and fat are likely to rot and make him sick if he doesn't eat them quickly. Since he doesn't lack for food, he didn't need to touch the stored bread. I bet if they didn't feed him for a day or two he would have gone back to the bread and congratulated himself on his wisdom in planning for the rainy day. But as for the aversion to yogurt, I don't have a clue. Could it have been tarted up with fruit or jam?

Seth Roberts (2011-11-30 21:02:48)

Scrambled eggs are a mixture of fat and protein, same as the rat's two other favorite dishes I am pretty sure they tested many fat/protein mixtures – other meats, for example. These three came out on top..

Anand Srivastava (2011-12-01 01:34:26)

Could it be that the yogurt was store brought and not made from real pastured milk, and there by didn't have the good profile in other preferred foods.

Elizabeth Molin (2011-12-01 08:30:55)

I am not a very good researcher, and, frustratingly, I've not been able to find any documentation, so the following is produced from my possibly (very) sketchy memory. Shortly after World War II, Dr. Clara Baker (?) conducted a nutrition experiment in the Chicago (?) area. She recruited 100 (?) babies who had never tasted anything but breast milk. Three (?) times a day the babies were set before an array of little dishes containing cereals, custards, scrambled eggs, and many kinds of pureed fruits, vegetables, and meats. If the baby stuck its fist into a dish and tried to lick it off, the attendant was allowed to feed the baby one bite of that food.. At the end of the experiment (six months?), Dr. Baker determined that although the babies' day-to-day intake was not necessarily nutritionally sound (e.g. nothing but mashed banana for two days), their diets were perfectly

nutritionally balanced over the long term, better balanced than the diets of a control group fed by a nutritionist.

Nancy Lebovitz (2011-12-01 08:56:59)

You probably need to study more than one animal. Cats tend to be very idiosyncratic about what people food they like. Some like fruit, some don't. Same for salad, hot pepper-flavored food, and commercial cat foods. I live with cats who aren't crazy about turkey, but there are so many cat foods with turkey that I bet there are cats who favor it.

john (2011-12-01 09:55:50)

...Cholesterol, choline, general protein & fat...?

by (2011-12-01 10:12:27)

Anyone have links to studies on this? (which foods are freely chosen by babies or animals) I think this is actually a valuable way to get insight on the proper human diet.

Seth Roberts (2011-12-01 13:41:51)

Anyone have links to studies on this? See the links I provided. Here's another: <http://blog.sethroberts.net/2009/08/16/dietary-self-selection-by-young-childr-en/>

Seth Roberts (2011-12-01 14:02:59)

Elizabeth Molin, thanks for motivating me to find the following link: <http://blog.sethroberts.net/2009/08/16/dietary-self-selection-by-young-childr-en/> which I should have included originally.

Elizabeth Molin (2011-12-01 14:11:00)

Thanks, Seth-I might have had more luck (and been more accurate) if I'd searched Davis, not Baker...

Lumiere (2011-12-20 21:44:44)

Leha (2012-02-17 20:14:38)

Eggs are notable for both choline and a high methionine-to-other amino acids profile. The thing about choline is that it's really hard to get enough of it from anything but eggs. Methionine is easier to come by. However, there may be some evidence to support that amino acid balance is almost more important than the old "complete protein" model. I'm saying this as a person who has speculated that \*less\* methionine might be healthier than more, but regardless of my personal opinion, Mr. T apparently liked something known to be pretty high in methionine, so I guess it's his word against mine. (-: My rats also hated yogurt, BTW. But they loved tapioca pudding, a formula that does contain a bit of egg...

## **iTunes For Windows is Horrible (2011-11-30 18:18)**

May I interrupt my usual posts to complain about something? Something minor?

It is that iTunes for Windows – from Apple, the maker of what are said to be brilliantly-designed products – is horribly designed. I have two examples.

1. Suppose I want to see what's in the iTunes Store. I open a new window. I can't close that window without closing iTunes! And if, after closing the whole program, I open it again, it still gives me the Stores window! Maybe the Stores window went away after a few weeks...I don't want to even think about it.

2. I pressed the wrong button and started 181 downloads. There is no way to cancel them! If I stop the whole program, they will resume the next time I start it. This is software design from the 1960s.

And this is iTunes version 10.something, not version 0.3.

---

Alex Chernavsky (2011-11-30 19:15:10)

I'm with you on this one. I have iTunes, and I'm underwhelmed with it. It's caused me many instances of puzzled head-scratching. It's true, though, that I never sat down and made anything like a serious effort to understand its intricacies and how it works – but I thought that the whole point of well-designed software is that you don't have to do that. In fact, I'm sort of puzzled by the whole "cult of Apple". The Macintosh was truly revolutionary when it came out. Everything else has been fairly unremarkable.

John (2011-11-30 19:22:17)

There's much to dislike about iTunes. I feel I have to pamper it. There are several scenarios that it doesn't disallow, but it doesn't reliably support either.

q (2011-11-30 20:34:29)

not just what you say, which i agree with, but itunes and the ipod in general are not up to the task of dealing with large music libraries. mine is 40GB and it's a complete organizational mess.

jordan (2011-11-30 21:09:00)

My wife has the latest iphone - not me. I hate the software. It's not intuitive and it's overly INVASIVE! (I have the pc version)

wcb (2011-11-30 21:16:59)

Seth, I experienced a similar problem some time ago. On a tip from a computer literate friend I was finally able to cure it by simply downloading the newest, updated version of iTunes from Apple's website. Hopefully that will work for you as well. Agreed that the system is aggravating and, I think, too geared to selling product that we may not really want. On the other hand, I really like the iPod Touch which I use solely for its WiFi capability when I want to go online and check email and other stuff (such as your blog) without having to fire up the desktop. :-)

Seth Roberts (2011-11-30 21:45:49)

Yeah, I did solve the downloading problem by simply updating the whole thing....of course that is ridiculous but it did work. I am in the extraordinary position of needing to postpone updates so that they are there when I need them to solve problems caused by something as common as hitting the wrong button. Which every other piece of major software in the entire universe solves with a Cancel or Are You Sure? button.

Jay (2011-12-01 01:07:04)

iTunes is a great example of how some needed features simply cannot be reduced below the elegance threshold set by Apple. I have 400gb of classical music. MP3 metadata is a non-option for organization (e.g. Rachmaninoff vs Rachmoninov vs Sergei

Rachmaninoff). The only option is folder organization. Good media players, such as foobar2000, allow you to sort by directory structure. Apple, in their stubborn pursuit of simplicity, refuses to add an option to sort music in this way. It's a shame because: 1) I need iTunes for my iPad (a device that I use often and quite like), and 2) on mac os x, there are very few music player alternatives. So you're kinda stuck with the program.

Seth Roberts (2011-12-01 01:33:19)

"some needed features simply cannot be reduced below the elegance threshold set by Apple." You mean some needed features cannot be implemented in a way that makes them elegant enough for Apple?

Robin Barooah (2011-12-01 02:04:53)

iTunes is pretty bad on Windows, and although it performs a lot better on MacOS is still not exactly 'magical'. It's actually a very hard problem for Apple at this point and I'm pretty sure they're working hard on it. iTunes is a 12 year old program that started off life on MacOS 9. It has an enormous number of features, and has to support a huge range of iPods, etc. It still runs on PowerPC based Macs and OSX Lion as well as Windows. All of this means that it is actually really really hard for Apple to improve it. Apple has been one of the most aggressive companies in the world at replacing old technologies with new ones, but in the case of iTunes, they have half a billion users relying on it to keep fitting in with their usage patterns. In many ways, iTunes is to Apple as Windows is to Microsoft. I don't know of an example in software history of anyone painlessly solving this problem. There is evidence in the newer versions of iTunes for Mac that Apple is retrofitting newer technologies behind the scenes, which will ultimately allow them to make major changes to it, but this is a pretty monumental task. My guess is that they'll start to split the functionality into separate and more elegant apps, like they have on iOS. But don't hold your breath for this, particularly on windows.

Glen Raphael (2011-12-01 08:59:13)

Jay: Have you explored using iTunes "smart folders" to consolidate whatever groups are meaningful to you? Or for that matter, iTunes plain old dumb folders? iTunes does, under the hood, store files by directory structure, but you're free to make up your own categories and put stuff in those categories to your heart's content. You could either fix the metadata or make a (Rachmaninoff OR Rachmoninov OR Sergei Rachmaninoff) smart folder or just type "Rachm" in the search bar to collect them on the fly. I don't listen to much classical music, but I also just noticed that the default smart folder called "classical" in the current (Mac) version of iTunes already includes the ability to (a) select by composer (b) grab groups of composers into a "grouping". So they might have already done some of the work for you. Seth: I'm going by how the Mac version works and I know the Windows version is less intuitive, but: with the Mac version if you \*single-click\* on "iTunes Store" it changes the main window to view the store, but if you then click something else on the left pane (like, say, "music", the store view is replaced with a view of your music. If you double-click it does open a new window, but when you relaunched that might be what happened - it remembered the last thing you looked at was the store, so you saw store content in the main pane and thought that was "the store window" when it was just the store \*view\* from the main window. Updating the software got you back to the default view, but clicking on "Music" in the left-side tab would have done the same.

Richard (2011-12-02 08:28:10)

I agree iTunes is not a great program, but you actually can cancel downloads. Just select the item(s) in the Downloads page and press the Delete key. Alternately, you can right click and select Delete. It's not the most intuitive interface in the world, but it does work. -Richard

Chris (2011-12-02 12:18:06)

Seth...I use iTunes for PC and don't have the problem opening the Store. I single click on iTunes Store in the left-hand column and it shows the store, which usually takes 5-10 seconds to load. To get out of the store, I simply single click on Music or another option in the left-hand column. Not sure if yours is set up just like mine, but I've never had to deal with a separate window opening as you describe above.

CeeJay (2012-02-07 04:27:02)

I love my iPod touch and use it constantly I do believe that Apple got things right there.. so why oh why have they got it so wrong with iTunes for windows. I think the thing that bugs me most about it (and I do have a lot of things in my list) is just how slow iTunes is. I own a computer that is so blazingly fast it scares the pants off of me and a broadband connection that is in the top 5 % of the country and yet when I open up iTunes it takes an age to sort itself out. I'm sat there twiddling my thumbs whilst it looks for and then slowly, oh so slowly connects to my iPod Touch. I am very much with Jay regarding the cataloguing of music. I too have a vast classical music collection and trying to organize it with iTunes is just pathetic. How I wish it iTunes was like 'MusicMatch' used to be in the days before Yahoo got a hold of it, ruined it and then killed it off.

## 6.12 December

### Bryan Caplan Disses College (2011-12-01 05:00)

In [1]this post, Bryan Caplan says ([2]again) that college is vastly overrated. Like me, he says that the only thing college professors know how to do is be professors and that is all they can actually teach. Graduate school, where professors teach students who want to be professors, makes sense. Undergraduate school, where almost no students will become professors, does not. Like me, he ridicules the idea that professors teach students "how to think".

He omits half of my criticism. It isn't just teaching ("how to think" – please!), it's also evaluation. Professors are terrible at evaluation. Their method of judging student work is very simple: How close is it to what I would have done? The better you can imitate the professor, no matter what the class, the higher your grade. This is one size fits all with a vengeance because there is no opting out. Sure, you can choose your major. But every class is taught by a professor. What if your strengths lie elsewhere – in something that your professors aren't good at? Tough luck. Your strengths will never be noticed or encouraged or developed.

At Berkeley (where Bryan went and I taught) and universities generally, the highest praise is brilliant. Professor X is brilliant. Or: Brilliant piece of work. People can do great things in dozens of ways, but somehow student work is almost never judged by how beautiful, courageous, practical, good-tasting, astonishing, vivid, funny, moving, comfortable, and so on it is. Because that's not what professors are good at. (Except in the less-academic departments, such as art and engineering.) To fail to grasp that students can excel in dozens of ways is to seriously shortchange them. To value them at much less than they are worth – and, above all, to fail to help them grow and find their place in the world after college.

At Berkeley, I figured this out in a way that a libertarian should appreciate: [3]I gave my students much more choice. For a term project, I said they could do almost anything so long as it was off-campus and didn't involve library work. What they chose to do revealed a lot. I began to see not just how different they were from me but how different they were from each other. One of my students chose to give a talk to a high-school class. This was astonishing because she has severe stage fright. Every step was hard. But she did it. "I learned that if I really wanted to, I could conquer my fear," she wrote.

One of my Tsinghua students recently asked me: "Are you a brave man?" (She wanted to give me a gift of stinky tofu.) I said no. She said she thought I was brave for coming to China. Perhaps. I have never done anything as brave as what my student with stage fright did. I have never done something that terrified me – much less chosen to do such a thing. Her homework hadn't been very good. When I read about her term project – conquering stage fright – I realized how badly I had misjudged her. How badly I had failed to appreciate her strengths. I saw that it wasn't just her and it wasn't just me. By imposing just one narrow way to excel, the whole system badly undervalued almost everyone. Almost everyone had strengths the system ignored. And it's a system almost everyone must go through to

reach a position of power!

This is related to what I call [4]the hemineglect of economists – they fail to see that innovation should be half of economics. Diversity of talents and interests is central to innovation because new things are so often mixtures of old things. By rewarding only one kind of talent, colleges suppress diversity of talent and thereby reduce innovation. (It's no coincidence that Steve Jobs, whom we associate with innovation, didn't finish college. He saw his talents wouldn't be valued.) Psychologists are also guilty of this. Many psychologists glorify IQ. Somehow having a high IQ is crucial to success . . . somehow a society that doesn't encourage people with high IQs will do badly. And so on. In The Bell Curve, Herrnstein and Murray showed that high IQ scores correlated with other measures of desirable social outcomes (e.g., income – people with higher IQ scores made more money). Like many successful people, they failed to see the possibility that the whole world had been shaped to reward the things that the people in power (i.e., they themselves) are good at. Not because those talents work (= produce a better economy). But because they are easy to measure (by college grades). The glorification of IQ has had a solipsistic aspect and has ignored what should be obvious, that diversity of talents and skills promotes innovation. Without a diverse talent pool, any society will do a poor job of solving the problems that inevitably arise.

---

Ashish (2011-12-01 08:11:34)

I went to Berkeley. Without disagreeing with much of what you say, college is valuable as a signaling device: where you get in (cost is changing that), what you choose to study, whether/how you get through it.

Shawn (2011-12-01 08:24:25)

I think you overestimate the usefulness of what you call a "diversity" of talents, if diversity is to encompass the entire range in IQ. There is no advantage in having a low-IQ (IQ is roughly 50 % heritable, BTW).

by (2011-12-01 10:40:27)

Just about everything you said in this post, I wouldn't have expected you to say.

Seth Roberts (2011-12-01 13:42:53)

Just about everything you said in this post, I wouldn't have expected you to say. Such as? I've made all of these points several times before.

Seth Roberts (2011-12-01 13:51:34)

There is no advantage in having a low-IQ Interesting point. I agree, to encourage a diversity of talents (in contrast to simply trying to get the highest possible IQ) among a group of people would indeed reduce their average IQ. But I don't see how this supports the idea that I overestimate the usefulness of a diversity of talents.

Seth Roberts (2011-12-01 13:54:36)

college is valuable as a signaling device, You mean: valuable to students? Only if you get into a good college. It's like grades: They are helpful if you are good at what they measure or want to be good at what they measure (then they provide useful feedback). If not, they are unhelpful. Suppose you want a career in public speaking. Grades don't measure that. They are

uncorrelated to your public speaking ability.

Jim Purdy (2011-12-01 15:58:29)

Since every credible theory has to have a name and an acronym, let me propose my "Molted Paradigm Theory (MPT)." In the first few years of life, each human is spoon-fed a whole set of overly simplistic explanations for the universe around us – Santa Claus, tooth fairies, gods, devils, talking serpents, whatever. Some people never outgrow those simplistic childhood myths. They become preachers, Fox News anchors, and Republican presidential candidates. It is not easy to shed old paradigms, and many people choose to never question the fables of their parents. This tendency is so strong that ancient creation myths become fossilized into religions that chastise anyone who dares question the old tales. Fortunately, many people eventually outgrow the most simple stories, and progress through a series of ever-more-complex paradigms. And that is where good schools and good teachers make a difference: They are there to help their proteges through the process of shedding or molting the old paradigms. The childhood paradigms are essential to teach early lessons about life and social responsibility (Santa's naughty or nice list?), but it can be troubling when it becomes necessary to discard those old comforting paradigms. That is where good teachers matter: to be there when an individual needs help shedding or molting an old paradigm. Seth, you and your colleagues don't have to know what your proteges will do in the future. You just have to encourage them as they molt.

by (2011-12-01 16:15:06)

[i]Such as? I've made all of these points several times before.[/i] I meant it as a positive comment. You criticized traditional education in other posts, but I didn't expect you to put forth the idea that students would be good judges of what activities to undertake to help them learn. I guess in general I expect mentors or teachers to feel that with their longer life experience, they can make better decisions for younger people on how to spend their time. I also didn't expect you to say that you didn't "think you were a brave man," or to give so much respect to a student for overcoming stage fright. I agree that that student did a brave thing, but didn't think you would think it worth mentioning how you compared yourself to her, and that you would say you misjudged her by looking at her homework scores. I may have missed earlier posts of yours though. I've read about 60 % of the posts on your blog.

Mark (2011-12-01 17:55:20)

Seth, I really appreciate these posts (and your blog in general, by the way). An anecdote you might appreciate: I went to Berkeley, too, and as a very bright and intellectually curious 17-year-old first semester freshman, I got a very surprising lesson. After getting the first "C" of my entire life on the first midterm of an intro sociology course, I went to an informational session about the grading of the midterm presided over by one of the grad student instructors. I listened very carefully to what the GSI said in response to each question posed to him by disgruntled students (all of which were variations on "why weren't my exam answers worthy of an A?") After maybe half a dozen responses by the GSI, I discovered a clear (albeit never explicitly stated) theme: to get an 'A', you needed to regurgitate EXACTLY what the professor had said in lecture. This completely shocked me (hey, I was only 17). This was a Sociology class taught by an (allegedly) "cutting edge" professor who said lots of radical things (well, they were radical to me). This had actually inspired me to make a genuine effort to analyze what he said and introduce my own ideas into my exam essay responses on the first midterm. If my analysis sucked (certainly possible), that would have been one thing, but I was stunned to have been penalized simply for \*attempting\* analysis! I never bothered to ask the GSI about my particular exam at that session. I walked out, proceeded to memorize the professor's lectures and (quite literally) transcribe them into subsequent midterm and final exam responses. I got perfect scores on every remaining test, and an A+ semester grade in the class. This approach worked in most of my other Berkeley classes, as well (I was a social sciences major). I got a whole lot of A's at Cal and graduated summa cum laude. Observers were impressed, and I was embarrassed to say to anyone how stupidly easy it had been.

Kim Øyhus (2011-12-02 00:07:43)

Real jobs are overrated. They are full of bullshit too. The jobs one gets are quite random, not much related to experience or knowledge. For example my current situation: I get paid well as a consultant programming C # and Windows Presentation Foundation, which I have almost no experience in, being a Linux kind of guy, while being dissed when I applied for a job at a finger print company, analysis of which I am one of the best in the world. This is typical, not an exception, and I see that other people are misplaced too. However, it is better than the alternative, which is not being placed at all, i.e. no job, no money, no food,

etc. My best explanation for what work life really is, is that it is tribes. Tribes where alphas dominate the rest, and get status by having more subordinates, and doing stuff that have some vague resemblance to actually producing stuff and making money.

Ahrand (2011-12-02 01:54:26)

Ken Robinson has some great insights on this, you can watch some of his work on TED talks : Some quotes : - from [http://www.ted.com/talks/lang/en/ken\\_robinson\\_says\\_schools\\_kill\\_creativity.html](http://www.ted.com/talks/lang/en/ken_robinson_says_schools_kill_creativity.html) "what is the ultimate goal of public education ? To produce university professors." - from [http://www.ted.com/talks/lang/en/ken\\_robinson\\_changing\\_education\\_paradigms.html](http://www.ted.com/talks/lang/en/ken_robinson_changing_education_paradigms.html) "The problem is that the current system education was designed for the intellectual culture of the enlightenment and the economic circumstances of the Industrial Revolution."

Harold Jarcho » Jobs, work and technology (2011-12-02 05:34:35)

[...] Seth's Blog: Without a diverse talent pool, any society [company] will do a poor job of solving the problems that inevitably arise: Diversity of talents and interests is central to innovation because new things are so often mixtures of old things. By rewarding only one kind of talent, colleges suppress diversity of talent and thereby reduce innovation. [...]

Seth Roberts (2011-12-02 05:58:12)

My best explanation for what work life really is, is that it is tribes. Tribes where alphas dominate the rest, and get status by having more subordinates, and doing stuff that have some vague resemblance to actually producing stuff and making money. The fact that salaries are rarely tied to profits helps employees ignore profits and spend their time trying to maximize something else. It is a large dose of communism right in the middle of capitalism.

Alex Chernavsky (2011-12-02 08:49:24)

@Kim: Off-topic for this thread, but have you seen this article about serious problems with interpreting fingerprints? If you've read it, what is your opinion of it? "[1]Do Fingerprints Lie?"

1. <http://www.michaelspecter.com/2002/05/do-fingerprints-lie/>

Seth Roberts on Diversity, Education and Innovation — Marginal Revolution (2011-12-02 11:16:31)

[...] Wonderful post from Seth Roberts. Not sure if I even agree but Seth makes me think about how I can better serve my students: People can do great things in dozens of ways, but somehow student work is almost never judged by how beautiful, courageous, practical, good-tasting, astonishing, vivid, funny, moving, comfortable, and so on it is. Because that's not what professors are good at....To fail to grasp that students can excel in dozens of ways is to seriously shortchange them. To value them at much less than they are worth — and, above all, to fail to help them grow and find their place in the world after college. [...]

mobile (2011-12-02 12:00:08)

> The glorification of IQ has had a solipsistic aspect and has ignored what should be obvious, that diversity of talents and skills promotes innovation. Without a diverse talent pool, any society will do a poor job of solving the problems that inevitably arise. What is an example of a problem that has not been solved very well because the group of people working on that problem put too much emphasis on the IQ of the problem solvers and not enough emphasis on the diversity of the problem solvers?

Seth Roberts (2011-12-02 13:36:00)

What is an example of a problem that has not been solved very well because the group of people working on that problem put too much emphasis on the IQ of the problem solvers and not enough emphasis on the diversity of the problem solvers? Here are two examples: 1. The 2008 financial crisis. The people in charge had/have high IQs. I believe a more diverse group of people would have found a better solution. (They would have had less of a status-quo bias, for one thing.) 2. Stomach ulcers. People with high IQs think that those two Australian Nobel Prize winners, Marshall and Warren, found the cause of stomach ulcers (a certain species of bacteria). I think a more diverse group of problem solvers would find a better solution. (Almost everyone who has the supposedly causative bacterium doesn't get ulcers.)

Becky Hargrove (2011-12-02 13:59:44)

Seth, Not since Buckminster Fuller was alive do I remember reading about human worth in this way, and lately I have missed him terribly.

Derek Scruggs (2011-12-02 15:39:29)

Re: the comment about no advantage to lower IQ. That's true, but in many fields there are diminishing returns above about 120. Think about how important (and highly compensated) sales jobs are. Do you think the average sales guy would benefit from a 150 IQ? Michael Milken made all his money not because he was brilliant, but because he was good at sales. Jack Welch and Ted Turner spoke of how much he seemed to care about their personal lives instead of just trying to push a transaction. Further, something like 20 % of successful entrepreneurs are dyslexic (including such names as Charles Schwab). Shouldn't such relatively rare learning disability predict failure?

Seth Roberts (2011-12-02 15:51:31)

Not since Buckminster Fuller was alive do I remember reading about human worth in this way. Becky, yeah, there is some similarity. I found this quote from Fuller: "Everyone is born a genius, but the process of living de-geniuses them." What were you thinking of?

dearieme (2011-12-02 16:10:08)

"The problem is that the current system education was designed for the intellectual culture of the enlightenment and the economic circumstances of the Industrial Revolution." That's not a problem - it suited me terribly well.

Ashish (2011-12-02 19:17:33)

» college is valuable as a signaling device, > You mean: valuable to students? School work may be largely (although not entirely) meaningless. But getting a degree demonstrates that you can follow instructions and work hard and achieve deadlines. It's not everything - but knowing this much about someone is more useful (to an employer) than not knowing anything.

Alex Chernavsky (2011-12-02 19:45:03)

It's difficult to teach those things that are most important to a successful career. I spent a huge amount of money to get an MBA degree, but I learned almost nothing that was useful to me. Off the top of my head, these are the skills that I think are most important to succeed in the business world (note that I don't claim to be good at any of them): 1) Getting along well with others, including navigating office politics 2) Maintaining a sense of optimism and enthusiasm even in the face of set-backs 3) Appearing sharp and "on the ball" at meetings 4) Being organized, dependable, meeting deadlines, and keeping your promises. There are probably others, but those are the ones that come to mind. None of these things were taught in business school (well, possibly indirectly - and not very well). The stuff that we *did* learn, like net present value calculations and the Black-Scholes pricing model, never came up again for me. And if they did, I probably could have learned them on the job.

Kim Øyhus (2011-12-03 02:58:01)

Lying fingerprints: All methods I have seen for analyzing fingerprints are inaccurate heuristics which throw away information and do not make proper estimates of uncertainty or the amount of information present in the prints. DNA analysis is a counterexample to this, because there are several very good deep statistical methods which do a very good job, but forensic people still mess it up in courts from time to time. Detectives McKie and fingerprint expert Bayle have been victims of the typical tribal nonsense, communism style, where status and hierarchy counts more than evidence and truth. Looking at the results from the 2006 Fingerprint Verification Competition, I see that the best fingerprint programs typically extract 5-8 bits of information from each print, with some outliers of 9-12 bits on easy tests. This is much less information than is actually present in most fingerprints. From my experience, what happens here, is that the programs are fragile. They do better when the prints are easy to recognize, but typically deteriorate a lot when there are even slight modifications to the prints, such as

being partial, deformed, dirty, scarred, worn, etc., which they typically are in real life. As a comparison, DNA tests today can read billions bits of information from a cell, though those methods are not used by forensics. My fingerprint analyzer, which was made about 10 years ago, read about 7 bits per print, and was fairly robust. This was fairly good at the time, unless one take into account that this was done on encrypted fingerprints, without having keys for decryption. Then it was quite fantastic, far beyond everything similar in the industry. To identify a person uniquely, 32.5 random bits are necessary, for 6 billion people. To identify all persons uniquely, twice this is necessary, 65 bits. In the article, they claim 99.97 % accuracy while searching the forensic database of fingerprints, which corresponds to about 12 bits of information, similar to the best entries in the FVC on easy prints. As for my education as a physicist: I could not have made my fingerprint analyzer without a lot of that math and physics.

Kim Øyhus (2011-12-03 03:06:03)

Einstein and Newton both did their revolutionary work outside of school. Newton at home while the university was closed due to a plague. Einstein while on his bicycle, or while working at the patent office.

Roger Sweeny (2011-12-03 08:24:32)

*After maybe half a dozen responses by the GSI, I discovered a clear (albeit never explicitly stated) theme: to get an 'A', you needed to regurgitate EXACTLY what the professor had said in lecture. This completely shocked me (hey, I was only 17). This was a Sociology class taught by an (allegedly) "cutting edge" professor who said lots of radical things (well, they were radical to me). A lot of what we call education is substituting one religion (sometimes even with a catechism!) for another. Jim Purdy, take note.*

Sarah (2011-12-03 13:40:01)

Most psychologists don't in fact glorify IQ, because they know that IQ is a construct that bears little relationship to ability. Nobody has even been able to pin down what intelligence actually IS. Is the rest of your article any better researched?

Becky Hargrove (2011-12-03 15:50:49)

After thumbing through Critical Path (yet again) it's hard to say exactly which quote impressed me most. His belief in the individual, however, really stayed with me. He believed that - if we would tell the truth - we had a great chance at not just survival but much more. He had the kind of hope for knowledge that I also hold, that it can somehow survive in the Universe for the long haul. Buckminster Fuller would stress to people that they should never give up on their own unique way of looking at the world, that our uniqueness was the very element that could make the difference. And in his day it was hard to be a generalist. While it is easier now, people still don't know how to relate to that because money is not really capable of reaching across disciplines much of the time.

Seth Roberts (2011-12-03 16:55:36)

Becky, thanks for the information.

Seth Roberts (2011-12-03 17:07:42)

Most psychologists don't in fact glorify IQ, because they know that IQ is a construct that bears little relationship to ability. Nobody has even been able to pin down what intelligence actually IS. Is the rest of your article any better researched? "Researched"? Huh? I lived it, am still living it. I am a psychology professor. I haven't encountered any researcher who worries that "nobody has even been able to pin down what intelligence actually IS". As to whether or not IQ has been glorified, can you tell me a book about some other mental ability that had the impact of The Bell Curve? Among psychologists, Howard Gardner and Robert Sternberg are important exceptions to the general rule of focusing on IQ as the most important way that people differ. IQ tests predict who will do well at school. We have a society that rewards people who do well at school. Then those very same rewarded/powerful people turn around and say: Doing well at school (= IQ) is the most important thing! When the circularity is pointed out, they get confused. They fail to understand the whatever is, is right feature of their argument.

Tracy W (2011-12-03 22:03:24)

I've read your examples here, and I think they're very interesting, but I wonder how much of what you do here you can do because you're a professor of psychology, and thus these things shouldn't be expected of every professor. Take for example evaluating whether someone has displayed courage - your student giving a talk to a high-school class - can a professor of mathematics bring anything to this evaluation more than a lay person? When I was 13, we had to give speeches at school and one of my friends was so scared she was crying while doing it, but she didn't run away, and since then I have considered her one of the bravest people I know. I haven't learnt anything from university that has led me to change my mind. You might have a special insight into the level of courage displayed from your psychology training, but what can a maths professor be expected to add? Or take your students' project, reading your linked article, it sounds like the students didn't do anything they couldn't have done without going to university, I know people who volunteer for a depression hotline despite doing a full-time paid job in a very different field. What you appear to have provided was a "kick-up-the-bum" to try something new. A good school teacher, or scouts leader, can do the same. As a psychology professor, you might be more competent at working out how to do this, and how to evaluate the results, than most people, but I can't see how a political science professor would have similar skills. And the other thing is that college is very expensive, a lot more expensive than high school, or joining toastmasters to practice public speaking, or taking a cooking course to improve the quality of your food, or trying your hand at writing funny stories and posting them online for feedback. Indeed, some ways you can even get paid for doing some of these things, for example if you want to demonstrate courage, joining the army and specialising in mine clearing would be one way. So college should be providing something that can't be gotten far more cheaply in other ways. Not being an expert, but I'd say that for most professors, the thing they can do that is unusual and not easily replicable by someone without their training, is to evaluate how close what the students are doing is to what said professor would have done (and perhaps provide the structure of learning, the only way I've been able to defeat my procrastinating tendencies when it comes to learning maths is by signing up for a formal class). As a psychologist you are, I think, unusually qualified to do different things.

Seth Roberts (2011-12-04 00:32:34)

for most professors, the thing they can do that is unusual and not easily replicable by someone without their training, is to evaluate how close what the students are doing is to what said professor would have done True. But in most cases college isn't optional. For a large fraction of good jobs, you must go to college. Professors have a captive audience. Their students did not choose to be there. This is why it is unreasonable for professors to simply do whatever they want to do. That would be abuse of power.

Becky Hargrove (2011-12-05 08:38:07)

I want to do a little thought experiment with what Tracy W said, "So college should be providing something that can't be gotten far more cheaply in other ways." College is but a small part of the world of knowledge, but should college offerings only be what people can "make a living at" there would not be much left to college at all. What, then, might people be missing? Quite a lot that makes the world go round. The problem for college is not that it is impractical. The problem for higher education is that it has not been able to integrate the actual use of knowledge in its many forms at local levels. When people can not actually validate their worth amongst one another through knowledge, they eventually react by insisting that knowledge is not even important. This is the real issue that formal education needs to address.

## **Flaxseed Oil Alleviates Psoriasis and Lichen Planus (2011-12-02 05:00)**

[1]Two months ago I wrote that camelina oil might be a good source of omega-3. A few days ago, a reader named Evelyn Majidi [2]commented as follows:

Based on this suggestion, I ordered camelina oil from the good farmers in Saskatchewan and began taking it using the same dose (3T/day) that I had been taking of flaxseed oil for relief of psoriasis and lichen planus. Unfortunately, the slow but sure improvement I had been experiencing over the past year with flaxseed oil stopped immediately and after a week my skin and mouth began to deteriorate. After using about 1/4 of a bottle of the new oil I went back to flaxseed and am delighted to report that I am [again] having good results with it. Since both of my conditions wax and wane without any reason identified by medical science I cannot state that it was simply the flaxseed oil that has led to this success. Based on my experience, however, I intend to continue taking the oil regularly and I recommend that others with psoriasis or lichen planus try it. For me, two tablespoons a day were not enough, I needed three tablespoons of the oil to see a change. I don't think it advisable to take capsules, you'd need to take too many to equal 3T of oil.[emphasis added]

[3]Psoriasis is a skin disease that usually involves "thick, red skin with flaky, silver-white patches called scales".  
[4]Lichen planus is "an itchy rash on the skin or in the mouth". To give some idea of how common they are, psoriasis has 36 million Google hits; lichen planus 1-2 million. ("Heart disease" has 64 million.)

Evelyn's experience provides four pieces of evidence that suggest flaxseed oil (FSO) improved her psoriasis and lichen planus:

1. When she started taking FSO at 3 T/day, they started improving. They did not improve with 2 T/day.
2. Over the first year of FSO, she saw steady improvement in both in place of the usual up and down.
3. When she replaced FSO with another oil, which she hoped would be better, the results were the opposite of what she wanted: The improvement stopped and the two conditions got worse.
4. When she switched back to FSO, the improvement resumed.

I can think of no plausible alternative to the conclusion that FSO helped. There is plenty of other evidence that supports this conclusion: the evidence that omega-3 is anti-inflammatory, FSO is high in omega-3, most of us don't get enough omega-3, and so on, including [5]my own experience. You could write [6]a book about the evidence that supports it. (Evelyn tried flaxseed oil because of reports on this blog that it improved/cured bad gums.)

In any case, the conclusion that FSO reduces psoriasis and lichen planus is new, in the sense that FSO (or another source of omega-3) is not a popular treatment for either condition. [7]Here are about 16 treatments for psoriasis, including topical corticosteroids. None includes omega-3. Here are [8]eight "lifestyle and home remedies" for psoriasis, including "take daily baths" (seriously, Mayo Clinic Staff?). None includes omega-3. After going through about forty-odd treatments, I found [9]a reference to fish oil: "Other research has suggested that taking oral fish oil supplements containing 1.8 to 3.6 grams of eicosapentaenoic acid (EPA) a day may bring improvement."

Same thing for lichen planus. FSO is not [10]a popular treatment.

If you take flaxseed oil or other omega-3 source to treat psoriasis or lichen planus, I hope you will let me know what happens.

Annette (2011-12-02 16:48:03)

I grew up as a kid with psoriasis and eczema and after a couple of topical steroid treatments my mom hoped to control my symptoms better. Since I can remember she would boil up the flax seeds to create that 'gel' was used as a kind of lotion after showering (also makes a great hair gel!) I wonder if one works better than the other? The benefit to my way is that it was instantly soothing to any of the itchy or redness symptoms

David (2011-12-02 22:34:36)

Not psoriasis or lichen planus, but drinking FSO cured a stubborn patch of eczema on my leg that had tormented me for several years. Steroid ointments worked to some extent to relieve the itching, but the underlying condition persisted until I discovered FSO.

michael (2011-12-03 10:50:07)

T-nation.com has an article titled flax oil vs fish oil which criticizes flaxseed oils omega 3 absorbability but praises it for its ability to lower excess estrogen levels in men

Andrew (2011-12-08 10:05:35)

Hey Seth, I think flax oil works due to its content of unprocessed linoleic acid (O-6), not the alpha-linolenic acid (O-3). Flax oil is 56-71 % ALA and 12-18 % LA and so my guess is that 2T of flax does not provide enough LA to produce therapeutic results. This is the reason why 2T has not effect, whereas 3T does. Here is a link (full free article) that delineates the composition of normal, healthy skin: <http://www.ajcn.org/content/71/1/361S.full> It is stated in the article that O-3 fatty acids are NOT present in normal skin. Rather, the preponderance of skin fatty acids are LA as well as its derivatives, arachidonic acid and GLA. I've experimented with cold-pressed pumpkin seed oil and sesame oil, which are rich in LA, with very good results. Great blog, Andrew

Seth Roberts (2011-12-08 14:26:22)

I've experimented with cold-pressed pumpkin seed oil and sesame oil, which are rich in LA, with very good results. could you say more about this? "very good results" with what?

Andrew (2011-12-08 17:17:53)

The red bumps on the back of my arm (chicken skin?) has nearly gone away and skin in general feels softer and smoother. I thought it would help with my acne after reading that paper, but I haven't noticed much change. I have found that the only thing that does make my acne disappear is eating a VLC, calorie-restricted, plain diet and maintaining low body fat. Works EVERY time for me.

Seth Roberts (2011-12-08 17:56:09)

The red bumps on the back of my arm (chicken skin?) has nearly gone away and skin in general feels softer and smoother. Many people who did the Shangri-La Diet by drinking olive oil reported that their skin felt a lot softer and smoother. I noticed the same thing. Olive oil is low in omega-3 but high in other fats. So, yeah, the smooth skin part is not due to omega-3. But your overall point that psoriasis and lichen planus improvements are not due to omega-3 but other fats is contradicted by the

bad results she got with a different oil.

Andrew (2011-12-08 18:11:07)

according to wiki the fatty acid composition of camelina oil is: ALA: 35-45 % LA: 15-20 % again, flax oil is: ALA: 56-71 % LA: 12-18 %. Camelina oil is still quite high in ALA, nearly as high as that found in flax, and higher than most other oils available. As far as I'm concerned, their fatty acid contents are the same. Did you get a chance to read the article? Psoriasis, as I understand, is an inflammation based condition characterized by over-proliferation of cells in the skin that leads to scaly plaquing. The metabolites of LA have anti-proliferative and anti-inflammatory activities. LA is also what is physiologically found in skin - not ALA. Could be worth a try to try a cold pressed oil with more LA. I would be interested to see if it produces faster improvements.

Seth Roberts (2011-12-08 23:46:00)

Camelina oil is still quite high in ALA, nearly as high as that found in flax, and higher than most other oils available. As far as I'm concerned, their fatty acid contents are the same. Then why did they produce such different results? That difference in results is why this is an interesting story. Perhaps you are right, but your idea doesn't even explain the available facts. Yeah, I read the article. Keep in mind: 1. Omega-3 is fragile. The camelina oil may have been treated in some way (e.g., too high temperature) that destroyed its omega-3. 2. Omega-3 is much rarer than omega-6. You are much more likely to get too little omega-3 than too little omega-6. 3. Omega-3 is far more anti-inflammatory than omega-6.

Andrew (2011-12-09 09:56:14)

If Omega-3 is much rarer in nature, does it make sense to take massive doses of it in a ratio that is nearly impossible to get eating a natural diet? What about land dwelling people in the past that did not have access to sea foods- the richest, most concentrated sources of O-3? Not everyone had access to seafoods. O-3 is not "far more anti-inflammatory than O-6." They are both important and O-6 metabolites such as prostaglandin E1 and prostaglandin D2 are very anti-inflammatory. The body produces prostaglandins as needed and they are produced in a balance to regulate blood pressure, inflammation, platelet aggregation, etc. If you're using the argument that O-3 is fragile, why can't you say the same for O-6? Yeah, LA has 2 double bonds and O-3 has 3, but they are both polyunsaturated and therefore both susceptible to oxidation/rancidity. What is more, the process of producing O-6 rich vegetable oils is very intensive and includes very high heat, bleaching, de-odorizing, etc. So whatever O-6 most people are getting is probably damaged. Again, I'm saying its the O-6, not the O-3. Don't know the company the patient got her camelina oil from but maybe its something unique about that product itself. Don't know the history of its use as an edible oil.

Seth Roberts (2011-12-09 13:55:21)

Andrew, thanks for the additional information. I only have time to address one point: If Omega-3 is much rarer in nature, does it make sense to take massive doses of it in a ratio that is nearly impossible to get eating a natural diet? "Much rarer in nature"? What makes you think that? The usual claim is that long ago people got roughly equal amounts of omega-3 and omega-6 in their diet. In this paper <http://www.westonaprice.org/know-your-fats/precious-yet-perilous> Chris Masterjohn points out that scaly skin (in rats) is a sign of omega-6 deficiency. Which supports your argument.

Andrew (2011-12-09 17:05:49)

I'll just add one more thing Seth. O-3 is not only limited in the skin, but there is not much of it in other tissues as well - with the exception of the brain and nervous tissue of course. Even in the brain, eyes, and nervous tissue, though, the turnover rate of fatty acids in their phospholipids and triglycerides is extremely slow and most of the O-3 fatty acids are of the longer and desaturated kinds (i.e. DHA, EPA). I just thought I'd say that because it concerns me when people start taking large amounts of an oil, long term, that does not have a long history of consistent use and without a physiological basis. "Much rarer in nature"? What makes you think that? The usual claim is that long ago people got roughly equal amounts of omega-3 and omega-6 in their diet. Look up the fatty acid profiles of various foods ([nutritiondata.com](http://nutritiondata.com)). With the exception of seafood, nearly all foods are predominantly O-6 - even plant foods. And the reason why fish need long chain, super unsaturated fatty acid chains is because they live deep in the cold waters, where these lipids are needed.

Seth Roberts (2011-12-10 02:48:30)

nearly all foods are predominantly O-6 – even plant foods. You're talking about modern foods. The usual claim is that long ago people ate a lot more animal fat which was high in omega-3.

Efaitch (2011-12-20 17:30:39)

Hi Seth, I used to have red scaly bumps on my arms (keratosis pilaris). It cleared up with flaxseed oil too. In bed on phone, so no linkage... However, it seems that it's a fatty acid deficiency that causes KP. I take CLO [cod liver oil] now rather than FSO and the KP is still under control. But, if I stop taking it, it comes back. It seems that the skin disorders are due to either fatty acid deficiency or fat soluble vitamin deficiency.... And, I have an autoimmune skin disorder (vulval lichen sclerosus) which is in remission too - this happened after the birth of my son, but FSO didn't really make a difference with that one.

Seth Roberts (2011-12-20 19:04:37)

Efaitch, thanks for your comment. What does "In bed on phone, so no linkage..." mean?

Nick (2012-03-04 09:54:20)

I am a life long suffer of psoriasis and also a big consumer of many types of oils including canelina, olive, macadamia, and flax seed oil for many years as soon as these types of oils became available to me. I don't see a connection with psoriasis consuming these oils orally and never experimented them topically. Aloe Vera seems to cause a flare?. My psoriasis overall goes into remission completely and flares up acutely. My psoriasis usually flares up with stress. Exercise helps reduce the flares in general. Calorie restriction also helps. If I get psoriasis on the bottom of my feet I find sleeping with socks helps ALOT.

Ryan (2012-03-09 22:19:57)

I've had psoriasis for 12 years, tried absolutely every alternative method I can think of - except Flax See Oil. Even though I've read about the benefits before, never tried it until a week ago. Results - first time in 12 years for patches to become less inflamed and some of them look to be contracting. I am taking 3 tablets a day, 1,000mg each. I have also combined this with Vitamin D3 (first attempt ever), uncertain if they are working together.

## **Butter and Eggs: What They Share (2011-12-04 05:00)**

To many dieticians and much of the general public, the similarity between butter and eggs is that both are bad for you. Butter: Fattening! Clogs arteries! Eggs: High in cholesterol! To me, it's the opposite: both seem to be unusually good for us. Butter seems to [1]make my brain work better and [2]may have reduced my risk of heart attack. Eggs – at least, scrambled eggs – are [3]especially well-liked by Mr. T, a rat. There are many similarities between rats and humans. Humans also like eggs. The foods we like are a guide (imperfect) to what foods are good for us.

Here's another similarity between butter and eggs: Both must be complete – contain all necessary nutrients – much more than any other food. Butter is large part of milk. When mammalian offspring are very young, mother's milk is their only food. Eggs, of course, must contain everything needed to become a baby chick (as [4]a commenter named Rashad pointed out). No other foods – not fruits, not vegetables, not whatever other foods [5]your great grandmother or other [6]ancestors ate – have been under this sort of evolutionary pressure.

[7]The evolution of lactose tolerance and my butter discoveries.

Ezer (2011-12-04 05:58:15)

Scrambled eggs with butter and cheese: superfood? I love it!

Elizabeth Molin (2011-12-04 08:13:32)

Seth, can you give me the source for the info you posted previously on Dr. Clara Davis? Thanks.

Ezer (2011-12-04 11:27:57)

I think the preference for the food is a guide to the importance of that food only in a sort of "environment of evolutionary adaptedness", in terms of the constraints under which humans evolved. For example, our taste for sweet evolved in an environment with scarcity of fruits and where the benefits of additional calories and vitamin C outweighed the harm of the fructose.

Ezer (2011-12-04 11:30:50)

In our actual environment, this taste for sweet is maladaptive, because there isn't restriction on the fructose available anymore.

Seth Roberts (2011-12-04 11:35:08)

Elizabeth, my post contained a link to my source. Here is another link: <http://www.cmaj.ca/content/175/10/1199.full> if you want more sources. search "clara davis diet self-selection".

Seth Roberts (2011-12-04 11:44:39)

I think the preference for the food is a guide to the importance of that food only in a sort of "environment of evolutionary adaptedness" (EEA) "only in" is too strong. Lab experiments – that is, not in an EEA – show that rats can choose a healthy diet, as I described in my original Mr. T post. I agree that away from an EEA the interpretation of food preferences – what they tell us about how to be healthy – isn't simple. But they still tell us something.

SB (2011-12-04 15:02:34)

What they share is my plate!!

Jeff (2011-12-04 15:42:21)

Seth - Just curious if you have ever determined an optimal dose for fermented food as you have with Flaxseed oil? I consume about 1/2 a cup of home fermented kefir including the cottage cheese like substance in my taste free smoothie daily. TIA

Ezer (2011-12-04 18:06:52)

I agree with you, an innate preference could be indicate something worthy of investigating, especially in consideration of an probable EEA. OT: How can I italicize text in a comment? [i]test of italic[/i]

Alex Chernavsky (2011-12-04 18:57:35)

@Ezer: Instead of the square brackets, use the less-than and greater-than signs.

UncleLongHair (2011-12-04 18:58:32)

Including the eating preferences of a single domesticated rat is pretty weak evidence.

Aaron Blaisdell (2011-12-04 23:09:19)

Aaron Blaisdell (2011-12-04 23:10:44)

I tried "" suggested by Alex, but it didn't seem to work. Btw, I love butter. I try to eat a tablespoon of grass-fed raw milk derived butter each morning along with my high-vitamin fermented cod liver oil.

Aaron Blaisdell (2011-12-04 23:11:54)

Yikes. In the "" in the above comment, I typed the less than sign followed by "test in italics" followed by the greater than sign. It seems to result in the text being entirely omitted from the comment. Would be nice to know how to create an italicized comment, though.

Tom (2011-12-05 00:08:16)

Aaron, it's a pretty standard markup. Hopefully the symbols will come through if I put in additional spaces: [Obviously, remove the extra spaces before and after the angle-brackets (shift-comma and shift-period) when you use them]: Start italics: *End italics*: Start bolding: **End bolding**:

Tom (2011-12-05 00:11:39)

Dang, it accepted them even with the spaces. Anyway, before the section you want to italicize, enter a shift-comma, then a lowercase i, then a shift-period. To stop italicizing, enter a shift-comma, then a forward-slash (unshifted questionmark), then a lowercase i, then a shift-period. (You can bold by replacing the lowercase i with a lowercase b.)

Sara (2011-12-05 03:21:21)

I am thinking about what might cause the effects you see with high butter consumption. As your diet was low fat, do you think you are experiencing the benefits of fat-soluble vitamins? (D, K and A specifically are quite high in butter, particularly Vit A, retinol form). If you analyse your diet as it was, perhaps you were low in these vitamins? The question of Vitamin D is interesting because eggs also contain it, but apart from fish, there are hardly any other dietary sources (milk, eggs, fish and some mushrooms, I think that's it for vitamin D). Do you think you might have been in a state of vitamin D deficiency perhaps and have rectified it with the butter and egg consumption?

Seth Roberts (2011-12-05 06:24:27)

As your diet was low fat, It was not low-fat. It was very high fat. Before I started eating lots of butter, I ate lots of pork fat (for the sleep benefits).

dearieme (2011-12-05 07:10:16)

What are the dietary benefits of blood? I'm thinking of "black pudding" and other "blood sausages".

Sara (2011-12-05 13:17:29)

Oops, I misread the link as 'low fat, high cho'. Sorry. I'm new to the blog but did a bit of reading. It seems you were already taking vitamin D3 as well. Maybe it's not related to micronutrients at all but the effect is very interesting, for sure. I've got to say, I would like to try the butter experiment but the amount of calories in that much butter scares me. I might get a fat butt, and that would give me anxiety.

Elizabeth Molin (2011-12-05 14:46:47)

Thanks again, Seth (did I say that I'm a very bad researcher?).

et (2011-12-05 18:35:34)

Why stop with cow's milk? Is milk from any mammal good for you?

dearieme (2011-12-06 04:52:43)

"Is milk from any mammal good for you?" Milk from goats and ewes is certainly good for cheese.

Nick (2012-03-04 09:37:53)

I agree with the milk and egg theory but I think it also comes down to the phenotype, life stage and life style of the person. I see these foods as anabolic overall, and if your system still contains anabolic capacity than it could be good for you, however if you do not have this anabolic capacity left than it can be detrimental. Staying on the edge of and measuring your Homeostasis is hard but swinging up and down between anabolism and catabolism on average would put you on that edge.

### **Taobao Cashes In on Singles Day (2011-12-05 05:00)**

All cultures, as far as I know, have festivals and special celebratory days. At least they are extremely widespread - [1]harvest festivals, for example. [2]I believe they have a genetic basis. The underlying genes evolved because they increased sales of high-end "useless" stuff. This helped skilled artisans - a big source of technological innovation - make a living. Economists speak of [3]the "deadweight loss" of Christmas because people buy stuff that would otherwise not be bought.

China retail giant Taobao (like Ebay, except better) has shown a shrewd understanding of the festival/shopping link. On Chinese campuses since the 1970s there has been a joke holiday called Singles Day (11-11). For people who are not in a relationship. In 2010 Taobao started having a sitewide sale on that day. [4]This year total sales were \$500 million. One retailer, one day. (For comparison, all US online retail sales for the 2010 holiday season were [5] \$33 billion.) No crowds, no difficulty parking, no long lines. Still stressful, yes, but in a good way: "This is so exciting - a war and a carnival at the same time," said one shopper.

1. [http://en.wikipedia.org/wiki/List\\_of\\_harvest\\_festivals](http://en.wikipedia.org/wiki/List_of_harvest_festivals)

---

jeff (2011-12-05 12:47:01)

This is why it's so easy to not take evolutionary psychology seriously, because most often amateurs, but in this case, even people with psychology degrees, can and do simply make up stories and declare them genetic in basis. You say "The underlying genes evolved because they increased sales of high-end "useless" stuff. This helped skilled artisans" but stop! The underlying genes became human-universal so that they could help a small cadre of people? No way! This is group-evolution theory at its subtlest! An evolutionary psychology argument that has even the slightest bit of probability needs to not just be a Just

So Story, but to propose a mechanism by which individuals with the genes in question benefitted over individuals without. Harvest festivals require massive participation to be beneficial, and would seem to benefit everyone once they exist. There is no mechanism (proposed or immediately obvious) by which this could influence the relative frequency of an allele. Wishful thinking is a common failure of amateur evolutionary psychologists, and it does a lot of damage to the credibility of the field as a whole. It takes very very careful analysis to discover a genetic basis to human behavior because of the massive adaptability of human behavior.

Seth Roberts (2011-12-05 14:44:41)

This is why it's so easy to not take evolutionary psychology seriously, because most often amateurs, but in this case, even people with psychology degrees, can and do simply make up stories and declare them genetic in basis. I suggest you read my paper and see if I "simply made up a story". That paper will also help you judge how plausible my explanation is. If you have another plausible explanation of the ubiquity of harvest festivals and the like, I would like to hear it. propose a mechanism by which individuals with the genes in question benefitted over individuals without. Groups with the genes innovated more than groups without the genes. The more innovative groups competed successfully against less innovative groups. I am sure you are aware of group-vs-group competition, even if critics of "group selection" have had trouble with the concept.

### **Vitamin D3 Reduces Mortality (2011-12-06 05:00)**

[1]A recent Cochrane Review summarizes several experiments that measured the effect of Vitamin D on mortality. Here is a summary:

This systematic review analysed the influence of different forms of vitamin D on mortality. In the 50 trials that provided data for our analyses a total of 94,148 participants were randomly assigned to either vitamin D or no treatment or a placebo. All trials came from high-income countries. The mean age of participants was 74 years. The mean proportion of women was 79 %. The median duration of vitamin D administration was two years. Our analyses suggested that vitamin D<sub>3</sub> reduces mortality by about 6 %,

Vitamin D3 helped; Vitamin D2 and other forms of Vitamin D did not. The doses of Vitamin D3 were usually low: less than 800 IU/day.

Stimulated by [2]Primal Girl's discovery, I have been taking Vitamin D3 at about 7 am in the morning, slowly increasing the dose to see if there are any clear effects on my sleep (or anything else). I am up to 4000 IU/day.

1. <http://onlinelibrary.wiley.com/doi/10.1002/14651858.CD007470.pub2/full>

2. <http://blog.sethroberts.net/2011/11/02/it-matters-when-you-take-vitamin-d-a-stunning-discovery/>

---

jay (2011-12-06 08:41:15)

Be careful with Vitamin D3 Seth. I started getting heart palpitations. I have since stopped the d3 (I was taking 4000ui a day), but maybe I'll start again and supplement with magnesium. I'm thinking about it. It's strange that I never got palpitations with sun exposure, since they're supposed to be the same thing - and you can get as much as 10,000ui from just being outside for a while in the summer. There are D3 deficiency tests out there, but I haven't taken one. <https://www.inspire.com/groups/national-osteoporosis-foundation/discussion/he-art-palpitations-with-vitamin-d3/>

TD (2011-12-06 09:36:49)

Are you still calling PrimalGirl's personal finding a discovery? I will be looking for the studies where this has already been accomplished within the scientific community and posting the links right here for you to see. Credit must be given to where credit is due.

Tom (2011-12-06 10:47:14)

Off-topic, Seth, but you may be interested in Paul Jaminet's post on fermenting vegetables:  
<http://perfecthealthdiet.com/?p=5165>

Alex Chernavsky (2011-12-06 11:49:49)

That's odd that D2 doesn't work. That's the form I take. Any ideas about why D3 would show the effect, but not D2?

Seth Roberts (2011-12-06 13:48:59)

Any ideas about why D3 would show the effect, but not D2? I've heard this ("take D3 not the others") before. I forget the reasons given.

Seth Roberts (2011-12-06 13:55:57)

Are you still calling PrimalGirl's personal finding a discovery? I will be looking for the studies where this has already been accomplished within the scientific community and posting the links right here for you to see. I don't know of any studies "within the scientific community" showing or even hinting at what Primal Girl found. If you can find such studies, I'd love to learn about them. Practically all Vitamin D studies look at blood concentrations of the vitamin, as if that is what matters. The blood concentration is quite constant with time of day. You seem to disparage Primal Girl's discovery by calling it "a personal finding". Several other people have reported similar results – changing the time of day that they took Vitamin D changed their sleep. I've seen thousands of recommendations to take Vitamin D that say nothing about time of day. Millions of people take Vitamin D. Primal Girl's discovery can help all of them.

