Between 1995 and 2002, we acquired another series of patients included in our study of fluoxetine treatment for young autistic spectrum children. We determined family history data as before and sought information about family members with special intellectual abilities or attainments, inspired by observing such individuals in many of the families. The abilities most often were scientific, mathematical, or computational but included others (e.g., professor of philosophy, professional musician). Analysis revealed a strong correlation among three groups: autistic probands responding to fluoxetine, family members with major mood disorder (especially bipolar disorder), and family members with special intellectual abilities. In this study, history of major mood disorder (in first- and second-degree parental relatives) was assessed in 151 families. One hundred and eleven families (74 %) had a history of major depression (in 102) and/or bipolar disorder (in 52).

In other words, mood disorders were more common among the relatives of autistic children who responded to fluoxetine (Prozac) than among the relatives of autistic children who did not respond to fluoxetine. I have wondered why autism seems to be increasing. This linkage suggests it may have something to do with the long-term increase in depression.

Mary (MPJ) (2007-10-28 09:06:32)

Always happy to be of assistance. I find the research fascinating because, of course, there is a history of mood disorders and autism in our own family.

KenF (2007-10-28 09:27:50)

I can't help but think that associative mating is part of what is going on with the rise in autism. In the old days "nerdy" girls and boys didn't find each other to mate, but as this becomes more prevalent, we see a rise in autism.

seth (2007-10-28 11:40:04)

The assortative mating explanation of the rise in autism has been proposed by Simon Baron-Cohen, an autism expert. It predicts that something else – whatever you get when you put two non-autism genes together – should also be increasing.

KenF (2007-10-28 12:18:49)

There's a very famous ethnic Chinese math prodigy, out of three children in his family, he is a math genius, one brother is extremely bright, the third is autistic, apparently. Autism may be price that has to be paid to produce certain types of genius. I'd put most of the smartest people I've known somewhere on the "autistic spectrum".

Dennis Mangan (2007-10-28 16:57:13)

God evidence exists for the theory that vitamin D deficiency is responsible for autism. Since vitamin D deficiency is also linked to depression, the correlation described above makes sense. <http://mangans.blogspot.com/2007/10/asthma-diabetes-autism-and-vitamin-d.html>

Donna (2007-10-29 13:03:42)

What about the idea that autism and mood disorders might be increasing because they are related to problems in the birth process, and deaths from these problems have dropped dramatically. Over the twentieth century there was a drop in infant mortality from about 100 per 1000 live births in the beginning of the century to about 7 per 1000 in 2000. Some research has shown autism being linked to using antibiotics and not breastfeeding. People with autism may have benefited more from improvements in antibiotics and formula. I think this makes a lot of logical sense, but has the problem of being counter-intuitive. Greater health leading to more people with disorders!

Carol (2007-12-04 23:13:08)

One of my 2 year old students has recently been diagnosed as having the Autism Syndrome Disorder. The parents of the child mentioned that Bipolar Disorder has been diagnosed in the case of several of this child's relatives. It is also very interesting that these relatives have very high IQs and the child is quite bright, inspite of his autistic tendencies.

Carol (2007-12-04 23:25:35)

My previous comment contained an error: Autism Syndrome Disorder. The correct term is Autism Spectrum Disorder.

## **How Things Begin: The Flynn Effect (2007-10-28 12:19)**

The [1]Flynn Effect is the steady improvement in IQ scores over the last 50 years or so in many places. It was documented by James Flynn, a professor of moral and political philosophy at the University of Otago. Flynn gave a talk at Berkeley recently. I asked him how the Flynn Effect came to be.

Flynn finished college at the University of Chicago in one year (lots of advanced placement) and went on to get a Ph.D. at the same school. His first job was at Eastern Kentucky University. It was during the Korean War; better schools were afraid he'd be drafted. He lost that job because of his CORE (Congress for Racial Equality) membership.

He got another assistant-professor job at Lake Forest. He lost that job because of his socialist views, although "sins" such as assigning readings beyond the set test were also given. He and his wife decided to go to New Zealand, where his politics would be more acceptable. He got a job at the University of Otago, where he has been ever since.

In the 1980s, he started to write a book defending humane ideals. One > question he wanted to answer was how to combat racism. He came across Arthur Jensen's work. Jensen's work was not easily dismissed. It was based on data. To properly answer Jensen, he believed, you needed data – a radical view for a philosophy professor. This was outside his area of training. He asked a professor of psychology for advice. The psychology professor was dismissive; his attitude was "what could you possibly contribute?" But Flynn did not see that psychology professors were substantially smarter than everyone else; the necessary skills should be within his reach, he thought.

He studied the math behind IQ tests for two years. He started looking at data. He looked at IQ test manuals and discovered that the raw scores kept increasing over time. He found six examples. He wrote a paper based on these examples and sent it to the Harvard Educational Review. The editors (who, unknown to Flynn, were [2]graduate students) rejected it. Everyone knows intelligence is going down, one reviewer wrote. This made him mad. He went out and found 14 more examples. With 20 examples, he wrote a paper that was accepted by Psychological Bulletin. The reviewers were stunned, he said, but couldn't find any holes in his case. It appeared in 1984.

Arthur Jensen pointed out that the tests concerned were heavily influenced by education and predicted that a test like Raven's would show no gains. Flynn collected data from around the world (14 nations) and found that the largest gains were on Raven's. The resulting article appeared in Psychological Bulletin in 1987.

Flynn said that only now (in his new book [3]What is Intelligence?) can he give a coherent explanation of the gains.

marmolillo (2007-10-28 13:49:15)

It is a interesting history but the truth is that probably the Flynn Effect is wrong. This article from [1]The Guardian shows a perfect example: same test, same number of children, incredible big and good test group, 15 years of difference.

1. <http://education.guardian.co.uk/schools/story/0,,1693061,00.html>

seth (2007-10-28 16:46:16)

Interesting article, marmolillo, thanks for the link. The study it describes implies that the Flynn Effect is not true everywhere always – but no one expected that. The interesting lesson to be drawn from the facts Flynn found is that IQ depends heavily on environment in mysterious ways. The study the Guardian article describes supports the same conclusion.

What is Flynn effect, and how it came to be? « Entertaining Research (2007-10-28 17:37:02)

[...] What is Flynn effect, and how it came to be? Seth at his blog recounts the story (that he heard from James Flynn himself): In the 1980s, he started to write a book defending humane ideals. One question he wanted to answer was how to combat racism. He came across Arthur Jensen's work. Jensen's work was not easily dismissed. It was based on data. To properly answer Jensen, he believed, you needed data – a radical view for a philosophy professor. This was outside his area of training. He asked a professor of psychology for advice. [...] What's more, these small initial differences are not necessarily even genetic. The children of a good basketball player could end up reaping the same amplifying effect of a small initial difference. It's what William Dickens and James Flynn, after whom the Flynn effect is named, call social multipliers. [...]

## **I Learned that if I Really Wanted To, I Could Conquer My Fear (2007-10-28 23:52)**

In an upper-division depression seminar I taught in 2002 the term project assignment was to do whatever you want related to depression so long as it does not involve library research and is off campus. Several students decided to give a talk about depression to a high school class, including Cindy Voong. She wrote this about her experience:

Five years ago, I graduated from Oakland High School, a public high school with a dominant African American and Asian population. A little over a week ago, I revisited my old high school as a guest speaker for Mr. Tinloy's 3rd period psychology class. It was not as bad as I thought it would be. I was quite nervous and terrified of speaking in front of a classroom full of juniors and seniors, but I made it out alive, and it was a good learning experience.

My friend, a former student of Mr. Tinloy, brought me to his classroom during the break between 2nd and 3rd period, and introduced me. I was pretty nervous. Speaking to teachers and professors always makes my heart beat a little bit faster than normal. I spoke to Mr. Tinloy very briefly. I introduced myself, explained why I was there, and asked him if he would be interested in having me speak to his class about depression. He was very nice. He wanted to know what I planned on talking about, so that he could critique it if necessary. I made arrangements to contact one of the students (I actually knew five of his students, much to my surprise) and get his notes on what they have covered in class so far before I decide what I wanted to talk about. We made a date for when I would come in (April 26), and before then, I was to email him an outline of my talk. That was the first step. Whew!

Shortly after my first meeting with Mr. Tinloy, I contacted Simon, one of his students, and got his notes for the class. After reviewing his notes, which covered articles and brief overviews of what depression is, I emailed Mr. Tinloy a tentative outline of what I might talk about. Now that I look back on it, the list was actually quite long. I don't know what I could have been thinking about. The outline is as follows: different types of depression, symptoms and signs of depression, treatment (both pharmaceutical and therapeutic), theories on why someone might become depressive (maybe including evolutionary viewpoints), depression in childhood and adolescence, suicide, social stigma (political perspective), and what one can do to help a depressed individual.

Before I emailed Mr. Tinloy, I took out all my psychology books and skimmed over the depression sections of the text. They all pretty much went over the same things, so I thought I would give them a review of what I thought they already know. Mr. Tinloy emailed me back that I should plan on about 20 minutes and that I should talk about whatever I felt most comfortable talking about. I was kind of surprised that he did not give me more feedback on what he thought I should cover, because when I spoke to him the first time, it seemed like he would be more critical about what I would talk about, but he was pretty relaxed and carefree about the whole situation.

When I received his email and read 20 minutes, my first thought was, "Yes! Twenty minutes only! I can talk for 20 minutes!" One of my biggest fears is talking in front of a big group. I was afraid that if I were given more time I wouldn't know what to say. Then I looked at my outline and thought, "Uh oh! Revision!" I knew that I could not possibly fit in everything in 20 minutes. So I looked over my list, and decided to focus on the evolution of depression. That was a topic I did not see in neither my psychology textbooks nor in Simon's notes, so I thought something different might be more interesting.

I had originally planned on having overheads, so that all the attention would not be on me, but it was just my luck that Mr. Tinloy did not have an overhead projector. This made my talk even more of a challenge. I was terrified of the idea of standing in front of that classroom and talk for 20 whole minutes. I have given five-minute presentations in class before, and even five minutes was too long for me. I thought I was going to go into that classroom and freeze up. My nerves were definitely working against me.

Mr. Tinloy teaches two psychology classes, 2nd and 3rd period. I was supposed to come in at 9:20 am, the last twenty minutes of 2nd period, and stay for the first 20 minutes of 3rd period. I arrived to the class at 9:25 am, five minutes late. The class was watching a video on autism, schizophrenia, and other psychological disorders. When I entered the classroom, my heart was pumping like crazy. I was so nervous I literally forgot my whole talk. I think Mr. Tinloy sensed how nervous I was, because he asked me if I wanted to start with this class, or if I wanted to wait for the next class. It was up to me. I tried really hard to gather my thoughts and settle my nerves, but I could not. I started to worry that 15 minutes would not be enough time for me to get through everything. Then I worried about what I should and should not talk about with my time limit. The thought of turning off the television, which only half the class was paying attention to, and having their attention turned to me frightened me even more. I was not yet comfortable in the classroom. It was extremely intimidating. I was definitely not ready to speak. I would have only succeeded in making a fool of myself if I decided to speak. So I did what I had to do. I told Mr. Tinloy I will wait for the next class. (Yes, I chickened out!) But I am very glad I decided to wait for the next class. For those 15 minutes, I calmed myself down, and made myself more at home in the classroom. I sat on a high chair in front of the class, getting myself accustomed to being in front of a class. I showed Mr. Tinloy my notes, and he thought that the four evolutionary ideas were interesting. He saw that I had questions I wanted to ask the class, and pointed out that it was really important to engage the students in discussion with questions to keep their interest. So I sat there and reviewed my notes.

When the class ended, and students from 2nd period started to file out as 3rd period started to trickle in, I found it less intimidating to be in the classroom as the students one-by-one came into the classroom than to come into a room filled with students already. My friend, who had introduced me to Mr. Tinloy, was also there to give me some moral support. As the students started to come in, I counted five kids whom I actually knew. At first I thought that it was kind of cool to have them there, and that it would make it less scary. But then it made me a little more nervous, because they were people I knew. What if I gave a totally lame lecture? I would never hear the end of it! So I started to have all these mixed anxieties again.

When class began, Mr. Tinloy introduced me to the class, and the stage was all mine. Thirty or so pairs of eyes looked my way. I smiled, and pretended I was extremely confident, and that I gave talks all the time. I gave them a general definition of depression. The first question I asked them was, "Are you guys familiar with the DSM-IV? Do you guys know what it is?" Gosh, those two seconds of silence was deadly. No response at all. The crowd was dead before I even started! Very, very discouraging! Then someone said, "Yeah." Mr. Tinloy then told me that they kind of went over that. That was my cue to keep going. I read them the DSM-IV criteria for depression to kind of jog their memory a little. I then introduced the topic of my talk: Why depression?

To get them to start thinking about what I meant by "the evolution of depression" and why there is depression in modern society, I posed them with a few questions from Solomon's evolution chapter. Why would such an obviously unpleasant and essentially unproductive condition occur in so large a part of the population? What advantages could it ever have served? Could it simply be a defect in humanity? Why was it not selected out a long time ago? Why do particular symptoms tend to cluster? What is the relation between social and biological evolution of the disorder? Why do we have moods at all? Why do we have emotions? What exactly caused nature to select for despair and frustration and irritability, and to select for, relatively speaking, so little joy?

I pretty much read off these questions, and did not realize that I was reading them off too fast to actually al-

low them time to think about one before I rambled on to the next question. Mr. Tinloy helped me out a bit, and asked that I repeat the first question. So I reread the questions, one at a time, slowly, to allow for discussion if any one questions struck the students at all. Unfortunately, the students were pretty reluctant in participating in discussion. Mr. Tinloy seemed to be the only person interested in what I had to say, and he tried to answer some of the questions I posed, which in itself led me into the next portion of my talk—the four proposed answers to all those questions.

Even though the students were not very responsive, I found myself getting more comfortable talking. Mr. Tinloy was asking questions, and I actually knew the answers! I was so proud of myself for being able to answer his questions with confidence, which made me more confident. I knew more than I thought I knew!

So I went into each of the "proposed answers to the 'why'". I would read off one proposal (e.g. Depression served a purpose in evolution's prehuman times that it no longer serves.), and explain to them what it basically meant, and where such a proposal came from. One thing I feared going into the lecture was that I would be reading off my notes the whole time, and not look at the class, so I decided to go into the classroom with just my outline. I was also afraid that I would freeze up and have nothing to go on if I just had my notes. But I am extremely glad I didn't have everything all typed up, because it allowed me to talk more freely. It also made me seem like I know my stuff. =)

So after each explanation, I would allow for any questions anybody might have. Mr. Tinloy kept asking me question after question, and I kept answering all his questions. I was really enjoying the talk. It was as if we were having a private intellectual conversation. We touched on a lot of interesting things that I had not intended to talk about, so I was extremely glad I had read all those chapters closely! We talked about things from why more females are depressed than males to medication to positive illusion. It was also during this portion of the talk that a couple of the students were starting to participate, so I was really excited. One of the students asked about medication, and getting off medication, so I was really excited to inform them that the myth that getting better meant getting off medication is not true, and that for most people, staying better meant staying on the medication.

For the last portion of my talk, I had four passages from [Andrew] Solomon's hope chapter [in *The Noonday Demon*] that I wanted to read to them, that I thought were very powerful. I wanted to end the lecture on a good note, something they could go home and think about. When I looked at the time, I realized that I had talked too long, and resorted to only reading two of the passages. This portion of the talk seemed to get the most response from the class. I started off asking them what comes to mind when they think about a depressed person. They pretty much gave a similar answer to how Solomon had described it. So I went on to read the first passage:

Psychiatric illness often reveals the dreadful side of someone. It doesn't really make a whole new person. Sometimes the dreadful side is pathetic and needy and hungry, qualities that are sad but touching; sometimes the dreadful side is brutal and cruel. Illness brings to light the painful realities most people shroud in perfect darkness. Depression exaggerates character. In the long run, I think, it makes good people better; it makes bad people worse. It can destroy one's sense of proportion and give one paranoid fantasies and a sense of helplessness; but it is also a window into truth.

I was pleased to find that half the class is no longer falling asleep. They were giving what I said some thought. Some actually responded!

The first passage I skipped was about the interaction between illness and personality, and that a sense of humor and love gives hope. The second passage I skipped was the part about how you are your choices.

I ended the lecture with one last passage from Solomon's hope chapter:

Depression in its worst is the most horrifying loneliness, and from it I learnedâ€¦ So many people have asked what to do for depressed friends and relatives, and my answer is actually simple: blunt their isolation. Do it with cups of tea or with long talks or by sitting in a room nearby and staying silent or in whatever way suits the circumstances, but do that. And do it willingly.

After that, the class clapped, and Mr. Tinloy asked the class if there were any more questions for me. There were a few questions like "What year are you?" and "Are you going to be a psychologist?" but that was it. I was pretty surprised that nobody had any questions about Cal, but I guess those who planned to go to college already know where they are going, and have pretty much become familiar with all the info. When all was done, Mr. Tinloy thanked me for coming, and told me that I did a very good job and that I should come back to visit anytime I wanted.

I walked out of the class with a huge sigh of relief. I was so glad that it was over with. The one thing that surprised me the most was that I kept talking, quite freely, without relying on my notes too much, and for FORTY-FIVE MINUTES! I was also very thankful that Mr. Tinloy was there to guide me through the whole process, and was there to keep the lecture going. I was even more thankful that I was able to answer all the questions he fired at me, because I was afraid I would be unable to answer a question, and the students would look at me and think that I was a flake.

Overall, this was a very difficult, but rewarding experience. I was able to overcome my many fears, and talk! It feels very different being in front of a class, and not in the class, hiding in the crowd, like I tend to do. It did not surprise me much that I got the response I got from the class. Five years ago, I was in their shoes. Guest speakers meant a break from the regular class work, nothing more. Most of them have senioritis, and do not want to do anything anyways. Nevertheless, I went in there hoping for the best. It was very nerve-racking and intimidating at first, but it was not too bad. I was disappointed that I bored most of them to death, but very glad that I held the interest of Mr. Tinloy and at least two students the whole time. I was also very surprised that the students' interest rose toward the end of the talk. It actually turned out much better than I thought it would, at least on my part.

I later on asked my friend for her honest opinion about my talk. She said that my presentation was good, and that I didn't look nervous at all, and that I knew my stuff, but she was fighting to stay awake, because the topic did not interest her one bit. She is a business major, and had no idea what I was talking about. She thought I did a better job that she expected.

I also asked one of the students I knew from the class what she thought. She said pretty much the same thing, that I did a good job, but that it was boring because she wasn't all that interested in what I was talking about, but it got more interesting toward the end when other students started to talk. "Nobody likes guest speakers, so it's okay." I don't know what to make of that. Is that a good thing or a bad thing?

I have always found high school students a very intimidating group to work with, because they are on the verge of adulthood, yet not quite mature enough. I don't know if it is because of the high school that I went to, but I find that high school students think they are on top of the world, and that they know everything, so they tend not to listen to adults as much as kids or even other adults would. Students in high school are there because they have to be, so not everyone is there because they want to learn. That is why I have to agree with Solomon when he said that it is easier to talk to a room full of psychologists than it is to talk to a room full of high school kids. With a room full of psychologists, you at least know that they will be interested in hearing what you have to say. This whole experience reconfirms my decision to stick to teaching grade school kids after graduation. Third and fourth graders are more likely to listen to what I have to say, and they are shorter than me. However, seeing Mr. Tinloy interact with his students make it a little less scary to teach in a high school setting. Mr. Tinloy seems to have a very comfortable and

close relationship with all his students. It is that bond that he developed with his students that made them respect and listen to him. If ever I was to teach at a high school, I think I would definitely have to adapt Mr. Tinloy's style of teaching.

Have I changed as a result of this class project? In a way, I have. I learned that if I really wanted to, I could conquer my fear, and do what I have to do. Speaking in front of any kind of crowd has always made my heart pump like there is no tomorrow. Forcing myself to speak in front of a high school class made me realize it's not as bad as I thought it would be. As long as I can put my fear aside, and carry some confidence, I can talk forever! (Well, you know what I mean.) And the most important part of having that confidence is knowing your stuff! Being able to answer questions is the biggest confidence booster there is. I think I will use this as an example for future reference. I know that this will not be the last time I have to give some sort of presentation in front of a group, and it won't be the last time that my heart starts racing when I get in front of a crowd, but I will be able to remember this experience, and tell myself, "It's not that bad."

I was enormously impressed by this paper. Not only by the pragmatism and courage she had shown, but also by the realization that conventional college assignments, including mine, would never have revealed she had these strengths.

### **My Theory of Human Evolution (early value system) (2007-10-29 06:02)**

From a [1]review of [2]The Surgeons: Life and Death in a Top Heart Center by Charles Morris:

For better or for worse, the quality of health care is driven by what Morris calls an "artisanal" value system, one that has little to do with institutional allegiances or administrative management objectives, but rather with "internalized systems of ethics and the expectations of other professionals."

My theory of human evolution says it started with hobbies. Hobbyists became artisans. It hadn't occurred to me that an "artisanal" value system exists but what Morris says makes sense. Such a value system should be powerful, easy to spread, and hard to eliminate.

3. <http://www.ajcn.org/cgi/content/abstract/55/2/350>

---

James (2007-10-29 16:41:52)

To me, Taubes missed another major flaw with citing Hirsch and Leibel – the study's minimum calorie proportion of carbs was 15 %, and all carbs were from celerose, which appears to be a form of glucose. So, if my math is right ( 9500kJ/d total \* .15 carbs / 16.7kJ/g = 85g carbs/d), even the "low carb" group was getting 3 ounces of straight glucose a day. I don't know the biology, but that seems like a lot of glucose; perhaps enough that higher doses would have no effect on the subjects.

David (2007-10-30 05:18:43)

I also find the Leibel et al. study of limited relevance because patients appear to have not been allowed to regulate their own food intake. Part of the reason low carb diets might work is that people who are sensitive to insulin are less hungry on them. There are several ways in which "a calorie is a calorie" as it is popularly understood might not hold.

James (2007-10-30 05:30:46)

I also think Taubes understands and believes in the set point concept – he cites the work of Sims and other related to set points – but he avoids "set point" because it's become a loaded term. Cabanac is right that there's widespread confusion between a set point and a reference, and, when it comes to obesity, Kolata and others have popularized the idea that set points are fixed and/or uncontrollable. Since Taubes' whole thesis is that permanent weight loss is possible, he implicitly agrees that set points are adjustable. What struck me when reading the book, particularly the description of how insulin drives hunger, is that SLD, at least in its oil form, is something of a stealth low-carb diet. The two-hour window around the oil essentially makes it a meal with a minimal insulin response, so one is guaranteed to be in a low-insulin state (no hunger, no carb cravings, etc.) once or twice a day. I also suspect that nearly all SLDers eat fewer carbs than they did before starting the oil. I have no idea how much of an effect this has, but I think it's worth considering that carb restriction might play a role in SLD.

seth (2007-10-30 05:51:26)

James, it turns out that Taubes does discuss the set point concept (pp. 427-428). He doesn't believe it ("the concept of a set point or a lipostat has little precedent in physiology"). When you do SLD by drinking sugar water, it is obviously not stealth low-carb. That the sugar water and flavorless oils produce roughly the same effect per calorie implies that carbohydrate reduction has nothing to do with the effect.

James (2007-10-30 07:36:17)

Professor Roberts, you're absolutely right, I'm confusing set-point-like local equilibria (which Taubes buys into) and a centrally controlled set point for adiposity (which I had forgotten was part of the SLD book). FWIW, my own self-experimentation has shown that sugar water is not as effective for me as oil when it comes to appetite suppression. (I really wanted sugar water to work, too – it would be much easier when travelling.) In fact, my first attempt with SLD was with sugar, and I had little AS in two weeks; a few months later, I tried the same number of oil calories, and started feeling the effects within days. To put this

in context, I started out quite heavy (365 lbs.) and I stopped eating refined carbs after starting oil-based SLD (it became very easy to do so), so I may be atypical.

Josh (2007-11-11 17:41:11)

I read Taubes' book awhile back and remember wondering about its relation to SLD. If I remember correctly, he dismisses the set-point theory, but goes on in the next few pages to discuss research linking an initial surge in insulin to the taste of food. I thought this actually dovetailed nicely with SLD, with low-flavor food diminishing the response/association. So maybe SLD isn't stealth low-carb, but is stealth low-insulin response. Admittedly, the sugar water is somewhat problematic for this hypothesis, but perhaps Dr. Roberts is right in thinking that sugar water that doesn't have other flavor is treated differently than sugar water with added flavor. In this case, the difference would be insulin response.

### **jobbook.org: up and running (2007-10-30 08:03)**

[1]jobbook.org, a website to help students choose careers, is up. [2]Aaron Swartz and I have been working on it for several months. We hope that it will eventually contain lots of first-hand information about jobs so that students (and anyone else) can learn what the jobs they are interested in are really like. Aaron has called it an "encyclopedia of jobs."

To decide what to do, Aaron and I visited several schools around the Bay Area. At San Francisco State, a nursing student said, "I'm a nursing major, but I barely know what nurses do." When I was in school, I could have said the same thing: By deciding to go to graduate school in experimental psychology I was choosing to become a "professor major" but I knew little about what professors did. Even as a graduate student I barely knew what they did. This reflects a truth about modern life: It is hard to learn what jobs are like. You can do an internship, but schools like UC Berkeley don't make that easy. And internships take a lot of time. The goal of jobbook.org is to provide the same information much more easily.

jobbook.org is a wiki – a Wikipedia-like website than anyone can edit. We hope that people on both sides – people with job knowledge and people who want job knowledge – will contribute.

If you have a job (any job!), we hope that you will offer to be interviewed about it. (To make that offer, just add your job, location, and contact info to the [3]home page.) You don't need to wait to be interviewed: You can simply describe an actual day of your job and add that description to the site.

If you are interested in learning about any job, we hope that you will request an interview. (To make that request, just add the job and your contact info to the [4]home page.)

We hope that these offers and requests will produce interview transcripts that will be added to the site. If you know of a helpful link (such as a book or magazine article), we hope you will add it.

Last night, there was a meeting for interested students in the Channing-Bowditch (a Cal dorm) lounge. I expected no one to show up. Four people did. Next meeting: next Monday (Nov 5), same place, see home page for details.

Sabine Alam, Khoi Lam, and Michelle Nguyen are the Advisory Board who have been giving Aaron and me sage advice. Thanks to them.

Charlie (2007-10-30 12:03:59)

Hi Seth! This is why there was no point to us doing things stealth... because if you we have a good idea, chances are, there are some smart people who are thinking about it at the exact same time... .and... here you are! Someone just left a comment about what you're up to on our blog... <http://blog.path101.com>. We're building a company around exactly what you've come to... that students, and really many other people, simply don't know what's out there to be done. Would love to chat sometime and see if there's a way to work together.

lasser11 (2007-10-30 20:53:00)

great idea. college students need to be more proactive in finding their career. But it is understandable why young people feel less urgent in finding a career now in comparison to 30 years ago. it has to do with the job market being more fluid and less receptive to college grads in their 20's. All of this ties into the growing inequality debate. Businesses are finding it much easier to reward their more productive employees, which is likely to be baby boomers with mba's and years of experience. businesses simply find it less financially rewarding to invest money into 25 year olds. so college students have less incentive to quickly find a career more now then 30 years ago. And this encourages college grads in their 20's to experiment more in different job fields.

lasser11 (2007-10-30 21:09:32)

I don't know if I was clear. personally, I chose a career path right out of college. And to be honest, I don't think I'm making too much more money than my friends who experimented in different job fields. bottom line: I can't wait for the baby boomers to retire to open up some upper level positions.

News » 2007 Review of Projects (2008-02-22 23:28:07)

[...] JobBook: Intermediate. An initial site is launched but I have not spent a lot of time on it nor is it progressing rapidly. Other people are pursuing it, though, so I feel less pressure. [...]

## **Why I Don't Hire College Graduates (2007-10-31 03:33)**

A 1924 magazine article called "[1]Why I Never Hire Brilliant Men" contains this:

Every year I picked up a half-dozen live young fellows who seemed to have a capacity for hard work, and shoved them in at the bottom of the pile, letting them make their way up to the better air and sunlight at the top - if they had it in them to do it. For a time I tried picking these youngsters out of the colleges. But my experience with college men was not fortunate. If I selected good students, I found too often that their leadership had been won by doing very well what their teachers had laid out for them. They had developed a fine capacity for taking orders, but not much initiative.

The notion of not hiring college grads now seems absurd, perhaps because the fraction of people who go to college has gone way up. But it's hard to believe that the selection pressures operating within colleges have changed. College professors are still a tiny fraction of the population.

I came across this magazine article randomly browsing but this quote is another way of saying what two of my recent posts – my student's [2]term project about overcoming stage fright, and [3]about [4]jobbook.org – were about. If most people must spend four years in a place (college) where those in charge (professors) value only a small fraction of their abilities, a lot is lost.

Pearl (2007-10-31 04:29:07)

This is really quite interesting; actually I think it was this type of mindset that caused a number of my family members to be quite opposed to me spending money on a college education, particularly one in music. Whereas most of my peers in the music school couldn't fathom their parents not having supported them the entire way through their musical upbringing. My family is mostly comprised of self-made men who never got college educations; a local politician, a self-taught plumber, and a military senior-master sergeant. It sounded absurd to them for me to invest in a college career, which would have caused me to go against everything I had learned in high school about having a career. It is curious to me why a college degree is so important now as opposed to then. I couldn't have gotten this cushy English teaching job if I hadn't had one because what are you if you haven't got a paper to prove you're something? Of course the tragic thing is that classical music has gone so downhill in America, that most of my generation are chasing a hell of a lot of pipe dreams. The only way to get a job now is to be willing to move anywhere in the world, preferably Europe where musicians are government-paid and receive great benefits.

Bob (2007-10-31 07:40:54)

I wish I hadn't gone to college & grad school.

Chris (2007-10-31 12:45:17)

A B.A. in the 1920s would be equivalent to an advanced degree today - at least in terms of status. I'm sure you can imagine someone preferring to hire B.A.s/B.Sc.s rather than grad students. They may or may not be brighter than the grad student, but they've opted to join the workforce earlier rather than later, which may suggest something about their character. A fair number of very bright, original thinkers don't have university degrees: think Robert Fulford and, oh yes, Jane Jacobs. That's going back a bit, mind you. I wonder if, nowadays, Jacobs could make a career with just a highschool diploma. Maybe: she worked her way up as a freelance journalist, and in journalism, as in sales, you're judged on what you produce, not on what your credentials say you ought to be able to produce. (J-schools have corrupted high-end journalism to some degree, especially in your country, I'm afraid.) "Fortunately my high school marks had been so bad that Barnard [College] decided I could not belong to it and I was therefore allowed to continue getting an education."

Chris (2007-10-31 12:46:40)

That last paragraph was an irresistible quote from Jacobs.

Mia (2007-10-31 15:06:38)

In response to the final line of this blog entry: "If most people must spend four years in a place (college) where those in charge (professors) value only a small fraction of their abilities, a lot is lost." It just strikes me odd that the writer thinks that professors are in charge. If I had believed that, college would have been hideous. As it was, I thought the whole thing was fun. Especially amusing: assignments. You can learn without being obedient. Silly rabbit.

Pearl (2007-10-31 20:26:57)

If professors are not in charge, who are you proposing is in charge?

### **Omega-3 and Dementia (2007-10-31 12:52)**

A [1]new study has found that older people with less omega-3 in their blood are more likely to suffer from dementia. The study involved about 1000 persons 65 or older randomly sampled from two Italian towns. They were given mental tests and divided into three groups: no cognitive impairment; cognitive impairment but not demented; and demented. In addition, their blood was measured. Worse mental function was more strongly associated with total omega-3 fatty acids ( $p = .01$ ) than any of the other fatty acid measures.

One more reason to think that consuming more omega-3 might improve your brain function.

1. <http://biomed.gerontologyjournals.org/cgi/content/abstract/62/10/1120>

---

Joanna (2007-11-01 08:26:11)

This is another good reason to take Fish Oil or Flaxseed oil daily.

Dennis (2007-11-01 09:55:26)

Do we know that taking supplements results in higher levels of omega-3 in the blood?

Dennis (2007-11-01 09:56:07)

And is there some threshold effect, where if your blood levels are above X then adding more Omega 3 does not help?

peter (2007-11-01 19:34:49)

the study emphasizes the deficiency of alpha-linolenic acid levels in people with dementia. Flax seed oil is especially high in alpha-linolenic acid. the benefit of fish oil is that it is higher in DHA. as i recall it ALA can be converted into DHA, but it takes a lot to produce a relatively small amount of DHA.

Lancaster (2007-11-02 11:38:24)

Positive omega-3 story from NPR. Also an explanation (at the end of the audio version) why there's no mercury in fish oil supplements (it's refined and distilled). <http://www.npr.org/templates/story/story.php?storyId=15823852>

## **2.11 November**

### **Mark Todd, the Cheese Dude, on Gourmet Food Business (2007-11-01 17:14)**

[1]Mark Todd (thecheesedude at aol dot com) is a cheese expert who lives near the Russian River. Today he was in a local store demoing a cheese ([2]Chiantino) that [3]he and his business partner import from Germany. We had a long and utterly fascinating conversation. He has met most of the chefs who appear on the Food Network. His favs:

The best cook: Jacques Pepin "hands down".

The most knowledgeable food expert: [4]Alton Brown. "He knows ten times more than all the rest of them put together."

How did he become a cheese expert, I asked. "Persistence," he said.

The details of that persistence were not what I expected. When he was 30, his dad, who was 58, died of a massive heart attack. At the time, he was a lawyer. He hated it. What do I really want to do? he wondered. Something with food. He and his wife moved from crowded Palo Alto to near the Russian River. At a food event in the months that followed, he met someone who was paid to carve cheese. Wow, you can get paid for that, he thought. He asked the guy if he needed help. No, he didn't. He and his wife hung out with the guy and his girlfriend. Several months later, the guy told him he needed help at an upcoming event in Monterey. He went down and helped and was paid \$500/day in addition to free hotel for him and his wife and conference admission (usually \$750). After the conference, he contacted the guy's boss. "I want to do this," he said. "What do you know about cheese?" he was asked. "Nothing," he said. "Well, then you're no use to us," he was told. Two weeks later he called the boss again. "I've read four books about cheese," he said. "Do you have any work for me?" No, he was told. "I really want to do this," he said. He called the next day. And the next day. And the next day. And the next day. And the next day. Finally the boss said, "I get it. You really want to do this." And he was hired for six figures a year to go here and there and talk about cheese. Now he works for many cheese organizations. Next week he's going to China to teach them about California cheeses.

I told him I was interested in how people come to appreciate "fine" food. Exposure, he said. "Are some exposures more powerful than others?" I asked. "Peer exposure," he said. When he was a sophomore in college (at Cal Poly, San Luis Obispo), he didn't like beer. He decided he wanted to learn about wine. One of his roommates had been to Napa and come back with notes. Teach me about wine, he said to his roommate. It takes time, his roommate said. They decided that Wednesday would be Wine Night. Every Wednesday for the next two years, he, his roommate, and another guy went to Safeway and bought three versions of the same varietal - e.g., three Chardonnays. Then they did blind tastings. His palate became better than most of the guys in the wine business, he said. Side-by-side tastings are crucial, he said. If you taste 500 cheeses on 500 different days, you won't know much. But if you taste those cheeses side by side, you'll learn a lot.

As wallpaper patterns, store displays, and millions of graphic designs reveal, we like to see similar things side by side. I have blogged [5]here, [6]here, and [7]here about side-by-side comparisons and human evolution.

His email address is given above.

## **The Preposterous Files (2007-11-02 04:37)**

The BBC has a most intriguing radio show (on Radio 4) that they are curiously hiding from potential listeners. It is called "[1]The Preposterous Files" and is about "cases that show up Civil Service bureaucracy." It was on their [2]Listen Again page yesterday but was taken off yesterday. Its Listen Again button (pre-disappearance) replayed a segment about fiddling, alas.