Robert (2011-12-06 15:36:52)

Hi Seth, I was wondering if you had seen this article/study from 2010 and what your thoughts about it might be.  
<http://www.sciencedaily.com/releases/2010/03/100310164011.htm> -Rob

Guv (2011-12-06 19:10:32)

Hi Seth, keep an eye (pun intended) on your vision as you increase your D3 intake. Increasing your D3 may create a Vit A deficiency (or imbalance). Paul Jaminet speculates that a healthy A to D ratio is 3 IU to 1 IU. Paul also suggest 1mg K2 per day as Vitamin D is known to deplete Vitamin K2. The Vit A, Vit D subject was discussed recently on PaleoHacks in relation to Night Blindness, see here; <http://paleohacks.com/questions/77024/creaky-knees-night-blindness-what-am-i-missing/80528#80528>

cremes (2011-12-06 20:07:09)

I changed the time of day when I consume my 8k IU of daily D3. I now take it between 7am and 8:30am. Within 2 days I noticed that I was waking up earlier than usual (5am). I wonder if this is the "breakfast effect" that Seth has written about before. I don't mind the early rising. I need to get going early anyway, so it's not a burden. I just thought I would document this n=1 result.

Seth Roberts (2011-12-07 01:13:31)

I changed the time of day when I consume my 8k IU of daily D3. I now take it between 7am and 8:30am. Within 2 days I noticed that I was waking up earlier than usual (5am). Thanks. More evidence that the time of day you take Vitamin D matters. As I've said, none of the several hundred million Vitamin D bottles says what time of day to take it.

Sara (2011-12-07 02:32:20)

This is extremely interesting. I take D3 in winter and will move it to the morning - insomnia has been a lifelong companion, I've practically given up on curing it, but there are a lot of things that help me not be a zombie all day, maybe this will

improve things further?. Worth a try. One of my lecturers is doing a lot of vitamin D research, so I'll have a look and see if she is investigating circadian rhythms at all. I think her focus is bone health. I don't want to be a wet blanket, but this vitamin can be toxic. In fact, Cholecalciferol is used as a pesticide here in NZ. Overdose (acute or chronic) can lead to dangerous arrhythmia and hypercalcaemia. Please be careful, especially the person taking 8000 IU a day.. you're scaring me a bit.

Dave Lull (2011-12-07 06:37:46)

"The case against vitamin D2" Posted on August 11, 2009 by Dr. William Davis <http://www.trackyourplaque.com/blog/2009-08/the-case-against-vitamin-d2.html>

cremes (2011-12-07 07:15:09)

Sara, I appreciate your concern and do not mean to frighten you. Based on my reading of Vitamin D research, Vit D toxicity generally comes from an imbalance of A, D and K. Therefore, I also take a Vitamin K supplement to avoid that imbalance. The human body produces 15k-20k IU of Vitamin D from 30 minutes of direct sunlight (assume shirt off). That little nugget of info should help ease your unease. :)

wcb (2011-12-07 11:49:58)

Seth said "I've heard this (take D3 but not the others) before, but I forget the reasons given." Seth, here's one explanation given by Dr. William Davis which may be useful, quoted below: "Vitamin D is measured in the blood as 25-OH-vitamin D and is distinct from 1,25-diOH-vitamin D, a kidney measure, a test you do not need unless you have kidney failure. The human form of vitamin D is cholecalciferol and is usually obtained via activation of a precursor molecule in the skin on activation by the sun. You can also take cholecalciferol and it increases blood levels of 25-hydroxy vitamin D reliably. However, there is a cheap, plant-sourced, alternative to vitamin D3, called vitamin D2, or ergocalciferol. D2 has far less effect in the body. Taking D2 or ergocalciferol orally is an extremely inefficient way to get D. Unfortunately, it's the form often used in milk and many supplements, even the prescription form of D. About half the multivitamins and calcium supplements I've looked at contain ergocalciferol rather than cholecalciferol. Taking vitamin D2 yields very little conversion to the effective D3. "

Alex Chernavsky (2011-12-07 14:54:44)

@wcb: But see <http://www.sciencedaily.com/releases/2008/01/080102122306.htm> I don't take D3 because it's animal-derived.

Jess (2011-12-08 09:38:13)

Vitamin D is the effect that the sun is giving u?/ what is in Vitamin D3

Jazi zilber (2011-12-09 06:56:55)

Vitamin d2 has a very short life in the body. D3 stays in the body for weeks, whereas D2 maybe half a day.

Txomin (2011-12-08 00:48:06)

I just want to thank you for continuing to call attention to academic fraud.

Michael (2011-12-08 06:57:55)

Did you see this story on the mouse research diet? [http://blog.cholesterol-and-health.com/2011/11/this-just-in-infamous-lard-bas ed-high.html](http://blog.cholesterol-and-health.com/2011/11/this-just-in-infamous-lard-bas-ed-high.html)

Matt Weber (2011-12-08 07:46:04)

Just curious to hear what appealed about the "Tale of Two Workers." It's a cute reversal, but the reversal changes the way you view the worker"s" – the initial framing describes two situations that anyone would describe as typical, and the twist turns it into a situation that anyone would describe as exceptional. Which supports the point made at the end, that "it's all in how you tell the story," but also vitiates the apparent point of the story, which is that more fortunate people aren't obliged to help less fortunate people because less fortunate people could do it themselves if they tried. (A proof of principle doesn't necessarily mean much if the phenomenon still doesn't happen very often. It may be true that anyone could write the next Harry Potter, but no amount of hard work will change the fact that most people won't.) Of course, the implied conservative/libertarian moral may be more mine than the author's. And I do think it's interesting how Worker A's "disadvantage" and Worker B's "advantage" are not as incompatible as they seem when the framing implicitly opposes them. That might be the most interesting thing about the story.

by (2011-12-08 10:05:17)

"A tale of two workers" was a very cool and creative story. A movie having a twist is par for the course, but this story had two, and did it in a few minutes instead of a few hours.

Tom (2011-12-08 11:22:06)

A more interesting tale than the "two workers" is the story of the massive, silent campaign to push memes like this, to distract from the obscene concentration of societal wealth in the hands of the top .1 % of the population – largely financial titans and CEOs (with lapdog compensation committees.) <http://krugman.blogs.nytimes.com/2011/11/03/inequality-trends-in-one-picture/>

Seth Roberts (2011-12-08 14:33:43)

Just curious to hear what appealed about the "Tale of Two Workers." I just thought it's a good story. The ending surprised me. If I wanted to draw some lesson from it, it wouldn't be what you say ("more fortunate people aren't obliged to help less fortunate people because less fortunate people could do it themselves if they tried"); it would be that life is less predictable than we usually assume.

Seth Roberts (2011-12-08 14:36:48)

the story of the massive, silent campaign to push memes like this, to distract from the obscene concentration of societal wealth in the hands of the top .1 % of the population Where is this story told? It's not told in the link you provided.

Nathan (2011-12-08 16:44:18)

<http://www.youtube.com/watch?v=KLjgBLwH3Wc> &feature=youtu.be this medical doctor changed her diet and reversed her MS symptoms so that she was able to walk again, after having been wheelchair-bound.

Tom (2011-12-10 17:20:29)

Seth, that link spoke more to the concentration of wealth. Here are some more links that speak more to the propaganda effort:

## **The Dominique Strauss-Kahn Victory Dance (2011-12-08 19:02)**

In May, Dominique Strauss-Kahn (DSK), as everyone knows, was accused of raping a maid. The story received huge worldwide coverage, reaching billions of people within days. Strauss-Kahn was greatly damaged. A week ago Edward Jay Epstein, [1]whose work I've praised, published [2]an article in The New York Review of Books with many new details that implied what happened was not as simple as the first reports suggested. Was DSK set up (a possibility not mentioned in the initial media reports)? New facts in Epstein's article – [3]which I called "great journalism" – made this a lot more plausible.

One such fact is that soon after the assault was reported to 911 (after a long delay), two men involved in the call performed what Epstein called a "victory dance". A plausible explanation of the celebration (which Epstein doesn't state, it's obvious) is that they were celebrating because they had succeeded in entrapping DSK and would get a huge payoff from his enemies. Epstein's article said the dance lasted three minutes. Critics of his article said the dance lasted eight seconds. Amy Davidson of The New Yorker had the poor taste [4]to joke about it. "But maybe it's all true, and the BlackBerry is not a red herring but the key, and another cell phone was passed in the soccer match box, with news of a character assassination, whereupon Sarkozy did his own dance of celebration," she wrote. Yesterday The New York Review of Books [5]issued a correction: The dance lasted thirteen seconds (a correction with which Epstein agrees). Davidson [6]continued her dismissiveness. "The victim of some sort of insidious conspiracy." The victory dance, she wrote, "doesn't seem outlandish, given the sorts of things men do in New York, particularly when talking about sport."

Missing from criticism of Epstein's article, which does suggest conspiracy, was a plausible alternative explanation. Why were the men celebrating? [7]They can't remember. Both of them. In spite of all the attention. Which began within hours. Perhaps a sport event, they said, but no such event has been identified. Excitement usually improves memory. The men are clearly excited. Failure to come up with a plausible alternative explanation supports Epstein's point that there is something very important about this we don't know.

What makes this especially interesting, at least to me, is that you can judge for yourself. (This blog is all about that.) Epstein has [8]posted on his website three items: (a) a recording of the 911 call that led to DSK's arrest ("she doesn't have any sustained injuries," says the caller), (b) CCTV video showing the security area at the time of the phone call, and (c) CCTV video showing the victory dance, which includes one man picking up the other man and swinging him around.

dearieme (2011-12-09 03:24:30)

"At one point, the larger man lifts the well-dressed man off the floor. " What mimsy stuff, especially since both men are wearing jacket, collar and tie. There is another characteristic available to distinguish one man from the other, which would be quite unambiguous.

spacenookie (2011-12-09 21:08:30)

yeah, but this was six months ago. Quick - "you were captured on video camera dancing and celebrating something for 8 seconds, six months ago. What was it?"

Seth Roberts (2011-12-10 03:18:46)

yeah, but this was six months ago. Quick - "you were captured on video camera dancing and celebrating something for 8 seconds, six months ago. What was it?" I assume you're a man. When was the last time you picked up another man and swung him around?

Someduded (2011-12-10 12:08:57)

> The victory dance, she wrote, "doesn't seem outlandish, given the sorts of things men do in New York, particularly when talking about sport." Really ? There was NO sporting event of note that day. And cheering like that ONE MINUTE after having called the police, are you kidding me ? Also, how comes the two guys are both struck with amnesia about this event ? How comes they can't remember having cheered about it ? The ACCOR group states they were cheering about a won bet on a (non existent) sport event. Given the way they cheered, obviously they won a LOT of money. How comes they can't remember it ?? That doesn't make any sense. They are ALL lying, this is obvious to any person who looks at this with a fair eye.

Somedude (2011-12-10 12:33:31)

Sorry, I should have read the whole post, I see that we share the same doubts. I want to add a few things that you guys may not know from your side of the Atlantic. 1) The first person who twitted about DSK arrest is a guy who belongs to UMP youths, (UMP is Nicolas Sarkozy's party). He twitted about something "exceptional" happening at the Sofitel about 15 minutes after the arrest. That's WAY earlier than any journalist. That was one of the first facts that led to the Sarkozy conspiracy hypothesis. 2) It seems to me that the Sofitel security called Paris BEFORE calling the NY police. They took one hour before calling the police. 3) It is now clear (as written by daily newspaper Libération on 12/09/2011) that the french ministry of foreign affairs (quai d'Orsay) called the prosecutor Cyrus Vance Jr on may 15th, the day after DSK's arrest, to weigh in to maintain him in prison. DSK's name was cited in an investigation in an affair of prostitution. The quai d'Orsay illegally communicated to Vance elements of this investigation that are normally protected by the secrecy of judicial instruction (in France, Justice is not independant from the executive, leading to such problems...). DSK was about to be released on parole against \$250,000, but after the call, the prosecutor changed his mind and DSK was incarcerated that very evening at Riker's Island. The initiative came from Paris and was completely stranger to any judicial procedure. 4) The director of security of the hotel is an ancient member of the DGSE/DCRI (the french secret services) who worked under the current chief of DGSE/DCRI. DSK was by far the most dangerous opponent of Sarkozy for the french presidential elections of 2012, beating him by more than 25 points in all polls.

Somedude (2011-12-10 13:02:15)

To sum up, many (most ?) french people now firmly believe in a political plot. I don't believe at all DSK is a rapist, but what is sure is, DSK's appetite for prostitutes (or should I say sexual disorder) would have, sooner or later, undermined him politically. Yet multiple sexual scandals didn't kill Berlusconi, the economical near collapse of Italy did. Still, DSK knew that his sexual misconducts would be the catalyst of his own demise. He also knew that Sarkozy knew everything about them, and that he would try to kill him politically with this weapon. So for me, everything was ready for a trap. I didn't mention that the behaviour of Ray Kelly, the chief of NY police, looks to me extremely suspect in this affair. He is very well known to Sarkozy (who awarded him the Legion d'Honneur medal), and I believe he is at the source of numerous police leaks with blatant lies, like the fact that DSK fled the hotel in a hurry (which is proven false by the video). He also fired the police officer in charge of sexual affairs, who quickly discovered that Diallo was lying (as was accounted by the NY Times). I suspect him to have done everything he could to slow down the investigations. There are many unanswered questions: - what was the role of N. Diallo in such a plot ? What did she do in room 2820 ? - who was the occupier of room 2820 (the Accor group refuses to give his name) ? - where is the "FMI telephone" ? - what was the content of the conversations between the Sofitel management and Paris ? It is clear that in Paris, there will be NO serious investigation, as the power of the judges are dependent on the ministry of Justice, which is indirectly under the orders of Sarkozy. So the hopes for any full understanding entirely resides in America.

Jean (2011-12-10 19:47:15)

"To sum up, many (most ?) french people now firmly believe in a political plot." I dont it is crazy. Political plot to down DSK Actors 2 Dancers 1 Hotel Maid with bad visa/status problems 1 Breakfast Waiter 2 Security Officers Sofitel Sofitel management who put Diallo on that floor Sofitel management who gave DSK that room Scene Suite Script Client rushing to get ready to go to meeting with his daughter Wait until 15 minutes after he should have left Get Breakfast waiter to go into room and check he is naked Send in hotel maid Take advantage of clients inability to leave any orifice empty I cant even see French agents cooking up such a crazy plot

TMS71 (2011-12-10 10:04:54)

So what does control the rate of innovation?

Tim Beneke (2011-12-10 12:43:29)

Isn't one reason we are stagnating because in order to generate wealth, to innovate, somebody – wealthy corporations, entrepreneurs borrowing from banks, the state – has to take risks, has to invest, has to believe in a possible future with a payoff; this requires a certain psychological orientation, of groups of people who believe. Americans lost maybe 20 % of their wealth in recent years; no one really understands the world economy, or the intricacies of capital flow and investment; and corporations are sitting on huge amounts of money and are still playing it safe. So there are reasons for such caution. Everyone knows we don't know as much about economic processes as we thought we did. There is some principle of herd pluralistic ignorance/knowledge at work. The tide may be changing as people get over the freak-out of the last few years and corporations start to invest.... I sure hope so...

Seth Roberts (2011-12-10 13:36:11)

So what does control the rate of innovation? I don't know. But I can guess: 1. The heavier the regulatory burden, the less innovation. For example, certain FDA regulations require that businesses have a ROOM for the FDA inspector. 2. Lower crime, more innovation. 3. The easier it is to leave your employer and set up your own business, the more innovation. So, for example, universal health insurance → more innovation. 4. The easier it is for a small business to advertise, the more innovation. 5. Cultural values. The more value placed on innovation, the more innovation. 6. The larger the percentage of people that live in cities, the more innovation. 7. The greater the education level, the more innovation. 8. The greater access to a wide range of information, the more innovation. (I think #7 and #8 were behind the Industrial Revolution. Printed books changed everything.)

Becky Hargrove (2011-12-10 18:15:18)

Okay, you're in my area of interest now but where to start? I started working on my own inner economic dialogue about seven years ago but am only beginning to learn the many languages of economics, especially the macro I've been so fascinated with. Consequently my ideas sound pretty loony. I don't believe that money is capable of doing all the things that people try to make it to do, not even close. But what it can't do, people still need and for me that's the place to begin - human capital. Just the same, ownership needs to be far more flexible and markets need to be completely opened up so as to offer what people actually need to work and live, as well as a 'floor' of survivability one can actually progress from.

andrew (2011-12-12 10:54:00)

Seth Are you reading the book Launching the Innovation Renaissance by Alex Tabarrok of Marginal Revolution fame?

Seth Roberts (2011-12-12 16:22:04)

Are you reading the book Launching the Innovation Renaissance by Alex Tabarrok of Marginal Revolution fame? yes, I am reading that book. It's very good.

Nancy Lebovitz (2011-12-12 19:28:11)

Possibly of interest: [1]7 Secrets of the Prolific by Hillary Rettig. It's specifically about writing, though there's also advice which would apply to anything, like getting yourself good tools. In any case, there's a description of making writing into a pleasure, and at least some of it overlaps with your self-experimentation. The idea is to make writing into a bunch of small experiments, so that the cost of failure is made lower.

1. <http://hillaryrettig.com/the-7-secrets-of-the-prolific/>

Charlie (2011-12-22 17:23:01)

I am not sure why you think understanding the rate of innovation is central to understanding the movement of the business cycle since 2007. The 1930s was an extremely innovative time period\*, but alas we still had the great depression. It doesn't seem like changes in the level in innovation are a good explanation for large changes in the unemployment rate. Why do you think this should be in his talk? \*Source <http://marginalrevolution.com/marginalrevolution/2011/04/a-great-leap-forward-1930s-depression-and-u-s-economic-growth.html>

Seth Roberts (2011-12-22 23:08:38)

It doesn't seem like changes in the level in innovation are a good explanation for large changes in the unemployment rate.

If you read between the lines of [1]Collapse by Jared Diamond, you will see that every case of collapse that he describes happened because the society stagnated badly – failed to innovate, kept doing the same thing over and over and over. In each case, just before the society collapsed, the level of unemployment became very high.

1. [http://en.wikipedia.org/wiki/Collapse:\\_How\\_Societies\\_Choose\\_to\\_Fail\\_or\\_Succeed](http://en.wikipedia.org/wiki/Collapse:_How_Societies_Choose_to_Fail_or_Succeed)

Charlie (2011-12-23 00:56:08)

"happened because the society stagnated badly — failed to innovate, kept doing the same thing over and over and over." Those are very strange examples, because it's very hard to show that the societies he chooses ever innovated at all. The Norse, Easter Island, Polynesians, the Mayan, it's very hard to show that these societies ever innovated. Like most of human history, these societies had next to no innovation, as it was very rare in pre-industrial societies to innovate (see Greg Clark's Farewell to Alms for the data). Collapse argues for environmental causes to societal breakdown, and while I agree that these societies didn't adapt to these conditions by innovating, since they weren't innovating before that seems completely beside the point. It almost appears that you might believe that if a society stops innovating that unemployment will follow, but most of human history is a counter example to that. There is no reason new technology or ideas are necessary to create new jobs. It's funny that Australia is one of the only modern western examples in Diamond's book as a cautionary tale of problems to come, and yet, Australia has been one of the best faring countries. Is there any evidence that Australia has markedly kicked up their innovation or is much more innovative than the U.S.? Taking a longer view, it's extremely difficult to pin today's unemployment on a lack of innovation in the U.S. ([http://www.washingtonpost.com/business/economy/economists-explain-2011-in-charts/2011/12/21/gIQA3lg9O\\_gallery.html#photo=16](http://www.washingtonpost.com/business/economy/economists-explain-2011-in-charts/2011/12/21/gIQA3lg9O_gallery.html#photo=16)), much less trying to pin cross country differences by innovation. The lesson of Diamond's book is that as societies are collapsing their ability to generate output (food, clothing, shelter, goods, services...) collapses with it, as well as their ability to utilize their resources (like labor). In some sense, saying a society that is collapsing will "fail to innovate" is much more accurate than saying a society that fails to innovate will collapse.

## **Worldwide Butter Shortage? (2011-12-11 05:00)**

The first sentence of [1]this article is:

The soaring popularity of a fat-rich fad diet has depleted stocks of butter in Norway creating a looming Christmas culinary crisis.

Except it's not a fad diet. It's not going to go away, I predict. I eat lots of butter because I discovered it [2]made my brain work better than a similar amount of pork fat. [3]Pork fat made me sleep better. Desire for better sleep and a better-working brain are not desires that come and go. I haven't even mentioned the conventional benefits (e.g., weight loss). The article continues:

Norwegians have eaten up the country's entire stockpile of butter, partly as the result of a "low-carb" diet sweeping the Nordic nation which emphasizes a higher intake of fats.

"Sales all of a sudden just soared, 20 percent in October then 30 percent in November," said Lars Galting, the head of communications at TINE, the country's biggest farmer-owned cooperative. . . .

Butter is now selling on Norway's top auction website, with a 250-gram piece starting at around \$13 (8.28 pounds), roughly four times its normal price.

At the Beijing store closest to me that sells butter, I seem to buy more butter than all other customers combined. Chairman Mao noticed the value of pork fat. What happens when the Chinese realize the value of butter?

Thanks to Dave Lull.

---

Q (2011-12-11 06:06:10)

Fwiw, I restarted sld a month or so ago with butter. Appetite suppression is very very good. Butter is available a lot of places - I can get it at the work cafeteria for free - I get three pats and eat them with nose plugged in the bathroom. Taste is gone in 2 minutes. Little or no stomach nausea. Have not been weighing myself but hunger is down a lot, which for me is the main reason for doing sld. Attention and time management. My other experience is that butter gives me an energy high similar to coffee, but more at the 2-3 tbsp level. Not as pleasant as coffee, a little weird feeling.

JohnF (2011-12-11 07:27:11)

I think you're making too big a deal about Norway's butter shortage. The market for dairy there is very messed up with virtually a central planner by virtue of a state granted monopoly and very, very high tariffs\*. Essentially it's Norwegian law that the vast majority of food has to be produced inside the country and almost everything imported is taxed to the point where it's economically unfeasible to import. Due to their crappy system they're left without any mechanisms to adapt decently quickly to any increased demand for things like butter. - They can't import butter to make up the shortage, as it's simply too expensive and there's no regular channels to do so. - The farmers making the butter have no incentive at all to increase production, since there's only one buyer who's already decided how much to buy in advance. - The monopolist dairy processor has no idea what's going on in stores as the price is pre-negotiated. And most likely do not pay any attention whatsoever to what the grocers say, if they say anything. Absent these issues, the Norwegians could very simply either have ramped up their internal butter production or imported more to make up the shortage. It's a failure of planning, rather than production not being able to deal with a massively increased butter demand. The bump in demand itself is somewhat artificial since it's largely fueled by people worrying they won't have any butter for Christmas, and hence stockpiling, rather than people actually consuming more butter on average. I don't know how much the average consumption has gone up, but I would guess it's just a few percentage points and the rest is a consequence of people reacting to media coverage and poor flexibility in the supply system. \* In Sweden it's becoming common for organized crime to smuggle "groceries" to Norway, rather than drugs, due to the dysfunction and high prices of the Norwegian food market.

Ed M. (2011-12-11 11:50:33)

There is no shortage of butter, there is a shortage of free trade. See Angus at Kids Prefer Cheese: <http://mungowitzend.blogspot.com/2011/12/mars-needs-women.html> -Ed

Tom (2011-12-11 13:36:12)

This has been a concern of mine. With the growing paleo community praising grass-fed butter, how long before demand overwhelms supply?

Kim Øyhus (2011-12-11 15:54:31)

Our farmers here in Norway could actually have delivered the butter needed, but were prohibited from doing so through regulations with quotas. So in this particular case, it was a failure of state socialism, not capitalism. I agree that this is probably going to continue for a long time, so I better learn making my own butter. Currently I am eating some specially imported French butter. One of the really bad things about this, is that the shops now sells large amount of margarine, which is really detrimental to health, since it is made of chemically modified plant fats, something we are not built to handle well.

Jahed (2011-12-11 17:17:35)

Poor bastards, my heart goes out to them, I can't imagine being without Kerrygold!

dearieme (2011-12-12 04:52:40)

"...eat them with nose plugged in the bathroom. Taste is gone in 2 minutes": one could easily mistake that for some sort of obsessional food puritanism. Why not just enjoy some butter on your potatoes, on your veggies, on your steak, on your toast?

Lisa Wainer (2011-12-12 08:51:19)

On my way to work today, I stopped to buy some butter from a local supermarket (in the UK) - and they had run out! I hope this is just a coincidence ... :)

charles (2011-12-12 14:18:24)

Seth.. Have you ever experimented with Cream instead of butter? Easy to drink a lot of it.

Seth Roberts (2011-12-12 16:21:22)

Have you ever experimented with Cream instead of butter? Easy to drink a lot of it. No, but I switched from adding half and half to my tea to adding cream. I agree, it's worth trying. There is a practical problems: In Beijing, where I am now, I cannot get enough cream. I have to go to up-scale supermarkets to get butter. Even those supermarkets don't have much cream. There is also a theoretical problem: It's unclear why butter and cream should have different results.

Joe E O (2011-12-12 17:12:01)

Wow, I can't believe how BUTTER (and only butter) controls my insane hunger. I have been trying to lose weight via IF [intermittent fasting] - which has work great in the past but have been having a tough time with hunger....3 or 4 tablespoons of butter seems to do the trick.

Seth Roberts (2011-12-12 17:44:18)

Joe E O, that's very interesting. You write: Wow, I can't believe how BUTTER (and only butter) controls my insane hunger. I What else have you tried?

Joe E O (2011-12-13 04:54:51)

What else have you tried? In addition to adding butter to my diet I have tried the following: 1) Elimination of Wheat - very effective. Starting in 2008 - I have mostly eliminated wheat from my diet (not 100 % compliant). This has lead to an 80 lbs weight loss. I have been "stalled" for about a 18 months because of can't seem to manage my hunger. See Dr William Davis's blog "Wheat Belly" for details. 2) Vitamin D supplementation. Somewhat effective. I started the Vitamin D supplementation

before I eliminated wheat. I don't recall the effect on my hunger - but made a significant increase in my quality of life. (I am sure I was significantly Vitamin D deficient) 2) Higher Protein/Lower carb/Lower Fat i.e "Body Builder diet" (think veggies and lots of egg whites/chicken breast/pork loin ) Not effective 3) Fiber supplementation (Oat Bran, acacia fiber) - Not Effective 4) Coconut oil - Not particularly effective by itself - seems to work when used with butter. 5) BCAA supplementation - Effective (Expensive and inconvenient)

Seth Roberts (2011-12-13 09:27:25)

Thanks, Joe, that's very helpful information. Could I ask some more questions? What was your starting weight (before giving up wheat)? How tall are you? When you say you've been "stalled for 18 months", you mean you want to lose more weight but you haven't because you get too hungry? At what weight are you stalled? I understand that eliminating (most) wheat from your diet allowed you to lose 80 pounds. I gather that at some point you started to eat much more butter. When was that? How much butter do you eat? What effect has the butter had on your weight? I understand it has reduced your hunger. But has it also reduced your weight?

Maria (2011-12-13 10:26:16)

Seth, I find your blog very interesting. I am sure you've answered this question somewhere, but I couldn't find it. Is there anything specific about the type of butter you eat? I mean, is it raw, pastured-raised, is it sourced locally, is it organic or is it similar to standard (American) pasteurized grocery store butter?

Joe E O (2011-12-13 10:43:41)

Ouch....you want me to admit how morbidly obese I was? I am 5' 10" and at my heaviest I was 320 lbs (man that hurts). I am currently at or about 240. I need to lose 40 more pounds. I generally do not track my weight on a daily basis. My weight loss has happened in spurts. I lose twenty or so pounds over 6 or 8 weeks period and then more or less stall for a period of time. When I am losing weight I am in the "zone" - meaning that I am: a) managing my hunger (as being hungry all the time is stressful) b) exercising vigorously (circuit training with heavy weights) c) I am fasting (which I have found it the easiest way to eat less calories) I actually misspoke - I have been stalled for less than 18 month - more like a year at this point. The last time I lost weight quickly was in Sept/Oct of 2011 when I went from 269 to 250 in about 6 weeks...I have slowly inched down from 250 to 240 during 2011 (after really working out like a dog over the summer). As I indicated above during 2011 I have been trying different method to control my hunger (the high protein/low carb/low fat diet, fiber supplementation, coconut oil, bcaas) - none of them really worked. I have started using butter about 2 or 3 weeks ago and it seems to be doing the trick as it really kills my hunger and makes fasting "do-able" Peace, Joe E O

Joe E O (2011-12-13 11:56:00)

because sharing is caring...In addition to the above details.... I have more or less eliminated all corn/vegetable oils and consume a minimal amount of olive oil. This started when I eliminated wheat. I have been supplementing with fish oil 3 to 6 grams daily for several years now (See Dr William Davis's track your plaque program) I have tried SLD using extra light olive oil - didn't notice a difference in appetite. Over 2011, I have tended to avoid lots of raw cabbage (which I used to consume copious amounts) as it is a goitrogen - haven't notice difference in weight. As far as hunger goes - after wheat the substance that most stimulates my hunger is Whey Protein powder.....

Seth Roberts (2011-12-13 12:48:00)

Is there anything specific about the type of butter you eat? I mean, is it raw, pastured-raised, is it sourced locally, is it organic or is it similar to standard (American) pasteurized grocery store butter? I've tried all sorts of butter, including Amish butter (\$11/pound). I have found no difference between the expensive organic pasture-raised butter and the more common Land O'Lakes butter. I've never done a careful comparison, I've just never noticed a difference when I change butters.

Eric (2011-12-14 17:33:13)

Hey Seth, My wife has made either hong shao rou (pork belly cooked in soy sauce) or lu rou fan (pork belly chopped super fine w/ mushrooms and a ton of spice, then boiled for hours) 2x per week for a few weeks now. I've eaten more fatty pork in the

past few weeks than I've ever eaten in my life, but I haven't noticed any extremely dramatic sleep or brain changes. That said, I don't track either of these things in any rigorous way at all, although I might start doing so. Do you think 2x per week is enough to notice something?

Jason (2011-12-15 17:24:39)

Joe - Congrats on the weight loss! I've been vegan for 10+ years, and a couple of years ago I started to crave raw cabbage. I ate copious amounts of vingered quick pickled mexican cole slaw to satisfy those cravings, until I read about ice chewing, and started taking an iron supplement. After that, no more desire to eat huge quantities of raw cabbage. I'm sure it was the same mechanism that drives some people to chew on ice: anemia induced cravings for crunchy things (theorized to resemble chewing on cartilage) - If your cabbage eating was the result of cravings rather than the result of a conscious dietary choice, or if you still have similar cravings, consider an iron supplement. My bloodwork indicated I was at the low end but within the "normal" range of iron, but once I started the supplement, the daily desire to eat raw cabbage completely vanished.

Seth Roberts (2011-12-15 18:31:05)

My wife has made either hong shao rou (pork belly cooked in soy sauce) or lu rou fan (pork belly chopped super fine w/ mushrooms and a ton of spice, then boiled for hours) 2x per week for a few weeks now. I've eaten more fatty pork in the past few weeks than I've ever eaten in my life, but I haven't noticed any extremely dramatic sleep or brain changes. That said, I don't track either of these things in any rigorous way at all, although I might start doing so. Do you think 2x per week is enough to notice something?

No. The effect of pork fat on my sleep lasted just one night. In other words, my sleep Tuesday night depended on how much pork fat I ate on Tuesday, but not Monday. And it takes a considerable amount of pork fat (80 g? 100 g?) to easily notice a difference.

Maria (2011-12-16 14:13:19)

Interesting. With all the talk these days about different nutritional properties of different substances, it's very interesting that you're getting those good results with standard butter. Definitely a relief to my pocketbook! I find our blog very interesting and inspiring. I'm trying to get into the habit of doing some self experimentation myself.

## **Vitamin D3 and Sleep Update (2011-12-13 05:54)**

A month ago [1]I blogged about a "stunning discovery": Primal Girl's [2]sleep got much better when she took Vitamin D3 in the early morning instead of much later (afternoon or evening). [3]Others pointed out a similar observation: Taking Vitamin D3 in the evening caused insomnia. These observations suggest that Vitamin D3 resembles sunlight in its effect on sleep: morning exposure good, evening exposure bad. Sunlight, of course, is hard to control and sometimes hard to get (which is why Primal Girl tried Vitamin D3). Sunlight is also time-consuming: it takes an hour to get one hour of sunlight. The timing and dosage of Vitamin D3 is much easier to control.

Now I've tried it. This isn't the first time. I've taken Vitamin D3 on and off several times through the years. Each time I didn't notice any change so I stopped. But then I'd hear an interesting argument (never anything as clear as what Primal Girl found), and try again. And stop again. This time I took the Vitamin D3 around 8 am. (In previous attempts, I never controlled the timing and never took it early in the orning.) I started with 2000 IU/day. I did that for nine days. No clear effect. Then I increased the dose to 4000 IU/day. The change was unmistakeable: I started to wake up feeling somewhat more rested and, for the first time, with a pleasant warm feeling. So far it's been eight days. Something is different and better.

I am writing about this now because the results are already interesting. My experience so far "proves" nothing, of

course. Let me make clear the limitations: 1. You might consider the effect small. I was already sleeping well. I fell asleep quickly, did not wake up during the night, and woke up feeling rested. Now I wake up feeling more rested. 2. Eight days isn't much. Maybe the effect will go away. 3. Maybe the effect doesn't depend on time of day. I haven't yet tried taking Vitamin D3 at other times of day.

Why do I think this is so important?

1. Sleep is central to health. You fight off infection while you are asleep. [4]When I improved my sleep, I stopped getting noticeable colds. I'm sure if people slept better, they would get sick less often. Heart attacks are more common in the winter. People sleep worse in winter.

2. Sleep is a huge problem. As far as I can tell, most adult Americans complain about their sleep.

3. No one expected this. Nutrition researchers, dieticians, and so on obviously didn't expect it. Nor did circadian rhythm researchers. They (or we) think that everyone, including plants, has one or more internal circadian clocks that is/are synchronized (= set) by the environment. The general public thinks that sunlight affects the clock. Lots of research supports this, but circadian-rhythm researchers know something the public does not: that those rhythms are also affected by the time of food and social contact. All three (sunlight, food, social contact) are part of the environment. Their power over our sleep makes sense (e.g., we should be awake when food is available.) Vitamin D3 is not part of the environment. Its power doesn't make sense. No one in the paleo community expected this. Stone-Agers got a lot of sunshine, yes. They did not take Vitamin D3 pills. Sure, many in the paleo community praise Vitamin D3 but I have never heard anyone say you should take it in the morning.

4. Vitamin D3 is safe, cheap, and widely available. It probably has many benefits, not just better sleep.

5. Taking pills is easy. There presently are no safe sleeping pills. Nor are there any cheap sleeping pills. Nor will drug companies ever invent them, if the past is any guide.

---

MikeW (2011-12-13 07:30:25)

A note on your "safe, ... widely available" comment. It seems some folks still doubt D3's safety. When I order 2000 IU D3 online (from Swanson), I am warned it can't be shipped to Canada. Turns out Canada limits vitamin D capsules to 1000 IU. That seems silly to me, you can always take more than one. But I live in the US, so it doesn't matter. I only take D3 in the winter months, when Chicago's climate keeps me indoors most days. Usually at my first meal. I can't say I've ever noticed a difference on my sleep, but I've never tried more than 2000 IU/day.

gwern (2011-12-13 09:32:06)

MikeW: yeah, it is pretty silly. In old people, they've done acute doses of hundreds of thousands of IUs, with reductions in mortality. So... Chronic is not acute, that is true, but still. > 5. Taking pills is easy. There presently are no safe sleeping pills. Nor are there any cheap sleeping pills. Nor will drug companies ever invent them, if the past is any guide. What's wrong with melatonin?

Tyler (2011-12-13 09:40:57)

I will be trying this myself, keeping track of the timing and my sleep.

TD (2011-12-13 10:41:51)

Glad to see some science and disclosures and boundaries behind this finding, Seth. A short search on Nexus and others did not yield any scientific literature about this. I think I just have a knee-jerk reaction when someone reports on something and it's suddenly a "newthing." Could it be that Primal Girlz really did make a deliberate discovery by blogging about her experience? Could be. But now let's move on to other matters.

TD (2011-12-13 10:44:43)

I would also like to see more about D3 delivery methods and dosage. I currently take 10-15,000 IU/day and this seems perfect for me. Can you elaborate, perhaps in an eventual blog post so that the message is not buried in the comments, how do you take D3? Do you then have to eat something in the morning because it's fat-soluble? I don't like to eat in the morning, and I believe your personal findings also don't justify breaking the fast first thing in the morning. How to get D3 then?

Tim Beneke (2011-12-13 11:52:13)

I've been taking about 8,000 IU of it whenever I get up for several weeks now. I cannot separate out causes because I've also been losing about 2.5 pounds a week during this period, and have reduced my hemoglobin A1 C number (diabetes) substantially. But: I am amazed at the change in sleep, to wit, I need much less sleep and no longer need the roughly 1.5 hour nap in the afternoon. I do not have attacks of fatigue any more. I don't know if this is solely the effect of losing weight, or if the Vitamin D is playing a role. In previous weight loss experiences nothing so dramatic has happened, so I'm inclined to think that the Vitamin D is having an effect. Does anyone know at what levels Vitamin D intake becomes "toxic" or unsafe?

Seth Roberts (2011-12-13 12:33:06)

Tim, you wrote:

But: I am amazed at the change in sleep, to wit, I need much less sleep and no longer need the roughly 1.5 hour nap in the afternoon. I do not have attacks of fatigue any more. I don't know if this is solely the effect of losing weight, or if the Vitamin D is playing a role. In previous weight loss experiences nothing so dramatic has happened, so I'm inclined to think that the Vitamin D is having an effect.

With 4000 IU/day I have noticed I am less tired in the afternoon. But I still take a nap. You have convinced me to try 6000 IU/day. How much less sleep do you need? In other words, how much were you sleeping before you started the Vitamin D3 and how much are you sleeping now? Weight loss certainly reduces sleep need but it would still be nice to know the details here.

Seth Roberts (2011-12-13 12:43:41)

how do you take D3? Do you then have to eat something in the morning because it's fat-soluble? I don't like to eat in the morning, and I believe your personal findings also don't justify breaking the fast first thing in the morning. How to get D3 then? I take my D3 in 1000 IU tablets. Tablets, not capsules. I suspect tablets are digested faster. I do not eat anything else, although I have a small amount of cream an hour or so later. Yeah, D3 is fat-soluble. I suppose I have enough fat already in my system. I do not eat for several hours after I take the D3, just as you say.

Jonathan (2011-12-13 15:19:01)

"I suspect pills are digested faster." Seth: Dr. William Davis of Heart Scan Blog, who monitors his patients' blood levels of Vitamin D, claims that many pills don't budge the serum D—they don't get absorbed properly. He insists that Vitamin D should always be taken in oil (gelcaps or drops—I really like the Carlson drops, as I hate swallowing pills). He's done this monitoring with thousands of patients, so I trust his observations.

Jazi Zilber (2011-12-13 15:50:09)

the centrality of vitamin D is clear in the literature. Shortage of vitamin D is related to most mortality causes, and the evidence sounds that the vitamin shortage is causing the health issues. Also, vitamin D shortage is unnatural. Ancestors wore not that much cloth. in Africa there is much sun. and no long winters. Also, evolution changes northerners to blonds with pale skin to get more vitamin D. Also, evolution made northerners having more health negative cholesterol in order to absorb more vitamin D. Enough?

Seth Roberts (2011-12-13 16:59:16)

"I suspect pills are digested faster." Seth: Dr. William Davis of Heart Scan Blog, who monitors his patients' blood levels of Vitamin D, claims that many pills don't budge the serum D—they don't get absorbed properly. He insists that Vitamin D should always be taken in oil (gelcaps or drops—I really like the Carlson drops, as I hate swallowing pills). He's done this monitoring with thousands of patients, so I trust his observations.

I should have said "tablets" rather than "pills" but your comment still holds. Perhaps the fact that I eat a lot of butter explains why I am having good results with tablets – there is plenty of fat in my system already. Perhaps most of Dr. Davis's patients are on low-fat diets. And that is why they have trouble with tablets.

Tim Beneke (2011-12-13 17:15:01)

Hi Seth, You write: "How much less sleep do you need? In other words, how much were you sleeping before you started the Vitamin D3 and how much are you sleeping now? Weight loss certainly reduces sleep need but it would still be nice to know the details here." My best estimate is that I went from needing about 9 hours to about 7.5 hours of sleep which is about where I am now. Upon reflection, what is most striking is that it happened very suddenly, shortly after I started the Vit D. There was no gradual period where I needed shorter naps, no transitional period. Suddenly I didn't need the nap one day, and then didn't the next, until I observed that I needed 2 naps over a 2 week period – both times for various reasons I had gone to bed late and gotten up early and the naps were a function of sleep deprivation. It is hard to believe that the weight loss could cause such a sudden dramatic change. Over this period I have not been as good about getting actual morning sunlight, probably because I see myself getting it in a pill...

Seth Roberts (2011-12-13 18:56:39)

Tim, you write:

My best estimate is that I went from needing about 9 hours to about 7.5 hours of sleep which is about where I am now. Upon reflection, what is most striking is that it happened very suddenly, shortly after I started the Vit D. There was no gradual period where I needed shorter naps, no transitional period. Suddenly I didn't need the nap one day, and then didn't the next, until I observed that I needed 2 naps over a 2 week period — both times for various reasons I had gone to bed late and gotten up early and the naps were a function of sleep deprivation. It is hard to believe that the weight loss could cause such a sudden dramatic change.

I agree. That convinces me it was the Vitamin D, not the weight loss. I had a similar experience. One afternoon after I started taking it recently (at 8 am), I noticed I wasn't tired in the afternoon. I was surprised. I have still been taking naps anyway, even though I need them less. As I said I am going to increase my dose of Vitamin D (from 4000 IU/day to 6000 IU/day) to see the larger dose has a bigger effect. What brand Vitamin D do you use? Is it Vitamin D3? Is it gelcaps or tablets? How many IU's per pill? How much did it cost?

Tim Beneke (2011-12-13 20:18:14)

Hi Seth, I've been taking Vitamin D3 by Nature Made, tablets, 2000 IU each. I usually have a little bit of food with it, the mush I make, which has a fair amount of almond meal and flax meal and other stuff so that I'm getting fat with it. I grab anywhere from 4 to 6 tablets as soon as I'm up. (Yes, I'm that sloppy about it.) I don't recall the exact cost but I got this kind because the GNC health food store had a "buy 1 get 1 free" sale. I take the kind that is second from the left here:

<http://www.naturemade.com/Products/Segments/Vitamin-D> It was not terribly expensive, maybe \$15 for 440 tablets at 2000 IU each And FWIW: A group calling themselves "The Vitamin D Council" claims: "What exactly constitutes a toxic dose of vitamin D has yet to be determined, though it is possible this amount may vary with the individual. Published cases of toxicity, for which serum levels and dose are known, all involve intake of ? 40000 IU (1000 mcg) per day. 1 Two different cases involved intake of over 2,000,000 IU per day - both men survived." <http://www.vitaminDcouncil.org/about-vitamin-d/what-is-vitamin-d/vitamin-d-toxicity/> Sounds like little is known about Vitamin D toxicity.

Richard (2011-12-13 21:25:18)

Seth, Is it possible you need MORE Vitamin D (4000 worked but 2000 didn't) because you don't take it with food? I also noticed persistent insomnia when I ate Vitamin D containing foods in the evening, such as salmon and yogurt. I stopped eating those foods, and had no insomnia but I never made the connection until Primal Girl's experiences chronicled in your blog. I actually thought it was the flax seeds I added to the yogurt. Now I eat yogurt with flax seeds only in the morning, and my sleep is dramatically better. I swim several times a week at noon so my vitamin D levels are probably already high.

Seth Roberts (2011-12-14 04:31:34)

Is it possible you need MORE Vitamin D (4000 worked but 2000 didn't) because you don't take it with food?

It's not only possible, it's likely. But it's easy and cheap to take one more pill, so it makes little difference.

gwern (2011-12-14 08:53:13)

> No clear effect. Then I increased the dose to 4000 IU/day. The change was unmistakeable: I started to wake up feeling somewhat more rested and, for the first time, with a pleasant warm feeling. So far it's been eight days. Something is different and better. Incidentally, have I mentioned yet that you really ought to get a Zeo or even just one of those little motion trackers? That would make your sleep observations a lot more interesting.

wcb (2011-12-14 11:00:30)

Seth said: Perhaps most of Dr. Davis's patients are on low-fat diets. And that is why they have trouble with tablets. Actually Dr. Davis advocates a low carb diet for his patients, with a particular focus on eliminating wheat. Since there is a lot of interest in and discussion of how much D3 should be taken, I thought I'd mention that Dr. Davis advocates checking the serum level of vitamin D in the body by use of the 25-hydroxy Vitamin D test from time to time. He suggests one should target a blood level of between 50-80 ng/mL year round for best results. Obviously, as Dr. Davis points out, it is the serum level that is important, not the dosage which will vary by individual and time of year. On the other hand, I will admit that I dose myself by how I feel, rather than going through the aggravation of obtaining and paying for the test. :-)

Seth Roberts (2011-12-14 14:43:54)

Actually Dr. Davis advocates a low carb diet for his patients, with a particular focus on eliminating wheat.

The problem is that Dr. Davis fails to advocate a high-saturated-fat diet. So his patients accept the conventional wisdom that saturated fat is very very bad.

Sam (2011-12-15 02:04:44)

On our local packages there is no dosage in IU - How many micro-grams is 1 IU for vitamin D3?

JohnF (2011-12-15 10:00:12)

I've had some positive effects of an increased vitamin D-dosage (and/or fishoil) the last few days. brief history: Starting January I were at about 94 kg and 30 % bodyfat. Started doing light if (first meal 13-14 last meal 22), light exercise and some

bodyweight exercise. Lost some weight. Basically I'd start every morning with 1-2 cups of coffee with some milk and kept that up the whole time. By April I exchanged the light exercise for heavy weightlifting and also started eating much more protein. By August I was at 82 kg, lower bodyfat and much stronger. In early September I had a personal crisis and became somewhat depressed. Kept up the training and I, but started eating a lot of junk food and sugary drinks. Sometime in October I started taking fish oil caps, magnesium tablets and vitamin D3 gel caps. 4000 mg fish oil, 120 mg magnesium and 2400 IU D3, mostly taken in the morning or early part of the day. I didn't really notice anything different. (I'll note here that I live in Sweden and hence have very little sunlight exposure this time of year. I usually have very low energy during the winter.) By November I had gained about 12 kg, and while significantly stronger, clearly a big fat gain. Throughout October and November I'd become increasingly more listless, and in December it started becoming a big problem. At the level where I barely went outside and only did the dishes once a week and started missing the 2-3 times a week gym sessions completely. 2 days ago I upped the dosage in D3 to 4000 IU and doubled the fishoil intake to 4000 mg (about half being omega3). The first night I became more energetic and today the difference in energy level is HUGE. I've cleaned the apartment, cooked a bunch of food and my level of anxiety has dropped by a lot. The only negative is that I do feel a small excess of slightly nervous energy and the need to move. It's nowhere near a panic attack or manic state, but a little unpleasant (though far better than being lethargic). I haven't thought much about the sleep aspect, as far as I can recall I've slept OK the last few months, with some early awakenings. Last night and today I've woken up at 9 and 10:30, though I haven't noticed anything different about the actual sleeping.

JohnF (2011-12-15 10:14:41)

My diet is very heavy on somewhat to very fatty cuts of meat, something like an average 4 eggs a day, fairly large amounts of dairy fat (whole milk, butter, cream and fermented cream), a little fruit, some vegetables, occasional potato or rice. Sugary drinks and junk food = Coca-Cola (almost every day during the last few months), crisps (maybe 250-500 g a week), chocolate bars (4-5 a week). Mostly eaten to lessen anxiety, but occasionally due to intense cravings.

Guv (2011-12-15 15:05:33)

Sam, 25 mcg (micrograms) Cholecalciferol (Vitamin D3) = 1000 IU. You can work the rest out from there.

Guv (2011-12-15 15:39:09)

I read/heard that high doses of Vitamin D3 can increase urination. Though I cannot find the source of this info. So I do not know what the definition of a 'high dose' is in this case. Just something to be aware of though as you increase your D3 intake. If you find yourself getting up in the night to go to the toilet this could be a factor.

Guv (2011-12-15 15:48:14)

interesting post from Dr Kruse...including some info headed "How do you tell if you are taking too much Vitamin D to get to optimal?". Here's some of the text: "...Vitamin A deficiency affects vision by inhibiting the production of rhodopsin, the eye pigment responsible for sensing low light situations. Rhodopsin is found in the retina and is composed of retinal, which is an active form of vitamin A, and opsin a protein made by the retina. Basically, if you "over do" the use of Vitamin D3, you will not make enough rhodopsin (from a relative Vitamin A deficiency) and you will suffer from night blindness. I pick this up in patients who notice night time visual driving issues....." <http://jackkruse.com/what-can-you-find-about-your-own-health/> Paul Jaminet has also mentioned the A/D3/K2 balance in his posts & book.

Pippy (2011-12-23 23:54:13)

Late to the party here, but wanted to report my experience. I was feeling really down and depressed without knowing why when this post came out. Then I realized that I just don't get enough sunlight at this time of year, so I started on 5000 IU of D3 in the morning (Nature's Bounty Brand, gel caps, with breakfast) and the difference in my mood is amazing. I have much more energy and depressive thoughts are gone since I started on the D3. The difference was noticeable in 2 days. No apparent

difference in sleep or weight for me, however. Thanks for the reminder of the importance of vitamin D.

Adilah (2011-12-24 03:00:52)

Hi Seth, MOOD: I've been taking vitamin D for about a month now. When I first started taking it (1000-2000 IU), I noticed that my mood improved. I was getting depressed I think... there was a very heavy feeling, but I couldn't explain why that was the case or what I should do about. However, it was a very similar feeling to what I had years before when I had a very long depression, so I was quite sure I was walking down the path again. After regularly taking vitamin D as soon as I woke up, my mood improved considerably. It is like the heaviness just disappeared. I did not yet notice improvements in my sleep however, until I upped the dosage to 4000 IU. SLEEP: Since being on 4000 IU (taken as soon as I woke up on an empty stomach with a glass of water or green tea), I have noticed remarkable changes in my sleep. The first is that, as you and Primal Girl have put it, I started feeling sleepy by 9-10PM. As a night owl who sleeps at different hours (although always sleeping for 8 hours no matter), it was an interesting feeling to receive these indicators from my body that I should sleep at 9-10PM. However, I do not always comply with these indicators (see 3rd point). Secondly, like Guv mentioned above, I started waking frequently to urinate at night. This somehow always occur around 5-6AM. Thirdly, I have been measuring my sleep-wake interval for about 2 months now. In the period that I took 4000 IU, I noticed that my sleep quality improved drastically! Despite waking at night to urinate AND despite nights where I only managed a total of 6 hours sleep instead of 8, I would wake up with lots of energy! It was the kind of waking up from a sleep then feeling, "Oh, I cannot go back to sleep anymore now, let's get out of bed", whereas before, any time I slept less than 8 hours, I just could not get out of bed, was not alert, wanted to continue to sleep.... For me this effect is quite remarkable. I'm going to continue measuring this effect. I am also considering lowering the dosage to see what will happen.

Adilah (2011-12-24 03:09:30)

Hmm I was debating whether I should mention this because it is only a hypothesis on my part at the moment. On the days when i slept less than 8 hours but still woke up feeling very awake, I felt like my body WANTED to wake up despite whatever amount of sleep I got. It seems as if my body has shifted from a sleep-quantity state to a state where it needs to be awake no matter what at a certain time. I'm not sure if I am explaining this well. It is like the reverse of the sleep-indicators that my body was telling me around 9-10PM that I should sleep. Instead of telling me to sleep, it is now telling me to wake... For me this is quite a marked change. I have tried, unsuccessfully, for many years, to regularize my wake hour. My body used to refuse to be awake unless I had 8 hours of sleep. That 8 hours was so constant, it seemed as if ingrained in my body that I need 8 hours of sleep otherwise I would wake up in a "fog". Also, when I used to sleep without the alarm clock, I would wake up after 8 hours of sleep, no matter whatever the time I slept was. Now however... I think there is a subtle change. Instead of 8-hours quantity, my body seems to go by a different signal. I am not quite sure what it is. I have only noticed this recently and am still investigating it, however, I decided to type it up as well in case anyone else has had the same effect or any theories as to why this is occurring.

### **UC Berkeley Joke (2011-12-14 04:35)**

From a Berkeley professor: "On Monday, Wednesday, and Friday, we have budget cuts. On Tuesday and Thursday, student protests. On the weekend, police brutality."

## Gelman and Fung versus Levitt and Dubner: How "Wrong" is Freakonomics? (2011-12-15 05:00)

In the latest issue of American Scientist, Andrew Gelman (an old friend) and Kaiser Fung [1]criticize Freakonomics and Superfreakonomics by Steve Levitt and Stephen Dubner (who [2]wrote about my work). Although the article is titled "Freakonomics: What Went Wrong?" none of the supposed errors are in Freakonomics. You can get an idea of the conclusions from the title and this sentence: "How could an experienced journalist and a widely respected researcher slip up in so many ways?"

Gelman and Fung examine a series ("so many ways") of what they consider mistakes. I will comment on each of them.

1. The case of the missing girls. I agree with Gelman and Fung: Levitt and Dubner accepted Emily Oster's research too uncritically.
2. The risk of driving a car. I think Gelman and Fung miss the point. Yes, the claim (driving drunk is safer than walking drunk) was not well-supported by the evidence provided because the comparison was so confounded. However, I read the whole example differently. I didn't think that Levitt and Dubner thought drunk people should drive. I thought their point was more subtle – that comparisons are difficult ("look how we can reach a crazy conclusion").
3. Stars are made not born. I think Gelman and Fung fail to see the big picture. The birth-month effect in professional sports, which Gelman and Fung dismiss as "very small," is of great interest to many people, if not to Gelman and Fung. It suggests what Levitt and Dubner and Gladwell and others say: Early success matters. That's not obvious at all. There are lots of similar associations in epidemiology. They have been the first evidence for many important conclusions, such as smoking causes lung cancer. Are professional sports important? Maybe. But epidemiology and epidemiological methods are surely important. By learning about this effect, we learn about them. Lots of smart people fail to take epidemiology seriously enough (e.g., "correlation does not equal causation").
4. Making the majors and hitting a curve ball. Gelman and Fung point out that one sentence is misleading. One sentence. This is called praising with faint damn.
5. Predicting terrorists. Gelman and Fung say that the terrorist prediction algorithm of a man named Ian Horsley, which Levitt and Dubner seem to take seriously, is not practical. But their review fails to convince me it was presented as practical. Since there are no data about how well the algorithm works, and Levitt and Dubner are all about data....
6. The climate change dust-up. I agree with Gelman and Fung that Nathan Myrvoid's geoengineering ideas are unimportant. ([3]My view of Myrvoid's patent trolling.) But in this case, I'd say both sides – Gelman and Fung and Levitt and Dubner – miss what's really important, namely that the usual claims that humans are dangerously warming the planet are held far too strongly. The advocates of this view are far too sure of themselves. I have blogged about this [4]many times. In a nutshell, the climate models that we are supposed to trust have never been shown to persuasively predict the climate ten or twenty years from now (or even one year from now). There is no good reason to believe them. That Levitt and Dubner seem to take that stuff seriously is the only big criticism I have of their work . At least in that geoengineering stuff Levitt and Dubner were dissenting from conventional wisdom. Gelman and Fung do not. They fail to realize that something we've been told thousands of times is nonsense (in the sense of being wildly overstated). It was Levitt and Dubner's comments about this that led me to look closely at all that climate-change scare stuff. I was surprised how poor the evidence was.

The biggest problem with Gelman and Fung's critique is that they say nothing about the great contribution of Steve Levitt to economics. They fail to grasp that he has made economics considerably more of a science, if by

science you mean a data-driven enterprise as opposed to an ideologically-driven or prestige-driven one (mathematics is prestigious, the more difficult, the more prestigious). He did so by pioneering a new way to use data to learn interesting things. His method is essentially epidemiological, except his methods are considerably better (better matching, less formulaic) and his topics much more diverse (e.g., sumo wrestling) than mainstream epidemiology. A large fraction of prestige economics is math, divorced from empirical tests. [5]This stuff wins Nobel Prizes, but, in my and many other people's opinion, contributes very little to understanding. ([6]Psychology has had the same too much math, too little data problem – minus the Nobel Prizes, of course.) To persuade a big chunk of an entire discipline to pay more attention to data is a huge accomplishment.

Levitt's methodological innovation makes Freakonomics far from what Gelman and Fung call "pop statistics". It is actually an amusing and well-written record of something close to a revolution. In the 1980s, a friend of mine at UC Berkeley took an introductory economics class. She told me a little of what the teacher said in class. All theory. What about data? I said. It's a strange science that doesn't care about data. My friend went to office hours. She asked the instructor (a Berkeley economics professor): What about data? Don't worry about data, he replied. Gelman and Fung fail to appreciate what economics used to be like. The ratio of strongly-asserted ideas to persuasive data used to be very large. Now it is less.

Thanks to Ashish Mukharji.

Adam (2011-12-15 05:11:38)

All of science is based on correlation, not causation. Causation can't be proven. We can only say that something is very unlikely to be due to chance (i.e.  $P < 0.005$ ) and has a rational explanation.

dearieme (2011-12-15 06:01:09)

As you know, they are not Nobel prizes, the economics ones. The fact that economists insist you call them Nobel prizes is testimony to that profession's attitude to the truth.

Wilbur (2011-12-15 08:10:06)

I read the American Scientist article and found it unseemly. Levitt and Dubner's shtick is to popularize ideas they find interesting. Neither the book nor the blog can be held to the same standards as peer reviewed literature. Gelman and Fung's criticism reminds me of the way so many PhD's used to nitpick Marilyn Vos Savant's column during its heyday. There were entire blogs devoted to pointing out her supposed errors. It was just a column in Parade, for God's sake, a publication used mostly to line bird cages. Intellectuals should have celebrated the fact that Middle America was being exposed to some mathematics instead of factoids about celebrities. In today's intellectual climate, dissenting from the conventional wisdom on global warming is about the worst sin you can commit. I'm sure you know this. The fact that Gelman and Fung saved the geoengineering stuff for last suggests to me that that was their main problem with Freakonomics. Bringing up the fact that scientists in the 1970s were worried about global cooling might just lead the reader to suspect that science doesn't know everything about climate. And we can't have that now, can we.

charlie (2011-12-15 11:09:01)

and the number of things outside experts can poke hole in is very limited.

## **Justification For Self-Experimentation and My Belief that N=1 Results Will Generalize (2011-12-16 05:00)**

At the Quantified Self blog, in response to [1]a video of me talking about QS and the Ancestral Health Symposium (paleo), someone named Colin made [2]the following comment:

Very interesting talk. I am just curious how someone can claim a study conducted with a sample size of one is "100 times better" than someone else's study. I do not know anything about the other study mentioned, but I do know that a study based on  $n=1$  cannot be considered scientific proof. And sure, he hears from people who have lost weight drinking the sugar water he prescribed, but it is quite possible there are 100 times as many people who didn't email him because they didn't see any positive results and decided to try something else. I think the QS stuff is very interesting and helpful on a personal level, but it seems like a stretch to generalize your results to others.

I responded:

I have two responses.

1. Sample size isn't everything. Sure, a study with  $n=1$  isn't "scientific proof". Nor is any other study, in my experience. "Scientific proof" has always required many studies. New scientific ideas have very often started with  $n = 1$  experiments or observations. Later, larger experiments or observations were done. Both — the initial  $n=1$  observation and the later  $n = \text{many}$  observations — were necessary for the new idea to be discovered and confirmed.

2. The history of biology teaches there are few exceptions to general rules. See any biology textbook. For example, a textbook might say "lymphocytes fight germs". This means no serious exceptions have ever been found to that rule. So, as matter of biological history, the person who managed to figure out what one particular lymphocyte does turned out to have figured out what they all do. Biology textbooks have thousands of statements like "lymphocytes fight infection" meaning that this sequence of events (you can generalize from one to all, or nearly all) has happened thousands of times. There is no shadow hidden history of biology that teaches otherwise.

1. <http://quantifiedself.com/2011/10/seth-roberts-on-qs-paleo>

2. <http://quantifiedself.com/2011/10/seth-roberts-on-qs-paleo/#comment-3984>

Eric (2011-12-16 05:40:09)

I think the first response is much more convincing than the second, and is really all that needs to be said on the topic. You might also explain that  $n=1$  is much better than  $n=0$ , and that many of the things QS folks are studying simply wouldn't be studied at all if they weren't doing it on their own! The second response seems shakier to me. The person who figured out what lymphocytes do must have done so with a series of observations that weren't so conclusive, and any one of them might have been NON-generalizable. Only once they were shown to be generalizable after all could they be used to support the conclusion that lymphocytes fight germs, for ex.

Jay (2011-12-16 09:29:31)

I think " $n=1$ " self-experimentation is entirely consistent with a Bayesian framework, which is all that is needed to claim the approach is scientific. A pet peeve along those lines: too many people get away with the phrase "scientific proof." Science is inductive inference etc etc Also, I thought you would respond by mentioning that 1 subject is different from 1 observation. Hundreds of observations can be observed from one subject and still be "scientific". No neuroscientist complains that H.M. was just "one" subject.

Tuck (2011-12-16 13:09:06)

Marshall got a Nobel for  $N=1$ ...

Jazi zilber (2011-12-17 01:39:48)

limits to  $n=1$  1) it is expected that very many changes will work specifically to specific persons. Hence, much Of the promise of self experimentation is exactly is that. For some people eating carbs for example makes them healthier (with limitations), for reasons related to complexity and individuality. There is a lot of situational I agree that many  $n=1$  things will replicate. But I think that many are inherently individualistic. 2) there is nothing to be ashamed about individualistic effects. The generalization is that for anyone there are some things that can be found. Ad that lack of evidence in others does not imply it will not work for this person.....

Txomin (2011-12-17 04:08:11)

What is scientific (or not) is the method. Proofs can be obtained by means of the scientific method on a  $n=1$  or  $n=100$  basis. It makes no difference.

Jazi zilber (2011-12-19 00:22:56)

3) you can get statistically significant results with  $n=1$ . Ayne who does not get this is an imbecile. There are limits. But the limits are limited. 3.1) generality. Indeed, the formal claim of an  $n=1$  result is local. This is what is verified. Yet, like any scientific result it may be true for other similar cases..... Other limit not now on my mind. Note the difference between my tone and the "non scientific" nonsense. There is a confusion between "instruction for making the perfect experiment" and "scientific". There are endless instructions students get, most of them irrelevant to study validity. Maybe 20 % of the instructions are relevant to validity (i.e. blinding, deciding the measures in advance, etc.) while most (i.e. ethics committee, balancing for sex and hair color etc.) are niceties. What happens is that students get entrapped in the whole instruction set. 1) they lose the sense of what and why is scientifically important. 2) experiments are perceived and taken as much harder than they should scientifically be

Colin (2011-12-20 21:38:00)

Interesting, of course the hard part about experiments, research, studies and trials where  $N=1$  is doing it all with the blindfold on.

### **Sleep, Mood, Restless Legs and ADHD Improved By Internet Research (2011-12-19 03:13)**

At the SLD forums, [1]Anima describes using several safe cheap treatments to improve his mood and sleep. First, he tried wearing blue blocker (amber) glasses in the evening. They made him fall asleep more easily and reduced or

eliminated hypomania. However, he was still depressed. Second, he tried getting twenty minutes of sunlight early in the morning. His mood improved. But he still had trouble synchronizing his sleep/wake cycle with the sun – that is, being awake during the day and asleep at night. He would stay up an hour later every night and wake up an hour later every day, meaning that half the time he was asleep during the day and awake at night. Finally, he tried adjusting when he ate:

I recently found the missing key to this: meal timing. I saw a talk that Seth gave where he talked about curing his problem with waking too early by skipping breakfast. My problem was difficulty waking. I read an article that suggested that our circadian rhythms are not just tied to light, but to food times as well. I used to eat late at night and never eat breakfast. I started eating breakfast immediately upon waking (ick) and stopping all food at least 12 hours before I wanted to wake. Basically, I did what Seth did only opposite. It worked. . . . I was even able to adjust my cat's circadian rhythm – he used to wake me up too early for his breakfast – by gradually moving his supper time.

In [2]another post he describes using B vitamins to treat his restless legs syndrome and ADHD:

I have been taking a supplement with all the B vitamins in amounts much higher than typically recommended. I have also been taking Epsom salt baths for magnesium. I have not experienced restless legs AT ALL since starting. This is quite remarkable to me, because it was such a problem. My ADHD is also much improved.

The idea of treating restless legs syndrome with niacin (a B vitamin) came from [3]Dennis Mangan. Anima had noticed that ADHD and restless legs syndrome often occur together.

He makes some reasonable comments about psychiatrists:

Why are psychiatrists still acting like neurological problems exist in isolation, when clearly they are all related? [In the sense that you can use what is known about how to cure Problem X to help you cure Problem Y, if X and Y often occur together.] I used to take Lamictal, Depakote, Adderall and Ambien every day. That doesn't include all the meds I tried that didn't work. I'm currently wearing amber glasses at night and taking a B complex, flax oil (SLD-style) and bathing in epsom salts three times a week. My mood is more stable than it was on medication, and my ADHD is controlled about the same. My sleep is much better. My psychiatrist told me that I would be on medication for the rest of my life. When I told him that I was using dark therapy and light therapy and had stopped taking my medication, he told me that I was "playing with fire," and that I would end up in a mental institution or commit suicide if I didn't resume my medication, despite the fact that I had stopped taking it for longer than it would be effective. I asked him if he had read the research on dark therapy. He hadn't, but he assured me that it is pseudoscience. I guess the definition of "pseudoscience" is any treatment that doesn't make him money. I puckishly asked him if I seemed manic or depressed, and he was forced to admit that I did not.

The ability of this psychiatrist to ignore contradictory evidence in front of him resembles [4]what happened to Reid Kimball. He told a UCSF gastroenterologist that he was successfully managing his Crohn's with diet. In my experience, Crohn's can't be managed with diet, the doctor said at the end of the appointment.

Just Me (2011-12-19 08:31:35)

The book "The Brain That Changes Itself" had a fascinating bit about attention deficit - researchers found that having kids memorize long poems and practice a new alphabet (handwriting, not computers) was more effective than drugs for treating AD - the author remarked that a generation ago, it was common for kids to learn poetry (most of our grandparents can still recite poems they had to memorize for school) and of course, there was great emphasis on penmanship. These things were jettisoned in the sixties, when educators figured the typewriter and recording devices rendered these skills unnecessary.

Ed (2011-12-19 11:04:27)

Hello Seth, Thanks for this post and your writing on this site. Have you tried using the Vitamin D in the morning and the leg stands together for better sleep? After reading for a while I started taking Vitamin D in the morning. I have been using the sleep cycle app on my iPhone. Yesterday I walked about 9.5 miles, and I fell asleep quickly and woke up rested, and according to my app it seemed I sleep more deeply as well. Have you heard of anyone mixing vitamin D and walking?

BlueMorrissey (2011-12-19 11:05:12)

As someone who is bipolar, I look forward to trying these suggestions. I have not had depression since using Seth's suggestions on morning faces. The only problem has been some mania and anxiety. I have these same problems with sleep. Going to bed very late and sleeping very late. Started back on ambien recently. Cutting out sugar has really seemed to help my anxiety of late. I realized I had really increased my sugar intake when my anxiety began. Of course starting back exercising has helped too. Cold showers helped my depression last year at this time. I was off medication for the first time in 9 years this summer, but the aforementioned problems from life stresses led me to get back on Cymbalta and Lamictal along with use of xanax when needed. The xanax seems to be the only thing that helps. Hope to eventually be able to get healthy on natural remedies only. Slowly and carefully.

Nancy Lebovitz (2011-12-19 14:15:46)

One more thing that might not be incurable- I can make tinnitus stop for months by relaxing the big neck muscle on the same side as the ear. I generally just move my attention down that muscle a number of times, but massage or visualization might be worth exploring, too. Writing this makes me realize that I should explore moving my attention along other muscles I want to relax. Note- I've never had major exposure to loud sounds, the tinnitus seems to be related to anxiety, perhaps especially anxiety about money. Another note to make all this more plausible- when I move my head, I've occasionally felt the way neck muscles connect to my ear.

Tom (2011-12-19 23:14:13)

*guess the definition of "pseudoscience" is any treatment that doesn't make him money.* Best quote ever.

Joseph Buchignani (2011-12-23 17:34:43)

This worked for me. I can't take vitamin D pills, but limiting nighttime blue light exposure gets me to sleep faster, and eating quickly after waking and stopping eating 12 hours before I want to wake up allowed me to shift my Circadian to normal hours. Awesome!

Anima (2011-12-24 17:07:17)

I am honored that Seth has referenced my posts on his blog, but I wanted to make one minor correction: I'm a girl. (I chose the user name because of Carl Jung's use of it, but I can see how it could be confusing, because men have an anima, but it represents feminine qualities.) My gender is not salient, but ADHD manifests differently in women, and both it and Non-24 are

far more prevalent in males, so I think it worth noting.

fot (2011-12-20 07:27:16)

Finkelstein's career has been ruined ever since he started taking on the powerful Israeli lobby. Several universities have been pressured out of hiring him. Meanwhile a liar and fraud like Dershowitz has a comfortable well paid seat at Harvard where he advocates legalized torture. With the recent death of Christopher Hitchens Steve Sailer wrote that no one has paid a price for being wrong on the Iraq war, - and no one who was right (that it would be a disaster) was rewarded or even acknowledged. Likewise, to date, not one top figure in the mortgage meltdown/crisis has gone to jail, despite obvious criminal activity. This is what a corrupt society looks like.

Jay (2011-12-20 09:03:18)

Thank you for the South Korean article – very interesting read.

dearieme (2011-12-21 02:06:41)

Does anyone like Dershowitz? Even his mother?

garymar (2011-12-21 05:51:39)

That South Korean article reminded me once again that South Korea is so much like Japan – just smaller and a lot more intense!

## Two Years on the Shangri-La Diet (2011-12-21 05:00)

Alex Chernavsky, who often comments here, has updated [1]his Shangri-La Diet (SLD) page. It now shows his weight over four years: two years before he started SLD and two years that he has been doing it.

Before he started SLD he was slowly gaining weight. After he started SLD, he went from 220 pounds (BMI = 32) to 193 pounds. He slowly gained a few pounds. Then (on my advice) he added a tablespoon of nose-clipped coconut butter and the steady climb stopped. Ffor about nine months has been steady at 195 pounds (BMI = 28). In other words, there is no sign that he is regaining the lost weight.

Because Alex has added a lot of omega-3 to his diet (via flaxseed oil), I'm sure his health has improved in other ways. Because he is a vegan, he had no interest in a conventional (Atkins) low-carb diet.

Alex reminded me that a doctor named Quigley left [2]the following comment:

I've tried to find data that your diet works for SUSTAINED weight reduction in a study that would be applicable to a generalizable population. As you know, temporary weight loss is relatively easy. Sustained weight loss (wt loss > 2 yrs), is hard. If your diet can do it, I'd prescribe it every day.

Michal (2011-12-21 05:52:27)

We should hold ourselves up to a higher standard. This guy sounds like he is still fat.

Alex Chernavsky (2011-12-21 06:11:55)

This is what I look like now. (This is the only full-body shot I could find.) [http://www.astrocyte-design.com/shangri-la-diet/alex\\_2011.jpg](http://www.astrocyte-design.com/shangri-la-diet/alex_2011.jpg)

August (2011-12-21 07:39:20)

Dr. Quigley should read my thread as well. I did SLD throughout my weight loss (I think that took about two years) and have been weight stable via eating paleo for the past two years at around 170 (it fluctuates a bit but always goes back down). I started at 285. I'm 6'3. If Dr. Quigley were actually the sort of person who understood he at least could be wrong, I'd be happy to talk to him. The difference between the old me and the new me is so striking that it shocks even me when I look in the mirror, and I find myself having to get comfortable with getting a lot more attention. Unfortunately, very few people appear to be able to take the transparently obvious evidence before their eyes.

Stephen M (Ethesis) (2011-12-21 09:58:28)

btw, <http://www.facebook.com/group.php?gid=47847323770> August, same here.

Steph (2011-12-21 16:01:44)

As I have just sent two copies of the book off to family members, I'm glad to see that the diet works in the long term. Thank you, Alex, for sharing this.

### **More Neglect of the Immune System: Bioterrorism Fear (2011-12-23 05:00)**

At UC Berkeley several years ago, I learned about an introductory epidemiology class. I knew the professor. I phoned him. "Are you going to discuss factors that make the immune system work better or worse?" I asked. "No," he said. I wasn't surprised. In my experience, epidemiologists completely ignore this question. As if the immune system had never been discovered. It sounds absurd, but there it is.

Epidemiologists aren't the only ones. All well-publicized attempts to "battle" or "combat" or "defeat" or "beat" viruses, such as cold or flu viruses, neglect this possibility, in my experience. Whole books on the subject do not mention the immune system. The latest example of the blindness is [1]an article by Michael Specter at the New Yorker website about fear caused by discovery of how to make a bird flu virus spread more easily. Maybe the knowledge could be used by terrorists. Specter writes as if the immune system doesn't exist. He doesn't mention it and ignores the possibility of defending against new viruses by improving immune function. For example, he writes:

Instead of focussing so heavily on human terrorists, we ought to take this opportunity to defeat a natural pathogen—one we can now recognize and manipulate with all the sophistication of molecular biology.

You don't need molecular biology to study immune function. He also writes:

There are three conditions necessary for a flu outbreak to become a deadly pandemic, like the one in 1918 that killed between fifty and a hundred million people. Those conditions rarely converge. First, a new virus—one that has never before infected humans and to which nobody would have protective antibodies—must emerge from the animal reservoirs where they originate. That virus has to make people sick. (The vast majority do not.) Finally, it must be able to spread rapidly and efficiently—through a cough, a handshake, or a kiss.

He writes as if whether a virus makes people sick and spreads rapidly depends solely on the virus. This is false: How well your immune system is working makes a big difference. If a virus is fought off quickly, you won't notice – you won't "get sick". Because you are infected more briefly, you will spread it less. (Possibly much much less. If a virus doubles in number [2]in 4 hours, then two fewer days of infection equals a huge reduction in the number of virus particles inside you while you are contagious.)

In this blindness, I'm sure Specter reflects the blindness of the scientists he talks to. They simply talk and think about what they do, which is molecular biology.

I became aware of the power of improving the immune system [3]when I improved my sleep and stopped getting colds. More recently, I have become sure that eating fermented foods improves immune function. I suspect that a lot of traditional medicine, such as Traditional Chinese Medicine, is effective because it improves immune function. (For example, [4]the use of bee venom to treat arthritis.) Everyone knows at an answer-test-question level that the immune system exists. A lot has been learned about how it works. But the vast majority of doctors and other health experts (and journalists) ignore this knowledge in practice.

Charlie (2011-12-23 06:56:26)

You conflating two things. You get bird flu, you die. No immune boosting there. More lucky genes. Is herd immunity better for populations or better health overall. A bit of both. The difference between individuals and groups.

Adam (2011-12-23 07:59:27)

Antibodies aren't the only mechanism of immunity. What exactly is Seth "conflating" (sic)?

Greg Harrington (2011-12-23 09:58:15)

Any thoughts on how a layperson can track/measure "immune function"? Seth has mentioned several times that he "stopped getting colds", but this is a pretty long-term measure. Any thoughts on some type daily measure of "immune function"?

Seth Roberts (2011-12-23 12:57:31)

Any thoughts on how a layperson can track/measure "immune function"?

I've looked into this. I have been unable to find a practical measure other than measuring how often I get sick and when I get sick how fast I get better.

Tim Beneke (2011-12-23 13:05:51)

Robert Trivers has a book out on self deception that focuses a lot on the immune system: "The Folly of Fools: The Logic of Deceit and Self-Deception in Human Life" [http://roberttrivers.com/Robert\\_Trivers/Welcome.html](http://roberttrivers.com/Robert_Trivers/Welcome.html) He spoke at Microsoft recently. <http://research.microsoft.com/apps/video/dl.aspx?id=156489> About 28 minutes in, he starts talking about self deception and the immune system. It is empirically clear to him that engaging in self deception (which we do primarily to successfully maintain deception of others, which has advantages) or holding in deep dark secrets for that matter, harm the immune system – but he does not yet know why or how it is biochemically mediated. He is looking for chemicals that are active in the brain and immune system to find an answer. He also looks at Pennebaker's work showing that writing about painful experiences initially lowers your mood because it is painful; but simultaneously improves your immune system. And over time your mood catches up with your improving mood system. Improving the immune system improves mood. No surprise – poor sleep and poor nutrition both harm mood and the immune system. The concept of immune function is one that needs clarification. Dean Edell, the doctor who had a call-in show and who reviewed medical findings, is scientifically very conservative in making claims and generally wants strong, controlled, double blind, research before he will endorse things. He is to me, competent at that conventional, rather uncreative level of analysis. When someone would claim that a substance would "enhanced immune function" or "strengthen your immune system" he saw this as either nonsense, or as negative, meaning that it would cause auto-immune dysfunction and disease. He could not give "strengthening the immune system" a positive, substantive meaning or interpretation. Yet the evidence is now clear that certain things protect us from disease. Perhaps most strikingly, being happy, according to Ed Diener and others, correlates with a longer life by a number of years. The "immune system" must be many different systems operating together.

Duncan (2011-12-23 13:24:05)

I read an article some years ago (partly) about the Australian swimming team, in New Scientist. I believe it said they regularly measured the athletes' IgE levels as an indicator of their immune system function. Low levels suggested vulnerability to infectious disease and they were prescribed light training until levels recovered. Prior to this, swimmers suffered colds as often as once a month because they didn't know when they were overstretching themselves. Unfortunately I can't access the article online, so my memory may be betraying me somewhat. I have the notion that it was a salivary test, but I haven't been able to find any kind of testing kit that would be available to the layperson, or even the medical professional. (Presumably the swimmers were tested daily, with fast turnaround of results.)

Seth Roberts (2011-12-23 14:10:07)

Thanks, Duncan. I have heard of IgE levels being used to measure immune function, but not in such a practical way. I don't know of any easy way to measure them.

Brice (2011-12-23 17:13:43)

An interesting and related anecdote just today at <http://www.jamesaltucher.com/2011/12/how-i-cured-my-constipation/> regarding immune system, Lyme disease, western medicine

Sheila Buff (2011-12-23 17:18:03)

The great influenza epidemic of 1918 killed the young and healthy in disproportionate numbers precisely because they were young and healthy and had good immune systems. The disease provoked an overwhelming immune system overreaction that killed quickly. (See *The Great Influenza* by John Barry for details.) So maybe boosting your immunity, assuming that can actually be done in any meaningful way, could be detrimental in some cases.

Ruth @ Ruth's Real Food (2011-12-23 23:36:53)

The 1918 general public were born vaginally, breastfed, never exposed to antibiotics. These people ate home cooked meals, many ate raw dairy and homemade fermented foods. The livestock they got their meat from wasn't raised in a huge factory, fed the wrong foods. They were doing all the right things (because that was the only option) except that they probably ate too much white sugar and flour and had some bad oils. All in all, they were already doing much of what I'm doing to promote good gut health and a good immune system, yet the death rate from the influenza epidemic was enormous. I completely agree that you can't talk about epidemiology without considering the immune system, but a good immune system can't ward off everything.

Eugene Woodbury (2011-12-24 11:30:06)

From the mid-19th century to the early 20th, Japan experienced cholera epidemics on the scale of the 1918 flu pandemic. This was probably the result of populations exploding in the cities. I've heard Japanese unironically compare the British engineer W. K. Burton, who designed Tokyo's first modern sewer system, to Jesus. Another critical factor is that early in the 20th century, rickets had reached epidemic proportions across the "developed world" due to changes in diet—especially an emphasis on processed grains—and lack of exposure to sunlight in the cities. In Japan, beri-beri, also related to dietary "improvements" (polished rice), became endemic.

Nathan Myers (2011-12-27 22:08:14)

I am finding it hard to believe that any epidemiologist could forget the role of immune function. Hygiene and vaccination are the epidemiologist's belt and suspenders: half of their prescription is to improve immune response. Maybe you mean they should also pay attention to countering practices that suppress immune function? We know that long-term stress suppresses immune function, and a long but poorly-known list of bad habits produce long-term stress. What should epidemiologists be doing to counter these habits? Do they have any chance of restoring population-wide immune function, through reduced stress, to a degree that would be detectable vs. the results they get concentrating on vaccination and hygiene? It is hard for me to imagine epidemiologists succeeding at reducing a population's long-term stress levels. That seems to be a political and educational challenge much harder than enforcing hygiene. In principle, though, it seems possible to break the connection

between long-term stress and suppressed immune function by directly modulating everybody's stress response. Perhaps, as is seen in some people, long-term stressors need not actually trigger the response that suppresses immune system function and damages health in numerous other ways. Is that what you meant?

Seth Roberts (2011-12-27 23:50:40)

Nathan, epidemiologists could pay more attention to sleep, for example. Do differences in sleep explain why some people get sick more than others? Do differences in sleep explain why some epidemics spread faster than others? There is no doubt that better sleep improves immune function.

Nathan Myers (2011-12-29 20:54:37)

I suppose I am assuming that sleep disruption causes the stress that has been suppressing the immune system. Better sleeping reduces stress, and thereby enables increased immune-system activity. It's not too surprising to me that epidemiologists don't pay much attention to reducing stress. Efforts to reduce collective stress necessarily operate on a time scale much longer than epidemiologists have to work in. Epidemiologists could point out every time a plague spreads that sleeping and eating better, and establishing a more secure social standing, improve your chances of survival, but at the point they get involved, they need measures that have large and immediate effects (e.g. vaccination, quarantine) to help contain a crisis. Stress reduction is more a topic for (i.e. neglected by) the family doctor. If by some cheap and easy intervention, long-term stress could be prevented from suppressing the immune system (and, perhaps, other systems), that could result in a large and immediate public health boon. People are attempting a superficially similar sort of intervention chasing a long-term goal by taking statins.

Jim Purdy (2011-12-24 05:33:58)

YOU SAID: "Evolutionary medicine reaches the BMJ. The word paleo does not appear." I don't get hung up over the word "paleo." The concept is still there. as evidenced by the fact that the much more important words "evolution" or "evolutionary" appear 70 times.

dearieme (2011-12-24 13:31:32)

Cod liver oil was still standard issue in British childhood in the 50s. So, for a different reason, was California Syrup of Figs. Olive oil was used mainly for treating earache.

## Christmas: An Evolutionary Explanation (repost) (2011-12-25 05:00)

I wrote this five years ago. Perhaps it is a holiday tradition to repost [1]old posts about the deadweight loss of gifts.

In a kitchenware store a few years ago I came across the [2]Rotary Nutcracker, a futuristic-looking device that cracks nuts in a new way. The girl at the cash register gave me a few walnuts to test it. It didn't crack any of them. This was a curious product, I thought. Who would buy it? The salesperson told me that they'd stocked it for less than a year. I was the first person to test it. It had sold well during holiday season. Now I understood: people didn't buy it for themselves, they bought it as a gift. As a gift, it mattered much less how well it worked — "it's the thought that counts." No wonder I was the first to test it.

Here, I saw, was [3]my theory of human evolution in . . . well, a nutshell. Part of it. Humans are the only animals with occupational specialization — we specialize, and trade. It started with hobbies. Hobbies became part-time jobs. Part-time jobs became full-time jobs. To support full-time jobs — to generate enough demand for the products of this or that specialization — there has to be enough expertise, which builds up slowly. To build up expertise, our brains changed so as to cause creation of special events like Christmas, Japanese New Year, Spring Festival (in China), and a thousand other examples around the world. Such events increase the demand for high-end craftsmanship, thus helping the most skilled craftsmen — the ones most likely to advance the state of their art — make a living. Christmas increases the demand for Christmas cards (fine printing) and Christmas-tree ornaments, for example. Traditional gift-giving has the same effect: It increases demand for "the better things in life." Most gifts, if you follow the usual norms, are (a) not something you would buy for yourself and (b) not something the recipient would buy. (As [4]Alex Tabarrok has noticed.) They are harder to make — and thus reward skilled craftsmen more — than the stuff we buy for ourselves, just as Christmas ornaments are harder to make than common household objects and Christmas-card printing is more difficult than most printing. Weddings, with the gifts, finery, invitations, etc., are another example. The Rotary Nutcracker didn't work in my tests but it almost worked. If enough people bought it as a gift, that would finance the research needed to improve it.

[5]Marginal Revolution and [6]James Surowiecki have recently written about the "deadweight loss of Christmas" — about how gifts tend to be worth less than their cost. I think they see this as bad thing but I see it as a good thing — at least, in our evolutionary past it was a good thing. Deadweight loss = research grant. Likewise, the denizens of [7]The Devil Wears Prada appear slightly defensive about the social value of fashion. They seem to believe that fashion is less useful than "curing cancer" (by which they mean doing research to learn how to cure cancer). Actually, high fashion, with its hard-to-make skirts, belts, and accessories, is the same as curing cancer — they're two ways of increasing the human skill set. Art is the old Science.

Tom (2011-12-25 16:49:15)

It's hard to get rich selling people what they need, as we need so little. But what we want never ends. Yesterday, I stumbled into a "Home Goods" store. It was the first one I'd ever seen, though apparently it's a major chain. And it occurred to me: Everything in this store is useless. No one needs ANYTHING in here!

Seth Roberts (2011-12-25 17:56:56)

It's hard to get rich selling people what they need, as we need so little. But what we want never ends.

I disagree. I think what we want is an excellent guide to what we need. When we are cold, we want warmth. When we are thirsty, we want water. Societies need innovation...you can't keep doing the same thing forever. Innovation costs resources. To get those resources, the need for innovation must be turned into wants that cause innovation.

Nancy Lebovitz (2011-12-26 07:56:25)

I think people need variety- new stimulation. Odd consumer goods may not be the best way to get it.

Sonny Eraut (2011-12-28 01:10:40)

Cultural products are software running on the operating system of human perceptions and emotions. I think it's more likely that instead of humans developing a tendency to observe days of celebration because it provides some opportunities for specialized trade, humans already had an ability to observe and respond to seasonal events, in common with other animals. Monkeys would show up at stands of trees at certain times of year, just when the fruit was ripe. There's also seasonal migration as part of the explanation of holidays. Now we aren't looking for where the food is in nature at certain exact times of year. We're creating the experience of that in our artificial ways, indoors. Christmas meant to me when I was little a long trip to see our relatives, and mandarin oranges, the smell of Christmas trees, and some other kinds of treats, including nuts. That should be a clue what secular holidays are, besides an oxymoron.

Seth Roberts (2011-12-28 18:35:27)

Thanks, Glen. Those are very helpful comments and I will study them carefully. You ask: "Have you ever been to a Chinese factory?" No, I haven't. Here's what I can add to the discussion. 1. It is far from the truth that Chinese factory workers are a sea of misery within a wider context of happiness and joy. In fact, a survey of happiness in China found that construction workers (not factory workers) were among the happiest of any group in China. Construction workers are quite different from factory workers, of course, but the point is that simple Western ideas about who should be happy and who should be sad are wrong. I agree that Halpern's reflexive assumptions along these lines (e.g., long hours = bad working conditions) are just wrong. It is utterly true that factory jobs are better than rural village jobs. That's why people migrate to get them, leaving behind their family and sometimes their children. 2. Comparison of raw suicide rates is not a good idea. Compare them after they are adjusted for age and sex and income. 3. Foxconn workers have legitimate complaints. Illustrated by Mike Daisey's show. [1]For example. "Daisey actually went there." 4. I don't believe that much is gained by Apple deciding that a Foxconn factory should be X, Y, and Z. That is the "audit" approach. I believe a lot can be gained by figuring out a way that Foxconn workers can have more power over their own working conditions. (Just as my work illustrates how one person can have more control of their health.) Isn't that one thing Apple supposedly sells: empowerment?

## Carl Willat on the Democratization of Magic (2011-12-26 05:00)

My friend Carl Willat (of [1]the Willat Effect) is an amateur magician. I sent him [2]this link ("Is the Internet Destroying – or Transforming – the Magic of Magic?"). He replied:

I hadn't seen that article, but I follow this debate and read both sides of it almost daily. He raises some good points and others I disagree with, but in the end it doesn't matter because the trend of revealing magic secrets is unstoppable, regardless of what I think. But calling it a good thing doesn't really make sense. Steinmeyer says people overestimate the value of secrets in magic by a factor of ten, and this is true in the sense that the secret is not the effect. I can enjoy magic performances even if I know the secret, but if I'm fooled I enjoy it more by a factor of ten, let's say. The engine isn't the only important thing in my car but it won't go without it.

I don't think it makes sense to compare a few people copying Vernon's \$20 manuscript with people giving away secrets on YouTube, because the distribution is so much bigger and it takes almost no effort or even serious interest to learn the secrets. The author also lost me by coming down on one side of the books vs. videos debate. They're each good for different reasons. A book can't always illustrate what something is supposed to look like in action. A video can never have all the detail you can get out of a good book. If all you want is to perform a trick exactly like someone else does, videos are particularly good. I actually think the main value of videos is to see a trick performed so you can see if you want to learn it or not. As time goes on I feel more and more reluctant to perform someone else's material, and when I do I change it around and add my own variations. Otherwise I don't feel like I'm contributing anything. One of the reasons Lennart Green's stuff knocked me out was that his material is mostly fairly original and not obviously related to standard techniques, so his whole performance seems magical.

It would have been interesting in this article to have included information about Armando Lucero, a magician who not only doesn't have any teaching books or videos, but tries to keep even his performances off the internet. I took a fairly expensive workshop from him, and we had to sign a non-disclosure agreement promising not to reveal any of his techniques. This seems to have worked, as his secrets haven't really leaked out, and there is still a kind of mystique around him and his magic. In my opinion that's what magic is supposed to be like. I've obviously benefited by the general availability of DVDs and books about magic, but I didn't just want to learn secrets, I wanted to perform. I think as soon as you have to put out some kind of effort to learn you're already separated from the merely curious, whether it be by getting a magic book out of the library or shelling out some money for a video at the magic store. It shows you want to perform, not just learn the secrets. But I think for most people looking at these internet videos it's just a break from Facebook and pornography.

Is there a relationship between your interest in the democratization of magic and your philosophy of self-experimentation? Because I can see how you might feel we should get out from under the tyranny of Big Magic and its oppressive secrets. (this is where I would put in a smiling emoticon if I knew how to make them)

This trend in magic seems related to the diminishing "specialness" in everything. For example everyone has cameras on their cell phones now and takes pictures all the time, so to be a "photographer" is nothing. My film students at the Academy refuse to think of film as art. Everybody makes films, there are a billion of them on YouTube, so why should we put any special effort into them? Their films all feature their roommates in the dorms. On YouTube everyone can be a magician. Ironically, a recorded video is about the worst way to experience a magic performance.

I replied:

Yeah, I agree, the democratization of science and the democratization of magic (not to mention photography and film-making) are related. Perhaps I should have a blanket opinion about this stuff but you are the first person to raise the issue.

In the 16th century or thereabouts, mathematicians had contests about solving equations. It wasn't known how to solve a 3rd degree equation (e.g.,  $x^3 - x = 5$ ). Finally one guy figured it out. It gave him a huge advantage. Of

course he kept it a secret. When mathematical knowledge became better known, because of books, they stopped having those contests. Mathematicians could no longer make money and impress women by winning them. Math stopped being a kind of sideshow similar to magic and eventually became the foundation of engineering and science. This couldn't have happened if it was still a bunch of secrets.

It is early in the democratization of magic, but I think a similar story is plausible – not likely, just plausible. One possibility is that democratization "cheapens" everything or at least makes it harder to make a living at magic. The whole enterprise withers and dies. Another possibility is that, as [3]the Masked Magician said, the revelation of techniques pushes people to invent new ones. They can no longer keep doing the old ones. I think he is perfectly correct. I think the reason that fashion evolved (a feature of our brains) is to push artisans to keep inventing. You really do need to give people a push, otherwise they will stagnate. A third possibility is that the democratization of magic will push the ideas out into a much wider range of people and these people will see the ideas in a new way. They won't merely invent new tricks; they will begin to grasp how the underlying ideas can be applied in other places.

As a professor of psychology I think I can say this: academic psychologists such as myself have almost no interest in using the ideas we discover and study to help people. (That I used them to lose weight is unprecedented.) It is all about publishing papers, getting tenure, getting promoted, perhaps even winning prizes. That's neither bad nor good, it's human nature. The magic you do, on the other hand, is applied psychology. It is entirely useful. So magicians have (a) figured out psychology that works and (b) use it all the time to get something they want (attention, money). That is no small achievement. But they have zero interest in systematizing it (asking: what are the general principles?) and applying those principles in other domains. Other people, however, could easily want to do this. The ideas have to reach those other people for the systematization and application to happen. Nowadays the ideas behind magic tricks are reaching a wider audience so this is becoming more likely to happen.

So I'm like someone in the 15th century who tells the mathematician who has discovered how to solve cubic equations: hey, tell other people your secrets, it will be great! It would sound crazy. But if you want my overall opinion, I think that magic has stagnated, like many other areas of life. I think the democratization has been a powerful force for innovation, just as the Masked Magician claimed, although you would know better than me. I also think, unlike anything the Masked Magician said, that the ideas behind magic are far more important than what present-day professional magicians are using them for. Professional magicians are too busy doing what they have done for the last 20 years and too busy trying to make a living to take advantage of this (which will have zero monetary payoff, at first). But other younger people are more flexible.

Alex Chernavsky (2011-12-26 07:34:46)

A couple of points: First of all, I recently read a book called, [1]*Sleights of Mind: What the Neuroscience of Magic Reveals About Our Everyday Deceptions*, by Stephen L. Macknik and Susana Martinez-Conde. It wasn't as interesting as I thought it would be, but I think the very existence of the book is a sign that magic is expanding beyond its usual domains. Second, I'm all in favor of revealing the secrets behind magic tricks. Hucksters like Uri Geller, Sylvia Browne, and Jonathan Edward (among many others) prey on naive people who don't realize how easy it is to be fooled by simple conjuring tricks. Perhaps if some of these tricks become common knowledge, the public will become slightly less gullible. One can only hope, anyway. (On the other hand, even people who ought to know better can be duped. See this write-up of James "the Amazing" Randi's [2]Project Alpha.)

1. <http://www.amazon.com/Sleights-Mind-Neuroscience-Everyday-Deceptions/dp/0312611676/>
2. [http://en.wikipedia.org/wiki/Project\\_Alpha](http://en.wikipedia.org/wiki/Project_Alpha)

Eugene Woodbury (2011-12-26 08:43:25)

Filmmakers will tell you exactly how they perform their cinematic magic, down to the equipment used and the technical specs. This wide sharing of knowledge has resulted in the quality of special effects rising, and the costs dropping, exponentially. The movie-going public has developed higher standards of verisimilitude as a result, but it hasn't put them off watching movies.

Sonny Eraut (2011-12-28 00:19:22)

Reading and writing are a form of magic: "grammarge." One of my brothers said as a conversation topic that he was going to learn everything he needed to know by watching videos. What kind of programmer would someone be who's only seen people sitting at terminals trying to program in videos and hasn't read anything about it? Enough said.

### **New Word: crapeterian (2011-12-27 05:00)**

At Christmas dinner I learned a new word:

crapeterian. n. A vegetarian who eats crap (e.g., Doritos, candy, doughnuts).

---

Analog Eye (2011-12-27 05:58:11)

In fairness, that should be ANYBODY who eats that kind of thing... hehehe

dearieme (2011-12-27 06:34:34)

Do profiteroles count?

Bill Strahan (2011-12-27 09:13:50)

Funny, I always called them vegetardians. :)

Adam (2011-12-27 18:54:05)

There's nothing quite like an obese vegetarian / vegan lecturing you about nutrition.

Ian (2011-12-28 14:11:15)

Why this is an awesome word: "vegetarian" looks like it should mean one who eats vegetables, rather than one who doesn't eat meat, while in fact many non-meat-eaters eat far more crap than vegetables. This explanation may be unnecessary for most, but I had to think about it for a few minutes before I really got it.

Seth Roberts (2011-12-28 18:50:48)

I agree. I would like to hear someone say: "You know, the usual word for what I am is vegetarian. But I prefer to call myself a crapeterian."

## The Legacy of Steve Jobs (2011-12-28 05:00)

Sue Halpern has written the first interesting assessment of Steve Jobs I've seen, in the form of [1] a book review of Isaacson's biography. It happens to be very negative. She says little about his now-well-known bad treatment of coworkers, friends and family ("a bully, a dissembler, a cheapskate, a deadbeat dad, a manipulator") and focusses on the effects of Apple Computer, which are obviously much greater.

She makes one very bad point. He should not call himself an artist, she argues:

There is no doubt that the products Steve Jobs brilliantly conceived of and oversaw at Apple were elegant and beautiful, but they were, in the end, products. Artists, typically, aim to put something of enduring beauty into the world; consumer electronics companies aim to sell a lot of gadgets, manufacturing desire for this year's model in the hope that people will discard last year's.

"In the end, products"? "Gadgets"? Are books gadgets? I cannot imagine a future without books. Nor one without cellphones and laptops. If they are lovely and work well, so much the better for all of us. Moreover, cellphones and laptops, much more than other necessities (food, clothes, housing, transportation, medicine) help us express ourselves – our hidden inner selves – in so many ways. (Like art and books, but better.) Mark Fraunfelder [2] made a similar point (obliquely).

"Products" and "gadgets" is Halpern's conventional anti-consumerism. She goes on to make two equally conventional but much better points:

According to a study reported by Bloomberg News last January, Apple ranked at the very bottom of twenty-nine global tech firms "in terms of responsiveness and transparency to health and environmental concerns in China." Yet walking into the Foxconn factory, where people routinely work six days a week, from early in the morning till late at night standing in enforced silence, Steve Jobs might have entered his biggest reality distortion field of all. "You go into this place and it's a factory but, my gosh, they've got restaurants and movie theaters and hospitals and swimming pools," he said after being queried by reporters about working conditions there shortly after a spate of suicides. "For a factory, it's pretty nice."

Apple had (and has) the power to improve working conditions at Foxconn. I completely agree: this was (and is) an enormous missed opportunity, for which Steve Jobs is completely responsible. No doubt he said that Apple products empower individuals (and they do) – well, how about empowering Foxconn workers?

Halpern's final point is about recycling:

Next year will bring the iPhone 5, and a new MacBook, and more iPods and iMacs. What this means is that somewhere in the third world, poor people are picking through heaps of electronic waste in an effort to recover bits of gold and other metals and maybe make a dollar or two. Piled high and toxic, it is leaking poisons and carcinogens like lead, cadmium, and mercury that leach into their skin, the ground, the air, the water. Such may be the longest-lasting legacy of Steve Jobs's art.

Yeah. Apple could (and can) lead the world in making their products easy to recycle. They haven't. Entirely Steve Jobs' fault. As Halpern says, this really matters.

Steve Jobs spent his working life (a) exploiting the commercial potential of new products (home computer, etc.) in

large part by (b) caring obsessively, much more than others in his rarefied position, such as Bill Gates, about how they made him feel. Apple made products that Steve Jobs enjoyed. Fine. The problem is what Steve Jobs enjoyed. My take on him is a lot can be explained by (a) he cared little what others thought of him and (b) he lived in a tiny, uncomplicated intellectual world – as illustrated by his remarks about Foxconn and his Stanford graduation speech. Nabokov might say he had the emotional development of a child and the curiosity of an adult.

He left behind a company that reflects the shallowness of what he cared about. Those who take over Apple Computer are likely to be less shallow than he was – most people are. I predict the company will begin to care more about working conditions, ease of recycling, and other things beyond immediate user experience.

Glen Raphael (2011-12-28 07:59:16)

Have you been to a Chinese factory? I have and the criticisms of Foxconn seem wildly overblown to me. People who go to China wanting to see suffering they can take umbrage at may find a way to do so, but it's not justified. For instance, consider the ambiguity in this line from the article: "walking into the Foxconn factory, where people routinely work six days a week, from early in the morning till late at night" That statement is trivially true about the factory but has a false implication about the people. Foxconn has \*shifts\*, so the people routinely working "early in the morning" usually \*aren't the same people\* as the ones routinely working "till late at night". Foxconn has \*half a million employees\* at their Shenzhen facility so it'd be quite surprising if they \*didn't\* see at least a dozen suicides a year - the suicide \*rate\* there was still quite low. Ditto for industrial accidents, use of bad chemicals, etcetera - a proper sense of scale diminishes all of them. Bad things happen sometimes; companies do what they can to mitigate and prevent, but overall that job does make life much better for the chinese workers...or the job wouldn't be in such high demand that they could staff such big factories! I submit that the people who choose voluntarily to work at these places probably know better whether the working conditions are \*what they want\* than do western reporters who are seeking whatever hard-luck stories they can find among a population the size of Wyoming. Jobs was almost certainly right in saying that "for a factory, it's pretty nice." Foxconn sounds better than the chinese factories I worked with a decade ago, which themselves were clearly much better places to work than the alternatives available to those workers. Halpern's final point about recycling is just wrong. Apple's products are all lead-free and mercury free already; they constantly work to shrink the packaging, reduce waste, and make products using fewer toxic substances. Every Apple product intro harps on this. (more here: <http://www.apple.com/environment/> ) The Isaacson biography wasn't very good. It was shallow; he didn't ask tough questions and often failed to follow up on key points. Given the level of access Isaacson had, it was a wasted opportunity. The best critical review of the book that I'm aware of was in John Siracusa's audio podcast Hypercritical - these two episodes: Episode 42: The Wrong Guy: <http://5by5.tv/hypercritical/42> Episode 43: The Scorpion and the Frog: <http://5by5.tv/hypercritical/43>

David (2011-12-28 08:15:24)

The management of Apple has one legitimate concern - to increase profits. That is the sole reason why shareholders invest in a company. If the board and management are successful in maximizing the return on shareholder equity, then they will be successful. All other concerns, such as those you mention, are only relevant to the extent they support greater profits. Bettering employee working conditions, or making socially acceptable products, or any other non-profit oriented concern, is a side-show. These may be related to increasing return on investment (although the data isn't clear), but certainly shouldn't be the primary concern of any company's management.

Robin Barooah (2011-12-28 09:45:07)

I don't know enough about the factory conditions to comment, although I did see "The Agony and Ecstasy of Steve Jobs" which paints an extremely grim picture of the reality of Foxconn. However, it seems to me that the claims about recycling and the related innuendo about what jobs cared about are simply not supported by facts. Apple actually does lead the world in recyclability of consumer products. Aluminium and Glass are two of the easiest to recycle materials available, and Steve Jobs was outspokenly aware of this when they started to use them. Apple is ahead of everyone else in removing the "Lead, Cadmium and Mercury" from their products. See this piece by Steve Jobs himself : <http://www.apple.com/hotnews/agreenerapple/> - It's worth noting that they have now completely eliminated mercury use as he said they would. They have also led the world in reducing packaging waste, fuel in transportation, and power consumption by their devices. They have a worldwide recycling program which will accept not only their own products but PCs and Phones from other manufacturers, either at their stores or by prepaid mail. They even pay reasonably for what is returned. 66 % of their product by weight is now recycled, and it's their goal to improve on this. But I think that a key point that is often overlooked is that Apple does care about durability. Apple products retain their value far better than PCs, I think to a great extent because if they are reasonably looked after they remain both fashionable and in physically good condition in a way that the petroleum based plastics used by their competitors do not. This means that there is a much healthier market for used equipment - so the path to the landfill (or more likely the path back to Apple for recycling) is actually a lot longer than with the competition. You can also see this at work with their phones. It's an easy accusation to claim that Apple only cares about getting people to upgrade each year. But the reality is that a used iPhone 4 still locked to AT & T could be sold secondhand for more than \$400. And Apple themselves are still selling models are over 2.5 years old. The most expensive new iPhone today is visibly indistinguishable from an 18 month old phone that they for \$99, and they continue to release software upgrades for all of these products. Compare that to their competitors who are shipping new flagship devices every few months and are abandoning them for upgrades after less than a year. The point here is that there is strong demand for old Apple products, not just new ones. It seems to me that Apple is leading by a long way on durability, reuse, and recycling. And that is by careful design. It's also in their interest to do this because they are in the minority position when it comes to sales share in both PCs and smartphones. By designing their products to be useful for longer, they magnify the installed base for their operating system and hence present a more attractive proposition for software developers. The claim that it's all about getting people to upgrade to the latest version doesn't stand up to scrutiny. They obviously do care about selling as many units as possible, but it matters strategically to Apple that each unit gets a long useful life and isn't just quickly discarded.

Glen Raphael (2011-12-28 10:05:28)

This Wired article on Foxconn is pretty good: [http://www.wired.com/magazine/2011/02/ff\\_joelinchina/all/1](http://www.wired.com/magazine/2011/02/ff_joelinchina/all/1) Though it does miss the simple mathematical point that if Foxconn workers face a \*lower\* risk of suicide than other workers in China - which seems likely from the evidence we have on hand - then buying products produced there is on-net \*saving\* worker lives in China.

by (2011-12-28 11:42:20)

I understand that his Foxconn remarks are insensitive and show his narrowly focused mind, but how did his Stanford speech show that to you as well?

Jazi zilber (2011-12-28 18:30:13)

Steve jobs was extremely focused. He improved products. He may have been able to leverage his company to endless world salvaging ideals. Would he had done so, we would have never had his wonderful products. This is a simple tradeoff. And I wish that everyone creating useful things will be as focused.

Jazi zilber (2011-12-28 18:39:43)

Jobs comment on the Chinese working conditions seems deeper for me. You only judge job quality relative to the other jobs available to people in the area. If the people would have been working 7 days 14 hours a week otherwise in the sun with no kind of food available, then Jobs comments on the nice facility with restaurant is very well pointed.

Seth Roberts (2011-12-28 18:41:11)

All other concerns, such as those you mention, are only relevant to the extent they support greater profits. Bettering employee working conditions, or making socially acceptable products, or any other non-profit oriented concern, is a side-show. These may be related to increasing return on investment (although the data isn't clear), but certainly shouldn't be the primary concern of any company's management.

As many many other people, such as Elizabeth Warren, have said, companies like Apple work within a context supplied by the rest of us. They use roads paid for by the rest of us. They use an education system paid for by the rest of us. Etc., etc. They should recognize that and give something back. That's how groups work – reciprocity. Quite apart from that Steve Jobs was no profit maximizer. It is perfectly possible to be a successful company without obsessing about profit.

Robin Barooah (2011-12-28 20:25:43)

"They use an education system paid for by the rest of us. Etc., etc. They should recognize that and give something back." Companies 'like Apple' do give a lot of things back - they develop new technologies and push the state of the art forward. They give us the choice to have computers in our pockets that we can actually use. They create new categories of work (e.g. programming apps), and transform and democratize existing ones (e.g. filmmaking, music, photography). I dare say they've contributed something to modern science too. The problem is that there aren't many companies 'like Apple'.

Glen Raphael (2011-12-28 22:12:51)

Apple had (and has) the power to improve working conditions at Foxconn. I completely agree: this was (and is) an enormous missed opportunity, for which Steve Jobs is completely responsible. No doubt he said that Apple products empower individuals (and they do) — well, how about empowering Foxconn workers?

Wait, how do we know Apple missed this opportunity? How *haven't* they been empowering Foxconn workers? What would it take to convince you they *have* been generally improving conditions at Foxconn and other suppliers? Apple has an extensive (and impressive) auditing program in place; some progress reports can be found here: <http://www.apple.com/supplierresponsibility/> It seems like "long hours" is still a significant issue. Apple's official standard is that a normal work week should be no longer than 60 hours and should include at least one day of rest per week. When they first started auditing in 2006, only 18 % of their suppliers met that standard. As of the 2011 report (based on audits in 2010) the share meeting that standard was...32 %. On the one hand that's a long way from a solved problem, but on the other hand: 32 is a lot more than 18. :-) What metrics do you think Apple should be tracking and pushing to improve with their suppliers that they aren't already doing? Reading the 2011 report it seemed to me like they've hit the high points already and then some. One thing I found interesting is that these jobs are apparently **so valuable** to employees that the employees are willing to pay huge kickbacks to middlemen in order to get them. Apple considers any fees of this sort larger than a month's salary a serious offense (because people borrow money to pay those fees, Apple considers the pre-committed portion of their work involuntary labor) and it's been an ongoing issue. The fact that employees are willing to pay *more than a month's salary* to get these jobs tells me the workers are in all likelihood *seriously overpaid* and/or have *unusually good working conditions relative to the other jobs available in the region*. Which I guess we already knew, but still: wow.

Zach (2011-12-28 23:33:28)

@David Beyond what Seth said, corporate management has many different "legitimate concerns". They are representing the shareholders, most of whom have interests extending beyond profits. Some people invest in companies because they like the product. I have encountered anecdotal evidence of people investing in Apple for this reason, the Green Bay Packers largely function on this model and many small companies raise initial funding based on this (see Kickstarter). Institutional investor such as academic endowment funds often choose to invest based in large part on the corporate practices regarding environmental concerns and human rights. Profit is a main concern, but not the main concern and certainly not the only one. As Robin said, in many ways Apple is quite the model citizen in these regards. A lot of what I've read suggests that management focused on a narrow definition of profit (the time-frame over which decisions are made is critical) is responsible for most corporate failure. In particular, Apple's near-death experience had at its root a loss of focus beyond short-term profit motives.

Seth Roberts (2011-12-29 03:28:52)

How haven't they been empowering Foxconn workers? What would it take to convince you they have been generally improving conditions at Foxconn and other suppliers?

If I were in charge of Apple, I (and other top execs) would meet with Foxconn workers and ask them how to empower them – that is, give them more control over their working conditions. I disagree with the impose-western-working-conditions approach. Which I called the "audit" approach and which is what Apple now does. I think the workers know a lot better what working conditions they want than whoever came up with the checklist for the audit. I don't mean the Western checklist approach is useless – I have no idea. I am sure however that it is less worthwhile than listening to the workers themselves about what they want. I believe that Apple hasn't done what I recommend (listening to Foxconn workers at great length). The evidence that would convince me that Apple is doing a good job here would be to read about how they have stopped trying to fulfill Western preconceptions about what a good workplace is and have done what they can to achieve the workers' ideas about what a good workplace is. Many times throughout history the top (here, Apple management) and the bottom (here, the workers) have gotten together to force the middle (here, Foxconn management) to treat the bottom better. The Ten Commandments, for example.