So far there have been 5 shows. Perhaps that's all there will ever be. (How unfortunate!) Here are their topics (taken from the show's [3]archives):

1. Deciding on the design, location and function of the police telephone box proved a dauntingly complex process. One difficulty was that most of the public had never used a telephone.
2. In 1900, the North of England press began to report a mysterious epidemic that was affecting thousands of beer drinkers. The medical profession declared that it was an outbreak of peripheral neuritis provoked by excessive alcohol consumption, but a sceptical chemist, working alone from a makeshift laboratory, thought otherwise.
3. In 1912, cost-conscious HM Customs replaced Falmouth's steam launch with a former sailing boat fitted with an auxiliary motor. Unfortunately, the motor proved unable to cope with the strong currents off the Cornish coast.
4. In 1954, stevedores reported finding an unconscious young man on board a Polish ship berthed at Bermondsey Docks. Was he an asylum seeker or a stowaway?
5. The transcript of the court martial of Flying Officer DR Kenyon, who retracted his plane's undercarriage whilst still standing on the runway prior to taking off for a bombing mission during the 1956 Suez crisis, makes extraordinary reading.

1. <http://www.bbc.co.uk/radio4/thepreposterousfiles/>
2. <http://www.bbc.co.uk/radio4/progs/listenagain.shtml>
3. <http://www.bbc.co.uk/radio4/thepreposterousfiles/pip/archive/>

Ben (2007-11-02 05:32:06)

Use this link for the latest show: [http://www.bbc.co.uk/radio/aod/radio4\\_aod.shtml?radio4/preposterousfiles](http://www.bbc.co.uk/radio/aod/radio4_aod.shtml?radio4/preposterousfiles)

seth (2007-11-02 05:51:17)

Thanks, Ben. When I go to that link I get the same wrong program I got yesterday – Highland Hip, a segment about "young musicians with new takes on traditional music." Pretty interesting, I admit.

Matthew Henty (2007-11-03 17:30:55)

Seth, It could be because the BBC listen again facility is often limited to seven days only, or just the most recent show. Quite annoying! Q & A here: <http://www.bbc.co.uk/radio4/help/index.shtml#question2>

## **Is Nutrition a Science? (2007-11-02 21:15)**

In [1] John Tierney's blog, Gary Taubes is very critical of nutrition researchers:

The last place you want a science to find itself is where obesity research is today, with hypotheses of causation that can explain none of the pertinent observations, but yet are believed so fervently that no one can challenge them without being ostracized or declared a quack.

Fair enough. But Taubes (and Tierney) make the usual mistake of being too critical and not enough appreciative. I figured the real wisdom would be in the comments, and I was not disappointed. Taubes thought physics functioned better than nutrition. One comment:

It's not that the scientists [in physics and nutrition] are any more or less skeptical, or that it takes any longer for the truth to emerge, it's that the public is more likely to be paying attention [to nutrition] in the meantime. And human beings as a group are extremely bad at reasoning under uncertainty.

Quite right. If Taubes and Tierney have trouble seeing the big picture (although Good Calories Bad Calories is a big-picture book) surely most people, and other journalists, do much worse. Another comment:

People like the old "correlation does not equal causation" slogan, but it's not correct to translate that as "correlations are completely uninformative,"

Well put. (I [2]blogged about this.) My favorite comment, however, was not wise:

Tierney stresses the errors and biases of nutrition science - but what of its successes? [Good start.] . . . As Tierney surely knows, there is a solid body of research that cumulatively demonstrates the positive effects of a balanced diet, lots of fresh fruit and veggies, avoidance of saturated fats, moderate consumption of calories and regular exercise. This is common sense, and science backs it up.

The history of nutrition teaches the opposite. The most helpful findings have not been "common sense". Folate supplementation greatly reduced birth defects. Not common sense. Eat oranges to cure scurvy: Not common sense. Pellagra due to nutrition rather than infection: Not common sense. The whole notion of vitamins: Not common sense (deficiency diseases were attributed to poisons). "Common sense" approaches to losing weight, such as "moderate calorie intake": Failed miserably.

It's true that [3]traditional foodways often turn out to be very healthy, but they can't be called "common sense" because they vary so much from one place to another.

Thanks to Dave Lull and Tim Beneke.

1. <http://tierneylab.blogs.nytimes.com/2007/11/01/is-nutrition-science-not-really-science/>
2. <http://www.blog.sethroberts.net/2007/02/10/what-should-correlation-does-not-imply-causation-be-replaced-with/>
3. <http://www.westonaprice.org/>

---

James (2007-11-03 05:59:45)

Well said. I see two problems with nutrition research: \* No hope of doing truly controlled experiments in humans. Yes, correlation tells us something, but it would be really nice to be able to say effect X happened because people ate more or less Y (for various values of Y – saturated fat, carbohydrates, etc.). In physics, an experiment can show which of two conflicting theories is correct, but similar experiments in nutrition are infeasible because you aren't allowed to totally control a person's food intake and see the long-term results. \* Terribly muddled communication with the general population. I've had "informed" people tell me that cane sugar is a "good for you" whole grain and that frozen vegetables are "bad for you". The relentless focus on marginal optimization and fringe beliefs has caused people to miss the fairly uncontroversial big picture. Many different diet plans (including SLD and even the later phases of Atkins) can be made to fit with the "conventional wisdom" of [1]Willett's food pyramid.

1. <http://www.hsph.harvard.edu/nutritionsource/pyramids.html>

seth (2007-11-04 12:30:49)

I agree. Except you can do well-controlled experiments when a nutrient affects the brain because you can maintain control for a short period of time and the brain reacts rapidly. My omega-3 research is all about that.

## **Better Nutrition, Better Behavior (2007-11-03 05:28)**

[1]Here is an abstract of an enormously interesting and already famous 2002 study of the effect of better nutrition on the behavior of prison inmates. The supplements included omega-3 fats.

The study was very innovative and no doubt extremely difficult. About as far from studying lab rats or college students as you can get. Here are the key results:

Those who received the active capsules committed on average 11.8 infringements per 1000 person-days, a reduction of 26.3 % (95 % CI 8.3-44.3 %) compared to those who received placebos. This difference between groups was statistically significant at  $P < 0.03$  (two-tailed).

In spite of a huge effect – huge at least in practical terms – the statistical significance was marginal. There isn't anything wrong with that, it indicates that we need a way of studying these very important issues that isn't incredibly hard. Of course the "easy" method will be "deficient" (according to overly critical critics) in a dozen ways; that's the price you pay. The authors of this article don't entirely understand this point. "Further investigations should include assessments of nutritional status from blood before and during supplementation," they write. Uh, no, you don't always follow a very difficult thing by trying to do an even more difficult thing.

Nothing is said about the difficulty of the study, which is extremely important, in this report. The difficulty of a scientific study is always important but almost always goes unmentioned in scientific articles. If you (the reader) have done similar studies you can guess okay but with an innovative study like this few readers could have any clear idea.

[...] Better Nutrition, Better Behavior [...]

## **Omega-3 Without Fish (2007-11-03 18:07)**

[1]Here is a very important omega-3 paper, titled "High Omega-3 Essential Fatty Acid Status in Nigerians and Low Status in Minnesotans," that a reader named Melissa linked to in the [2]comments. It shows you can have much more omega-3 in your blood than Americans even if you don't eat fish.

Rural and urban Nigerians had similar omega-3 levels. Here's what they eat:

The major carbohydrate-rich staples are the starchy tubers such as yams, cocoa-yams and cassava, the cereals rice and maize, and minor foods such as plantains and bananas. The major protein staples include legumes such as beans and pulses, seeds, nuts, cereal proteins and leaf proteins, some of which are rich in 18:3w3. Animal protein sources such as milk and eggs are virtually nil for rural communities, and are very limited for the urban population. Meats and fish . . . are in limited supply. Crayfish and dried fish are important but cost constraints limit intake.

The effect:

Nigerians have more than twice as much essential w3 EFA in their plasma lipids as do Minnesotans.

There was a negative correlation between blood levels of omega-3 and blood levels of omega-6. Perhaps raising omega-6 levels lowers omega-3 levels, even when the amount of omega-3 in the diet is constant. The theoretical mechanism is competition for the same enzyme. I haven't yet studied this via self-experimentation; I will.

Thanks, Melissa.

1. <http://www.epress.com/w3jbio/vol2/holman/holman.html>
2. <http://www.blog.sethroberts.net/2007/07/14/omega-3-i-can-see-for-myself/>

---

Dennis Mangan (2007-11-03 21:38:57)

Interesting: the Nigerians are eating a very low-fat, high-fiber diet, just what Taubes thinks is all wrong.

seth (2007-11-03 21:51:47)

Taubes dislikes refined carbohydrates, such as bread and sugar. I don't think he dislikes high fiber foods.

James (2007-11-04 05:54:21)

I don't think the article mentions relative macronutrient intake, so it's hard to know what to make of most dietary fat being in the form of palm oil, which is high in saturated fat and has a [1]45:1 omega 6:omega 3 ratio.

1. <http://www.nutritiondata.com/facts-C00001-01c208E.html>

## **New Evidence for the Aquatic Ape Theory (2007-11-04 05:31)**

When I watched [1]Planet Earth, I was impressed that the most successful aquatic animals were mammals (whales and dolphins). Fish had had a huge head start. Mammals such as whales and dolphins had moved back into the water after long evolution on land. Something promoted by terrestrial evolution allowed them to dominate their new world. That "something" is probably learning ability, although research on whale learning has yet to be done.

This is one reason the aquatic ape theory of human evolution makes sense. Judging from whales and dolphins, a little brain power can go a long way. Early humans had not only brains but hands. The combination made sea creatures extremely vulnerable. The threat was so flexible and different than previous threats they couldn't tweak a few genes and escape. To take advantage of this new food source, humans had to wade into the water – the presumed initial reason (by those who believe in the aquatic ape theory) for bipedality.

Anthropologists at Arizona State [2]recently reported evidence that early humans did indeed live on coastlines, with

ready access to fish and shellfish. Other researchers had found evidence of this as early as 120,000 years ago; the new evidence pushes the date of earliest coastline habitation even earlier, to about 160,000 years ago.

“We also found what archaeologists call bladelets “ little blades less than 10 millimeters in width, about the size of your little finger,” [one of the anthropologists] says. “These could be attached to the end of a stick to form a point for a spear, or lined up like barbs on a dart “ which shows they were already using complex compound tools.”

If you have watched Survivor, you will remember tools much like that being used to catch fish.

Thanks to Michael Vassar.

new evidence in favor of the (exceedingly awesome) aquatic ape theory « Onwards and Forwards (2007-11-04 06:39:24)  
[...] new evidence in favor of the (exceedingly awesome) aquatic ape theory Filed under: evolution, science — eenauk @ 14:39  
Ok this has nothing to do with ethics or religion, but i'm a big fan of the aquatic ape theory. Seth points us to new evidence from the University of Arizona that our ancestors were coaxed by watery ways into the beginnings of human evolution. [...]

Varangy (2007-11-06 13:52:18)

*When I watched Planet Earth, I was impressed that the most **successful** aquatic animals were mammals (whales and dolphins). Fish had had a huge head start. Mammals such as whales and dolphins had moved back into the water after long evolution on land. Something promoted by terrestrial evolution allowed them to **dominate** their new world. That “something” is probably learning ability, although research on whale learning has yet to be done. I think you are subjectively anthropomorphizing. Define what you mean by *successful* and *dominate*. It is not clear to me.*

Marc Verhaegen (2007-12-30 17:35:30)

For recent discussions & links on AAT, please go to <http://groups.yahoo.com/group/AAT> or google “aquarborneal”.

seth (2007-12-31 17:43:43)

Whales dominate in the sense that they are huge and eat others but are not themselves eaten. Top of the food chain, in other words. Similar for dolphins. They eat a vast number of fish that cannot eat them.

## Improving SLD (2007-11-04 11:47)

John Tukey once said that a good way to have new ideas is to tell others the ones you have already. This was part of why I wrote The Shangri-La Diet: It would be much easier to get better ideas about weight loss if I told people the ones I already had. Call it open source weight control.

I think it's working. In the SLD forums, Sean Curley, who tried SLD before the book (thanks, Levitt & Dubner!), made this [1]brilliant post:

Two years ago (before the book came out), I lost about 27 lbs on SLD, using fructose water. In hindsight, I probably lost too much weight going from 183 lbs to 155 lbs (I'm male, 6' 1"). I stopped doing what had worked, and got sloppy about SLD in general, and put most – but not all – of it back on over the course of a year or so. So, now I'm doing it again, but having read about how hepatotoxic and lipogenic fructose is, started doing oil instead – ELOO, Walnut Oil and Canola, usually mixed in equal parts, and usually not breathing through my nose when I drink it to avoid any flavor at all.

My MO, historically, and what worked well for me, was doing – don't gasp – 750 calories/day of SW (previously) and then oil (more recently). Both worked well, although truth be told, I think SW worked even better. Because of my concerns about fructose, and sugar in general, that's not really an option for me anymore. My one concern about SLD has always been, am I replacing too many regular, "nutritious" calories with calories that aren't? (Although I am aware of the healthy benefits of the oils.) I have tried various protein powders – whey, rice, and some soy – with noseclips followed by a mouth rinse, but haven't had good AS with that (maybe negative AS, actually). Not sure if it's too much residual flavor, too "simple" in its form, but for whatever reason, they just didn't work well for me. Also tried Tim Beneke's flavorless mush balls, but too much of a hassle, and just a little awkward for me.

I've always wondered if "real" protein in some flavorless, non-processed form wouldn't be even more effective, but for some reason, I never got around to trying it until three weeks ago. I thought that eating full-fatted cottage cheese, which is very high in protein, and pretty bland, with noseclips on, might be worth a try. And, wow, did it work! My approach to SLD has always been to have the first 750 cals of my day as flavorless, going to dinner time on nothing but flavorless calories – as needed, in 50 calorie "doses" (oil or SW), and then allowing myself to eat whatever I wanted after that. But, it usually took 750 calories to get me there, sometimes a little less, but not usually. So, 750 flavorless calories was my "benchmark."

The first day I tried the nose-clipped cottage cheese, It took only 420 calories to get to dinner time, with a MUCH greater feeling of fullness and AS than I had ever experienced on SLD. That effect has held consistent for the last two or three weeks, sometimes needing as few as 360 cals to dinner, but never more the 560, although usually 425 is the number. That's a substantial reduction (43 %) in the number of flavorless calories required to get the same (probably better, actually) AS effect. Then, two days ago, I thought: I wonder how bland, plain chicken breast meat would work? (again with noseclips). The answer, after two days, appears to be even more effective –more on the order of 360 calories required to get the same effect.

In both cases, I use nose clips, and typically eat about 60 cals at a time, as needed for hunger, AND I rinse my mouth out two or three times before I take the noseclips off to wash out any residual flavor.

For me the effect of going from oil to flavorless "real" protein has been as remarkable as the effect I got from going from pre-SLD to SLD originally.

As I posted there, the theory behind SLD is all about regulation of energy storage. You want to store neither too little nor too much – and you want to store more when food is cheap. But food is more than energy. It is also building blocks. Which means protein, mostly. So it is quite plausible that there is a whole regulatory system designed to get the right amount of protein. Sean's observations suggest exactly that.

Besides the conceptual plausibility the details of the new method are excellent:

1. The raw materials (cottage cheese and chicken meat) are readily available and easy to eat.
2. The notion of eating the first calories of the day flavorless and then anything for dinner matches what's clear about self-control: We have a lot more earlier in the day. This method uses self-control when it is plentiful and not when it is scarce.

I'm not going to stop drinking flaxseed oil (nose-clipped). But I am going to try adding chicken meat (nose-clipped).

---

Claire Bickell (2007-11-04 15:24:10)

Catalyst reported on research suggesting that protein is a key factor in how much we eat. I found it interesting and it made me wonder how such research might integrate with set point theory. [http://www.abc.net.au/catalyst/stories/s\\_2069308.htm](http://www.abc.net.au/catalyst/stories/s_2069308.htm)

John (2007-11-04 15:44:27)

Very cool post. Instead of salting my morning eggs, I'm going to try eating them unseasoned with my nose clipped.

SusanJ (2007-11-05 11:22:11)

Is this guy eating a mouthful of cottage cheese seven times a day? I thought with SLD you should only have to take the flavorless calories once. It sounds more like he's getting AS by keeping his blood sugar under control rather than how SLD supposedly works.

SFC (2007-11-05 14:37:36)

Yes, that is what I am doing. That has been my MO all along with SLD, even when doing oil or sugar water . . . using it throughout the day as opposed to just one or two times a day. What's interesting to me, though, is how much more effective the cottage cheese and chicken are than just the oil or sugar water.

LemmusLemmus (2007-11-06 09:14:39)

"The notion of eating the first calories of the day flavorless and then anything for dinner matches what's clear about self-control: We have a lot more earlier in the day." Quite a claim. Do you have a cite for the assertion that self-control is easier in the morning (preferably controlling for alcohol consumption).

seth (2007-11-06 12:36:49)

No, no citation. I've noticed it in myself and others – unprompted – have said the same thing. One documented assertion, although I can't give you a reference, is that people eat a large fraction of their calories in the evening. That seems to be when dietary control breaks down.

Patri Friedman (2007-11-12 17:54:49)

Hi. My experience w/ SLD was that the effectiveness of any source of calories decreased over time, presumably because I got enough flavor to develop some association. This theory seems to fit Sean's case, and is an alternative to the hypothesis that cottage cheese or chicken are any more efficient than oil for SLD. That said, nose clips + washing mouth out with water is more than I have ever tried, so I will try that and see if I get a slower efficiency decay. On a totally different note - Hey Seth, have you tested / written much about using fish oil for SLD to get maximum omega-3s? I've been using Carlson's fish oil on and off, figuring that whether or not it works for SLD (due to having noticeable flavor) I'm getting tons of omega-3s. I'm also curious whether there is such a thing as "too much" omega 3. For the outcomes you self-study, at what dose does the response taper

off? How much becomes dangerous due to too little clotting?

seth (2007-11-12 19:37:37)

I don't think sugar water has any flavor at all. And its effectiveness did not noticeably decline over the three years I used it. I've haven't tried using fish oil for SLD. I tried different amounts of flaxseed oil and found that while 3 tablespoons/day was clearly better than 2 T/day, 4 T/day was not clearly better than 3 T/day. Now I do 4 T/day to be on the safe side. I'm assuming what's close to optimal for the brain will be close to optimal for the rest of the body – because the whole structure was shaped with the same amount of omega-3 in the blood.

Igor Carron (2007-11-14 15:59:45)

### **Omega-3 and Snake Oil (2007-11-04 16:45)**

Julia Powell, the inspired [1]Julia/Julia blogger (the first blog to be made into a movie), wrote in the [2]Washington Post she was "almost 95 percent sure that Seth Roberts, author of THE SHANGRI-LA DIET: The No Hunger, Eat Anything Weight-Loss Plan (Putnam, \$19.95), is a snake-oil salesman." Almost 95 %?

How about [3]100 %? Snake oil, it turns out, is [4]high in omega-3.

Recently in Japan, a group of scientists at the Japanese National Food Research Institute led by Nobuya Shirai turned their attention to snake oil . . . Shirai and his team evaluated the effects of Erabu sea-snake oil on a number of outcomes in mice, including maze-learning ability and swimming endurance. In both cases, snake oil significantly improved the ability of the mice in comparison with those fed lard. . . .The original Chinese purveyors of snake oil offered something that probably did exactly what they claimed it would do: help fellow workers relieve the pain of their labors.

Thanks to [5]Tucker Max.

Tom (2007-11-06 06:25:31)

A discussion of the various memes is the closest nutrition writing gets to experimentation, but tipping your hat to meta doesn't mean you know anything about what's true. A sneer isn't science. God forbid she should try it, even once, before mocking it!

## Google vs Yahoo: Scientific Implications (2007-11-05 06:09)

[1]Google vs Yahoo over several years. A fable for scientists. Yahoo is worth countless billions of dollars less than Google, in spite of a big head start. The moral: methodological complications, always seen as "improvements", have a price. The benefit of a more complex experiment is easy to see, while the increase in cost (difficulty) usually goes unremarked.

My usual comment on proposed research is that an easier experiment – often smaller, often less "well-controlled" – would be better. I seem to be the only person who says this, yet I say it all the time.

1. <http://www.codinghorror.com/blog/images/yahoo-vs-google-1996-to-2005.png>

---

Mike Kenny (2007-11-05 08:42:34)

Is there a means one could come up with to help get a sense of the likelihood of any given self experiment working, or having good results? Maybe self experimenters on average deviate from later more reliable, but presumably more costly, studies by x percentage points, so when you're doing your particular self experiment, you say, "Well, self experimenters tend to have exaggerated figures on average, by x percent compared to later more reliable findings, so I can account for that," and you account for that by trying to get even greater findings. You perhaps say, "Well, x percent of generalizations from a sample of one are off by x percent compared to later more reliable studies, so I'll account for that too," and you expand your sample to a few friends to decrease the variation. You then say, "Well, small, non-random sample tends to deviate from large random samples by x percent on average, so I'll try to focus on findings that are large enough to be larger than the average deviation." Would this approach be useful (does such information exist about large randomized sample studies compared to self experimentation)? I'm not terribly knowledgeable about probability and statistics. This approach does seem to be in keeping with your idea of making your findings as pronounced as possible. I'd love to hear your thoughts and perhaps you can clear up misconceptions I have if you're so inclined.

seth (2007-11-05 10:11:40)

"good results" would be learning something you wouldn't know otherwise. It is hard to imagine that not happening. Usually the alternative to self-experimentation is doing nothing. as for getting "wrong" results, you have to look long and hard through the history of science to find cases where the results of self-experimentation were misleading; it doesn't take long at all to find cases where they pointed in the correct direction.

Mike Kenny (2007-11-05 10:59:59)

I guess what I'm wondering is what kind of generalizations can we feel comfortable making about self experimentation, and what biases should perhaps be controlled for when looking at our data? I think it makes sense to self experiment, and in an informal way I think we all do it, and it seems your formal approach is way better than the informal self experimentation. I'd just like to have a sense of what reasonable inferences we can draw from the facts we've uncovered via self experimentation. For example, if I were to observe that my pulse is 70 beats per minute, and I generalized, saying "I would guess the average person's heart rate is that," I'd probably be close (I think). But if I observed that I could read 100 pages in a half an hour, and assumed this was average, I'd be wrong (I wish I could!). I'm just wondering if there are some useful approaches or information out there to help in interpreting data from self experimentation that helps one make good inferences. For example, would it be useful to have a sample of self experimentation results compared to more conventional studies and see the differences in conclusions. "Oh, the average self experimentation results varied from the conventional study results by x percent. Oh, x percent of self experimentation findings approximated the findings of more conventional studies. I can use that info in judging

the results of my own self experimentation.”

### **Omega-3 and Sports Injuries (2007-11-05 14:02)**

Tucker Max wrote:

I compete in MMA (mixed martial arts/ultimate fighting)–amateur of course, but I train with professionals. As you can imagine, full contact fighting leads to all kinds of sprains, strains, dislocations, etc. Ever since I started taking flaxseed oil–in caplet form, equivalent of 2 tablespoons a day–I have noticed a serious reduction in the number of small, inflammation-type injuries, and a reduction in recovery time for those injuries.

I asked what he meant by “inflammation-type injuries”.

That would be any injury where inflammation is the key component of the damage, for example:

- sprain
- strain
- bruise

This is opposed to injuries where the key component of damage is something more significant, for example:

- break
- dislocation
- tear

Another way to put it would be that I don’t seem to get as many small injuries, and when I get them, they seem to heal quicker. I used to have to take like four Advil every day before I went to class, simply because I was so sore from the things we had done the previous days . Now, I don’t take any–and I haven’t changed anything else other than the flaxseed caplets.

Tissue inflammation is a huge part of most sports injuries. You ever watch Sportscenter, and see the post game interviews in the locker rooms? Notice how the athletes–especially pitchers–always have ice wrapped on their arms or knees or whatever? That is to reduce the tissue inflammation that occurs with high stress use. The general acronym for treating a minor sports injury is RICE (Rest, Ice, Compression, Elevation). Each of those are primarily designed to reduce tissue inflammation in the damaged areas, because once that is reduced, the body can heal itself much faster (I am simplifying this, but you get the point).

If high levels of omega-3’s really do reduce this sort of sports injury inflammation, it would be a HUGE discovery in sports medicine.

It makes sense. Injuries heal faster when the body’s “natural response” is reduced? Apparently the “natural response” is excessive.

### Women's Health Initiative (2007-11-06 15:40)

[1]Here's a nice essay about the Women's Health Initiative, a nine-year mega-million-dollar experiment to measure the effect of "healthy eating" especially a low-fat diet.

48,835 postmenopausal women . . . were randomly assigned . . . to either their regular unrestricted diet or to a "healthy" diet that was low-fat (20 % fat) and high fiber, with at least 5 servings of fruits and vegetables, and 6 servings of grains a day. The "healthy" eaters endured an "intense behavioral modification program by specially trained and certified professionals" to keep them on their diets. While they backslide a little, they did surprisingly well in sticking to the diet "as good as dietary prescriptions will ever get and money can buy" at a cost of \$8,498 spent per person!

Oops, no effect. "The results of this huge study, despite the hundreds of millions of dollars of taxpayer money spent on it, were quietly buried."

I conclude two things: 1. People in charge of spending vast sums on nutrition research don't know very much about what constitutes a healthy diet. 2. The same people know very little about how to do experiments. The most basic lesson is to do the smallest experiment possible.

Sandy Szwarc, the author of this essay, concludes:

When we enjoy a variety of foods from all of the food groups "as most everyone naturally does when they're not trying to control their eating" and trust our bodies, we'll get the nutrients we need to prevent deficiencies. And that is the only thing that nutritional science can credibly support.

There is some truth to this, both (a) we instinctively eat to avoid certain deficiencies and (b) nutrition science has found conclusive evidence that we need certain chemicals. But she is quite wrong in the sense that most Americans appear to suffer from huge omega-3 deficiencies ([2]my posts about this). Many of them, probably most of them

"enjoy a variety of foods from all of the food groups."

Thanks to Dave Lull.

David (2007-11-06 17:22:20)

Another advantage of small studies is that the political power of the investigators and other vested interests in any given study is likely to be lower. That would make the spinning of results more difficult.

seth (2007-11-06 17:27:38)

Interesting comment, David. Along similar lines, smaller studies would allow more even-handed interpretation of the results, since results opposite to expectations would be less embarrassing.

Rich (2007-11-06 17:39:34)

“The results of this huge study, despite the hundreds of millions of dollars of taxpayer money spent on it, were quietly buried.” please, the paper was published in JAMA and covered in the new york times, for pete’s sake! its hard for a scientific article to get less buried than that.

seth (2007-11-06 18:06:00)

Rich, coverage in the NY Times (once?) doesn’t make your point. Was it covered on the Today show? Good Morning America? Oprah? A hundred other places? How much coverage did it deserve? Well, the notion that Americans have been given poor nutrition advice for a long time is very important – had the advice been better, lots of lives would be better. I think the results deserved lots of discussion about “where we went wrong” or “where the experts went wrong” or “where the funding system went wrong” – whatever you want to call it. There was none of that.

lasser80 (2007-11-06 18:45:51)

“When we enjoy a variety of foods from all of the food groups – as most everyone naturally does when they’re not trying to control their eating – and trust our bodies, we’ll get the nutrients we need to prevent deficiencies.” There is something pleasantly Jane Jacobs like or Hayekian in that statement (very anti-central planning/anti-expertise). But sadly, in my personal experience, if I let myself spontaneously choose what I want to eat, I’ll eat very unhealthy.

Pearl (2007-11-06 20:11:24)

Unhealthy foods exist as a result of engineering and mass production. If they didn’t exist, we would be able to trust our bodies and eat well. That’s why they shouldn’t exist.

Rich (2007-11-06 20:41:53)

Seth, The original quote was that the results were “quietly buried.” you may believe the results deserved wider coverage, but that’s quite different than suggesting they were “quietly buried.” I do think publication in one of the pre-eminent medical journals and coverage in a pre-eminent newspapers is ample evidence against quiet burial.

seth (2007-11-06 21:10:13)

Reasonable point. I quoted too selectively and misled you about what the author meant. You are right, by one meaning of “quietly buried” they were not. The author meant they received far less coverage than they would have had they come out

differently. She meant "by comparison, they were quietly buried." That isn't clear from the single sentence I quoted.

David (2007-11-07 07:16:22)

Does anyone know why they chose 49,000 participants, which is an astoundingly large number? It seems that kind of number would pop out of a power calculation if you expected the effect to be very small and/or the background variation to be very large. If its the former, it makes the interesting point that the study cost will be decreasing in the magnitude of the effect you expect to find. This isn't to say that some very small effects might have a big social benefit and that you would want to know about them, but it is still a perverse property of research!

michael vassar (2007-11-07 09:29:47)

Great point David.

### **My Theory of Human Evolution (intricate art edition) (2007-11-07 04:52)**

[1]Kris Kuksi is an artist who graduated in 2002 from Fort Hays (Kansas) State University. Here is an example of his work:

[2] 

Very intricate. What the world calls good art is almost always intricate. Artists, driven by their own preferences and the preferences of customers, move in that direction. Intricacy is technically difficult. The desire for intricacy causes technological innovation.

[3]More intricate art, with great soundtrack.

4. <http://www.blog.sethroberts.net/2007/09/13/modern-veblen-the-less-than-obvious-value-of-evolutionary-explanations/>

---

lasser80 (2007-11-07 18:39:05)

Hmmm, I understand what your saying about Gould's and Jacobs apparent dismissal of evolutionary explanations. But doesn't experimentation take priority over the inward theoretical debates of evolutionary scientist. It's true you can go to scientist and back up your SLD experiment with an evolutionary explanation. But the breakthrough appeared to come when you confronted a daily life problem (overeating) with an experiment. The evolutionary explanation is a secondary effect. I think Jacobs also had much stronger faith in daily problems solving rather than the abstract theoretical debates which evolutionary scientist often engage in. Jacobs argues that solutions usually arise on the ground level where people are more intimately connected with their environment. To borrow a term Hayek used, there is a "spontaneous order" to our lives, outside the boundaries of human knowledge.

seth (2007-11-08 05:22:43)

I think Jacobs just liked Gould's Natural History columns. Evolutionary ideas helped me decide what experiments to do; that's how they were useful. Much as correlational evidence helps decide what experiments to do.

### **Jobbook Diary (2007-11-07 18:16)**

I asked my mom, a retired librarian, if she could find some good librarian blogs to add to [1]jobbook.org. She found four, but she wanted me to add them to the home page. She didn't know how to edit wikis and she didn't want to learn.

If you have trouble, I said, something is wrong. (My mom is more computer-literate than I am. She was using email before 99.9 % of the rest of us – before me, for example. Her mom told her in the 1950s that computers were going to be a big thing.)

She reluctantly agreed to try. She clicked on edit on the home page, which brought up an edit box. To add her line, she erased everything in the box. You don't want to do that, I said. Hit the delete key, I said. To demonstrate – this was over the phone – I hit the delete key on my screen. Oops, the whole page was gone!

I couldn't figure out how to restore it. Which shows how much I know about wikis. I emailed Aaron and he fixed it. You restore a page, it turns out, by going to the history page, clicking the edit link for the version you want, and Save-ing it.

Page restored, my mom tried again. She successfully added a line for librarian with a blog link. However, she had found four blogs she liked, so it seemed like a good idea to add more links, if only to make the point that there could

be more than one link per line. Since there were no pre-existing examples of multiple links per line, it wasn't obvious how to do this. I think you do it like this, I said:

librarian: [blog] (address) [blog] (address)

Correct, it turned out. Now the issue is how to separate links. They now appear on the page separated by one space, which isn't enough, my mom thinks. I don't know how to increase the spacing but maybe Aaron does.

1. <http://jobbook.org/>

---

david (2007-11-07 19:19:31)

In that context you'd probably use commas to separate the items. Another suggestion would be to make the link text more descriptive (i.e. instead of just "blog", "Name of the blog").

seth (2007-11-08 05:19:21)

Thanks for the suggestions.

marmolillo (2007-11-08 22:33:52)

I have always said Wikipedia is not that simple to edit and that is a reason why it is not even bigger. There are thousands of people unable to edit such a mess of Wikitext. Nowadays it is crazy that Wikipedia can not admit simpler editions.

seth (2007-11-08 23:21:46)

Good point.

### **A Good Day for Free Speech (2007-11-08 06:08)**

Negotiations between NBC and Rosie O'Donnell about a talk show were broken off by NBC after Rosie said something about them to the media. Rosie blogged about it [1]here in her endearing style.

Remember that A. J. Liebling saying: "Freedom of the press is guaranteed only to those who own one"? For the low price of blogging, Rosie owns one.

A [2]great day for free speech.

1. <http://www.rosie.com/blog/2007/11/07/the-show-that-never-was/>

2. [http://www.huffingtonpost.com/seth-roberts/a-great-day-for-free-speech\\_b\\_59872.html](http://www.huffingtonpost.com/seth-roberts/a-great-day-for-free-speech_b_59872.html)

---

Dennis Mangan (2007-11-08 09:33:37)

Given that James Watson was recently publicly browbeaten, humiliated, and ultimately fired for giving a scientific opinion, free speech isn't in very good shape in this country, in my opinion. Rosie O'Donnell is a popular media personality who is arguing against a corporation, which are widely hated by the media and opinion makers. That Chapman guy recently had his TV show canceled for a private utterance. Say something truly against current received wisdom and you'll find out just how free your speech really is.

seth (2007-11-08 09:54:27)

True. We're a long way from anyone can say anything. But we're closer. Rosie can say she's gay, for example.

### **Self-Experimentation in Medical Discovery (2007-11-08 09:58)**

An [1]editorial by William Bains, a biotechnologist and entrepreneur, questions the usual drug development process:

Translational Medicine [about going from research to practice] conferences are full of discussions of PET fMRI, gene arrays and proteomics, far beyond the means of the GPs that see 95 % of patients, and divorced from the simple clinical observations that resulted in the discovery of drugs as diverse as aspirin and viagra.

Because this is the way that biomedical research (especially drug research) is done, it is assumed that the features of this process are features that have to be part of the biomedical research process. These include:

- (i) that only professionals operating in established organizations can have the knowledge to identify new areas of medicines research;
- (ii) that biomedical research can only be done using cutting edge technology, which is enormously expensive;
- (iii) that only tests on huge numbers of people can validate a new approach.

None of these is true.

There is precedent for other ways of doing things:

The majority of clinical advances in the last 20 years of dermatology have been made by individuals working outside the mainstream of academic research, but possessing a keen observational eye, strong, skeptical analytical skills and constant contact with patients

[http://www.sciencedirect.com/science?\\_ob=ArticleURL&\\_udi=B6WN2-4R11KF5-5&\\_user=4420&\\_coverDate=10%2F29%2F2007&\\_rdoc=1&\\_fmt=&\\_orig=search&\\_sort=d&view=c&\\_acct=C000059607&\\_version=1&\\_urlVersion=0&\\_userid=4420&md5=0b17c508d399c137816df7cbc2cffb6b](http://www.sciencedirect.com/science?_ob=ArticleURL&_udi=B6WN2-4R11KF5-5&_user=4420&_coverDate=10%2F29%2F2007&_rdoc=1&_fmt=&_orig=search&_sort=d&view=c&_acct=C000059607&_version=1&_urlVersion=0&_userid=4420&md5=0b17c508d399c137816df7cbc2cffb6b)

## Curiously Small World (2007-11-08 23:55)

1. I meet one of Leonard Syme's students at a party.
2. I learn about Syme's unusual [1]teaching methods (and later [2]interview him about them).
3. One of Syme's students, Michael Marmot, writes a book called [3]The Status Syndrome (2004).
4. Nassim Taleb, author of The Black Swan, writes an excellent [4]review of The Status Syndrome:

You are a hot shot in a company, though not the boss. You are paid extremely well, but, again you have plenty of bosses above you (say the partners of an investment firm). Is it better than deriving a modest income being your own boss? The counterintuitive answer is NO. You will live longer in the second situation, even controlling for diet, lifestyle, and genetic predispositions.

5. I [5]quote Taleb's research ideas approvingly.

1. <http://www.blog.sethroberts.net/2007/09/18/how-accurate-is-epidemiology-part-3/>
2. <http://www.blog.sethroberts.net/2007/09/21/leonard-syme-on-teaching/>

## How to Start a Food Demo Company (2007-11-09 05:46)

At the Berkeley Whole Foods a few days ago, a friendly man named Hunter Austin was demoing [1]Alvarado Street Bakery Sprouted Wheat bread. "Baked locally, sold [frozen] nationally," he said. He was giving out little grilled cheese sandwiches. It turned out he had his own demo company - food companies hire him to demo their products. He had started the company four years ago. Before that he had owned and run a restaurant. He made lots of money but he was working seven days a week. The pay worked out to \$15/hour.