Glen Raphael (2011-12-29 09:10:21)

The way they do the audits does include interviewing workers (including giving the workers info so they can call back later and blow the whistle if things change) and asking what the biggest concerns are as well as getting feedback on specific issues. An example of a thing workers complain about unprompted is having to wait in long lines. Lines for the bus to work, lines at the cafeteria, or lines to get through security. I think the reason Apple has such trouble reducing *long hours* is that if you ask the workers themselves, long hours aren't actually a problem. So long as they can get *paid* for their overtime hours, the workers tend to want to do as much work as possible. Some years ago there was a news item about a riot at a factory (not one related to Apple) that started *because* the factory owners cut down on overtime! I doubt any worker ever complained that the exit doors at the cafeteria open inward and/or require two hands to open...that'd be an example of the sort of thing Apple includes in their checklists after consulting with relevant independent experts. If Apple stopped trying to fulfill Western preconceptions and let the workers themselves decide we'd probably see a lot more underaged workers than the one-in-ten-thousand we see now. Which I don't view as a problem, but Apple would get a lot of flack (more than they already do) if they just turned a blind eye to the occasional 15-year-old who gets a fake ID so they can work at the factory. (Apple has already cut off one supplier that didn't care about this issue.) Seriously, read the 2011 Progress Report - you'll be a lot more informed than your other sources on this subject. (And more informed than I was in my initial post at the beginning of this thread.) Here's the link: [http://images.apple.com/supplierresponsibility/pdf/Apple\\_SR\\_2011\\_Progress\\_Report.pdf](http://images.apple.com/supplierresponsibility/pdf/Apple_SR_2011_Progress_Report.pdf)

Steve (2011-12-29 11:12:33)

I bought the first iteration of the Mac mini, buying into the line that Macs are durable, that you are saved from the endless merry-go-round of software upgrading and escalating system demands that often makes Windows PCs unusable after a few years. Now, years later, yes the hardware still purrs along, but Apple no longer offers a browser that is fully functional in that old OS. Nor does anyone else offer such a browser. Also, there is now no way of upgrading the OS so that it will run a functional browser. So, depending on what I am working on, the computer is of limited usefulness. Yet the Windows notebook I'd bought four months later, running XP, is still up to date. I don't clog it with unnecessary software and run it fairly lean, and it runs fine. Microsoft still updates XP and it, and other developers, still offer completely up-to-date browsers. Maybe the machine has retained its value as Robin claims, but that's no use to me if I simply want to be able to do online research for work or do my banking online and can't. The only advice Mac dealers can give me is to upgrade the machine! But the machine sure is pretty.

Robin Barooah (2012-01-02 12:07:07)

STEVE: Have you tried OmniWeb? <http://www.omnigroup.com/products/omniweb/> It is listed as supporting OSX Tiger, and is a Universal binary that runs on PowerPC. I've used it for research and it works fine with my online bank accounts.

## **Acne Cured By Self-Experimentation (2011-12-29 04:24)**

In November, at Quantified Self Europe, Martha Rotter, who lives in Ireland, gave a talk about how she cured her acne by self-experimentation. She [1]summarizes her talk like this (slides [2]here):

When I moved to Ireland [from Seattle] in 2007, I began to have skin problems. It began gradually and I attributed it to the move, to stress, to late nights drinking with developers and clients, to travel, to whatever excuses I could think of. The stress was multiplied by the anxiety of being embarrassed about how my face looked, but also because my new job in Ireland involved me being on stage in front of large audiences constantly, often several times a week. A year later my skin was perpetually inflamed, red, full of sores and very painful. When one spot would go away, two more would spring up in its place. It was a tough time. I cried a lot.

Frustrated, I went to see my hometown dermatologist while I was home for holidays. He told me that a) this was completely normal and b) there was nothing I could do but go on antibiotics for a year (in addition to spending a fortune on creams and pills). I didn't believe either of those things.

I was not interested in being on an antibiotic for a year, nor was I interested in Accutane (my best friend has had it multiple times and it hasn't had long term results, plus it can be risky). What I was interested in was figuring out why this was happening and changing my life to make it stop. I refused to accept my dermatologist's insistence that what you put in your body has no effect on how you look and feel.

I began systematically cutting things out of my diet to see how I reacted. First chicken and soy, based on a recommendation from a food allergist. Over the course of a year I cut out sugar, gluten, carbs, starches, caffeine, meat, fish until finally the magical month of December 2010 when I cut out dairy. My skin was my own again by New Year's day this year.

It took a year to figure it out. It was completely worth it. There's nothing wrong with Irish dairy, it just doesn't work for me. I drink Americanos instead of lattes now, I don't eat cereal; none of that is a huge deal. For what it's worth, I can drink goat's milk.

A great example of the power of self-experimentation compared to trusting doctors. One quibble: I'll be more sure "there's nothing wrong with Irish dairy" if she finds that American dairy also causes skin problems. The evidence so far (she didn't have skin problems until she moved to Ireland) suggests that at least for her American dairy (i.e., dairy where she lived in America) is better than Irish dairy. I have heard Irish dairy praised. They sell Irish butter at Beijing stores near me. I won't be buying it.

At the end of her post she makes a very important point:

Quantified Self isn't for everyone, but everyone should feel they have the power to change things in their body and their life for the better.

I agree. By learning about examples of people who have done just that – such as Martha – we will come closer to having that power. Right now, as far as I can tell, most people feel helpless. They do what doctors or other experts tell them to do, even if it doesn't work very well.

Long ago, hardly anyone could read. This left them in the grip of those who could. But eventually came mass literacy, when the benefits of reading finally exceeded the costs (e.g., because more books were available at lower prices). Reading is primitive science: if you read about things that happened, it is information gathering. It resembles doing a survey. Nowadays, almost everyone (in rich countries) reads, but almost no one does experimental science. This leaves them in the grip of those who can do experimental science (e.g., drug companies). I think my work and Martha's work suggest we are close to another turning point, where, for nonscientists, the benefits of doing experiments exceed the costs.

Thanks to Gary Wolf.

gwern (2011-12-29 09:22:44)

> The evidence so far (she didn't have skin problems until she moved to Ireland) suggests that at least for her American dairy (i.e., dairy where she lived in America) is better than Irish dairy. I have heard Irish dairy praised. They sell Irish butter at Beijing stores near me. I won't be buying it. Or it could be an equilibrium effect - she tolerated whatever it was in dairy until a shock to her system weakened her. Could retrospect for similar massive shocks (going to college? a parent dying?) and try to recall if there were any acne outbreaks. You've probably seen [https://www.nytimes.com/2012/01/01/magazine/tara-parker-pope-fat-trap.html?\\_r=2&pagewanted=all](https://www.nytimes.com/2012/01/01/magazine/tara-parker-pope-fat-trap.html?_r=2&pagewanted=all) which discusses an equilibrium shift for obesity. (I think something similar happened to my sister which lead to her gluten allergy becoming a huge problem and then discovered.) In any case, if you like the taste of Irish-style butter and don't have acne problems, this doesn't seem like a good reason to shun it.

Jay (2011-12-29 09:45:16)

I'll never stop buying my delicious Kerrygold Irish butter!

Glen Raphael (2011-12-29 09:49:37)

Another quibble: she'd need to *resume dairy for a bit* (and see the acne return) to conclude it was the dairy and not something more like regression to the mean. Her treatment course as described sounds a lot like what convinced doctors to over-trust depression meds. To wit: *I have condition X, so I try treatment A. That doesn't help so I try treatment B. Then C. Then D. At the end of a year, condition X resolves and I credit the last thing I tried right before the improvement - which was treatment H.* If you try one thing and get better right away, that's evidence that the thing you tried worked. But if you try 10 things over the course of a year it's a foregone conclusion that you were trying *something* when you get better, but the evidence is weak that the getting better had to do with the specific last thing you tried. (The things she mentions trying are the removal of: chicken, soy, sugar, gluten, carbs, starches, caffeine, meat, fish, dairy). Ten things. Heck, for all we know it could be one of the earlier ones (with some delay in effectiveness). Or none of them.

Sarah Madden (2011-12-29 10:25:08)

For what it's worth I live in Ireland and used to have acne, cutting out dairy didn't do a thing, increasing it helped though. What was the ultimate cure for me was increasing intake of vitamin E. Anytime people cut out a food they replace it with something else. For all we know that's what made the difference. I would eat Irish dairy which is grass-fed and natural as they come before chinese dairy that has god knows what contaminants in it..

Martha Rotter (2011-12-29 10:55:38)

Hi Glen, good points! What I may not have done a great job explaining in my blog post that I covered in great detail in my talk is that each of those things I cut out for a month. So no caffeine for a month - no result? Okay, caffeine back in. When I cut dairy out it was dairy only. Everything else in my diet was the same. As you mention, it would be impossible to attribute it to one thing otherwise! Now I have introduced goats milk back in to my diet and occasionally cows milk cheeses. But at this point, when I do have cream or milk with coffee or something dairy like a dessert I feel like indulging in, it's often just a matter of hours before I can feel my face heating up somewhere and I know I'll have a spot the following day. But the difference is that now I can weigh the cost and I know what I'm getting in to. Hope that clarifies a little, sorry for any confusion.

Seth Roberts (2011-12-29 13:38:41)

But at this point, when I do have cream or milk with coffee or something dairy like a dessert I feel like indulging in, it's often just a matter of hours before I can feel my face heating up somewhere and I know I'll have a spot the following day.

This does not fit the grass-fed/non-grass-fed emphasis we usually hear when discussing the quality of dairy products (grass-fed = good, non-grass-fed = bad). Grass-fed is supposedly better because grass has more omega-3 than the alternative to grass (e.g., corn). The presence/absence of omega-3 in cream or dessert is unlikely to make such a big difference so quickly. Nor is it clear how omega-3 can cause skin problems. It sounds like something else about Irish dairy is causing the problem.

Seth Roberts (2011-12-29 13:43:56)

I would eat Irish dairy which is grass-fed and natural as they come before chinese dairy that has god knows what contaminants in it.

I agree. There has just been another scandal about contaminated milk in China. In Beijing, I eat American butter (Land O'Lakes). The cream I use is from Nestle but thanks to your comment I see it is made in China - I won't buy it again. No wonder it was much cheaper than other cream. I cannot avoid buying Chinese milk but I buy the most expensive brand.

threepipeproblem (2011-12-31 06:36:39)

I also think you should question eschewing Irish butter from this one tale. Kerrygold is one of the few grass-fed butters that is widely available. It tastes awesome, has a higher omega-3 content, and vitamins such as choline and K which are almost nonexistent in traditional butters.

Darrin Thompson (2012-01-01 09:46:44)

We give Kerrygold to our autism kids because we've found it contriutes to peace around the house. Because we get it at Costco and it's priced well, I wonder how it's being processed, etc. There's got to be something wrong with it, right? I'd like it if there was a third pary who could verify what exactly grass-fed means to Kerrygold and how the product is handled before it makes it to the store shelf. However, the results are pretty good. So, yay Kerrygold. To your point about grass-fed not neccessairly meaning good, what is grass? As consumers we want to imagine cows in a patorial scene grazing lazily in a field of deep green beside a crystal stream of mountain snow melt. I imagine the commercial or regulatory definition (if there even is one) of grass-fed is much broader. It could be that Kerrygold is racing to the bottom by being cheap. Or it could be they're the second

coming of Warren Edward Deming in the dairy industry, an application of scientific method to the process of creating butter with a long term focus on the integrity of the product and the business. Who knows? In the end, I'm happy with the results in our family and we eat a lot of it. What I don't see after a quick perusal, where did she move to Ireland \_from \_? What about \_that \_ dairy? What's the difference? :-)

Seth Roberts (2012-01-01 19:14:02)

What I don't see after a quick perusal, where did she move to Ireland \_from \_? What about \_that \_ dairy? What's the difference?

She moved to Ireland from Seattle. My guess is that Irish dairy is less processed (e.g., less heated) than Seattle dairy. Milk contains dozens of different molecules. Seattle processing destroyed something that the Irish processing left intact. Another possibility is that Irish cows are better nourished and certain allergens were at higher concentrations in Irish dairy than in Seattle dairy.

Peter Andrews (2012-01-04 11:34:36)

My guess is that she may have a dairy sensitivity that only occurs when vitamin D levels are low. I don't know where she is from but Ireland has a very cloudy climate. Dr. Cannell at the Vitamin D council has also written of a vitamin D and acne link.

Seth Roberts (2012-01-04 13:56:26)

My guess is that she may have a dairy sensitivity that only occurs when vitamin D levels are low. I don't know where she is from but Ireland has a very cloudy climate.

Seattle - where she lived before Ireland - is also very cloudy. On the other hand it is possible she spent more time outdoors in Seattle.

jbug (2012-03-21 05:04:58)

does she have a leaky gut and the milk casien is leaking into her system causing and autoimmune/inflammatory response?

### **Ten Interesting Things I Learned From Adventures in Nutritional Therapy (2011-12-31 05:00)**

A blog called [1]Adventures in Nutritional Therapy (started March 2011) is about what the author learned while trying to solve her health problems via nutrition and a few other things. She usually assumed her health problems were due to too much or too little of some nutrient. She puts it like this: "using mostly non-prescription, over-the-counter (OTC) supplements and treatments to address depression, brain fog, insomnia, migraines, hypothyroidism, restless legs, carpal tunnel syndrome, and a bunch of other annoyances." In contrast to what "the American medical establishment" advises. Mostly it is nutritional self-experimentation about a wide range of health problems.

Interesting things I learned from the archives:

1. Question: Did Lance Armstrong take performance-enhancing drugs? I learned that LiveStrong (Armstrong's site) is a content farm. Now answer that question again.
2. "If you return repeatedly to a conventional doctor with a problem they can't solve, they will eventually suggest you need antidepressants."
3. "When I mentioned [to Dr. CFS] the mild success I'd had with zinc, he said it was in my mind: I wanted it to work and it did. When I pointed out that 70 % of the things I tried didn't work, he changed the subject. Dr. CFS' lack of basic reasoning skills did nothing to rebuild my confidence in the health care system." Quite right. I have had the same experience. Most things I tried failed. When something finally worked, it could hardly be a placebo effect. This line of reasoning has been difficult for some supposedly smart people to grasp.
4. [2]A list of things that helped her with depression. "Quit gluten" is number one.

5. [3]Pepsi caused her to get acne. Same here.

6. [4]100 mg/day of iron caused terrible acne that persisted for weeks after she stopped taking the iron.

7. "[5]In September 2008 I started a journey that serves as a good example of the limits of the American health care system, where you can go through three months, 15 doctor visits, \$7,000 in medical tests, three prescriptions and five over-the-counter medications trying to treat your abdominal pain, and after you lose ten pounds due to said pain, you are asked by the "specialists" if you have an eating disorder." I agree. Also an example of the inability of people within the American health care system to see those limits. If they recognized that people outside their belief system might have something valuable to contribute, apparently something awful would happen.

8. [6]Acupuncture relieved her sciatica, but not for long. "By the time I left [the acupuncturist's office] the pain was gone, but it crept back during my 30-minute drive home."

9. Pointing out many wrongs does not equal a right. She praises [7]a talk by Robert Lustig about evil fructose. I am quite sure that fructose (by itself) did not cause the obesity epidemic. For one thing, [8]I lost a lot of weight by drinking it. ([9]Here is an advanced discussion.) In other words, being a good critic of other people's work (as Lustig may be) doesn't get you very far. I think it is hard for non-scientists (and even some scientists) to understand that all scientific work has dozens of "flaws". Pointing out the flaws in this or that is little help, unless those flaws haven't been noticed. What usually helps isn't seeing flaws, it is seeing what can be learned.

10. [10]A list of what caused headaches and migraines. One was MSG. Another was Vitamin D3, because it made her Vitamin B1 level too low.

She is a good writer. Mostly I found support for my beliefs: 1. Of the two aspects of self-experimentation (measure, change), change is more powerful. She does little or no self-tracking (= keeping records) as far as I could tell, yet has made a lot of progress. She has done a huge amount of trying different things. 2. Nutritional deficiencies cause a lot of problems. 3. Fermented food is overlooked. She never tries it, in spite of major digestive problems. She does try probiotics. 4. American health care is exceedingly messed-up. As she puts it, "the American medical establishment has no interest in this approach [which often helped her] and, when they do deign to discuss it, don't know what the # %@! they're talking about." 5. "Over the years I've found accounts of personal experiences to be very helpful." I agree. Her blog and mine are full of them.

Thanks to Alexandra Carmichael.

More [11]Her latest post mentions me ("The fella after my own heart is Seth Roberts, who after ten years of experimenting . . . "). I was unaware of that when I wrote the above.

Alex Chernavsky (2011-12-31 07:44:30)

Reading your (Seth's) blog has convinced me of the value of self-experimentation. But I have doubts about the validity of the conclusions that are presented in "Adventures in Nutritional Therapy" (and other, similar blogs/articles I've read). The author of the "Adventures" blog seems unaware of – or at least unconcerned with – possible confounding factors like regression to the mean, placebo effects, and various cognitive biases. She also lacks skepticism with regard to such dubious things as blood tests for neurotransmitters. And, as Seth pointed out, she make little attempt at making measurements and keeping careful records of them.

HelenMarie (2011-12-31 08:10:10)

Hi Seth, Blessing today and all the days of 2012. Please don't stop taking D3 up the B vitamins. It has helped me through a winter without a serious depression. By depression I mean when it is too much trouble to even take a shower or brush my teeth. When the normal activities that I do without notice become so burdensome that every move is like moving through tar. The western medical system shines if you have broken your arm or have been in a gun fight. The eastern medical system shines for chronic conditions. Nutrition and diet are the last bastion of the snake oil salesperson. Nutrition changed my life, finding out I am allergic to dairy changed my life, restricting gluten seems to be doing the same thing. I gave that up for the holidays and guess what I am sick and.....I realized I am sick more often than not during this period and I also noticed I allow myself unrestricted access to all my favorite cookies, tarts, and anything else with lots of sugar and lots of wheat. Happy eating, continued nutritional adventures. hugs, hm

Tom (2011-12-31 08:36:41)

Re #4, Curing Depression, while she put 'quit gluten' as number one, she says that zinc supplementation (50 mg/day for a year) helped the most. (Not sure why she didn't put zinc first on the list.)

Caleb Coop (2011-12-31 11:01:18)

Of \_supplements\_, zinc was the most helpful.

Seth Roberts (2011-12-31 11:36:11)

The western medical system shines if you have broken your arm or have been in a gun fight.

I think it has other strengths as well. Vaccination greatly reduced polio and tuberculosis. Delivery of babies has gotten much better.

Seth Roberts (2011-12-31 11:49:21)

The author of the "Adventures" blog seems unaware of — or at least unconcerned with — possible confounding factors like regression to the mean, placebo effects, and various cognitive biases.

She's aware of the possibility of placebo effects – see Point #3. I don't know what cognitive biases you are talking about. Regression to the mean is rarely a good explanation when Possible Solution #7 worked and Possible Solutions 1-6 did not work. On the other hand, I agree about the numerical measurement, in the sense that if she made numerical measurements and made graphs and so on, you and I and others would probably find her conclusions more convincing.

john (2011-12-31 12:49:01)

One thing I don't like, which you kind of mention, is that she doesn't seem to try actual foods. Almost every isolated nutrient I've tried has had a neutral or negative effect (Mg, vitamin K complex, alpha tocopherol, gamma tocopherol, D3). I feel like one always runs into problems with comparative deficiencies when not using real foods. #9 is an excellent point that has caused me to stop reading several blogs.

spacenookie (2011-12-31 13:50:51)

personally, I look at a self-experimentation anecdote as a source of ideas to test, and ideas about testing. A persuasive, data-driven approach would lend an air of false authority, after all this is just a random internet person making health claims. Well-designed self-experimentation is "cheap, easy, and quick" so I suggest going directly to replication if you find an experiment interesting.

Jay (2011-12-31 19:28:48)

"I think it is hard for non-scientists (and even some scientists) to understand that all scientific work has dozens of "flaws". Pointing out the flaws in this or that is little help, unless those flaws haven't been noticed." Put this on a plaque. Every time I go to a journal club (I'm a scientist), the participants basically masturbate over their ability to recognize such "flaws." When this behavior is taken to excess, I usually take it as an indication that the person lacks abstract reasoning, or at least difficulty in understanding the concept of parsimony. For example, a mathematical model might be reduced description of some phenomena, such that the equations are capturing the "essence" of the phenomena, and omitting the irrelevant details--i.e. if the details \*were\* included, the model would be nevertheless be "isomorphic" to the original, simpler description. Many people get high on their ability to point out flaws without understanding the underlying framework.

Seth Roberts (2011-12-31 21:10:03)

Every time I go to a journal club (I'm a scientist), the participants basically masturbate over their ability to recognize such "flaws."

Yeah. At UC Berkeley I attended a journal club about animal behavior. The other faculty, like me, thought the pointing out of flaws was greatly excessive. Now and then we would say this but the graduate students couldn't stop themselves. Or so it seemed.

Jazi zilber (2012-01-01 09:40:41)

Impssive blog! It also shows how formidable is the task of changing health by playing with all these things (basically fine tuning of multiple parameters) One needs lots of erudition. you can see how much she knows on all miniscule effects bioavailability and relationships. Lots of work and persistence, And a high level of clarity as for the outcome measure. I have no idea how such feats can become commonplace. (it is OTOH strange. Because in ICU the system does the idea of fine tuning multiple parameters forcefully. It is doable. Just so formidable a task. But if someone manages to make it more practical for the masses.....)

Aaron (2012-01-03 03:11:03)

Just a short comment about fructose: Isn't it possible that the effect of fructose follows a J or inverted U curve? No fructose is irrelevant or bad, a little amount of fructose (say, from fruits) is beneficial (faster resynthesis of liver glycogen) and only large amounts (from excessive sugar/HFCS) are bad for your health?

Sara (2012-01-04 04:02:35)

I like her attitude. You can't take no s\*\*t from the medical profession. If they can't 'see' it (either physically or in tests), they will say it's 'in your mind'. I had a very lengthy health battle with a difficult to diagnose health problem (funky kidney - a congenitally 'spiral' ureter, the kidney would block and swell up to the size of a football (major bump in my front), but randomly empty). No doctor believed me that I had a randomly appearing lump. After three years I was progressively told I was stressed, depressed and perhaps even schizophrenic (like my father). Finally the kidney permanently blocked and I went in there to show off my

'alien baby'. Immediate action/surgery. What's that Foucault said about the 'medical gaze'? I lost 80 % of kidney function on that side (thank goodness for having two kidneys!), but did I get an apology for being called insane? Nope. Fructose - I was just blogging a bit about this because I'm doing Lentzner's junkfree jan and was confused about it. I think the demonisation of it is an over-reaction to the acknowledged problems of HFCS and sucrose - high intakes could certainly exceed the liver's ability to deal with it as the usual metabolic control systems don't work with fructose. I haven't found any studies that use fruit, fruit juice, dried fruit or crystallised fructose though. As far as I know, all the research has been done using HFCS (which brings in issues of GM, amongst other things). Somebody put me right if that's not the case.

TMS71 (2012-01-02 09:36:39)

What opinions in the article about scientific fraud do you disagree with?

Seth Roberts (2012-01-02 14:10:01)

Here are two opinions I disagree with in the "mass scientific fraud" article: 1. "There is now enough evidence to say what many have long thought: that any claim coming from an observational study is most likely to be wrong – wrong in the sense that it will not replicate if tested rigorously." I disagree. I think epidemiology has taught us a lot of useful stuff. For example, that heavy smoking causes lung cancer, that folate deficiency causes birth defects. It's true that epidemiologists persistently overstate the strength of their evidence but that doesn't mean their evidence isn't worth anything. To say "any claim" is "most

likely to be wrong" is black-and-white thinking, not to mention a vast overstatement. 2. "Science, at its most basic, is the effort to prove new ideas wrong." Science is also, at its most basic, about coming up with new ideas worth testing. That isn't easy.

### **Tokyo Visit (2012-01-02 03:29)**

I will be in Tokyo from Friday (January 6) through Tuesday (January 10). If you – my one Tokyo reader – would like to get together, let me know.

If you – my other readers – have suggestions about what to do in Tokyo, let me know those, too.

My overall view of Japan is simple: They understand fermented food. Better than anywhere else (France is second).

---

garymar (2012-01-02 05:58:40)

sounds like a plan! You've got my email so drop me a line. Good that you'll be here on the weekend.

Andy (2012-01-02 07:55:02)

Damn, missing you by 1 day Seth! Have been reading your blog for months from Tokyo, but I recently moved to Taiwan with my wife. I will be returning to Tokyo on the 11th to close out some stuff and go snowboarding. If you are looking for some off-the-beaten track restaurants I may have some suggestions for you. Personal favorite Tokyo lunch is Saba-Miso-Ni(mackrel with a miso sauce) with natto and raw egg on rice,

KenF (2012-01-02 10:20:56)

Going to the Tsukiji fish market early in the morning, seeing the goings-on, and then getting sushi is a lot of fun. You want to eat somewhere with a long line. The big department stores have huge food markets in the basements with prepared foods as well as pickles, etc., go there to sample the foods. If you are in Tokyo train station, you can also find small markets selling food from all over Japan. . If you want to see temples, the best thing is to take a day trip to Kamakura, but that's really a full day trip.

Seth Roberts (2012-01-02 14:02:18)

Going to the Tsukiji fish market early in the morning, seeing the goings-on, and then getting sushi is a lot of fun. You want to eat somewhere with a long line. The big department stores have huge food markets in the basements with prepared foods as well as pickles, etc., go there to sample the foods.

I have done both those things in the past and really enjoyed them. For me one of the highlights of a trip to Tokyo has been smelling the many kinds of miso available for sale (in a department store food court) and buying some really good miso to take home.

KenF (2012-01-02 17:55:14)

Well, here is something I just found doing a Google search a miso specialty store, apparently they have several branches in Tokyo: [http://www.gov-online.go.jp/pdf/hlj\\_ar/vol\\_0023e/30-31.pdf](http://www.gov-online.go.jp/pdf/hlj_ar/vol_0023e/30-31.pdf) Looks like the Sumo tournament will be going on while you are there, that is A LOT of fun: <http://sumo.pia.jp/en/sumo01.jsp>

KenF (2012-01-02 17:57:58)

I posted a reply with two links, maybe it requires approval to get posted. Anyway, I was suggesting going to the Sumo tournament in Tokyo. I also found an article about a miso specialty shop that looked interesting. You can find the article by Googling "miso food for the samurai" (include the quotes).

Seth Roberts (2012-01-02 19:37:10)

KenF, replies with links are sometimes classified as spam. thanks for letting me know. In any case those sound like great suggestions – I've never been to a miso specialty shop. I did go to a specialty pickle shop once.

chris (2012-01-07 03:24:25)

Hope you're enjoying your trip. On Monday you might get a chance to refine your theories on evolution by being near a city hall or shrine that's doing a 'Coming of Age' day ceremony. You'll see lots of 20 year olds dressed in kimonos and then getting drunk around the city. It's been amazing to me how differently Chinese, Japanese and Korean cultures evolved quite differently while keeping some commonalities.

### **Steve Jobs' Graduation Speech: My Opinion (2012-01-02 05:00)**

In [1]a recent post I said that Steve Jobs seemed to live in a very limited intellectual world. I gave [2]his Stanford graduation speech as an example. Someone asked me to explain. Here is my explanation.

The speech shows no sign of having read a book. It shows no sign of any intellectual interest outside his job.

It makes the insanely self-centered point that "if I had never dropped out, I would have never dropped in on this calligraphy class, and personal computers might not have the wonderful typography that they do."

It shows no sign of learning from anyone else (except his calligraphy teacher, which hardly counts). It shows no sign of even having noticed anyone else – it is all Steve all the time. It mentions Stewart Brand, but only to comment about the Whole Earth Catalog.

It makes the banal point what seemed like bad news was actually good news ("it turned out that getting fired from Apple was the best thing that could have ever happened to me").

It ends with a long string of banalities about death: "And yet death is the destination we all share. No one has ever escaped it. And that is as it should be, because Death is very likely the single best invention of Life. It is Life's change agent. It clears out the old to make way for the new." A high school student could have said that – at a funeral, perhaps.

This is from someone at the center of an enormous on-going revolution. I tried to find praise for it but all I found was that [3]someone in the Ukrainian government had plagiarized it.

Jay (2012-01-02 10:13:44)

I sort of liked his calligraphy example. Life is chaotic (in the mathematical sense), meaning you can't very easily predict the future by analyzing the present. But I guess he had an optimism bias – things tend to work out for the better. I disagree there; the calligraphy course could just as easily resulted in an undesirable outcome.

Robin Barooah (2012-01-02 10:23:27)

I think that whether the comments in the speech are 'banal' or not depends a lot on whether you think that Steve Jobs himself is interesting. You say his comments about death 'could have been made by a high school student'. A high school student could have said the following: "You must sleep sometime between lunch and dinner, and no halfway measures. Take off your clothes and get into bed. That's what I always do." Which, had it been said by a high school student it would be banal and uninteresting. It's interesting because it was said by Winston Churchill. If contemplating death really was one of the most important factors in how Steve Jobs lived, isn't that unusual for a CEO and something that it was very valuable for him to attempt to convey? Similarly, the comment about getting fired was also interesting - it sounds to me that he was saying that if he'd carried on being one of the most 'successful' twenty-somethings in modern history, he would not have learned things that were important to his later accomplishments. In any case, I don't think the commencement speech provides evidence either way for Steve Jobs's 'limited intellectual world. He wasn't there to prove that he'd read widely. The students were at Stanford, so presumably they were exposed to intellectual riches from other sources. Whether or not we agree about the paucity of Steve Jobs's intellectual life, I do have a question: What do you wish he'd been exposed to intellectually that you think may have helped him do a more worthwhile job, and how do you think these sources might have influenced him?

wr (2012-01-02 12:32:45)

Seth: THANKS. I intended to flag my appreciation for your earlier post, but forgot. Having read the (truly poor) Isaacson bio, I find myself in complete agreement with you. He was an ethically and intellectually shallow, incredibly adept salesman. Many people lament the bio as a "missed opportunity" to find out what Steve really thought about the "big issues of our time", be they technological or political or what have you. Spoiler: there is zero evidence Steve had deep thoughts about anything. He shares some shallow thoughts – literally – about the surface of various objects, but precious little else. Singe-mindedness is surely not incompatible with great success – he's proof of that. It may even be helpful, and there are many other examples. I do not think his was a happy life, though many will judge it as a great one. On that score I haven't decided for myself.

LemmusLemmus (2012-01-02 12:46:36)

Robin: I would say that if a speech is only interesting because it was made by someone interesting, this means the speech is not interesting.

Seth Roberts (2012-01-02 13:59:25)

What do you wish he'd been exposed to intellectually that you think may have helped him do a more worthwhile job, and how do you think these sources might have influenced him?

I think he could have learned a lot from reading Jane Jacobs. Jacobs constantly criticized top-down solutions to problems – the idea that "we know what is best for them". For example, when she was asked "what should be done with the Twin Towers site (in New York)?" she suggested asking the people who worked there. In dealing with Foxconn, Apple – no doubt with Jobs's approval – has taken a PR approach: Let's do what looks good, lets make sure they conform to Western ideas of goodness (e.g., age of workers, working hours). This is "we know what is good for you" thinking. When the "we" and "you" are far apart it is absurd (but good PR, so it continues). A student of Jacobs would have let the workers say what is good for them.

Seth Roberts (2012-01-02 14:17:39)

I disagree there; the calligraphy course could just as easily resulted in an undesirable outcome.

What you have just said is more interesting than anything Jobs said in that speech.

Seth Roberts (2012-01-02 14:25:09)

A high school student could have said the following: "You must sleep sometime between lunch and dinner, and no halfway measures. Take off your clothes and get into bed. That's what I always do." Which, had it been said by a high school student it would be banal and uninteresting. It's interesting because it was said by Winston Churchill.

I find that quote funny and quirky – not banal. I can't imagine a high-school student saying it. (In my experience, high school students save their sleeping for classrooms.) I might even take it seriously. I take a nap almost every day with my clothes on. What would happen if I took off my clothes?

Robin Barooah (2012-01-02 16:20:16)

Not liking top-down solutions is definitely something I can appreciate. I personally dislike being told what to do, and would probably hate to work for Apple in Cupertino, let alone Foxconn in China. Clearly Steve himself disliked being told what to do, but 'hypocritically' thought it was ok for others. So, let's agree that Apple itself as an organization functions as a monument to top-down thinking. What great non top-down examples of large scale human technological cooperation can you point to that we can compare to them?

Robin Barooah (2012-01-02 16:31:05)

Seth: When I was at high school, I experimented with both napping in the afternoon, and at a separate time, with reducing my sleep to 4 hours per night. I could easily have said (and maybe did) something like the Churchill quote. I have also had brushes with death, and can assure you that those changed my outlook more than the sleep experiments. I think I'd have been much better off taking the reality of death seriously earlier in my life, and yet I don't recall a single adult - certainly not anyone at college making that point. To me, it doesn't seem like a banal point to make in a commencement speech. I think you're clearly right that It's not an intellectually great or even interesting speech if taken out of context. I'm questioning why you are judging it as such when it was meant to be heartfelt life-advice. LemmusLemmus: I disagree. Whether what someone says is interesting depends on what you know of their background. For example: If the chairman of the federal reserve delivers a speech about how capitalism is fundamentally flawed, it would be much more interesting than if a protestor at Occupy Wall Street delivered the same speech.

Seth Roberts (2012-01-02 19:54:02)

I think you're clearly right that It's not an intellectually great or even interesting speech if taken out of context. I'm questioning why you are judging it as such when it was meant to be heartfelt life-advice.

My overall point is that Steve Jobs's legacy reflects the sort of person he was. To be blunt and harsh, he was shallow and incurious. I'm not saying such people should be prohibited from giving graduation speeches, I'm saying that when such people manage to gain control of one of the world's most powerful companies, there will be room for improvement in how that company behaves. I only discuss the Stanford graduation speech because it is evidence about what kind of person Jobs was. You are right, so what if a graduation speech is shallow. I think Apple Computer's response to the Foxconn suicides, which was a great opportunity to improve factory working conditions in many places, was squandered because of Steve Jobs. I also think that a wiser CEO would have pushed much harder to improve recyclability of Apple products. I am afraid that a shallow CEO hires shallow people. I hope I am wrong. Next week This American Life appears to be devoting a whole show to working

conditions at Foxconn. Perhaps it will make the same point I am making here.

Seth Roberts (2012-01-02 20:08:09)

So, let's agree that Apple itself as an organization functions as a monument to top-down thinking. What great non top-down examples of large scale human technological cooperation can you point to that we can compare to them?

It's not Apple the organization – it's Steve Jobs the CEO. He was remarkably successful, compared to other CEOs, at getting his way. In particular, to get Apple products to be enjoyable for him to use. How he did this I don't know. I doubt it was the organization chart. I also doubt it was as simple as he was an insensitive jerk. Lots of people are insensitive jerks. Maybe it was the context, the product, the people he hired (who could see past the bullying) – I don't know. But to answer your question, Southwest Airlines is well-run with happy employees and a very low rate of accidents. I would probably like a graduation speech by the head of Southwest Airlines.

Alex Chernavsky (2012-01-02 20:47:34)

What great non top-down examples of large scale human technological cooperation can you point to that we can compare to them?

I'd say Wikipedia and open-source software are good examples.

Robin Barooah (2012-01-02 23:10:40)

Seth: I don't understand the value of making these 'frank' judgements about Steve Jobs character. I know a number people who have had direct contact with Jobs. Almost all of them have attested to his character flaws, but a lack of curiosity was not amongst them, indeed some of them reported quite the opposite. It's hard to see your comment that he "managed to gain control of one of the world most powerful companies" as anything other than a distortion of well known history. You must know that when Steve Jobs regained control of Apple it was only a few months away from bankruptcy. He did not gain control of one of the world's most powerful companies. He gained control of a company that was on the verge of failure and then over a decade and a half built it into one of the worlds most powerful companies. It seems to me that you're angry about something that Steve Jobs represents, but it's not at all clear what that something is. I don't think it's obvious what level of influence Steve Jobs had over how Foxconn operates. He couldn't just order it to be done differently - it was done by negotiation. How many competitors to Foxconn could Apple turn to if they didn't get their way? He wasn't a deity, and despite his charisma, there were plenty of people who he had to go along with to get things done. Alex: I think those are good examples too. However they also show the limits of what we know how to do so far. How would a bottom-up organization build billion gate 22nm processors? What about unibody laptop chassis, or battery technology? How about six-sigma defect levels in products that ship at a volume of 100m a year? I'm not saying it can't be done, just that these things took decades for top-down organizations to learn to manage and that is real understanding about how to do them in a distributed bottom-up way that we simply haven't developed yet, and I don't see why it's Steve Jobs' fault for not developing them.

LemmusLemmus (2012-01-03 01:20:09)

Robin: We may be talking past each other. I read your original statement as saying that a speech can be made more interesting if you take the speaker's background into account. I disagree with that. If the chairman of the fed and an OWS protester give the same speech, these speeches are equally interesting, because, by definition, they're the same speech. (I am assuming no substantial differences in delivery.) What is more interesting about the chairman of the fed's speech is not the speech itself, but \*the fact that he would speak out against capitalism\*. Even if it is a very poor speech, \*this fact\* would still be newsworthy. But that doesn't make the speech itself interesting. Along those lines, one might argue that Jobs' speech is interesting because it teaches you how to be successful, but such an interpretation would be wrong, as quite a few commenters have pointed out

after the video went viral. If you want answers to those questions, you want, at minimum, an n»1 sample with variation in the dependent variable.

Seth Roberts (2012-01-03 03:52:16)

Robin, yeah, I should have said Jobs built Apple into one of the world's most powerful companies. I'm not angry at him. I'm sorry he squandered big opportunities to make the world a better place. It's hard for me to be sure how much influence he could have had at Foxconn, I agree, but I don't think he even tried.

Robin Barooah (2012-01-03 11:08:09)

LemmusLemmus: I think we have a philosophical difference of perspective. I don't regard a communication as bearing information outside of it being a communication between a sender and a receiver. To me, this means that a printed speech is just a message in-transit and is only distinguished from noise at the point when it's read. Whether it's interesting depends on how predictable it is relative to the receiver's preconceptions about the sender. When a receiver is blind to the identity of the sender, they still create a hypothetical model of the sender based on their own history. (my view is basically a straightforward interpretation of Shannon's information theory) Seth: Fair enough. I do think it's an interesting question - what could Steve Jobs have done better, and more importantly what tradeoffs would it have involved?

Nancy Lebovitz (2012-01-03 14:33:42)

"In particular, to get Apple products to be enjoyable for him to use. How he did this I don't know. I doubt it was the organization chart. I also doubt it was as simple as he was an insensitive jerk. Lots of people are insensitive jerks. Maybe it was the context, the product, the people he hired (who could see past the bullying) — I don't know. " Hypothesis: Jobs was unusually good at figuring out what he wanted. I think people generally are much better at knowing what they don't want than what they do want.

Seth Roberts (2012-01-03 19:27:52)

Hypothesis: Jobs was unusually good at figuring out what he wanted. I think people generally are much better at knowing what they don't want than what they do want.

Interesting idea. The same has been said about Alice Waters. She can't cook very well but she is a great critic of food other people have cooked.

LemmusLemmus (2012-01-04 01:58:15)

Robin: Yeah, I disagree with pretty much everything you say in your paragraph, so I think you have identified our points of disagreement clearly and comprehensively.

Robin Barooah (2012-01-07 11:36:33)

Seth & Nancy: I think what you're talking about here is a key aspect of how Steve Jobs functioned - and one of the unusual things about his life was that starting at an early age, he had a huge set of opportunities to practice criticizing product design and then see the consequences. Very few people have the opportunity to do this even once, whereas Steve Jobs had thousands of chances to practice.

Robin Barooah (2012-01-07 11:42:32)

LemmusLemmus: Success!

ShardPhoenix (2012-01-09 05:23:40)

So Steve Jobs didn't engage in some tokenistic behavior (recycling, really?) along your preferred political lines, therefore he's "shallow"?

Seth Roberts (2012-01-09 07:01:52)  
Recycling is "tokenistic"? What does that mean?

Dr. Tim Hadley (2012-01-09 17:52:59)  
Thanks, Seth. You're a breath of fresh air in the world of insane Jobs-worship. Your analysis and openness to discourse make your blog one of the best I read.

Christopher Burd (2012-01-17 10:14:38)  
Jobs got a lot of humanities cred out of having taking one calligraphy course.

Seth Roberts (2012-01-03 19:22:44)

Inflammation is a reaction, a link in the chain of cause-and-effect. What causes the inflammation in the first place?

Perhaps the inflammation is an overreaction. Maybe it is caused by infection – e.g., infection by bacteria in the mouth.

joseph (2012-01-03 19:57:09)

"•Weak evidence that bacteria in food stimulate the immune system" Why is it weak and not strong evidence? im actually not sure of you'r point or rather opinion of the study? concurring or disagreeing?

Seth Roberts (2012-01-03 20:37:46)

Why is it weak and not strong evidence? im actually not sure of you'r point or rather opinion of the study? concurring or disagreeing?

I agree with the conclusion of the study. It is weak evidence because the signal isn't especially strong and the design isn't terribly good.

Jim Breed (2012-01-04 14:09:58)

Re: Inflammation. I was doing SLD using flax seed oil for two weeks before my last dental appointment. My pockets that were 4's and 5's magically changed to 2's and 3's. I had my dentist print both the reports because I was so grateful that they stopped talking about some really painful sounding root work. My brushing and flossing were totally unchanged. I was expecting the result because of what I've read on the blog, but nothing this good. I am convinced that taking flax=reduction in gum inflammation, at the very least.

Alex Chernavsky (2012-01-05 07:48:02)

@Jim, I used to have big problems with staining on my teeth. I had to get my teeth cleaned every three months. After I started taking flaxseed oil daily, the staining was greatly reduced. I did not change my flossing or brushing habits, and I didn't cut down on my coffee consumption (the dental hygienist seemed to think that the staining was caused by the three cups of coffee I drink daily). I wonder if the staining was related to some sort of inflammatory process.

Tuck (2012-01-05 20:18:31)

"Perhaps the inflammation is an overreaction. Maybe it is caused by infection — e.g., infection by bacteria in the mouth." I suspect that's a secondary symptom as well. The folks who've studied non-Western people looking for signs of the diseases of civilization find a lack of heart disease and a lack of tooth decay... Are you familiar with Burkitt's "Western Diseases, Their Emergence and Prevention"? The most fascinating finding from that book was that autoimmune diseases were absent in Africa prior to the adaptation of the Western diet... <http://www.hup.harvard.edu/catalog.php?isbn=9780674950207>

## Assorted Links (2012-01-04 05:00)

- [1]More evidence that the SCD (Specific Carbohydrate Diet) diet really helps people with Crohn's Disease. "Since starting this diet, I have had no pain. Some might attribute this to surgery, but I am convinced the diet has so much to do with it. My blood work is normal, and it hasn't been in 8 years. The sed rate level in the blood is normal instead of elevated outrageously."
- [2]How to improve on lectures when teaching physics.

- [3]More selenium, less risk of cancer. Contrary to what the researcher quoted in this article says, there is already substantial evidence that selenium reduces cancer risk. For example, in a county-by-county map of USA cancer rates, there is a clear rift in the north east. On one side of the rift rates are clearly higher than on the other side of the rift. The rift corresponds to geological fault line. On the low-cancer side of the rift, there is more selenium in the soil. There are also rat experiments. You certainly should take selenium supplements.
- American health care plays a surprisingly large role in [4]an excellent story by Peter Hessler in The New Yorker about the Japanese yakuza (mafia). 1. From 2000 to 2004, [5]four yakuza members got liver transplants at UCLA at a time when liver transplants were hard to get. A few months later they made large donations to UCLA. The money went into a general fund at the surgery department. According to a UCLA spokesperson, [6]there was no connection between the transplants and the donations. According to [7]a UCLA press release, "No money or donation was offered or paid to anyone at UCLA as a quid pro quo for getting a transplant or moving up on the list." Because a general fund is not a person, this is literally true. 2. In the early 1990s, at a Columbia, Missouri hospital, a nurse was suspected of killing patients. Hospital administrators covered it up. "Everyone took part in the coverup was promoted, everybody who tried to expose it was punished," said someone who tried to expose it.

Thanks to Alex Chernavsky.

## **Is Epidemiology Worthless? The Case of Calcium (2012-01-05 05:00)**

Epidemiology has lots of critics. In [1]this article, for example, it is called "lying on a grand scale." Every critique I have read has ignored history. Epidemiologists have been right about two major issues: 1. Heavy smoking causes lung cancer. 2. Folate deficiency causes birth defects. In both cases, the first evidence was epidemiological. Another example is John Snow's conclusion about the value of clean water. In my experience, epidemiologists often overstate the strength of their evidence (as do most of us) but overstatement is quite different from having nothing worth saying.

Let's look at an example. Many people think osteoporosis is due to lack of calcium. Bones are made of calcium, right? The epidemiology of hip fractures is clear. In spite of the conventional idea, the rate of hip fracture has been highest in places where people eat a lot of calcium, such as Sweden, and lowest in places where they eat little, such as Hong Kong. ([2]For example.) In other words, the epidemiology flatly contradicted the conventional idea. This was apparently ignored by nutrition experts (everyone knows correlation does not equal causation) who advised millions of people, especially women, to take calcium supplements to avoid osteoporosis. Millions of people followed (and follow) that advice.

[3]Thanks to a recent meta-analysis we now know that experiments and better data firmly support the earlier epidemiology, which suggested that calcium supplements are dangerous. Here are its main conclusions:

In meta-analyses of placebo controlled trials of calcium or calcium and vitamin D, complete trial-level data were available for 28,072 participants from eight trials of calcium supplements and the WHI CaD

participants not taking personal calcium supplements. . . .Calcium or calcium and vitamin D increased the risk of myocardial infarction (relative risk 1.24 (1.07 to 1.45),  $P = 0.004$ ) and the composite of myocardial infarction or stroke (1.15 (1.03 to 1.27),  $P = 0.009$ ). . . . A reassessment of the role of calcium supplements in osteoporosis management is warranted.

If the epidemiology had been taken more seriously, many heart attacks might have been avoided.

Is this an "anecdote" – a single example – proving nothing? Here's how you can check. Randomly select a meta-analysis of epidemiological studies. Thousands have been done. Then ask if the results summarized in the meta-analysis appear random. Better yet, randomly pick two meta-analyses. Suppose the first summarizes 5 studies and the second summarizes 6. If the 11 results were shuffled together, how well could you assign them correctly?

1. <http://www.numberwatch.co.uk/epidemi-reviews.htm>

2. <http://mydrmo.com/2011/10/got-milk-the-truth-about-osteoporosis-calcium-dairy-products/>

---

Lemniscate (2012-01-05 05:52:37)

I think epidemiology is a field of study that is particularly ill suited to the modern research environment. The pressure to continuously publish results, especially results pertinent to public health policy, produces mass false positives. Government policy can help entrench these false positives. This is a "boy who cried wolf" situation. People will ignore important results like the calcium result because they're used to epidemiological results being false positives.

Valtsu (2012-01-05 06:24:23)

Hmm... One reason why there are more fractures in Sweden than in Hong Kong might be climate. More snow and ice in the winter?

Jonathan (2012-01-05 06:52:39)

While this isn't directly relevant to the main point of your post, readers might be interested to know that current thinking leans toward the idea that both osteoporosis and arterial calcification are problems not of insufficient/excessive calcium, but of the body's failure to distribute calcium to its proper places. Likely candidates for the driving factors include hyperinsulinemia and deficiencies of the fat-soluble vitamins D, K2, and A. To avoid osteoporosis or heart attacks, there seems to be a good case for supplementing D (or sunlight) and K2. When your metabolism is putting calcium into the blood vessels instead of the bones, it seems like a reasonable hypothesis that more calcium would increase the risk of heart attack. Regarding epidemiology: I think most of the correlations found by epidemiologists do not reflect direct causation; rather than  $A \rightarrow B$  or  $B \rightarrow A$ , they usually mean that both A and B have a common cause that was not measured. Unfortunately, many epidemiologists and nearly all readers of popular science articles have not grasped this.

charles (2012-01-05 07:07:29)

Supposedly, most of the forms of Calcium supplements that people use actually remove calcium from the bones. Calcium citrate, etc. Calcium carbonate (like from eggshells, oysters) works correctly though..

Jazi zilber (2012-01-05 12:40:17)

I have read that only 20 % of epidemiological findings turn true in controlled experiments. 80 % are refuted. It is a question of the cost of different mistakes. + whether people can accept information with the idea that it has a very low probability of being true. Many people cannot handle informatiothat way

Becky Hargrove (2012-01-05 12:54:54)

My dad has a nice batch of mustard greens in the garden. I'll stick with them!

Seth Roberts (2012-01-06 01:57:36)

I think most of the correlations found by epidemiologists do not reflect direct causation; rather than  $A \rightarrow B$  or  $B \rightarrow A$ , they usually mean that both A and B have a common cause that was not measured.

I am curious why you think this. Your belief seems much stronger than the available evidence warrants. "Most of the correlations" is a very large set. My impression is that most of the correlations discovered by epidemiologists are still unexplained – that is, we are not sure why they happened. To think they suggest cause and effect simply means they make a cause-effect statement (e.g., A causes B) more plausible. Almost always they do. I see nothing wrong with epidemiologists pointing this out. It is also true that an A/B association makes a common cause explanation more plausible. Epidemiologists often point this out, too.

Seth Roberts (2012-01-06 01:59:37)

I think epidemiology is a field of study that is particularly ill suited to the modern research environment. The pressure to continuously publish results, especially results pertinent to public health policy, produces mass false positives.

I agree (although I have no idea about the number of false positives). Is epidemiology worse than any other area of health research? I tend to think it is better because it is not distorted by vast amounts of drug company money. All researchers are under pressure to publish.

Alex Chernavsky (2012-01-06 08:07:47)

Gary Taubes had an interesting article about epidemiology and some of the problems associated with it: <http://www.nytimes.com/2007/09/16/magazine/16epidemiology-t.html?pagewanted=all>

Lots of Links « Sceptically Fit (2012-01-07 14:50:42)

dearieme (2012-03-13 09:47:13)

Thanks for the Taubes reference, AC: a very useful summary.

Faevia (2012-04-10 01:15:05)

It's good to do some research about things like calcium. Not only do you need calcium, but magnesium is important too, but most people do not know that they work together. People get enough calcium, but common calcium sources like milk have very little magnesium, so instead, people should focus on getting more magnesium to improve their bone strength. If anyone would like to read more about this, here is an article that explains how to make the most from calcium: <http://faevia.com/2012/02/getting-the-most-out-of-calcium/>

## Why Language Began: Words Say What We Want (2012-01-06 05:00)

[1]My theory of human evolution posits that many features of human nature began because they increased specialization and trade. One is language. Language began with single words, I assume. The use of single words began and grew because they helped the two sides of trade find each other. The first language, in other words, was the first advertising. Advertising has two sides: (a) saying what you have too much of and (b) saying what you have too little

of.

Single words are still used this way. Stores are often adorned with single words that say what they sell. When you go to an unfamiliar store, you may use single words to find what you want ("thermometers?"). The use of single words to convey desires is clear in a paper by Alexander Graham Bell, which I learned about from *Electric Universe* by David Bodanis. Bell (the inventor of the telephone) was a teacher of the deaf and wrote [2] a paper about teaching deaf children language. His method involved labeling objects around the house with their names. One of his students was a five-year-old boy:

One morning he came downstairs in high spirits, very anxious to play with his doll. He frantically beat his shoulder with his hands, but I could not understand what he meant. I produced a toy-horse; but that was not what he wanted. A table; still he was disappointed. . . . At last, in desperation, he went to the card-rack, and, after a moment's consideration, pulled out the word "doll" and presented it to me.

For a different view of why language evolved, see [3] this paper by Hauser, Chomsky and Fitch.

Tim Beneke (2012-01-06 11:41:33)

"The use of single words began and grew because they helped the two sides of trade find each other." But surely the necessity for sounds that provided warning of threat from predators (and other danger) preceded words for trade? And perhaps vocalizations that encouraged silence in the presence of predators. Before we could trade we had to be able to survive... And the need to communicate specificity of edible plant locations might have encouraged enough fine-grained cognition so that words developed – think of the bee wagging behavior that locates pollen. I'm not saying your theory is wrong, but parts of it are perhaps over-stated.

Josh (2012-01-07 14:48:30)

I see words as a representation. As what they represent gets more complex, so do the patterns used to create them. I think the most pure form of communication is sharing an experience. However even that experience is limited by a person's perception. I often lose perspective on what communication really is, it's an abstract, not the reality of the moment. It intrigues me as to how much is perceived without words. This would reason to place great emphasis on health and awareness to maximize perception and cognition. To better understand and communicate with one another to get what we want and also redefine what we want.

Nathan Myers (2012-01-10 21:28:11)

The most persuasive arguments I've encountered on the origins of language trace it to mother/child interactions. Babies' wants are very simple, and not different from those of other species, so cannot sustain language development. Teaching is an activity can take advantage of every conceivable improvement in language technology.

## Tokyo Restaurant Recommendations – and Why They Might Be A Bad Idea (2012-01-07 05:00)

An earlier post asked for Tokyo recommendations. A kind reader (Andrew Clarke) provided the following recommendations of off-beat restaurants:

One place I always recommend is Andy's Shinhinomoto, in Yurakucho: [1]<http://www.frommers.com/destinations/tokyo/D61101.html>. I have never seen a travel show that has covered the place, but it's a best kept secret within the ex-pat community. Its menu is a standard Japanese Izakaya (pub) menu with some of the freshest sashimi (and fish in general) in Tokyo, and the strangest thing - it's ran by a long-term British ex-pat, who is so renowned for his ability to pick good ingredients that he selects and delivers fish for several local sushi shops. Upstairs seating is best for atmosphere, but the food is the same downstairs. They have an English menu, and I'd also recommend the fish head and tempura. It's also not super expensive, somehow I never manage to spend more than 7000Y with alcohol.

Teyandei is another one that I would generally recommend: [2]<http://www.bento.com/rev/2133.html>. You'll be lucky if you manage to find this one, most taxi drivers I have ever asked couldn't find it even with GPS, it's located in a residential area of the back of Roppongi. Great atmosphere, and again Izakaya style but not fish oriented, and not strictly traditional. The most memorable dish I had was a french baguette, vanilla ice cream and maple syrup slider - which was very good, but to be enjoyed occasionally. Outside of that they have many great dishes, with more of a meaty or stuff on sticks vibe.

Last general recommendation is for sushi: [3]<http://tokyofood.blog128.fc2.com/blog-entry-52.html>. I used to live in Tsukiji town and this place is a friendly joint that attracts many locals in the evening. Probably because it's not super-expensive, but great quality and I particularly recommend the Uni if that is your thing. Their 'aburi (blow torched)' dishes are great too, and the Aji (mackerel) and the tsuki maguro (marinated tuna).

[follow-up:] The Moroccan place, I'm not sure why I didn't include this the first time, as it is possibly the most strange and off-the-beaten-path: [4][http://www.dalia58.com/d\\_map.html](http://www.dalia58.com/d_map.html). [5]Google Maps. The owner is a Japanese lady who spent 1 year in Morocco on a home stay. She loved the home cooked food and fastidiously learned to replicate them the way only Japanese people can. I learned about from a Moroccan co-worker who swears it's the most authentic Moroccan food he has had out side his homeland. You definitely need to book ahead, there are only maybe 12 seats in the place and only 4 of those are not on the ground. The menu is fairly small and changes every once in a while as the owner travels back to Morocco regularly, but usually I have the meatball tagine (best), fish tagine, freshly baked wheat bread and vegetable couscous. I have never been there alone, you'd need at least two people to eat all that.

[6]Alexandra Harney, author of The China Price, who has spent years in Tokyo, recommended:

My favorite watering hole: Asahi Shokudo in Nogizaka, near Tokyo Midtown. Unless you speak Japanese, the best thing to do is probably to have someone call ahead, make a reservation (a very good idea) and fax you a map. Their tel: 03-3402-6797. GREAT food, very good atmosphere, sake good too. It's not fancy, but authentic and creative.

Tyler Cowen's forthcoming book ([7]An Economist Gets Lunch: New Rules For Everyday Foodies) says a lot about Japanese food and restaurants. In an email he said "Pierre Gagnaire Tokyo was the best meal I've ever had...that is

expensive, though.”

I am in Tokyo now. Last night I took a long walk around my hotel ([8]Hotel Changtee), which is in Ikebukuro. I have stayed here three times before. On my walk, for the first time, I noticed a Spanish restaurant (Agalito) a few blocks from my hotel. In Beijing, I often have Japanese food, so I decided to try it. The menu (mostly tapas) looked good. It wasn't expensive (Ikebukuro is full of relatively cheap restaurants).