Why did you choose this as your escape route? I asked. "You want to know the truth?" he said. "Because it looked really easy." He did demos for someone else for a few months then decided to strike out on his own. He made a brochure advertising his services. Then he went up and down the aisles at a supermarket writing down the names and addresses of companies whose products he liked. He sent them his brochure. What happened? I asked. "I got business," he said.

That's how his business began. It turned out to be harder than it looked. "The first ten demos are fun," he said,

"the next twenty are sobering, and after that it's a job." Now he mostly hires people to do the actual work. This was the rare demo he did himself. His company is called Demo Demon.

1. <http://www.alvaradostreetbakery.com/>

---

MARCY (2007-12-18 21:42:54)

WHAT DO YOU CHARGE THE FOOD COMPANIES TO DO DEMOS? I AM CURRENTLY DOING DEMOS FOR A COMPANY AND GET PAID \$25.00 AN HOUR I WOULD LIKE TO BRANCH OUT AND OPEN MY OWN BUSINESS AND HIRE OTHER PEOPLE. WHAT DO YOU PAY YOUR EMPLOYEES?

seth (2007-12-19 07:46:50)

I'd guess he charges the food companies about twice what he pays his employees.

MARCY (2007-12-22 20:56:00)

SO IF I PAY MY EMPLOYEES \$20.00 AN HOUR FOR 4 HOURS THEN I SHOULD CHARGE THE FOOD COMPANY \$40 OR \$50.00?

seth (2007-12-23 00:01:16)

Something like that would be my ignorant guess, yes.

marcy (2008-04-13 12:49:32)

May I ask what you pay your employees? If you pay them \$15 or 20, do you charge the company \$45 an hour or 50" Can you email me a copy of your brochure just to give me an idea??

seth (2008-04-13 14:49:10)

I don't have any employees. I don't run a food demo company.

Hunter (2010-01-20 20:29:54)

Better late than never...thedemodemon@yahoo.com-I can field your questions if you ever happen back to this site.

Mary Broady (2010-04-20 14:40:50)

I am very much interested in starting my old demo product business. send info on how to quickly get started.

TammieWalker (2010-10-21 18:24:38)

Hello Seth you have inspired me, I'm interested in learning as much as possible from you if you would please contact by email at moodoggy2@yahoo.com that would be great!

Donna Ezrow (2010-11-18 11:59:26)

Seth, I as well have done this after being in the food biz for Disney as well as myself. Your right when you talk about the hours you have to work. having displayed many products for other companies I find they come of short. I am on a crusade for selling a \* Brand \* no matter who it is. Promoting a new brand for a small biz or one of the well known brands we are all familiar with.OK Having said all that I enjoy doing a real showy demo.I like to gather a crowd and break down the cost as I cook with the ingredient or product.I would love you to send me good info as to how to do this myself.

Gayle (2011-07-31 16:48:24)

I do demos for \$9 an hour. Every time I suggest starting my (our) own demo company my demo friends say it is impossible. Can someone really get started on a shoe string budget?

Ruth (2011-09-18 09:52:45)

Very interested in starting a demo company, would love to learn from you... How can I learn....

Kathy (2012-01-29 04:46:50)

I was wondering what all needs to be in the contract that you set up with the food company? Do you have a sample contract?

### **My Theory of Human Evolution (Hallelujah edition) (2007-11-09 23:32)**

The latest episode of Ugly Betty ended with Jeff Buckley's version of Leonard Cohen's Hallelujah. I was entranced. I ran to YouTube to hear the whole thing:

What a great performance! Could anyone else come close? I usually like Rufus Wainwright:

Not close.

K. D. Lang?

No.

Leonard Cohen himself?

Well, the best of the rest.

I am a lot more interested in [1]Jeff Buckley than I was an hour ago. From Wikipedia: "The night before his death [by drowning], Buckley excitedly told his girlfriend Joan Wasser that he believed he had found the cause of his dramatic moods, namely bipolar disorder."

1. [http://en.wikipedia.org/wiki/Jeff\\_Buckley](http://en.wikipedia.org/wiki/Jeff_Buckley)

Lori (2007-11-10 10:44:10)

Thanks for this great selection of "Hallelujah" versions. As a fan of Leonard Cohen, I prefer his own performance of it, and there is a huge fan base for him where I come from.

David (2007-11-10 10:56:56)

What about John Cale's version? Btw., often the live versions of songs you find on youtube often don't represent what people are used to hearing on the radio/their cd players. For the Cale cover, this one sounds like it has the standard CD-version (so just ignore the animated video part). I assume it's being on youtube is a violation of some copyright tho. I'd rank them Cale (favorite), Wainwright, Buckley, Cohen, Lang. Interesting that there are so many covers of the song and so many are so good. What other songs have been covered as often and as well? Something by Dylan maybe?

David (2007-11-10 10:57:43)

Oops...the url in my previous post was omitted: <http://www.youtube.com/watch?v=ekHeeJWsNJA>

seth (2007-11-10 11:24:39)

I didn't listen to Cale – there were so many I had to stop somewhere. Now I will, thanks for pointing it out.

Ian Bicking (2007-11-10 17:06:29)

I can't get myself to like any Leonard Cohen performances after 1972 or so. Still a great songwriter (as this song shows), but it's always bizarrely overproduced and just not as good as the song itself. If you are looking up songs in YouTube you might like this new site: <http://www.songza.com/> – though you'd miss out on the awesome background to L.C.'s version ;)

ResultsNotTypical (2007-11-10 20:55:07)

If you liked that, listen to Jeff Buckley's 'Last Goodbye'.

## **How Bad is Saturated Fat? (2007-11-10 05:27)**

[1]This Men's Health article is a nice summing-up of the lack of evidence that saturated fat is bad.

In 2000, a respected international group of scientists called the Cochrane Collaboration conducted a "meta-analysis" of the scientific literature on cholesterol-lowering diets. After applying rigorous selection criteria (219 trials were excluded), the group examined 27 studies involving more than 18,000 participants. Although the authors concluded that cutting back on dietary fat may help reduce heart disease, their published data actually shows that diets low in saturated fats have no significant effect on mortality, or even on deaths due to heart attacks. "I was disappointed that we didn't find something more definitive," says Lee Hooper, Ph.D., who led the Cochrane review. If this exhaustive analysis didn't provide evidence of the dangers of saturated fat, says Hooper, it was probably because the studies reviewed didn't last long enough, or perhaps because the participants didn't lower their saturated-fat intake enough. Of course, there is a third possibility, which Hooper doesn't mention: The diet-heart hypothesis is incorrect.

Thanks to Dave Lull.

1. [http://www.menshealth.com/cda/article.do?site=MensHealth&channel=health&category=heart.disease&conitem=a03dd2eaab85110VgnVCM10000013281eac\\_\\_\\_\\_&page=0&print=true&url=http%3A%2F%2Fwww.menshealth.com%2Fcda%2Farticle.do%3Fsite%3DMensHealth%26channel%3Dhealth%26category%3Dheart.disease%26conitem%3Da03ddd2eaab85110VgnVCM10000013281eac\\_\\_\\_\\_%26page%3D0](http://www.menshealth.com/cda/article.do?site=MensHealth&channel=health&category=heart.disease&conitem=a03dd2eaab85110VgnVCM10000013281eac____&page=0&print=true&url=http%3A%2F%2Fwww.menshealth.com%2Fcda%2Farticle.do%3Fsite%3DMensHealth%26channel%3Dhealth%26category%3Dheart.disease%26conitem%3Da03ddd2eaab85110VgnVCM10000013281eac____%26page%3D0)

---

## Omega-3 and Veterinary Medicine (2007-11-10 20:02)

The November 2007 issue of [1]Acres USA, a magazine about organic/sustainable farming, has an article (not online) about using omega-3s to cure farm-animal problems. Here are the best parts:

One family reported that their dog had failed obedience training three times. Our therapy of cod liver oil (Nordic Naturals), Fasttrack probiotic, and a homeopathic prescription enabled him to pass on the next attempt. . . . Dogs experience panic attacks for a variety of reasons. One frantic German shepherd dog jumped through a plate glass window to escape the house and get near his owner. The solution to his panic and anxiety attacks proved to be cod liver oil, the correct homeopathic medicine, and a whole-food diet rich in omega-3 oils and quality live probiotics.

The obedience-training story resembles my story of taking flaxseed oil capsules and the next morning being able to easily put on my shoes standing up. With the difference that I'd had trouble several hundred times in a row, not just three.

Thanks to Joshua Schrier.

1. <http://www.acresusa.com/magazines/magazine.htm>

---

NE1 (2007-11-21 22:57:43)

Ah, a perfect study! Except for the confounding effect of the homeopathic remedy. Your attitude with stories like this is just astounding. It's almost enough to make me think you don't really want Omega-3's to become legit, commonplace supplements.

seth (2007-11-22 06:23:23)

Where do new ideas come from?

NE1 (2007-11-23 13:13:16)

Ideas are worthless. There are billions of them. Most people can think of 6000 ideas before breakfast. This is no longer a question of where they come from. You are now trying to pass this idea off as a truth. You do not confirm, validate, or bound an idea by lumping it in with homeopathy, feckless whole-foodism, and hearsay anecdotes. My grandmother takes honey for her arthritis, and rubs yogurt on her age spots. What shall I say when she hears about flax seed oil? The only reason why I am paying attention at all to your blog (or ideas) is because of the data you record and present, yet you refuse to take the standard next steps to limit or reinforce your conclusions. It's like you live in a dream where the first thing you think of is reality. This

fetish for ideas has you satisfied in believing things which may not be true, and you broadcast this further to the world. That's what I don't understand.

seth (2007-11-23 17:49:38)

By "new ideas" I meant plausible new ideas – ideas worth taking the effort to test further. They are remarkably hard to come by, in my experience. There are not "billions" of them—in some fields, there appear to be none. "Things that may not be true"? I think the new data – including stories from others, such as Tyler Cowen – that I've presented here make a strong case for the benefits of flaxseed oil. And the virtues of self-experimentation, which uncovered new and useful facts on a heavily researched topic.

### **The Resource Curse (2007-11-11 07:22)**

In an excellent [1]Authors@Google talk based on his book [2]The Birth of Plenty – about the increase in GDP growth that started around the Industrial Revolution – William Bernstein mentions what he calls "The Resource Curse":

If all your wealth comes out of a couple of holes in the ground, the quickest way to become wealthy . . . is control of those holes and access to those holes. It breeds corruption, and it breeds poor government, and it drains the entrepreneurial spirit. The best way to get rich is to have no natural resources at all. Think Singapore, think Japan.

Could the same be true of science? Could access to resources – say, a lot of grant money or expensive equipment – breed corruption and poor government, and drain the entrepreneurial spirit? It isn't obvious why not. Surely human nature is essentially the same in both places. This may have something to do with Gary Taubes' complaints about poor nutritional science in Good Calories, Bad Calories.

I rarely mention in this blog my animal learning research, which [3]in recent years has been about exactly this – with animals (rats and pigeons). The results of our experiments are easy to sum up: When animals have access to rich sources of food, it drains the entrepreneurial spirit. In psychology-speak, when the probability of reward for actions is high, there is less variation in what animals do than when the probability of reward is low. I got into this line of research [4]by accident.

---

David (2007-11-12 14:16:53)

An essential part of the resource curse story is that it induces an economy to specialize in exploiting the resource and not to engage in other activities that have better long-run growth prospects, such as knowledge industries. After exploiting the

resource until it runs out, the economy finds it difficult to return to the other activity unless it has wisely invested in the abilities needed to do so. ([http://en.wikipedia.org/wiki/Dutch\\_disease](http://en.wikipedia.org/wiki/Dutch_disease)) I think there is an analogy here to "normal science" and "paradigm-shifting" science. It is easy for funding agencies to justify large investments in the former, since they produce reliable returns in the form of publications and so forth, but without investments in the latter the long run looks bleak. In some ways it seems that nutritional science is suffering from too little investment in path breaking work....

### Omega-3 and Cognitive Function in the Elderly (2007-11-11 18:01)

Two papers in the [1]latest issue of the [2]American Journal of Clinical Nutrition provide more support for the idea that omega-3s improve brain function.

The first was a cross-sectional study involving about 2000 persons 70-74 years old in Norway. Their fish consumption was measured and they took a battery of cognitive tests. The more fish you ate, the better your score on every test, even after adjustment for several things.

The second used data collected as part of a 3-year experiment about something else (the effect of folic acid) with 800 persons aged 50-70. They measured the omega-3 concentrations in the blood of their subjects. Would these predict anything? Their results were more ambiguous:

Higher plasma n-3 PUFA proportions predicted less decline in sensorimotor speed . . . and complex speed . . . over 3 y. Plasma n-3 PUFA proportions did not predict 3-y changes in memory, information-processing speed, or word fluency. The cross-sectional analyses showed no association between plasma n-3 PUFA proportions and performance in any of the 5 cognitive domains.

Cross-sectional correlations between a measure of omega-3 (fish consumption) and cognitive performance are exactly what the first study did find.

1. <http://www.ajcn.org/current.shtml>

2. <http://www.ajcn.org/>

---

Timothy Beneke (2007-11-12 09:59:27)

So maybe it's something else in the fish that's enhancing cognitive functions?

Leo (2007-11-12 10:14:05)

Seth, FYI: Curves, women and Omega-3 <http://www.telegraph.co.uk/news/main.jhtml?xml=/news/2007/11/12/ncurves112.xml>

seth (2007-11-12 10:18:09)

I think it's just a comment on the generalizability of research. Lots of things are important that the experimenters don't realize.

And these vary from one lab to another.

Seth's blog » Blog Archive » Omega-3 and Cognitive Function in the Elderly: The Opposite Result (2007-11-12 22:27:01)  
[...] Omega-3 and Cognitive Function in the Elderly [...]

### **In Japanese (2007-11-12 05:59)**

If you read Japanese you can read about the Shangri-La Diet here:

- [1][http://www.suda.tv/archives/2007/03/post\\_580.php](http://www.suda.tv/archives/2007/03/post_580.php)

### **Omega-3 and Cognitive Function in the Elderly: The Opposite Result (2007-11-12 22:24)**

Peter Spero has sent me the following abstract from a [1]paper published in 2003 in the Journal of Alzheimer's Disease:

It has been suggested that the dietary intake of omega-3 polyunsaturated fatty acids could be inversely related to the risk of dementia and cognitive decline. This analysis examined the association between plasma concentration of omega-3 polyunsaturated fatty acids and prevalence and incidence of cognitive

impairment and dementia. Data are reported on subjects 65 years or older who had a complete clinical evaluation at the first two waves (1991-1992 and 1996-1997) of the Canadian Study of Health and Aging. Main outcome measures were cognitive impairment and dementia by mean relative plasma concentrations of fatty acids in the phospholipid fraction at baseline. Results were adjusted for age, sex, education, smoking, alcohol intake, body mass index, history of cardiovascular disease, and apolipoprotein E e4 genotype. In the cross-sectional analysis, no significant difference in omega-3 polyunsaturated fatty acid concentrations was observed between controls and both prevalent cases of cognitive impairment and dementia. In the prospective analysis, a higher eicosapentaenoic acid ( $p < 0.01$ ) concentration was found in cognitively impaired cases compared to controls while higher docosahexaenoic acid ( $p < 0.07$ ), omega-3 ( $p < 0.04$ ) and total polyunsaturated fatty acid ( $p < 0.03$ ) concentrations were found in dementia cases. These findings do not support the hypothesis that omega-3 polyunsaturated fatty acids play a protective role in cognitive function and dementia.

The people with worse-functioning brains had more omega-3 in their blood than everyone else. Which is opposite to one of the two studies I [2]described yesterday.

I'd love to have seen what reviewers made of this.

---

john (2007-11-19 14:15:36)

Could they be not using the omega-3 due to inability to process it in their metabolism, kind of like a diabetes for omega-3? It would be interesting to co-relate their high concentration of omega-3 vs diet differences.

### **My Theory of Human Evolution (the Henry Rosenthal Pennant Collection) (2007-11-13 07:59)**

Henry Rosenthal, the San-Francisco-based producer of the documentary [1]The Devil and Daniel Johnston (the best movie ever made about mental illness), has a large collection of pennants. No sports teams, no schools, only North America – those are the rules. Hundreds of pennants. Most are for places (Mexico, the Grand Canyon, San Francisco). A few are for events (a Chicago trade show). "I've been collecting since early childhood," Henry told me. "I made two pennants myself years ago, one for Joseph Albers and the other for Robert Rauschenberg."

For years I wondered why people collect. By collect, I mean collect gift-like objects, such as frog figurines or erasers with pictures or stamps or refrigerator magnets or pennants. I understood it was enjoyable – you derive pleasure from your collection. It was the evolutionary reason I couldn't figure out. When I eventually thought of my theory of human evolution – it is all about the growth and encouragement of occupational specialization – I realized this was one of the puzzles it solved.

Will Henry pay more than the average person for new and well-made pennants? Very likely. Will he appreciate an especially well-made pennant more than the rest of us? Undoubtedly. Like most collectors, Henry has placed the items of his collection side by side, making it easy to compare them and, I believe, [2]promoting connoisseurship. Studying his collection – covering the walls and hanging from the ceiling of a large room – made me a connoisseur of

pennants.

Collections increase the demand for finely-made things, helping their makers make a living and advance the state of their art, whatever it might be. that people collect all sorts of finely-made things encourages the growth of a wide range of technologies.

Incidentally, Henry is currently working on a movie about [3]Tiny Tim. If you can't wait for the movie, you can read [4]a book it will be based on.

[...] My Theory of Human Evolution (the Henry Rosenthal Pennant Collection) [...]

KenF (2007-11-14 16:39:01)

I heard that often men collect as children, don't collect in their 20s/30s, then get back into collecting in middle age. I don't know if this applies to women as well.

Richard Hollerith (2007-11-16 10:18:56)

Seth, you are using group selection to explain the behavior. Mistake. You have to show how the behavior benefits the gene that causes the behavior. That it advances the state of the technical arts, helps artisans make a living or encourages occupational specialization do not explain how the gene's frequency would increase.

seth (2007-11-17 23:55:33)

Richard, genes spread through populations that live together. The genes I am talking about helped perpetuate themselves because they provided advantages to the group of people who had them.

Richard Hollerith (2007-11-18 17:34:11)

A mutation will "fixate" (spread) only if the male (female) who bears it has greater reproductive fitness than the other males (females) in the population that lives together. By helping the artisans in the population, the collector is aiding his competitors in the competition for sexual partners, so that cannot be why the mutation fixated. You are making a very common mistake. Ask 100 evolutionary biologists and they will all tell you that. Don't worry, you are in good company: Darwin persisted in the same error.

seth (2007-11-18 23:42:53)

I believe a mutation can spread a considerable distance – for many generations and thru many people – even if it confers no advantage or even if it slightly reduces fitness. There is random spread, in other words. So people living close together tend to share mutations. A gene that produces a slight disadvantage to a single person among others who don't share it can spread widely enough so that it reaches a group of people who collectively benefit from it. Call it a critical mass.

Richard Hollerith (2007-11-19 11:09:42)

Let us say that it did happen that through genetic drift a collector mutation ("allele" would be a better word) spread to an entire group of humans living together, with the result that the group benefits. You have failed to explain why that mutation would persist to the present day. Since the allele confers no advantage to the individual, why would the descendents of the group not eventually drift the other way? Note that the fact that a group composed wholly or mainly of collectors has a reproductive advantage over other groups does not take away from the fact that within the advantaged group, collectors have no reproductive advantage over non-collecting group members. Now let me stress that I tentatively agree with you that the tendency to collect things conferred a fitness advantage to humans in the environment of evolutionary adaptation. It is just your argument I disagree with, not your conclusion. It might help for you to read <http://www.overcomingbias.com/2007/11/evolving-to-ext.html> and other posts by the same author.

### **Who Reads Blogs? (2007-11-13 16:39)**

An article in the current issue of the American Journal of Epidemiology is about participants in a large health survey. It compares people who turned in the questionnaire via the Web with those who answered via mail.

Over 50 % of 77,047 participants chose to enroll in the study via the Web . . . The authors compared the demographic and health characteristics of Web responders with those of paper responders. Web responders were slightly more likely to be male, to be younger, to have a high school diploma or college degree, and to work in information technology or another technical occupation. Web responders were more likely to be obese and to smoke more cigarettes and were less likely to be problem alcohol drinkers and to report occupational exposures.

The study began in 2001.

---

### **My Theory of Human Evolution (Make edition) (2007-11-14 09:26)**

The path to human nature, I propose, began with capable hands. No surprise there. In our brains formed a desire for hobbies, to take advantage of what our hands allowed. Hobbies were the first step toward occupational specialization, which led to the full flowering of human nature (trading, language, procrastination, art, holidays, rituals, fine wine, fashion, Veblen's Instinct of Workmanship, etc.).

The Hobbyist Within Us is especially clear in the pages of [1]Make, a young magazine devoted to higher-tech DIY. [2]Turn your old scanner into a camera. [3]Make a Joule thief. It started as a website, which was so successful that a print version was launched. More recently, [4]Maker Faires have started.

Thanks to [5]Niall Kennedy, who has written for Make.

Nansen (2007-11-15 13:53:01)

If you were to write a book titled "Discover Your Inner Hobbyist", what sort of practical advice and insight would it contain?

seth (2007-11-15 20:58:52)

I don't know. I guess I would do journalistic research on hobbyists and try to figure out what the range of hobbies is and what the benefits of different hobbies are.

### **Omega-3 Research (2007-11-15 12:36)**

Summaries of a vast number of omega-3 related research articles can be found [1]here. Nothing about gum disease or balance or the sort of cognitive tests I've been doing, however.

1. <http://www.omega-research.com/index.php>

---

Igor Carron (2007-11-16 03:06:22)

Seth: Unrelated to this but still in your area of investigation: <http://www.physorg.com/news114358249.html> and <http://www.graphicology.com/blog/2007/11/12/131-ad-of-the-week-buckleys.html> Igor.

Catherine (2007-11-16 18:24:59)

One study mentions periodontitis. <http://www.omega-research.com/researchview.php?ID=418&catid=8>

### **Omega-3: What Happens When You Stop? (2007-11-16 06:46)**

[1]Tucker Max wrote again, with new data:

I started taking two tablespoons of flax seed oil about a month after reading [2]this post by you [about Tyler Cowen's dental experience] (sometime around the beginning of August, I think). I decided to try it because I have had bleeding gums for about as long as I can remember. This has always confused me,

because I don't have any cavities and have otherwise good dental health. I would always ask my dentists about this, and they would always tell me I didn't floss enough, but even when I would floss regularly, the bleeding wouldn't totally stop. After about a week or so of two tablespoons of flax seed oil a day, I had virtually no gum bleeding. I didn't change anything else.

Then, about two weeks ago, my girlfriend pointed something out to me: I was not taking pain relievers anymore. I train in amateur mixed martial arts (MMA), which is a very intense, full contact combat sport that combines boxing, muay thai, brazilian jiu-jitsu, and wrestling. For as long as I've been training in it, I have had to deal with muscle soreness and pain in my joints, and to deal with it, I would take 4-6 ibuprofen before training. But, for about the past three months, I wasn't in enough pain to need it. I didn't really think about it at first, just chalking it up to getting tougher. But that doesn't make sense-I've been training in MMA for well over a year, and the only thing I have done differently in the past three months is start taking flax seed oil. I wasn't 100 % sure that the flax seed oil was making the difference, but considering the effect it has on inflammation-which is what ibuprofen is for-it made sense.

That was when I sent you the emails you [3]posted. One of your commenters [4]accused me of falling victim to the placebo effect, so I decided to test it. I stopped taking flaxseed oil on November 5th. At the time, my gums were not bleeding, I had no joint pain or soreness of any significance, and I felt great overall.

As I write this it's November 15th. My gums have bled heavily when I brushed this week, especially the past few days, and I have intense pain in both shoulders, soreness in my left elbow, and my knees are throbbing. I had intended to go two weeks without taking any flaxseed oil, but I am stopping the experiment now because this is all the proof I need.

One more interesting fact: I took four tablespoons a few hours ago, instead of the regular two, thinking that maybe I could load up and it might help me get back to normal quickly. The pain is pretty much the same, and I just brushed and my gums bled, so obviously the flaxseed oil takes more than a few hours to affect those problems. But-and I haven't measured this with reaction tests like you do-I feel considerably more mentally alert right now. I don't know if I felt like this before, and maybe I didn't notice it because it came on slowly, or maybe I need four tablespoons at once to see a difference, but I really do feel the difference.

---

August (2007-11-16 08:01:18)

When I take flax seed oil, I get something similar to a sinus headache- like something in the oil is causing a histimine reaction. The longest I've been able to take it was two weeks. I noticed an improvement in my gums, but that strange headache feeling masked any other improvements. I'm hoping I can avoid the adverse reaction by finding a different source of Omega-3s.

Timothy Beneke (2007-11-16 08:29:20)

I've been taking the flax seed oil for several months, now; I was at 2 tablespoons and have gone to 4 in the last 3 weeks. I've had bad gums for years. 2 months ago I had gum surgery. My orthodontist warned me that it would take a long time to heal and there might be problems with one area. When I returned after 2 weeks she said, "I'm surprised! It's healing very well!"

Then when I returned after 2 months, she said, "You're doing very well! You must be working very hard to keep your gums in shape!" The truth is I have not been working that hard, not been doing everything she recommended, at best doing what's adequate. It seems to be the flax seed oil.

David (2007-11-16 09:42:25)

August, I have been using Nordic Naturals Cod Liver Oil for about three weeks with good success. It has virtually no fish flavor, only the faintest hint sometimes. My understanding is that the Omega 3s in flax and fish oils are different, though.

NE1 (2007-11-16 11:26:00)

I have been taking fish oil 3x a day for the past month and a half. A week ago, I just sprained my ankle worse than ever before. It's still purple and swollen, tender to the touch. Clearly omega-3 delays the healing of more internal wounds and soft-tissue growth. ...

anonymous (2007-11-17 08:52:01)

Every time I drink flax seed oil, I have some shortness of breath. It goes away pretty fast but it happens.

sj (2007-11-19 20:06:28)

NE1, you sprained your ankle worse than ever before. Your words. CLEARLY, nothing is clear about Omega-3. Take some of your popeye vitamins, you'll feel better soon.

john (2008-05-10 09:45:48)

you people are funny. suspecting flax seed oil is causing or fixing all your problems. crackpots are too many. I would strongly look into the daily amounts that you consume. everybody is different. I read several sources claiming 2-3 grams is best, exceeding does not add any more benefits, possibly triggering reactions or side effects at higher doses. for me I take a small teaspoon of flax seed oil daily, or around 2 grams.. reason being.. duh! eat fish soy, tofu tempeh and you get more omega three on top.. getting different omega three from fish is a nice way to add more. oh oh..i have an elbow pain...could be I am not drinking enough flax seed oil?

Renea Johnson (2009-09-30 10:39:35)

I have been looking for information on what has happened to me since I began to take omega 3,6,9, I have had surgery for a Chiari malformation in my brain, and have ruptured all of the disc in my neck. Needless to say I have lived in pain for the last 7 years. my normal routine for taking pain meds is Lyrica (antiinflammatory), Ultram (pain) and a muscle relaxant 2x daily and inbetween I would lay on Icedoc and take ibuprofen. The pain was bearable but never gone. I had been taking omega 3 and seen some relief but I still hurt. I went to Sam's and found the omega 3,6,9, on sale so I decided to get some the first night I took it and when I got up I was pain free, so I took it again in the morning making me take 2x the suggested dose daily. I have seen my pain get better and this last weekend when I held my sick grandson for the whole weekend I hurt but after a day of rest I was back to having relief and it usually would have taken a week for me to get back to my normal pain level. I have quit taking my morning meds and am planning on weening off of my night pain meds. Praise be to God for creating a body that would respond to foods so well. I look forward to being my drugfree self again soon for the first time in over 7 years.

Blog-watch: Omega 3 (2011-11-24 14:02:11)

[...] improves mental ability (it certainly appeared to). This summer Seth Roberts noticed that, just as Tucker Max had observed with flaxseed oil (a source of omega 3) back in 2007, a larger than usual dose of flaxseed oil [...]

## **I Wonder What Seth Has Written (2007-11-18 00:18)**

I've been too busy at the Psychonomics Convention to blog – I will resume tomorrow. Tonight I looked at the Firefox button for my blog and thought: It would be nice to read something new. Then I realized, alas, that my blog does not

write itself.

---

Ben Webster (2007-11-18 14:31:52)  
It would if you had cobloggers!

### **The David Lawrence Effect (2007-11-18 17:29)**

Two days ago I was on the [1]David Lawrence Show, which Mr. Lawrence produces in his home in Los Angeles. This was the second time; the first was in June. The show lasts three hours and consists of three interviews. Between my first and second appearances on his show, Mr. Lawrence stopped doing regular shows to concentrate on acting. He now does new shows now and then.

During my second appearance, he told me that radio was going downhill even faster than network television. That may be, I said, but your show had a much bigger impact on interest in my diet than almost any other interview I'd done, TV or radio – and I'd done about 50. He was surprised. Really, I said, I'll make a graph and send you a copy. Later he asked me to compare his show to the other radio shows I'd been on – what was the percentage difference between the impact of my show and the other shows, he wondered. "2000 %" I said. "20 times?" he said. Yeah, I said, maybe even 50 times. He looked surprised.

Here is the data.

This shows the maximum number of people reading the Shangri-La Diet forums at any one time for each day. (This is an easy-to-compute proxy for the number of distinct visitors.) The first media to have a big effect was a [2]35-minute interview on the Dennis Prager Show, which was replayed twice. The next was a [3]Woman's World article. The third was the first David Lawrence Show interview.

It is stunning that the David Lawrence Effect was of the same order of magnitude the effect of the Woman's World article. Woman's World, of course, is a huge operation, with millions of copies sold each week.

After the David Lawrence effect wore off, the function continued its steady climb at roughly the level you would extrapolate from before the DL effect started. My interpretation is this: As persuasive as that show turned out to be, and as large its audience – its effect was small compared to the total effect of word of mouth, which is what is pushing interest up.

1. <http://www.thedavidlawrenceshow.com/>
2. <http://www.sethroberts.net/reviews/dennispragermay3interview.mp3>
3. [http://www.sethroberts.net/reviews/2006-10-03\\_Womans\\_World.pdf](http://www.sethroberts.net/reviews/2006-10-03_Womans_World.pdf)

---

Noumenon (2007-12-25 10:58:28)

The point you want to make is good, but if David Lawrence is like me he won't be very impressed by the chart. His spike is not 20 times as high as Prager's spike. You would need to post a chart of visitors with the baseline at zero for his spike to look impressive.

### **Too Skeptical = ? (2007-11-19 05:52)**

Paul Meehl, a famous clinical-psychology researcher, once said that when he was a student he was taught "the general scientific commitment not to be fooled and not to fool anyone else." Yes, the. I've heard a dozen variations of this: "In graduate school I learned to think critically," for example. How weirdly unbalanced. Isn't it just as important – or more important – to figure out what can be learned from evidence? Not just what can't?

The bias shows up in language. Skeptical is good, credulous is bad. There is no word that means too skeptical, no word that means under-credulous, no word that means the right amount of credulous.

When I hear comments like Meehl's – when someone says "correlation does not equal causation," for example, and does not stop to wonder what can be learned from the particular correlation being discussed – I think: You're only using half your brain.

---

katya (2007-11-20 14:43:56)

I think the word you're looking for (in terms of "just credulous enough") is "charitable": e.g. I'm willing to give the results of self-experimentation a charitable interpretation. Meehl's statement (out of context) isn't precisely skeptical = good, credulous = bad; self-experimentation isn't "fooling other people" as long as you make it clear that your N = 1 and includes the experimenter. Self-experimentation is just a more rigorous way of talking about your intuitions, and since most experiments proceed from intuitions, it shouldn't be abandoned. Also, skeptics are roundly believed not to be very much fun at parties. :)

Nansen (2007-11-20 16:57:04)

George Polya discusses the "heuristic syllogism" and the nature of plausible reasoning in *How to Solve It* (1957), sections 6 and 7 of the article "Signs of Progress", p. 186-190. These sections are online here: <http://reposeinthee.blogspot.com/2007/02/heuristic-syllogism-and-nature-of.html> In section 2 of the same article ("Signs of Progress", page 181) he notes: "If you take a heuristic conclusion as certain, you may be fooled and disappointed; but if you neglect heuristic conclusions altogether you will make no progress at all."

seth (2007-11-20 17:08:39)

Thanks, beta, that's a good quote. I suppose it supports my point that it comes from a mathematician rather than a scientist. yes, "charitable" may be the closest word. It isn't quite right though – charitable is not the opposite of skeptical or credulous.

Chris (2007-11-20 18:06:31)

Let's coin a word: "creditive", meaning 'tending to give credit', 'tending to believe'. While we're at it, let's start using "under-credulous", "over-credulous", and "appropriately credulous", to help spread the idea that skepticism is not an unconditional virtue.

seth (2007-11-20 21:37:00)

That sounds about right. I would add "over-skeptical".

### **A Better Way to Do SLD? (2007-11-19 12:25)**

The most interesting recent posts on the Shangri-La Diet forums have been from Roger Garrett (id [1]Fastneasy), who has come up with what seems to be an especially potent version of the diet: He has a three-hour food window every day that starts when he eats his first meal; the rest of the day, he drinks sugar water and doesn't eat anything else. He takes weekends off.

He's 36 years old. Starting weight: 269 pounds. After about a month, he writes, "I've lost 24 pounds so far. This has been incredibly easy! No hunger, no struggle, and tons of energy." He did almost the same thing eight years ago with one difference: no sugar water.

The difference between then and now is [now] I'm shedding the fat at three times the speed and with no anguish and fatigue that's associated with the fasting. I'm not hungry, my stomach doesn't growl. I have tons of energy and feel great in the morning. Also the funny thing, after waking in the morning after fasting for 21 hours, I'm not starving. I remember with the fast before I would wake in the night stomach growling and ready to eat. When I would wake up, I could kill to eat.

1. <http://boards.sethroberts.net/index.php?topic=5804.0>

---

Stephen M (Ethesis) (2007-11-19 17:51:18)

That is interesting. I found the best thing about the diet was that my metabolism didn't shut off after losing the first twenty pounds. That was a miracle, and it looks like it is happening for him.

seth (2007-11-19 18:42:40)

Yes, I agree. Your metabolism isn't fighting against the weight loss.

medi (2007-11-19 20:35:07)

Seth, i was wondering if you could give me quick snapshot as to what you are taking (exactly) at the moment for SLD and appetite supression. I believe it is an oil of some type - specifics please. Thanks!

seth (2007-11-19 21:34:39)

I'm taking 4 T/day flaxseed oil (nose-clipped) and 100-200 calories/day bland chicken (nose-clipped).

Chris (2007-11-20 17:59:56)

That's your maintenance dosage, is it?

seth (2007-11-20 21:38:05)

I haven't done it long enough to see where it will put me.

Coldnose (2007-11-20 22:24:31)

I've been experimenting with my own weight loss, like starvation dieting and eating huge amounts of various foods for AS's-sake. (Sushi and unsweetened applesauce give good AS, I've found). My experience is exactly the opposite of Roger Garrett's. The best solution for me is to take a large (400-600cal) dose of flax oil in the morning, then restrain myself from eating for as long as possible, because as soon as I taste food, my AS goes out the window. I flirted with starvation dieting before that, and I found that, from the moment I wake up, I can go without eating for a long time. Even if I went to sleep extremely hungry, I wake up with no craving for food whatsoever (though my stomach may grumble uncomfortably). As soon as I eat food, however, my self-control fails for the rest of the day. (just another data-point for you, Seth)

### **Blood Donation, Weight Loss, and Humor (2007-11-20 05:41)**

At the Shangri-La Diet forums, karky, who has lost 75 pounds on SLD, [1]wrote:

In July I experienced a plateau, and wrestled with the same 5 lbs all month. At the end of July, I donated a pint of blood. WooHoo! Weight loss is back! I think to myself, hmmm... coincidence. In November, another plateau, wrestling with 3 lbs. I donated a pint of blood Monday. Today is Wednesday, I have lost 5 lbs since Monday, 3 lbs Tuesday morning, 2 lbs this morning.