I had seven dishes. Every one surprised me and tasted great. I had pickles, a vegetable terrine, deep-fried shrimp and avocado (the avocado was also deep-fried), mackerel, a dish of large mushrooms and bacon, marinated cherry tomatoes (skins removed), and baked/grilled cheese and tomatoes. Far better than the tapas I had in Barcelona (or anywhere else). Far better than the tapas at a Berkeley restaurant (Cesar) next to Chez Panisse owned by Alice Waters' ex-husband. The pickles were a small dish of carrots, cucumber, cabbage, and red pepper. The best pickles I've ever had, and I've had pickles hundreds of times, as anyone who knows my passion for fermented food will understand. They are a staple of Japanese and Szechuan cuisine. I've had Japanese pickles at dozens of places. The carrot pickles were so good, such a great blend of sweet and sour, so perfectly crunchy, that I want to start trying to recreate them. I didn't know carrot pickles could be that good. The tomato and cheese dish also opened my eyes. I never knew that cheese and tomatoes could go so well together. I want to get special equipment (the baking pan) just to make this one dish. I want to try many different cheeses and tomatoes to find the best pairing. No meal at Chez Panisse or anywhere else has pushed me to do two new things. A tiny number (five?) have pushed me to do one new thing.

This restaurant is a few blocks from my hotel. No one recommended it. The meal, with drink, cost \$60. I'm told that if you ask a Tokyo resident what are your favorite restaurants? they look at you blankly. Now I see why. There are so many great restaurants it doesn't matter. This meal also taught me that recommendations may be counter-productive. Recommended restaurants are often expensive. Expensive food is likely to require lots of labor, special tools, and expensive ingredients. Making it harder to copy and thus less inspiring. Whereas this "plain" meal, with cheap ingredients and relatively little labor, will continue to influence and teach me whenever I do stuff it has inspired me to do.

"I never knew that cheese and tomatoes could go so well together": I'm baffled. Cheddar and tomato in Britain; Brie and tomato in France; dish after dish in Italy .....

Seth Roberts (2012-01-07 13:05:51)

"I never knew that cheese and tomatoes could go so well together": I'm baffled. Cheddar and tomato in Britain; Brie and tomato in France; dish after dish in Italy.

I've had tomato and mozzarella many times...it is not a good example of the power of the tomato/cheese pairing because the cheese is too weakly-flavored and the tomato is not roasted. Neither is at their best. It's not enough to put the two together. You have to optimize the combination – choose the best cheese, the best tomato, and the best proportions.

Seth Roberts (2012-01-07 13:09:41)

"I never knew that cheese and tomatoes could go so well together" Umm, pizza?

It did remind me of pizza, yeah. I suppose the pizza I've had has had too much toppings. This makes me want to compare pizza with and without toppings.

Seth Roberts (2012-01-07 13:16:14)

Rashad, I cannot find it online. The name is something like Agalito. If you want to go there, go to the Ikebukuro Station, leave by Exit C6, go in the direction away from the station on the main street until you reach the Seiko building (very close, 2-3 blocks) and then turn left and go about 4 short blocks. You can also follow the directions to the Grand House Chang Tee, which are probably online. It is a few blocks before the hotel.

garymar (2012-01-08 01:26:03)

The real foodies in Japan are in *Osaka*. They have a phrase there that goes back to the Edo period: "kui-daore", literally "eat-fall", meaning "go bankrupt overeating (extravagantly expensive food)". It's almost impossible to get a bad meal there, in any price range. Aren't the Italians like that as well?

Perfect Health Diet » Around the Web: Epiphany Sunday Edition (2012-01-08 16:55:01)

bob (2012-01-10 08:13:08)

I have no doubt the tapas were good, but none of those sounded even remotely authentic. Avocado? As typically Spanish as grasshopper. Spanish food is not really about tapas, but about what Americans would call stews and soups. What a Spaniard would have for lunch, not what he'd have for dinner if he is not at home or in a restaurant

## Flaxseed Oil and Gum Disease: Still More Success (2012-01-08 05:00)

[1]The following comment was left a few days ago:

I was doing SLD using flax seed oil for two weeks before my last dental appointment. My pockets that were 4's and 5's magically changed to 2's and 3's. I had my dentist print both the reports because I was so grateful that they stopped talking about some really painful sounding root work. My brushing and flossing were totally unchanged. I was expecting the result because of what I've read on the blog, but nothing this good. I am convinced that taking flax= reduction in gum inflammation, at the very least. [emphasis added]

Take that, "[2]decline effect" (big experimental effects, when the experiment is repeated, get smaller)!

The commenter sent me the records of the two cleanings. At the pre-flaxseed-oil cleaning (April 28, 2011), he had 24 sites (13 teeth) with pockets of depth 4 or 5. At the cleaning after he started flaxseed oil (July 28, 2011), he had no sites with pockets of depth 4 or 5.

You can find many similar reports [3]here.

Jazi zilber (2012-01-08 06:13:52)

I have experienced another effect worth mentioning. I have one pocket, and after eating spareribs (i usually eat full rack, = lots of pork fat), it gets inflamed seriously, No spareribs, no inflammation. It was repeated several times. Initially, i thoughts it is the chewing. (most of my food is not that hard to chew, and i feel the effort different). But then i tried chewing on the other side, or very gently, mbut still inflammation and serious pain! Once i stopped spareribs, i forgot the pocket, the pain inflammation. As if it never happened.....

gwern (2012-01-08 08:34:42)

> Take that, "decline effect" (big experimental effects, when the experiment is repeated, get smaller)! "Take that, reporting bias (small experimental effects, when the 'experiment' is repeated, get bigger)!"

David (2012-01-08 12:30:07)

Jazi: What type of pork was this? Grass fed pastured or conventional?

Seth Roberts (2012-01-08 13:05:31)

Gwern, your use of the term "reporting bias" is different than Wikipedia's definition: "reporting bias refers to a tendency to under-report unexpected or undesirable experimental results, attributing the results to sampling or measurement error, while being more trusting of expected or desirable results, though these may be subject to the same sources of error." I have never heard of "reporting bias" being used to mean what you say it means.

gwern (2012-01-08 16:31:38)

Anecdotes selectively reported are useless; and the stronger your reporting bias, the further from truth the effect size becomes - if everyone reports their results, good, if only people with strong effects report, bad, if only people with very strong effects report, even more bad. Is this an unfair characterization of the anecdotes you post, which are selected for their enthusiasm? Perhaps, but your decline remark is even unfairer.

Nancy Lebovitz (2012-01-08 19:32:05)

Jazi, is that the only pork you eat? Could it be something about the sauce?

Seth Roberts (2012-01-08 21:33:14)

Anecdotes selectively reported are useless

There's a strong statement. Care to provide evidence for it? I think I understand your explanation - you mean that what gets reported will be biased upwards. Sure, it's clear that if you repeat an experiment you should expect a smaller effect. It's also true that the first report of an effect is unlikely to be the maximum possible size of the effect...so making a big deal of this bias is not a good idea.

Sara (2012-01-09 02:43:23)

I have a self-experiment if you are interested. It's off topic to the post, but interesting, I think. I have familial high-cholesterol - it was 8.4. About twice the norm (I know in America you measure it on a different system). I was prescribed statins but begged for six months to try natural intervention - they told me it wouldn't work. I took high dose vitamin C and niacin (flushing - not niacinamide/nicotinamide) for six months, but was still nervous at the test. When I rung for my results the nurse told me she had never seen statins work so well. When I said I hadn't taken any she said the first test results must have been wrong :D I've stayed at the high end of normal since then. Side effect: I used to have terrible acne. Within two weeks of staring that regime (5-10g vitC a day and 50mg niacin when I remembered - about 4-5 times a week) it went away completely. As in.. completely and without recurrence. Through experimentation I've determined it was the niacin that had this effect on my skin. There's two more for you 'anecdotal' files of no scientific significance, Seth!

Tim Beneke (2012-01-09 10:20:27)

There is rat research plus correlational and controlled human research on fatty acids and gum disease - we obviously need a lot more, but it's encouraging - see the following: - With rats: <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2220053/> "The purpose of this study was to examine the potential anti-inflammatory effects of PUFA supplementation, by administration of fish oil as a source of the n-3 PUFA, eicosapentaenoic acid, and borage oil as a source of the n-6 PUFA, gamma-linolenic acid (GLA), to adults with periodontitis." <http://www.ncbi.nlm.nih.gov/pubmed/12591005> - From Harvard Medical: "We found that n-3 fatty acid intake, particularly docosahexaenoic acid and eicosapentaenoic acid, are inversely associated with periodontitis in the U.S. population," <http://www.colgate.com/app/CP/US/EN/OC/Information/Articles/ADA/2010/article/ADA-10-Polyunsaturated-Fatty-Acids-Lower-Gum-Disease.cvsp>

Out of the fishbowl (2012-04-01 03:30:16)

I also read that an aspirin a day has shown results in reducing pocket depth. Thank you for the information. I will start my Flax therapy ASAP!

- Edward Jay Epstein on [1]The Lessons of Le Carre (the spy novelist)
- [2]Gary Taubes recommends five excellent books, including Weston Price.

- [3] This article about the Marc Hauser case tells a brief story about a Harvard coverup in the 1960s. "In the late 1960s I was eating lunch in William James Hall with a few fellow assistant professors in the Harvard psychology department when a woman named Patricia Woolf sat down at our table. . . . She asked whether we had heard anything about the fabrication of data by one of our colleagues."
- [4] This sad and fascinating post tells how pediatricians encourage Vitamin D deficiency by warning parents to keep children out of the sun. Then, making things even worse, children with broken bones due to Vitamin D deficiency are assumed by pediatricians to be victims of child abuse. "Dr. Carole Jenny, head of the American Academy of Pediatrics Section on Child Abuse, implies such tragic miscarriages of justice simply don't happen. She then claims, "We have been checking every child with multiple fractures for metabolic bone diseases for several years and have not identified a single child with vitamin D deficiency." How can that statement be true if every other researcher is reporting infantile and early childhood vitamin D deficiency to be rampant in normal children? Furthermore, how can an infant beaten severely enough to cause multiple fractures not be bruised or in distress? Dr. Jenny cleverly avoids the question."

Tom (2012-01-09 06:27:32)

Seth, thanks for linking to the Taubes interview. It contains the pithiest explanation of the obesity epidemic that I've ever read: "The experts decide that Americans get fat by eating fat. Then they find strains of rat that get fat eating fat, then they breed those strains. And now that they have found an animal model that confirms their preconceptions they argue that the preconceptions must be true too – obviously humans get fat on fat because the rats do. Then some journalist like me comes along, and says, "What about all the other animals that get fat on grains and vegetable matter?" And they look at you and say, "Oh, you're one of those Atkins people aren't you?"

Seth Roberts (2012-01-09 18:32:27)

The experts decide that Americans get fat by eating fat. Then they find strains of rat that get fat eating fat, then they breed those strains. And now that they have found an animal model that confirms their preconceptions they argue that the preconceptions must be true too – obviously humans get fat on fat because the rats do.

Most rats do not get fat eating fat. This was a big reason that Sclafani developed the supermarket diet (consisting of supermarket foods, such as salami and cookies) – so that rats would get fat more quickly (making it more easy to use them to study obesity). You cannot get a rat fat quickly simply by feeding him a high fat diet, Sclafani told me.

John (2012-01-10 21:29:50)

The link to the Vitamin D post seems to be broken.

Seth Roberts (2012-01-10 22:07:21)

Fixed the Vitamin D link.

## Why We Touch Our Mouths So Much: Forewarned is Forearmed (2012-01-10 05:00)

When I taught Introductory Psychology, I came across a study in which researchers put people in a room with food and watched them. They were looking for cycles in eating and drinking. They noticed that their subjects spent a lot of time touching the face near their mouth – what they called “the snout area”. After I read that, I noticed the same thing countless times. Right now I am at an airport waiting for a flight. Looking around, I see three of about 50 people touching their mouth or nearby.

Why do we do this? I propose an evolutionary explanation: To expose our immune system to all the germs near us in small amounts. Mouth-touching is part of a larger sampling process: 1. We touch many things constantly. In particular, we shake hands, hug, and otherwise touch people near us. Germs that have managed to live in or on other people are the most dangerous. 2. We lick our lips often, moving germs on our lips inside our mouths. 3. When you eat, food transfers bacteria from the inside of your mouth to your tonsils, which circle your throat. Tonsils are full of lymphocytes, the immune-system cells that detect germs. Once we have developed antibodies to a microbe, of course, we are much less vulnerable to it. The whole sampling process is a kind of self-vaccination.

We need conventional vaccination when self-vaccination fails. Polio vaccination was the first big vaccination program, and it worked: polio was nearly wiped out. Before around 1900, polio was not a big problem. It became a big problem at roughly the same time that public health measures and the replacement of horses by cars caused cities to become much cleaner places. Others have theorized that this is why polio became a big problem. As recently as 1951, thousands of children died from polio.

This is related to but different than [1]my ideas about our need for fermented food. (I believe we need to eat plenty of fermented food, day after day, to be healthy.) When we eat fermented food, we ingest large amounts of bacteria that are familiar and safe. The amount is large because the food has been fermented. The bacteria are familiar because we eat the same food repeatedly. They are safe because the insides of our bodies are dramatically different than what we eat (e.g., different temperature). The sampling system I am proposing here exposes us to small amounts of unfamiliar dangerous bacteria. However, this sampling system and the factors that push us to eat fermented food (our liking for complex, sour, and umami flavors) both act to produce the best environment for our immune system. Fermented food resembles exercise and practice; the mouth-touching system resembles information.

A similar sampling system is our love of gossip. We love to hear it, we love to spread it. Gossip spreads information about the dangers around us. Again, forewarned is forearmed.

I am in Tokyo (for a few more minutes), an admirably clean city. Public rest rooms, for example, are convenient, clean, and free. (Unlike New York, Los Angeles, San Francisco, Beijing . . . ) The practical point of this idea isn't that there is something wrong with public health measures, it is that they can go too far.

Tomas (2012-01-10 05:54:17)

Re:polio this article recounts how methods of counting polio cases were changing over time  
<http://insidevaccines.com/wordpress/2010/06/02/polio-and-acute-flaccid-paralysis/>

threepipeproblem (2012-01-10 06:35:03)

Years ago, I recall a doctor made the rounds in the media claiming that nose picking is essentially the same thing.

Scott Pierce (2012-01-10 08:32:26)

I have seen studies relating the increase in nut and other allergies to our modern obsession with cleanliness. When I was a kid in grade school, there was that kid in some other class or maybe in another grade that you had heard about having a nut allergy that would kill him if he came within 20 feet of a peanut but they were almost a myth. Now it seems every third kid has some kind of allergy issue. Maybe it is perception on my part.

Scott Pierce (2012-01-10 08:33:33)

Oh and I have always seen gossip as the means by which we tear others down that we might be built up.

Alex Chernavsky (2012-01-10 08:39:02)

These two books look promising: [1]*Good Germs, Bad Germs: Health and Survival in a Bacterial World* [2]*Why Dirt Is Good: 5 Ways to Make Germs Your Friends*

1. <http://www.amazon.com/Good-Germs-Bad-Survival-Bacterial/dp/0809016427/>

2. <http://www.amazon.com/Why-Dirt-Good-Germs-Friends/dp/1427798044/>

Alex Chernavsky (2012-01-10 08:43:19)

@Scott – part of the problem is that food allergies seem to be "trendy" now. Many people who *think* they're allergic to foods are really not allergic to them:

J Psychosom Res. 1999 Dec;47(6):545-54. Psychological characteristics of people with perceived food intolerance in a community sample. Knibb RC, Armstrong A, Booth DA, Platts RG, Booth IW, MacDonald A. School of Psychology, University of Birmingham, UK. [rebecca.knibb@nottingham.ac.uk](mailto:rebecca.knibb@nottingham.ac.uk) Abstract In most adults who believe themselves to be food intolerant there is no objective supporting evidence. It has therefore been proposed that the misperception of intolerance to food is linked to psychiatric illness or personality disorder. This hypothesis was tested in a community-derived sample of individuals who attributed an adverse symptom to a type of food. A random mailing recruited 955 participants aged > or =18 years, of whom 232 perceived themselves to be food intolerant (PFI). All recruits were sent two questionnaires, the General Health Questionnaire-28 (GHQ-28) and the shortened version of the Eysenck Personality Questionnaire (EPQ-R). A total of 535 GHQ-28 and 518 EPQ-R forms were returned that were correctly completed, an overall response rate of 55 %. For the subscales of the EPQ-R, neuroticism was greater in those with a PFI than those without. Women with a PFI were more extroverted than

control women. For the GHQ-28 subscales, women with a PFI had significantly higher scores than control women on somatic symptoms, anxiety, insomnia, and severe depression. There was a greater percentage of psychiatric caseness among women with a PFI than among men with a PFI or control women. Nevertheless, this percentage was no greater than that reported among a reference sample derived from NHS and university staff. It is concluded that perceived food intolerance is associated with psychological distress in women with a PFI, and neurotic symptoms in both men and women with a PFI, but there is no greater prevalence of psychiatric disorder among women or men with a PFI than there is in some professional groups. PMID: 10661602 [PubMed - indexed for MEDLINE] <http://www.ncbi.nlm.nih.gov/pubmed/10661602>

gwern (2012-01-10 09:11:17)

Much more plausible explanations: 1. the mouth region, for obvious reasons, is one of the most sensitive and nerve-dense regions; face-touching is about dealing with itches and transient discomfort, in the same way people knead their fingers or scratch their hands or what not. (Look around, how many people are doing fiddling with their fingers in some way? I thought so.) 2. Body language; the face in general is a major source of cues about one's state. One's hands can hide the face. Such obscuration is very useful in public. 3. The head is fairly heavy and modern people do not get much exercise. It's simply about resting the neck muscles. Germs... I would be quite surprised if that turned out to be the explanation. Well, at least it's testable (manipulate immune systems with immunosuppressants, etc).

dearieme (2012-01-10 16:54:27)

I'd always enjoyed mixed nuts but at about age 60 they started upsetting my stomach. I stumbled across the explanation in Jim Watson's book on DNA - he alluded to an allergy to the protein in Brazil nuts. Now if I stick to almonds, hazelnuts and walnuts, all is well. One Brazil seems to do little or no harm - a handful is bad news. To my surprise, when I checked the wikipedia page on Brazils no mention was made of the problem.

Jim Purdy (2012-01-11 11:20:16)

Seth, you said: "I propose an evolutionary explanation: To expose our immune system to all the germs near us in small amounts." So exposure to lots of germs is good for our immune system? In recent years, each time that I have been in a hospital it takes them about 2 days to give me a staph infection, 2 more days to give me MRSA, and another 2 days to give me VRE. If being exposed to germs is good, then I must be getting very healthy from all these hospital-acquired infections. But maybe I could get the immunity-conferring benefits without the inconvenience of a hospital stay: Maybe I could just sit in a hospital ER waiting room for an hour a day, and get acquainted with lots of germs.

Seth Roberts (2012-01-11 13:39:43)

So exposure to lots of germs is good for our immune system?

Lots of germs in small amounts is good. You want your first exposure to Germ X to be a small amount, not a large amount. If it is a small amount, you will survive later exposures to large amounts of the same germ. If your first exposure is to a large amount of Germ X, well, good luck.

Tim Beneke (2012-01-12 10:26:23)

One aspect to keep in mind is that we may touch our face as an act of self soothing. Dacher Keltner had his students go to restaurants and observe people as they entered - more than 80 % of the time, they touched their face. My impression is that when entering a room with a crowd of strangers, it can feel rather overwhelming; touching your face can ground and soothe you, or at least it can me Notice the woman in the bottom right who is holding her cheeks: <http://andrewsullivan.thedailybeast.com/-2011/11/the-devastating-blissful-life-of-a-fan.html> I think I touch my face to make myself feel more secure - this does not contradict other motivations/effects necessarily of course.

Nick (2012-03-04 09:21:21)

It's interesting that usually the first response to eating a novel food is NOT having an allergic reaction to it.

### **Tonsillectomy Confidential (2012-01-11 05:00)**

I wrote [1]a piece for Boing Boing about tonsillectomies that has just been posted. It stemmed from a comment on this blog by a woman named Rachael. A doctor said her son should have a tonsillectomy. When Rachael did her own research, however, it seemed to her that the risks outweighed the benefits. I looked further into tonsillectomies and found that the risks were routinely greatly understated, even by advocates of evidence-based medicine.

More [2]Here is a page on a doctor-run website called MedicineNet that grossly understates the risks of tonsillectomies. Compare their list of possible bad effects to mine.

1. <http://boingboing.net/2012/01/10/tonsillectomy-confidential-do.html>

2. <http://www.medicinenet.com/tonsillectomy/page2.htm>

---

threepipeproblem (2012-01-11 05:44:16)

Link is broken. Should be <http://boingboing.net/2012/01/10/tonsillectomy-confidential-do.html>

Seth Roberts (2012-01-11 06:23:47)

Thanks, link fixed.

ck (2012-01-11 07:12:13)

Are there analogous risks/benefits to be found for appendectomy?

ck (2012-01-11 07:25:26)

I'd like to expand a little on my comment above "Are there analogous risks/benefits to be found for appendectomy?": Wikipedia mentions that the appendix could play a role in immune function, in particular in maintaining the gut flora. Like tonsillectomy, appendectomy also has been a routine operation (I have been told that many doctors used to remove the appendix of their own children per laparoscopy at an early age). Unlike tonsillectomy, appendectomy can be strongly indicated, that is in case of acute appendicitis. It would be interesting to know if people who had their appendix removed show signs of lowered immune function or have an increased risk of gut diseases.

jeff borsato (2012-01-11 08:35:53)

enjoy the blog on a daily basis, but Seth, please note the response from the folks at my other fav blog Science Based Medicine, they pose some reasonable questions that would be interesting as a f/u piece.. <http://www.sciencebasedmedicine.org/index.php/tonsillectomy-indications-and-complications/> #more-18655

SB (2012-01-11 09:46:41)

Great article - thank you for writing it.

Tuck (2012-01-11 10:55:38)

The blog "Science-Based Medicine" posts a rebuttal to this post here: <http://www.sciencebasedmedicine.org/index.php/tonsillectomy-indications-and-complications/> I find their rebuttal less than convincing, but judge for yourself.

Science-based medicine purports to be more scientific than evidence-based medicine, but is still not quite scientific medicine, sadly.

Jim Purdy (2012-01-11 10:59:26)

Your Boing Boing article is fascinating, especially the many correlations between tonsillectomies and various health problems. Here's a correlation that I've noticed: The more doctors I see, the more drugs and surgeries they say that I need. In 2010, I had two very unpleasant interactions with medical professionals. First, in early 2010, orthopedic surgeons told me that I would die unless they amputated my right leg because of a severe diabetic ulcer; I did not have the amputation, and my leg healed fine. Then a few months later, cardiologists told me that I could die at any moment unless they did quadruple coronary artery bypasses. I did not have any bypasses, and I have no chest discomfort as long as I avoid very large meals. Heart problems? Maybe, but perhaps a hiatal hernia, or GERD. But I learned two lessons: 1. Stay away from orthopedic surgeons if you want to keep your limbs intact. 2. Stay away from cardiovascular surgeons if you want to keep your heart intact. As a rule, I give my body time to heal itself using natural defenses that developed over many millions of years of Darwinian evolution. As a result, many doctors have called me crazy and suicidal. And I call those doctors (expletive deleted).

Seth Roberts (2012-01-11 13:35:29)

Thanks. I have posted a reply to that post. Not yet approved. Here it is: There are many factual mistakes in your comment on my article. 1. "Roberts displays a persistent bias toward downplaying the benefits and exaggerating the risks of tonsillectomy while accusing the medical establishment of doing the exact opposite." I do not say that the Cochrane reviewers exaggerate the benefits of tonsillectomies. Your post does not contain a single example where I say the medical establishment exaggerates the benefits. 2. "Roberts fails to mention that the benefit described above – one fewer sore throat – was for the mild group only." That's wrong. I do mention it. Rachael's son would have been in the mild group. I wrote "(two instead of three for children like Rachael's son)". 3. "In his article Roberts assumes that the only indication as a preventive measure for tonsillectomy is for recurrent sore throats." Nowhere do I assume that. You give no examples. 4. "while not understanding the evidence." I failed to find any examples in your post of my "not understanding the evidence." I omitted some of the evidence for benefit because that was not the main point of my post. Omission of evidence does not equal misunderstanding of evidence. 5. "Roberts accuses physicians of ignoring relevant information about tonsillectomy, but he ignores published practice guidelines that look much more deeply into the issue than is reflected in his analysis." I said that doctors ignore relevant information about tonsillectomies when making statements to parents about the risks of tonsillectomies. For example, they fail to tell parents that tonsils are part of the immune system. What you say about practice guidelines does not contradict that. 6. "Roberts engages in very simplistic reasoning – the tonsils are part of the immune system, removing them therefore compromises immune function and is a bad idea." Because tonsils are part of the immune system, removing them runs a considerable risk of compromising immune function, just as removing part of the brain runs a considerable risk of causing brain damage. I say this in the post. It is common sense. 7. "He ignores the fact that those tonsils that are removed are unhealthy." What you call a "fact" is not a fact – it is a theory. As you say yourself in the next sentence ("perhaps they have become counterproductive"). 8. The "summary of current thinking" is a theory of unknown validity. By failing to say this, you overstate your case. 9. "There are no studies to date that demonstrate a significant clinical impact of tonsillectomy on the immune system." Since practitioners of evidence-based medicine refuse to take seriously evidence that doesn't come from a placebo-controlled double-blind experiment, there will surely never be – for ethical reasons – a study that "demonstrates a significant clinical impact of tonsillectomy on the immune system." To say that one's point is supported by the absence of evidence that cannot exist is not serious argument. 10. "Roberts' endorsement of the naturopathic approach to chronic sore throats. . . . he then offers as an alternative that is blatantly not evidence-based." I suggest you look further at the Vitamin D evidence I link to. There is evidence that Vitamin D supplementation helps. Rachael searched for evidence. My post includes a long paragraph about her search. To call what she did "blatantly not evidence-based" is like saying white is black. 11. A biased view of evidence is shown by the following which you quote approvingly: "However, available scientific evidence does not support claims that larch bark is effective in treating cancer or any other disease in humans. Early laboratory evidence suggested that larch arabinogalactan may stimulate the immune system. However, a more recent study in mice contradicts this finding." In other words, there is some evidence supporting the value of larch bark ("early laboratory evidence") and some evidence ("a more recent study in mice") not supporting the value of larch bark. Given this, to say "available scientific evidence does not support claims . . ." is false. An accurate statement is that some evidence does and some evidence doesn't. 12. You recommend "summaries of the

evidence prepared for the non-expert.” The Cochrane review that I discuss included a summary of the evidence for non-experts. That summary – the only summary for non-experts I found – was grossly misleading. Unless you can point to a tonsillectomy summary for non-experts that is not misleading, the available evidence (one bad summary, zero good summaries) contradicts your recommendation. 13. Here are your most serious factual mistakes: “In none of the cases [of bad side effects] is a cause and effect established. He wonders why doctors do not list all of the complications he found – that’s why.” I listed more than a dozen bad side effects associated with tonsillectomies (polio, obesity, etc.). The associations – association is not causation – were made by the authors of the articles and PubMed indexers, not me. Mistake One: I did not claim these associations reflected cause and effect. Mistake Two: I did not “wonder why doctors do not list all of the complications he found” – I simply pointed out that the Cochrane reviewers did not list them. These are serious factual mistakes because they reflect a poor understanding of risk and what parents (and other people contemplating medical treatments) want to be told. They go to the heart of my objection to how “evidence-based medicine” is practiced. Consideration of evidence is good, of course. Omission of evidence is bad. Omission of evidence of danger, when telling parents about the pros and cons of a treatment, is very bad. Right here you endorse exactly that – omission of evidence of danger. You are not alone, of course. “Evidence-based medicine” practitioners endorse omission of evidence over and over and over. If it were called “some-of-the-evidence-based medicine” it would be less deceptive. Risks are inherently uncertain. In contrast to benefits, risks are usually low probability or hard to measure. It will always be difficult (and sometimes impossible) to go beyond association to causation. To wait for certainty of causation before mentioning them is to deprive parents of useful information. Parents do not want to wait for certainty before being told of the risks of tonsillectomies. If tonsillectomies have been associated with obesity, they want to be told this. They do not want this information to be omitted simply because it hasn’t yet been established that the association reflects causation. If tonsillectomies have been associated with a 50 % increase in heart attacks, they want to be told this. They don’t want this information to be omitted because it is uncertain whether it reflects causation. Yet you endorse that omission.

Seth Roberts (2012-01-11 13:36:29)

Thanks, Jeff. Again, please note my reply (above).

Seth Roberts (2012-01-11 14:12:17)

It would be interesting to know if people who had their appendix removed show signs of lowered immune function or have an increased risk of gut diseases.

I agree. The 2011 study that associated tonsillectomies with a higher rate of heart attacks found a similar but weaker association with having your appendix removed.

Seth Roberts (2012-01-11 14:13:31)

Science-based medicine purports to be more scientific than evidence-based medicine,

I thought they were similar.

jeff borsato (2012-01-11 15:18:19)

Great response Seth. Im torn because I value the analysis from Science Based Medicine as much as I value your approach to medical issues. I believe an important conversation is taking place here and hopefully they respond to your post. I do think that debates about “evidence based” vs. “science based” and the like detract from the ultimate good both sites are hoping to achieve. SBM does a great job of dispelling myths that are perpetrated in the absence of truth or evidence. Essentially saying that evidence must consist of something showing at least some effect as claimed. The reason their attack against chiropractic has worked is because Chiro’s have long been able to claim that people confirm pain relief after their treatment but no evidence can support their reasons why people enjoy pain relief.

worthwords (2012-01-11 15:41:30)

For the appendectomy query above. The primary indication for an appendectomy is acute appendicitis. The consequences of not removing an appendix that is likely to burst is likely to be feces entering the abdominal cavity causing a septic shock-> death. For a doctor, missing a presentation of appendicitis case can be a devastating experience. There was a time when the appendix would be removed prophylactically while performing other abdominal surgery, since it was seen in the patient's best interest to avoid a future appendicitis. The appendix does seem to have a role in immunity, there were some theories about helping to recolonise the gut with bacteria post gastroenteritis. However, as with tonsillectomy - there is no global immunocompromise from having it removed, and immunological changes seem quite subtle rather elusive. It's worth reading up on the sorts of awful infections a patients with AIDS to understand what a deficient immune system looks like.

Deidre (2012-01-11 16:06:30)

Per this article, "Your Appendix Could Save Your Life": <http://blogs.scientificamerican.com/guest-blog/2012/01/02/your-appendix-could-save-your-life/>

Evelyn M. (2012-01-11 19:34:28)

I would like to respond, "Hear! Hear!" to Mr. Purdy's advice. I worked for many years with physicians in public health. The key medical and scientific journals published in English all passed my desk. I never saw any articles describing research that was undertaken to bolster the claims made by the various specialties about the necessity for their patients to have annual physical examinations, certain laboratory tests, etc. One day I asked my boss, an M.D., MPH, about this. He replied that the standards we see are just made up out of whole cloth by the medical community. He added that as far as the medical community is concerned "a healthy person is just a patient who hasn't been fully worked up."

ck (2012-01-12 01:26:21)

@Deidre Thanks for the link. Interesting article. Kind of what I expected from prior knowledge. Now the question is: Should people who had their appendix removed do things different? For example, should they eat more or less fermented food than people with intact appendix? Guess it is time for some n=1 experiments for me.

Seth Roberts (2012-01-12 06:04:12)

Thanks, Jeff. They have yet to approve my reply.

Tuck (2012-01-12 08:16:40)

Great response. Neither "evidence-based" nor "science-based" medicine is really adequate. But scientific medicine would leave doctors with little to do. @Seth: here's the first post from SBM, explaining the difference between SBM and EBM. <http://www.sciencebasedmedicine.org/index.php/hello-world/> I've had lots of discussions in the comments there on various articles. The treatment you received is pretty typical. The best explanation I've ever heard of how modern medicine operates was from an old French play, reviewed here: "Get to Know Your Inner Hypochondriac" <http://online.wsj.com/article/SB10001424-052748703866704575224280938569458.htm> I saw the play based on that review and it was terrific, and deeply disturbing. Dr. Knock \*is\* modern medicine, and is in line with Evelyn M's quote: "He added that as far as the medical community is concerned 'a healthy person is just a patient who hasn't been fully worked up.'" Or as Dr. Knock explains: "'To get sick, what does that mean? That's a worn-out idea. It doesn't hold up against modern science. . . . In my experience people simply are more or less sick, with more or less numerous diseases that progress more or less rapidly. Now naturally, tell people they're well, they're only too happy to believe you. But why lie to them?'"

Bob (2012-01-12 08:20:19)

Seth, they approved your reply and posted it, followed by a couple of responses.

Seth Roberts (2012-01-12 12:29:33)

Thanks, Bob. I saw it and wrote another response.

Seth Roberts (2012-01-12 12:35:33)

Thanks, Tuck. Yes, I was wrong to equate science-based medicine and evidence-based medicine. I do think science-based medicine is an improvement for exactly the reasons they say. I hope to see "Dr. Knock" (the play) some time. I didn't know about it.

Ann (2012-04-09 19:11:59)

Funny. I had stomach problems my whole life. After my appendectomy, for acute appendicitis, my stomach problems went away.

### Peter Lawrence on the Ills of Modern Science (2012-01-13 05:00)

Peter A. Lawrence is a British biologist who has written [1]several papers about problems with the way biology and other areas of science are now done. In[2] this interview a year ago he summarizes his complaints:

- Scientific publication "has become a system of collecting counters for particular purposes – to get grants, to get tenure, etc. – rather than to communicate and illuminate findings to other people. The literature is, by and large, unreadable." There is far too much counting of papers.
- "There's a reward system for building up a large group, if you can, and it doesn't really matter how many of your group fail, as long as one or two succeed. You can build your career on their success." If you do something on your own it is viewed with suspicion.
- There is too much emphasis on counting citations. "If you work in a big crowded field, you'll get many more citations. . . . This is independent of the quality of the work or whether you've contributed anything. [There is] enormous pressure on the journals to accept papers that will be cited a lot. And this is also having a corrupting effect. Journals will tend to take papers in medically-related disciplines, for example, that mention or relate to common genetic diseases. Journals from, say, the Cell group, will favor such papers when they're submitted."
- Grant writing takes too much time – e.g., 30-40 % of your time. "There is an enormous increase in bureaucracy – form filling, targeting, assessment, evaluations. This has gone right through society, like the Black Death!"
- "Science is not like some kind of an army, with a large number of people who make the main steps forward together. You need to have individually creative people who are making breakthroughs – who make things different. But how do you find those people? I don't think you want to have a situation in which only those who are competitive and tough can get to the top, and those who are reflective and retiring would be cast aside." I've said something similar: Science is like single ants wandering around looking for food, not like a trail of ants to and from a food source. The trail of ants is engineering.

I agree. I would add that I think modern biology is far too invested in the idea that genes cause disease and that studying genes will help reduce human suffering. I think the historical record (the last 30 years) shows that this is not a promising line of work – but modern biologists cannot switch course.

What explains the depressing facts Lawrence points out? I think it is something deep and impossible to change: [3]Science and job don't mix well. The demands of any job and the demands of science are not very compatible. Jobs are about repetition. Science is the opposite. Jobs demand regular output. Science is unpredictable. However, jobs and science overlap in terms of training: Both benefit from specialized knowledge. They also overlap in terms of resources: More resources (e.g., better tools) will usually help you do your job better, likewise with science. So we have two groups (insiders – professional scientists – and outsiders – everyone else). Both groups have big advantages and big disadvantages relative to the other. In the last 50 years, the insiders have been "winning" in the sense of doing better work. Their advantages of training and resources far outweighed the problems caused by the need for repetition and predictability. But now – as I try to show on this blog – outsiders are catching up and going ahead because the necessary training and tools have become much more widely available (e.g., tools have become much cheaper). And, as Lawrence emphasizes, professional science has gotten worse.

[1]Celia Green and other members of the Oxford forum decry the loss of personal capital. The wealthy, the aristocrats- these people were independent enough to either do independent research themselves or fund others.

1. <http://celiagreen.blogspot.com/>

Bob (2012-01-13 08:04:43)

I just came across Michael Nielsen's Reinventing Discovery that looks relevant to this topic. <http://michaelnielsen.org/blog/reinventing-discovery/>

Nandalal Rasiah (2012-01-13 08:42:45)

What exactly do you mean regarding genes and disease? It's already a non-controversial argument that following single genes and developing drugs to target them individually ignores the networks more likely responsible for the disease in question. i.e: <http://blogs.discovermagazine.com/gnpx/2012/01/missing-heritability-interaction-edition/>

Nandalal Rasiah (2012-01-13 09:06:38)

<http://www.genetic-inference.co.uk/blog/2012/01/phantom-heritability-and-additivity/> that's a bit clearer re additivity.

dearieme (2012-01-13 09:48:43)

Pippard used to draw a distinction between overcrowded and underpopulated fields of science. The latter can be recognised because even quite important results won't have been replicated. The former can be recognised by the ruthless competition to be first to some discovery - and often after one research group gets there first, another one or two groups will get the same result within weeks. The latter field tends to be characterised, he said, by bad behaviour - his own subject, Physics, was prone to this, he said.

Seth Roberts (2012-01-13 10:11:05)

What exactly do you mean regarding genes and disease? It's already a non-controversial argument that following single genes and developing drugs to target them individually ignores the networks more likely responsible for the disease in question.

Yes, I've heard that. As far as I can tell, it is pure speculation - meaning there is no evidence - that these "networks [are] most likely responsible for the disease in question". I have yet to see a single example where studying genetic networks has led to useful results. If you know of one, I would like to hear about it. What is happening here, as far as I can tell, is that when it turned out that Assumption 1 (single genes matter in common diseases) was wrong, biologists have shifted to Assumption 2 (networks of genes matter in common diseases) that has not yet been disproved. They have no evidence for Assumption 2, just as they had no evidence for Assumption 1.

Mark (2012-01-13 10:37:30)

I agree that the whole idea that "genes cause disease" is silly. It's possible that genes might serve to subdivide a population into groups, some of which might be, for whatever reason, more susceptible to certain diseases, but this in no way implies cause and effect. Take for instance the most basic genetic trait, gender, and one of the most prevalent "diseases", pregnancy. Being female is certainly a necessary condition for being pregnant, but it is ludicrous to think of it as a cause.

Daniel Lemire (2012-01-13 11:28:15)

This is a fantastic find Seth. I agree with Bob that Nielsen's book is a must if we are to address these issues. For those who won't buy the book immediately, you can check my recent commentary on this topic: Open science: why is it so hard? <http://lemire.me/blog/archives/2012/01/10/open-science-is-hard/>

Seth Roberts (2012-01-13 14:57:34)

I agree that the whole idea that "genes cause disease" is silly. It's possible that genes might serve to subdivide a population into groups, some of which might be, for whatever reason, more susceptible to certain diseases, but this in no way implies cause and effect. Take for instance the most basic genetic trait, gender, and one of the most prevalent "diseases", pregnancy. Being female is certainly a necessary condition for being pregnant, but it is ludicrous to think of it as a cause.

Yes. I'd put it like this: Genes move susceptibility to this or that environmental deficiency up and down but their effect – in the case of common diseases – appears to be so small relative to the environmental influence that "it is ludicrous to think of [them] as a cause." For example, genes no doubt move susceptibility to scurvy up and down but it is ludicrous to think of them as a cause of scurvy. At the moment this is the empirical picture. Powerful environmental influences, much weaker genetic ones.

Jazi zilber (2012-01-14 01:24:38)

Just reading on the fantastic breakthroughs of gentlemen in the 19th century. For them it was a personal love affair with knowledge, not a job. There is denigration of simple stuff. Genes, drugs, enzymes, all ultra sophisticated stuff are over studied. While simple but enormously useful questions (sleep details. Which mattress is better? Will you be more healthy eating yogurt?) are ignored. As if the glare is most important than life usefulness

Seth Roberts (2012-01-14 02:48:57)

For them it was a personal love affair with knowledge, not a job.

Yes, that is a good way of putting it.

Jif (2012-01-17 17:24:53)

Professional science has only gotten worse by some standards. The best science is continually getting better. The rate at which science is being done is increasing. However, the average level of science is decreasing. This makes it easier and easier to find examples of bad, sloppy or pointless work being done to satisfy external bean counting. This is sad but it is not reflective of the best work being done. And, to sneer that science is a "job" and hence less meaningful, reliable or whatever is nonsense. I know of no good scientists (the type this blog ignores) who could not at least double their salaries and greatly decrease their administrative loads by working in industry. We are driven to do science as a passion and put up with the other nonsense so that we can do what we love not as an end to itself. The problems mentioned above are real and serious and getting worse. They come from the need for "accountability" to the tax payer and will never improve until we can all be grown ups. Cheers, Jif. PS the plural of anecdote is not data.

Lemniscate (2012-02-08 03:22:19)

I broadly agree with Seth that a lot of science is about funding and prestige and not useful innovation. This can especially be the case with genetics/genomics, which requires massive capital investment and sounds very sophisticated. However, I think you're being a little premature in writing off the utility of genetics in understanding disease. The greatest promise does not come from accounting for the missing heritability but from discovering relevant biological mechanisms by looking at the genetic influence on disease. There's no reason why looking for genetic influences on disease and environmental influences on disease have to be in conflict, either: understanding one should help understand the other and build a complete and detailed picture.

## Assorted Links (2012-01-14 05:00)

- One of my Tsinghua American colleagues [1] writes an op-ed: "China wants you. Job prospects are abundant."
- [2] Robert Anton Wilson's skepticism about skeptics. "Those people claim to be rationalists, but they're governed by such a heavy body of taboos. They're so fearful, and so hostile, and so narrow, and frightened, and uptight and dogmatic. . . . None of them ever says anything skeptical about the AMA, or about anything in establishment science or any entrenched dogma." I agree. They should be called one-way skeptics.
- [3] Excellent Vanity Fair article about Occupy Wall Street. Better than The New Yorker's article covering similar stuff.
- [4] The many side effects of statins. I am impressed by the new way of learning about drug side effects.

Thanks to Ryan Holiday and Gary Wolf.

Elizabeth Molin (2012-01-14 09:11:19)

Thanks for the link to Seneff's excellent article. I have passed it on to everyone I know.

dearieme (2012-01-14 11:45:44)

Hm. But the Wikipedia entry says that the quotation you carry was about "...scientific types with overly rigid belief systems...". That doesn't sound like the people I think of as sceptics.

Evelyn M. (2012-01-14 20:55:12)

Many thanks for the link to the article about statins; you do good work on this site!

Txomin (2012-01-15 03:25:14)

The kind of people RAW refers to should not be called skeptics at all.

Nathan Myers (2012-01-18 19:15:53)

But they call themselves skeptics. If he's not talking about you, what should you call yourself to distinguish yourself from them? That paper by S. Seneff has more astonishments per page than anything I have read in years. All by itself, it's easily worth all the time I have spent keeping up with this site. I am breaking my rule against spamming my address list for this one.

## More about Tonsillectomy Confidential (2012-01-15 05:00)

The blog Science-Based Medicine ran [1] a long critical comment about [2] my recent Boing Boing piece ("Tonsillectomy Confidential: doctors ignore polio epidemics and high school biology") followed by a back-and-forth (my reply, their reply to my reply, on and on) in the comments.

The exchange had three curious features.

1. In Tonsillectomy Confidential, I described how Rachael critically evaluated what a naturopath told her:

Rachael and her son went to see a naturopath that a neighbor had recommended. The naturopath was especially knowledgeable about nutrition and supplements. After an hour interview, she suggested Vitamin D3 (5000 IU/day), a multivitamin, Vitamin C (500 mg/day), and powdered larch bark. Rachael searched for research about these recommendations. She found many studies that suggested Vitamin D might help. Her son is a pale redhead and used sunblock a lot. It was easy to believe he wasn't getting enough Vitamin D. Because Vitamin D won't work properly without other vitamins (called co-factors), a multivitamin was a good idea [Rachael discovered during her research]. Rachael found studies that implied that a multivitamin was very unlikely to be very harmful. She found few relevant studies about Vitamin C. Maybe extreme claims about its benefits had scared off researchers – "Linus Pauling burned that bridge," said Rachael. But she took the Vitamin C recommendation seriously because the naturopath had made other reasonable recommendations, the recommended dose was not large, Vitamin C is easily excreted in urine (in contrast to building up in the body), and Rachael had never heard of anyone having trouble at that dose. The naturopath had said that larch bark had reduced ear infections in children with chronic ear infections. A little bit of theory supported this, Rachael found, but overall the larch-bark research was "dodgy," she said.

This was described by the Science-Based Medicine critic (Steven Novella) as "blatantly not evidence-based".

2. In my first reply to the criticism, I wrote:

In other words, there is some evidence supporting the value of larch bark ("early laboratory evidence") and some evidence ("a more recent study in mice") not supporting the value of larch bark. Given this, to say "available scientific evidence does not support claims . . ." is false. An accurate statement is that some evidence does and some evidence doesn't.

This got the following reply from a second critic (David Gorski):

No, Seth. Note two words Steve used, "in humans." Steve was quite correct. If there is only a preliminary animal study, even if positive, that does not support the efficacy of larch bark in humans.

Apparently Gorski thinks animals (e.g., rats) and humans share no DNA. A few sentences later, contradicting himself, he notes that animal studies are used as screening tests.

3. Finally there was this, from Steven Novella:

It is fine to search for information yourself, and no one here is advocating "blind trust" in anyone. We are all activist skeptics. But it is folly to substitute one's own opinion for that of experts who have spent years mastering a subject.

What a lovely motto for this blog: "It is folly to substitute one's own opinion for that of experts who have spent years mastering the subject." And, after all that study, think animals and humans share no DNA.

---

Jay (2012-01-15 05:52:52)

Maybe they could read this article: <http://yudkowsky.net/rational/bayes> and understand what evidence really is? Science is not about picking cute statements that serve as epistemic axioms. ("correlation is not causation", "anecdotes are not data", "rat studies say nothing about humans"). It's about evaluating evidence in the context of Bayesian inference. It's infuriating to see rational people not understand this.

Alex Chernavsky (2012-01-15 07:28:03)

Steven Novella is a professor of neurology at Yale Medical School. He's an entrenched insider. His status necessarily limits the scope of his skepticism. I occasionally read his blog, and it's fine as far as it goes. But he usually focuses on easy targets.

Seth Roberts (2012-01-15 09:44:12)

Science is not about picking cute statements that serve as epistemic axioms. ("correlation is not causation", "anecdotes are not data", "rat studies say nothing about humans"). It's about evaluating evidence in the context of Bayesian inference.

Yeah, I agree. That's a good way of putting it. Evidence pushes belief in Statement X up (toward agreement) or down (toward disagreement).

Seth Roberts (2012-01-15 18:55:36)

Steven Novella is a professor of neurology at Yale Medical School.

I didn't know that. It makes him more quotable.

Kirk (2012-01-16 14:16:15)

I found four things odd in the whole exchange. First, I couldn't tell whether the folks at the SBM blog think Rachael should continue her current approach (nutritional), or should withdraw those efforts and instead choose surgical removal of the tonsils. (After all, the nutritional approach had been suggested by one of those 'quack naturopaths'.) Secondly, they make no distinction between levels of risk. If one's femoral artery is cut, it would be poor personal risk management to insist, upon arrival at the ER, that the doctors first search PubMed for the perfect solution before taking any action. On the other hand, for a situation where a mother has been coping with a child who has had six sore throats in a year, the risk of delaying surgery for one more month while trying a nutritional approach seems to me to be low. The third problem is that they fail to acknowledge that experts disagree. Every one of us has to curate which experts to believe. The most obvious example is in the area of nutrition. And finally, probably due to legal issues, I suspect that most doctors feel they cannot recommend nutritional approaches. For example, I had a year-long issue which caused numbness in my right foot. My doctor said he could prescribe a Big Pharma product which had a low probability of success and a history of negative side-effects, but he would do so reluctantly and only if I insisted. I appreciated his advice and chose not to use that product. What he did not tell me is to look for alternate approaches. I looked online for advice and, yes, I considered advice from people without an M.D. behind their names. Now, after a year of nutritional changes, supplementation, and topical treatments, that condition has mostly cleared. I strongly

suspect that my efforts caused that condition to reduce, rather than it clearing by its own. I can't prove it and since there is no money to be made by producing a trademark product, it is unlikely that research will be funded for trials on this type of solution.

Seth Roberts (2012-01-16 19:00:27)

First, I couldn't tell whether the folks at the SBM blog think Rachael should continue her current approach (nutritional), or should withdraw those efforts and instead choose surgical removal of the tonsils. (After all, the nutritional approach had been suggested by one of those 'quack naturopaths'.)

Good point. The question "what should Rachael have done?" wasn't answered. And Novella's claim that what actually happened (her son had no more sore throats) provided "evidence against" Rachael's approach couldn't be more ridiculous. What are they putting in the water at Yale Medical School?

Juergen (2012-01-17 02:50:16)

I used to have serious problems with my tonsils; whenever I got sick they'd start to hurt & stayed that way for weeks if not months. And I was sick a lot; I'd have this several times per year ... It stopped when I started taking fish oil about 18 months ago (I also started weight training at the same time, but I've had periods where I exercised a lot before; the fish oil was new). I take around 3-5 g of fish oil per day. In those 18 months I was sick once - just a case of the sniffles; but the tonsils never got inflamed and I was well again after a week. No lingering pain in the throat! I don't think I can communicate how awesome that is. These days I also take Vitamin D3, but I've only been doing so for 6 months; the tonsil problems were gone long before that.

Darrin Thompson (2012-01-17 09:05:25)

Request: Next do "Botulism Confidential."

Tuck (2012-01-17 12:13:32)

Thought you'd find this article in today's WSJ of interest: "What if the Doctor Is Wrong?" "Hardeep Singh, chief of the health policy and quality program at Michael E. DeBakey VA Medical Center in Houston, says a growing number of centers are requiring an internal second review of pathology reports to prevent misdiagnosis. If the second opinion differs markedly, a third opinion may be necessary to get a consensus on what course of treatment is best." <http://online.wsj.com/article/SB10001424-052970203721704577159280778957336.htm> I That nicely puts "It is folly to substitute one's own opinion for that of experts who have spent years mastering the subject." into perspective. We're supposed to trust the experts when the experts won't trust the experts? Do the doctors at SBM think we're all fools? (I think they do, but you should draw your own conclusions... :)

Josh M (2012-01-17 17:20:28)

"Apparently Gorski thinks animals (e.g., rats) and humans share no DNA. A few sentences later, contradicting himself, he notes that animal studies are used as screening tests." You know when you read something, and it's as if the words themselves manifest into a face-palm and make you exhale with a mixture of pity and impatience? That's exactly what I feel when reading something that lacks any logical credibility. Objective achieved with those two sentences there.

Gyro Protagonist (2012-01-17 17:21:27)

I'm not sure why you think Gorski's quote is conclusive evidence that he doesn't think humans and mice/rats share any DNA. He simply brought up the point that drugs/compounds/botanicals that produce a biologic effect in mice might not produce the same (or indeed any) biologic effect in humans. Mice and humans have many homologous genes, but rodents have massively different CYP450s than humans (these enzymes often help metabolize drugs). So it's not at all unreasonable to ask for proof of efficacy in, you know, actual humans. Regarding the "contradiction," it's certainly possible for someone to point out that while evidence of drug efficacy in rodents is promising (hence why they are used for screening), it doesn't mean that the drug is guaranteed to work in humans (even though we share TEH DNA). And yeah, if you couldn't do a proper literature search/don't have an idea about how drugs are tested, you should probably refrain from bringing the snark when corrected by someone who actually knows something about the subject.

æk (2012-01-17 17:21:51)

"What are they putting in the water at Yale Medical School?" Hubris

Shannon (2012-01-17 17:56:47)

There are arrogant and unreasonable physicians. There are also arrogant and unreasonable bloggers and commenters. I don't think that being smart and accomplished always = arrogant. Most doctors and researchers are genuinely good people seeking to do right by others. Just like, presumably, most bloggers are genuine and good people. I think the esteemed doctor is well aware that mice and human genomes share similarities, that kind of snark does little to bolster your argument. I don't understand how his statement about rat studies are not equated human evidence is contradicted by sharing DNA. We share DNA, but have vastly different anatomies proteomic expression, et al. That's why we do clinical trials in medicine: bench research, animal testing, then small scale human, then large scale human studies. There are examples of promising drugs in animals that are ineffective or harmful in humans. And for every story of fish oil curing chronic sore throats, there are examples of naturopathic approaches being harmful to the point of mortality (see Steve Jobs). Both are anecdotes and not a substitutes for an evidence based approach. I know this sway no one in the blogosphere, but I hope it will dampen the shrillness of the debate.

Doug (2012-01-17 18:01:32)

The fact that humans and rats share DNA does not mean that conclusions reached in rats are always relevant in humans. The patent office is littered with drug candidates that behaved very differently in humans than they did in model organisms like rats. I think Novella's statement is absolutely accurate. Having an opinion is great, but trusting experts is a necessary byproduct of living in a society based on specialization. Reasoned challenge of experts' viewpoints and (especially) examination of their motives and biases is necessary. However, adopting an anti-expert viewpoint is counterproductive.

Amber K (2012-01-17 18:46:32)

"Apparently Gorski thinks animals (e.g., rats) and humans share no DNA. " Where on earth did you get this idea? Of course mice are used in screening tests...that's where we start. Then we move to animals that are closer, genetically to humans and finally to human trials. A positive result in an animal study is no indicator that the treatment will work in humans, but a negative result will usually inhibit further research. The point is to see if it's POSSIBLE the treatment will work. A mouse study is not conclusive of anything except that further research is needed. Dr Novella is also the lead host of The Skeptic's Guide to the Universe, the biggest podcast in skepticism and is known as an excellent science educator, especially in evaluating research. He's also a huge proponent of Bayesian inference which he has spoken on at length. The point of his article was not to advocate for or against tonsillectomy, but to evaluate your understanding of the research, which he found flawed because of lack of expertise and bias. Dr Novella is a neurologist and therefore would not presume to make a recommendation for or against tonsillectomy, but would presume to be able to get a consensus of what the research shows is the best treatment. His podcast can be excellent tutorial for evaluating research and I highly recommend it.

The nagging truth (2012-01-17 18:53:53)

Do you honestly think that a little DNA homology is all that's needed to ensure efficacy of medical therapies transfer between species? There is more to it my friend. Post transcriptional splicing? I suppose they never taught you about that at Berkeley? Your continual oversimplification of complex issues in an attempt to achieve folksy populist charm may work on many, but not us "experts" :)

Sirkowski (2012-01-17 19:04:03)

Your second point is pretty dishonest. Gorski didn't say there's no shared DNA in mice and humans. He didn't say that AT ALL. You just made that up.

ShadowfaxMD (2012-01-17 19:14:44)

Kirk: You're creating quite a false equivalence with the modest statement "Experts disagree," when the relative weight of evidence for varying viewpoints is so disproportionate. There is essentially zero good evidence for vitamin or nutrition based

treatment for recurrent sore throats, compared to the reams of data, both pro and con, for tonsillectomy. Seth, the reason Novella demurred on the question of whether your friend's child should proceed with surgery (other than the folly of trying to diagnose/treat over the Internet) was explicitly stated: he wanted to point out a clear example of biased reading of the evidence, not make a treatment pronouncement outside of his specialty. And, sorry, the unqualified litany of ostensible risks of tonsillectomy without acknowledging (or being aware of) countervailing evidence or problems with the suggested risks raises the question of bias. I'll give you the credit of assuming that any bias is accidental, due to cursory or inexperienced reading of the data, rather than intentional (as is often the case with, say, anti-vaxxers).

Seth Roberts (2012-01-17 20:08:25)

And, sorry, the unqualified litany of ostensible risks of tonsillectomy without acknowledging (or being aware of) countervailing evidence or problems with the suggested risks raises the question of bias. I'll give you the credit of assuming that any bias is accidental, due to cursory or inexperienced reading of the data.

"Countervailing evidence" to the conclusion that tonsils are part of the immune system? Care to say what that is? This comment raises the question of education – whether you have been educated well enough to know (a) how the immune system works and (b) the evidence behind that understanding.

Seth Roberts (2012-01-17 20:10:15)

Do you honestly think that a little DNA homology is all that's needed to ensure efficacy of medical therapies transfer between species?

"A little"? It's more than a little. It's obvious that there are great similarities between rat physiology and human physiology. If they are not based on DNA overlap, what are they based on?

Seth Roberts (2012-01-17 20:13:55)

A mouse study is not conclusive of anything except that further research is needed.

Not so. The many similarities between mice and humans mean that if Statement X is true for mice, X is more likely to be true for humans than if X is not true for mice.

Seth Roberts (2012-01-17 20:15:53)

Both are anecdotes and not a substitutes for an evidence based approach.

Could you explain why you think anecdotes are not data? I hear that a lot. But it seems to be more of an insult ("you stink!") than an empirical statement.

Seth Roberts (2012-01-17 20:20:43)

He simply brought up the point that drugs/compounds/botanicals that produce a biologic effect in mice might not produce the same (or indeed any) biologic effect in humans.

That's not what he said. He made a stronger point – that a positive result in mice does not make a positive result in humans more likely (his exact words: "If there is only a preliminary animal study, even if positive, that does not support the efficacy of

larch bark in humans"). That's absurd, but that's what he said.

Seth Roberts (2012-01-17 20:23:28)

However, adopting an anti-expert viewpoint is counterproductive.

I believe that you should look at evidence whenever possible – at least where doctors are concerned. Is that "anti-expert"? If so, what is counter-productive about it?

Seth Roberts (2012-01-17 20:36:37)

Curious. Here's what Gorski said:

If there is only a preliminary animal study, even if positive, that does not support the efficacy of larch bark in humans.

Here's what I said in response:

Apparently Gorski thinks animals (e.g., rats) and humans share no DNA.

I reached that conclusion because I could not think of another explanation for the pattern of results that Gorski refers to: results with animals tell us nothing about what will happen with humans. In other words, knowing that X is true for rats tells us nothing about whether X will be true for humans. Let's assume it's true that animal results tell us nothing about what will happen with humans. Can you think of another plausible explanation for this pattern of results besides zero DNA overlap?

Amber K (2012-01-17 20:40:58)

"Not so. The many similarities between mice and humans mean that if Statement X is true for mice, X is more likely to be true for humans than if X is not true for mice." Yes, and therefore more research is needed. It is not conclusive evidence of efficacy in humans. It shows a possibility of efficacy. Which I stated in my comment.

Kirk (2012-01-17 21:10:08)

@ShadowfaxMD You say, "There is essentially zero good evidence for vitamin or nutrition based treatment for recurrent sore throats, compared to the reams of data, both pro and con, for tonsillectomy." Color me skeptical. Wouldn't this have been highlighted by one of the editors for the Science-Based Medicine blog? All they would need to do is cite the studies. Can you list those PubMed papers which show SBM-approved double-blind studies indicating no efficacy? Since you have so bravely joined the give-and-take over here, I would like to post a few questions to you. If this situation was happening to a child in your extended family, would you counsel scheduling immediate surgery once the physician communicated that opinion? (I assume you are aware of the risks of surgery.) Or would you say to the parents, 'There is an alternative, and I'll be the first to say it may be a long-shot, but, you know, the risks are low for delaying surgery for a month. You might consider a nutritional approach like the one which reportedly worked for Rachael and her son.' Do you think Rachael should stop the nutritional approach and schedule surgery? And finally, I'd like to make a point about experts. Experts are great. I was one in a particular field several years ago. And yet, sometimes we ignore experts when the risk is low. The major illustration is nutrition. I'm guessing from your handle that you're an MD or somewhat associated with the medical field. If so, are you an MD who treats patients exclusively about nutritional problems? My guess, no, that's not your exclusive focus. You're not a nutritional expert and thus you probably base your Way of Eating on one of the eating plans developed by an M.D. Am I right? Which one? Dr. Atkins, Dr. Ornish, Dr. Willett? And here's the key issue . . . do you completely and absolutely comply to that diet? Or do you subtract something, or adjust a ratio, or add something? For example, it may be a low-salt diet but you like salt and your own research indicates there's nothing wrong with a reasonable amount of salt. If so, then you're ignoring an expert. And why do you ignore an expert? Because the risk is low and you've done your homework.

David Gorski (2012-01-17 21:44:09)

That's not what he said. He made a stronger point — that a positive result in mice does not make a positive result in humans more likely (his exact words: "If there is only a preliminary animal study, even if positive, that does not support the efficacy of larch bark in humans").

Nice straw man ya got there, Seth. Let's put it this way. A positive animal study might mean it's more likely that a treatment will work in humans, but it is still not evidence of efficacy in humans. (Amber K's comment was spot on.) In other words, it's suggestive that a therapy might work, not evidence that it will. That's why no clinician bases therapy decisions in humans on animal studies. I can only conclude that you really don't understand this or being deliberately obtuse about this point. As for your comment about my supposedly thinking that rats and humans don't share DNA, now really. That was just plain dumb. I'm sorry, but there really is no other politer way to put it. As others have pointed out, just because we share DNA does not necessarily mean that results in rats will translate into humans.

Seth Roberts (2012-01-17 22:21:50)

it's suggestive that a therapy might work, not evidence that it will.

Huh? I fail to understand this. You seem to be using "evidence" in a way I have never encountered. The usual meaning of "evidence" is this: Observation X is evidence for Statement A if and only if Observation X makes Statement A more plausible. With this usage, anything that is "suggestive that a therapy might work" (= makes it more plausible that a therapy will work) is also "evidence" that it will work. Could you explain what you mean by "evidence" in your sentence?

As others have pointed out, just because we share DNA does not necessarily mean that results in rats will translate into humans.

Of course not. But that's not what you said. You made a stronger statement:

If there is only a preliminary animal study, even if positive, that does not support the efficacy of larch bark in humans.

Whereas I think that a preliminary animal study, if positive, does support (= make more plausible) the efficacy of larch bark in humans. My belief is based on the many many similarities that have been observed between lab animals and humans (e.g., any physiology textbook). Can you explain the basis of your belief ("If there is only a preliminary animal study, even if positive, that does not support the efficacy of larch bark in humans")?

"Nice straw man . . . deliberately obtuse . . . just plain dumb"

Curious. You think such terminology improves your argument?

Jeff Alexander (2012-01-18 00:13:58)

Huh? I fail to understand this. You seem to be using "evidence" in a way I have never encountered.

Evidence of efficacy in humans would be the observation of an effect after administering to humans. Administering to a rat can only provide evidence of efficacy in rats. Seeing an effect in rats might lead you to believe that there will be a similar effect in humans but it is not evidence of such an effect. This is why it is suggestive but not evidence of efficacy. There have been plenty of therapies that looked promising based upon animal studies which have later failed when tested on humans. If evidence of efficacy in rats truly was evidence of efficacy in humans there would be no such failed transfers.

Mike Scott (2012-01-18 00:35:22)

You're being unfair here, whether deliberately or accidentally. Everything is made of the same particles and works in the same way, so everything is technically evidence for everything. In the field of evidence-based medicine, we must thus restrict ourselves to *useful* evidence. Experience has found that the results of a small number of animal studies do not constitute useful evidence for what works in humans, merely a promising line of attack to conduct further research and build up a body of evidence that is useful.

Seth Roberts (2012-01-18 04:38:01)

Everything is made of the same particles and works in the same way, so everything is technically evidence for everything.

Care to provide evidence for that?

Seth Roberts (2012-01-18 04:40:48)

Evidence of efficacy in humans would be the observation of an effect after administering to humans. Administering to a rat can only provide evidence of efficacy in rats.

You mean the statement by David Gorski that I have been complaining about is true by definition? I thought we were discussing science, not mathematics.

Jazi zilber (2012-01-18 05:00:27)

I think there is a Wording issue here. "evidence" has two meanings. 1) any kind of information 2) conclusive proof In the jargon of SBM folks evidence means (like in court) conclusive proof. Hence their use of the word.

Jazi zilber (2012-01-18 05:03:11)

Miriam webster give both definitions here <http://www.merriam-webster.com/dictionary/evidence>

Nam (2012-01-18 05:27:28)

Let's assume it's true that animal results tell us nothing about what will happen with humans. Can you think of another plausible explanation for this pattern of results besides zero DNA overlap?

Yes, different metabolism and breakdown of compounds. Differences in physiology, etc. Extending your logic would say, for example, cows can digest cellulose, and since we share a lot of DNA with cows, therefore we should be able to digest cellulose too. Since we can't digest cellulose we must have zero DNA overlap with them, its the only explanation.

Seth Roberts (2012-01-18 05:33:23)

Yes, different metabolism and breakdown of compounds. Differences in physiology, etc.

Since our metabolism and other aspects of physiology are heavily dependent on our DNA, I fail to see how this is a substantially different explanation.

Seth Roberts (2012-01-18 05:38:46)

Here's what that linked-to definition says: 1a : an outward sign : indication b : something that furnishes proof : testimony;

specifically : something legally submitted to a tribunal to ascertain the truth of a matter 2: one who bears witness; especially : one who voluntarily confesses a crime and testifies for the prosecution against his accomplices Not the two meanings you give.

Josh Neal (2012-01-18 06:04:26)

Seth, these guys aren't the bad guys. They are trying to help you understand what they mean. You aren't addressing many of the points made in response to you. 1. If I kill a mouse, is this evidence that I will kill a man? 2. What is your explanation for things that affect different animals in different ways? 3. What if the Doctors are being honest when they tell you what they mean by the word evidence? 3.

Amber K (2012-01-18 08:55:25)

Seth, I think this can help you understand the meaning of evidence as we're using it. "scientific evidence: Results when a theory or hypothesis is tested objectively by other individuals such as in an experiment or in a controlled environment." The mouse experiment is testing the hypothesis that the treatment is efficacious in mice vs the null hypothesis, the treatment has no effect in mice. The results from the experiment are evidence of whether or not the null hypothesis or the alternate hypothesis is disproved. If we disprove the null hypothesis (i.e., the treatment is efficacious in mice) then we will set up further experiments, each testing a new set of hypotheses. It is not until we get to a controlled, double-blinded study in a human population of significant size that we are testing the hypothesis, "this treatment is effective in humans." Therefore any evidence gathered until that time is not considered evidence that the treatment is effective in humans. It is only evidence for the hypotheses that were tested in each experiment. So in a nutshell, each step of the process infers a possibility of success in the next, but is not evidence for it. Why? In order to make the statement that evidence of efficacy in mice is evidence of efficacy in humans, we would have had to set up an experiment to test that hypothesis and proved the null hypothesis invalid. We have no need to do that, however, because of the large number of studies that have proved efficacy in mice and not in humans (in other words, it's already been done). I hope that makes things more clear.

Alex Chernavsky (2012-01-18 09:30:49)

Doug wrote:

...adopting an anti-expert viewpoint is counterproductive.

I disagree. Here are three books that illustrate why experts should be treated with deep suspicion: [1]*A Random Walk Down Wall Street*, by Burton Malkiel. The author provides convincing evidence that stock analysts (and other Wall Street professionals) don't know what they are doing. Note that this is a separate issue from corruption. [2]*Mistakes Were Made (But Not by Me): Why We Justify Foolish Beliefs, Bad Decisions, and Hurtful Acts*, by Carol Tavis and Elliot Aronson. What's particularly interesting about this book are the examples where experts are shown to be dreadfully, horribly wrong - but then stubbornly refuse to admit it. [3]*Anatomy of an Epidemic: Magic Bullets, Psychiatric Drugs, and the Astonishing Rise of Mental Illness in America*, by Robert Whitaker. The author argues that "expert" psychopharmacologists have produced drugs that are not only ineffective but are actually harmful, though most mental-health professionals continue to swear by them.

2. <http://www.amazon.com/Mistakes-Were-Made-But-Not/dp/0156033909/>

3. <http://www.amazon.com/Anatomy-Epidemic-Bullets-Psychiatric-Astonishing/dp/0307452425/>

Nam (2012-01-18 09:34:11)

Since our metabolism and other aspects of physiology are heavily dependent on our DNA, I fail to see how this is a substantially different explanation.

Not sure what you mean. But yes, while we share some DNA and aspects of our physiology with other species, we also have substantial differences. Thus whatever effect a certain drug or treatment may have in a rodent, there is by no means any guarantee that it will have the same effect in humans. In some cases it might even have the opposite effect. Animal studies are important in that they allow us to test the plausibility of certain treatments and have allowed for a great many

medical advances. But they have a limit as most doctors and scientists know. Which is why translational research is important for bridging the gap between basic science and medical treatment. But you just can't jump to the conclusion that because something may work in rodents, then you have evidence that it works in humans.

Seth Roberts (2012-01-18 10:00:05)

It is not until we get to a controlled, double-blinded study in a human population of significant size that we are testing the hypothesis, "this treatment is effective in humans."

What is the evidence for this claim? Which would shock epidemiologists, by the way.

Amber K (2012-01-18 10:17:38)

"What is the evidence for this claim? Which would shock epidemiologists, by the way." Sigh. I tried, Seth. I really tried. No epidemiologists would be shocked by rigorous experimental practices to remove subjective bias. It seems to me you are just cherry-picking statements from everyone's comments to try to mine some kind of semantic victory for yourself. This is petty, purposefully obtuse and I am done playing this game. Good luck to you.

Seth Roberts (2012-01-18 10:49:43)

It seems to me you are just cherry-picking statements from everyone's comments to try to mine some kind of semantic victory for yourself.

No, I'm trying to learn something. I'll never know where your beliefs come from – what is behind them – unless I ask. I pick one statement (what you call "cherry-picking") to make responding more manageable.

Jazi zilber (2012-01-18 10:51:44)

I referred to 1a vs. 1b definitions.

Seth Roberts (2012-01-18 12:27:27)

The 1b definition does not mean "conclusive proof". Not even close. It just means the sort of stuff that is called "evidence" in legal proceedings.

Sirkowski (2012-01-19 00:11:11)

Seth Roberts Says: Since our metabolism and other aspects of physiology are heavily dependent on our DNA, I fail to see how this is a substantially different explanation.

Humans have a gallbladder, rats don't. Rats have whiskers, humans don't. I could go on. I mean, seriously? I don't think genetics work the way you think it does.

Josh Neal (2012-01-19 07:29:09)

It's very simple. Some things work the same in mice and humans, yet some things don't. If you are really trying to learn something here, then why not engage the points that people have made to you. Instead of deciding what you think other people mean, why not listen to what they tell you they mean.

Josh Neal (2012-01-19 07:34:31)

Also kind of strange that the person above gave three books about how experts fail us. I guess those authors are experts on the matter?

Someone (2012-01-19 07:46:09)

Treatment that works well for mice does not automatically work for humans. There are tons of failed treatments for humans, which worked on lab rats. Which is bad news for my son...

Greg (2012-01-19 10:27:11)

Such a long and an interesting conversation...that seems to be winding down. I had my tonsils removed forty years ago and can still see the video in my mind's eye of my tearful plea to my father: "Don't let them take me away!". I remember that the promised course of post-surgery therapeutic doses of ice cream did not materialize as soon as expected. With what I know now (I utilize alternative and nutritional therapies more so than pharmaceutical and surgical ones), I may have kept my tonsils a bit longer. In arguments, it is easy to keep gnawing at one tree. Gorski responded to Robert's challenge of the widespread practice of tonsillectomy by suggesting that laymen does not always know how to interpret and prioritize the data. Roberts has taken the bait regarding this minor question of mice and men and evidence and the trap has snapped shut. I must give points to the doctors on this one, but wish Gorski would respond to the spirit of Robert's original blog: Is questioning standard surgical practices a good thing?

Seth Roberts (2012-01-19 12:38:42)

Greg, thanks for your final question ("Is questioning standard surgical practices a good thing?"). What I am really questioning is how evidence-based medicine is done. They omit a lot of evidence. Often the omitted evidence is much more negative than positive. This leads to a huge positive bias in what outside observers see – the treatment under review appears much better than it actually is. Yet the possibility of such a bias is never mentioned.

Seth Roberts (2012-01-19 12:41:31)

Some things work the same in mice and humans, yet some things don't.

That's why rat studies help us predict what will happen when a similar experiment is done in humans. They don't provide certainty, of course – the results of an animal study doesn't allow us to predict with certainty the results of a human study – but they are better than nothing. This is why Gorski's complete dismissal of a "preliminary animal study" is so strange.

Sam Fen (2012-01-19 14:45:23)

Last year I put a lot of compost in the ground and my carrots grew much bigger than they had before. By your argument, since humans share a great deal of DNA with carrots (about 20 %), this is evidence that putting a human in compost will cause them to grow bigger. Suppose someone suggested that this was not evidence at all. We could then just copy-and-paste your argument:

Let's assume it's true that the [carrot] results tell us nothing about what will happen with humans. Can you think of another plausible explanation for this pattern of results besides zero DNA overlap?

Now this argument is clearly absurd. There are hundreds of plausible explanations for why this carrot result is not evidence for the conclusion, and it is a strawman to say that the only possibility would be if there were "zero DNA overlap" between carrots and humans. On the other hand, if you do actually believe that my "carrot study" above *is* evidence that putting a human in compost will cause them to grow bigger, then you are using such a definition of "evidence" that is so useless to research as to be virtually meaningless, and, in any case, this is not the kind of "evidence" that a doctor should rely on when prescribing medicine.

LisaW (2012-01-19 15:07:33)

Alex, I would like to add another book to your list about being wary of experts 'Future Babble' by Dan Gardner. It examines not only the so called experts but also why we often believe them.

Seth Roberts (2012-01-19 23:06:09)

Okay, Sam Fen, two questions: 1. Let's assume results from Organism X (carrots, perhaps) tell us exactly nothing about what will happen when humans get the same treatment. What's your plausible alternative to the zero DNA overlap explanation? 2. What did you think of the main point of my article – that "evidence-based-medicine" practitioners ignore too much evidence?

Sam Fen (2012-01-20 12:49:14)

Let's assume results from Organism X (carrots, perhaps) tell us exactly nothing about what will happen when humans get the same treatment. What's your plausible alternative to the zero DNA overlap explanation? Simple: Carrots and humans have an extremely different physiology, despite sharing a large percentage of DNA. Therefore, the fact that putting carrots in compost makes them grow faster tells us virtually nothing about whether putting humans in compost will achieve the same thing. Now let me ask you the question straight out: 1) Do you think that my "carrot study" is evidence that putting humans in compost would make them grow? 2) If yes, how much evidence? Enough evidence that a family doctor should use it when suggesting a course of treatment for a child?

Seth Roberts (2012-01-20 16:12:57)

Sam Fen, if you answer my Question #2, I would be happy to answer yours.

Myk (2012-01-21 16:35:43)

Clinical practitioners should only use evidence of efficacy in the species they are treating. Researchers can use evidence in similar species to guide their efforts. That's David Gorski's point that you seem to have completely missed.

Seth Roberts (2012-01-21 19:15:00)

Clinical practitioners should only use evidence of efficacy in the species they are treating. . . .That's David Gorski's point that you seem to have completely missed.

You mean Gorski's point was true by definition (of "evidence of efficacy")? Huh. I thought we were discussing science, not law.

Josh Neal (2012-01-22 02:36:51)

In response to the above question number two. I'm sure you would agree that not all the studies in the literature stand equally. Therefore doctors and scientists must choose which studies to believe. For this they need to have a consistent system to help separate the good from the bad. This system is always evolving and getting better. Some of the principles that have come out of this system are: human studies are more relevant than animal studies. Large studies outweigh small studies. Blinded studies outweigh non blinded studies. Double blinded studies outweigh blinded studies. Effects with explainable mechanisms outweigh effects with unexplained mechanisms when dealing with small effect sizes.

Seth Roberts (2012-01-22 04:39:41)

I'm sure you would agree that not all the studies in the literature stand equally. Therefore doctors and scientists must choose which studies to believe.

I agree with your first statement (not all studies equal). However, your second sentence ("therefore doctors...") doesn't follow from it. Instead of "choosing what studies to believe" doctors and scientists can assign each study a degree of belief. And consider all of them. Not ignore any of them. In my experience this is what scientists usually do. Only doctors and evidence-based medicine advocates and the like promote black-and-white all-or-nothing thinking about evidence. Bayesian statistics is a formalization of what most scientists do.

Sam Fen (2012-01-23 06:53:04)

What did you think of the main point of my article — that “evidence-based-medicine” practitioners ignore too much evidence?

I can't possibly answer that, not knowing the majority of evidence-based-medicine practitioners. How can I possibly make a generalization like that based on your anecdotes? But I was dealing with a very specific point, not an abstract one: should a family doctor make a medical recommendation based on one rat study?

Seth Roberts (2012-01-23 11:56:52)

I can't possibly answer that, not knowing the majority of evidence-based-medicine practitioners. How can I possibly make a generalization like that based on your anecdotes?

If you knew more about evidence-based medicine, you would know that the situation I described in Tonsillectomy Confidential is typical: A vast amount of evidence is ignored. Even if you didn't know that, you could comment on the particular example I described.

Sam Fen (2012-01-24 07:53:30)

You haven't answered any of my questions yet, you just keep asking more of your own.

### **Vitamin D3: More Reason to Take it First Thing in the Morning (2012-01-16 05:00)**

At the Fancy Food Show, one of the exhibitors asked me what I did. I said I studied how food affected the brain. That's interesting, she said. She proceeded to tell me that Vitamin D3 has really helped her.

When do you take it? I asked.

First thing in the morning, she said.

Why? I asked. Because she had tried taking it at bedtime and it hadn't worked. So she switched to first thing in the morning and it worked well. It gave her energy and raised her mood. Her 28-year-old son had the same experience.

I told her I had seen the same pattern several times. The time of day really matters, I said. She said she had never thought of that – that what was true for her was true for other people. She had told lots of people about the benefits of Vitamin D3 but she hadn't told them what time to take it.

I hope to interview this woman at length and get more details.

As far as I'm concerned, [1]the totality of evidence, including this story, is overwhelmingly persuasive. Taking Vitamin D3 at the right time of day is crucial. Take it at the best time of day (first thing in the morning), it will have a powerful good effect. Take it at the worst time of day (evening), it will have a bad effect.

Why Vitamin D researchers missed this, and how long it will take them to stop dismissing “anecdotes” about it, are interesting questions.

1. <http://blog.sethroberts.net/category/sleep/vitamin-d3-and-sleep/>

---

Daniel (2012-01-16 05:37:24)

Seth, What does this mean for multivitamins?

thuphaer (2012-01-16 06:44:44)

I usually skip breakfast. Should I still take the vitamin D first thing in the morning ?

Seth Roberts (2012-01-16 07:20:41)

I usually skip breakfast. Should I still take the vitamin D first thing in the morning ?

Based on my experience, yes. I skip breakfast and take Vitamin D first thing in the morning.

Seth Roberts (2012-01-16 07:23:23)

What does this mean for multivitamins?

It means you should take a multivitamin since Vitamin D3 requires co-factors to work properly.

cremes (2012-01-16 07:27:41)

Which co-factors does Vitamin D3 require? I googled around for it but all I could find were discussions about keeping a (roughly) 2:1 ratio between vitamins A & D (e.g. 10k IU of Vitamin A needs 5k IU of Vitamin D3 to balance).

Seth Roberts (2012-01-16 08:21:49)

Yes, Vitamin A is the known co-factor of Vitamin D. Perhaps there are others.

Karen (2012-01-16 08:42:00)

Taking vit D early in the morning has been a game changer for me. I take it first thing after getting out of bed. I take 15k IU. I started doing this after reading the suggestion on your blog. I'd been taking it for years at different times of the day but never early in the morning. It hasn't helped my sleep but the upgrade in mood and energy has been staggering. I started taking vit K and CLO (for the A) along with the D and the affect diminished. I dropped the K and CLO and it came back. I wish I had thought to try this years ago. Thanks for passing the tip along.

Tom (2012-01-16 09:59:19)

Vitamin K2 is another co-factor, with a role in bone and arterial health. [http://en.wikipedia.org/wiki/Vitamin\\_K](http://en.wikipedia.org/wiki/Vitamin_K) #Vitamin\_K\_and\_bone\_health Apparently D3, A, and K2 are all needed to carboxylate osteocalcin, and osteocalcin is what keeps calcium in the bones and out of the arteries. (When it's undercarboxylated, osteocalcin can't 'hook' the calcium molecules, so they aggregate in the circulatory system, and show up on calcium scans.) Many people don't get enough of D3, A, or K2.

Jenny (2012-01-16 11:14:30)

I too discovered independently that D3 first thing in the morning works. I have also found that the best time of day for 5HTp, if you need that, is about 40 minutes before bed. And by the way, if you wake up stiff- thinking you are getting old, try the 5HTp. Muscles need serotonin too, and stiffness will show up before depression.

david (2012-01-16 13:23:23)

Tomorrow, I'm going to start taking D3 first thing in the morning. I am having a very hard time getting up in the morning when I need to. Last week I began eating breakfast (two eggs scrambled with bacon and cheese) soon after waking (within 30min). By the end of the week, waking up was not any easier. Let's see if adding D3 helps.

Daniel (2012-01-16 19:47:23)

Re: multivitamins. Yes, but if the timing is important, when do you take the multivitamin? I take Vit-D in the morning and magnesium at night. but my multivitamin has both what to do then?

Adam (2012-01-17 04:01:10)

Rather than taking a multivitamin, you could get the other necessary vitamins from whole foods. Liver, dandelion greens, carrots and sweet potatoes are the top 4 sources of vitamin A. Vitamin K is usually pretty high in dark green, leafy vegetables.

Iwan (2012-01-17 09:31:06)

I am about to run a self-experiment on using timing and levels of Vit D ingestion to combat jet lag. Does anyone else have experience with this method? Thanks

Paul Winter (2012-01-17 20:22:54)

I grew up in England, for the past few years I have been in NZ, does the change in locations make a difference. I will let you know. P Winter.

### **Tara Parker-Pope, "The Fat Trap" and the Shangri-La Diet (2012-01-17 05:00)**

Years ago I had lunch with a woman whose father ran a chain of weight-loss clinics. They were very successful and he was often invited to give talks. He never accepted these invitations, his daughter said, because he was seriously overweight – like 300 pounds.

I was reminded of this by [1]Tara Parker-Pope's recent New York Times Magazine article "The Fat Trap". Parker-Pope tells us she is "at least 60 pounds" overweight, a bit of brave honesty for which I give her credit. I give her less credit for unskeptically quoting expert after expert – her article is essentially a review of expert opinion. If these experts are as wonderful and accurate as she says (by repeating their ideas), why is she 60 pounds overweight?

She never answers this question. She doesn't even seem to ask it. However, someone else asks it. "The Fat Trap" includes this:

In most modern cultures . . . to be fat is to be perceived as weak-willed and lazy. It's also just embarrassing. Once, at a party, I met a well-respected writer who knew my work as a health writer. "You're not at all what I expected," she said, eyes widening. The man I was dating, perhaps trying to help, finished the thought. "You thought she'd be thinner, right?" he said. I wanted to disappear, but the woman was gracious. "No," she said, casting a glare at the man and reaching to warmly shake my hand. "I thought you'd be older."

I already knew it was "just embarrassing" to be fat. What's interesting is that the story that follows this unremarkable idea doesn't support it. Her date wasn't saying she's fat. Sixty pounds overweight is not surprisingly fat. The "well-respected writer" can't possibly have been surprised simply by that. Her date knows this. He's bringing up something that puzzles him ("if you know so much about health, why are you fat?"), a reasonable question. By "you thought she'd be thinner, right?" he means "you thought, because of her job, she'd be thinner, right?" Parker-Pope and her editor don't notice this.

Parker-Pope continued to reshape reality in [2]an interview she gave, which included the following:

Q. What were your hopes in writing "The Fat Trap"?

A. My hope was that people would leave the article feeling informed and empowered. . . . [I got the story idea talking] with Dr. Michael Rosenbaum at Columbia about the science of weight loss. . . . [He told me what dieters already know:] that most people who are fat, are going to stay fat. . . . The truth is: Once you've gained weight, it's really, really hard for most people to lose weight and keep it off.

Is she sure this "truth" is empowering? To me it sounds discouraging.

The speed of the obesity epidemic – 30 years ago, Americans were much thinner – implies that the obesity epidemic has an environmental cause. Genes don't change that fast. Something about the environment – something that controls weight – has changed. Not exercise. Thirty years ago, Americans probably exercised less than now. It is likely that something they ate kept them thin, without trying. Parker-Pope fails to understand this. Or at least failed to ask the experts she spoke to about it. What about the environment has changed? she should have asked. If I were her, I'd be angry. The obesity epidemic is 30 years old! Thirty f—ing years! Why is it taking so long to figure out the cause?

The length of the obesity epidemic reflects research failure. Against her own self-interest, she doesn't grasp this. At the end of "The Fat Trap", like a brainwashing victim, she says:

I do, ultimately, blame myself for allowing my weight to get out of control.

I disagree. She should not blame herself for not knowing how to stay thin – hardly anyone knows. No, her failure is journalistic: (a) not grasping that the obesity epidemic must be due to changes in what we eat (lots of people understand this), (b) not grasping this means there must be a way to be almost effortlessly thin (in the 1970s people were much thinner with little effort), and, above all, (c) not confronting the experts she interviews. Her insensitive date spoke an uncomfortable truth. Now she is failing to ask uncomfortable questions (why is it taking so long?) Much worse.

[3]My theory of weight control says the crucial environmental change that caused the obesity epidemic was increased consumption of foods that produce very strong (= very fattening) smell-calorie associations. To produce a very strong smell-calorie association, a food must (a) have a strong smell (a strong "flavor"), (b) have quickly digested calories (e.g., a high glycemic index), and (c) have exactly the same smell each time. All three features, especially the third, are much more true of factory food, fast food, and junk food than of handmade food. Typical food processing almost always increases flavor (e.g., add spices) and speeds digestion (e.g., cooking). Factory and chain restaurant food processing produces much less variable flavor than ordinary human food processing. Exactly when the obesity epidemic started, there was a big shift toward factory and chain restaurant food. One reason was microwave ovens. Microwave entrees taste exactly the same each time. Another reason was an increase in eating at chain restaurants. The Shangri-La Diet goes into more detail.

At the end of "The Fat Trap" is this:

All the evidence suggests that it's going to be very, very difficult for me to reduce my weight permanently.

No, not all the evidence. [4]Alex Chernavsky used the Shangri-La Diet to lose 25 pounds and has kept it off easily and apparently permanently.

john (2012-01-17 07:27:59)

Hi Seth, I think it's unlikely that obese people ever break free of the standard gluttony-sloth idea. You probably have a similar proportion of people "breaking free" of the "saturated fat 'clogs' your arteries" idea. Most people are unquestioning followers of authority and don't have experience, or maybe even capability, in thinking scientifically. I have literally presented papers to people to support an idea, but they simply re-tell me what [Dr Oz] has said. They don't register the science as evidence; I think they consider differing ideas as opinions, which they technically are not. I don't know how we can change that sort of culture. Off topic a bit, did you have specific reasons for giving up rice, bread, and potatoes? Was low carb self-experimentation that brought you to that (with all carb sources having negative effects), or was it an idea based on readings, etc, and you found it worked well?

MikeW (2012-01-17 08:23:44)

TPP's "very, very difficult" comment isn't surprising - the one successful longterm dieter she profiles in that article is a hopelessly obsessed calorie-counter. Daily food diary for 5 years, weighing all her food, researching restaurant menus online every time she eats out, exercising 100-120 minutes every day to burn exactly 500 calories. I'm glad it works for her, but who wants to live like that? Whether it's SLD, Paleo, Atkins, whatever - I'm sure there are lots of folks out there who have achieved longterm weight loss by adopting simple, easy-to-follow rules. If Ms. Parker-Pope had focused on one of those success stories, maybe she wouldn't have given herself such a gloomy prognosis.

tom (2012-01-17 09:37:00)

I know this isn't Seth's or Parker-Pope's focus, but imagine if getting fat once really does re-set your body to make you fat for life, as the article seems to say. There have been so many news stories about girls/women with anorexia where the author blames American culture for being obsessed with keeping them thin. But if the biggest cause of life-long fatness is simply getting fat once, then maybe family/cultural disapproval of fatness serves an important function.

charlie (2012-01-17 10:54:23)

The article set itself up to fail — looked at a crash diet program. I'm not even sure the program was meant to lose weight - it was a research program. Is anyone surprised that a bunch of fatties fed minimal protein shakes for six weeks regain their weight? The real point is does something happen to fat people? answer - probably yes. But is it hard to lose weight? No. It is hard to keep that weight off - well, it requires some changes.

Tim Beneke (2012-01-17 14:59:06)

Using various applications of Seth's core ideas I can report that I've lost 33 pounds and kept them off for 11 years, about 12 % of my body weight. And even this is a very misleading statement because for roughly 10 of those 11 years I had lost more than 50 pounds and kept them off. And about 5 of those years I had lost more than 70 pounds. For 2, about 90. For 1, about 100. I'm currently about 70 pounds lighter than I was when I started applying Seth's ideas - from 280 in November 1999, to 210 or so now - 25 % weight loss. And I'm working hard to get thin again... Obviously it's a long story. The key point is that the flavor environment profoundly influences hunger and it's relatively easy to stay lighter if you are not hungry - assuming you do not eat when you are not hungry. If you eat when not hungry, it's probably impossible to lose weight long term. One thing I would add: It's my distinct impression that the more nutritious the food you consume, the less hunger you will have, so a 1000 calories of poor nutrition should leave you hungrier than a 1000 calories of good nutrition. Last time I checked a few years ago - there seemed to be little scientific research on this, something I found strange. Also, in trying to lose weight and keep it off, it's very easy to confuse bad method with weakness of will. You need both willingness to do the work, plus a good method. Before encountering Seth's ideas, I was very good at heroically enduring hunger to lose weight - and inevitably gained it back and then some. Strong will is not enough if the method is bad. I'm hopeful - perhaps naively so - that eventually truth will out and Seth's discoveries about weight loss will be widely recognized and accepted. It's depressing that the Times is running articles by respected health journalists who are recycling old ideas that have obviously failed. Basic science: if you make causal claims, you need to be able to accurately predict something. If you claim to know what can cause people to permanently lose weight, you need to be able to show people permanently losing weight with your methods.

Glen Raphael (2012-01-17 16:46:56)

*All the evidence suggests that it's going to be very, very difficult for me to reduce my weight permanently.* No, not all the evidence. Alex Chernavsky used the Shangri-La Diet to lose 25 pounds and has kept it off easily and apparently permanently. *Assuming by "reduce my weight permanently" she means reduce it to a socially-acceptable "normal" weight level,* SLD doesn't really answer to that. Yes, SLD clearly helps some people lose some weight but what percentage of SLD-ers get from "very overweight" to near their "goal" weight? What percentage don't find it "very very difficult" to reach their goals at all, much less to do so "permanently"? SLD is arguably a step in a better direction, but it's not a complete solution. It still takes willpower to stick with SLD and even if you do, the effectiveness varies. If there's really a way to get and stay "effortlessly thin" it probably hasn't been found yet.

dearieme (2012-01-17 17:32:30)

Is there a rational way to determine a sensible target that is practical for a particular individual? Not just on grounds of classification variables - age, sex, race, and so on - but for that specific individual?

Cliff Clayton (2012-01-17 18:47:37)

I am male. At 49 I discovered, to my horror, I weighed 205lbs. I was 165 all through high school. I understood nothing about diets or weight loss then, but in less than two years I lost 35lbs by mainly starving myself. At that point I decided to get in shape too, so now I ride a bike through the hills of PA at 17mph average and lift weights in the winter. I eat low carb, hi fat, hi protein, I am never hungry unless I do a fast. I hit a low of 165 late fall when I'm riding long and hard (I do 4-5000 miles a year), and hit 175 in the winter when I bench 1rep max of 200lbs. I am 58 now. I don't weigh myself any longer. My asthmatic wife would love to lose 25lbs. We have two children. She eats excellent, no crap, cakes, pies, fast food, chips, no crap. IE we eat basically the same. She does no exercise to speak of (walking) but she is not sedentary or lazy. She is very active until she crashes at 8pm. Each of us seem to have reached a weight that we can't get below. From my experience (n=2) low carb takes off weight, exercise keeps it off. With that said, I'll let you know how that works out when I'm 68. I tell anyone who asks: "Don't eat white stuff (flour, sugar, milk) and do something fun that sends your heart rate to your max as often and for as long you can stand it, everyday if possible.

Seth Roberts (2012-01-17 22:49:22)

did you have specific reasons for giving up rice, bread, and potatoes? Was is low carb self-experimentation that

brought you to that (with all carb sources having negative effects), or was it an idea based on readings, etc, and you found it worked well?

I gave them up because they have a high glycemic index. I found that substituting a low-glycemic-index food for higher-glycemic-index foods led to easy weight loss. As my weight-loss theory predicted. My theory was based on both self-experimentation and lots of reading. my theory: <http://sethroberts.net/about/whatmakesfoodfattening.pdf> related self-experimentation: <http://escholarship.org/uc/item/2xc2h866>

Sara (2012-01-18 01:46:30)

I wrote an undergraduate paper on the FTO gene and the way it is reported in the media. I looked at the research behind the media reportage and it just wasn't as conclusive as what the media made out. But, if the media reported the equally correct headline 'Modern life proves fattening for 33 % of the population' where would this lead? 'Science' magazine can't publish that. Funding bodies aren't interested in studying aspects of society - they want to find 'the gene' and develop an expensive drug to turn it off. In my case, dealing with obesity required a holistic approach and took a really long time. I can't even say how I did it because it was so haphazard - you couldn't put it into a book. But somehow now I'm thin and it's easy to stay that way. I wish I could pinpoint the exact thing or things I did that turned off my appetite. I don't know if was psychological or physical, but I worked on both aspects. It is possible to lose weight and keep it off, I've done it, but I couldn't really say how.

Robbo (2012-01-18 05:42:02)

I shed c 45 lbs about seven years ago, and have kept it off since, using Atkins / Paleo / LCHF. It was never very hard, but I do take a little care not to get into a cinnamon bun habit. In my view Tara's problem is that she is following the wrong advice. This usually has the effect of making even simple things difficult. If I was being unkind, I would ask why she hasn't figured out that she has been following the wrong course and tried a different one (or two, or three,). And she's a journalist !

Seth Roberts (2012-01-18 06:17:43)

In my view Tara's problem is that she is following the wrong advice.

I agree. Another way to put it is: Experts are giving her the wrong advice.

tom (2012-01-18 10:01:22)

But Seth, do you believe in the 're-set' idea? Do you think set points change and that it's much easier to stay thin if you don't let yourself get fat to begin with?

Seth Roberts (2012-01-18 10:48:05)

I believe set points change, yes. I believe they are changing all the time - going down between meals and up during meals. I believe your set point depends on the food you eat (it also depends on other things, too). I don't know what the "re-set idea" is.

Tom (2012-01-18 12:53:43)

I feel bad for her. It's hard to question authority(-ies) when you're on a first-name basis with all the key ones. (As she is by virtue of her position.) I wonder if she's ever read Good Calories, Bad Calories. But I don't doubt that she's talked to both Dean Ornish and Mehmet Oz about how wrong Taubes is.

Kevin (2012-01-19 06:28:30)

disagree. She should not blame herself for not knowing how to stay thin — hardly anyone knows.

This is completely false. Everyone knows how to lose weight. Eat less. It just takes discipline so no one wants to do it. Before I accepted this simple truth - that it does not matter what I eat, provided I eat less of it - I was struggling with diets (paleo, low

carb, you name it) and was chronically fat. Simply accepting the disagreeable and unwelcome truth that I need to eat LESS (in my mind, it meant less pleasure in my life. As it turned out, that was a flawed belief. I actually began to enjoy my meals much more) finally liberated me to lose weight and I went from 200 lbs to 155 lbs and have stayed there for 5 years so far. All I do is eat less, but I eat anything I want (sugar, desserts, fat, meat, pasta - anything)

Something about the environment — something that controls weight — has changed. Not exercise. Thirty years ago, Americans probably exercised less than now. It is likely that something they ate kept them thin, without trying.

While you are right that this has to be caused by environmental changes, you make 2 logical mistakes 1) The changes can easily be CULTURAL and not in what we ate (as in loss of self-discipline, loss of a willingness to put up with deprivation, marketing that encourages us to always want MORE of everything, including food) 2) It does not follow that people were \*effortlessly\* thin in the 70s. It is quite possible that people were simply willing to put up with more deprivation and self-discipline was valued. Heck, even a cultural force like fat shaming can be the catalyst for change. I know you say that there is fat shaming in today's culture, but it is not really serious.

Seth Roberts (2012-01-19 06:52:18)

The changes can easily be CULTURAL and not in what we ate (as in loss of self-discipline, loss of a willingness to put up with deprivation. . . . It is quite possible that [in the 1970's] people were simply willing to put up with more deprivation [than now] and self-discipline was valued [more than now].

That's an interesting idea. In addition to the obesity epidemic, where else can we see evidence for this?

dave schutz (2012-01-19 07:04:33)

In the 70s, lots of people smoked, a lot. They were thinner than people who didn't smoke. I'm interested that this does not seem to be mentioned at all as a possible cause for all of us ballooning in the 30 years since.

Seth Roberts (2012-01-19 08:42:35)

In the 70s, lots of people smoked, a lot. They were thinner than people who didn't smoke. I'm interested that this does not seem to be mentioned at all as a possible cause for all of us ballooning in the 30 years since.

Less smoking does not explain why children are now much fatter than 30 years ago.

Kevin (2012-01-19 14:59:03)

That's an interesting idea. In addition to the obesity epidemic, where else can we see evidence for this?

Seth, I spent a lot of time on business in Thailand and Japan, where the people are incredibly thin and eat tons of carbs and sugars, etc. After a while you grasp that the people are not thin \*effortlessly\*. There are strong traditions governing how much to eat and what you eat (traditions we have lost), and there is a MASSIVE social stigma to being fat. It just is not acceptable. There was an article a while ago in the NYT about how Japanese women obsessively watch what they eat in order to stay incredibly thin. Portions are much smaller too, which studies have shown play a role in feeling full. To me, this is some amount of evidence in support of the idea that cultural factors are the culprits here. Also, if EVERYONE is eating much less and it is just part of the tradition governing food consumption, it really IS much easier, but it is not \*effortless\* in the sense that no self-discipline is involved and one can just eat impulsively.

john (2012-01-19 17:39:11)

Seth, n=1 In 1968 I was doing my honours year in a science faculty in australia. On Saturdays, I was one of the very few doing their project in the labs, others were at the football match or getting ready for parties. At 1230pm I was hungry and there was only one lunch place open within 3 miles, a greek hamburger joint, ONE! We were all a thin cohort then, except for the exception. Today in 2012, temptation to the brain through the eyes is everywhere through the explosion in coffee shops, food shops etc, and I can feel the brain assessing and visualising food images as I walk to the train, walking the dog, etc, past the multitude of temptations, it's everywhere. The reverse to 1968 is now apparent to me as a time evolution experiment.

tom (2012-01-19 21:44:12)

Seth, on re-setting set points, your articles speak of it differently than Pope's sources: Scientists are still learning why a weight-reduced body behaves so differently from a similar-size body that has not dieted. Muscle biopsies taken before, during and after weight loss show that once a person drops weight, their muscle fibers undergo a transformation, making them more like highly efficient "slow twitch" muscle fibers. A result is that after losing weight, your muscles burn 20 to 25 percent fewer calories during everyday activity and moderate aerobic exercise than those of a person who is naturally at the same weight. That means a dieter who thinks she is burning 200 calories during a brisk half-hour walk is probably using closer to 150 to 160 calories. .... A full year after significant weight loss, these men and women remained in what could be described as a biologically altered state. Their still-plump bodies were acting as if they were starving and were working overtime to regain the pounds they lost. \_\_\_\_\_ Pope is saying that there is something about getting fat itself that makes it harder for a person to be thin. That's the 're-set' that I'm talking about, and it's very different from your concept. If that's at all true, then imagine how much more important the cultural argument is. The best way to be thin is never to get fat?

Seth Roberts (2012-01-19 23:33:30)

I think the effects of losing weight probably vary greatly depending on how the weight is lost. If you lose weight WITHOUT lowering your set point, I think this is when you see all the changes you mention. But if you lose weight BY lowering your set point, I think the long-term consequences are far less. Cabanac has pointed out the enormous subjective difference between the two kinds of weight loss. The first is painful, the second is not.

Jim Purdy (2012-01-20 09:24:51)

Seth, I just read an interesting little article from the Association for Psychological Science, with the title: To "Think Outside the Box", Think Outside the Box. It studied whether people were more creative when they literally were physically inside or outside a large box. According to the article, people really were more creative when situated physically outside a box. I don't have much room in my apartment for big boxes, but I'm trying a variation of this, using two very small boxes, one on my desk, and one in my refrigerator. The idea is that every time I get a food craving, I will see a box, and maybe, just maybe, it will get me to "think outside the box" and find a healthier way to satisfy the craving. Silly idea, maybe, but isn't it in the spirit of self-experimentation? The article: <http://www.psychologicalscience.org/index.php/news/releases/to-think-outside-the-box-think-outside-the-box.html> My blog comment about it: <http://jimpurdy.blogspot.com/2012/01/thinking-and-dieting-outside-box.html>

Link love for January 14th through January 20th | FitChutney (2012-01-20 11:26:28)

tess (2012-01-22 07:39:32)

I find it interesting that it's men in this comment section who claim that losing weight is easy.... for men, it DOES seem to be easy - my husband is the same. Women find it much harder to lose weight, especially as they progress into midlife. A lifetime of trying to be thin is a handicap, which limits our progress with every new attempt. Add to this other hormonal changes which

skew the body toward wanting to store more fat. for those women who are also getting bad advice about ideal diet, i imagine it seems impossible. i'm incorporating Seth's (thank you!) SLD tweak to my strict paleo regimen (i was 80-20 before); the first week, weight POURED off me. the second week, with no change in menu, the loss was not consistent – some days my weight was up. i'm into my third week now, and far less hopeful of reaching my goal any time soon (WON'T be moving to Step 2 at the 30-day mark).... btw, i'm only moderately overweight – less than 28 bmi. so, YEAH – it IS hard to lose weight as well as to keep it off – if you're a woman.

Kevin (2012-01-23 09:14:47)

No one said it was easy, tess, just that it is simple and we know exactly how to do it. Simply eat less. There is no mystery. Everyone pretends that there is this incredible mystery in how to lose weight - ironically, it is precisely this belief that might be preventing people from coming to terms with the reality of what needs to be done. Instead they waste time on fad diets like low-carb which promise you you can still eat lots and lose weight. Most people are shocked when they discover how few calories the body really needs to maintain itself and how few we have to eat to lose weight. For instance, we have this idea that a \*healthy\* calorie intake per day is around 2000 for men. Even a very large man over six feet needs much less than that! Most people today would believe they are eating \*unhealthy\* and be in \*starvation mode\* if they ate the number of calories they really needed to lose weight and be healthy. It was living in Japan and Thailand that helped open my eyes to this truth. The good news is that this idea that you have to eat this ridiculous amounts to be healthy is just something programmed into us by our deficient culture, and we CAN de-program ourselves. The fact of the matter is that the initial stages of weight loss can be quite difficult as you learn to de-program yourself from all the messages that you will \*feel miserable\* on anything less than 1800 calories per day (for a man) - its complete nonsense - and that you need to eat 5 times a day and always eat MORE bla blah. Yes, it can be difficult. But it is simple. And we know how to do it. There is no mystery.

tess (2012-01-23 13:38:36)

Kevin, this is exactly the attitude that pisses me off. you don't know diddly-squat about managing a middle-aged woman's body, and yet you're very eager to offer your opinion on it. YES, it is EASY for my husband to lose weight. CICO. two weeks into eating a VERY low calorie paleo diet, and MY weight has ALREADY plateaued, despite the appropriate levels of exercise. certain vegetables, even – which everybody agrees are great weight-loss foods – that others can eat with impunity create havoc with my metabolism. so you say it's SIMPLE to know what to do to lose weight? BS.

Kevin (2012-01-24 02:16:01)

Tess, weight loss was NOT EASY for me (at first) nor for ANY MALE that I know. It was an incredible STRUGGLE and for you to simply dismiss my dedication and effort as \*easy\* is incredibly rude. It sounds like you are simply making excuses for why YOU are not losing weight. When people start complaining that weight loss is \*easy\* for some but not for \*them\* (because of gender, or \*my metabolism is just slow\*, lol) they are simply making excuses. Trust me, I used to do the SAME THING all the time before I got thin! It was a major mental block I had to overcome. The truth is, the INITIAL stages of fat loss (first 6 months at least) are easy for NO ONE. Not you. Not me. THINGS ARE NOT ESPECIALLY HARD JUST FOR YOU. Get over the self-pity. You may THINK you are eating \*low calorie\*, but if you are not losing weight then you are not eating LOW ENOUGH. You are either cheating in ways you are not aware of (a little cookie here or there), or just dont really understand how little you have to eat. It might shock you learn how little you actually have to eat, but it is the truth. This is the mental block we all have to overcome to lose weight. There is NO such thing as a weight loss plateau (how do you think people starve to death? Why dont they just plateau lol? They have done studies on Army rangers where they put them in massive caloric deficits for a few months and they just kept on losing to incredible levels. No plateaus). If you \*plateaued\*, you have to eat even LESS. I once bought into plateauing also - I \*fixed\* it by just adjusting my calories down. There IS such a thing as a weight loss slow down because as you lose fat the body has less fat available to burn, but there is no such thing as a total stall IF you are eating less calories than you burn. Its simple science. Two things might suggest the culprit here 1) Exercise will not help you lose weight. You burn a tiny amount and then frequently compensate by either reducing activity the rest of the day through exhaustion (thus burning the same amount total, making the exercise pointless), or overeating out of hunger. 2) You are still messing around with nonsense like PALEO, which suggests you have not fully internalized the message that you simply have to EAT LESS.

Kevin (2012-01-24 02:24:06)

certain vegetables, even — which everybody agrees are great weight-loss foods — that others can eat with impunity create havoc with my metabolism.

More culprits here. *There is no such thing as a great weight loss food.* There is only calories in calories out. If you eat 300 calories of chocolate muffin or 300 calories of veggies you *gain the exact same amount of fat*. Second culprit - *your metabolism is not special*. They have done studies on *\*naturally\** thin people who supposedly can eat whatever they want and have discovered that they are *eat less without even being aware of it*. Conversely, fat people *underreport* what they eat while not being aware of it. When YOU see these thing people eat socially they just ate 3 gigantic slices of pizza - what you DONT see is how little they ate at home. Perhaps they eat nothing the rest of the day. I lived with no less than 3 very thin people in my life and had occasion to observe first hand how they remained thin - they were all convinced they could eat whatever they wanted and just had fast metabolisms. It was nonsense. They simply ate almost nothing without being aware that this was not how other people ate. This was another eye opener in my path to thinner.

Seth Roberts (2012-01-24 04:22:01)

There is only calories in calories out. If you eat 300 calories of chocolate muffin or 300 calories of veggies you gain the exact same amount of fat.

In two studies published in the 1970s, Michel Cabanac and his colleagues found that two different ways of eating the same number of calories per day (about 2000) produced very different results. They produced the same weight loss, but different psychological effects. One way (eating the same foods, but less of them) produced considerable hunger and suffering. The other way (switching to a SlimFast-like drink) produced no hunger and little suffering (the main suffering was boredom).

Kevin (2012-01-24 12:36:39)

Yes, but as you correctly note, the difference is primarily psychological, not physiological. In a society like ours saturated with messages to eat more, going *\*cold turkey\** (slim-fast drink) might be an effective way to purge oneself of the psychological addiction to food, at least in the short term. But I don't for a moment believe that such a radical solution is necessary. French women, and Thais and Japanese, all eat deliciously, yet little, and do not suffer greatly. It took me some time to get over my addiction to food - even to recognize that I had an addiction to food that was psychological and cultural in origin - and I did suffer when I ate less, but over time, the suffering vanished. Today I can eat tiny amounts and feel quite good. The key is to remove all the stumbling blocks preventing you from recognizing that the suffering is psychological not physical.

## SOPA Strike (2012-01-18 05:00)

SOPA is an example of what Thorstein Veblen called "the vested interests" trying to prevent change. In an essay called "[1]The Vested Interests and the Common Man" he [2]pointed out "the existence of powerful vested interests which stand to gain from the persistence of the existing, but outdated system of law and custom." Jane Jacobs said much the same thing. The most important conflict in any society, she wrote at the end of *The Economy of Cities*, isn't between

the rich and poor or management and labor; it is between those who benefit from the status quo and those who benefit from change. If those who benefit from the status quo usually win, problems stack up unsolved.

2. <http://forums.infoshop.org/viewtopic.php?f=25&t=9007>

---

Mike (2012-01-18 10:12:53)

What problem is stacking up, unsolved? IP protection, like patent protection, is meant to encourage creators to create, by giving them a monopoly over their work. Do we have a shortage of books, movies, music? If not, what is the problem stacking up unsolved?

Seth Roberts (2012-01-18 10:44:10)

IP protection, like patent protection, is meant to encourage creators to create, by giving them a monopoly over their work. Do we have a shortage of books, movies, music? If not, what is the problem stacking up unsolved?

You seem to be saying we do NOT have a shortage of books, etc. If so, why do we need SOPA? If we have enough books, etc., creators have enough encouragement without it. As for the problems stacking up unsolved...in several ways health is getting worse. Obesity is getting worse, for example. A free Internet helps people explore solutions to health problems.

Mike (2012-01-18 11:46:55)

I think I mis-read your post, thinking you were saying \*opponents\* of SOPA were \*supporters\* of the status quo, allowing problems to remain unsolved. I guess it's hard to see what the status quo is here: is it a system of mechanical reproduction and physical distribution being overturned by digital zero-marginal-cost copying? Or is the status quo the current state of easy-to-offshore piracy and whack-a-mole infringement? I clearly side with the anti-SOPA people, but I don't think it has to do with wanting to preserve or subvert the status quo.

Seth Roberts (2012-01-18 12:27:02)

The supporters of SOPA want to return to the status quo of a few years ago. That's what I meant.

Jill (2012-01-18 12:31:25)

I don't have anything to say about SOPA, but your statement, "If those who benefit from the status quo usually win, problems stack up unsolved," suggests that the status quo is usually problematic and change is usually beneficial for solving those problems. I'd think you should be a little more circumspect. If there is a problem caused by the status quo, change would be necessary to solve it, but that doesn't mean any change that benefits someone is going to solve the problem (it can and often does make the problem worse). Also, just because someone benefits from change doesn't automatically mean there's a problem with the status quo. Of course, I do understand that your focus is innovation.

Outis (2012-01-21 10:50:39)

For background, read Lawrence Lessig's *Free Culture* (available for free on the internet in a variety of formats). [https://en.wikipedia.org/wiki/Free\\_Culture\\_%28book%29](https://en.wikipedia.org/wiki/Free_Culture_%28book%29)

## Vitamin D3 and Sleep: More Good News From Primal Girl (2012-01-19 05:00)

Late last year, Tara Grant (aka [1]Primal Girl) considered the possibility that taking Vitamin D3 has the same effect as sunlight exposure. For example, taking Vitamin D3 at 7 pm is like getting sunlight at 7 pm. This idea – with my advice about how to sleep well (get an hour of sunlight first thing in the morning) ringing in her ears – [2] led her to try to improve her sleep by taking Vitamin D3 first thing in the morning. It worked:

I usually took my supplements mid-afternoon. I vowed to take them first thing every morning. If I forgot, I would not take the Vitamin D at all that day. I tried it the next day and that night I slept like a rock. And the next night. And the next. Days I forgot and skipped the D3, I still slept great. That was the only change I made to my lifestyle and my sleep issues completely resolved.

I called this "[3]a stunning discovery" and have [4]blogged about it several times. I recently asked Tara for details and an update. She replied:

I am so happy to hear that 1) other people didn't make the connection easily so I'm not a little slow and that 2) there seems to be something to my discovery. :) I've had a few comments from people who have said it has worked for them too. So let me answer your questions:

[What type of Vitamin D3 do you take?]