Chrianna [2]replied:

you certainly make a good argument for donating blood!

Which made me chuckle.

I cannot come anywhere near explaining karky's observation. But maybe I can explain – someday, not right now – why Chrianna's reply amused me. I once wrote down about 50 laugh-inducing sentences I heard on the the sitcom Cheers, looking for patterns. Several were obvious. For example, many of the laugh-inducing sentences were insults. Maybe I should resume this quest.

It is a good way to pass the time. A few days ago, I heard the following on a Chevrolet radio ad:

Male voice: With Pilates, three kids, and a house full of laundry, Diana is too busy to think about fuel economy.

Female voice: I'm sorry. Did somebody say something?

Funny! I was driving. I turned off the radio and thought about it for the rest of the trip. What's the rule? What general pattern is it an instance of? I couldn't figure it out. I'm not the only one interested in this question. In an interview I can no longer find, Robert Mankoff, cartoon editor of The New Yorker, said he wanted to write a scientific paper about the patterns he saw in New Yorker cartoon caption contest submissions. Which reminds me: I have written about [3]patterns in New Yorker cartoon captions and [4]talk-show monologue jokes.

Dennis Mangan (2007-11-20 08:46:45)

Blood donation could put one's metabolism into a "fight or flight" mode, i.e. blood loss makes one's body think an emergency is occurring. So maybe appetite decreases, metabolism increases.

Mike Kenny (2007-11-20 09:58:03)

My theory (and perhaps others have expressed it too, can't recall) is that humor is a means of venting anxiety caused by surprise that turned out to be harmless or not seriously harmful. Someone breaks wind—initially your ancestral-environment-oriented brain thinks "Is that sound dangerous?!" Then, "Oh, it was just Jim." You laugh, venting the anxiety. The surprise could be more complex. Giving blood could be thought of as a signal of altruism. "I wish to demonstrate I am a valuable person to the tribe." Giving blood for obviously selfish reasons damages the signal and could be potentially dangerous, until you realize it's not. You feel anxiety and then relax, seeing that expressing selfish motives for giving blood isn't likely to be worth worrying about.

James (2007-11-20 10:43:07)

You might want to read 'Made to Stick' by Chip and Dan Heath. The book discusses what makes ideas memorable to humans but includes a great deal on what makes things funny (since this also makes things memorable). Largely boils down to this: 'violate my expectations'.

seth (2007-11-20 11:20:06)

I blogged about Made To Stick: <http://www.blog.sethroberts.net/2007/04/06/made-to-stick/> Violation of expectations is part of humor – nothing we expect is funny. But humor requires more. In neither of my two examples (blood donation and Chevy ad) is there a clear expectation that is violated. I think anxiety makes us more likely to laugh. Nervous laughter. The "oh it was Jim" sounds more like the insult category than a "relieved to be safe" category.

Timothy Beneke (2007-11-20 12:11:58)

I've spent a lot of time on humor over the years. Historically, there are 4 major insights. 1. Hobbes has the "instant glory" notion; we laugh because we feel superior. You fall on a banana peel; I'm up, you're down ha ha. 2. Freud of course writes about conspiracies of aggression, using humor to express what's covert; this is in line with releases hidden anxieties we don't want to talk about etc... 3. Bergson, talked about the seeing the mechanical as animate, like a slinky toy going down the stairs... 4. The best writing on humor, which "contains" all of the above, is Arthur Koestler's "The Act of Creation". He gets to the heart of the matter. It's bisociation. We start from one matrix of thought, i.e., we are functioning with one set up background assumptions or modes of intelligibility, one frame of understanding. Why did the chicken cross the road? (Assumption: I'm telling you a joke) To get to the other side. (Assumption: I'm giving you obvious factual information about the chicken.) The two frames collide. Think of puns. We laugh to dispel a kind of cognitive disorientation, an eruption of confusion and then return to normalcy. Laughter is 85-90 % exhalation – try laughing while inhaling. All exhalation slows down heart beat and calms the ANS. Laughing at humor is pleasureable reconstitution of cognition; notice that groaning at puns or bad jokes is less pleasureable, but also involves exhalation. (Of course we laugh in many contexts; a psychologist at Vanderbilt is studying laughter rigorously and trying to break it all down.) In the radio commercial, the announcer is making a statement about how busy Diana is so that she can't think of certain thing; and Diana says she thinks she may have heard someone say something. My girlfriend has told me she thinks my hearing is getting worse. I respond by saying, "What did you say." She repeats it, and I say, "What?" Then

she gets that I'm making a joke. It's 2 frames colliding. In the commercial, there is the frame of an announcer in a commercial, and some implicit expectation that Diana is part of the commercial; there is a dramatic reality implicit in this. Then it's as if she doesn't know she's in a commercial or that he is present and speaking even. She's that busy. We are not quite used to this collision of frames; 50 years from now we might be and it might seem trite. Sometimes "matrices of thought" are hard to pin down exactly – those are often the best cases of humor. But When Robin Wright says, "I keep an enormous collection of seashells scattered across the beaches of the world. Perhaps you've seen them." It's very simple, but brilliant. I believe a computer could generate humor randomly by generating collisions of frames; most of it would not be funny, but there would be enough of it generated so we could find the funny examples. I've tried writing humor from Koestler's theory with some success...

dilys (2007-11-20 22:11:05)

Another take on humor strategy (from a course with Neil Simon's brother Danny) especially serially like sitcoms, is setting up, then satisfying an expectation from a character. Jack Benny being mugged – "Your money or your life" – "I'm thinking, I'm thinking." The greatest funny line in Cheers IMO ends the episode with John Cleese (of Monty Python) as a famous marriage counselor, who obviously considers Sam and Diane a disastrous couple. Diane, of course, won't accept this answer, and badgers Cleese mercilessly, at dinner, in the bath, etc. to his very funny outrage. Finally, to get rid of her and get some peace, he sarcastically screams that they are the greatest, most successful, most sublime match since Adam and Eve. Diane's one-word triumphant fade-out line: "See?!" Do you remember how you categorized this one?

Guys .. [www.thefirstblood.tk](http://www.thefirstblood.tk) is the website that collects blood donors' details and helps the blood seekers with the donors' info when there arises a need for blood. If you are interested to donate blood and help the needy in dire situations, please register in this website. Registration takes just 2 minutes of your life time but by this you can save lives of many people. Look website also for Voluntary Blood Donors Info when there is a need for blood .. Jai Hind ..

## More On Humor (2007-11-21 11:26)

When I was an undergraduate, I came up with an idea about why people laugh: Laughter is triggered by sudden pleasure. Not pleasure alone, it must increase quickly. Sudden pleasure is the necessary and sufficient condition for laughter. The threshold goes up and down – easier to make someone laugh if they're nervous or cold, for example – but the basic rule never changes. (Tickling is an exception, of course.) Two old friends unexpectedly encounter each other, they embrace, laughing.

Humor is a subset of what causes laughter. Obviously we enjoy humor and jokes have punchlines – the necessary conditions are met. Maybe humor can tell us something about evolution: What is funny reveals what we enjoy, which may have a genetic basis.

I figured out that many jokes derive their pleasure from more than one source. These sources include:

1. Something forbidden. We have something we want to say or would enjoy saying; humor lets us say it. Insults, sexual stuff, scatological stuff (for children), swear words. Political jokes, a much bigger deal in the former Soviet

Union than in America, tell forbidden truth about the government.

2. Something clever. Connecting two things that are quite different.

3. Something incongruous. Many New Yorker cartoons involve [1]animals talking or children talking like adults.

Many jokes are clever insults, for example. Maybe the "did somebody say something" joke that I was [2]puzzled about is an example. The speaker is saying "I don't care about what you care about" (an insult of sorts) in a clever way.

I suspect this list is incomplete – but now that I've made it I can test it.

2. <http://www.blog.sethroberts.net/2007/11/20/blood-donation-weight-loss-and-humor/>

---

Geremiah (2007-11-21 13:11:22)

Interesting. This has always seemed to me like an incredibly tricky nut to crack (necessary/sufficient conditions for humor), but here are some thoughts. I think "pleasure" is wrong, because most cases of physical pleasure I can think of are counterexamples. When you're starving to death and you tear into a sandwich, that's a pretty sudden increase in pleasure. Or when you're freezing and someone lets you into a heated room (or vv). Those don't tend to cause laughter. My leading theory has to do more with relief, but a particular kind of relief - simultaneously empathizing with a belief about the world and seeing that it's completely wrong. Nearly every case I can think of where I have a "bird's-eye view" of someone's situation, and can see why their interpretation of it and reactions to it are totally misguided, is funny. (This describes a surprisingly large # of jokes and funny scenes, so if you can't think of examples I haven't put it well enough.) Another thing that is pretty reliably funny is watching two people come from completely different perspectives, and seeing just how out of whack each's perception of the other is (while understanding the perspective that leads them to this crazy perception). Even slapstick seems to work this way: a guy walking merrily along before falling into a pothole or bumping into a pole is funny (again, the viewer sees what he "should have known"). But a piano falling on a guy who's been walking cautiously along, actively looking for something dangerous, is not funny. This also would explain why a joke's power fades with familiarity. You stop feeling the relief at having escaped the wrong belief about the world, because you get so used to how wrong the belief is that you lose any empathy for it. Similarly, it would explain why there is no easy or systematic way to come up with funny jokes, except when targeting a very stupid audience. You need to create relief in your audience - that means finding a belief that is wrong but still draws them in in some way.

Geremiah (2007-11-21 13:17:01)

A couple more thoughts: 1. The counterexamples to your theory aren't just physical. Watch someone as they watch their sports team turn a win into a loss in under a second (this happens with buzzer-beaters in basketball, walkoff HR in baseball, etc.) You'll see shouting and displays of aggression, no laughter. 2. My theory is also consistent with the fact that humor nearly always feels "profound" - it seems like there is something higher about laughter and comedy than strict pleasure (or stories with happy endings). Under my definition, humor is always built on recognizing a fallacy, so it always represents "learning" something in some small sense.

seth (2007-11-21 13:25:01)

"When you're starving to death and you tear into a sandwich." The sandwich isn't unexpected. The increase in pleasure is therefore gradual - it started long before you actually started eating the sandwich. Likewise someone letting you into a heated

room. Relief would not explain why old friends laugh upon unexpected encountering each other. Lots of everyday examples of laughter don't involve relief.

Varangy (2007-11-26 18:37:45)

Evolutionarily speaking I think laughter has little to do with the reasons, while interesting, you list above. I think that laughter is a hard-to-fake social signal of group cohesion, liking and affection. Some food for thought: 1) Why do we tend to like funny people? That is actually the wrong way to think about it. Think about it this way, the more we like someone, the more funny we tend to find them. 2) Why does laughter hurt? For example when a group of people are laughing at the expense of one in the group. The laughter signals who is part of the in-group and who is part of the out-group. 3) Why is fake/forced laughter so annoying? Sometimes people want to be liked and force themselves to smile/laugh – when done poorly, they repel those they want to attract.

seth (2007-11-26 22:04:02)

Your team suddenly loses and nobody laughs – why is that a counterexample? It isn't pleasant to see your team lose. Sure, laughter is a signal. But a signal of what? Humor and laughter obviously go together – humor if good enough provokes laughter. Humor exists in non-group settings. New Yorker cartoons are still funny when I look at them by myself. Laughter may indeed promote group cohesion because we like it when someone makes us laugh and it is much easier to make someone laugh if you know them well—if the two of you are in the same group.

Mike Kenny (2007-12-02 21:03:49)

One puzzle I contemplate—why do babies cry at surprises sometimes, and other times laugh? Babies seem more likely to laugh at visuals and more likely to cry at loud noises.

## Drugs and Depression (2007-11-21 12:04)

The most gripping portions of [1]Let Them Eat Prozac [by David Healy] narrate courtroom battles in which Big Pharma's lawyers, parrying negligence suits by the bereaved, took this line of doubletalk to its limit by explaining SSRI-induced stabbings, shootings, and self-hangings by formerly peaceable individuals as manifestations of not-yet-subdued depression.

Yeah. From an excellent [2]book review. The author of the review, an English professor, doesn't understand methodology, but the facts are nicely presented. I assigned some of Healy's book to my students. Healy did experiments that showed that Prozac caused suicidal thinking in a non-trivial fraction of ordinary people.

2. <http://www.nybooks.com/articles/20851>

lasser11 (2007-11-21 19:09:11)

Seth, you don't the history of Psychology. I know the history of Psychology. ha, just joking. Tom Cruise had a point.

### **Perception vs. Reality: Nuclear Power (2007-11-22 06:14)**

[1]A fascinating post by Stephen Dubner – with help from Gwentyth Cravens – says that our perceptions of the danger of nuclear power have been warped, and not in a good way. Years ago I saw a scatterplot that showed perception of risk versus actual risk for many possible dangers: auto accident, being hit by lightning, and so on. Nuclear energy was a whopping outlier. Its perceived risk was much greater than you'd expect from its actual risk. From that outlier, a book with a great title: [2]Power to Save the World.

1. <http://freakonomics.blogs.nytimes.com/2007/11/21/do-not-read-this-if-you-are-anti-nuclear-energy/>

2. <http://online.wsj.com/public/article/SB119551341776798449.html>

---

Ben (2007-11-22 10:01:28)

Hi Seth, Do you remember where you saw that scatterplot?

seth (2007-11-22 12:36:54)

I think it was during a talk by Ken Craik, a professor in my department. I can't remember why he was showing it.

Ben (2007-11-22 14:49:19)

Thanks!

### **At Thanksgiving Dinner... (2007-11-22 22:44)**

...My sister said that – curious from reading this blog – she increased her daily dose of flaxseed oil from one capsule (10 calories) to 1 Tablespoon (110 calories) per day. She noticed three positive effects. One is that the skin around her fingernails improved. It cracked less often. (I'd say the same – hadn't realized it until she mentioned it.) Another, first noticed by her dentist ("I didn't say anything"), is that her gums were in better shape. The third, more subtle than the first two, is more energy. She has noticed no negative effects.

---

### **The Truth About Advertising (2007-11-23 08:07)**

At a recent party, I met a brand manager for a very large company. He explained how advertisements are designed. You do a focus group to find out the real reason people buy your product – what they really want from it – then you make your advertisements reflect that reason. For example, people do not buy [Product X] because it does [the

stated function of Product X]. They buy it because they want to feel confident. So the ads for [Product X] show people appearing confident.

I had heard this before, but never so clearly. A NY Times [1]article about Western Union provides another example:

Having once stressed efficiency (â€œthe fastest way to send moneyâ€?) [in its ads], Western Union now emphasizes the devotion the money represents. One poster pairs a Filipino nurse in London with her daughter back home in cap and gown, making Western Union an implicit partner in the familyâ€™s achievements. â€œSending so much more than moneyâ€? is a common tag line.

1. <http://www.nytimes.com/2007/11/22/world/22western.html?pagewanted=1&ei=5090&en=5df21be09f41e1d4&ex=1353387600&partner=rssuserland&emc=rss>

### **Please, Mr. Kirn, I Want a Summary (2007-11-23 21:31)**

Years ago, Bill McKibben gave a reading at Black Oak Books, a Berkeley bookstore. After the reading he chatted with a friend. The grade of B his book had received from Entertainment Weekly came up. "It settled arguments around the house about who's the better writer," McKibben said. His wife's most recent book had gotten a B+. McKibben and his friend then decried the EW practice of giving grades to books as if they were term papers. Perhaps they called it "simplistic".

Whereas I think EW has exactly the right idea. I liked Ha Jin's Waiting. I respect Walter Kirn. I was pleased to see that Kirn [1]reviews Ha Jin's latest book, A Free Life, in the current New York Times Book Review but I became a little dismayed as I read Kirn's review: What exactly was he trying to say?

Volatility, after all, is a measure of health in a free market, and the elementary algebra of Jin's narrative pace â€” as slow, implacable and steady as interest accumulating in a savings account â€” implicitly promises that his dimes and quarters of mundane description and petty conflict will result in a full piggy bank for all. Neither does Jin give his people flaws or problems grave enough to threaten their well-being. Pingping's chronic fretting is not disabling, and Nan's nascent ambitions as a poet aren't the kind that lead to leaps off bridges if they go unattained.

Huh? Kirn seems to be saying the novel is too predictable but I'm not quite sure. I would really have liked a grade at the end so that I could have figured out what Kirn thought overall.

Kirn wrote for Spy; I met him there once and told him I loved his article about "The First 100 Lies" (of the Bush pere presidency). Where is Review of Reviewers, one of Spy's best features, when we need it?

1. <http://www.nytimes.com/2007/11/25/books/review/Kirn-t.html?8bu&emc=bu>

---

### **Fish, Omega-3 and Human Health (2007-11-24 06:58)**

I ordered [1]Fish, Omega-3 and Human Health (2005, 2nd ed.) by William Lands from Amazon in March. It came a few days ago. It is published by the [2]AOCS Press. AOCS = American Oil Chemists' Society.

A jewel of a book. Like a research monograph, it has lots of data, graphs, and references; unlike a research monograph, it tries to reach any scientifically literate reader, not just specialists. It has much more about mechanism than other books on the subject. "Health" in the title mainly means circulatory system health (heart disease, strokes); there is also a chapter on the immune system and a chapter on cancer. Almost nothing about mental illness or the brain. Nothing about gum disease.

I read the first edition a year ago. It is a sign of changes in my thinking that I didn't notice a comparison of epilepsy rates in Eskimos (high omega-3 diet) and Danes (low omega-3 diet) living in Greenland. The Eskimos have twice as much epilepsy. It is the only big negative effect of the Eskimo diet. The epilepsy difference fits something I think now but didn't think a year ago: omega-3 makes neurons more easily excited. Three observations led me to this: (a) In my choice reaction-time experiments, flaxseed oil caused an increase in anticipation errors. To reduce them, I changed from a two-choice task to a four-choice task. (b) A friend said I have become more talkative, apparently due to consuming much more flaxseed oil/day. (c) I found that [3]flaxseed oil reduces simple RT - latency to press a button when something happens.

The two-to-one epilepsy ratio is the only case where the Eskimos are clearly worse off. The ratios in the other direction are much larger. The Danes had 20 times more psoriasis than the Eskimos (as I [4]noted earlier), and 25 times more bronchial asthma.

1. <https://www.aocs.org/catalog/product.asp?ID=w204&dept=10>

2. <https://www.aocs.org/press/>

3. <http://www.blog.sethroberts.net/2007/10/25/science-in-action-omega-3-simple-reaction-time/>

4. <http://www.blog.sethroberts.net/2007/02/10/omega-3-facts-of-the-day/>

---

Ben A (2007-11-25 13:52:26)

I recall from undergraduate lectures that Eskimos also suffer from increased risk of haemorrhage, and this was linked to increased omega-3 intake. Take [1]this paper for example (although it doesn't investigate diet).

1. [http://www.ncbi.nlm.nih.gov/sites/entrez?Db=pubmed&Cmd=ShowDetailView&TermToSearch=6837347&ordinalpos=7&itool=EntrezSystem2.PEntrez.Pubmed.Pubmed\\_ResultsPanel.Pubmed\\_RVDocSum](http://www.ncbi.nlm.nih.gov/sites/entrez?Db=pubmed&Cmd=ShowDetailView&TermToSearch=6837347&ordinalpos=7&itool=EntrezSystem2.PEntrez.Pubmed.Pubmed_ResultsPanel.Pubmed_RVDocSum)

seth (2007-11-25 19:21:51)

Yes, good point.

### **My Favorite Comment (2007-11-24 11:05)**

Thank you, j n kalhan, for [1]your comment on a [2]post of mine that speculated that Joyce Hatto and Ranjit Chandra might be twins separated at birth:

It is not true. I have personal knowledge. Dr. Chandra has no twin brother.

1. <http://www.blog.sethroberts.net/2007/09/13/joyce-hatto-and-ranjit-chandra-separated-at-birth/#comment-756>

### **The Most Surprising Sentence in Good Calories, Bad Calories (2007-11-25 04:07)**

Gary Taubes' Good Calories, Bad Calories is overall a very good book, especially in its description of evidence. But there is also this:

Life is dependent on homeostatic systems that exhibit the same relative constancy as body weight, and none of them require a set point.

How does he think body temperature is regulated? Taubes continues:

It is always possible to create a system that exhibits set-point-like behavior or a settling point without actually having a set-point mechanism involved. The classic example is the water level in a lake, which might, to the naive, appear to be regulated from day to day or year to year, but is just the end result of a balance between the flow of water into the lake and the flow out.

No, lakes do not "appear to be regulated" because they do not exhibit anything like hunger or feeling cold. When the water level in a lake is lower than usual, nothing happens to push the level back up. Taubes continues:

When Claude Bernard discussed the stability of the milieu interne and Walter Cannon the notion of homeostasis, it is was this kind of dynamic regulation they had in mind, not a central thermostatlike regulator in the brain that would do the job rather than the body itself.

[1]Michel Cabanac would not enjoy reading this. Whatever Bernard and Cannon had in mind, there is a "central thermostatlike regulator in the brain" that controls body temperature. It makes us seek warmth – take a warm shower, drink hot drinks, put on a jacket – when our body temperature is too low and do the opposite – such as drink cold drinks and eat ice cream – when our body temperature is too high. When our body temperature is too high, we find a warm shower more pleasant than when our body temperature is too low. These changes are obvious – at least, once you look for them – and imply a thermostat in the brain.

1. <http://jap.physiology.org/cgi/content/abstract/100/4/1338>

---

Dennis (2007-11-25 13:37:23)

I don't know if you've seen this: <http://www.arthurdevany.com/webstuff/WhyWeGetFat.pdf> Thought you might be interested in it, given your writings about set points and evolutionary explanations.

Tim Lundeen (2007-11-25 16:25:59)

Another example is re blood sugar levels. Dr Bernstein writes about sampling thousands of normal blood sugar levels, and finding them all at 83, +/-3. Some of this may be a matter of semantics, though, rather than disagreement about mechanisms. The set point for blood sugar appears to primarily due to pancreatic machinery that is "set" for 83, rather than something in the brain per se. Still, the brain is intimately connected to glucose homeostasis, and controls diet and cephalic-phase insulin when you eat familiar foods.

seth (2007-11-25 18:31:59)

I don't know much about blood sugar regulation. But it is clear that with body weight and body temperature, counter-acting behavior (e.g., seeking warmth when you are cold) helps keep the level constant. This implies brain involvement and a regulatory system more complicated than the forces controlling the level of a lake.

Timothy Beneke (2007-11-26 00:56:38)

I find it hard to know how much of this is semantic. Science often proceeds by understanding biological functioning in terms of technology. We didn't know the heart was a pump until someone invented a pump; that is not metaphoric – the heart actually is a pump of sorts. I'm told that radar technology helped get the mind back into psychology in the 1940s... Understanding weight control in terms of a thermostat may just be a metaphorical mapping where some parts hold but others do not. There is a regulatory system with causal interactions that can be identified – exposure to poorly learned tastes reduces hunger, to

strongly learned ones increases it; enduring hunger and losing weight (in my view) increases "sensitivity" or readiness for the system to learn or respond to taste-calorie associations – but how much does it really matter if we add the notion of an entity, a noun, "a thermostat in the brain". If we find some controlling mechanism in the brain that does that, fine. And is there really a "point" that the "brain" sets in some way? Is this a metaphor? Or is there just a set of causally interactive processes at work that are easier to understand if we talk this way? When do we need to say that there is a central regulator regulating a biological system and when do we say there is just a system that regulates itself? Does positing a "thermostat in the brain" explain the system or merely re-describe it? Perhaps that will only be known if one is identified. Or is it obvious that there \*must\* be one given the functioning of other neurobiological systems? How do we empirically determine the difference between a system that merely behaves as if there were a thermostat in the brain and a system where there actually is one? Ad nauseum...

seth (2007-11-26 02:38:11)

Why does it matter whether there is a "thermostat in the brain"? That Taubes is wrong about something pretty obvious makes it more plausible to me that he is wrong about something less obvious – whether there is a set point for weight. If you think there is a set point for weight you can entertain the possibility that the set point is adjustable. If you think it is adjustable you can entertain the possibility that it is adjusted based on environmental conditions (as Cabanac concluded the temperature set point is). If you believe in an adjustable set point based on environmental conditions you can begin to wonder what the exact rule is. The more detailed your theory, the easier it is to derive predictions that you can test.

Timothy Beneke (2007-11-26 09:47:22)

Still not convinced there is a disagreement of substance. Taubes is not denying that you can intervene in homeostatic systems; you can reduce body temperature with aspirin or cold. Or even change the depth of a lake. He is just saying the regulatory system may be the whole body itself rather than a thermostatic system in the brain, a little homunculus in charge of things. The existence of the system for hunger control is to me, undeniable; and god knows we can intervene in it, but whether there is the equivalent of a thermostat in the brain may be an open question. The causal system may resemble a thermostatic system without their being some special mechanism "in the brain" that "sets" hunger levels. Yes, thinking of it in the way you do may lead heuristically to better interventions. It actually seems kind of conceptually tricky because we have a biochemical neurological system interacting with consciousness – awareness of flavors and memory of previous flavors – so straight biochemical concepts are not quite enough. The thermostat has no consciousness; it's straight chemistry. The brain/body does... John Searle claims there is a lot of intellectual confusion because people confuse behaving according to a rule, and following a rule... Assuming all of this makes it easier to intervene. You are making a conceptualist argument; there is a system that can be intervened upon sure, I guess the question is whether it "sets" a hunger level the way a thermostat does, or whether what is set, is constantly changing, which is where the metaphor breaks down... Of course thinking about it this way enables you to intervene; it clearly is a system of causal forces, analogous to a thermostat... Part of the system can be destroyed and it no longer regulates; a person can have a stroke and their temperature regulation system can fail... Whether there is a homunculus in the brain, or just a more diffuse systemic bodily system. Taubes would not deny that you can intervene in the other systems; you can lower body temperature with aspirin or cold packs; you can lower hunger by getting calories without taste, or sugar water (the latter would blow Taubes' mind).

David Brown (2007-11-30 20:18:35)

The appetite regulating mechanism is probably far more complex and variable than any of us currently imagine. There's ghrelin and leptin and insulin, all interacting to regulate hunger and satiety and fuel availability. Probably, then, the biggest hindrance to developing a good working model of the appetite regulating mechanism is the biochemical variability of the metabolic machinery in cells and the physiological variability of the various organs of digestion, absorption, and hormonal regulation. Taking data on all of this variability with all of its attendant uncertainties and making statistical sense of it is a major challenge for modern science. Perhaps we shouldn't argue passionately about particulars at this point.

Sara R (2008-03-06 17:24:44)

I think the point of the book was that we tend to get dogmatic about all of this instead of looking at the facts. We don't have all the facts yet. In the context of set points, even though there is evidence that they exist in the human body, we still cannot

prove that they do. It is very hard to prove until we understand how all of the related factors correspond on the entire system. This is not religion we are talking about, though and we cannot go on faith. It has to be based on science. I think that was the point of the book.

### **Omega-3 and Sports Injuries (more) (2007-11-25 12:10)**

Anonymous found, to his surprise, that [1]his martial-arts injuries healed faster after he started taking flaxseed oil (2 T/day). A [2]comment about Popeye vitamins led him to [3]stop taking flaxseed oil. Within ten days, his gums got worse, and his sports injuries became more painful. He has written again:

After going off flaxseed oil for about ten days and seeing all sorts of negative side effects, I have now been back on it for about ten days (this time with four tablespoons a day instead of two), and I am totally back to where I was before I stopped. Gums aren't bleeding at all, joints and tendons don't ache, and I feel great. Anecdotal evidence yes, but very persuasive to me. I have kept taking four tablespoons instead of the previously normal two because I think it increases my mental acuity

Very persuasive to me, too, regardless of what it is called.

Matthew (2007-11-25 12:43:38)

I had a very similar experience. I'm a recreational cyclist, 30 years old, and I ride a decent amount—maybe 100m/week. I actually started cycling when I developed severe Planar Fasciitis as a runner and required surgery about 2 1/2 years ago. For a long time I battled knee pain when I rode, but I was able to control it with exercise to balance my leg strength to make the kneecap track properly and a professional bike fitting. During this time (about a year ago) I started doing SLD with flaxseed oil (after having lost 25lbs. on sugar water the year before in an effort to take some of the weight off of my feet but being unable to run), and I noticed that the pain went away, along with most of the foot pain. I also had a much easier time during allergy season and experienced less symptoms of exercise asthma that I usually get during the winter. Anyway, about 2 months ago I did sort of an accidental experiment on myself by running out of fish oil capsules (I switched to these because I don't tolerate swallowing the oil well) and being too busy/lazy to go buy some more. Within a week, the knee pain was right back to where it was. I could hardly make my 5 mile commute by bike without moderate to severe knee pain. I finally got around to replacing my fish oil supply, and then within 5 days of resuming my regimen, the knee pain was gone completely.

seth (2007-11-25 13:28:58)  
Excellent story, Matthew.

willy (2007-11-26 10:51:07)

How long does it take to notice the effects from flax oil when you start it (mood and energy)? A week in general?. I also notice a difference between flax and fish oil. Thanks.

seth (2007-11-26 11:51:42)

I noticed an improvement in balance from flaxseed oil within about 12 hours. In my recent experiments it takes about 2-3 hours to see improvement in brain function. Keep in mind that I have lots of the necessary enzyme because I have been taking flaxseed oil for months. A beginner may not. So if you have enough of the enzyme, the effects of a large-enough dose should occur in hours. Effects on gums take longer – perhaps a week or two to reach full strength. What difference did you notice between flax & fish oil?

Willy (2007-11-26 14:17:25)

Flax oil seems to give me more energy than fish oil, but I did not compare equal doses. Do you mean the anzyme that converts EFA to EPA?. I did not know the enzyme upregulates when more omega 3 is available. I started taking one tablespoon of flax oil about two weeks ago, so maybe I still have to wait.

seth (2007-11-26 16:12:03)

yes, the enzyme that converts short-chain to long-chain. Many enzymes work that way: when there is more stuff to be converted, more of the enzyme is made. You might try 2 T/day flaxseed oil to see effects more clearly than with 1 T/day.

Mike (2008-02-15 10:31:18)

Great information about flaxseed oil! I've been taking it for a little over a week, and noticed my lower body joints no longer hurt. Before the flax, it would hurt to walk downstairs, the day after running. My question is, when do you take flax? I try to take it before lunch so my stomach is pretty empty and nothing will hinder the digestion process. But I don't know when the optimal time is.

seth (2008-02-15 10:50:23)

I don't think it matters when you take it. I take it at all different times – before lunch, after lunch, before bedtime. I don't take it at meals so that it acts to reduce my weight. As this post shows, the effects take about a week to build up. That kind of slow build up means that the exact timing is unlikely to be important.

ebrageem (2009-03-13 23:02:34)

what i the effect of omega 3 on heart during sport ?please send it for me

## **A New Kind of Advertising (2007-11-26 12:19)**

This doesn't look like an ad, but it is:

[EMBED] It points to a website where the product – a Samsung mobile phone – is more obvious. Watching the video a second time I can see something is fake about it – it's too generic – but that wasn't obvious the first time I watched.

---

## **Omega-3 and Blood Pressure (2007-11-26 15:07)**

I was surprised to see a chapter in Fish, Omega-3 and Human Health devoted to hypertension. Isn't high blood pressure caused by too much salt and too much weight? Well, yes, but a special strain of rats used as an animal model

of hypertension turned out to have a defect in their immune system. Perhaps high blood pressure is also caused by immune-system over-reaction.

A [1]1993 meta-analysis of studies of the effect of fish oil on blood pressure concluded:

Diet supplementation with a relatively high dose of omega-3 PUFA, generally more than 3 g/d, can lead to clinically relevant BP reductions in individuals with untreated hypertension.

The sizes of the blood pressure changes:

Weighted, pooled estimates of SBP [systolic blood pressure] and DBP [diastolic blood pressure] change (mm Hg) with 95 % confidence intervals were -1.0 (-2.0 to 0.0) and -0.5 (-1.2 to +0.2) in the trials of normotensives, and -5.5 (-8.1 to -2.9) and -3.5 (-5.0 to -2.1) in the trials of untreated hypertensives.

A [2]different meta-analysis reached essentially the same conclusion.

Note the use of fish oil. Fish oil has long-chain omega-3 fats, while flaxseed oil – which I have used in my self-experimentation – has only the short-chain omega-3 fat, which is converted to long-chain omega-3 after you eat it. Fish oil is often considered better because the omega-3s don't need to be converted. But this way of thinking misses something. Because the omega-3s in flaxseed oil are converted to long-chain omega-3s by enzymes, the amount of long-chain omega-3 in the body rises more slowly (and thus lasts longer) than if you take fish oil supplying the same amount of long-chain omega-3. Flaxseed oil supplies a kind of time-release long-chain omega-3. A long low dose [3]could easily be more potent than a short high dose.

Thanks to Dave Lull.

---

NE1 (2007-11-26 19:43:56)

I'm sure something in Dr. Davis' past education prompted his speculation about dose frequency, but he does not sound very convincing. The liver holds vitamins until needed, surely the body has some way of dealing with the oh-so-important omega-3 fats. His theory sounds more like pandering to our voodoo instinct: be sure to shake the bottle 7 times before it's opened, too. It activates the molecules at their resonant frequency.

seth (2007-11-26 21:56:49)

I agree that Dr. Davis is remarkably vague: "more frequent dosing may provide a larger effect. The least effective dosing is once per day; twice per day is far more effective. Three times per day, although cumbersome, provides even greater effect." He never says what "effect" is being measured. Why not?

Dave Lull (2007-11-26 22:57:41)

I think the "effect" that Dr Davis is looking for is a decrease of triglycerides to 60 mg/dl or less, and the elimination of "intermediate-density lipoprotein, or IDL, also called 'remnant lipoproteins' on a VAP panel." \* \* See "How much omega-3s are enough" here: <http://heartscanblog.blogspot.com/2007/05/how-much-omega-3s-are-enough.html>

Igor Carron (2007-11-27 10:48:56)

on an unrelated note, it seems to have an effect on Parkinson's <http://www.sciencedaily.com/releases/2007/11/071126110453.htm> Igor.

### Israel Ramirez on Gary Taubes (2007-11-26 20:52)

The [1]theory behind the Shangri-La Diet was inspired by [2]research of Israel Ramirez, which I describe in an appendix ("The Science Behind the Theory Behind the Diet") to the book. I recently asked Ramirez what he thought of Gary Taubes' idea in Good Calories, Bad Calories that we are fat because carbohydrate consumption pushes our insulin levels too high. He is especially well-qualified to judge because he has done [3]experiments in which insulin injections induced obesity in rats. His reply:

As I understand Gary Taubes, he has resurrected Atkins's™ idea that carbohydrates stimulate insulin which lowers blood glucose and thereby induces more eating. The evidence for this is not very compelling. You can induce overeating with insulin in lab rats but you have to give so much insulin that the animal is in danger of dying. I am not aware of any experiments of this sort in people but diabetics don't™ often report being hungry after accidentally giving themselves too much insulin. There are exceptions to this pattern; for people and lab rats, glucose levels tend to fall shortly before eating.

There are clinical trials in people and lab rats showing that high protein, low carbohydrate, diets suppress intake. For people, the effects are modest in the long term, amounting to a few pounds greater loss than for people given a low fat diet at the end of a one year trial. There is some evidence that this weight loss might not be maintained after the first year. Trials showing weight loss on low carbohydrate diets required eating less carbohydrate than that consumed by 99 % of lean people.

Cross national and historic data don't strongly support Taubes. People in countries where traditional high carbohydrate diets are still consumed are often lean, i.e. Japan and China. In recent times, as people in these countries have shifted away from traditional starch diets, frequency of obesity has increased. Intake of soft drinks, on the other hand, does roughly parallel incidence of obesity. I interpret the beverage correlation as a psychological phenomenon but it is also consistent with Taubes.

Even if Taubes were entirely correct about carbohydrates, it would not contradict the idea that learning influences the amount of food you eat. Nor would it mean that extremely low carbohydrate diets are best or easiest way to lose weight; Seth Roberts's™ method may still be easier for many people.