I take Trader Joe's brand of Vitamin D3, which is a 1000 IU gelcap, in olive oil. 180 capsules for \$4.99. Best deal I've found. I tried the tablets years ago and they had no affect on me (even on 8000 units a day plus tanning twice a week my blood levels were only at 58.)

[Has your sleep remained solid?]

My sleep HAS remained solid. I have not had ONE night of bad sleep since I started paying attention to when I was taking my Vitamin D.

[How much do you take?]

I was initially taking 10,000 units a day. After about 2 months, I cut that back to 5000 units to see if there was a difference. I did not wake up quite as rested, but I still slept soundly through the night. On days that I increase my dosage, I sleep better, deeper and feel more rested the following morning. I've tried this several times, even when I've been spending the night away from home, and it has made a difference. I have also tried eating sugar shortly before bedtime and caffeine in the afternoon (both things that would always make my sleep restless in the past) and I still sleep well!! I've also thrown exercising into the mix to see if it makes a difference but it doesn't change the quality of my sleep - it just makes me tired earlier in the evening. I continue to change my dosage randomly and monitor the results.

Paul Sherrard (2012-01-19 07:31:40)

I started taking Vitamin D3 about six months ago, but at first I wasn't paying attention to what time of day I took it. When I read on this blog that it was best to take it first thing in the morning I began doing so. Prior to that, I had sometimes had trouble falling asleep. Once I started taking D3 first thing in the morning this ceased to be a problem. I get very tired right around bedtime, fall asleep quickly, and wake up feeling rested. This is one of the two invaluable pieces of information I've picked up here—the other is flax oil, which did for my gums what it seems to do for everyone else's. (There have also been a few things that have NOT worked for me: Skipping breakfast, which I tried for a few weeks, had no noticeable effect on the quality or quantity of my sleep. Eating half a stick of butter daily seemed to make me mentally slow. And the SLD has not worked for me [although I should note that I'm not overweight; I was interested in the SLD because I'm very busy and it would be extremely convenient to not get hungry.]) I realize I've gotten off the subject here, but this brings me to a question I've been wanting to ask for some time. I'm interested in what you write about fermented foods and probiotics, and I'd like to eat more of them, but I don't know much about them and don't know where to start. Have you ever posted some kind of recommended daily regimen or diet for them? I couldn't find one, but didn't do an exhaustive search.

Seth Roberts (2012-01-19 08:45:30)

I'm interested in what you write about fermented foods and probiotics, and I'd like to eat more of them, but I don't know much about them and don't know where to start.

I suggest you read my posts about them, which you can find by clicking on the "fermented foods" category.

Erica (2012-01-19 14:08:41)

I'm curious about the cut off time. I believe I've read all of your posts on taking D3 in the morning and I see a lot of talk about 7 am and not taking it later in the day if you forget it. But, I'm not seeing a range. When does "later in the day" start? I ask because I am not a morning person. I have to try very hard to get up at 9 am and even then that rarely lasts for longer than a wk. I invariably get back to getting up b/w 11am-12pm. I am a night person and I have a hard time wanting to go to bed earlier. Even if I do start getting up at 9am and therefore going to bed around 12-1am I will always be more tired during the day than if I slept the same amount of hours but got up at 11am. I think possibly my circadian rhythm is not on a 24 hour cycle. Anyways, I take my D3 when I wake up, but I would like the benefits I am reading about here. So, is there a suggested time I should not take it. Like is it ok to just take it before 12pm or is even 9am kind of late?

Tyler (2012-01-19 14:41:55)

Erica, My first guess would be that you have some larger cortisol issues that need to be resolved. I'm fairly convinced that there is no such thing as a "night person" (as I used to consider myself), but rather there are people with irregular circadian rhythms due to hormonal issues. Ideally, your cortisol should spike in the morning and peter off throughout the day, leaving you naturally tired by the time darkness comes around. Check other life stressors that could be contributing to your inability to fall asleep earlier at night. Start by aiming for 10:30 or so, even supplementing with melatonin of Natural Calm to boost start the reset. But getting cortisol under control will come first. Another option I heard good results with is Seriphos taken around dinner time. I'd be interested to see when the wake-and-D3 benefits start to kick in. My guess would be that D3 may help in regularizing sleep, but if you have other hormones sending even more powerful signals you won't reap the full benefits.

Seth Roberts (2012-01-20 05:03:15)

I see a lot of talk about 7 am and not taking it later in the day if you forget it. But, I'm not seeing a range. When does "later in the day" start?

If D3 has effects similar to sunlight, you shouldn't take it after dark.

Margaret (2012-01-20 08:21:00)

Erica, What if you set your alarm for 7 or 8 in the morning, and when it goes off, just sit up, swallow some D3, and go back to sleep? Could you try that? It might help reset your circadian rhythm.

Erica (2012-01-20 17:31:36)

Thanks Tyler, Seth, and Margaret. @Tyler: I probably do have cortisol issues. I started eating paleo/primal in Aug. My weight loss stalled at the beginning of Nov.. by the end of Nov my hair started falling out more noticeably. My mother has hypothyroidism.. I'm thinking I may have it now too. Unfortunately, I have no money or insurance therefor I can't get anything tested. Sadly, I'm fighting for ever pound lost now. I just looked into adrenal fatigue as well. So, maybe. Only thing is I've been this way my whole life.. even as a child and teen. At that time I was very healthy. Not overweight, woke up refreshed every day, pretty active, ect. Idk it's hard to do too much when I can't get any blood tests at this time. But, I still want to take my D3 as I know it's an extremely important vitamin/hormone. @Seth: Ok, I wasn't sure about it being earlier. Only because I read the Vitamin D Solution book awhile ago and he talks about most places you can only get D during like 7-12/1pm.. So, I was thinking that maybe there would be an earlier cut off point if we naturally don't make D much later than 1pm. Now, I don't remember if that holds true somewhere closer to the equator as I live in Ohio so I remember that specific comment for where I lived. @Margaret: I was thinking of maybe trying that actually. Maybe it would help put on a more "normal" schedule. I'll try it this wk. Thanks. :)

Jazi zilber (2012-01-21 04:22:18)

Erica, From what i read what is important is regularity rather than the exact time. If for you, 10am is the beginning of the day, i think everything that others do at 7 am should work for you as well on 10 am

Robert (2012-02-26 10:14:48)

Has anyone observed a difference between taking vitamin D in the morning without food and taking it in the morning with food? Also, from my own n=1: When I first started taking 10,000 IU vitamin D a month ago, my sleep instantly improved (e.g. I used to wake up multiple times during the night and suddenly I could sleep through the night) and I felt more refreshed upon waking. I was so excited to have found a "cure." Fast forward to today, and the last week or so my sleep has regressed to what it was like before (multiple awakenings) and I feel like I've hardly slept when I wake up. Additional details: I try to fall asleep around 11:15, but usually lay in bed for varying lengths of time (from 15 minutes to hours). I wake up and take the vitamin D at 8:15. If anyone has any advice, I would appreciate it. I imagine what I am feeling is the feeling of someone who tries an amazing drug (I'm thinking something like soma from "Brave New World") and then loses their lifetime supply. Not cool.

## **The Beauty and Tragedy of Tokyo (2012-01-20 05:00)**

I told a Chinese friend I would stop in Tokyo on my way home. "Tokyo is a beautiful city," she said. "Sort of," I said. After a day in Tokyo, I realized she was right. Tokyo is beautiful, not sort of beautiful. Tokyo business signs and outdoor advertising aren't beautiful but they are swamped by many things that are:

1. Small irregular streets. On foot, the weird address system works fine.

2. Plenty of parks and greenery.
3. Many small neat attractive shops selling a huge variety of goods. A miso store, for example. Many parts of Tokyo are like Greenwich Village, in other words.
4. Clean convenient free public restrooms. Unlike other cities, as I've said.
5. Excellent service in shops. Unlike Paris and Amsterdam.
6. Excellent map and direction signage. In subways, for example, way-finding signs tell the distance, not just the direction, of the destination. This is so basic (distance and direction are orthogonal) yet other places, such as New York, don't do it. Such creative attention to detail, such improvement on something so old (wayfinding signs) isn't just helpful, it's inspiring. I came across a construction site sign that appeared to say how loud the work would be. Again, serious improvement on tradition.
7. Everyone I asked for directions was helpful, although many were surprisingly ignorant (e.g., didn't know which direction to Roppongi).
8. So very walkable. Partly because the streets are curvy, partly there are so many little interesting things everywhere I went but also because when I got tired of random wandering, I could simply go to the nearest subway station and get to my ultimate destination.
9. The proportions of buildings. Slightly thin, slightly tall.
10. The repeated exterior details of apartment buildings. They are not smooth slabs. They have visible balconies, stairs, etc.
11. The food shops in the basements of department stores. There are dozens of small booths. One sells miso, another sells pickles, a third sells salads, a fourth sells eel, and so on. Not only is the food itself often beautiful – Japanese food packaging is supremely lovely – but it is beautifully arranged. You could learn a lot about aesthetics (the hidden laws of beauty) by comparing these displays with similar (less attractive) displays in other countries.
12. Clean air, clean streets. In spite of heavy use.
13. Well-maintained neat small houses.
14. Temples scattered throughout the city.
15. Healthy-looking people, especially old people. I think it's all the fermented food they eat (e.g., miso, pickles), not the health-care system.

I did not find Tokyo expensive, even with the dollar way down against the yen. I never took a cab (and never wanted to – in Beijing I always want to). Equated for quality, I think Tokyo is cheaper than New York.

The tragedy of Tokyo is the lack of human diversity: few foreigners. Such a great city should draw people from all over the world, but it doesn't. It has a lot to teach the rest of us about how to live in cities (for example, where does Japanese perfectionism come from?) but somehow this sharing hasn't happened. Like a cure for cancer in a journal no one reads.

Shawn (2012-01-20 06:47:28)

"The tragedy of Tokyo is the lack of human diversity: few foreigners." Its lack of diversity is its strength as it allows the city to be composed of people who are relatively high-IQ. If Tokyo had diversity more like NYC, for example, the city itself would resemble the deficient NYC.

Andy C. (2012-01-20 08:36:44)

Thanx, very poetic ! I am looking forward to visiting such an interesting city ! Bye, Andy C. - Italy

gwern (2012-01-20 08:40:25)

> Excellent map and direction signage. In subways, for example, way-finding signs tell the distance, not just the direction, of the destination. This is so basic (distance and direction are orthogonal) yet other places, such as New York, don't do it. Such creative attention to detail, such improvement on something so old (wayfinding signs) isn't just helpful, it's inspiring. I came across a construction site sign that appeared to say how loud the work would be. Again, serious improvement on tradition. I recently binged through 4 of Edward Tufte's books, and I couldn't help but notice how many of his graphics examples were Japanese. I couldn't help but wonder if there was some connection to kaizen and artisanal pride and lifetime employment.

Ashish (2012-01-20 12:41:51)

Seoul is similar in many respects - even including the distances on the subway signs, which are comical when pointing out an entrance "5 meters" distant, i.e. right in front of you. I wonder how much of this can be generalized to other Japanese (and Korean) cities.

Gayle (2012-01-20 15:18:11)

Apropos #11: have you ever seen the book How to Wrap Five Eggs by Hideyuki Oka?

Kevin (2012-01-21 01:51:04)

Really? I found Tokyo the prototypical ugly industrial city utterly lacking in any kind of charm whatsoever. Its a typical Asian \*shambles\* city (everything is thrown together higgledy piggledy without any regard for aesthetics or beautiful architecture) . Many of your points refer to convenience and not beauty. For me, a really characterful city would be Amsterdam, London, Paris, Rome - now THAT is beautiful. New York and Boston are much more beautiful than Tokyo also. Whats \*beautiful\* about Tokyo is not the setting, which is ugly, but the human element - not in the sense that they are especially beautiful per se, but rather because they all make an effort to be wonderfully thin and fit looking and dress exquisitely and often even picturesquely. The human element represents the true \*beauty\* of Tokyo.

Seth Roberts (2012-01-21 07:35:35)

"Many of your points relate to convenience." True, but I would put it differently: Many of my points relate to great care taken with small things. To me, this is beautiful.

D (2012-01-21 08:46:53)

"Its lack of diversity is its strength as it allows the city to be composed of people who are relatively high-IQ. If Tokyo had diversity more like NYC, for example, the city itself would resemble the deficient NYC." Bingo. Such an obvious point it's amazing that it had to be said. But it did.

E (2012-01-21 18:19:56)

If you want to experience a vibrant, diverse city you might try Detroit.

Shawn (2012-01-21 20:00:38)

D, Seth is very smart guy; funny how very intelligent people can miss such obvious things...

Deidre (2012-01-27 07:38:01)

The WSJ has a wonderful piece "Made Better in Japan" in case you missed it: [http://online.wsj.com/article/SB10001424-052970204542404577157290201608630.htm?mod=WSJ\\_Magazine\\_LEFTSecondStories](http://online.wsj.com/article/SB10001424-052970204542404577157290201608630.htm?mod=WSJ_Magazine_LEFTSecondStories)

garymar (2012-01-27 17:51:28)

Deidre, pretty good article! There's a long-running Japanese manga series (started in 1983) called *Oishinbo*, which has also become an animated series, a movie, and even a game. It's all about a group of food reporters who visit restaurants and have various food and cooking-related adventures. Remember, this is a *cartoon*. During the New Year holiday I caught a rerun of the animated series on TV, and the storyline was about a bartender and his little bar in Shinjuku. One of the reporters said this bar had the best on-the-rocks whiskey in town, so they all went there, drank some, and agreed it was tops. But the owner was sad because he had to close the bar soon. Why? Because the rural company that made his ice was going out of business, and without that special ice, made from the water coming from a particular well, he couldn't make the best on-the-rocks ever. So the plot was how the gang went off to the country and solved his problem by securing his ice supply! The whole story was presented as a *crisis of conscience* for the bar owner. If he couldn't make it just so, he wouldn't make it all – he refused to break faith with his customers. Just another indicator of the level of obsession they bring to food here.

Traherne (2012-02-04 15:45:33)

Diversity?!?!?! Merciful Father... Right. More black people! More chicanos! Invite the world! That's exactly what Japan needs... No. The only reason why Japan can have such a orderly, united, peaceful country is precisely because of it's homogeneity. Let it be. "Striving to better, oft we mar what's well."

Seth Roberts (2012-02-04 17:43:29)

The only reason why Japan can have such a orderly, united, peaceful country is precisely because of its homogeneity.

I did not praise Tokyo's order, unity, or peace. I praised its beauty. If by "order" you mean clean public bathrooms, I don't agree that diversity must surely cause dirty public bathrooms.

Traherne (2012-02-04 18:30:49)

Right. Diversity wont surely cause dirty public bathrooms because in a more diverse society there wouldn't be pristine public bathrooms to sully in the first place. Neither would there be much beauty without order, unity, and peace. There are sociological preconditions to the beauty and unique culture of Japan. A high level of trust is one of them. And high levels of trust and other forms of social capital are inversely correlated with diversity.

Traherne (2012-02-04 18:38:05)

Also, like you point out above about how care taken with small things is a form of beauty to you, consider the contribution that things like perfectionism and orderliness &c make to your perception of beauty.

Sadie (2012-02-23 10:20:41)

I also loved Tokyo for all the reasons you describe so beautifully. I particularly liked that that many people have small gardens, some just six inches wide or in wall-mounted planters, and everyone hung their laundry out to dry. The sheer practicality of nearly everything was so appealing.

## Google Analytics: "Make This Version Default" (2012-01-20 22:21)

I use Google Analytics to measure web traffic to my blog, forums, and website. A few months ago a new version was introduced and, as far as I can tell, made the default. The new version is worse than the old version. Every time I use GA, I click on "old version".

In an excess of confidence, the new version isn't merely the default, it also has a link called "make this version default". The old version has no such link. There seems to be no way to make the old version the default. It is a Google version of "this sentence is false."

More Apparently someone from Google read this or was told about it. The problem has been fixed.

Even More And then someone changed it back – it remains unclear how to make the old version the default.

---

Jarno Virtanen (2012-01-20 23:33:59)

Heh, I guess they are trying to unify the look-and-feel of several different webapps and in the process they are making a lot of them worse. They will probably completely deprecate the old versions eventually.

Jazi zilber (2012-01-21 04:15:25)

Same thing with wordpress.com I have to work hard every single time I land on a wordpress.com blog to maneuver to the use standard site link, and every time a new

threepipeproblem (2012-01-21 06:18:09)

Is Google making some crazy decisions lately or what? I could not believe they just killed off PostRank, probably their coolest acquisition ever, without ever letting it's coolest feature see the light of day in Google form (the feature that automatically identified top posts on any blog). As Kirkpatrick of ReadWriteWeb summarizes this and other dismal closures, "Google announced today that it is closing a number of services that it wasn't able to attract millions of users to without making any effort."

R. Vincent (2012-03-08 09:36:30)

The old version is vastly superior.

## Vitamin D3 First Thing in Morning: Story 6 (2012-01-21 05:00)

In November, [1]I wrote about Tara Grant (aka Primal Girl)'s discovery that taking Vitamin D first thing in the morning rather than later improved her sleep. Then several people commented that they had observed something similar – some in response to my post (my post led them to try it), some independently. Perhaps people who tested her observation and found it wasn't true didn't comment.

One way to assess this possibility is to ask people who have tried it what happened. In the comments to one of [2]my posts about this, Tyler Tyssedal [3]said he would try it. A few days ago I asked him what had happened. Here's his reply (shortened):

I have been tweaking the timing of my Vitamin D3 intake since I made that comment [on December 13 – one month ago]. I have also made a few other life changes (such as supplements), so the changes I've experienced cannot be attributed only to Vitamin D3 (5000 IU) timing. But yes, taking D3 first thing in the morning instead of later noticeably improved my sleep quality. I have been experiencing perpetual, involuntary biphasic sleep on and off for years. I would go to bed around 11 and wake up every day between 4 and 6 am, conscious enough to check the time and sigh. I had been taking my D3 with lunch or dinner, sometimes never. I changed my D3 intake to first thing in the morning. Within a week I noticed I would wake up two out of three nights, around 6 (so a little later), a marked improvement.

I am a 6'2", 160-lb male. I live in Minneapolis, Minnesota. Desk job, lift 2-3 times per week, 45 min-1 hr per session with 15 min walking to and from gym. I typically eat two meals a day (1-2 pm and 6-8 pm). In the morning (between 7:30 and 10am) I consume about 20-30 oz of coffee with 1-3 T cream. I also eat 1 T coconut oil with my coffee and 1 T of it with my dinner.

When I changed my [4]400 mg magnesium citrate supplement to early afternoon rather than right before bed, I experienced even better sleep. After all these changes, I no longer wake up in the middle of the night. I sleep straight through. A week and a half ago I started taking ALA and NALC with my D3, coconut oil and coffee in the morning. The results have been fantastic and I feel a strong clear headedness in the morning.

Here's a summary:

WAKE (7:30-9:30am): 5000 IU D3, 500 mg acetyl L-carnitine, 250 mg alpha lipoic acid, 1 T coconut oil, 20-30 oz coffee, 1-3 T cream.

LUNCH (12-2pm): 30 % food for the day, typically lowish carb, 400 mg magnesium citrate, 1.2 g EPA/DHA fish oil (on days I don't consume sardines or salmon, which is 2-3 days a week), Vitamin K2 (1000 K2 MK4, 1000 K2 MK7).

DINNER & POST DINNER: Rest of food (100-150 g carbs post workout workout days; 50-100 g non workout days). On restless nights, 2-5 mg melatonin.

I've been pleased with 2-5 mg melatonin before bed on days when I am not heavy eyed by 9:30 pm. I have taken melatonin on and off for years and would still experience biphasic sleep, with or without it.

Vitamin D3 First Thing in Morning: What Happens If You Try It? « Thor Falk's Reading List (2012-01-21 08:38:47)  
[...] Seth's Blog » Blog Archive » Vitamin D3 First Thing in Morning: What Happens If You Try It?. [...]

Guv (2012-01-21 16:19:32)

I wonder if there is a relationship between serum 25(OH)D levels, morning D3 supplement and sleep? For instance may be this relationship is more common in people who are D3 deficient. Personally i have stopped supplementing with D3 at the moment as it is summer here in Australia and my 25(OH)D level is already a bit higher than i prefer.

John (2012-01-21 16:48:29)

Would anyone care to comment on this recent item from the New York Times: "Risks: When Too Much Vitamin D Is Too Much" [http://www.nytimes.com/2012/01/17/health/research/risks-when-too-much-vitamin-d-is-too-much.html?\\_r=1&scp=1&sq=vitamin%20D&st=cse](http://www.nytimes.com/2012/01/17/health/research/risks-when-too-much-vitamin-d-is-too-much.html?_r=1&scp=1&sq=vitamin%20D&st=cse) The original medical journal article is here: [http://www.ajconline.org/article/S0002-9149\(11\)02748-2/abstract](http://www.ajconline.org/article/S0002-9149(11)02748-2/abstract)

Guv (2012-01-21 21:51:06)

John, the following links me be of interest to you. They all discuss the study you mention. <http://blog.vitaminadecouncil.org/2012/01/11/response-to-crp-and-vitamin-d-association-finding/>

Andrey Shestakov (2012-01-22 00:32:30)

I started taking D3 first thing in the morning yesterday. I drink 1.5 T cod liver oil and immediately after that 4500 IU of D3 concentrate with a plate of sauerkraut. Prior to that I took 2000 IU of D3 in the morning and 2000 IU before bed for three weeks. I'll take D3 for another three weeks, then try to plot different things I measured (mood, bedtime and waketime, efficiency tracked via your R percentile feedback script). I also drink a cup of kefir with chelated magnesium right before bedtime.

Tom (2012-01-22 08:59:41)

Andrey, Have you considered adding some K2 to balance the D3 and A you're getting?

Andrey Shestakov (2012-01-22 10:26:14)

Tom, I eat sauerkraut as suggested by Tim Ferris: "It has also been hypothesized that vitamin D toxicity is often a result of vitamin K deficiency. If you choose to supplement with vitamins A and D, as I do with cod liver oil and liquid vitamin D, it is important to ensure adequate K(2). Suggested sources include butter from grass-fed cows and the aforementioned lacto-fermented foods." But I didn't, in fact, checked his suggestion for validity yet (which might be really dumb).

Tom (2012-01-22 18:53:39)

K2 from fermentation is the Mark 7 form, not the animal form. I hadn't heard that sauerkraut was a source; K2 Mk7 typically comes from natto (a fermented Japanese delicacy.) Most of what I've read is that the better form for humans is the Mk4 type. (Pastured dairy is a good source of Mk4.) Both are available in supplement form. I actually take both, along with cod liver oil (for A) and D3. When I take all three my teeth feel slippery for several days. When you have adequate D3/A/K2, the calcium phosphate in the tartar on your teeth is actually being taken up (rather than deposited) by your saliva, so they feel as if they've just been cleaned. It's very cool. And I like to think that something similar is happening to the calcium in my arteries. More info: <http://wholehealthsource.blogspot.com/2008/11/can-vitamin-k2-reverse-arterial.html>

Andrey Shestakov (2012-01-23 00:08:57)

Thanks a lot, Tom! I will look into K2 Mk4. Apparently it isn't easy to get it in supplement form in Russia (much like pastured dairy). I thought about eating liver for K2, but I live in a highly industrial area, so I'm afraid it can contain mercury and lead. What do you think is the right proportion of K2 to D3?

Tom (2012-01-23 03:30:20)

Andrey, I'd recommend reading Chris Masterjohn on the subject, and you can search for "K2" to bring up specific posts. [blog.cholesterol-and-health.com](http://blog.cholesterol-and-health.com)

Louise (2012-01-26 00:30:17)

I've always been a night owl who found it difficult to get going in the morning. I was also someone who really didn't like breakfast. After going through your blog I started taking vitamin d3 tablets as soon as I woke up in the morning and found they certainly made a difference to my energy level. About 2 hours after ingesting the d3, it was like a lightbulb went off in my head and I suddenly felt energetic. I don't know if I my sleep was any deeper but I did wake up earlier and feeling somewhat alert. I then started eating breakfast (normally something small and light) and found this made a significant difference in how early I woke up. After three weeks of combining the two I went from an average wake up time without alarm clock of 8am to an average wake up time without alarm clock of 6am. This is regardless of the time I went to bed the night before. I also find that I am alert and energetic as soon as I wake up. Before the combined D3/breakfast routine it took me about an hour before I felt completely alert and energetic. Although I still have to force myself to eat first thing in the morning, the benefits for me are worth it. Hopefully the longer I do this, the more it will feel natural, rather than a bit of a chore. Thank you so much for your blog, it's one of my favourite internet indulgences.

## Centenary of the Theory of Continental Drift (2012-01-22 05:00)

One hundred years ago (January, 1912), at the annual meeting of the Geological Association in Frankfurt, Germany, Alfred Wegener, a meteorologist, presented his theory of continental drift for the first time. It was almost uniformly dismissed by geologists. One of them called it [1]"mere geopoetry". Much later, he was proved right.

To me, this is a classic example of [2]the power of what I call insider/outside. Wegener had a great deal of scientific training, including a Ph.D. in astronomy. Unlike professional geologists, however, (a) he had the freedom to say whatever he wanted about geology without endangering his job (as a meteorologist) or prospects for advancement and (b) was under no pressure to publish. He could spend as much time on his theory as he wanted.

1. <http://pangaea.org/wegener.htm>

2. <http://blog.sethroberts.net/category/scientific-method/insideroutsider/>

---

dearieme (2012-01-22 07:18:22)

When I started Secondary School geography in the late 50s, Continental Drift was where we started. Our teacher did warn us that it wasn't universally accepted but predicted that it would be, in due course.

Jay (2012-01-22 10:50:33)

This could be a useful example in favor of "undiscriminating skepticism" (or two-way skepticism): [http://lesswrong.com/lw/1ww/undiscriminating\\_skepticism/](http://lesswrong.com/lw/1ww/undiscriminating_skepticism/) The Less Wrong article suggests that a good litmus test for rationality (as opposed to just adopting the opinions of your "tribe") is whether or not you can argue for a non-mainstream position.

Becky Hargrove (2012-01-23 18:21:34)

In a time when it seems the middle class is disappearing, one might argue that economists don't have the ability to venture too far outside the theories of the last 100 years...which is unfortunate given that so much of the current situation really is new and different from what has happened before.

JPB (2012-01-23 09:27:47)

Re the radiation issue: I have been ridiculed for asking about maintenance and calibration issues at both medical and dental offices. Too many doctors and dentists are cavalier about radiation exposure for their patients!

Darius Bacon (2012-01-23 14:50:19)

JPB, what do you ask them? I suppose I should be asking about that too. (Though my doctor was already deflecting other questions, like about the type of contrast agent they'd use.)

Kim Øyhus (2012-01-23 15:14:27)

I actually took my geiger counter with me to the dentist a long time ago. As a student, I could not afford an expensive model, so it is small, has a small aperture, and clicks once for each particle/ray measured. It does not have a dial or readout. Apart from that, it seems to be very good, biologically representative, and sensitive. So, seconds before the X-ray machine pointed at my jaw was about to fire, a few seconds after the dentist wisely left the shielded room, I put the counters sensitive end to the other side of my jaw, where the rays not stopped by the lead plate behind the photo film could hit it. It sounded somewhat like static on the radio, for a large fraction of a second. The normal background radiation is heard as clicks about 4 seconds apart. The amount of radiation I got seems to have been about the same as a month of natural background radiation. In that respect, it does not seem too much. However, considering that we now know that nature's error correcting mechanisms have the same properties as the ones in computers, namely the ability to fix a few errors at a time very well, while failing when more of them comes, this was somewhat bad.

Seth Roberts (2012-01-23 18:01:05)

I have been ridiculed for asking about maintenance and calibration issues at both medical and dental offices.

JPD, the next time this happens I hope you will email me with the details (where, what was said, etc.) I would like to report this on my blog. There seems to be considerable room for improvement here.

Jim Purdy (2012-01-23 23:29:05)

Drug industry fraud, cavalier attitudes about radiation, there's always something scary going on in the "health" professions. All this just make me feel more comfortable with my tendency to stay away from doctors and hospitals. I think I'll start my own church – The Congregation of the Almighty Placebo.

JPB (2012-01-24 12:18:05)

Seth, I will certainly let you know if this happens again. One dentist told me that you get as much radiation from walking out to get the mail as you get from a dental X-ray. He was using very old machines, hence my query about calibration. He was very offended but I still declined! There were several articles in the NY Times in the last year or so about the lack of oversight on the equipment used in imaging including those used in the irradiation of babies. We have cause to be concerned. I don't understand why our medical professionals are not concerned also!

### **Vitamin D3 in Morning Improves Falling Asleep (Story 7) (2012-01-24 05:00)**

I recently learned that a reader named Paul improved his sleep – he now falls asleep more easily – by taking Vitamin D3 first thing in the morning. He had previously taken the same amount of D3 at other times of day for five months with no obvious effect. Because of [1]my first post about D3 first thing in the morning, he started to take his D3 at that time. Right then his sleep improved.

I asked him for details.

Tell me about yourself.

I live in Jersey City, NJ. I work in advertising. I'm 39 years old, 6 foot 1 inch, and 180 pounds.

How much D3 do you take?

5000 IU/day.

What time?

Usually around 8:00 a.m., but sometimes as early as 7:15 or as late as 10:30.

What brand, etc.?

I take Mason softgels. Each softgel is 5000 IU, "from fish liver oil." Other ingredients are soybean oil, gelatin, glycerin, and purified water.

Tell me more about what happened?

Before taking D3 first thing in the morning, I was having trouble getting to sleep quite often: I'd say 3 times a week on average. I would just feel wound up for no apparent reason. I would toss and turn, usually till 1:00 or 2:00 but sometimes until the sun came up. (It's possible this was caused by taking D3 in the evening, which I sometimes did. But this had happened to some extent for as long as I can remember, going back to my childhood.) I read your blog post this past November 2 about "Primal Girl"'s experience with D3, and began taking it right after getting up. Right away (I don't remember whether it was the first night or not, but it couldn't have taken more than 2 days because it felt immediate), I started getting tired right around 11:00 or 11:30, which is when I ought to be falling asleep.

Not just "tired," though—extremely tired. So tired that if I didn't get to bed I'd fall asleep on the spot. It took me by surprise at first, so that I had to struggle to stay awake while I took out my contact lenses and brushed my teeth. When I went to bed I was out like a light. This continued through most of December.

Over the holidays I went out of town for 8 days and wasn't taking D3. By the end of my vacation I was having insomnia again. When I got home, I forgot to start taking it again right away and noticed that I was not getting tired like I had been last Fall. I started taking D3 again around the 4th or 5th of January with the same result as previously. I continue to take it and experience the same result.

Addendum by Seth. One reason this story is interesting is that it supports the idea that Vitamin D3 acts like sunlight – which is different than acting like a stimulant (e.g., caffeine). A stimulant will push you toward being awake a few hours after you ingest it. Sunlight, on the other hand, will push you toward being awake a few hours after you are exposed to it and push you toward sleep a dozen hours after that.

1. <http://blog.sethroberts.net/2011/11/02/it-matters-when-you-take-vitamin-d-a-stunning-discovery/>

---

Darrin Thompson (2012-01-24 07:06:33)

Chris Masterjohn has been writing lately that the best source of vitamins A & D is cod liver oil and/or liver when the animal is pastured. Furthermore, there is evidence that they have positive effects on autoimmune diseases. <http://www.westonaprice.org/blogs/cmaterjohn/2012/01/22/new-evidence-of-synergy-between-vitamins-a-and-d-protection-against-autoimmune-diseases/> At our house we are planning to try Chris Kresser's "liver pill" trick. (I've honestly tried to like liver. So far I'm failing.) Also, I wonder if some of the observed benefits of flax seed oil are due the flax seed oil having a similar effect on the "messaging" mechanism Chris Masterjohn described in the link above.

Alex Chernavsky (2012-01-24 10:08:35)

For what it's worth, I've taken vitamin D at different times of the day, and I've never noticed any effect on my sleep. Of course, my sleep is already pretty good, in the sense that I fall asleep quickly and don't usually wake up during the night. (My sleep is *not good* in the sense that I don't get enough of it.)

Greg Harrington (2012-01-24 13:44:17)

I have had very similar results from first-thing in morning D3. Differences: - NOTE: I have great flexibility in my schedule (I can sleep/awake whenever I want), so I have been most focused on "restful" sleeping. - My pre-D3 issue was restless sleep (waking up frequently), not failure to fall asleep. - The effect of sleeping all the way through the night was definitely immediate—very first night. - Also, most days I also wake up feeling more "rejuvenated". This is not 100 % though. - I take 50,000 IU. (Why? Don't know...Amazon sells that large of a dose, so I wanted to maximize the effect! I think I calculated this as 75-90 minutes of full-body sunlight equivalent. - I take D3 at 8a typically. I do not take it any later than 9a, so if I wake up late or forget, I

skip that day. Does anyone have any info about side-effects of taking this much D3? I haven't observed any, but I'd like to know what to watch for. \$19.99 for a 3 month supply of restful sleep is an amazing bargain!! ;-) This is the product I use: [http://www.amazon.com/gp/product/B000A0F2B2/ref=as\\_li\\_ss\\_tl?ie=UTF8 &tag=harrslife-20 &linkCode=as2 &camp=1789 &creative=390957 &creativeASIN=B000A0F2B2](http://www.amazon.com/gp/product/B000A0F2B2/ref=as_li_ss_tl?ie=UTF8 &tag=harrslife-20 &linkCode=as2 &camp=1789 &creative=390957 &creativeASIN=B000A0F2B2)

Jim (2012-01-24 18:01:10)

Greg, That's a high dose. Some people take such doses weekly or bi-weekly, not daily (see the description at the Amazon link you posted. It has references for further inquiry). I think many people would recommend that you request a routine 25 hydroxyvitamin D test from your physician to establish your own Vitamin D3 blood levels now, and in a few months.

Tom (2012-01-24 20:58:38)

Greg, Chris Masterjohn has written a lot recently on how it is important for D3 to be balanced by adequate A: [blog.cholesterol-and-health.com/2012/01/my-interview-with-carl-lanore-on.html](http://blog.cholesterol-and-health.com/2012/01/my-interview-with-carl-lanore-on.html) Very high D3, unbalanced by enough A, may increase likelihood of soft-tissue calcification (kidney stones, etc.)

Meegs (2012-01-25 07:16:11)

I started taking D3 recently, and it definitely helps me fall asleep faster. Being able to fall asleep has always been a problem for me, and taking this supplement seems to be helping so far.

Robert (2012-01-25 12:46:04)

Question: do you take your vitamin D with or without food? I thought you needed fat to absorb vitamin D, but I also thought most people here skipped breakfast.

Seth Roberts (2012-01-25 22:09:27)

I take my Vitamin D without food.

Charlene (2012-01-26 04:12:06)

I just started using this less than a week ago. I'm a terrible insomniac - waking all through the night with eyes wide open, roaming my house, going to the bathroom. No lie, I have not slept 8 hours or anything, but since I started taking it, I have slept straight through without once waking up to go to the bathroom or just because my brain is so wired. I take 5000 IU with about 1/4 cup water at approximately 7:00 a.m. before leaving for work.

Tim G (2012-01-26 05:41:23)

My blood tests earlier this year showed I had low Vitamin D levels and was put on a 50,000IU/week regimen for 3 months using a prescription D2 (ergocalciferol). A recheck then showed my level had hardly changed. A search of PubMed showed conflicting views on using the D2 form. So for the next 3 months I used ProHealth D3 Extreme 50,000IU (via Amazon.com) instead of another D2 scrip my doc had given me. I always took the D2 or D3 in the morning (just lucky happenstance.) A second recheck after the second 3 mo. showed my vitamin D level as normal. I hadn't put it all together until seeing this post, but when using the D3 I had the same effect of when I got tired, I got \*really\* tired right at bedtime, and slept like a rock. However, even though it has been less than a month since ceasing the weekly dose, I have noticed my sleep degrading somewhat, and lately not even being tired when I should. I'll be setting up a maintenance dose regimen ( 5,000 IU/day) now!

Robert (2012-01-29 11:36:03)

Thanks, Seth.

ync (2012-02-01 09:25:45)

I get my fat soluble nutrients, including D3, from a great paleolithic quality raw handcrafted oil I recently found: <http://ratfishoil.org/> I take 12 drops twice a day. It contains balanced levels of nutrients and no synthetic vitamins or nutrients.

### **Vitamin D3: Which is Better, Gelcaps or Tablets? (2012-01-25 05:00)**

I have been getting good sleep improvement from Vitamin D3 (early in the morning) using tablets. However, Tara Grant and Paul have gotten good results with gelcaps. Apparently both formulations work. Which is better?

This story, from a woman I'll call JMW, suggests gelcaps are better:

Sorting out all the nutrition for [celiac disease], about 3 years ago, [my two boys and I] started taking D3 - 2000 IU of Solgar in capsule form. That first winter, NO ONE had seasonal affective disorder [= depression]. I had had it since I was 21, can't remember further back than that, the youngest had had it since he was 4 yrs old, can't remember the others.

We unintentionally proved it needs to be in capsules (i.e. oil) rather than tablets when I mistakenly repeat-ordered with tablets, and everyone got worse until I got the capsules again.

---

Valtsu (2012-01-25 09:12:48)

Hi Seth! You might find this article interesting: <http://suppiversity.blogspot.com/2011/12/fat-d-ficiency-do-you-really-need-more.html> The title is: "A Fat D-Ficiency! Do You Really Need More Vitamin D or Simply More Fatty Foods? Study Shows, Even 50.000 IU of Vitamin D3 Useless, When You Ingest It Without Fat."

by (2012-01-25 09:34:03)

Just curious, Dr. Roberts. I remember before you stating that your sleep is extremely good: a significant improvement was going from 99.3 % to 99.7 %, or something like that. Why are you so interested in further improvements to your sleep ability (this Vitamin D discovery)?

Brody (2012-01-25 10:22:34)

I've had good luck with liquid Vitamin D. It makes the dosing less precise, but I like it better than swallowing a gelcap.

Andrew (2012-01-25 10:24:31)

What about liquid drops, taken sublingually?

Ross (2012-01-25 10:29:19)

There are other reasons to consume Vitamin D, including the health of your teeth. See [1]Dr. Guyenet's article here. Specifically see this picture: ( [2]here's a link to the picture if gt; img lt; tags are not allowed). Basically, vitamin D drastically reduces cavities and my wife is anecdotal evidence. She used to have at least one cavity \*every\* time she went to the dentist, and after I put her on 2,000 I.U. of vitamin D per day, her last two visits to the dentist have been cavity free. - Ross

1. <http://bit.ly/AtTexU>

2. <http://bit.ly/xvSXJ1>

Seth Roberts (2012-01-25 10:51:22)

Why are you so interested in further improvements to your sleep ability (this Vitamin D discovery)?

I am interested in this discovery for several reasons: 1. It is surprising. Vitamin D has been heavily studied but this has been missed. 2. It is practical. Lots of people have sleep problems. 3. I was involved in the discovery. 4. My sleep has room for improvement. 5. Maybe I can take Vitamin D3 in place of one-legged standing. That would be much easier.

Michael Cole (2012-01-25 11:00:50)

I'm confused. I was under the impression that Vitamin D basically completely ineffective without oil. Is there any reason you are taking tablets, instead of gelcaps, in first place? Although in your case you may be digesting oil near enough to taking the tablet D3 to metabolize it properly.

Seth Roberts (2012-01-25 11:06:58)

Is there any reason you are taking tablets, instead of gelcaps, in first place?

Because they were what I had lying around. Perhaps the tiny amount of cream I would have with tea around the same time made a difference.

Tyler (2012-01-25 12:48:04)

>Because they were what I had lying around. Perhaps the tiny amount of cream I would have with tea around the same time made a difference. I typically have cream with the coffee I consume shortly after my Vit D supplement in the morning, too. Hm.

Joe E O (2012-01-25 16:09:48)

Cardiologist Dr William Davis (<http://www.trackyourplaque.com/blog/>) treats all his patient with Vitamin D. The end goal of his vitamin D treatment is to raise individuals vitamin D blood level to 60 - 80 NG/ML. He has found that using anything OTHER than gelcaps does not work to raise his patient's vitamin D levels Peace Joe E O

Jonathan (2012-01-25 17:41:44)

I think that I've mentioned here before that the cardiologist Dr. William Davis has discussed this multiple times on his blog. He tests the blood Vitamin D level of all his patients, and has found with many patients that Vitamin D tablets often barely budge their serum levels. After a lot of bad experiences, he started insisting that all his patients take D in gelcaps or oil drops.

Chris U (2012-01-26 07:11:08)

A couple of years ago, in the winter, I was taking 4000 IU vit D in tablets daily. A blood test showed that My levels were at the top end of what my doctor considered safe, nearing toxicity levels. Therefore, in my case, the tablets were effective at increasing my vit D levels. I always take them with a meal, so perhaps I ingest enough fat along with the tablets.

Maurile Tremblay (2012-01-26 20:06:05)

No need for a pill. Fermented cod liver oil.

Anne Wright (2012-01-30 18:25:10)

Thanks. This is very interesting. I have run across one other person talking about a sleep-vitamin D connection: [1]Dr. Stasha Gominak who has a YouTube video up on this topic. She found that her patient's sleep got better when they were supplementing D3 and got their 25(OH)D3 blood levels up into a certain range (I think it was 50-80 ng/ml). She claimed that she'd seen sleep quality get worse again when that range got overshoot ( 90 ng/ml or over).

### **Vitamin D3 First Thing in Morning: 4000 IU Better Than 2000 IU (Story 8) (2012-01-26 05:00)**

On a status update, Alexandra Carmichael (of [1]CureTogether) noted she was taking 4000 IU of Vitamin D3. I asked her for details:

I've been taking 2000 IU of D3 every morning for many months, but after hearing about your Meetup talk topic from Gary/Ernesto ["Vitamin D3 and Sleep"] and talking to [redacted] about his experience with it, I decided to switch to 4000 IU, starting yesterday. I take it between 6 and 7 am, with my other morning supplements/meds.

Yesterday I noticed an unusual sense of "clear and smooth" mood for much of the day, which is very odd for me. The day after a meetup, I usually experience intensely fluctuating moods (I've been tracking hourly moods, and on my worst days, it's a 3-hour cycle between peaks, like a super rapid cycling, ultra-dian bipolar - my therapist suggested this term when I showed him my mood tracking data.)

I also slept unusually well - I've been having a good deal of trouble sleeping lately, both falling asleep and night waking. Last night I slept a solid 8 hours!!!

That's a very small sample (one day) of what happens with 4000 IU. However, Alexandra's experience is similar to mine. I found that 2000 IU of D3 had no clear effect compared to nothing. However, the very first night after I upped the dose to 4000 IU (from 2000 IU) my sleep was noticeably better.

Alex is using Nature's Bounty 2000 IU Vitamin D3 gelcaps.

Merv (2012-01-26 06:32:06)

Is there a upper limit for consumption of D3 before toxicity starts?

Scott W (2012-01-26 06:41:28)

Seth, you talk a lot about fermented foods. I'm wondering about your thoughts on fermentation of grain to make its nutrients more accessible. It's cooked after it is fermented, so I don't think it falls into the same category of fermented foods you favor, but certainly seems to be another good use of fermentation for natural food processing. Here's a very brief discussion: <http://wholehealthsource.blogspot.com/2009/04/new-way-to-soak-brown-rice.html> I have not been reading for a long time, so forgive me if this has been covered in the past. Scott W

Seth Roberts (2012-01-26 07:11:56)

I'm wondering about your thoughts on fermentation of grain to make its nutrients more accessible.

I think that is a minor benefit. Our preference for microbe-rich food is so strong I believe other mammals will show the same thing. The major benefits of fermented foods, in my opinion, are digestion improvement & immune-system improvement.

Seth Roberts (2012-01-26 07:13:21)

I don't know what the upper limit is, no. But no doubt there is one and for that reason I believe in figuring out the minimum dose that produces the maximum effect and using that. For example, if 4000 IU/day produces the same benefits as 6000 IU/day, I would use 4000 IU/day.

M. Love (2012-01-26 07:43:30)

As a counterpoint, I've been taking 4-5,000 IU of D3 for a couple of months now, and while it \*might\* be making me feel better in other ways (more vital, upbeat, and energetic), it has coincided with a stretch of poor sleep for me. I have what they (hilariously) call "terminal insomnia"; that is, I usually have no trouble at all falling asleep, but I wake regularly at night and am permanently awake very early, often from 4:30am onwards. This has been a periodic problem for a few years now, though this stretch is notably tolerable, for some reason.

skyricho (2012-01-26 10:30:35)

@M. Love What time of the day do you take D3? I would be surprised if it is first thing in the morning.

skyricho (2012-01-26 10:33:00)

I work night shift 1.30pm to 8am. I sleep from 1pm to 5pm and 10.30 to 1.15am I would like to self-experiment if taking D3 will make me =me to be alert during my night shift and then sleep better around midday. Does this mean for me i should I should take D3 when I wake up at 1.15am?

Eugene (2012-01-26 14:15:00)

M. Love, I had the same problem and rhodiola extract works wonders for me.

Guv (2012-01-26 15:33:19)

I would advise/recommend that anyone taking D3 long term have their blood levels tested. At least twice a year to begin with until you have your dosing dialled in. And it will probably need to be adjusted over time. When i was taking 4,000 IU per day for a while, my highest serum 25(OH)D level was tested at 85 ng/ml. I prefer to keep my 25(OH)D in the 50-70 ng/ml range.

Jim (2012-01-26 15:51:55)

I agree with Guv about testing blood levels. Vitamin D accumulates in the system over time. Prior to Seth's posts on using D3 for sleep aid, most of what I've read about D3 was based on getting blood levels built up to a certain levels (e.g., for bone or cardiovascular health). In contrast, the specific line of thinking being explored by Seth here has to do with daily morning supplementation of D3 to simulate or mimic early morning sun exposure, to help with sleep cycles. Thus, I'm wondering if the daily morning effect would be changed by an overall increase in stored D3 in the body over time (i.e., raised blood levels). For sleep benefits, perhaps a low dose is needed so that the overall long-term accumulation of D3 is minimized, to accentuate the contrast between morning and evening levels of D3 in the body.

Jonathan (2012-01-26 17:49:22)

The Vitamin D Council says toxicity has been seen at doses over 40,000 IU. I have never heard of a report of toxicity in adults at doses of 10,000 IU, though. The main long-term risk of too much Vitamin D is tissue calcification. (Of course, arterial calcification is a risk of too little Vitamin D, too.) Children's doses should be smaller, of course, proportional to body weight. Some references I've read suggest that the toxic effects of Vitamin D may be partly a result of competition with Vitamin A, and that getting enough Vitamin A may oppose those effects. (Could it compete with Vitamin K2 as well? I don't know.) The Council also says that the most common cause of symptoms on taking Vitamin D is that it unmask a magnesium deficiency. Magnesium deficiency seems to be the norm among Americans, so supplement that too.

M. Love (2012-01-26 20:59:22)

@Skyricho I usually take my D3 at around 6:30am, with my coffee. I don't usually eat breakfast or lunch, so I'm wondering if the D3 is metabolizing correctly in the absence of any other nutrients.

Nancy Lebovitz (2012-01-27 05:17:53)

Any advice on a good ratio between vitamin D and vitamin A?

## **Vitamin D3 in Morning Increases Energy Levels: Story 9 (2012-01-27 05:00)**

I know [1]Robin Barooah from Quantified Self meetups. When I learned he had started taking Vitamin D3 early in the morning, I asked him what happened:

I've been taking it since December 20. I initially thought of trying it immediately on my return from London because I thought that it might help to reduce jet lag, given its apparent coupling with the circadian rhythm.

It didn't seem to have a dramatic effect on my jet lag - which was as bad as I usually experience it for about the same number of days (around 3-4). However it had a very pronounced effect on my general energy levels. At first I was almost hyperactive, yet my concentration was good. I was using 5000 IU per day, at 7:30 am. The hyperactive feeling subsided but the dramatic improvement of my energy levels (and increased concentration) continued until I decided to reduce the dose to 2000 or 3000 IU per day

[from 5000 IU/day]. My mood has improved too, although I think indirectly though feeling more capable and productive.

I decided to reduce the dose because I was concerned that my sleep wasn't noticeably better than before taking the D3, and might have been worse. Reducing the dose caused a huge reduction in my energy levels and concentration, and no improvement in sleep. After a week of that I went back to the 5000 IU dose, and again am very happy with the effects. The improvement in sustained concentration is so dramatic that it's disturbing to think of how much this could have changed my life had I been using it for years (assuming the effect lasts).

It's possible that my sleep quality has improved in some way that isn't reflected in my subjective experience of sleeping, and this has caused the improved energy and concentration. I am sleeping about the same length of time, and waking up in the night just as often and feeling about as rested as before I started (which is not quite as rested as I'd like to feel, despite having a lot of energy). I am not taking a multivitamin, so it's also possible that I'm not getting all of the possible benefit.

Without doubt, this is one of the most effective things I've ever tried.

Emphasis added. He takes Now Foods Vitamin D3 (easy to buy on Amazon), the 5000 IU and 1000 IU softgels. He also said:

I used to get quite severe tiredness (enough to need to lie down) at numerous times during the day. Now I seem to get tired just a little in the afternoon, and then progressively so into the evening. There's a very distinct slowdown in my energy that happens very obviously around 5pm, which is coincidentally around dusk here at the moment.

I have noticed something similar. Before Vitamin D3 early in the morning, I used to get really tired around 10 am. Enough to make me lie down. This happened on more than half of all days. Now that I am taking a lot of D3 (8000 or 10000 IU) first thing in the morning (8 or 9 am) it doesn't happen at all. (I may eventually go down to a lower dose, such as 5000 IU/day.)

Jonathan Erickson (2012-01-31 21:19:03)  
Wow this is really good to know!

### **Vitamin D3 in Morning Helped Her Sleep Through Night (Story 10) (2012-01-28 05:00)**

A woman named Jenny West, who lives in Chiltern Hills (west of London), [1]commented that she "discovered independently that D3 first thing in the morning works." I asked her for details:

I (and my family) started to take Vitamin D3 because we are all dyslexic/dyspraxic and had Seasonal Affective Disorder (SAD, a type of depression). Previously we had tried using light boxes (minimal effect), getting out every lunchtime (more useful) and finally 5HTp – which works but is expensive and if you start it once you are in SAD you can end up 'wired'. Our SAD symptoms were mainly sleepiness and lack of energy (= hibernation), and brain fog (= difficulty concentrating).

We started taking D3 (2000 IU, Solgar) in gelcaps. That first winter, for the first time ever, no one had any seasonal affective disorder. I had had it since the age of 21, my youngest child when only 4 yrs old, and my other two children by the time they were 18 yrs old. At this point, we were taking the D3 at random times, commonly lunchtime or later, often when everyone was together and the vitamin pot was handed around!

This autumn, all the youngsters had moved out. I found I was forgetting the D3, so I moved it to the bathroom and started taking it first thing in the morning (8-9 am). Then in September, I started taking 3000 IU (instead of 2000 IU). We'd been in Greece and had come back to a gloomy autumn and I wanted to make sure SAD didn't kick in. In a month I started sleeping through the night most nights.

Before I started taking D3 first thing in the morning, I only slept through 10 % of my nights, and had been doing so for at least 15 years. I would wake at 3-4 am, but didn't get up unless I had been awake for more than 3/4 hr. Then I would be awake until 6 am. Now I sleep without a break (other than turning over) from midnight to 8 am. I sleep like this 95 % of my nights, and that includes the odd night when I took the D3 much later in the morning because I had slept in – and consequently woke the following night.

As a coeliac, I take the supplements many coeliacs take – probiotics, minerals, vitamins – but none of these affected my sleep either way. So it really looks as if it is the timing plus the correct dose of D3.

BTW the extra daytime energy is fantastic.

She is 5 feet 4 inches, 64 kg. Notice that 2000 IU first thing in the morning did not improve her sleep but 3000 IU first thing in the morning did. I had a similar experience: 2000 IU had no clear effect but 4000 IU did.

1. <http://blog.sethroberts.net/2012/01/16/vitamin-d3-more-reason-to-take-it-first-thing-in-the-morning/#comment-946262>

babar (2012-01-28 11:48:02)

Negative result here: I've taken 5-8k per day for 2 weeks, first thing in the morning, and not found myself sleeping through the night or with significantly improved energy.

Daniel (2012-01-28 12:54:41)

If we had consistent sunlight exposure throughout the day, wouldn't steady dosage of Vitamin D during daylight hours work better? Or is the high "shock dose" just important to program circadian rhythms?

Cap (2012-01-28 17:10:48)

I wonder about what Daniel asked too. I might have guessed taking D3 at noon when sunlight is most intense would be the most natural thing to do. In any case after the morning D3 entries started to appear here sometime before Christmas, I switched to taking my D3 first thing in the morning too (between 4-7000 IU) and so far I've noticed significantly increased feelings of sleepiness at bedtime, with moderate improvement falling asleep, reduced wakings throughout the night, and much better ability to sleep in.

Seth Roberts (2012-01-28 17:36:14)

If we had consistent sunlight exposure throughout the day, wouldn't steady dosage of Vitamin D during daylight hours work better? Or is the high "shock dose" just important to program circadian rhythms?

All sorts of things slow down and spread out over time D3 uptake starting with the need to digest the gel around the D3. But I guess that your second idea ("important to program...") is correct.

Ted (2012-01-29 19:20:00)

I've been taking my D3 (4,000 IU) at various times throughout the day but haven't noticed it having any effect on my sleep. (One thing I have noticed having an effect on my sleep was taking iodine in the form of kelp in the morning. It gives me a real boost during the day and helps me sleep better at night.)

nydwacu (2012-01-30 06:49:54)

I've been taking 3000 IU for the past two weeks or so. It's not enough to affect my restfulness much, I think (I'm about 6'5"), but it does keep my sleep schedule regulated; ordinarily, I'd wake up half an hour later every day, but now I wake up between 5 and 7 every day. (Interestingly, I'm much more rested when I wake up at 7 than I am when I wake up at 5 or 6, even if I got less sleep.)

Seth Roberts (2012-01-30 06:56:30)

it does keep my sleep schedule regulated; ordinarily, I'd wake up half an hour later every day, but now I wake up between 5 and 7 every day.

That supports the idea that Vitamin D3 is acting like sunlight.

Mathew Ferguson (2012-01-31 05:24:46)

Hi, I was wondering about the levels of Vitamin D that some of these people are taking. Various websites I've looked up list as low as 600 IU as a recommended maximum dose for adults. At the levels noted here they list a range of negative side effects (mostly due to calcium in the blood). Are there any long-term vitamin D users at the 3000+ IU level around who are doing well on the blood chemistry front?

Sarah Madden (2012-01-31 13:28:21)

I've been following all the stories with interest so I decided to start yesterday (6,000IU) and the results have been pretty quick. Slept better and woke up easier this morning which is very unusual for me. Too soon to judge completely so I will let you know.

Seth Roberts (2012-01-31 16:23:43)

thanks, Sarah, yes, please let me know what happens after more experience.

## **One Doctor's View of Personal Science: "You Won't Learn Anything" (2012-01-29 05:00)**

Bryan Castañeda, who lives in Southern California, told me this:

The law firm I work at specializes in toxic torts. We represent people who have been occupationally exposed to chemicals and are now sick, dying, or dead. Most of our clients have been exposed to benzene and developed some kind of leukemia. We sponsor various leukemia charities, walks, and other events. [On January 21, 2012] in Woodland Hills, CA, the Leukemia & Lymphoma Society held[1] its first annual Blood Cancer Conference. Although the speakers were mainly doctors, it was a conference meant for laymen. The chair was an oncologist from UCLA Medical Center.

After introductory remarks and the keynote speaker, there were several breakout sessions. I attended a session on acute lymphoblastic leukemia and acute myeloid leukemia. The speaker was [Dr. Ravi Bhatia,] a doctor specializing in leukemia from City of Hope in Duarte, CA. His talk was almost exclusively about new drugs and clinical trials. Very dry and dull. Things got more interesting during the question period. At one point, [Dr. Bhatia] told an attendee not to experiment on his own because "you won't learn anything and others won't learn from it, either."