---

Dave Lull (2007-11-26 21:37:48)

Gary Taubes comments on the Chinese diet here: [scroll down to the bottom:] <http://livinlavidalocarb.blogspot.com/2007/10/gary-taubes-continues-his-dietary-truth.html#1207525350668233528> And he comments on the Japanese diet here: [http://www.nytimes.com/2007/09/23/magazine/23Taubes.html?\\_r=1&fta=y&oref=slogin](http://www.nytimes.com/2007/09/23/magazine/23Taubes.html?_r=1&fta=y&oref=slogin)

Laura Ramirez (2007-11-26 23:43:47)

The effect of insulin on hunger is only part of Taubes' premise. Another part, is how insulin contributes to obesity by impairing the body's ability to utilize stored fat for energy. Taubes' survey is a critique of the culture of science and research, and the weakness of evidence for the current recommendations to the public about how to lose weight, avoid cancer, heart disease and stay healthy.

Pearl (2007-11-27 03:36:25)

Unfortunately I don't agree with Taubes' response to the Japanese diet. He's right; they don't eat a lot of sugar. But if what's he's saying is true, then most of us English teachers, who usually eat a bowl of rice with school lunch, would all be getting obese because we're not used to digesting the sugars. This is quite the contrary. All of the teachers in my city had their weight fluctuate, but it went up or down depending on the person. The most often cited case for weight loss was not being used to the food and feeling lack of hunger and pleasure from eating. For weight gain, it was increased snack and fast food or increased alcohol consumption that seemed to cause it. It was actually considering the Japanese diet that caused me to really have faith in the flavor-calorie association theory; Japanese food is traditionally very low in flavor and with the exception of rice, slowly digestible. When I sit down to bowl of rice, some pickles, and a bowl of miso soup, I feel full far faster than on western food, with far fewer calories. Processed foods usually vary in flavor as well, even sodas come in flavors like wasabi, banana, or cucumber, that change every season. And there are very few "secret sauces" to get addicted to. Seth's explanation makes sense in the context of the Asian diet. The low carbohydrate diet leaves a huge loophole when you consider the diets of the some of the healthiest nations on the planet.

Lancaster (2007-11-27 12:07:22)

Pearl has a good point. Compare mashed potatoes (as served in the U.S.) and rice as served in Japan. Rice served with a meal in Japan is white and unflavored. The idea of "seasoning" white rice in Japan is as unthinkable as eating mashed potatoes plain in the U.S. But when looking at a country like Japan, another obvious variable has to be taken into consideration: price. The retail cost of rice in Japan is 2-3 times that in the U.S. Interestingly, though, a Big Mac is not. And neither are tremendous variety of "traditional fast food" meals served at the ubiquitous mom & pop shops that compete directly with McDonalds (and deliver!). Taubes is quite right that sugar (HFCS)-based junk food in Japan is considerably more expensive and is served in smaller portions.

Pearl (2007-11-27 16:29:45)

Actually, they do sometimes season white rice with "furikake"; toppings made with seaweed, sesame, salt, pickled plum, beefsteak leaf, dried fish, or dried vegetables, so it's not exactly "unthinkable" to season rice, but it is far more common to see it served plain. You wouldn't get furikake on rice in a restaurant, for example. It also depends on what your definition of seasoning is. Spices are generally not found in foods other than curry, which itself is considered a food borrowed from foreign countries. A lot of traditional food is mostly a balance between salty and sweet, or salty, sweet, and sour.

Lancaster (2007-11-28 11:34:59)

By "seasoning," I was thinking in terms of mashed potatoes, where the whole bowl of carbohydrates is heavily buttered and seasoned, so that every bite tastes the same. Like a big bag of potato chips. The only comparison I can think of is the common faux pas foreigners commit by dumping soy sauce directly on white rice (treating it like mashed potatoes). One exception might be onigiri, where the rice can be very lightly seasoned. Emphasis on "very lightly." Onigiri is actually a good case in point, where a lot of rice (practically unflavored) is interrupted by small, concentrated bits of unique flavor.

SciLibby (2007-12-12 07:35:44)

I wonder if genes that make certain people or populations sensitive to large intakes of carbs would make Taubes' theory true \*in those people\*. It seems that moderation is a good rule of thumb for most people, but for some, much less carbs might be the ticket, and this could be a result of their genes that control how their bodies respond to carbs.

### **Interview with a Discoverer of the Importance of Omega-3 (2007-11-27 15:31)**

Dr. Jorn Dyerberg was one of two Danish doctors who discovered that Eskimos in Greenland, with low rates of heart disease, have much more omega-3 in their blood than Danes in Greenland, with normal rates of heart disease. This was the beginning of the great interest in omega-3s. [1]Here is an interview with Dr. Dyerberg. Among his comments:

As for ALA, an omega-3 from plants that is converted in the body to EPA and subsequently DHA, he was unconvinced. In terms of biological effects of DHA and EPA, Dr. Dyerberg said there are many. "We don't know of any specific biological effects of ALA," he said.

"Tissue experiments give you an ALA concentration of zero. This omega-3 is either burnt or converted," he said. "And the conversion is low."

"If we want the benefits of omega-3, we have to eat them as long chain," he said, referring to EPA and DHA.

[2]My research – revealing very clear benefits of flaxseed oil, no doubt because of its ALA – shows this is quite wrong.

Thanks to Dave Lull.

1. <http://www.nutraingredients.com/news/ng.asp?n=81606>

2. <http://www.blog.sethroberts.net/2007/02/24/omega-3-greatest-hits/>

---

anonymous coward (2007-11-27 17:31:33)

Isn't it a wee bit misleading to end the quote where you do? With your edit, you can say "My research – revealing very clear benefits of flaxseed oil, no doubt because of its ALA – shows this is quite wrong." But Dr. Dyerberg continues directly "But it wasn't all doom and gloom for ALA, as Dr. Dyerberg said it could be effective: "If you change your diet dramatically, you can achieve the same EPA and DHA levels in cells on an ALA diet, but you have to change your diet totally," he said. "Diet compliance will be poor," he added." Most observers would have to agree that changing the diet to ingest 500 calories per day of flaxseed oil, which is something like 25 %-30 % of a person's total daily calories (with little other nutritional value), is a very major ("dramatic") diet change, and one that most people would tire of rapidly. You have changed your diet "dramatically", and "achieve[d] the same EPA and DHA levels in cells on an ALA diet", which pretty much agrees with Dr. Dyerberg's remarks.

seth (2007-11-27 22:20:38)

I did want to put Dr. Dyerberg in the best possible light – even though it might seem exactly the opposite. I thought quoting someone saying 2 wrong things was not a clear improvement over saying 1 wrong thing. As Tyler Cowen and Anonymous and several others can attest, you can get fabulous benefits from just 2 T/day of flaxseed oil. Taking 2 T/day of flaxseed oil isn't "chang[ing] your diet totally" – quite the opposite – nor is it hard to do forever.

### My Theory of Human Evolution (osechi) (2007-11-28 11:09)

Sure, you know that in Japan, New Year's is the big winter holiday. But did you know that [1]osechi, a kind of fancy bento box, is a holiday tradition? Here are some examples:

ordering osechi as a set. . . . Price is determined by contents and the reputation of the wholesaler or restaurant which put it together. For example, a relatively unknown shop may whip up three 20 square centimeter boxes for ¥22,000 [= \$200], whereas Kicho, a famous restaurant in Kyoto offers three circles of the same size for a hefty ¥196,000 [= \$1800]. The rest of the sets, ranging anywhere from one to four tiers cost between ¥30,000 to ¥50,000 on average and most Isetan customers buy their ready-made osechi in this price range.

Osechi is another example of how holidays [2]create a market for expensive difficult-to-make things. The Stone-Age predecessors of holidays helped support skilled artists, artisans, and craftsmen, the technological pioneers of the time.

Addendum: Bento boxes [3]inspired the design of the IBM Thinkpad.

1. <http://snakelyone.com/osechi.htm>
2. <http://www.blog.sethroberts.net/2006/12/24/christmas-an-evolutionary-explanation/>

### **How Dangerous is Bariatric Surgery? (2007-11-28 14:13)**

From the abstract of a [1]new paper on the question:

The 1-year case fatality rate was approximately 1 % and nearly 6 % at 5 years. . . .There was a substantial excess of deaths owing to suicide and coronary heart disease.

Six percent chance of dying within 5 years . . . Your chance of survival is probably better if you are posted to Iraq. On the other hand, another study found a 6 % death rate within 5 years for matched obese persons who didn't have the operation.

1. <http://archsurg.ama-assn.org/cgi/content/abstract/142/10/923>

---

Chris (2007-11-28 16:15:12)

Ah, so not the miracle cure for diabetes it's been held up as.

seth (2007-11-28 20:39:07)

I agree. If it were effective in a big way surely the long-term death rate would be lower than that of a similar unoperated group.

Chris (2007-11-29 13:23:15)

It's an interesting experiment, but not one I like to see carried out on humans. Bariatric surgery was developed as a weight-loss measure for the extremely obese, and of course weight loss typically improves outcomes for diabetics, even leading to remission in some cases. Weirdly, the surgery seems also to have an anti-diabetic effect independent of weight loss, and there have been some experiments performing operations on non-obese diabetics. In other words, they're on bridge of the UFO starcruiser, they have only a vague notion of what any of the buttons mean, but they find that pressing a certain pattern of buttons has certain desirable effects. As well as certain effects they don't know about or don't understand.

## **The Decline of Fact Checking at The New Yorker (2007-11-28 22:42)**

In the latest New Yorker, [1]an article by Bill Buford begins:

Meat-eaters . . . have more recently had to accept that their diet is probably the source of much of the world's . . . obesity.

Gary Taubes' new book Good Calories, Bad Calories argues the opposite. Even if the fact checkers hadn't read Taubes, surely they knew of the Atkins diet?

Addendum: Buford also blames heart disease on meat. In [2]this talk Malcolm Kendrick notes an inverse correlation between saturated fat consumption and heart disease. Thanks to Dave Lull.

1. [http://www.newyorker.com/arts/critics/atlarge/2007/12/03/071203crat\\_atlarge\\_buford](http://www.newyorker.com/arts/critics/atlarge/2007/12/03/071203crat_atlarge_buford)

2. <http://uk.youtube.com/watch?v=XPPYavcXo1I&feature=related>

---

Peter (2007-11-28 23:19:42)

maybe the author meant 'global warming' instead of 'obesity'?

## **What Causes Heart Disease? Malcolm Kendrick's Views (2007-11-29 05:58)**

In this video Malcolm Kendrick, a Scottish doctor, points out the lack of cross-country correlation between cholesterol levels and heart disease rates.

[EMBED]

In this video Kendrick explains why he believes that extreme stress – often caused by emigration – is a big reason for high rates of heart disease.

[EMBED]

This view is supported by research by Michael Marmot and others on the [1]social gradient: People higher in occupational level have better health than those below them. This seems to be because lower jobs are more stressful. The lower your job, the less control you have. Lack of control is the problem.

Kendrick's view calls into question the usual interpretation of migrant studies. When persons emigrate across countries – from Japan to America, from India to England – they usually have higher heart disease rates in the new country. This is often attributed to differences in diet – the old-country diet is presumed healthier than the new-country diet. Kendrick lays the blame elsewhere. He also makes an interesting point about Finland. Finland used to have a very high rate of heart disease. Kendrick points out that in the early 1950s, about 700,000 persons of Finnish descent were pushed by the Soviet government out of the Soviet Union and into Finland. Kendrick also mentions Roseto, Pennsylvania, a town created by emigration en masse from Roseto Italy. The old customs and social networks survived the move intact and the people of Roseto Pennsylvania were for many years [2]remarkably healthy.

Previous posts on heart disease: [3]Omega-3 and heart attacks (also [4]here). [5]The Framingham Study.

Thanks to Dave Lull.

Addendum: Kendrick on "[6]The Great Cholesterol Myth."

Dennis Mangan (2007-11-29 08:28:55)

Seth: Finland still has high rates of CHD. Causes, according to this: <http://www.springerlink.com/content/b011711g64k05142/>, include high serum cholesterol levels, smoking, and hypertension. As per the first video, Australian aboriginals also have high rates of obesity, alcoholism, and diabetes, leading to high CHD rates. As for the "social gradient" theory of CHD, I think that has been definitively put to rest by Deary and Gottfredson: Childhood IQ is moderately strongly correlated with adult socioeconomic position. Lower IQ is also associated with increased rates of all-cause mortality (1, 2), cardiovascular disease (2&€"4), hypertension (5), contact with psychiatric services (6), and other negative health outcomes (7). These associations remain after controlling for socioeconomic position in early life. <http://www.udel.edu/educ/gottfredson/reprints/2005scienceletter.pdf> See also Gottfredson's "Intelligence: Is it the epidemiologists' elusive 'fundamental cause' of social class inequalities in health?" <http://www.udel.edu/educ/gottfredson/reprints/2004fundamentalcause.pdf> Further, as to "stress", heart disease rates in German-occupied Europe during WW2, in The Netherlands and Norway for example, went down, exactly the opposite of what one would expect if stress were a cause.

Timothy Beneke (2007-11-29 11:11:45)

One has to wonder after all the failed nutrition research to what degree nutrition is a factor in heart disease. How does one go about making estimates in the first place if you don't know what other factors are in play? It's all guess in the dark. Robert Levenson' and other emotion researchers find that if you have subjects watch a disturbing video of an arm amputation and are told to keep a poker face and show zero emotion in response to it, they have 2x the cardiovascular stress in heart rate and blood pressure as subjects who watch it and respond naturally. And generally, suppressing any emotion, positive or negative, causes much added cardio stress. Perhaps immigrants, especially from radically different cultures, must suppress a lot of emotion, or feel cognitively overwhelmed, and that causes heart disease. The depression research is showing great increases in heart disease among depressives, based on correlational studies – again more guessing, but interesting. Stress hormones like cortisol are tied to depression and heart disease. When you don't know what you don't know, you have to be very careful about making causal claims – it should be written on wind and running water!

seth (2007-11-29 19:42:54)

Dennis, the drop in heart disease during WW2 has been attributed to a dietary shift from meat to fish, which makes sense. Although Kendrick doesn't believe in the value of omega-3, I do. "The social gradient" is an observation, not a theory – it can't be "put to rest" unless the data turns out to be false. As for its explanation, sure, IQ could be important, especially in controlling what job you end up getting. Whether IQ remains important after degree of control over one's job has been accounted for remains to be seen. A study that equates IQ across the groups being compared is the famous study of London transit workers in the 1950s that found that drivers of double-decker buses had a higher rate of heart attacks than the ticket takers on those buses. The first explanation was that the ticket takers got more exercise (presumably up & down the stairs); I have suggested they got more sunlight and stood much more so they slept better; others have suggested that driving in London traffic is stressful. No one has proposed that the crucial difference is IQ.

Dennis Mangan (2007-11-29 22:20:19)

Seth: Good points except, I think, for the last one: the London bus drivers vs. ticket takers doesn't involve a social gradient. Or if there is one, it ought to be the drivers who are higher on the scale. The studies I've seen involving social gradients were workers with bureaucratic functions who had precisely defined positions and pay, but all doing sedentary work. As for the possibility of decreased CHD resulting from a switch to fish from meat, I really wonder whether those in the occupied countries had much access to fish. However, I haven't seen any data on this. I haven't heard that those in unoccupied countries like Britain had lower CHD rates.

LemmusLemmus (2007-11-30 12:30:52)

I would argue that the social gradient speaks against a stress-heart disease connection, not for it: Who works longer hours - the CEO or the blokes at the assembly line and in accounting? Who has a higher responsibility and thus more to worry about? I will admit that this is somewhat compensated by lower-level workers having to worry more about making ends meet, but I don't think this comes close to making up for work-related stress - at least not in first-world countries where low-level workers are relatively well-off.

seth (2007-11-30 13:16:40)

Perhaps "stress" is the wrong word. People lower in the hierarchy have less control of their work and their working conditions. Working on an assembly line is the ultimate in terms of lack of control. Being the CEO is the opposite of that.

## **Mitch Kapor on Second Life (2007-11-29 14:12)**

Yesterday I heard Mitch "Lotus 1-2-3" Kapor give the third of three talks at the UC Berkeley I-School on "[1]Disruptive Innovations I have Known and Loved" ([2]podcast). This talk was about Second Life; the first two were about the PC and the Internet. It was a very nice talk I would have enjoyed more if I hadn't had a cold. Even with a cold I was

pleased by two things:

1. A graph of on-line Second Life activity. It was increasing at roughly the same rate as [3]SLD-forums activity.
2. A comment that the short-term effect of similar technologies is less than expected; the long-term effect is far greater than expected. One long-term effect Kapor predicted is virtual meetings. I knew someone who was head of design for a very large powerful company – supposedly a dream job. But he had to travel all over the world to meet with his subordinates. Incredibly exhausting. So it wasn't a dream job, and he gave it up.

I knew about the "disruptive technologies" idea from my work on [4]variation in rat bar-pressing, which led me to read Clayton Christensen's excellent [5]The Innovator's Dilemma. Disruptive technologies can be as simple as hydraulic power, which caused several steam-shovel companies to fold.

I had not thought of SLD as a technology; but I realized that's what it is: A weight-loss technology. Disruptive, who knows, although Aaron Swartz was [6]optimistic quite early. And today in the SLD forums I read [7]this:

I've lost 85 lbs. and I have 25 lbs. to go and I just. Can't. Quite. Process that idea. . . I'm at a new job where no one knows that I used to be incredibly heavy and there's even a really cute fellow faculty member who seems to like me. He smiles at me. A lot. It's nice. Everything is so . . . fantastic. I'm so happy I'm practically beside myself. . . . Almost every morning . . . I catch sight of myself in the full-length mirror out of the corner of my eye and the first thought is still "Is that me?". And I have to stop. And look. And wrap my arms around my tummy - my much, much smaller tummy - and think "Oh that's right. That IS me." It always makes me laugh.

Podcasts of his earlier talks [8]here (PC) and [9]here (Internet).

Del (2007-11-30 06:49:05)

NIFTY! I'm going to have to read this more regularly. I was fascinated by the Aaron Swartz article. Y'all's, Del

Timothy Beneke (2007-11-30 11:18:17)

The quote from the forums is wonderful and something I can relate to. I'm around 100 pounds lighter than I used to be now, and have ranged from 80-100 pounds lighter for more than 2 years. I still get a thrill when I see people I haven't seen for a long time, usually acquaintances or people who I'm friendly with but not exactly friends. I start talking with them, they wonder who the hell I am and then go through a shock of recognition – "Tim?!" And at a dinner party a few months ago with a number of people who had weight problems present, a woman I was meeting for the first time asked, "Have you \*always\* been thin? How do you do it?" I delight in being asked that. I have not had the experience of a new job with people who only know me as thin. That must be interesting, like taking on a social identity... Cheers!

seth (2007-11-30 12:01:31)

I love hearing stories like that, of course. Having a new job with people who only know you as thin must be like a Twilight Zone episode. The opposite of wearing a fat suit. Except it's true.

Mikes (2007-11-30 15:16:08)

Hey Seth – interesting post, but also noticing that you report having a cold, and recall you had gone I think several years without one having virtually perfected your sleep. Has the record been broken for a while? Any new thoughts/comments/developments in this sleep/immunity situation? Would be interested to hear. I have tried the standing technique and not achieved similar improvements in my sleep.

seth (2007-11-30 16:40:39)

I haven't had a cold like this – obvious symptoms, lasting a week – in about 10 years, ever since I started standing a lot, etc. But it isn't completely surprising because recently my sleep has been the worse it's been in a very long time. I don't know why. So in a way this new cold supports my idea that better sleep = more resistance to colds. To get reliably better sleep by standing I found I had to stand about 8 hours. Below that the effects were unclear. No new developments on the sleep/immunity connection.

## **The Wisdom of Crowds (Babylonian edition) (2007-11-30 12:17)**

[1]Herodotus on Babylon:

They have no physicians, but when a man is ill, they lay him in the public square, and the passers-by come up to him, and if they have ever had his disease themselves or have known any one who has suffered from it, they give him advice, recommending him to do whatever they found good in their own case, or in the case known to them; and no one is allowed to pass the sick man in silence without asking him what his ailment is.

Surowiecki's book, like this example, was actually about the wisdom of passers-by (unconnected individuals) rather than crowds.

Thanks to David Cramer.

## 2.12 December

### Eskimos, Heart Disease, and Omega-3s: The Plot Thickens (2007-12-01 09:54)

David Marcus made the following [1]comment on an [2]earlier post:

It's a myth that Eskimos have low rates of heart disease. Actually, recent studies have shown they have high rates of cardiovascular disease (50 % higher than western populations) despite diets that are very high in fatty fish.

Mr. Marcus makes a very good point (and it is wonderful to get such informative feedback). Myth is wrong. A Greenland doctor's casual observation – Eskimos almost never died of heart attacks – was confirmed by a detailed study, published in *Acta Medica Scandinavica* in 1980. A recent study, however, found this:

**OBJECTIVES:** The thirty-year-old hypothesis that omega-3 fatty acid (FA) may "reduce the development of thrombosis and atherosclerosis in the Western World" still needs to be tested. Dyerberg-Bang based their supposition on casual observations that coronary atherosclerosis in Greenlandic Inuit was 'almost unknown' and that they consumed large amounts of omega-3 FAs. However, no association was demonstrated with data. **STUDY DESIGN:** Cross-sectional study. **METHODS:** 454 Alaskan Eskimos were screened for coronary heart disease (CHD), using a protocol that included ECG, medical history, Rose questionnaire, blood chemistries, including plasma FA concentrations, and a 24-hour recall and a food frequency questionnaire assessment of omega-3 FA consumption. **RESULTS:** CHD was found in 6 % of the cohort under 55 years of age and in 26 % of those > or = 55 years of age. Eskimos with CHD consume as much omega-3 FAs as those without CHD, and the plasma concentrations confirm that dietary assessment. **CONCLUSIONS:** Average daily consumption of omega-3 FAs among Eskimos was high, with about 3-4 g/d reported, compared with 1-2 g/d used in intervention studies and the average consumption of 0.2 g/d by the American population. There was no association between current omega-3 FA consumption/blood concentrations and the presence of CHD.

A well-written abstract, by the way.

Science is like a game of telephone. It would be truly weird if the initial observation was wrong, given that it was later confirmed in detail and productively followed up – and no one doubts that omega-3 increases clotting time. But "replications" are never exact. This study, for example, measured "in vivo" CHD, whereas the initial observation was about causes of death. The group of Eskimos studied is probably different; and their lifestyle, especially their diet, may have changed substantially in the last 30 years. On the other hand, these new observations are consistent with the great difficulty there has been in confirming the idea that omega-3 fats reduce heart disease.

2. <http://www.blog.sethroberts.net/2007/10/02/what-causes-heart-attacks/>
3. [http://www.ncbi.nlm.nih.gov/sites/entrez?Db=pubmed&Cmd=ShowDetailView&TermToSearch=16277122&ordinalpos=8&itool=EntrezSystem2.PEntrez.Pubmed.Pubmed\\_ResultsPanel.Pubmed\\_RVDocSum](http://www.ncbi.nlm.nih.gov/sites/entrez?Db=pubmed&Cmd=ShowDetailView&TermToSearch=16277122&ordinalpos=8&itool=EntrezSystem2.PEntrez.Pubmed.Pubmed_ResultsPanel.Pubmed_RVDocSum)

---

Dennis Mangan (2007-12-01 12:05:07)

Eskimos' fish consumption with consequent high protein intake is also responsible for their high rates of osteoporosis.

DAvid Marcus (2007-12-02 04:41:21)

I also noticed that in another post you mentioned the Israeli Paradox, where Jewish Israelis who consume polyunsaturated fats are supposed to have higher coronary disease rates than Non-Jewish Israelis who consume monounsaturated fats. A few recent studies have actually found that Arab Israelis have much higher heart disease risk than Jewish Israelis - among the highest rates in the world in fact - despite the fact that they drown their food in olive oil. See, for instance, <http://ije.oxfordjournals.org/cgi/content/full/35/2/448>

peter (2007-12-02 21:33:23)

marcus's authority re high rates of heart disease in Palestinians is consistent with Kendrick explanation, i.e., that extreme stress is the cause of heart disease (altho i tend to think that no single factor is absolutely controlling).

Aaron Ashmann (2007-12-08 21:40:31)

Seth, I think there is more to be done in testing polyunsaturates vs monounsaturates and saturates. Do you think you can perform some more tests on flax vs butter and flax vs coconut oil (for cognitive tasks). This might give us more light on if the weston a price crew was on to something. Also, are you familiar was ray peats work on the subject. If the weston price crew is correct that saturates allow for better functioning of omega 3 and 6 - and this is said on both weston a prices website and ray peats- then your test of flax vs butter and flax vs coconut oil- should show the saturates coming on top- or at least being better over time. There main argument is that saturates promote better brain functioning- lets look at this! Your tests vs olive oil didn't say much because both the above camps say that monounsaturate consumption doesn't nessasarily lead to better brain function.

## The Wisdom of Google (2007-12-01 12:26)

Can I use emoticons [with Google Chat]?

Yes. Emoticons make your chats funnier.

[1]Source. Should I laugh or cry?

1. <http://mail.google.com/support/bin/answer.py?answer=34056>

---

Willy (2007-12-01 22:14:46)

Cry. Many applications and web services are bloated just to use emoticons.

David (2007-12-02 06:51:12)

I think you should laugh. Emoticons provide inflections to chat conversations that would be conveyed in speech by tone of voice. They are a way of enhancing the meanings that can be conveyed in chat, making it more like a speech conversation. I find the emoticons :-) and ;-) to be particularly useful.

### **Experimental Mathematics (2007-12-02 23:11)**

The journal [1]Experimental Mathematics, started in 1992, publishes "formal results inspired by experimentation, conjectures suggested by experiments, descriptions of algorithms and software for mathematical exploration, [and] surveys of areas of mathematics from the experimental point of view." The founder wanted to make clearer and give more credit to an important way that mathematicians come up with new ideas. As the journal's [2]statement of philosophy puts it, "Experiment has always been, and increasingly is, an important method of mathematical discovery. (Gauss declared that his way of arriving at mathematical truths was "through systematic experimentation.") Yet this tends to be concealed by the tradition of presenting only elegant, well-rounded, and rigorous results."

When John Tukey wrote Exploratory Data Analysis (1977), he was doing something similar: shedding light on how to come up with new scientific ideas plausible enough to be worth testing. Tukey obviously believed this was a neglected area of statistics research. I was told that the publisher of EDA was uninterested in it; they only published it because it was part of a two-book deal. The other book, with Frederick Mosteller, was more conventional.

My paper titled "[3]Self-experimentation as a source of new ideas" made the same point as Tukey about an earlier step in the scientific process: data collection. How to collect data to generate new ideas worth testing was a neglected area of scientific method. Self-experimentation, derided as a way of testing ideas, might be an excellent way of generating ideas worth testing.

I think of it as crawling back into the water. In the beginning, all math was conjecture and experimentation. In the beginning, all data analysis was exploratory. In the beginning, all science was tiny and devoted to coming up with new ideas. From these came methods of proof, confirmatory data analysis, and methods of carefully testing ideas. Human nature being what it is, users and teachers of the new methods came to greatly disparage the earlier methods. Gary Taubes told me that he spoke to several obesity researchers who thought that the field essentially began with the discovery of leptin. Nothing before that mattered, they believed.

## Adventures in Eating and Sleeping (2007-12-03 06:54)

Since the beginning of time everyone has been eating and sleeping – a lot. If you thought this meant there couldn't be any new and cool twists on these activities, you'd be wrong.

1. Eating. "Last night I tried to "race myself" because I knew I would get full fairly quickly but I really enjoyed what I was eating so I ate fast." [1]This is from the [2]SLD forums. Outcome of race: Lost. "I still couldn't get through the whole salad, just too full to eat another bite. That's amazing to me."

2. Sleeping. Someone I know used to wake himself up in the middle of the night because he enjoyed falling asleep.

1. <http://boards.sethroberts.net/index.php?topic=5806.msg61241#msg61241>

2. <http://boards.sethroberts.net/index.php#1>

---

alexis gallagher (2007-12-03 09:13:54)

Being woken up just to enjoy falling asleep again is not a completely new twist: "Others feel the pleasure of content and prosperity; I feel it too, as well as they, but not as it slides and passes by; one should study, taste, and ruminate upon it, to render condign thanks to Him who grants it to us. They enjoy the other pleasures as they do that of sleep, without knowing it. To the end that even sleep itself should not so stupidly escape from me, I have formerly caused myself to be disturbed in my sleep, so that I might the better and more sensibly relish and taste it." – Of Experience, Michel de Montaigne, 1580. (full text at <http://oregonstate.edu/instruct/phl302/texts/montaigne/montaigne-essays-8.htm> I)

Mike Kenny (2007-12-03 09:33:04)

Michel de Montaigne used to wake himself up so he could fall asleep again at night, for the same reason, enjoyment of falling asleep. His writings, what I've heard of them, seem not so much self-experimentation as recollecting of data from experience and theorizing, which is very similar. It seems more appreciated, perhaps, than self experimentation, though I'm not sure why.

Timothy Beneke (2007-12-03 13:17:17)

When in December 2003, I changed from going to bed around 3 a.m to around 11:30-12 (following Seth's counsel), and also began religiously getting sunlight early in the day, not only did I undergo a powerful positive shift in baseline mood, with behavioral consequences, but I also experienced sleep, especially going to sleep, much differently. It became more pleasureable. I began to look forward to the relaxation that came as it got dark and my body began to shut down. And getting into bed to read and then sleep, my body would have this warm, relaxed quality that I basked in. I said to friends that I no longer fell asleep but went to sleep. Previously for many years, I just stayed up into the night, and when sleep overtook me, I fell asleep. After going to bed early, I would know when my body was ready to sleep and take pleasure in it and prepare for it. It felt like something my body and I were doing together. I assume that changing my circadian rhythms increased wave amplitude, so I was more awake when I was awake, and more asleep when I was asleep, and it felt – and still feels good... There is a sweetness and honesty to Montaigne's writings that make them very charming....

KenF (2007-12-03 22:27:05)

in college I knew a guy who didn't drink or do drugs. But he stayed up far past his bedtime once and was overwhelmed with excitement at feeling a little punchy because of it.

## Jane Jacobs and Art (2007-12-04 07:02)

⌘

The Cleveland painter [1]Michelle Muldrow was a musician for ten years before becoming a painter – although she got a BFA (Bachelor of Fine Arts) before that. From an unusual background, an [2]unusual creative process:

Interviewer: Describe your working process when creating a new work.

MM: Usually I begin reading about environmental issues, urban development, really anything touching on the subjects of land use, as well American history and fiction. I guess I sort of consider myself a sponge at the beginning stages of work, then usually some travel helps and I take tons of source photos. From there I organize my photos into different obsessions, be it the artificial horticulture and landscaping in the modern developments, or the death of inner ring suburbs, subdivisions, etc, at that point I look for what I am most interested in painting. It's sort of like all my intellectual obsessions still must go through a filter of how I feel, and that is an important element to my work- nostalgia. I suppose I attribute that to the rootlessness of my childhood, I am always trying to make sense of my landscape and home. Then I begin the body of my work. I tend to approach my work as a series or body rather than as individual images. I always prep, underpaint and paint at least 4-5 paintings all at once, never one at a time. I freehand draw, then do a monochromatic underpainting, and from there, I paint.

Painting, in other words, resembles blogging: You can blog about anything, you can paint anything – so long as you care about it.

One of her favorite writers is Jane Jacobs. She used to live in San Francisco, where there seemed to be no upper limit on the value of property. In Cleveland, with boarded-up homes everywhere, there seems to be no lower limit.

⌘

2. <http://thevisualmovement.com/the-visual-movement-interview-with-michelle-muldrow/>

---

Andrew Gelman (2007-12-05 17:10:28)

You write, "Painting, in other words, resembles blogging." I would substitute "writing" for "blogging" (or else substitute "posting paintings on the web" for "painting.")

seth (2007-12-05 18:12:23)

Interesting. Maybe you are thinking that painting and writing are "large" while blogging is "small". What I was thinking is that painting and blogging are activities that inherently involve a lot of emotion. Writing may or may not. Do newspaper writers care a lot about their assigned topics? Often not. Do technical writers care a lot about the stuff they write? Probably not. Is there emotion behind every letter? No, a lot of letters are purely functional. Behind every blog post? I think so, unless it's a job.

Andrew (2007-12-05 20:29:45)

No, I'm just saying that blogging is a way of publishing. Writing is the creative activity, blogging is the medium. But your last comment reminds me of something I recently noticed about applied research and teaching, which I'll blog about sometime soon when I have a moment.

### **Everyday Humor (part 1) (2007-12-05 08:32)**

I returned vol. 3 of Not Only the Best of the Larry Sanders Show to my public library but forgot to include the DVD. I got a phone call about it. I returned with the DVD, which I had put in a paper envelope.

Here it is, I said. As I was leaving, the librarian asked if I wanted my envelope back. "In case this happens again," she said. Everyone laughed.

Type of joke: veiled not-serious deprecation.

[1]Blood donation, weight loss, and humor. [2]More on humor.

1. <http://www.blog.sethroberts.net/2007/11/20/blood-donation-weight-loss-and-humor/>

2. <http://www.blog.sethroberts.net/2007/11/21/more-on-humor/>

---

Weightloss » Blog Archive » Everyday Humor (part 1) (2007-12-06 06:47:26)

[...] seth put an intriguing blog post on Everyday Humor (part 1)Here's a quick excerptAs I was leaving, the librarian asked if I wanted my paper envelope back. "In case this happens again," she said. Everyone laughed. Type of joke: veiled not-serious deprecation. Blood donation, weight loss, and humor. More on humor. [...]

Timothy Beneke (2007-12-06 10:33:08)

Another phrase for "veiled not-serious deprecation" through humor is affectionate teasing. Teasing, when it is friendly, serves to remind the teased of their characterological deficiencies without overtly putting them down. In Seth's example it was a nicer way of reminding him to try to return his DVDs with the DVD enclosed. I am a life-long unregenerate slob and have gotten a lot of teasing for it. I'd much rather be teased in a playful way than have someone overtly moralize at me or seriously put me down for it. Friendly teasing is nice. Of course there is cruel, hostile teasing which is another matter...

### **Everyday Hedonics (2007-12-05 20:09)**

Conversation on a Berkeley lawn:

[1]Andrew Gelman: You'd think we prefer an upward spike in pleasure – we're happier for a while, then return to normal – to a downward one, but the evidence isn't clear.

Seth: I know someone who woke himself up so he could enjoy falling asleep.

Andrew: Really?

Seth: Yes, really.

Andrew: Was that you?

Seth: No, it wasn't me.

Andrew: If I heard about someone doing that, I'd think it was you.

[2]Phil Price: That's brilliant, actually.

Leonard Mlodinow, author of [3]Euclid's Window (about geometry), [4]Feynman's Rainbow, and a forthcoming book on probability and chance, and co-author with Stephen Hawking of [5]A Briefer History of Time, was the brilliant sleeper. (Not [6]Montaigne.) He might have woken himself up while he was a grad student at Berkeley (in physics). After Berkeley, he became an assistant professor of physics at Caltech. He left Caltech to become a writer. As unorthodox in a big way as waking yourself up so that you can fall asleep is in a small way.

Michelle (2007-12-06 01:35:48)

You know the most interesting people

Lori (2007-12-06 06:46:13)

Stop it! You're deepening this hopeless devotion.

michael vassar (2007-12-06 07:32:52)

My wife does that too.

## The Power of Prayer (2007-12-06 08:33)

From [1]Nassim Taleb:

I truly believe that it was rational to resort to prayers in place of doctors: consider the track record. The risk of death effectively increased after a visit to the doctor. Sadly, this continued well into our era: the break-even did not come until early in the 20th Century. Which effectively means that going to the priest, to Lourdes, Fatima, or (in Syria), Saydnaya, aside from the mental benefits, provided a protection against the risks of exposure to the expert problem. Religion was at least neutral –and it could only be beneficial if it got you away from the doctor.

This gives placebo effect a whole new meaning. And it defends religion in a new and reasonable way.

A belief similar to Taleb's is why I began the long-lasting self-experimentation that led to my paper "[2]Self-experimentation as a source of new ideas": I didn't want to see a doctor about my sleep problem (I awoke too early in the morning and couldn't fall back asleep). I was sure that what the doctor would prescribe (sleeping pills) would do more harm than good.

2. <http://repositories.cdlib.org/postprints/117/>

---

Chris (2007-12-06 12:07:01)

Here I am working against a deadline, and I've just spent an hour on Nassim Taleb's blog, without regret. That fellow is erudite.

Michael Blowhard (2007-12-06 22:33:59)

FWIW, I remember hearing or reading someone saying that Christian Science – loony as it may seem to many now – made good sense back in the days when it was invented. Sleep a lot, pray, be nice, work hard, eat wholesome ... You'd almost certainly have done a lot better following those tips than you'd have done seeing doctors back in 1880. Someone else (Roy Porter, maybe, the historian of medicine) wrote somewhere that until the 20th century doctors did on balance far more harm than they did benefit. Lucky us to be living in the 21st century, when doctors can be of some use.

michael vassar (2007-12-07 06:20:14)

I have said this in the past, and possibly to you Michael. Not many people know it, but while doctors \*can\* be of net use through the use of medical science, if they care to use it [http://www.newyorker.com/reporting/2007/12/10/071210fa\\_fact\\_gawande](http://www.newyorker.com/reporting/2007/12/10/071210fa_fact_gawande) in practice it still seems, at least anywhere near the margins, not to be <http://sciencethatmatters.com/archives/category/medicine>

Chris (2007-12-07 14:52:02)

In Medical Nemesis, Ivan Illich estimated the crossover year (when doctors began to save more people than they killed) at 1910. Thinking about Michael's recent postings about the (growing?) incompetence of our institutions is starting me thinking about Illich; I must dig out some of his books.

seth (2007-12-07 20:21:52)  
Chris, which Michael?

Chris (2007-12-08 16:31:31)  
"Michael Blowhard", your second commenter. I'm a regular reader of his blog - where I found out about the SL diet, by the way.

seth (2007-12-08 18:10:05)  
thanks, Chris

Stephen M (Ethesis) (2007-12-28 23:14:12)  
When I talked with critical path specialists, they estimated that if you took trauma care and vaccinations out of the picture, the break even point was in the 1980s. Given that the doctors of New York City put a stop to public health nurses in the early 1900s (who were keeping too many people from getting sick), I think that it is important to factor changes like that into any final statistics, not to mention doctors banning pain killers for new borns and very young children and the wave of deaths that caused.

## Psychology Blogs (2007-12-07 05:28)

[1]This is a nice blog about psychology research, including a section on [2]"weird" research. [3]This is a blog about the origins of language that I look forward to exploring. [4]Here is a long list of neuroscience blogs.

Thanks to Michelle Nguyen.

## Golden Handcuffs (2007-12-07 14:11)

In *The Innovator's Dilemma*, Clayton Christensen gives many examples of how industry-leading companies lost their lead, often so badly they went out of business. As I've said before, this is something I've studied [1] in rats writ large. In a [2] great talk about the beginnings of the PC industry, Mitch Kapor describes meeting Ken Olsen, the CEO of Digital Equipment Corporation (DEC), a \$15-billion-sales-per-year company destroyed by the PC.

"Meeting the needs of people who had never previously used computers was the foundation of this entire [PC] industry," says Kapor. "Even after we [Lotus] had started to become successful, this was still not clear to some people." This is what Christensen says, too: Disruptive innovations begin downmarket, among users not previously thought worthy of notice. For example, hydraulic-powered shovels started in sizes appropriate for digging ditches. The pattern Christensen saw was that the industry-leading companies ignored this market until it was too late. DEC was no exception. Olsen wanted to meet Kapor, who was flown by DEC helicopter to DEC headquarters. When they met, Olsen complained for 15 minutes about the flimsiness of the PC case.

"The stuff that made him smart was the stuff that was now making him incredibly dumb," says Kapor. "They didn't understand that they needed to stop doing all the things that had made them successful in order to have a chance to succeed." I would put it differently. Our experiments with rats made one thing clear: The more successful you are – and DEC was very successful – the harder it is to try new ways of doing things.

[3] Comment on another Kapor talk.

3. <http://www.blog.sethroberts.net/2007/11/29/mitch-kapor-on-second-life/>

---

Chris (2007-12-07 14:41:25)

The bit about the helicopter made me laugh. I worked in marketing for DEC for a few months in the late 80s. The pièce de résistance of all our sales strategies was always just that: fly 'em to DEC headquarters in the company helicopter, they'll be putty in our hands!

knackeredhack (2007-12-11 03:35:32)

Seth, I've seen this throughout my career. What is strange is that everyone knows these stories in business, and yet they still seem to think they are not the stupid ones. The problem is getting worse, as Paul Graham's essay showed and which you pointed to in an earlier post. The cost of startups, at least software startups, is now almost zero, so they are proliferating. The majority will lack any social proof, so it takes a different skill plus luck to differentiate the wheat from the chaff. Graham argues that those, like Google, who have sat the other side of the table and been ignored by large corporates and investors, will be better equipped to function in this more uncertain ecology, where the acquisition of the right collections of talent and technology will determine success. But the tendency in business will be to cluster around what is known, like Hollywood does with stars, who then grab a disproportionate share of the cashflows, while not necessarily delivering success.

## Gary Taubes's Berkeley Talk (2007-12-08 05:29)

Gary Taubes spoke at Berkeley a few weeks ago; the title of his talk was "The Quality of Calories: What Makes Us Fat and Why No One Seems to Care" ([1]webcast). Did you know that the last edition of Dr. Spock's baby book advocated a vegan diet? One of many fascinating details. Also this:

There's a group at the University of Cincinnati that did an Atkins vs. low-fat study and they found that the Atkins people lost twice as much weight and they liked the diet much better. I was interviewing the dietitian who did the study. She had agreed to talk to me but she was very hesitant – she didn't offer up any information. Finally, at the end of the interview, the one thing she offered freely: I asked her who funded it and she said the American Heart Association.

I said, "Well, I have to give them credit for funding it."

She said, "Don't. They funded it because we proposed it as a study that would refute the benefit. And when we found that the Atkins diet really worked and worked better than the low-calorie diet, now we're trying to get money to look further into it and they won't give it to us."

Thanks to Dave Lull.

Dennis Mangan (2007-12-08 08:47:16)

The Atkins diet helps people lose weight, but so do chemotherapy, depression, and amphetamines. Just because something helps you lose weight doesn't mean it's healthy. In this particular case, Atkins causes ketosis, a state akin to starvation.

Tom (2007-12-08 09:33:41)

You're confusing two completely different things: ketosis and ketoacidosis. Ketoacidosis is a dangerous condition, ketosis is simply how our cells derive energy from fat (as opposed to sugar.)

David (2007-12-08 10:51:20)

It would guess that the body is probably pretty well adapted for ketosis. Our hunter-gatherer ancestors must have experienced periods of low food intake and starvation quite frequently in which they would live off of accumulated fat and muscle stores. People with poor tolerance for this state were probably weeded out of the genetic pool a long time ago.

seth (2007-12-08 16:05:10)

"Chemotherapy, depression, and amphetamines"? Not to mention famine. These strike me as fundamentally less healthy than avoiding bread, desserts, and pasta.

Dennis Mangan (2007-12-08 21:15:49)

Like I said, Atkins is about as healthy as chemotherapy. And ketosis is *\*not\** the default metabolic state; it happens in the absence of carbohydrates, such as occurs in a famine.

Tom (2007-12-08 22:20:24)

Reliable evidence (ie, not the discredited slanting of the China study) would be delightful - if hard to find for such a claim. And ketosis is the default metabolic state if you lay off the potatoes, pizza, muffins & cookies.

Dennis Mangan (2007-12-08 22:32:27)

Hey, Tom, you got a last name, so we can see who you're affiliated with? The fact that your man Atkins was obese and likely died of a heart attack ought to give you a little pause.

Tom (2007-12-08 23:23:04)

For a Vegan/PETA member who takes great care to hide that fact, you're very interested in my affiliations. I'm just a guy who knows that carbs are sugars, and I'm doing my best to avoid them. Your arguments are all of the hoary Vegan propaganda pieces (though you don't reveal your agenda.) And Atkins was not obese and died when he hit his head. A google search immediately reveals that (and the orchestrated PETA campaign to smear him.)

Stephen M (Ethesis) (2007-12-09 19:15:05)

Interesting how this side track shows up all over. Really too bad how people feel a need to smear Atkins. Wish I understood the visceral drive some have on the topic.

Dennis Mangan (2007-12-09 21:32:03)

Tom: Carbs are not sugars, but the reverse is true, sugars are carbs. Take a physiology class, for God's sake. All this bullshit about my "agenda" is just that, bullshit. I don't belong to any animal rights group, and I'm not "taking great care" to hide anything. I am a vegetarian, if that floats your boat. The fact is, it's irrelevant, we're talking about diet and nutrition, not me. As far as being interested in your affiliations, you're the one that brought it up. Seth: I think you know very well that the Atkins diet is about a lot more than avoiding white flour and sugar, as you imply. <http://www.cbsnews.com/stories/2004/09/0-2/health/main640566.shtml> "The most frequent complaints with low-carb diets are constipation and headache, which are readily explained by the lack of fruit, vegetables and whole grains, Astrup said. Also, bad breath, muscle cramps, diarrhea, general weakness and rashes are more often reported on low-carb diets than on low-fat diets, Astrup found. "The majority had some of these side effects in the Atkins group. In the control group, almost nothing," he said. These side effects are consistent with carbohydrate deficiency, because the brain and muscle do not get enough sugar from carbohydrates to maintain their normal function, Astrup said. "We have known for many years that there is a minimum intake of carbohydrate necessary to maintain the normal function of your body and that is approximately 150 grams a day," he said. "But, if on the Atkins diet you go down to 20 to 30 grams in the induction phase, then maybe go up to 100 grams, still you are far below what your body needs." The body can coast along for a while with the carbohydrate stores in the liver and the muscles, but eventually problems start to occur, Astrup said. "I think these symptoms are signs that something is wrong," Astrup said. "Great: constipation, bad breath, diarrhea, weakness, just what Dr. Atkins ordered. There is no way that this diet is healthy.

Tom (2007-12-09 22:03:54)

It has nothing to do with Atkins; he's simply a symbol for the consumption of animal flesh. The PETA/Vegan endgame is outlawing meat consumption, and they'll never get there if they can't bury the fact that chronic carbohydrate consumption makes people sick.

Tom (2007-12-10 02:15:37)

Dennis, carbs are sugars. Some are simple sugars like glucose, others are complex sugars, a/k/a starches. Thanks for the ad hominem, though. You brought up the question of my name and affiliations, and you're more than a vegetarian: "for many years now I've refrained from reading books, and even most articles, in support of animal rights, for the simple reason that I know in advance that I am going to agree with nearly everything said. I gave up eating meat fifteen years ago, and for a number of those years, including now, I've been almost entirely vegan, that is, I eat no animal products whatever and avoid things like the use of leather and anything else in which animals are cruelly used." (And if you can't even be bothered to read something that supports your position, I suppose it'll be a cold day in hell before you read Taubes!) Anyway, re: the

study you quote, you certainly had to Google past a ton of pro-low-carb results before you found that thing. It's no surprise you had to settle for some guy doing a meta-analysis. Meta-analyses are notoriously unreliable because they're so easy to slant to fill an agenda. One simply cherry-picks the studies that prove one's point, mixes them all together without noting that they have all been done to different standards, or have tiny populations, or aren't blinded at all. All these deficits are conveniently hidden when they're dumped into the meta-blender. They are so misleading that scientists have organized to create protocols under which meta-analyses can be trusted. Look into "Cochrane Collaboration" if you care to learn more, or start here: <http://snipurl.com/1v130>

David (2007-12-10 06:51:24)

Also from the article cited by Dennis: "More people stayed in the low-carb group than in the low-fat group, so you've got to wonder how severe those side effects were if more people kept to the low-carb diet," said William Yancy, a Duke University researcher who conducted one of the major studies that Astrup reviewed. Certainly I have found a low carb diet easier to adhere to than a low fat one. And I've experienced essentially no side effects. In any case, healthy is a relative judgment, not an absolute one. Perhaps there are unhealthy side effects from a low carb diet, but they have to be weighed against the effects of obesity, both physiological and psychological, and the relative efficacy of different diets at promoting weight loss.

sj (2007-12-13 20:35:48)

I tried the Atkins diet few years ago out of sheer curiosity - I was not overweight. I found it easy to stick with, did not experience any untoward side effects (headache, constipation, etc.) and had one unexpected yet gratifying benefit - an absence of flatulence. Once I began to eat carbs again - gas. Sigh.

### **The Twilight of Expertise (part 13: ICU doctors) (2007-12-09 07:14)**

The other shoe drops. A year ago Atul Gawande [1]wrote in The New Yorker about the [2]Apgar score, a low-tech measurement of newborn viability that led to vast improvements in obstetrics. That's the "how to improve?" side of things. Now Gawande has written about something equally simple and powerful on the "here's how to improve" side of medicine: the use of checklists to improve ICU treatment. The first article was called "The Score"; [3]this one is called "The Checklist".

Checklists are the idea of Peter Pronovost, an ICU doctor at Johns Hopkins Hospital. His first checklist, in 2001, was designed to prevent infections on tubes inserted into patients. Nurses made sure that doctors followed the checklist. It's like the Ten Commandments: the top and bottom getting together to improve the behavior of people in the middle. Checklists involved the empowerment of nurses (bottom) by hospital administrators (top) to improve the performance of doctors (middle). No coincidence, I'm sure, that the Apgar score also involved female empowerment: Virginia Apgar was one of the first powerful women in medicine.

Pronovost told Gawande:

The tasks of medical science fall into three buckets. One is understanding disease biology. One is finding effective therapies. And one is insuring those therapies are delivered effectively. That third bucket has been almost totally ignored by research funders, government, and academia. It's viewed as the art of medicine. That's a mistake, a huge mistake. And from a taxpayer's perspective it's outrageous.

Not to mention a sick person's perspective. I completely agree. Several years ago I heard an industrial designer give a talk to an interface design group. He said that new high-tech products go through three stages: (a) used only by gadgeteers and professional engineers (e.g., the first home computers); (b) used by experts (e.g., billing software for

lawyers); and (c) mass market (e.g., cell phones). The discipline of engineering, he said, was good at designing for the first two stages but not the third.

The similarities suggest a common explanation. I think one reason goes back to Veblen: It is low status to do useful work. It may also have to do with male dominance of medical research and engineering. When balancing status versus usefulness, men may weigh status more highly.

More innovation in the delivery of medicine: [4]house calls. No kidding. [5]More about Peter Pronovost.

Tom (2007-12-09 08:43:38)

Interesting insight about the three stages of industrial design. Apple seems to be proof of this idea. They dominate personal audio players (and have a good shot at dominating cellphones) despite being late entrants into both sectors. Before I had an iPod, I had an iRiver audio player – great technology with an interface that made you want to slam it into the wall every time you used it. And I still have a cellphone that Verizon insists be loaded with its confusing, ugly interface, one that only allows it to store 50 txt messages (despite 90 % of the phone's memory being empty.)

Mary (MPJ) (2007-12-09 10:56:24)

Interesting perspective. I used to work in user interface and don't see the problem being so much that design for an end user is female or low status, but that may be because I worked for companies that highly valued the usability of their products. The engineers and scientists who create the products have highly specialized knowledge in a very narrow field; they create the products in a way that makes sense to them and the way they view and interact with the world. Part of the problem is that there are very few people who understand both the way the end users are going to interact with the product and the way the engineers see the product. The process requires usability testing directly with the kind of people who will use the product; it requires people who carefully watch those interactions and can improve the design; and it requires people who can translate the design vision to the engineers in a way that they can understand it.

## **The Value, Not So Hidden, of Blogging (2007-12-09 23:36)**

The evolutionary sequence is:

1. Facial expressions and vocalizations.
2. Language (speech and writing).

### 3. Blogging.

Each makes clearer to everyone else what is inside us. Human nature being what it is – [1]closely tied to occupational specialization – it should be no surprise that blogging is very useful in getting a job, as Penelope Trunk [2]says. To get a job you need a skill. Your skill is inside you; blogging makes it much more apparent. Blogging shows not only that you have a skill but that you have an emotional attachment, too: Bloggers write about what they care about. Not only does blogging help you get a job, it helps you get a job you want.

There should be software that creates networks of blogs based on similarity. I wish I knew which blogs were most like mine, for example.

1. <http://www.blog.sethroberts.net/category/human-evolution/my-theory-of-human-evolution-directory/>

2. <http://blog.penelopetrunk.com/2006/05/23/blogging-essential-for-a-good-career/>

---

david (2007-12-10 09:10:57)

That should be possible. For music, there are sites like <http://www.last.fm> where you have your mp3 player log the music you listen to. Since it collects listening habit data from lots of people, it can tell you what people who like the music you like also like (or you can just type in an artist and it will show you what other people who like that artist like). For bookmarking, there are social bookmarking sites that also collect the bookmarks and folksonomy tags for lots of people, but the focus there is more on the tag-to-bookmark relationship rather than on figuring out what sites are similar. Still, you might be able to figure something out. On [del.icio.us](http://del.icio.us), 19 people have tagged your blog using tags like "blog diet food health psychology science statistics weightloss": <http://del.icio.us/url/fbf301d0377f949dc10848f957fa3cba> If I search delicious for exactly those terms, I don't get much: [http://del.icio.us/search/?fr=del\\_icio\\_us&p=blog++diet++food++health++psychology++science++statistics++weightloss&type=all](http://del.icio.us/search/?fr=del_icio_us&p=blog++diet++food++health++psychology++science++statistics++weightloss&type=all) But if I search for fewer terms, I get: [http://del.icio.us/search/?fr=del\\_icio\\_us&p=blog+science+health+diet+psychology&type=all](http://del.icio.us/search/?fr=del_icio_us&p=blog+science+health+diet+psychology&type=all) Explore that 2nd link and you should find sites that are similar to yours. David

Thanks, David

katya (2007-12-10 17:30:55)

One could set up a blog similarity rating machine using Latent Semantic Analysis. LSA does similarity ratings based on co-occurrence of words between (and within) multiple texts. The only hard part (programatically, from my perspective as a linguist rather than a web coder) would be crawling the blogosphere for the appropriate texts. Then you'd have a list of keywords that you could use in a way similar to how the [del.icio.us](http://del.icio.us) tags were used above. You could also get a rating of how internally consistent a blog was, e.g. whether the next post was more likely to be on the same topic as the last 10 posts, on a different but related topic, or on a completely irrelevant topic.

knackeredhack (2007-12-11 04:19:47)

Seth, connecting this to your post about Golden Handcuffs, the more people blog and blog well, the less we look at the press. But when you hear people in the press talk about blogs, they'll often focus on the bad ones or the outright eccentric, rather than understand the sheer volume of content now available, and so much of it good fun, from people

in whom we learn we can actually put our trust. For instance, this blog and Andrew Gelman's represent that for me in spades in the areas of the blogosphere where I hang out. With blogging, my own experience suggests that it takes time to feel comfortable and enjoy it, and that it might not suit everyone. But that might have more to do with my being a journalist, steeped in the caution of the news agency ethos. I came across the expression "curating a blog" the other day, and it seems to me it fits rather well, particularly as it was applied for students in the context of preparing them for employment.

### **Omega-3 and Depression (2007-12-10 18:28)**

From the [1]abstract of a 2003 article titled "A Double-Blind, Placebo-Controlled Study of the Omega-3 Fatty Acid Docosahexaenoic Acid in the Treatment of Major Depression":

Thirty-six depressed patients were randomly assigned to receive DHA, 2 g/day, or placebo for 6 weeks. Response was defined a priori as a  $\geq 50\%$  reduction in the score on the Montgomery-Åsberg Depression Rating Scale. Thirty-five participants were evaluable; 18 received DHA, and 17 received placebo. RESULTS: Response rates were 27.8 % in the DHA group and 23.5 % in the placebo group. The difference in response rates between groups did not reach statistical significance. CONCLUSIONS: This trial failed to show a significant effect of DHA monotherapy in subjects with major depression.

This study is unusual in that it used DHA rather than EPA. EPA studies have been more successful. Excerpt from an [2]overview:

One meta-analysis combined all the studies involving adults with unipolar or bipolar depression reported above, in which omega-3 fatty acids were used to augment existing treatments or as monotherapy. Best-case and worst-case analyses were carried out, and omega-3 fatty acids were found to produce a statistical improvement compared to placebo under both scenarios (best-case  $p = 0.02$ , worst-case  $p = 0.03$ ). A second review including the same data has also suggested a benefit of omega-3 fatty acids in major depression. However, as the authors of both reviews point out, there is significant heterogeneity among the included trials, and this undermines the reliability of the combined results.

Here is the conclusion from another [3]review article:

Trial evidence that examines the effects of  $n-3$  PUFAs on depressed mood is limited and is difficult to summarize and evaluate because of considerable heterogeneity. The evidence available provides little support for the use of  $n-3$  PUFAs to improve depressed mood.

A weak effect, in other words. I would be surprised if omega-3s helped a lot with depression. My [4]self-experimentation pointed to a different cause of depression – seeing faces too little in the morning and/or too much at night.

---

Nansen (2007-12-12 14:00:32)

You point out that the Pennsylvania Amish have a one-year rate of unipolar depression of about 0.1 percent (page 238 of your paper). I guess it's a pretty safe bet the Amish don't consume large amounts of either fish or flaxseed oil.

seth (2007-12-13 04:47:31)

Or eat a lot of fish. Yeah, good point. Someone should measure their omega-3 levels. The Amish don't have unusually low rates of bipolar disorder. Bipolar disorder might be more sensitive to omega-3 than unipolar depression. There is a large cross-national negative correlation between rate of bipolar disorder and fish consumption, if I remember correctly.

Sans (2011-06-21 22:37:02)

Hey Seth, if you don't mind I could use some of your advice here. For the past few months I've been steadily going into a mild depression, and the pattern fits your findings on seeing faces in the morning almost perfectly - I'm generally in a very bad mood during the day, which causes me to sleep in until afternoon when my mood begins to go up. Finally night time comes and I'm either at a party, which causes me to sleep in late, or at home going through insomnia and unable to sleep. Either way I go to bed late and the next day the cycle continues. Fortunately I'm about to start my internship, which will allow me plenty of interaction with my co-workers in the morning and which will force me to go to bed at a decent hour, thus fixing most of the factors that cause the depression. However, my problem is thus - I appear to be addicted to clubbing. Again, your theory would support this fact for if clubbing is my main way of getting social interaction then I would grow to be quite dependent on it. But at least at the moment I am slightly hesitant to cut off all of my clubbing entirely, as being a student this is quite a big part of my social life. (doubly so for being an extremely social person that I am). My first thought was to compromise and only go clubbing until say 11-12 at night, but your article says that the amish go to bed even earlier than that (9pm), which is a bit impractical for me. What would you recommend here? Would it be better to have a small amount of clubbing nights that end quite late, or a more frequent amount of clubbing that ends early? Or should I cut out clubbing entirely?

Seth Roberts (2011-06-21 22:47:19)

You should cut out clubbing entirely. You can watch TV during the day to reduce your need for human contact late at night. Once you start your internship, you should feel much better.

Sans (2011-06-21 23:31:55)

Thanks for the advice, Seth, I can see the logic behind it. How long before going to sleep do you think I should start limiting my social interaction with others?

## **Everyday Humor (part 2) (2007-12-11 08:50)**

At a wine tasting, I was chatting with two women who are friends.

Me (to one of them): How did your friend entice you to come to this event?

Woman: She told me I was coming.

Laughter.

Type of joke: ?. Actually, it was the truth. Even armed with my idea that laughter is caused by sudden pleasure I still find it very hard to say why we laughed. How odd this is! Laughter is a big and important part of life. Visible, common, highly desirable – yet mysterious.

---

David (2007-12-11 09:22:20)

I think this is funny because using the word "entice" sets up the expectation that the first woman used persuasion to convince the second one to come. This is the kind of interaction we view as normal between friends. That expectation is violated when the second woman implied she was ordered to come, not persuaded. A lot of comedy seems to depend on setting expectations and then violating them. Now, why THAT is the case is mysterious.

seth (2007-12-11 18:09:22)

Good answer, David. I also think we find it funny when an adult is ordered around – treated like a child. It is another sort of incongruity.

Seth's blog » Blog Archive » The Softer Side of Blogs (2007-12-11 19:03:43)

[...] Everyday Humor (part 2) [...]

Montclus (2007-12-11 22:02:55)

In this case, it may not have been the quality of the joke, but the intended social interaction. See this article: [http://discovermagazine.com/2007/brain/I\\_aughter/article\\_view?b\\_start:int=0&-C=](http://discovermagazine.com/2007/brain/I_aughter/article_view?b_start:int=0&-C=)

Kai Carver (2007-12-18 07:53:04)

To me it's funny and clever because of the paradox: 1. I'll be enticed to go to a party where cool people are coming. 2. I'm a cool person. 3. She tells me I'm coming, so I definitely want to go. Sorry if my explanation isn't funny, but this is:

<http://www.youtube.com/watch?v=5P6UU6m3cck>

Mike Kenny (2007-12-18 11:09:20)

In keeping with my view that humor is a way of venting tension after being surprised with something that isn't harmful, I'd say that the laugh comes from a sense that what she says has a certain shock because you don't expect someone to say something like that. There's confusion in you, and then you realize there's nothing wrong with this situation. I translate the interaction this way: "She ordered me to come even though I didn't want to, and I'm coming, even though I wouldn't if not compelled, and am, surprisingly, not showing the normal desire to maintain a certain level of easygoingness during a social event, or deference to the wishes of the authority, the person ordering me here, by calling attention to how I was ordered, and don't want to be here.' Your mind initially thinks this, but then 'says' "Of course she's not saying that. Why would she?" and laugh at how the surprise, which could have been unpleasant (uncomfortable social interaction, possibly an argument) turned out to be a friendly exchange. Laughing releases the anxiety that popped up at the initial remark. Imagine if she had been serious about being ordered there! You might have laughed, then saw she wasn't laughing, and felt uncomfortable. The initial judgment of taking her serious would be correct. Laughing could be partially releasing tension, but also a means of signalling to others "I'm uncomfortable and really wish that whatever just happened that makes me uncomfortable be taken in the harmless way rather than in the unpleasant way."

Noumenon (2007-12-24 21:43:38)

Here's another theory of humor that might explain it - [1]Link

1. <http://www.tomveatch.com/else/humor/paper/node2.html>

Inappropriate laughter? « N=1 (2010-03-31 09:03:17)

[...] I remember a post by Seth Roberts where he said "Laughter is a big and important part of life. Visible, common, highly desirable" yet mysterious." [...]

mike kenny (2011-11-14 16:00:30)

i'm now guessing i got that theory about laughter—that it signals to others that a surprise is not dangerous—from alex backer. here he puts forth his theory: <http://alexbacker.pbworks.com/w/page/1721182/The-Evolutionary-Advantage-of-Humor>

## **The Softer Side of Blogs (2007-12-11 19:03)**

[1]Michelle Nguyen told me that in [2]Palo Alto, professional contacts expect you to have a blog. If you don't have a blog, you're not a serious person.

At a recent [3]wine tasting, I encountered the other, nicer side of the coin. I met Colleen and Vanessa, two of the three women behind [4]Wishbone Clover, a blog without a theme. "We just blog about what we care about," Vanessa said (as I [5]have guessed). It's a way of talking to each other and, oh yeah, other people can read it.

I said I had a blog, too.

"Have you ever been stalked on your blog?" Colleen asked. This might be the friendliest question I've ever been asked at a party.

"Stalked?" I said.

She meant that someone had repeatedly left very nasty comments on her blog, such as "you draw like a 4-year-old" (she is a graphic designer and often posts drawings).

I said no, most comments are favorable. No one has ever left nasty comments.

She explained that she had been at a museum party in Boston and a woman at the party thought that she (Colleen) had been hitting on her (the stalker's) girlfriend. that's what caused the stalking. It really upset her.

The women behind Wishbone Clover met when they worked at Wells Fargo. All three were told working at Wells was an "awesome opportunity"; all three left. Colleen now works at another bank. Vanessa is a writer; she has a writing job at UCSF and writes fiction. I forget what the third one does.

Wishbone Clover has a great list of categories, including aggrieved, I am so mad right now, glimpses, special guest star, exchanged (conversations), and the mysterious hlp. I especially liked an entry called "[6]My Mother's Royal We." It begins:

One recent morning I chatted, via IM, with my BFF, EB. I noticed a quirk in our conversation: when I describe some difficulty, especially related to poorly behaved gentlemen, she tends to respond in the third person, for example:

We don't have time for that bullshit. Let's drug his drink, leave him in Nebraska, and see how he fares.

However, she doesn't like it when her mom uses the royal we. "We don't like raw fish," her mom once said.

---

colleen (2007-12-12 09:45:52)

Seth! The ladies of WC thoroughly enjoyed your company at the sparkling wine tasting event. That bottle top is living in my apartment right now: [http://wishboneclover.typepad.com/wishbone\\_clover/2007/12/swords-champagn.html](http://wishboneclover.typepad.com/wishbone_clover/2007/12/swords-champagn.html)

seth (2007-12-13 04:55:28)

Thanks, Colleen. Maybe you will have a show in that gallery. And maybe the bottle top will be part of it.

### **Dietary Paradoxes and a Highly Anticipated Talk (2007-12-12 05:13)**

[1]Here's a nice post about dietary puzzles in which a group of people who should have a high or low rate of heart disease don't. For example,

[2]Spanish paradox. Those naughty Spaniards are eating more fat and less carbs and getting LESS heart disease, now there's a surprise. Good thing their medical system is so marvelous.

[3]Sri Lanka paradox. In Sri Lanka they eat <25 % calories from fat and still get lots of heart disease. Tut tut.

I have blogged about the [4]Israeli Paradox. These paradoxes go away, the author notes, "when you realize saturated fat is not the cause of heart disease."

[5]Elsewhere on his blog he discusses studies that found that eating less fruits and vegetables improved health. Thanks to Dave Lull.

Not unrelated to all this, Ken Carpenter, a [6]co-author of mine and an excellent speaker, is giving a talk next week in the Nutrition Department at UC Berkeley titled "When Nutritionists Go Wrong". It is on Wednesday, December 19, 2007, at 4:10 pm Room 114 Morgan Hall. Ken has written wonderful books and [7]articles about the history of nutrition and I am eagerly awaiting this talk.

Timothy Beneke (2007-12-12 10:08:04)

Do we really know the degree to which nutrition is important in health, that is, assuming we get basic amounts of protein, carbs and fat? Maybe the fundamental assumptions about the relation between nutrition and health outcomes are just plain wrong. And no matter how many times correlations are repeatedly found in epidemiological studies, it can never show causality. There are so many correlational studies controlling for confounds that are themselves based on correlations. It's all a big guessing game and it's obvious now that nutritionists have been guessing wrong. The lesson is: when it's nearly impossible to do controlled, randomized studies, be humble and admit that you are just guessing...

David (2007-12-12 11:29:38)

I think Tim understates the utility of correlations. They are relatively cheap and can be guides about whether theories are reasonable and then what to do a randomized study on. Correlation suggests causation. Then we have to go further. We also have to be careful not to base policy on correlations, especially when we have good reason to believe confounding factors will be important.

seth (2007-12-12 11:59:19)

The first evidence that folate prevents birth defects came from correlational studies. See for example <http://www.kofinasperinatal.org/download.cfm?DownloadFile=244A9AD1-BB1E-A39E-81BE645F04C090B2> Later this idea was tested with experiments. It turned out to be correct.

Dennis Mangan (2007-12-12 13:12:52)

Seth: So, what \*does\* cause heart disease? Seriously, I'd like your opinion. The current state of knowledge would have it that it's multifactorial, for instance related to diet, exercise, smoking, hypertension, etc. Obviously lots of people get heart disease in this country, but they don't all have the same risk factors. How does one explain, e.g., the runner Jim Fixx, who died of a heart attack and who seemingly had only one risk factor, high cholesterol? Then there's data like that in which vegetarian Adventists outlive non-vegetarian ones. If the ideas that you've been writing about here turn out to be even half-correct, well, I just don't get it.

Tom (2007-12-12 14:08:47)

They're only paradoxes if you believe Ancel Keys and Senator McGovern were right. It's getting pretty clear they were disastrously wrong. Distance running IS a risk factor. It's a bizarre behavior with no evolutionary *raison d'être*, and it's incredibly inflammatory. We didn't evolve to do anything of the kind. We evolved to be largely stationary, with short bursts of extreme exertion – sprinting. And in fact, sprinting exercise is anti-inflammatory and anabolic. (The idea that the Marathon is the pinnacle of human physical health is kind of insane, even before you acknowledge that it's the commemoration of a runner's death.) We also evolved to eat – also in short bursts – large amounts of (can't help myself, dude) protein and fat. Carbs just weren't around in non-trivial quantities. And even then, we evolved to go quite a while between feeds. And indeed, intermittent fasting is anti-inflammatory, compared to constant noshing. And, also, anabolic. In other words, you get big and strong if you eat one meal a day of protein and fat. Six small meals, less so. Add carbs, even less. Why? We're probably tuned for our ancient environment.

Timothy Beneke (2007-12-12 16:19:35)

David: Most correlations only suggest hypotheses to be tested; if they are enormously strong they may begin to suggest causation. I agree that when something jumps out at us in a correlation, it should be tested to see if there is causality. The problem is that it's enormously difficult, expensive, and ethically limited to do controlled nutritional experiments. It's not clear to me that replication of correlational studies should be taken very seriously, because you may just be replicating correlations that have nothing to do with cause. The controlled nutritional studies like the Women's Health Initiative seem to suggest that diet matters less to health than was previously believed. I don't know how we go about sorting out all of the correlational data and controlled studies to try to determine if nutrition, within a basic range of getting reasonable protein, carbs and fats is really that important.

Lancaster (2007-12-12 16:38:43)

The Japanese remain the world's longevity champions. CHD mortality rates have declined even as meat consumption has doubled. When I first lived in Japan 25 years ago, the beef bowl and katsudon had already become staples of the Japanese fast food diet. (As Homer Simpson would say, "Mmmm . . . katsudon.") Most paradoxical is the persistently high smoking rate. And it would seem that the stressful Japanese lifestyle would only make things worse. But this is where I think alcohol enters the equation in an interesting way. It's still *de rigueur* for Japanese businessmen to hit the bars after work on a daily basis. Getting soused and blowing off steam is culturally acceptable, even smiled upon. Add to this a cohesive, community/religion-centered culture (though most Japanese claim not to be "religious"). This is a "cradle-to-grave" society that manages to avoid being actually socialistic. Free-market capitalist that I am, there's a lot to the argument that the stress alleviation provided by a paternalistic society and "good enough" socialized medicine may well offset the deficiencies. Another beneficial aspect of the Japanese lifestyle is the huge amount of walking and biking they do. Not for "exercise," but merely to get around. Seriously, the only people I ever saw jogging in Japan on a regular basis were other Americans. (Plus, this is a culture that puts a high premium on hygiene.)

David (2007-12-12 16:52:20)

Tim: I agree with you. I think the main problem with studying nutrition is that it is so multidimensional. How do you begin to do a reasonable mapping of the eating behaviors of a population onto a set of outcomes that you care about? If the goal is to set some recommended nutrition policy this is very hard. Even if you could do studies that plausibly estimate causality for some outcome over some range of the nutrition variable, you would still need to worry about its interactions with everything else, and with the multiplicity of outcomes that people are concerned about. Its even worse that the outcomes we are really interested in are long run mortality and morbidity.

seth (2007-12-12 17:01:08)

Dennis, I don't know what causes heart disease. However, if I had to guess, I think the evidence is strongest for: 1. Stress. The social gradient is large and everywhere and seems to be due to less control of one's job at lower positions. Kendrick's examples of displaced peoples provides a different kind of evidence for this factor. Perhaps stress acts by disturbing sleep, which causes one's immune system to malfunction. 2. Inflammation. The strong correlation between gum disease and heart disease. I think gum disease is due to too much inflammation.