I would have liked to ask Dr. Bhatia three questions:

1. What's the basis for this extreme claim ("you won't learn anything and others won't learn from it")? Ben Williams, a psychology professor at UC San Diego, wrote a whole book ([2]Surviving "Terminal" Cancer, 2002) about taking an active approach when faced with a very serious disease (in his case, brain cancer). Likewise, the website [3]Patients Like Me is devoted to (among other things) learning from the experimentation of its members. Lots of forums related to various illnesses spread what one person learns to others. [4]MedHelp has many forums devoted to sharing knowledge.
2. What's so bad about "learning nothing"? Why should that outcome stop one from trying to learn? It doesn't seem like a good enough reason.
3. Do you have a bias here? In other words, what do you want? Do you prefer that your patients not self-experiment? Doctors may prefer that their patients not experiment for their (the doctors') own selfish reasons. When a patient self-experiments, it makes their doctor's job more complicated and makes the doctor less important. If Dr. Bhatia is biased (he wants a certain outcome), it may bias his assessment of the evidence.

2. <http://www.virtualtrials.com/pdf/williams1.pdf>

3. <http://www.patientslikeme.com/>

4. <http://www.medhelp.org/>

Dennis Mangan (2012-01-29 09:05:18)

Wrt brain cancer, Thomas Seyfried has written a number of journal articles showing the efficacy of a ketogenic diet for that condition when little else works. So it appears that "taking an active approach" could be literally a lifesaver.

Perfect Health Diet » Around the Web; Why I Blog Edition (2012-01-29 10:49:19)

[...] Seth Roberts defends personal science. [...]

JPB (2012-01-29 11:26:33)

I suspect this doctor does not want informed patients who might question the "orders."

Jim Purdy (2012-01-29 14:09:31)

" ... a doctor ... new drugs ..." Those four words say all I need to know before I head for the exit.

WCB (2012-01-29 15:10:14)

It is that kind of mindset that has seriously damaged the credibility of the medical profession and the overall system of medical care. This is leading more and more people to conclude that the term "health care" is a gross misnomer, in that the health of the individual is largely irrelevant. All too often, it's mostly about money and conflicts of interest.

Sara (2012-01-29 15:59:07)

I live very close to an 'integrative' medical centre (medical doctors that also practice so-called 'fringe' medicine, like intravenous vit C). One of these doctors was the subject of a documentary here because she came out and claimed that intravenous vitamin C can save lives in cases of viral infection. She presented a case of a man that was literally hours from death from the Swine Flu and recovered after his family paid privately for her to administer intravenous vit C. They did this against the advice of the doctors that were watching him die. The program interviewed doctors from the Auckland hospital and none of them had tried it, they just kept repeating 'there is no science behind it' and that they wouldn't use it even when asked because it 'would give the family false hope'. That last statement I found... astounding. You have a terminal patient, the family has NO hope left and you are scared to try what they ask in case it gives them some?? There is no logic. So, the patient dies and the family is left forever wondering what would have happened if they 'had' tried it. People should be allowed, encouraged to try anything they think will help them. In the case of terminal illness, even a bit of placebo effect might be a good thing (as a Psych., I'm sure you know that placebo effect is sometimes biochemically measurable). It makes me annoyed when I read about doctors beating down self-experimentation. Oh, and that's on top of the way that environmental contamination already makes my blood boil.  
..

Seth Roberts (2012-01-30 07:03:59)

The program interviewed doctors from the Auckland hospital and none of them had tried it, they just kept repeating 'there is no science behind it' and that they wouldn't use it even when asked because it 'would give the family false hope'. That last statement I found... astounding. You have a terminal patient, the family has NO hope left and you are scared to try what they ask in case it gives them some??

I agree. And I would also say: How do these doctors know the hope is "false"? If the idea is untested, as they say, why are they sure it is wrong? That makes no sense.

Nina (2012-01-30 13:21:38)

Interesting comment from the lawyer and links between benzene and leukemias. I'm currently looking out for evidence of correlations between leukemias and osteoporosis medication.

bob r (2012-01-30 16:43:58)

Maybe he should tell [1]Terry Wahls that "self" experimentation won't allow you or anyone else to "learn from it." I guess he thinks she should have just stayed in her wheelchair.

1. <http://www.youtube.com/watch?v=KLjgBLwH3Wc>

Seth Roberts (2012-01-30 22:32:08)

I guess he thinks she should have just stayed in her wheelchair.

good point!

### The Great Climate Change Debate: Which Side is Funnier? (2012-01-30 05:00)

A few days ago the Wall Street Journal published [1]a letter from 16 people saying what I say, that the case that humans are warming the planet is much weaker than you'd guess from mainstream media. An excerpt:

The number of scientific "heretics" is growing . . . Perhaps the most inconvenient fact is the lack of global warming for well over 10 years now.

Here is [2]a rebuttal by a biological anthropologist named [3]Greg Laden:

Shameful. . . . Out and out lie, easily falsified . . .  
"16 scientists" who signed this letter: They are idiots  
judgements is now in serious question. . . . Let Googl

Peter Gleick, MacArthur "genius" Fellow, also wrote [4]a re  
years? Here's Gleick:

The authors claim there has been a "lack of warming  
year in a row in which global temperatures were abo  
the warmest years on record.

I have not omitted quotation marks. Here's how [6]Peter F  
same point:

The authors claim there has been a "lack of warming"  
[7]35<sup>th</sup> year in a row in which global temperatures we  
were the warmest years on record.

I went to the link given to support the "35th year in a row"  
link:

[8]

Annual Global Temperature  
1950 - 2011

---

Wilbur (2012-01-30 05:32:40)

Yes, the rebuttals seem to have missed the point. If global warming has indeed stopped as the original letter claimed, and we have entered a period where global average temperatures will routinely be about 0.55 degrees above the historical average, then conceivably we would still see "record warm years" all the time. Personally I think that given the variance in the data, 10 years is not a lot of time to reach the conclusion that the warming has "stopped". Looking at the data up to 1988 only, one might have concluded that the data from 1978-1988 showed no warming trend either. A rebuttal along these lines would have made more sense.

Nile (2012-01-30 07:23:50)

From the Daily Mail "The supposed 'consensus' on man-made global warming is facing an inconvenient challenge after the release of new temperature data showing the planet has not warmed for the past 15 years. . . Based on readings from more than 30,000 measuring stations, the data was issued last week without fanfare by the Met Office and the University of East Anglia Climatic Research Unit. It confirms that the rising trend in world temperatures ended in 1997." Oops! No warming for 15 years? Those folks at the East Anglia Climatic Research Unit better get busy and "hide the decline" with this data or they will find their grant money drying up.

threepipeproblem (2012-01-30 07:27:53)

This blog may be worth looking through for those exploring the skeptical position: <http://themigrantmind.blogspot.com/>

Seth Roberts (2012-01-30 08:02:47)

Yes, I agree – good blog. Good series on the urban heat island effect. For example, <http://themigrantmind.blogspot.com/2011/02/urban-heat-island-in-pictures-part-4.html>

Steve G. (2012-01-30 13:26:51)

11 cooling years 1950 to 1976 and none since then?. What does this reveal? Aren't 2005 & 2010 the two hottest years on record? Does this mean that human activity is not creating global climate change? What if the the earth is naturally cooling while we humans are warming it up? Do we do nothing? While name-calling adds nothing except to signal strength of emotion and to perhaps-and only perhaps-to cover a weak logical argument, I still don't understand the glee in the skeptics, nor for that matter, how they differ from say, Republican presidential candidates.

Jenny (2012-01-30 14:17:56)

An interesting sideline - in December, UK's Natural World programme on British Butterflies noted that butterflies, which respond very sensitively to temperature, are coming out of their chrysalids earlier and earlier, and the warmth-loving ones are

moving further and further north. These countryside butterflies are acting as if their world is still warming; they are also those that have a varied diet and are free to move following their food supply. Presumably, when the world starts to cool again, they will move back south.

Nathan Myers (2012-02-01 21:01:58)

What is it that is supposed to be funny about that graph? It looks to me like it supports the assertion, and also that 9 of the last 11 highest temperatures ever recorded happened since Justin Bieber entered grammar school. You can talk about a "medieval warming period" all you like, but the tundras didn't turn to mud then, nor at any time in many thousands of years, as they are now. Nile: The "heat islands" trope was debunked long ago. To trot it out again only suggests that you don't have valid arguments to draw upon instead. The joshua trees' range is also moving north. Sadly, unlike the butterflies, the joshua trees cannot move north with it. Land north of the Joshua Tree National Monument is not available for annexation, not even in exchange for the denuded southern reaches. In a few years it will be as devoid of joshua trees as the Glaciers National Park is of glaciers. It's not just temperature; ocean acidification follows CO2 levels, too. How many years before Australia's Great Barrier Reef is as devoid of coral, and is neither a barrier to storms in the Pacific, nor a reef?

et (2012-02-02 03:08:41)

I don't understand what you are saying either. As Nathan Myers mentions above the graph does seem to point to a warming trend.

Seth Roberts (2012-02-02 06:10:40)

As Nathan Myers mentions above the graph does seem to point to a warming trend.

The graph shows that during the most recent 10-15 years there is no warming trend (= a line fitted to the data of the last 10-15 years has a near-zero slope). As the WSJ letter said.

Tim Beneke (2012-02-02 11:08:07)

It is disturbing that those who believe humans are overwhelmingly the cause of global warming will not explain why the temperature has stabilized for the last 10-15 years. It's a very simple question. (Their response, to point to the 2 highest years on record being in the last decade is utterly unscientific and silly, and reminds me of the childhood joke about the contest between the US and USSR where the US won; the USSR put out propaganda saying the USSR came in second and the US came in next to the last.) They can only know the role that humans are playing in global warming if they know what other factors are at work, and it's fairly obvious that our knowledge is limited. Does anyone know if there is a serious attempt by scientists to explain the recent stabilization? More greenhouse gases have entered the atmosphere in the last 15 years, so it should be getting hotter and it's not. Why? On the other hand, my rough impression from eyeballing the graph is that one can pick other 10-year periods like '84-'94 where it has been stable, and yet the longer term trend is towards higher temperatures. But if the stability continues for another 5-10 years, the mainstream climate scientists will have some serious explaining to do.

mike (2012-02-04 10:44:51)

The graph is calibrated in tenths of a degree Celsius, a tiny amount. The graph would be a horizontal line if it were calibrated in whole degrees, showing no warming.

Nathan Myers (2012-02-07 01:52:33)

I see. By looking at few enough samples of any noisy sequence, you can assert no clear trend. But look! There's a clear *downward* trend if you look at the last two years! Likewise, since this afternoon! Spare me.

George (2012-02-18 21:53:25)

This post saddens me. I stumbled upon this blog and was quite impressed, at least until I saw this. The graph looks like a

(somewhat noisy) step function to me. By looking at a small enough segment of data, you can prove anything you want. @mike, .6 C is not "no warming". what in the hell do you think is happening all around us, with plant and animal ranges changing, permafrost melting? Honestly, the denialists astound me.

Seth Roberts (2012-02-18 22:57:03)

George, I am sure the world is warmer now than during the Little Ice Age. The question is: why? I don't believe the answer is as clear as AGW advocates say. World temperature went up and down by large amounts long before humans started burning lots of carbon.

mike (2012-02-24 16:57:17)

@mike, .6 C is not "no warming". George, The WSJ article talks about the last 10 years, not the full extent of the graph. There has been no warming for 10 years. (and there will be no warming for the next 30 years)

Dennis Mangan (2012-01-31 07:48:05)

Not quite personal or amateur science, but according to the second linked item on alcohol and longevity in worms, the lead researcher did the work as an undergrad.

Alex Chernavsky (2012-01-31 07:55:03)

@Dennis, I remember seeing a paper on neuroanatomy that was authored by five people – the principal investigator and four high school students who had done a summer internship. It was a decent paper.

Seth Roberts (2012-01-31 11:34:27)

the lead researcher did the work as an undergrad

Interesting point. Maybe undergrads can do more risky research.

vimspot (2012-01-31 11:39:37)

Does the Spanish study have any real implications for the United States where people don't tend to fry food in Olive Oil, and don't tend to eat a Mediterranean diet more generally?

## 7.2 February

### **Vitamin D3 in Morning Makes Her Fall Asleep Faster and Sleep Better (Story 11) (2012-02-01 05:00)**

I have heard many stories about Vitamin D3 and sleep, often in the comments section of this blog. From now on I am going to number them. (I retitled earlier posts.)

Elizabeth Funderburk emailed me:

I've always suffered, rather lightly I guess, from SAD in the winter. In 2010 I started eating primal, which I thought would help - it helped in many ways but I still got gloomier all winter and didn't even realize it til that first warm sunny spring day when I "woke up." [1]Your November post about D3 reminded me that I wanted to try it this winter, so I got a bottle and started taking it in the morning. I forgot a few times and took it in the midday or afternoon, and yes, I felt noticeably more spazzy and awake those evenings. Now, if I forget, I just skip it if I remember later than 10 am. I do think I sleep better. I take 4000-6000 IU daily.

I asked her for details.

Tell me about yourself.

I live in Reno, NV, USA, and I'm 34. I do home renovations.

What brand?

Kirkland D3 2000 IU gelcaps. The first bottle I got was from Walgreen's, so I guess it was Nature's Bounty gelcaps. Both seem to work equally well. I have not tried capsules. I take the D3 while I'm waiting for my coffee, usually 6 or 7 am.

How has your sleep improved?

With D3, I would guess I fall asleep in 10-30 minutes most of the time (trouble falling asleep once every 7-10 days). The wave noise thing by my bed is on a 45 minute timer. If the wave sounds stop and I'm still laying there conscious, I categorize that as a "trouble falling asleep" night and I will usually get back up and read for an hour. In the fall before I started the D3, I'd take more than 45 minutes to fall asleep more often than after starting D3.

But I think more importantly, the quality of my sleep was not restful more often before D3 - I slept well (lightly, vivid dreams, woke up briefly, woke up feeling rested) maybe twice a week. I slept poorly (heavy, dark pit of sleep, no remembered dreams, unwilling to wake up and get up) 5 nights a week. It's pretty binary; I usually sleep well or poorly, not "so-so." Now, taking D3, I sleep well 6 nights a week, and poorly once a week.

What do you mean by "spazzy" ("more spazzy in the evening")?

When I did take it in the afternoon, I noticed that I felt energetic when I'd prefer to feel sleepy - really raring to go at 7 or 8 instead of starting to wind down. I think it would be a fabulous tool for people working swing or graveyard shifts!

"thanks for the reminder" - you mean you had read elsewhere that Vitamin D3 first thing in the morning is a good idea?

You gave me the idea to take it IN THE MORNING. You "reminded" me about it in the sense that it's one of the few supplements Mark Sisson ([2]mark's daily apple) suggests everybody could benefit from - I noted that when I gave up grain and started eating primal in early 2010, but it wasn't something I'd bothered to take at that point, because I spend a lot of time outside in the spring/summer/fall. (Winter, too, but because I'm all covered up in clothes and the sun is so weak, I don't seem to get the natural level of D3 I need.)

1.

2. <http://www.marksdailyapple.com/>

---

Valtsu (2012-02-01 06:23:27)

"But I think more importantly, the quality of my sleep was not restful more often before D3 - I slept well (lightly, vivid dreams, woke up briefly, woke up feeling rested) maybe twice a week. I slept poorly (heavy, dark pit of sleep, no remembered dreams, unwilling to wake up and get up) 5 nights a week." Question: Should we see dreams while sleeping, or is dreaming a marker of good sleep? Usually, I don't remember any dreams when I wake up but today I remembered two different dreams I saw during the night. Hmm... I take vitamin D (5000IU) in the morning too, but usually 1 to 1.5 hours after waking (at breakfast).

Henk Poley (2012-02-02 23:51:59)

About the time of day to take D3. Apparently the appropriate amount of UV-B in sunlight for D3 photosynthesis to happen is when the sun is at 40 degrees in the sky. Given that the earth rotates 360 degrees in 24 hours you calculate this for the equator:  $40 / 360 * 24 * 60 = 160$  minutes before and after noon. So, 2h40m before and after 12:00 is: between 9:20 and 14:40 Your skin has the appropriate metabolites replenished during the night, so most of the photosynthesis happens early on. So the most natural time to take D3 would be around 9:30.

## Law Schools Sued For Lying About Post-Grad Employment (2012-02-02 05:00)

If it isn't clear [1]for whom law schools exist, now [2]it is clearer:

The saga began last year, when Strauss and Anziska, both veterans of corporate legal work, filed lawsuits against New York Law School and Thomas M. Cooley Law School, in Michigan. The allegation: That Cooley and NYLS, by allegedly inflating post-graduate employment numbers, had committed fraud and violated local consumer protection acts. . . . The job market for lawyers has been contracting for years; hiring is down across the board. At the same time, law schools have continued to crank out young lawyers at an alarming rate.

This is the legal version of [3]the joke that people go to law school because they aren't good at math. So far twelve schools have been sued. I look forward to learning how the teachers at those schools react. Which side will they take?

[4]More about the lawsuits. [5]I blogged about the deception a year ago. The California Culinary Academy in San Francisco [6]was successfully sued for similar deception a few years ago. [7]Inside the Law School Scam, a blog.

---

JPB (2012-02-02 11:29:03)

As bad as the problem is with law schools, it is equally bad in other fields. Colleges and universities have been expanding at a breath taking pace. They NEED ever more warm, tuition- paying bodies! There is definitely a bubble here and eventually, there will be some really bad fall-out. Perhaps this suit will help focus attention on the problem!

Bryan (2012-02-02 12:05:55)

Fascinating. I'm surprised my 4th tier school wasn't one of the ones sued. BTW, the Law School Scam blog is absolutely correct about how law schools game their employment numbers. Just recently Chapman Law School went from a 4th to 2nd tier school. One of the reasons their rank increased was post-graduate employment. I had friends that went to Chapman and, although they were happy their school went up, they were cynical about the U.S. News ranking process. They said the school made a BIG push among alumni to get them to hire recent graduates, even if it was for part-time work. Also, the undergraduate school hired a Nobel Prize winner (Vernon Smith) which also had a halo effect on the law school's prestige. But the way law school lies to its students is even deeper than the employment numbers or star faculty. The bigger scandal is that law school – ostensibly a professional school – is NOTHING like the actual practice of law. The ABA accreditation standards ensure a specific model that hasn't changed much in 100 years, discourages innovation, and does not adequately prepare students for the day-to-day practice of law. Law school trains appellate lawyers when the vast majority of students will become litigators or trasactional attorneys. And don't even get me started on the waste of time that is the law review.

wcb (2012-02-02 12:59:45)

@Bryan The civil action filed against Widener Law School this week is pending in the USDC, New Jersey, although the main campus of the school is located in Wilmington, Delaware. Of course, Widener recruits students from NJ and PA, as well as Delaware and other surrounding areas. The case, which seeks class action status, is based on the Delaware Deceptive Trade Practices law, Title 6, Sections 2531 et seq. As noted by Seth in his piece and in the provided links, the factual basis of the complaint is allegedly-inflated, post-graduate employment data used by the school as part of its recruitment program for new students. Counsel for the plaintiffs have filed a very interesting, 30-page complaint with allegations which, if proven, will obviously be very damaging for Widener, both reputationally as well as financially, since the suit apparently seeks to claw back student tuition costs, among other monetary claims. (As an aside, one factoid which seemed surprising to me is that the law school dean was recently being paid more that \$300K per annum in total comp. This seems over the top for a lower-tier institution whose admission standards are alleged in the complaint to be comparatively low.) Here's a link to the text of the complaint for

those who may be interested. <http://www.scribd.com/doc/80168175/Filed-Widener-Lawsuit-Without-Index-Number> -2

Nancy Lebovitz (2012-02-02 13:00:52)

It wouldn't surprise me if law schools are at greater risk of being sued.

Tom (2012-02-02 16:48:27)

This lawsuit is particularly exciting, because it's just the leading edge of the wedge. The truth is that most higher education is a scam. If this case succeeds – and I think it has a good chance – it has the potential to set off the unraveling of the entire higher education cartel.

Tom (2012-02-02 16:50:41)

By the way, AdSense is hilarious – I love how this page is filling up with ads for expensive for-profit universities. :-)

Seth Roberts (2012-02-02 17:42:23)

Colleges and universities have been expanding at a breath taking pace. They NEED ever more warm, tuition- paying bodies! There is definitely a bubble here and eventually, there will be some really bad fall-out.

Yeah. I find it curious that the two sectors of the economy that I criticize the most – health care and higher education – are also the two sectors of the economy with out-of-control cost increases, far outstripping inflation. My criticism has nothing to do with price, it is about quality of the product. The usual explanation of health-care cost increases is that it is hard to shop around (e.g., compare hospitals). But it is easy to shop around in the case of colleges. On the face of it the two products (health care and education) are quite different.

garymar (2012-02-02 18:53:02)

Elite universities can take care of themselves. What we need is unstinting support for our *community college* system. This is the real backbone of higher education, where a lot of real education takes place.

Sara (2012-02-02 19:23:01)

This certainly makes me feel better for ditching law in favour of Psychology and Nutrition. At least in these fields they make it clear that you're doing it more for the love than the money... ;) Several of my classmates have law degrees and could not get the required practice hours.

Sara (2012-02-02 19:32:07)

Interesting also about cost increases. It's not just cost, but time taken to complete a qualification. Psychology is a very good example. You used to be able to practice with a bachelor degree and internship (this is NZ I'm talking about so it might be different in the US), now it is minimum masters degree plus postgraduate diploma. Minimum six years to be a Psych in general practice, seven or eight years for a Clinical Psych, 9 or 10 years if you do a PhD as well. Total student loan? Somewhere upward of \$30,000 depending on scholarships. To register as a nutritionist used to take three years (undergrad. degree). You can still do it in three, but registration then takes five years. Or you do a postgrad diploma or masters plus two years to register. For every profession they are trying to keep us at university for longer AND they are sometimes not upfront about the requirements. In my third year of Psych. I learned that internship was no longer part of the masters degree and now takes the form of a postgrad 'practicing diploma' (or you can go and try and find an internship yourself, but they are hard to get).

Alex Chernavsky (2012-02-02 20:50:48)

This post reminds me of a passage from an excellent book called, [1]*Travels with Lizbeth*, by Lars Eighner:

"The purpose of welfare systems is not to help poor people. If the object were to help poor people, then that would be most surely done by giving money to poor people. But that is not the idea, as our tax code proves. If you give twenty dollars to someone on the street, there is not a way in the world you can deduct that donation from your

taxes. To claim a deduction you must give the money to an organization that employs clerks and administrators and social workers and that, more than likely, puts nothing material into the hands of the poor... When the agency makes an accounting of the good it has done the poor, it will count the money it spent on paying social workers to hold the hands of the poor the same as money, if any, spent on bread. The purpose of welfare systems is to provide jobs for social workers and bureaucrats. I told Billy he should be grateful to have a job in the poverty industry, but to ask that such a job be meaningful is to ask too much."

1. <http://photo.net/travel/travels-with-lizbeth>

WCB (2012-02-03 06:10:20)

@ Alex Excellent quote. The same might be said for a number of high profile "charitable" 501c3 organizations that pay outrageous compensation to their executives.

JPB (2012-02-03 09:07:22)

Seth: It is interesting that the 2 out-of-control industries (medicine and academia) either do not respond when asked the reasons for the high rates or they just say that there is no way to make any cuts! Of course, the "authorities" never offer to show the books...

Jim (2012-02-05 18:13:06)

Another issue is that many law school graduates, while getting jobs, get those jobs outside of the legal industry. Some do this by choice, but many do so because they can't get a job within the legal industry. The law schools spin this by stating that law school trains your mind, and that such training is good for any endeavor. But using a legal education as training for a career outside the law is an inefficient use of time and money at best, and a total waste of time and money at worst.

C. Shoemaker (2012-02-14 16:25:35)

No education is worth 200,000 dollar debt plus lost wages for three years. If someone is willing to take this risk, with slim job prospects after graduation, it shows they can't make good decisions and use critical thinking skills.

## **Vitamin D3 in Morning Has No Clear Effect on Sleep (Story 12) (2012-02-03 05:00)**

Alex Chernavsky, who has [1]used the Shangri-La Diet successfully for two years, recently [2]commented as follows (emphasis added):

For what it's worth, I've taken Vitamin D at different times of the day, and I've never noticed any effect on my sleep. Of course, my sleep is already pretty good, in the sense that I fall asleep quickly and don't usually wake up during the night. (My sleep is not good in the sense that I don't get enough of it.)

By email, I learned that Alex is now taking Vitamin D3 - [3]this particular product, which is vegan ("plant-source") - at 5000 IU every other day. On weekdays, he takes it at about 8:00 am, on weekends, 9:30-10:00 am.

What might explain Alex's failure to notice better sleep?

1. Not enough D3. I found that 2000 IU/day had no noticeable effect, whereas 4000 IU/day did produce noticeable benefit. Alex is getting 2500 IU/day - or less, if he takes it too late on the weekends.

2. His source of D3.

3. Individual differences large enough to matter. If you do sensitive psychology experiments, you will learn there

are individual differences in everything.

4. Ceiling effect. Alex's sleep is too good to notice improvement.

Those are the just the obvious possibilities.

1. <http://www.astrocyte-design.com/shangri-la-diet/index.html>

2. <http://blog.sethroberts.net/2012/01/24/vitamin-d3-first-thing-in-morning-improves-falling-asleep/#comment-947481>

3. <http://www.amazon.com/gp/product/B0042DDP44/>

---

Francesco (2012-02-03 06:13:58)

I also didn't see an effect. Tried 2000 and 4000. Low-quality sleep in either case. I use Duane Reid gelcaps. No effect of standing on both legs or on just one (to exhaustion). I guess I am hopeless

Paul (2012-02-03 08:32:54)

5. Vitamin D3 doesn't improve sleep. Should be included for the sake of intellectual cleanliness.

David (2012-02-03 08:45:35)

Since you started posting these, I've been taking D3 in the mornings and notice that I wake up much more easily. I started with just 400 IU, then increased to 800 IU. One day I took 1200 IU and woke up at 4:00 AM the next day. I've gone back to 800 IU since 4:00 AM seems a bit early. For the past week, I've also been giving one of my daughters (11 years old) 400 IU each morning, and she seems easier to wake up in the morning (normally it's quite difficult). Sorry I'm too lazy to keep detailed records. I'm taking NOW Softgels. I do wonder if there would be an initial effect that goes away over time as your body adjusts.

David J (2012-02-03 10:55:40)

Lack of fat. You need fat present to absorb the D3. I've been taking A,D3 & K2, chased down with Jersey cream for 1 week. I think I have improved sleep, but it's very subjective.

Randy Knudson (2012-02-03 11:47:44)

Seth- I started taking D-3 4000 IU, this week. My sleep has definitely gotten much better. I typically have no problem falling asleep, but wake up at 12, 2 and 4. Last night I slept until 2:30 and overall feel like I'm much more rested. One thing I have experienced which has not been mentioned is that my dreams are much more vivid, and I recall them more easily. Thanks for alerting me to this very interesting and useful nutritional idea.

Chris U (2012-02-03 14:56:34)

I suspect that those already replete with vit D will not see an effect. Anybody who is taking vit D should have their blood levels tested from time to time both to avoid toxicity (rare but possible) and to provide some insight to the dose required to achieve a target blood level. The folks at grassrootshealth have some good info on target levels and how to choose dosage.

David (2012-02-03 22:03:19)

For the last 4 weeks, I've been eating within 30min of waking up and taking 4000 IU D3 (Kirkland brand, just like Elizabeth from story #11) along with a multivitamin. I am trying to get my body to wake up, rested and energetic, at 6:00 am everyday. This regimen has not helped me wake up any easier. In fact, this last week I've had to skip eating breakfast in order to not be late for work. I did take 10,000 IU of D3 one day. I had a tremendous initial bust of energy. I literally could not sit down for the next 3 hours. But it was not any easier to get out of bed the next morning. My number one desire right now is to improve my ability

to get up early. I had high hopes for the early breakfast/D3 combo. I'm pretty frustrated that it has not worked for me. I'm not sure what to try next.

Adrien (2012-02-03 23:52:50)

I have not tried vitamin D as a means to sleep improvement. As I know vitamin D has little or no effect on sleep.

Seth Roberts (2012-02-04 04:59:00)

For the last 4 weeks, I've been eating within 30min of waking up and taking 4000 IU D3

I discovered long ago that eating breakfast caused me to wake up less rested. You might want to try D3 alone.

Five Daarstens (2012-02-04 06:42:46)

I'm on 1000 a day D3 in the morning. I have not noticed any difference in sleep, but my rosacea has cleared up considerably.

David (2012-02-04 13:24:12)

I discovered long ago that eating breakfast caused me to wake up less rested. You might want to try D3 alone.

I'll give it a try.

Juha (2012-02-12 08:57:49)

I have difficulties in falling asleep, I rarely wake up feeling refreshed and I often feel slightly exhausted during the day. I've been taking vitamin D3 a couple of years now with doses ranging from 1000 to 6000 IU, but I don't remember ever noticing any effect of D3 on my energy levels or sleep. Before coming across Seth's writings about the timing of D3 I usually took my pill sometime in the evening (7 to 9 pm perhaps). Now I've been taking my D3 in the morning, but I haven't noticed an effect. (In fact, I feel that my sleep might have been a bit worse, but if so, it's probably unrelated.) A while ago I was still taking a shower and brushing my teeth before taking the D3 so that I could consume it with a spoonful of coconut oil. When that didn't seem to help, I started taking D3 before getting up from the bed - no effect. I wouldn't be particularly surprised if D3 didn't have a noticeable effect on me - not many supplements do. If there's something that I could still try it might be increasing the dose. I'm tall, I've got at least a little muscle and my metabolism seems to be quick (I eat a lot and stay lean) so it's possible that I have a floor effect on my current dosage. I'm a bit hesitant to increase the dosage though since I don't know if I'd get some adverse effects, too. I'm planning to try taking D3 in the evening to see if it makes my sleep or energy levels worse. I'll probably go back to taking it in the morning since that's probably the best, but I'm curious to see if my body responds to the timing of D3 in any way at all.

Mary (2012-02-05 08:58:22)

I still take only 2000 IU vit. D but I've been taking it solo first thing in the morning and it's made a noticeable difference. I have more energy and now rarely get sleepy mid-afternoon. I also notice a big difference in 'tossing and turning' frequently during the night. Next I'm going to increase it to 3000 IU daily—at least for the remainder of the cool weather. I live along the gulf coast so I get a lot more sun exposure during the rest of the year.

Stephen M (Ethesis) (2012-02-08 20:57:31)

Climate scientists are "stunned" By TigerHawk at 2/08/2012 09:47:00 PM Even though the warmists claim the science is "settled," they keep getting surprised: The world's greatest snow-capped peaks, which run in a chain from the Himalayas to Tian Shan on the border of China and Kyrgyzstan, have lost no ice over the last decade, new research shows. The discovery has stunned scientists, who had believed that around 50bn tonnes of meltwater were being shed each year and not being replaced by new snowfall. ## **Vitamin D3 and Sleep: 5000 IU Better than 3000 IU (Story 13) (2012-02-05 05:00)**

Jenny West, the Englishwoman [1]who discovered independently the value of taking Vitamin D3 in the morning, wrote again:

Since reading some of the other D3 stories, I increased my D3 [morning] dosage to 5000 IU/day [from 3000 IU/day] two days ago.

1. I immediately slept even better – no longer being aware of mid-sleep turning-over.
2. I've had a large boost of energy and the clarity of thought that both [2]Robin Barooah and [3]Alexandra Carmichael mentioned.
3. A year-long injury – specifically a dislocated coccyx – has suddenly taken a step forward, and I found myself running for the Tube last night – something I can't remember when I last did it. Is this a direct effect of the D3, or an indirect one resulting from much better sleep?

This agrees with what both Alexandra and I experienced: a dose of 4000 IU worked much better than a dose of 2000 IU.

Mike (2012-02-05 06:34:39)

Interesting posts on Vit D & Sleep, Seth. It would be nice to know optimal 25(OH)D levels and sleep...makes me wonder just how depleted, (or not), they folks are that have positive anecdotes.

Jenny (2012-02-05 17:12:02)

Being coeliac, I am almost certainly depleted. Coeliacs don't absorb fat easily, even when they have apparently 'healed guts'. I have have been gluten free for 6.5 years, and various other things 'healed' at the 2 year point, but the nutritionist warned me that absorption can always remain problematical.

mr magoo (2012-02-06 01:49:17)

all good but also at least nod to the notion that this could be ascribed to a placebo effect. its well documented that inceasing the dosage of a sugar pill, e.g two pills rather than one, makes a placebo more effective. that's the problem with relying on anecdotes alone.

JBB (2012-02-06 03:58:27)

I've had SAD (Seasonal Affective Disorder) every Fall and Winter that I can remember, though it's been more severe as I became a young adult and middle-aged adult. I had been trying Vitamin D, in doses of 2000, 4000, and 5000, with very little, if any, effect. This year I saw a new variety - D3 in 10,000. I figured I'd try it... And I am going to go down to 5000 again! I've definitely had more energy during the day, less sleepiness (though I'm still tired during the day, if you see the difference between sleepiness and tiredness). But it's lasted too long, and pushed my bedtime back an hour and a half before I can really feel like falling asleep. What I didn't think of was the delivery mode. I'd been taking tablets of D3 before. This much higher dose isn't just a higher dose, it's a geltab filled with oil. It seems much, much more effective... too effective. I'm going to try the 5000 dose also in the same oil-filled gel tab and see if that's a better fit for me.

Seth Roberts (2012-02-06 05:36:39)

all good but also at least nod to the notion that this could be ascribed to a placebo effect.

Right now I'm trying to answer the question: Is there an effect? Does D3 in the morning make a difference? How to explain the effect - if there is one - comes later.

BlueMorrissey (2012-02-06 10:06:47)

I have needed to use a light box for Seasonal Affective Disorder every winter since I self diagnosed myself 10 years ago. I have upped my Vitamin D usage up since Seth began advocating it. This is the first January/Feb I have not felt the need to use or used the light box in 10 years.

## 50,000 IU Vitamin D3 in Morning Once/Week Improves Sleep (Story 14) (2012-02-06 05:00)

A reader named Tim G [1]commented:

Blood tests last year [2011] showed I had low Vitamin D levels so I was put on a 50,000 IU once/week regimen for 3 months using a prescription D2 (ergocalciferol). A recheck after 3 months showed my level had hardly changed. A search of PubMed showed conflicting views on using the D2 form. So for the next 3 months I used ProHealth D3 Extreme 50,000 IU (via Amazon.com) instead of another D2 scrip my doc had given me. I always took the D2 or D3 in the morning (just lucky happenstance.)

The second recheck, after the second 3 mo., showed my Vitamin D level was normal. I hadn't put it all together until seeing this post, but when using the D3 I had the same effect [as what is described in [2]this post] – when I got tired, I got \*really\* tired right at bedtime, and slept like a rock.

Even though it has been less than a month since stopping the weekly dose, I have noticed my sleep degrading somewhat, and lately not even being tired when I should.

I asked for details:

Tell me about yourself.

I'm a 50 year old reasonably healthy guy who is a lifetime Massachusetts resident. I'm in the IT profession (managing computer systems, programming and such). So I am someone who 1) lives at a higher latitude, 2) during the day garners minimal Vitamin D from the glow of LCD displays and fluorescent lights, and also 3) generally dislikes the heat of summer and burns easily.

Why did you take D3 once/week rather than once/day?

My intent was to mimic the original doctor's prescription of a single 50K/wk dose, while substituting D3 for the prescribed D2. At the time, I had no good reason to change to a daily schedule, although it intuitively struck me as odd to take a single large dose rather than smaller, more evenly distributed doses.

What time in the morning did you take it? What time do you get up in the morning?

I get up around 6-6:30 am. I would take the D3 around 6:15-6:45 am.

Why did your doctor prescribe D2 rather than D3?

I think it was simply rote procedure and cost. When I asked him after my first 3 months on D2, he said that the prescription D2 was cheaper than the prescription D3, and that he had seen the D2 usually work quite well to bring up Vitamin D levels, although it did sometimes take multiple 3-month courses to achieve normal levels. He seemed unaware of the literature criticizing the use of D2 as a supplement.

You write: "When using the D3 I had the same effect of when I got tired, I got \*really\* tired right at bedtime, and slept like a rock" What was it like when you were taking the D2? What was your sleep like before you started the D2?

To the best of my recollection I did not have a similar response when taking D2. However, since this was not something I intentionally tracked, I may be mistaken.

Before taking D2 or D3 I thought I slept reasonably well. However, in retrospect, I would awake a few times during the night, take longer to fall asleep, and awaken less refreshed than with my "Vitamin D sleep".

You write: "not being tired when I should" – when is that?

What I meant is that when I'd get into bed at night, rather than feel tired (in the sense of "an onset to sleep", not "worn out") I would feel either wide awake or worn out, or both. By contrast, when taking the D3, almost as soon as I would lie down in bed I would feel an onset to sleep. Yesterday morning, I took one of my leftover 50K D3 pills and last night's sleep did seem to confirm the efficacy of the D3.

When you took the D3 once per week, you slept better every night? Or just the night after you took the D3?

To the best of my recollection, I slept well every night. I don't recall there being any noticeable variance relative to the day I took it.

Addendum by Seth. It is impressive that two things appear true: (a) the time of day D3 is taken mattered (other stories) and (b) a dose once/week at the right time improved sleep for seven nights (this story). The combination of the two supports the idea that our sleep is controlled by an oscillator and D3 at the right time gives that oscillator a push, increasing its amplitude.

Guv (2012-02-06 16:15:27)

The once per week dosing is very interesting. Makes me wonder what the minimal dose would be in this once-per-week dosing scenario. Given that other posters ( & yourself i think?) have mentioned that smaller daily doses did not help sleep. ie. (from memory) 2000 IU not effective, 4000 IU effective. I wonder if 28,000 IU once per week (7 x 4000) would have the same sleep benefits throughout the week as 4000 IU per day (all taken in the morning of course).

Guv (2012-02-06 16:17:12)

.... & 'minimal does' should read 'minimal dose'.....

Guv (2012-02-06 20:02:20)

just thinking some more about this, if you were going to experiment with a larger weekly dose; it would probably be better & more interesting to start with a smaller "big" dose & see how many nights the sleep benefit (assuming you saw a benefit) lasted. ie. take 12,000 IU one morning & monitor your sleep over subsequent nights.

## **How Things Begin (honey wine vinegar) (2012-02-07 05:00)**

At the recent Fancy Food Show in San Francisco, the most impressive product I encountered was a honey wine vinegar made by [1]Slide Ridge Honey, a small family business in northern Utah. I interviewed the developer, Martin James,

about how the business and product began.

How did your business begin?

I started keeping bees when I was 9 years old. It was a hobby. When I was in my thirties, I wanted to start a business. I'd been doing flooring. Carpet, linoleum, that sort of thing. Large commercial jobs and residential. I wanted to be my own boss, control my own destination, have my own business. I started a honey business with my two sisters, one older, one younger. That was 10 years ago.

How did this product begin?

We wanted a more unique product. We wanted to expand beyond Utah. When you ship butter somewhere, it's already there – local honey. So it's hard to enter the market. We wanted to diversify our business so we weren't only selling honey. We wanted higher profit margins.

My sisters and I discussed lots of possible products. Eventually vinegar came out the favorite. There are only two other people making honey wine vinegar – one in Washington State (Honey Ridge Farms), the other in Italy. If you put our products side by side, you'll see they're totally different.

The development took 7 years. The first step was to use honey to make wine. I got yeasts from wine shops, brewing shops, and mail order. I needed to find a yeast that was compatible with honey. The first ones I tried produced off flavors – for example, the wine smelled like gasoline. I finally found a yeast that was compatible with honey, that made an excellent honey wine. The next step was [2] to produce vinegar. To do that I used an acetobacter – a microbe that eats alcohol and makes acid. It feels like piece of wet leather. What kombucha makers call a SCOBY. I found the acetobacter I needed from a vinegar maker in Napa Valley – a vinegar maker.

There was also four years of paperwork. Local, state, federal.

What has surprised you?

The reception. When they taste it, people's eyes light up. I hadn't prepared myself for the product to take off so well. Repeat customers buy 3 bottles. A lot of specialty chefs have taken an interest. A lot of TV chefs have come by.

1. <http://www.slideridgehoney.com/>

2. <http://www.popsci.com/diy/article/2008-12/making-vinegar-home>

wcb (2012-02-07 12:50:46)

Seth, the honey wine product sounds interesting. Can you specify what it was that impressed you with it and what you think the benefits might be.

wcb (2012-02-07 12:58:17)

Checked the slideridgehoney.com website and they are selling a bottle of the vinegar for 22 bucks, but no indication of how many ounces. Would be interested in your description of how it tastes and what "applications" you think it has. Seems like it might be great on salads, but what else? :-)

Seth Roberts (2012-02-08 04:12:27)

The honey wine vinegar tastes really good ... I suppose because it combines complexity, sweetness, and sourness better than other vinegars and other products. Not giving the bottle size is a serious omission, I agree. I'd probably use it on ice cream and meat.

Clyde Adams III (2012-02-08 09:43:24)

As best I can make out from the label on the bottle in the photo, it says: "8.5 FL OZ (250 mL)"

## **Vitamin D3 in Morning Has Ambiguous Effects on Sleep and Energy (Story 15) (2012-02-08 05:00)**

A reader named Murray Love [1]made a comment about Vitamin D3 and sleep that at least sounds negative:

As a counterpoint [to [2]this post], I've been taking 4-5,000 IU of D3 for a couple of months now, and while it might be making me feel better in other ways (more vital, upbeat, and energetic), it has coincided with a stretch of poor sleep. I have what they (hilariously) call "terminal insomnia" – that is, I usually have no trouble at all falling asleep, but I wake regularly at night and am permanently awake very early, often from 4:30am onwards. This has been a periodic problem for a few years now, though this stretch is notably tolerable, for some reason.

I asked for details:

Tell me about yourself.

I'm an engineer, Victoria, BC, age 44. A big confounding factor with me is that I started a new job in November, for which I get up at 6 am and (on most days) ride my bicycle about 12 km (7.5 mi) to work, instead of walking a few blocks as I did with my previous job. I started taking the D3 and having this round of sleep problems all within a few weeks of starting the new job, so it's difficult to disentangle all the correlations.

What time of day do you take the D3? What brand?

I take it around 6:30 am with my coffee. London Drugs (generic Canadian drugstore brand) 1000 IU tablets, though I'd prefer higher-IU gelcaps for ease of swallowing. I usually don't eat anything for breakfast unless I'm cooking for my sons, in which case it's meat and eggs with some fruit. Other times, when I'm not cooking but feeling hungrier than the norm at that time of day, I'll have a handful of almonds or mixed nuts around the same time as the D3.

You started taking D3 because of my posts about it?

That sparked my interest, since I thought it might help with early-morning insomnia. But I've also been reading about the benefits of D3 for a while, such as at Dennis Mangan's blog [3]here and [4]here.

You write: "This has been a periodic problem for a few years now," What do you mean by "periodic"? For the last few years – before the D3 – on what fraction of nights did you have this problem?

"Periodic" means that I experience it almost every day (weekends included) for several weeks or a few months at a time, then it goes away for some reason and I sleep more normally for several months. The usual pattern for my insomnia is: I go to bed at 10:30, give or take 90 minutes, fall asleep almost immediately, wake up 1-2 times during the night (usually briefly), then around 4:30 am wake up and either a) doze lightly and intermittently until my 6 am get-up time, or b) stay awake.

Since you started the D3, on what fraction of nights do you have this problem?

I'd guess 85 %. Once in a while, I manage to get some catch-up sleep and surprise myself by sleeping in.

You write: "this stretch is notably tolerable, for some reason." Could you say more about this? What do you mean by "notably tolerable"?

It means I am surprised that my typical 4.5- to 7-hour sleeps do not seem to be affecting my energy level, mood, or ability to concentrate, even over several days. Since I went low-carb mixed with intermittent fasting back in 2008, I don't tend to get mid-morning or early-afternoon energy dips, but since I started taking D3 (NB. plus new job, plus riding my bike again) I seem to be much more alert and cheerful, almost regardless of sleep. My experience seems remarkably similar to [5]the other reader's comment you posted this morning (27-Jan).

5. <http://blog.sethroberts.net/2012/01/27/vitamin-d3-first-thing-in-morning-more-experience/>

---

Daniel Lemire (2012-02-08 06:58:07)

My own experience. I have irregularly taken 1000 UI in the morning for years with no noticeable effect. For about two years, I have had poor sleeping patterns characterized mostly by the fact that I tend to go to bed at 1am or later (and then I get up around 7h15 am). Whenever I would try to go to bed earlier, I would simply fail to fall asleep. After reading this blog, I increased my intake of D3 to 4-5,000 IU. I'm now falling asleep about an hour earlier. This could be a placebo effect, of course, but I consider it a very significant improvement. It is unclear whether I have more energy. I don't know how to measure such an effect. I expect that I'm less irritable, but that's a side-effect of getting more sleep. I plan to continue to see whether the effect is sustained over months.

Shawn (2012-02-08 08:12:20)

"...for which I get up at 6 am and (on most days) ride my bicycle about 12 km (7.5 mi) to work,..." High-intensity early morning exercise can cause people to wake up earlier than expected. I used to do heavy cardio first thing when I woke up but noticed I would wake up 1-2 hours earlier with my heart beating fast and I would not be able to fall back asleep. The problem went away when I stopped exercising early in the AM.

gm (2012-02-08 09:17:11)

I have WEAK evidence that taking 4000 IU Vit D at 8am will cause me to wake spontaneously at 6am. I have no trouble going back to sleep. The sample size is small and I conjecture that the dosage is insufficient because the Vit D is not making me tired.

Vi (2012-02-08 10:27:20)

I also have terminal insomnia and also have found no effect on sleep from taking Vit D3 early in the morning. In fact, I also feel my sleep might be a bit worse from it. I do wonder though if there is perhaps some genetic variability at work here. My ancestors are from Northern Europe/Scandinavia. If they lived in that part of the world for many thousands of years wouldn't it be possible that they evolved a different way of handling Vit D, (perhaps a need for less, a super efficient way of handling small amounts, a preference for D from a different source (fish liver) for example) from those ancestors who lived in warmer, sunnier climates over the same period, and who consequently didn't have a need to modify the way they handled Vitamin D.

Ginna (2012-02-08 10:37:56)

Hey Murray, I started taking Vitamin D with gelcaps (on sale), and had good results. (I always slept well, but seemed more alert during the day.) But then my frugality kicked in, and I bought the tablets from Walmart, probably similar to the London Drugs. They don't seem to have the same effect, so I wonder if active ingredient works as well. I will have to bite the bullet and try the gelcaps again. Regarding why "this stretch is notably more tolerant", it could be that this new job situation is making the difference. I know I slept much better... :)

Stone Glasgow (2012-02-08 16:02:17)

5,000 IU of D3 wakes me up for a few hours and then I am very tired, needing a nap. 50,000 IU kept me up all day. I think my body needs a constant dose of it every few hours and "withdrawal" induces sleep.

Paul Sherrard (2012-02-09 08:27:54)

My immediate reaction to this was: "He's drinking too much coffee." Not that I could actually know that, but when I drink more than 2 cups a day this "terminal insomnia" thing happens to me until I cut back. Just a thought.

Seth Roberts (2012-02-09 10:21:09)

My immediate reaction to this was: "He's drinking too much coffee."

Interesting idea. I will try to find out.

M. Love (2012-02-09 23:39:24)

I do drink a lot of coffee, yes. Two or three cups of strong coffee between 6:15-7:15am, and then another two or three (of far inferior quality) at work between 8-11am. I don't usually drink coffee in the afternoon. What's the half-life of caffeine in the bloodstream? Around 5-6 hours, apparently, so maybe there's enough remaining to interrupt sleep. Maybe I'll give up coffee for Lent one of these years and see what happens, but the fact remains that the insomnia comes and goes while my coffee consumption remains more or less constant. And if I had to choose between coffee and getting a bit more sleep ... I might well choose the coffee, especially since the insomnia doesn't seem to be affecting my functioning this time.

## **What is a Healthy Scientific Ecosystem? (2012-02-09 05:00)**

An area of science is an ecosystem in the sense that research builds on other research. In an ordinary ecosystem the animals and plants need each other. Different organisms add different things. Their contributions fit together. In a healthy scientific ecosystem, different types of research add different things and fit together.

Personal science (science done to help yourself) differs greatly from professional science (science done as a job). The big differences help personal science and professional science benefit from each other. They are likely to benefit each other because they have interlocking strengths and weaknesses. Personal science is fast (experiments can be started quickly), has great endurance (experiments can last years), cheap, and intensely focussed on benefit. Professional science has none of these features, but it has other features that personal science lacks: it is "wealthy" (allowing expensive equipment and tests), peer-reviewed, and not intensely focussed on benefit, which allows studies without obvious value. These differences suggest that a system that contains both kinds of science is going to function better than a system with only one kind. Peer review, for example, is a helpful filter but may also suppress the diversity of ideas that are tested. Which implies that not all science should be peer-reviewed.

The relation between personal and professional science somewhat resembles the relation between animals (= personal science) and plants (= professional science). Animals and plants are very different, as are personal and professional science. Animals move faster than plants; personal science moves faster than professional science. Animals range more widely than plants. Likewise, a personal scientist can test a much wider range of treatments than a professional scientist. If you want to sleep better, for example, you can try almost anything. Professional scientists cannot try almost anything. For example, they cannot test treatments considered "crazy".

Animals and plants helped each other evolve, in the sense of diversifying to exploit new habitats. Animals helped plants exploit new habitats because they increased seed dispersal. This helped plants "test" more locations, helped them survive difficult circumstances such as drought (because some places are drier than others), and reduced competition between seeds (allowing more resources to be devoted to overcoming bad features of new places). Animals are like catalysts that speed up the combination of old plant and new environment to yield new plant. Likewise, plant evolution helped animals evolve because new plants in new places provided more food, more diverse food, and more places to live.

It is likely that personal science and professional science will help each other "evolve" (e.g., solve problems). Personal science wouldn't function well without professional science. For example, statistical packages, which help personal scientists, wouldn't exist without professional science. In the other direction, personal science can help professional science "evolve" (e.g., solve problems, build better theories) in two ways. One is idea generation, especially discovery of new cause-effect relationships. Personal scientists can easily do large amounts of trial and error. They can easily test many "crazy" (= low-probability-of-success) treatments, one after the other, until they find something that works. Professional scientists cannot do this sort of thing, which in the world of professional science has a derogatory name: fishing expedition. The other way personal science can help professional science involves idea application. Personal science can tailor ideas from professional science to individual circumstance. Professional scientists don't like to do this. They would rather do a big study in which all subjects are treated alike. Making better practical use of ideas from professional science is what Richard Bernstein did when he invented home blood glucose monitoring. He made better use of already-known cause-effect relationships.

I have not heard scientists talk about science as an ecosystem. If they did, it might cut down on the dismissiveness (correlation does not equal causation, the plural of anecdote is not data, etc.), evidence snobbery, and one-way skepticism.

dearieme (2012-02-09 05:21:17)

But "correlation does not equal causation" is a vital truth, the ignoring of which has led to two generation's worth of drivel health advice/instruction to the population.

Jim Purdy (2012-02-09 05:21:34)

Obviously, when different entities interact in an ecosystem, they co-evolve. However, these interactions are not always as benign as your portrayal. The players may be also be predators and prey, for example. And in the case of individuals and BigScience (or BigMedicine, or BigPharma), they may be rivals, especially when the large institutions dismiss N=1 evidence as "anecdotal." Whenever I have to choose between a large expensive study and my own N=1 experiences, I will feel comfortable going with N=1.

John (2012-02-09 10:06:06)

Seth, You recently posted about someone who experienced breakouts and [Irish] dairy. I think I have noticed this with Fage [full fat], but I have not tightly controlled my variables. Have you had any comments like this before? Would you suspect a difference between homemade yogurt (I like strained) and Fage?

Seth Roberts (2012-02-09 10:08:09)

Whenever I have to choose between a large expensive study and my own N=1 experiences, I will feel comfortable going with N=1.

Me too. But I am saying here that this choice – deciding which is better – doesn't do justice to the relationship. For example, people who do N=1 studies may be able to learn from large expensive studies. My first self-experimentation of any interest was a comparison of two Big Pharma treatments for acne. One worked, the other didn't. It was helpful to know that one worked.

Seth Roberts (2012-02-09 10:19:44)

But "correlation does not equal causation" is a vital truth, the ignoring of which has led to two generation's worth of drivel health advice/instruction to the population.

I disagree. I call "correlation does not equal causation" a phony critique. It appears to be helpful but actually isn't because it ignores the complexity of specific cases (the extent to which a correlation implies a specific causation depends on the plausibility of alternative explanations – about which no blanket statement is possible). I explain the poor health advice of recent decades as due to poor science – the health scientists involved (e.g., the ones studying weight control) are unable to make progress. A large fraction of them do experiments – e.g., the large clinical trials that "correlation does not equal causation" advocates are fond of. The lack of progress provided by large clinical trials cannot be explained by a failure to understand that "correlation does not equal causation".

dearieme (2012-02-09 17:11:02)

But much of the dud health advice - particularly but not solely dietary advice - is sourced not in large RCTs but in correlational studies, the sort of things that reveal (to quote an old joke) that it's people who wear bras whom are most prone to breast cancer.

Seth Roberts (2012-02-09 17:34:39)

John, several studies have pointed to dairy as one cause of acne. Even in America.

wcb (2012-02-09 18:24:52)

Seth, for me this is a very profound and astute insight. It is also expressive of what I think should be an ideal for real scientific discovery and progress. The caveat here, as I see it, is that the "professional" side of scientific study/ experimentation/inquiry

must be done more honestly and not be influenced or corrupted by special interests and/or those with an axe to grind. All too often, it appears to me that the "professionals" are engaged in the opposite of true scientific method; i.e. the research/inquiry is not conducted with a focus of trying to disprove a hypothesis, but rather to seek a specific result for financial or other material gain. (Have any of those guys ever heard of Karl Popper?) I'm sorry to say that pharma company research / drug development practices come to mind as one glaring example. So at this point I have to side with Jim P. on the virtue of N=1, but I certainly agree that professional science could (and should) be an invaluable aid to progress, but only if the corrupting incentives of \$ \$ can be removed from the equation, or at least attenuated.

Jim Purdy (2012-02-10 11:48:19)

1. Faces ... no Seth Roberts? 2. Quantified Self movement a fad? Hardly, but hopefully all the intrusive gadgets will be a short-lived fad. Henry David Thoreau's book about his time at Walden Pond was a great self-experiment, especially since gadgets weren't distracting him from his self-observations.

Andrey Shestakov (2012-02-15 01:57:46)

Yesterday I watched about half an hour of the talks with bigthink's experts. Today I feel especially well—almost euphoric. The change is very easy to notice. I will look into it further. I must admit that my prior attempts to watch Bloggingheads didn't have any noticeable effect. The difference between Bigthink and Bloggingheads is that I actually enjoy Bigthink's videos a lot more, so I constantly look at the experts' faces. When I watched Bloggingheads I oftentimes looked away, because I usually listened to a podcast instead of Bloggingheads own audio. Because of that, my perception of time spent actually looking at faces may

be skewed.

### **What Is a Good Word For This? (2012-02-10 22:39)**

Can you help me? I am looking for a word – maybe a new word – to describe the transformation of an activity from (a) something done only by trained specialists, as part/all of their job to (b) something done by the general public, not as a job. For example:

- word processing software has made producing an attractive manuscript something that you no longer need hire a secretary to do – you can do it yourself.
- digital cameras and software have made producing high-end photographs something you no longer need a professional photographer to make.
- When I was a graduate student I hired a professional to make publication-quality figures for my scientific papers. Now I make them myself.

The transition I am talking about is part of a longer historical sequence that goes like this:

1. Hobby
2. Part-time job
3. Full-time job
4. Specialization (= division of labor)
5. [new word goes here]