Willy (2007-12-12 17:08:47)

Tom, this is very interesting: > sprinting exercise is anti-inflammatory and anabolic. > you get big and strong if you eat one meal a day of protein and fat. Can you please point me to some further reading?. Thanks

David (2007-12-12 18:26:28)

I've heard a theory of the evolution of human beings in the ecological niche of East Africa that suggests our species spent a lot of time following herds of large migrating animals and scavenging those that died or were killed. This is said to explain bipedalism since that configuration of the body is the most efficient at shedding heat. In this setting it made sense to eat the most energy dense portions of the animal first-brains and so forth-that are mainly fat. I haven't read the science, just a lay account, but I found it very suggestive.

## **Ulcerative Colitis and Flaxseed Oil (2007-12-12 17:40)**

Ulcerative colitis is a disease of too much inflammation. The Mayo Clinic [1] recommends several dangerous and expensive anti-inflammatory drugs. Based on [2] its effect on inflamed gums (gingivitis), I suspect flaxseed oil would be very effective, much safer, more convenient, and much cheaper, assuming you get the right dose (about 2 table-spoons/day).

Flaxseed oil is not on the Mayo Clinic list. Nor is any other source of omega-3. In a store today I ran into a woman seeking herbal treatments for ulcerative colitis. She hadn't heard of using flaxseed oil.

Does anyone reading this have direct experience about what happens when you take flaxseed oil for ulcerative colitis?

The Mayo Clinic website [3] doesn't say anything about using flaxseed oil (or other omega-3 sources) to treat gingivitis. (And the Mayo Clinic [4] claims expertise on alternative medicine.) Nor does it say gingivitis is caused by too much inflammation. [5] In two weeks, you can see for yourself they are wrong.

1. <http://www.mayoclinic.com/health/ulcerative-colitis/DS00598/DSECTION=8>

2. <http://www.blog.sethroberts.net/2007/11/06/omega-3-and-dental-health-even-more/>

4. <http://bookstore.mayoclinic.com/products/bookDetails.cfm?mpid=35&trkid=20477S13939270>

5. <http://www.blog.sethroberts.net/2007/11/16/omega-3-what-happens-when-you-stop/>

---

Pearl (2007-12-12 18:28:22)

My mother had colitis, I'm not sure if it was ulcerative. They had her on a lot of drugs and it was quite bad for a couple years until she heard from someone about drinking juiced carrots, green tops are the best for some reason. You have to drink the real stuff, not processed. She drank it a couple times a day and it cleared up in about half a year. Now she only gets a rare bout if she eats too much spicy food or drinks red wine. She hasn't tried flax seed oil that I am aware of although I think she takes fish oil capsules for the omega 3. I will recommend flax oil to her.

peter (2007-12-12 20:02:08)

why don't you share your research w/ the Mayo; perhaps they'll conduct a mini study.

Paul Brentano (2007-12-12 23:06:26)

I have ulcerative colitis but fortunately it has quieted down on its own for the last couple of years. My doctor prescribed an anti-inflammatory and told me I'd have to take it the rest of my life but the pills made me sick so I quit taking them after just a couple of weeks. I do take flaxseed oil now after reading your blog so perhaps it will help prevent a relapse.

seth (2007-12-13 07:35:23)

Peter, thanks for the suggestion. I don't think the Mayo Clinic does dental research. I do hope that an interested academic dentist will try to repeat the dental observations I've reported here, how flaxseed oil cures gingivitis. I think about 1 in 1000 dentists would be interested and it's not obvious to me how to find him or her.

Tom (2007-12-13 09:41:35)

How about making the request here? UC forum: <http://www.healingwell.com/community/?f=38> It appears to be quite active. (In fact, if you jump up a level in the hierarchy, there are many forums where you could make a similar request. Perhaps flax doesn't work for UC, but cures Crohn's...who knows?) health forums: <http://www.healingwell.com/community/default.aspx?c=4> (This is just one site, too...I suspect there are many such forums on the net.)

Timothy Beneke (2007-12-13 09:49:06)

As I've posted before, I had gum surgery, now about 12 weeks ago. For the final assessment yesterday, my gum surgeon said, "Wow, I'm amazed! If I keep doing such great work, I'll have to call myself God!" She laughed and was joking, but both her and her assistant were surprised at how well my gums were doing. And praised me highly for how hard I must be working to keep my gums in such great shape. I actually haven't been working very hard, I must confess. It's only after I started doing the flax seed oil - an average of about 3 tablespoons a day - that I have been getting these kinds of responses. I would love to see some research on this.

Tim (2007-12-13 10:03:18)

I imagine that the lady you met must have been newly diagnosed. I have had ulcerative colitis since 1996. Most of the people that I know with u.c. take omega-3, though perhaps more commonly as fish oil. All of my gastroenterologists have agreed that it can be a useful adjunct to other therapies. In fact, one of the drug companies is developing a supplement drink that combines omega-3's with the soft fiber found in bananas, vitamin D and some other foods that are very beneficial to u.c., but hard to get in the right proportions. In general though, doctors seem reluctant to recommend diet-only solutions. I have a relatively mild case, but have had two bad flare ups. Consequently I take two of the drugs listed in addition to fish oil. I am hopeful that one day I will get off the other meds, but for now I just take a very low dose of the drugs thanks largely, based on my self-experimentation, to the omega-3s. The other therapy that doctors downplay for u.c. is nicotine. Even though I have never been a smoker, nicotine gum can stop an oncoming flareup with fewer side effects than steroids and without the knee-jerk doctor's response of increasing the dosage of my other meds.

peter (2007-12-13 11:10:26)

i doubt that any practicing dentist would be interested; you'd have to contact a university. I'd also mention oil pulling, which i sense will also be effective (it has been for me). The much more serious disease is ulcerative colitis, especially since the drugs have a hi rate of AE's. that's where i think Mayo could be interested in seeing if omega-3 oil are useful, although probably w/use of a lower dose of an anti-inflammatory.

seth (2007-12-13 11:38:06)

"AE" = adverse effect?

peter (2007-12-15 10:32:42)

yes, AE = adverse effects

Seth's blog » Blog Archive » Ulcerative Colitis and Flaxseed Oil (continued) (2007-12-17 00:21:19)

[...] Ulcerative Colitis and Flaxseed Oil [...]

Swift Loris (2007-12-23 16:33:16)

For whatever it's worth: I've had Crohn's since 1996. Before I sought treatment I had several very bad bouts of it, but it's been under excellent control symptom-wise with Asacol for almost 10 years. I started with a low dose, but last year my gastroenterologist wasn't happy with my test results and colonoscopy findings and doubled the dose, despite my symptoms being minimal. I'll be getting new tests and another colonoscopy shortly, so I'll know more then about how things are progressing. I've been taking fish oil in the Dr. Sears Zone Omega Rx formulation, which is supposedly "ultra-refined" to remove impurities, for several years, 5 capsules a day (5000 mg fish oil containing 2000 mg EPA and 1000 DHA). As noted, it hasn't seemed to have brought about any improvement in my Crohn's. Dr. Sears himself recommends a significantly higher dosage for Crohn's, but my gastroenterologist isn't comfortable with my taking that much, so I've stayed with 5 capsules/day. On the other hand, as it happens, I have a terrible dentist-phobia and have avoided for years getting my teeth professionally cleaned (I do brush regularly with an electric toothbrush but don't floss). By all rights I should have serious gum disease by now, but my gums never bleed and I have no swelling or other gum symptoms, so I'm hopefully assuming I'm OK on that front.

slackersdelight (2008-02-01 14:05:20)

From my 7 year sever bout with UC, I've learned a couple of things (about myself, everyone might be different): 1. Stay away from steroids, they only cause other problems. 2. 3 pills 3x per day of Asacol is way too much, try one after every meal; better results. 3. Cut back on dairy. 4. No sugar or bread. Sorry, the complex sugars, wheat, and yeast will cause you gut to overreact. 5. And this is the biggest one! Buy a coffee grinder and whole seed flax seed to mix into your morning cereal (I use almond milk). Every morning grind about 2 table-spoons and pour the meal right into the cereal (low sugar granola works best). Give it a try, but be patient it could take 3-6 months to clear up.

Allan Coffey (2008-02-17 11:48:43)

I have also had UC since 1996. first few years were hellish with two very bad flare ups which required hospitalisation & heavy steroid / Imuran & salazopyren doses. not good. had fluctuating health for a few years with another severe flare up a few years back which had me on the brink of major surgery. Western meds are not the answer to Chrons or Colitis. I have put together a programme which now sees me in consistently good health with occasional digestive problems but overall a very normal life. came accross a book, "Self healing Colitis & Crohns" by David klein. It basically promotes a whole food /vegan diet which cuts out foods that puts stress on your gut & causes fermentation. the book also deals with the problems caused on an emotional level. I do not follow the plan strictly but even following it generally leads to vastly increased condition of the gut. I grow my own wheatgrass which is a very powerful healer. I have a veg juice every morning, using a masticating juicer with no blades, always with some flax seed oil. To keep stress levels at bay I meditate, cycle, swim. all in all my life is back on track. I still have maintenance daily dosages of salazopyrn & Imuran but I hope to some day be able to stop taking them. Western medicine has no interest in prescribing a diet to fix these debilitating conditions but it does work & how! all it takes is discipline & motivation to be healthy again. Allan in Ireland

Brandi (2008-05-14 17:37:46)

Doing some research here. I was diagnosed with U.C. in 2006 and have had three bouts with it thus far. I am currently trying Turmeric and Fish Oil for the anti-inflammatory effects associated with these. I am not willing to start prescription drugs but I am becoming desperate to find a better treatment. I do believe that dairy and complex sugars do play a huge role in this disease. I will try the flax seed and report back. It is probably best to grind the seed yourself but can you just take the flax seed oil pills? Any suggestions or advice would be greatly appreciated. Brandi in Illinois

seth (2008-05-14 17:58:54)

Brandi, I believe drinking the oil is best. At least 2 tablespoons/day. I take 4 per day. If you take the pills you won't get enough. You'd have to take about 25 pills to get the oil in 2 tablespoons.

Thomas (2008-08-26 21:22:12)

I just bought a Flax Seed Oil Bottle from Whole Foods this evening. A little history, I've had U.C. since 1988 (20 years) Took the gambit of meds early on. Woke up to the fact that Western Meds don't do much of anything. I started doing things naturally in the med to late nineties. I fell off the Horse a month ago, and am having a flare-up. Trying to rid the diarrhea, it's been bad the last few weeks. I'm on Probiotics, going back to what I used to eat, good healthy stuff and now I bought the Flax Seed Oil. I usually put it in my Oatmeal.

Chris (2008-11-05 20:45:46)

Could you tell me how use use Flaxseed oil for gum disease and in what amounts. Thank you.

Phil (2009-04-25 15:28:01)

I've had U.C. for about 11 years now. Does anyone know if rhubarb is a bad thing to eat. I've been eating some every morning. My U.C. hasn't let up for about 8 months now. Also I had my gall bladder removed almost 2 years ago. About a year later I seem to have gotten worse. You never know if one thing is related to the other. I ate lots of live foods through most of it. I can't even to that anymore.

overpopulation is here (2009-05-11 10:17:42)

It seems obvious that everyone's similar IBD \*symptoms\* are caused by various intestinal imbalances that are different for every person. Each person simply needs to experiment to find what works for their case. I have had UC for 8 months now; first flare that led to diagnosis, and now a second flare I'm getting over(lasted 3months!). On my first flare after diagnosis, I got REALLY sick after starting taking ASACOL (allergic), so I started Prednisone @30mg day instead and also started the SCD diet- and my flare cleared up to NORMAL stool in about 2 weeks (no use of Flax Oil, Probiotics, or anything else). I started to read up on supplements/etc for UC and then started taking ALOT of Garden of Life Probiotics/HSO's according to that Makers Diet. I think these products really messed me up on my next flare by introducing too many & new bacteria strains to my system... Had a 2nd flare 3 months later immediately (next day) after going off strict diet and eating potato & cake bites-only. This time I also had Candida/Eczema which I had to clear up with Candex and Coconut oil. Then I finally went to the Dr. who put me on 50mg Prednisone and that helped start clearing things up. This flare was bad and I found that I could not eat foods with any sugars in them, even fruit- all I was eating was nuts,seeds, and cheese since it minimized my D to 3-6/day. Until I finally stumbled on the fact that I may be intolerant to Lactose(Prednisone filler!) or Fructose like most IBD'ers, or have SIBO. I found another Dr. who could do tests, and I was tested positive for severe SIBO- which is why my flare was so bad and not easily clearing up with strict diet & Prednisone. Took antibiotics for 2 weeks to quell the SIBO and then I could eat normal SCD foods again. So now I say "Get tested for everything you can." I had to research and request these extra tests that Dr.'s never seemed to mention. Try different probiotics. Another of my Dr's patients found that taking Florastor (S. Boulardii-yeast just like Ganeden Crohns/Colitis pills) keeps him normal with no meds. I tried it and found this made \*me\* worse- maybe because it's a yeast and I probably have some lingering SIBO(too soon yet). I've found that Acidophilus (small Intestine bacteria) makes me worse. Tried Bifidum (large intestine bacteria) instead, and seem to be improving... 1-3 formed BM's/day. This is in the form of Natren Healthy Trinity right now...but it is expensive... Note that for a portion of this 3 month flare when I had D, I tried a Flax remedy that a friend from the Ukraine recommended: Boil then simmer 2TBSP flaxseed/half liter water to extract oils. Pour everything into a

thermos. Drink this thick solution 3x day before meals to coat your insides. It helped. Now that my stools are more normal I only continue to take 2TBSP day bottled flaxoil & 2tsp/day of Cod Liver Oil. +5 fish oil caps of EPA/DHA 300/200. Taking DGL & Glutamine powder also helped get MY stool back in form. Scrutinize your supplements: I definitely got better after finding that my Multivitamin, Calcium, & Amino Acid contained Calcium Carbonate filler (basically an antacid). I stopped taking these and things improved. If you take Prednisone, take it with a Lactase pill to help neutralize the main ingredient in those pills- lactose filler!

Renay (2010-04-06 09:16:01)

Fieldwork Denver is a market research firm, conducting a private informal group discussion with individuals diagnosed with Ulcerative Colitis. This discussion pays \$125 CASH and takes place on either the 12th or 15th of April in Denver. If you want to be invited to participate please click on this link and provide some basic information... you will be contacted with more information. OR CALL 303-825-7788 ASK FOR RENAY [https://fieldwork.formbin.com/forms/dnv\\_medical\\_conditions](https://fieldwork.formbin.com/forms/dnv_medical_conditions)

Teri (2011-03-13 16:27:27)

I have a 10 year old daughter that was diagnosed with UC in July 2010!! I am desperate to look for an alternative "natural" treatment as the prescribed medications I do not feel are working. I was recently advised to give her the Flax Seed 3 x's a day in a tea form and to add a bit of sugar and cinnamon(i guess for flavor) but, I just read in another article that the flax seed should not be exposed to heat as it can cause toxins. Does anyone know if this is a true fact? desperate Mom in Florida!!

correct facts and research helps a lot (2011-04-21 21:23:57)

I notice that "overpopulation in here" seems to be listing a lot of things that are very contradictory to one another. Yes, everyone is different when it comes to disorders of the gastrointestinal system, but it seems that he/she is stating a lot of things that are not correct. \*you cannot really have too many "new" strains of bacteria introduced to your system. The most probable cause to your problems is that you were taking very strong medications (Asacol and Prednisone) which were causing the problem, NOT the probiotics. And having bacterial overgrowth is not tied to taking probiotics. Just have to know what probiotics to take. \*the vast amounts of anti-biotics and steroids which doctors tend to administer to control these disorders is simply acting as a band aid, not a true treatment (Asacol is a perfect example). \*Of course foods high in sugar will tend to aggravate your stomach, as well as the acid from fruit. If all you were eating was nuts, seeds and cheese, you are going to make your digestion work on overtime to digest those things. You were eating things that are polar opposites in their digestive properties. What made you think that eating nuts, seeds and cheese was a good idea? Those are very hard things to digest. \*go to a knowledgeable health food store/pharmacy, where the pharmacist is familiar with autoimmune disease. Many people do not know that colitis is an autoimmune disease. \*make sure you are not taking pills that are going to counteract one another. Vitamins can be very harsh on your system, but having bowel disorders usually makes it difficult to absorb our nutrients properly. Make sure to have something to help prep your stomach for whatever pills you are taking, unless the pill specifically needs to be taken on an empty stomach.

flaxseed info for Teri (2011-04-21 21:29:17)

Teri- There is no reason to heat the flax seed oil at all. You can get the seeds and grind them down finely in a coffee grinder, but you can also purchase the oil itself and put it in oatmeal, in a shake or other. You do not want to get whole flax seeds for her to take, as the key factor of the seed is its oil. That oil will not properly be digested in seed form. Keep in mind, flax seed oil can cause more bowel movements per day, which means that it can have her stomach working overtime. What other things have you been administering to her? I highly recommend researching probiotics which have a high "count" and multiple strain. Whole Foods has a good variety, but make sure to look into which strains are geared towards different parts of the digestive tract.

Clair Pickering (2011-11-12 21:34:46)

My 17 year old daughter was diagnosed with U.C about 3 years ago. She had a very rough time. We went to a specialist who recommended adding wheatgrass to her diet. We were reluctant to try it, but to our surprise, it seemed to be helping. The wheatgrass is run through a juicer. It has diminished her symptoms greatly. She had to get used to drinking it, however it beats the alternative.

Joe (2012-01-06 19:38:15)

My wife was diagnosed with colitis about 4 years ago. After being prescribed a medication that clearly didn't work, and 2 years of suffering, I decided to put her on supplements of potassium and magnesium. This calmed things down a little. But when her knee swelled up a year ago, she was diagnosed with rheumatoid arthritis. This seemed strange. She's only 36. This led me to search for things that would help with inflammatory diseases. That's when we found GROUND FLAXSEED! After taking two tablespoons per day,(in only two weeks), her knee swelling went down. And, within a month, all of her colitis symptoms were gone. It has been over a year, and still no symptoms. She eats anything she wants(even her favorite buffalo wing pizza), with no consequences. GROUND FLAXSEED has truly changed her life!

### **The Legacy of Jane Jacobs (2007-12-13 05:35)**

Because of reading Jane Jacobs, I could begin to understand [1]this fascinating post by E. M. Risse about trade vs import replacement. I hadn't before heard his point that between-region trade tends to favor people at the top of the economic food chain. I'm not sure I completely understand Risse's post but I am intrigued enough to want to look at his (four-volume!) book, [2]The Shape of the Future, shape meaning settlement pattern.

### **My Omega-3 Talk at Psychonomics (2007-12-13 21:31)**

At the November meeting of the Psychonomic Society, a group of experimental psychologists, I gave a 15-minute talk ([1]PowerPoint) about my omega-3 research. (Anyone know how to add audio to a PowerPoint file?) Almost all the data in the talk I've posted here, but it had one not-blogged idea, which I summarize like this:

optimize brain -> optimize body

The intake level of a nutrient that optimizes brain function should be close to the level that optimizes the function of

everything else. In particular, the omega-3 intake that makes the brain work best should be close to the level that makes the rest of the body work best. This is because the brain and the rest of the body are bathed in the same blood.

It is easy to see why this is so. I have many electrical appliances: clock, telephone, TV, microwave, refrigerator, laser printer. In spite of vastly different innards and functions, all of them run best when their electrical supply is very close to house current. The electric current that makes my laser printer work best is very close to the electric current that makes my refrigerator work best. Of course, this is by design. Likewise, the different parts of our body, although doing vastly different things, have all been adjusted by evolution to work best with the nutritional equivalent of house current. Just as we might study laser printers to learn what current to use with our refrigerator, we can study the brain to learn what nutrients optimize immune function.

This is a new idea in nutrition (at least, new to me). It is supported by and explains some of the most interesting data I've posted. It explains why Tyler Cowen's gums got [2]so much better so quickly – because he was taking almost exactly the best amount of flaxseed oil for his gums. Tyler chose his intake of flaxseed oil based on my behavioral data, which suggested the best amount was between 2 and 3 tablespoons/day. The gums and the brain could hardly be more different, but the best level for the brain turned out to do a wonderful job of healing his gums. Same thing with [3]Anonymous and sports injuries.

By the way, this shows the scientific value of blogging. My gums got better, too, but not as impressively as Tyler's. I didn't have a lot of injuries to heal. The big improvements noticed by Tyler and Anonymous were "accidents" (unintended consequences). Science thrives on accidents; blogging, it turns out, is a new way to generate them.

NE1 (2007-12-14 16:59:57)

This is really sketchy reasoning. Your appliances were designed for 2 things: to be useful, and fit your 120V line. Evolution happens at the edge of life or death, and my first inclination would be to say that only one of the advantages: anti-inflammation or better reaction time etc, is necessary at any one cusp. The probability of needing optimums of both is (to first order) unlikely. In any case, without more specific examples (specific proteins and vitamins from the past, and studies showing the optimal coupling of the involved systems) I wouldn't have made the strong statement about "should". Could, might? Maybe.

seth (2007-12-14 19:13:29)

NE1, I don't follow your reasoning. If you have a different explanation of why a dose of flaxseed oil chosen based on brain measurements did such a good job of improving gum health, I'd like to hear it.

NE1 (2007-12-14 19:54:11)

For one thing, I dispute your ability to notice a decline in gum health with excessive amounts of fat intake (or a plateau, or lowest effective dose—these things require more subjects. shocker.) Without this, you're stuck saying "brains need this much, but any amount is good for gums." 2-3 tablespoons of oil seems like a large amount even for early coastal humans, let alone those on the savanna. It seems a stretch to claim an optimum. In fact, browsing your presentation, I notice you didn't even find the optimum for the brain, only a plateau in effect. An easy (and easily confirmed) explanation for this is that storage has maxed, but there are others just as relevant as your conclusion.

seth (2007-12-15 03:58:34)

Thanks, NE1. I'm unable to find an alternative explanation in what you wrote.

### **Best Reference to the Shangri-La Diet (2007-12-13 22:05)**

The year isn't over, but we have [1]a winner:

I am going to learn Russian.

I feel so enchanted when I gaze into his handsome face. His eyes are so commanding. I cannot look away.

Should I try the Shangri-la diet?

### **Omega-3 and Parkinson's Disease (2007-12-14 18:35)**

The [1]press release had a curious title: "Omega-3 fatty acids protect against Parkinson's." The certainty suggested an experiment, but Parkinson's is too rare to study prevention experimentally. The press release turned out to be about a rat study that used a drug called MDPT to cause brain damage that resembles Parkinson's. Rats given a high-omega-3 diet suffered much less damage – apparently none – from the drug.

Rats given the high omega-3 diet had much less omega-6 in their brains than control rats – one more reason, in addition to the [2]Israeli Paradox, to think that omega-6 may be just as bad as omega-3 is good. Omega-3 may act by displacing omega-6 (they are almost identical physically).

The results could have been taken to suggest both (a) eat more omega-3-rich foods, such as fish and (b) eat less omega-6-rich foods, such as most nuts and vegetable oils, but only the first recommendation [3]reached the public.

1. <http://www.sciencedaily.com/releases/2007/11/071126110453.htm>

---

David Marcus (2007-12-15 03:57:34)

Suggesting that people avoid nuts seems counterproductive. Nuts are among the only foods for which consumption is consistently and dramatically linked to lower heart disease (and all-cause) mortality in epidemiologic studies, and lab and animal studies are also suggestive of protection from vascular diseases.

seth (2007-12-15 04:53:44)

Thanks, David, that's a good point. I was aware of experiments suggesting that walnuts – which are high in omega-3, one of the few nuts that is – have heart-protective effects. But I'd forgotten about the studies you mention. I found this in a 1999 paper: "Perhaps one of the most unexpected and novel findings in nutritional epidemiology in the past 5 y has been that nut consumption seems to protect against ischemic heart disease (IHD)." It's also true that while vegetable oils are high in omega-6, nuts contain far more than fat. Vegetable oils are close to the sum of the fats they contain; nuts aren't.

peter (2007-12-15 11:54:21)

<http://ifitandhealthy.com/healthy-diets-the-mediterranean-diet/> When it comes to a fatty acid composition of oils, the best omega-6 to omega-3 ratio is found in flaxseed, canola, walnut, olive, and avocado oils. Omega-6:Omega-3 Ratio in oils: Flaxseed " 0:24 Canola " 2:00 Walnut " 5:08 Olive " 13:1 Avocado " 13:0 In nuts, the best omega-6 to omega-3 ratio is in walnuts, macadamia, pecans, cashews, and pine nuts. Omega-6:Omega-3 Ratio in nuts: Walnuts " 4:2 Macadamia " 6:3 Pecans " 20:9 Pine " 31:6 Cashews " 47:6 If you have a choice, it is a good idea to use nuts and oils with a good omega-6 to omega-3 ratio.

L. Atkins (2009-03-20 13:48:45)

Thanks to Peter! I've been looking for that nut info all over the Internet.

## **Gary Taubes on the Religious Nature of Obesity Research (2007-12-14 23:13)**

From an excellent [1]interview with Gary Taubes:

Martin: You write that the "enterprise" of diet, obesity and disease research "purports to be a science and yet functions like a religion." In what ways?

Taubes: Simple. The researchers and authority figures in this business seem utterly uninterested in finding out whether what they believe is true or not. It's as though their God, whichever one that might be, told them that obesity is caused by eating too much – by gluttony and/or sloth – and so they believe that unconditionally, and no amount of contradictory evidence, no failure to explain the actual observations can convince them to question it. They have unconditional faith that they know what the truth is, and there's no place for this kind of faith in the pursuit of science. Science requires skepticism to function. Religion requires faith.

I agree with Taubes about the facts: Obesity "authority figures" do "seem uninterested in finding out" etc. Yes, it resembles religion, not science. Taubes's summing-up, however, is one-sided. To say "science requires skepticism" is to miss the point that science also requires paying attention – finding, noticing, thinking about facts you can't explain. Religion doesn't. The Atkins Diet caused millions of people to lose plenty of weight in a way that mainstream weight-control theories could not explain. No one powerful in obesity research managed to notice this was a puzzle worth trying to explain.

Science isn't just about testing ideas (Taubes's "skepticism"); it also requires generating them. I'm hoping if I blog about this often enough I will find a humorous way to say it.

Thanks to Dave Lull.

---

Tom (2007-12-15 08:22:32)

I think scientists were noticing, and they had better ideas than Ancel Keys and Senator McGovern [who was trying to do Pritikin (an Ornish predecessor) but couldn't stick with it.] My opinion: Science, at least in some fields of inquiry, also requires an appetite for self-immolation. Would you publish your research if you were quite sure that doing so would mean your income, reputation and career were destroyed? Physiologists watched it happen to their peers. These days, depending on field, scientists may have their labs wrecked, their test animals "liberated" and come home to find protesters taunting their kids. Even during the McGovern hearing, it was already clear that the costs of speaking truth to power would be astronomical. And the cascade only gathered power from there, especially when it became clear that it was a license to print money [from huge-markup, low-labor, cheaply-shipped carb products.]

Timothy Beneke (2007-12-15 09:13:42)

I am eternally grateful to Gary Taubes for opening my eyes on nutritional matters; if I were religious, I'd pray that he read Seth's work. But he doesn't seem to know much psychology and would do well to read research on belief perseverance, which is roughly the tendency to keep on believing something even in the face of disconfirming evidence. Good science has safeguards against this, but nutrition appears not to be a scientific field, because it's so expensive and difficult to do the science that actually tells you something, in this case you need controlled randomized studies with large samples that you observe over many years. To understand nutritional belief perseverance, we also need to understand people's blindness to their social roles. To be an expert supposedly protecting people's health, guiding them towards longer lives with reduced suffering and misery, does have an almost priestly component – I am protecting you against death and misery. The role encourages belief perseverance because of the shame and sense of public humiliation that you risk if you have to admit you were wrong. It's also tied to intolerance of contradiction and cognitive dissonance. If I have lots of correlational studies showing that people who eat whole grains, fruits and veggies have better health and longevity, and have concluded that eating those cause better health outcomes, how do I cope with the contradiction that when actually put to the test in the randomized, controlled Women's Health Initiative,

my beliefs turn out to be wrong? Changing my beliefs is humiliating and shaming, so I just dismiss the study or ignore it. Below are quotes and a couple of URLs on belief perseverance if anyone is interested: [http://changingminds.org/explanations/theories/belief\\_perseverance.htm](http://changingminds.org/explanations/theories/belief_perseverance.htm) "Once we have decided that we believe something, we will tend to keep on believing it, even in the face of disconfirming evidence. Particularly if other people know of our belief, it can be embarrassing to climb down from our previous assertions. It is also difficult to remove a belief which has been woven into a wider web of belief, without disturbing those other beliefs." And here: [http://209.85.173.104/search?q=cache:GjBritgPZUMJ:www.psychology.iastate.edu/faculty/caa/abstracts/2005-2009/06A.pdf+%22Belief+perseverance%22&hl=en&ct=clnk&cd=4&gl=us&lr=lang\\_en](http://209.85.173.104/search?q=cache:GjBritgPZUMJ:www.psychology.iastate.edu/faculty/caa/abstracts/2005-2009/06A.pdf+%22Belief+perseverance%22&hl=en&ct=clnk&cd=4&gl=us&lr=lang_en) "Three different types of belief perseverance have been extensively studied. One involves self-impressions, beliefs about oneself. Examples include beliefs about your athletic skills, musical talents, ability to get along with others, or even body image. Perhaps you know someone who is extremely thin but who persists in believing that she is too fat. Such a mistaken and perseverant belief can lead to a serious consequences. Another involves social impressions, beliefs about specific other people. Examples include beliefs about your best friend, mother, or least favorite teacher. The third type involves naive theories, beliefs about how the world works. Most perseverance research on naive theories has focused on social theories, beliefs about people and how they think, feel, behave, and interact. Examples include stereotypes about teenagers, Asian-Americans, Muslims; beliefs about lawyers, artists, firefighters; even beliefs about the causes of war, poverty, or violence."

seth (2007-12-15 11:28:01)

That's very interesting, Tom. I'm curious what specifically you are referring to. "Physiologists watched it happen to their peers. . . Even during the McGovern hearing, it was already clear that the costs of speaking truth to power would be astronomical." Could you give examples or links?

Tom (2007-12-15 20:25:45)

Hi, Seth, here's one place to start re: Ancel Keys and what happened if you challenged him: <http://www.proteinpower.com/drmike/lipid-hypothesis/the-low-fat-diet-cascade/> Keys' fame brought him power and money, and he was quite ruthless about destroying opposition. - Tom

seth (2007-12-16 05:13:57)

Thanks, Tom, I see what you mean. Tim, yes, I agree. The importance and difficulty of the subject caused opinions to be more rigid. Charisma and scientific effectiveness don't mix.

Nick DiGiacomo (2007-12-20 13:04:28)

Taubes insights into the role belief has on the business of science is relevant to another emerging nutrition topic - food safety ratings. More here: <http://blog.identitycommerce.com/index.php/2007/12/20/beware-food-rating-systems/>

## **Fighting Cancer Via Self-Experimentation – With Success (2007-12-15 15:10)**

About 10 years ago, a UCSD psychology professor named Ben Williams, who is in my area of psychology (animal learning), managed to successfully cure his own terminal cancer by self-experimentation. He wrote a book about it called [1]Surviving Terminal Cancer. As [2]this WSJ story shows, his approach – which can be summed up think for yourself – is spreading.

Just as my dermatologist was irritated by my acne self-experimentation ("Why did you do that?" he asked), Ben's oncologist, a University of Washington med school prof named Marc Chamberlain, was against what Ben did. Chamberlain now tells the WSJ that Ben's self-treatment "probably contributed" to saving Ben's life. Which is like a math professor saying  $2 + 2$  "probably equals" 4.

A [3]long essay by Williams about his experience.

Addendum: Williams's book, which had an amazon rank of about 1,000,000 when the WSJ article appeared (Dec 15), is now (Dec 18) ranked about 29,000. Dec 24, ranked about 30,000.

NE1 (2007-12-15 16:14:07)

Incurable diseases are heartbreaking, especially in children. That said, who knows if anything he was doing was helping? You saw him vacillate in agony over one vitamin addition when the diagnosis was reversed in only a couple days. The doctors surely had 2 things in mind, after delivering the original prognosis: the remaining quality of life for the child, and the possibility for malpractice type suits. I'm heartened that in most cases the afflicted were eventually able to find doctors willing to oversee treatment. But it seems like someone with a little more training could have overseen the addition of copper-absorbing chemicals and omega-3 doses (or monitor Accutane et al), for the peace of mind of the parents, if not the child.

Andrew Gelman (2007-12-16 10:36:03)

Seth, They always teach us in statistics that you don't know what would've happened if something else had been tried. Sometimes diseases go away on their own. I don't know anything at all about this example, but just in general you can never be sure about causation from before-after data in the context of individual variation. I understand that you (and your colleague) feel strongly about this situation, but saying that a before-after pattern proves causation as strongly as "2+2=4" is going overboard. You can legitimately be angry at the doctor without needing to claim an impossible certainty.

Yvan F (2007-12-16 12:19:20)

Hi, Interestinn blog. Here is a new updated ( august 2007 ) link to his long essay by Williams about his experience. <http://virtualtrials.com/pdf/williams2007.pdf>

seth (2007-12-16 13:09:45)

Thanks, Yvan, I've updated the link.

Tim Lundeen (2007-12-19 12:55:13)

Superb book, thanks for the reference! Re the concerns about whether his cocktail approach saved his life or he would have had a remission regardless, there is of course no way to know for a single case. We do know that the additional supplements/drugs he took all show significant benefits in other cases, and he survived an illness with an a-priori 1-2 % remission rate. So there is a very high probability that his cocktail approach saved his life. For me, the key points in the book are the necessity of taking charge of your own case, the major problems with the FDA approval process, and the blindness of oncologists to the cocktail approach. (Also well written and a pleasure to read, I couldn't put it down.)

## **Ulcerative Colitis and Flaxseed Oil (continued) (2007-12-17 00:21)**

Tom [1]commented on my [2]earlier post on this topic:

I imagine that the lady you met must have been newly diagnosed. I have had ulcerative colitis since 1996. Most of the people that I know with u.c. take omega-3, though perhaps more commonly as fish oil. All

of my gastroenterologists have agreed that it can be a useful adjunct to other therapies. In fact, one of the drug companies is developing a supplement drink that combines omega-3s with the soft fiber found in bananas, vitamin D and some other foods that are very beneficial to u.c., but hard to get in the right proportions. In general though, doctors seem reluctant to recommend diet-only solutions. I have a relatively mild case, but have had two bad flare ups. Consequently I take two of the drugs listed in addition to fish oil. I am hopeful that one day I will get off the other meds, but for now I just take a very low dose of the drugs thanks largely, based on my self-experimentation, to the omega-3s.

The lady I met (who had ulcerative colitis) had had the problem for 14 years. She had not previously heard of using flaxseed oil. "This is your lucky day," I told her, not because I told her to try flaxseed oil but because I could tell her a good dose (at least 2 T/day). How much is crucial information.

It is very difficult to do experiments, even self-experiments, that measure the effect of different doses of flaxseed oil on ulcerative colitis. I'm sure they haven't been done. It was her lucky day because I'm pretty sure I was the only person in the world who could have told her with confidence what dose to take. (Which I could do because of the [3]optimize brain -> optimize body principle.) The gastroenterologists who recommend omega-3 as useful additions - they couldn't say what the best dose is. The drug company making a supplement drink can't say what the best dose is.

Until you know the best dose of a drug or nutrient - the one that delivers the largest possible effect - you are very likely to underestimate its effectiveness. If Tom starts using a large-enough dose of flaxseed oil he may no longer need other medications.

---

Dennis Mangan (2007-12-17 10:36:46)

" To begin to understand the cause of this disease, you must know that ulcerative colitis is found only in parts of the world where people follow the Western diet, high in meat and dairy foods. This is an autoimmune disease, where the immune system attacks the body (in this case, the bowel primarily). The course of ulcerative colitis is characterized by frequent exacerbations (relapses). Previous studies have found a high intake of dairy products, and a low intake of dietary fiber, are associated with relapses. Patients with ulcerative colitis also have higher concentrations of sulfur in their intestines and the course of the disease correlates with that amount.<sup>2</sup> Sulfur appears to be toxic to the intestine. So, where does all this sulfur come from? The amount of sulfur in the intestine is increased by consuming animal products, which are inherently high in sulfur-containing amino acids, like methionine and cysteine." <http://www.nealhendrickson.com/mcdougall/2004nl/041100pufavorite5.htm>

seth (2007-12-17 12:51:03)

Thanks, Dennis. In authoritative discussions of what causes gingivitis, you won't find any mention of over-reactive immune system, just as it isn't mentioned in what you quote. Here's an example from the National Library of Medicine: "Gingivitis is due to the long-term effects of plaque deposits. Plaque is a sticky material made of bacteria, mucus, and food debris that develops on the exposed parts of the teeth. It is a major cause of tooth decay. If you do not remove plaque, it turns into a hard deposit called tartar that becomes trapped at the base of the tooth. Plaque and tartar irritate and inflame the gums. Bacteria and the toxins they produce cause the gums to become infected, swollen, and tender." <http://www.nlm.nih.gov/medlineplus/ency/article/001056.htm#Causes,%20incidence,%20and%20risk%20factors> Nothing in that description would lead one to suspect

that enough flaxseed oil would eliminate gingivitis. But it does.

Paul Brentano (2007-12-17 13:14:34)

How many milligrams to you estimate equates to 2 tablespoons?

Chris (2007-12-17 20:18:29)

Two tablespoons equals 30 millilitres, so if flax oil were the same density as water, that'd be 30 grams, or 30,000 milligrams. Since oil's lighter than water, say 20,000 - 25,000. That means about 11,000 to 14,000 mg of omega-3.

Caleb Cooper (2007-12-18 11:35:13)

is ground flaxseed a workable substitute for Flaxseed oil (I like to mix it in smoothies and other dishes)? How many T ground flaxseed would give the equivalent of 2 T flaxseed oil? thanks.

Tracy (2007-12-18 13:33:28)

Caleb, I don't have UC (although a friend does), but I'm vegan and eat ground flaxseed every day for its fiber and omega 3s. My bag says that a serving size is 3 Tablespoons, so I generally grind 2-3 Tablespoons of flaxseeds every morning and mix them with my cereal. For those of you who have never used ground flaxseeds, just buy a bag of whole flaxseeds and grind them as you need them in a coffeegrinder. Whole flaxseeds do not need to be refrigerated, but ground flaxseed does. (Which is why I only grind what I'm going to eat that morning.) Tracy

seth (2007-12-18 19:54:19)

Caleb, 1 cup of ground flax has about 600 calories; about 75 % of those calories are from fat. That gives about 450 calories of oil. Flaxseed oil has about 120 calories/tablespoon. To get about 240 calories of oil, then you need about half a cup (8 tablespoons) of ground flax.

Swift Loris (2007-12-23 16:41:28)

Seth, I have Crohn's, which is similar to ulcerative colitis. Based on the amount of EPA/DHA in the fish oil capsules I'm taking (1000 mg fish oil containing 400 mg EPA and 200 mg DHA per capsule), could you give a recommendation for an appropriate dosage of these capsules for Crohn's? I'm currently taking 5 a day. (I left a comment on your previous post about ulcerative colitis and flaxseed oil with more details.)

Alice (2009-02-04 15:50:33)

I am worried that having the flax oil when on a low calorie diet will compromise the diet. Am I being a neurotic fool or is Flax oil a very high calorie addition to diet? I heard that it stimulated the metabolism and could help weight loss. Is that true?

Marek (2010-02-06 16:27:16)

Alice, you needn't worry about the effect flaxseed oil will have on the diet. Because it is a super-unsaturated omega 3 oil, the fatty acids are oxidised at such a rate that intake of omega 3 oils actually increase the metabolic rate. It is for this, and their anti-inflammatory effect amongst others, that I recommend omega 3 oils to all my clients. Should this be in the form of flaxseed oil, I would suggest around 20-30ml per day.

### **Everyday Humor (part 3) (2007-12-18 19:57)**

Not quite everyday humor . . . but very funny.

"Dammit George, you picked up while I was doing the Internet!"

Type of joke: Feeling superior? (That is, it's funny for the reason we laugh when someone slips on a banana peel.)

From [1]product investment, which has other great links.

### **Lowell's Listings (2007-12-19 20:49)**

At the reception before [1]Ken Carpenter's talk ("When Nutritionists Go Wrong" – meaning make mistakes) at the UC Berkeley Nutrition Department, I met Lowell Moorcraft, who maintains a calendar of events called [2]Lowell's Listings. It is a listing of events at or near the UC Berkeley campus that are free or almost free. He compiles it from about 300 sources, he told me. Scanning recent weeks, I was very sorry to see I missed [3]a talk by Reed Hundt. There should be an emoticon for kicks oneself in the head. He spoke [4]at Google last year. To make up for missing the Berkeley talk, I'll watch it again.

More localese: The Berkeley Public Library posts a shockingly good video.

[EMBED]

### **A New Kind of Outreach (2007-12-19 23:17)**

My phone rang at 6 am. Who would call so early? "Hello?" I said. No answer. "Hello?" No answer. I heard people talking. A Christmas song was playing.

I kept listening. Now and then someone speed-dials me by mistake – while their cell phone is in their pocket, for example. By listening it becomes clear who it is. I heard people talking but they didn't sound like anyone I knew. It was too early. They must be in a different time zone.

I made out bits of conversation. Something about religion. Then a voice became clearer. A woman was teaching religion. "The Constitution is based on the Law of Moses," she said. My phone said Conference Call, I saw.

It was no accident. My phone number had been chosen at random. It was religious outreach, like Mormons knocking on doors.

[1]A new kind of advertising.

1. <http://www.blog.sethroberts.net/2007/11/26/a-new-kind-of-advertising/>

---

pd3 (2007-12-20 09:21:28)

An unfortunately ignorant statement which only undermines their thesis: that the constitution was based on the law of Moses. The motive of that statement was probably to support a conservative political viewpoint; it had nothing to do with actual theology, I speculate. More here about why the Constitution was not based on the law of Moses, although it certainly may have been informed by it, among many other sources: <http://www.commondreams.org/views05/0303-30.htm>

### **Diet and Acne (2007-12-20 21:19)**

Two years ago I guest-blogged at the Freakonomics blog about [1]diet and acne. I wrote that the claim of dermatologists that there is no link between diet and acne was absurd, not only because I had seen for myself such a link but also because it was an impossibly broad generalization.

In an [2]article in the Boston Globe, Cynthia Graber, a science journalist, describes quite a bit of evidence that yes, diet affects acne. The research on which the no-link claim was based tested only two foods (chocolate and sugar)! From which committees of dermatologists generalized to all foods.

SO WHY HAVE DOCTORS been taught for so long that there's no link? The anti-diet hypothesis . . . arose solely from two studies from the late 1960s and early 1970s. . . . One compares real chocolate bars with fake ones and was conducted at the University of Pennsylvania School of Medicine with funding from the Chocolate Manufacturers Association. . . . The other study examines sugar in the diet of a small group.

It's like that scene in the Wizard of Oz where the Great Oz is revealed to be an ordinary man behind a curtain. All those knowledgeable-sounding claims by dermatologists, based on nothing more than this.

Conventional research on the subject is difficult, both because of funding problems – drug companies won't fund such research; and dairy farmers won't fund experiments to find out if dairy causes acne – and because it's clear that many different foods are involved. On the other hand, determining the effect of Food X or Y on your own acne is easy. I wonder why someone doesn't build a website to gather information from such self-experiments. If I had [3]super-powers, I would.

[4]More about diet and acne.

---

david (2007-12-20 22:11:09)

Maybe you do have superpowers and just don't know it. I think the first thing you would need is a general collaborative framework for hosting self-experimentation studies. This would be a webapp with various features. Ability to create users, control access to various parts of the site based on roles that users have, forums for sure, and some wiki-like areas, but also some facility for allowing participants to submit their data. Maybe some generic spreadsheet like area where the study coordinator could create a spreadsheet template that participants use to submit their own data for a particular experiment. You'd probably need some kind of plugin architecture so custom modules could be added for specific studies. Anyway, thing out loud (i.e. blog) about what you'd want. What you're actually doing is creating a spec ("specification" or document describing what a piece of software should do; typically when software is written, it is written to implement a spec. So when it's tested, the tester checks to see if the software actually does what the spec says it should do). Perhaps someone out there will know of some combination of existing free software that already does what you want. Perhaps there's a developer out there with acne and some free time who will start implementing it as an open source project for you.

seth (2007-12-21 06:15:17)

Thanks, David. Were I to try to create such a website, I think I'd start with a forum. Each food or food group or other possible cause (e.g., washing your face too much, too little sunlight) would be a branch of the forum. Perhaps each branch would have two subbranches: yes (this does cause acne) and no (this doesn't cause acne). People with relevant experience would post their experience in the appropriate place. For example if you tried avoiding dairy for 3 weeks, you'd post about what you did and what you found under either the dairy-yes branch or the dairy-no branch.

michael vassar (2007-12-21 08:12:40)

It reminds me of the patently false generic claim that myopia has nothing to do with reading.

August (2007-12-21 08:29:43)

Someone, somewhere tested bread and came up with the idea that it, and probably other foods based on processed carbs increases the likelihood of acne. I suspect this particular blurb came from some weightlifting magazine, so I'm not sure of the source. I have, however, been on a bread making kick for the last few months, and I've also noticed more acne. Probably not nearly scientific enough, but it seems to match.

david (2007-12-21 09:43:11)

You definitely could do the whole thing with just forums. I'm assuming though that in many cases the coordinator will need some empirical results to process (e.g. number of small, medium, and large pimples each day during the period; estimated amount of sunlight exposure that day, and so on). The coordinator would then have to do all the work of compiling results reported back through forum posts, which might involve a lot of manual data entry. But I assume test results would typically be numeric values, so a better solution is for the participants to enter their data directly into the site in a form that the coordinator could then analyze the aggregate data easily and without much time consuming, error prone manual reentry. Tangent: One thing I noticed about the SLD was that when I started eating less food, food allergies were less of a problem. In my case, I've always had problems with dairy. I can tolerate small amounts of dairy and when I started eating less overall, I was less likely to hit that limit.

seth (2007-12-21 14:59:05)

David, I think the forums might have a person who would be in charge of each possible cause who would keep track - who would write summaries of what the evidence so far meant.

losing-it (2007-12-22 14:55:11)

I have had rosacea (adult acne), a neurovascular disease for about 10 years. Eating certain foods is known to aggravate it and trigger outbreaks in those who have this condition, which has been most recently thought to be an auto-immune disorder. In my case, consuming cayenne and other hot peppers, alcohol, and also coconut oil are definite triggers. Hot weather/hot

flashes/hot water...i.e., heat is also a trigger, at least producing ruddiness of skin (per Chinese medicine, I wonder if those consumed substances would be classified as heat-producing in the body). Using coconut oil steadily for the SLD on several occasions made me aware that it caused severe breakouts for me. I had begun to wonder if it was an auto-immune condition because of that. I had pimples as a teenager and well into my late twenties, although those substances did not trigger rosacea. I'm not certain what food and substances, if any, caused or affected it. I wonder, though, since health is often a matter of chemical balance and imbalance, if it might be possible that ordinary acne and adult acne could have similar causes related to certain proteins/peptides. Here is an excerpt from ThaiMed: "The team found that small proteins called anti-microbial peptides caused the same skin symptoms that are seen in rosacea. The peptides are part of the body's immune system (and there are many other articles on the medical report to be found on the Internet).: 'When we then looked at patients with the disease, every one of them had far more peptides than normal,' Dr. Richard L. Gallo, chief of the division of dermatology at the University of California, San Diego School of Medicine, said in a statement. Gallo, who led the research team, also is part of the dermatology section of the Veterans Affairs' San Diego Healthcare System. A precursor form of these peptides known as cathelicidin normally helps protect the skin from infection. Indeed, some skin problems occur when there is too little cathelicidin. But it turned out that people with rosacea had too much cathelicidin, and it was different from the form in people without the illness. Rosacea patients also had high levels of stratum corneum tryptic enzymes (SCTE), the precursor of the disease-causing peptide. 'Too much SCTE and too much cathelicidin leads to the abnormal peptides that cause the symptoms of this disease,' said Gallo." <http://www.thaimed.us/rosacea-red-skin-disorder-treatment/2007/08/02/>

Comment on Diet and Acne by losing-it (2008-01-20 01:45:35)

[...] admin wrote an interesting post today onHere's a quick excerptI have had rosacea (adult acne), a neurovascular disease for about 10 years. John Anderson (2009-11-05 22:11:03)

I started working out 45min a day 5 times a week, and at first I would just starve myself, I would eat like an apple and some juice, for the day. I lost weight, but once the weekend hit I totally caved, and I was like oh well I can just diet again once the week starts, but I would really like to know what food and how much of it I should eat.

## More Natto, Please (2007-12-21 10:31)

Natto. This is on the list because, for one, it's one of the few foods I've eaten that I truly don't like. But mainly, it's here because we've really messed up the way we eat soy. Natto is fermented soybeans and very popular in Japan, which is where I had it. It's becoming more popular here and this is most likely due to its health benefits. Nearly all the soy options we're offered in the U.S. are non-fermented. The list of health benefits of fermented soy is a mile long. It's associated with reducing the risk of cancer, minimizing the likelihood of blood clotting, aiding digestion, increasing blood circulation, an improved immune system, improving bone density, lessening the likelihood of heart attacks, more vibrant skin, and reducing the chance of balding. And it also has strong antibiotic properties, among other things. So you might want to ditch the soy crisps, soy ice cream, and your iced soy mochas and add some natto to your diet.

From [1]10 Foods You Should Eat. It's a very reasonable list.

1. <http://fitnessvillage.wordpress.com/2007/12/20/10-foods-you-should-eat/>

---

Varangy (2007-12-21 12:43:32)

*reducing the chance of balding*. C'mon. Already. This is snake-oil. I fear that the soy bandwagon is just another false information cascade. It is not often mentioned that the soy phyto-estrogens **may** encourage cancer cells to grow in women have had breast cancer. Somewhere I saw a reference to a linkage between soy and reduced sexual drive in rats as well as endometrial hyperplasia (abnormal vaginal bleeding). The more I read Gary Taubes' stuff, the more and more skeptical I am of the nutrition/diet industry.

Tom (2007-12-21 13:54:47)

That soy is healthful is anything but established: <http://www.soyonlineservice.co.nz/>

Booker Roach (2007-12-22 05:47:35)

Skin cancers and melanomas are the curse of God against white people for their skin sins and continued evil of today. In Daniel, Isaiah and Revelations God warns He will curse the evil with the Sores That Do Not Heal. Skin cancer and melanomas are these sores. Based on their skin color, whites exalted themselves above everyone else on the planet and called everyone else: ugly, evil and inferior. Now, that giving everyone else life burns whites'™ skin. That giving everyone else life is God. The sun is God. The sun hates white people. God Hates White people. God has fixed His holy light to discriminate between black and whites so that it burns the whites. Ultraviolet light is the fire of the 2nd Rapture burning evil from the earth.

seth (2007-12-22 07:37:20)

Tom, I completely agree, which is why (a) I eat much less soy now than I used to and (b) this post is particularly interesting. If fermentation makes soy healthier, that is curious. It isn't easy to explain.

Comment on More Natto, Please by Booker Roach · Skin Cancer Information (2007-12-22 10:22:32)

[...] Original post by unknown [...]

Aaron (2007-12-23 09:51:50)

I found an important paper providing and exhaustive review of the medical literature on soy-based infant formula, many in comparison to cow-based infant formula. Here's a link: <http://www3.interscience.wiley.com/cgi-bin/fulltext/113339995/PDFSTART>.

Chris (2008-01-02 10:23:30)

Natto is supposed to be an acquired taste, to put it mildly. What about tempe and miso? They are also fermented soy products (less fermented, I supposed).

Robyn (2008-10-31 15:33:18)

The difference between fermented and unfermented Soy beans can be found on Dr Mercolas website. he is a Doctor but well into the healthy side of life. The falsehood about the orientals living healthy and long lives was thought by the western world to be because of the consumption of normal soy beans. Apparently that is wrong, and is actually due to fermented Soy, as in sauces and Natto. The fermenting makes certain chemical changes which makes it a very different food source. Having soy sauce every day can help balance the hormones and helps ladies with hormone flushes. I cannot say whether the risk of hormonal cancer would still be there..Dr Mercola may have something to say about that. It is a long time since I looked at the subject. I thought, since the fermented soy balances, rather than escalates, then that particular danger would be gone. Certainly I feel very unwell on the Western world's soy powders and drinks, but I don't on Soy sauces. I haven't tried Natto as I can't find a source in my country so far. Apparently ALL fermented Soy products are safe, unless of course someone has decided to add something horrific to it !!

Robyn (2008-10-31 15:40:35)

Correction The ( fact ) about the orientals living healthy and long lives was thought by the western world to be because of the consumption of normal soy beans. Apparently that is wrong, and is actually due to fermented Soy, as in sauces and Natto. The fermenting makes certain chemical changes which makes it a very different food source. I put falsehood instead of fact....sorry...

seth (2010-02-04 18:38:14)

Now that I have lived in China and spent more time in Japan, I think it is the fermented food, not the soy. Lots of fermented food in both China and Japan.

Matthew Anderson (2010-06-17 18:49:50)

Bob Marley died of Melanoma right ?-.'

### **Waterboarding, Self-Experimentation, and Human Evolution (2007-12-22 07:14)**

Someone named Scylla [1]waterboarded himself and provided a detailed account of what happened. "Old" self-experimentation, you could say, was doctors doing dangerous things to themselves for a short time to prove some idea that they already believed (e.g., a dentist using laughing gas as an anesthetic); "new" self-experimentation is me doing something perfectly safe for a long time to solve a problem that I have no clue how to solve. What Scylla did is between the two. Short duration, not completely safe, done to find out if waterboarding is torture or not. Scylla had no strong opinion about this when he started.

Before he got to using saran wrap it wasn't particularly bad. Here's what happened with saran wrap:

The idea is that you wrap saran wrap around the mouth in several layers, and poke a hole in the mouth area, and then waterboard away. . . . So far I would categorize waterboarding as simply unpleasant rather than torture, but I've come this far so I might as well go on. . . It took me ten minutes to recover my senses once I tried this. I was shuddering in a corner, convinced I narrowly escaped killing myself.

Here's what happened:

The water fills the hole in the saran wrap so that there is either water or vacuum in your mouth. The water pours into your sinuses and throat. You struggle to expel water periodically by building enough pressure in your lungs. With the saran wrap though each time I expelled water, I was able to draw in less air. Finally the lungs can no longer expel water and you begin to draw it up into your respiratory tract.

It seems that there is a point that is hardwired in us. When we draw water into our respiratory tract to this point we are no longer in control. All hell breaks loose. Instinct tells us we are dying.

I have never been more panicked in my whole life. Once your lungs are empty and collapsed and they start to draw fluid it is simply all over. You [b]know[/b] you are dead and it's too late. Involuntary and total panic.

There is absolutely nothing you can do about it. It would be like telling you not to blink while I stuck a hot needle in your eye. . .

I never felt anything like it, and this was self-inflicted with a watering can, where I was in total control and never in any danger. And I understood.

Waterboarding gets you to the point where you draw water up your respiratory tract triggering the drowning reflex.

This shows something non-obvious: We are hard-wired to avoid drowning and like all good safety systems, the system kicks in well before damage occurs.

For such a system to evolve, humans must have spent a lot of time in water deep enough to drown in. We don't now, of course. The sheer fact of Scylla's post – the fact that waterboarding is torture isn't obvious – shows this.

All this – Scylla's initial ignorance, what he experienced and concluded – is consistent with the [2]aquatic ape theory of human evolution and inconsistent with alternatives to that theory (e.g., the savannah theory), which assume no long aquatic phase. Belief that the aquatic ape theory was probably true was one reason I started [3]omega-3 self-experimentation, which led to the discovery of very clear experimental effects.

This interests me not only because of what it says about human evolution – to me, it's substantial new evidence for the aquatic ape theory – but also for what it says about science. Scylla has no scientific credentials (I assume). His report wasn't peer-reviewed. It wasn't quantitative. It wasn't long. It was closer to an anecdote than a conventional experiment (where you compare two conditions). He wasn't trying to test any theory. Yet it provided helpful new info on a major scientific question (human evolution), which is very hard to do.

Bosco (2007-12-22 11:17:39)

hi seth, been lurking on your site for a while. just wanted to chip in and say that it truly puzzles me why there's such a severe reaction against the aquatic ape theory in mainstream biology. i'm a professional computational biologist so i feel like i have some qualifications in judging a theory. while not completely fool-proof, aquatic ape theory seems to be, at least, the equal of any other theory of human speciation from apes. yet otherwise even-handed writers like phyrngalia and others scienceblog dismiss it out of hand, without pointing out how ridiculous the other theories are. just saying.

seth (2007-12-22 15:26:41)

That's a very good question. My guess is that the aquatic ape theory is dismissed out of hand because it came from outside anthropology (from a marine biologist) and is so different from what anthropologists have proposed.

Mike Kenny (2007-12-22 16:35:37)

reading this made me think waterboarding with saran wrap is a bit like holding an unloaded gun in someone's mouth, telling them there's one bullet in it (a lie) and then pulling the trigger, and then demanding answers. if you told me we did this, i would have a greater sense of what is going on than with waterboarding, which even when i've seen explanations, is hard to grasp. sylla gets me a more concrete sense of what is going, assuming his take is true (more people expressing similar experiences would be helpful!) the concreteness i think is most important in explaining the experience, in keeping with the 'made to stick' idea of getting ideas across. perhaps concreteness of experiences also helps us think about things in a useful way, and self-experimentation helps us along these lines.

seth (2007-12-22 16:43:09)

Good point. I think one appealing feature of waterboarding – appealing to the people who use it – is just what you say: It is hard to understand. Because of this, it seems more innocuous, i.e., more humane, than it is.

JoeCitizen (2007-12-23 18:40:02)

"For such a system to evolve, humans must have spent a lot of time in water deep enough to drown in" And with that, I kindly suggest you take that reference to the scientific method off of your masthead. Shall we begin with the form of the argument? That any piece of evidence can ever necessitate one and only one explanation? If the life of the rational mind tells us anything, it is that any number of explanatory hypotheses can be generated to explain any observed phenomenon. And of course, coming up with a hypothesis does absolutely nothing to give reason for accepting it as valid. What about the idea of testing? Then we get to the substance of your contention. That an aversion to drowning means we must have spent time during our evolution in or about water deep enough to drown in. Why is that? Let's say, for arguments sake, that some species never encountered water at any greater depth than a puddle. For that species too, taking water into the lungs would lead to death. Why do you think that the species would not have an aversion response to that? Start thinking about that, and maybe you will find yourself on the right path. Here is a hint how to proceed (it's a nice general first-step whenever you think about evolutionary adaptations). First, what is the generality, phylogenetically speaking, of the phenomenon? Are humans the only primates, the only mammals, the only terrestrial vertebrates with an aversion to drowning? Go stick your dog's head in the bathtub and see what happens (no DONT DO THAT - just a rhetorical point). If you discover that an aversion to drowning just might have a greater generality than only amongst humans, then you can't support an argument that it is a human adaptation. Now, I will admit, I have not done these experiments. But my suspicion would be that an aversion to taking water into the lungs, and an escape reaction to such a situation, is probably found in ALL air-breathing vertebrates. And so the evolutionary novelty is best explained as arising at that level. Given that the first air-breathing terrestrial vertebrates had a close proximity to deep water in their recent evolutionary past, maybe your logic can work, at least at that level, rather than at the ape level. The aquatic ape theory is seen as nutty because it consists essentially, of a set of speculations of just this kind. No evidence, just speculative hypotheses about cherry-picked phenomena that seem, on the surface, to be consistent with the theory. One could almost say it's a Republican theory. :)

Whispers (2007-12-23 19:50:17)

Isn't this just a "just so" story? "All this...is consistent with the aquatic ape theory of human evolution and inconsistent with alternatives to that theory (e.g., the savannah theory), which assume no long aquatic phase." There are much better arguments for (and against) the aquatic ape hypothesis listed at Wikipedia. I can see why this theory would be discounted: the divergence time from chimpanzees is only 5 MYA, and the AAH would require a long period of time near water, separated from simian ancestors, a claim that is not supported by any fossil evidence. Right? I think the criticisms at Wikipedia are much stronger than the theory, which seems to lack any evidence and consists mostly of wandering hypotheses.

seth (2007-12-23 20:37:27)

JoeCitizen, sure, if you found such a reflex in other primates, it would no longer support the aquatic ape theory. I fail to see the force of this point; I don't know of any evidence for anything whose interpretation couldn't be changed by new data. I said this observation favored one hypothesis over another because one hypothesis explains it much more easily than the other. I fail to see how that's a mistake. Whispers, for a comment on "just-so stories" see <http://www.blog.sethroberts.net/2007/09/13/modern-veblen-the-less-than-obvious-value-of-evolutionary-explanations/> You say the theory "lacks any evidence." The theory was suggested by subcutaneous fat in humans. Not found in other primates, but found in marine mammals. That was the first piece of evidence. Much more has come along since then. I think there is fossil evidence – evidence of pre-human habitation along the African coast. It was discovered within the last year.

QrazyQat (2007-12-23 20:42:20)

*That's a very good question. My guess is that the aquatic ape theory is dismissed out of hand because it came from outside anthropology (from a marine biologist) and is so different from what anthropologists have proposed. The claim that it was dismissed out of hand is one that has been carefully cultivated by the idea's chief proponent for over 3 decades. It's untrue, but becomes part of her heroic outsider against the closed-minded establishment stance (which you may notice is a mainstay*

of fringe and pseudoscience ideas). There are excellent reasons that the idea was dismissed: start with claims that are counter to long known evidence, claims that researchers said the opposite of what they actually said, altered quotes, and extreme misunderstanding of basic concepts of evolutionary theory. I've documented a lot of this at my site on the theory, which is the primary source for critical, accurate info on the idea. It has been used as a source for The Straight Dope, the Fortean Times (which did what was for me a surprisingly good writeup on the idea), and lately a fair number of college courses; I've also written the entry on the AAT for the Sage Encyclopedia of Anthropology. If you have any questions, my site is [1]Aquatic Ape Theory: Sink or Swim? and there's a feedback mailto link at the bottom of each page. Feel free to ask me anything I haven't made clear.

1. <http://www.aquaticape.org/>

QrazyQat (2007-12-23 20:49:33)

BTW, I should have mentioned a couple of specifics. One is that the omega-3 info does not support the AAT; check my page specifically on "the Omega-3 gang" for that, as well as a short bit on my "objections" page. Omega-3 fatty acids are good to get, and I support the excellent work of the folks I refer to as the "Omega-3 gang" when it comes to nutrition and getting awareness of those fatty acids out to the public, but they do themselves no favors by tying the accurate info to a leaky theory like the AAT. The other is that one problem with drowning is powerful evidence against the AAT. When animals which are adapted to diving run out of oxygen, they have internal mechanisms which keep them from gasping for air, which would obviously be a bad thing to do underwater. We, like other terrestrially-evolved animals, do not, to disastrous effect. If we had evolved as we have due a swimming and diving lifestyle, as the AAT insists, one wonders why we drown so easily. Gasping for a breath when you're underwater is one major reason we drown, and evidence against a semi-aquatic past for our species.

Skeptic (2007-12-23 22:24:07)

Hi Seth, It's true that the anthropological community at large is outrightly dismissive of the aquatic-ape hypothesis, but at least one critique of the idea has been published in a peer-reviewed journal within the last 10 years. Here's a quote: "Humans have an unusual amount of subcutaneous fat that functions for bouyancy and to a lesser degree for insulation in place of fur. This is a parallel adaptation with many aquatic mammals. However, the fat-and-sweat strategy of thermoregulation may be adaptive for a species that is more concerned about shedding internally generated heat. Insulative fat, rather than hair, permits the bloodstream to bypass it as needed, taking hot blood from the core of the body to the surface to be radiated or lost through evaporation." (Langdon, 1997, p. 483-484, Journal of Human Evolution). Nearly all of the features invoked in support of the AAH can be explained in another context, and most damningly, the fossil record is not on the side of the hypothesis. I can send you a copy of the article if you want to read it. I looked for an email contact on your site but couldn't find one. (BTW - the savanna theory is no longer an accepted explanation for the origin of the human lineage. Recent fossil evidence indicates that the first human ancestors probably evolved in a forested setting. So the savanna theory is really a straw man.)

seth (2007-12-23 23:01:05)

Skeptic, yes, I would like a copy of the article. my email address is twoutopias (at) gmail.com. "Most damningly the fossil record is no on the side of the hypothesis." If I remember correctly the fossil record was in the beginning not on the side of conclusions drawn from mitochondrial DNA analysis about when humans diverged from other primates. But eventually it was conceded that the DNA was right and the fossils wrong.

JoeClitzen (2007-12-23 23:30:12)

Seth, "I said this observation favored one hypothesis over another because one hypothesis explains it much more easily than the other. " Gee, I must of missed that. I see an assertion on your part, but thats all. WHY do you think the AA hypothesis better explains the drowning response? You offer no reason for your assertion. Why would a close proximity to water make an air-breathing vertebrate more averse to drowning than an arid-habitat-living species? Both of them share the same physiological fact - taking water into the lungs will kill them. And as to the phylogenetic argument. Do you think that all air-breathing vertebrates that havent had a semi-aquatic phase in the history of their individual species would simply drown peacefully if you put water into their lungs? I don't think the AA hypothesis offers any insight whatsoever into the drowning response. If you catch a fish and toss it into your boat, it will have a similar response to someone who is being waterboarded - does this support the terrestrial fish evolutionary hypothesis? I checked out your link in your response to Whispers. Wow.

A defense of just-so stories! Have you just given up on doing the hard work of science - i.e. actually committing to testing hypotheses before you grant them credibility? Coming up with hypotheses is fun, and easy. Sure its better than doing nothing, but once you do it, all you have is an unsupported hypothesis. Its only value is that it lays out for you the next phase, the hard work - i.e. it gives you something to test. It deserves no credibility whatsoever until that is done. Thats why they are mocked and derided when they show up in scientific literature - its not that they shouldn't exist on the face of the earth, its just that no rational person should grant them credibility until they are tested.

Skeptic (2007-12-24 05:54:57)

SETH SAID: "If I remember correctly the fossil record was in the beginning not on the side of conclusions drawn from mitochondrial DNA analysis about when humans diverged from other primates. But eventually it was conceded that the DNA was right and the fossils wrong." Actually, the argument you are referring to was not about mtDNA. Check out this link for a quick summary of Sarich and Wilson's classic study: [http://en.wikipedia.org/wiki/Vincent\\_Sarich](http://en.wikipedia.org/wiki/Vincent_Sarich) In any event, the reluctance of paleoanthropologists to accept the molecular evidence was due in part to the fact that many assumed a priori that the divergence between humans and apes must have been very, very deep, given the marked differences between these two groups. It wasn't based on any fossil evidence in particular. The assumption of a deep split led paleoanthropologists to "search" for human ancestors in the earliest fossil record of apes (e.g., Proconsul, Kenyapithecus), way back in the early and middle Miocene. The molecular evidence was only accepted after paleoanthropologists demonstrated that fossil species believed to be human ancestors were in fact fossil apes (google "Ramapithecus"), and that the human lineage could not be traced back into the middle and early Miocene. Long story short – your comparison between this issue and the aquatic-ape hypothesis is a non sequitur; as soon as paleoanthropologists realized that the fossil evidence could not sustain the deep-split hypothesis, it was abandoned. If there was an aquatic phase in human evolution, there is absolutely zero evidence for it in the current fossil record, which is of course incomplete, but it is also the most studied fossil record of any organism that ever walked, crawled, swam, flew, floated, or just sat on earth. If someone could point to a single disputable piece of fossil evidence that supports the AAH, then they would have by now. The article is in the email. Please let me know if you don't receive it.

Skeptic (2007-12-24 05:59:05)

Erratum: In my previous post, "disputable" should be "indisputable."

seth (2007-12-24 06:06:03)

Why do I think the AA hypothesis better explains an anti-drowning response than other hypotheses? Because it implies there was more danger of drowning – thus more selection pressure for an anti-drowning response – than other hypotheses.

QrazyQat (2007-12-25 20:37:36)

As I mentioned already, what you see (and expect to see due to evolution) in an aquatic or semi-aquatic animal (or one with such a past) is a response that helps keep one from drowning. We have the opposite, just like other terrestrially-evolved animals and unlike semi-aquatic-evolved animals; especially because we have an automatic urge to inhale when we run out of oxygen even if we're underwater.

seth (2007-12-25 23:03:05)

I wouldn't say the description of waterboarding given above implies a response that is "the opposite" of an anti-drowning response. At the risk of stating the obvious, it shows that we get terrified when we get anywhere close to drowning. Perhaps it is this response – which kicks in long before there is any possibility of drowning – that lets us have a different response when we run out of air. The terror response has replaced the response you refer to.

Skeptic (2007-12-26 01:40:54)

JoeCitizen already mentioned this, but the fear brought on by waterboarding can simply be explained as a reaction to not being able to breathe. The fear can't be specifically connected to drowning because drowning falls under the umbrella of "things that inhibit proper respiration." Given that respiration is essential to all terrestrial vertebrates (to mention only one group), it should come as no surprise that natural selection has produced mechanisms that ensure its proper function. Plug your nose and put duct tape over your mouth and a similar reaction will most likely ensue. Supporters of the AAH must demonstrate that

ONLY drowning prompts the response in question. Otherwise, the explanation is ad hoc. Ad hoc explanations make for poor science. Only those who already believe will be convinced.

seth (2007-12-26 10:29:19)

"The fear brought on by waterboarding can be simply explained as a reaction to not being able to breathe." No it can't. Waterboarding is considerably more complicated than preventing breathing. As Scylla demonstrates, the details are necessary to produce the effect.

Skeptic (2007-12-26 17:39:36)

I have read Scylla's description, and there is nothing in it that convinces me that the effect of waterboarding is not simply a general reaction to the impairment of proper respiratory function. In a system as essential to life as breathing, natural selection will "build" powerful fail-safe mechanisms. No paleoanthropologist would argue that early human ancestors were not exposed to water – they probably had to make the same dangerous trip to the water hole that many African mammals do today. But the reaction Scylla describes is probably even more ancient – likely dating to the first terrestrial vertebrates, as implied in JoeCitizen's post.

Marc Verhaegen (2008-01-10 07:44:27)

Hi all. Nice to see AAT discussed. For recent views please see <http://groups.yahoo.com/group/AAT> <http://users.ugent.be/~mva-neeche/outthere.htm> or google "aquarboreal"

FireWire Card (2011-11-30 09:08:42)

What a really good post...

### **Science in Action: Procrastination (evidence or anti-evidence?) (2007-12-22 20:31)**

Evidence is the raw fuel of science: We collect data, it pushes forward our understanding. But there is also anti-evidence: observations that have the effect of holding back our understanding. The clearest example I know comes from experiments that supposedly "tested" mathematical learning theories in the 1950s and later. The observation was that the theory could fit the data. Theorists wrote papers to report this observation. In fact, the theory was so flexible it could fit any plausible results. The papers, which were taken seriously, retarded the study of learning because they wasted everyone's time. They gave the illusion of progress. Hal Pashler and I [1]wrote about this.

Another example of anti-evidence, I think, is the sort of data that linguistic theorists have been fond of: Observations that this or that sentence or sentence fragment strikes the theorist as grammatical, i.e., possible. Not studies of how people actually talk; the observation that a speaker of English or whatever could say this or that. The theorist's judgment based on introspection. I'm not saying that this isn't actual data of some sort; I just suspect that the value of these sorts of observations has been overrated and the net effect has been to keep linguists from collecting data that would push theorizing forward.

Months ago I blogged about how I found that when I made playing a game contingent upon clearing off my kitchen table, I was [2]able to clear off the table. Which had been messy for quite a while. My question: is this evidence or anti-evidence? If I think about this, and try to understand it, will I be deluding myself, as the mathematical learning theorists and the linguistic theorists deluded themselves? On its face, it seems like a very ordinary, very narrow observation, much like the observation that "George played with the game Dave brought over" is a possible English sentence. On the other hand, it is something unusual and helpful that actually happened, unlike an observation that this or that is a possible English sentence.

When someone says "the plural of anecdote is not data," you can be sure their grasp of scientific method is weak;

lots of important discoveries have begun with accidental single observations. But those productive single observations are always surprising. My table-clearing observation was slightly surprising...

1. <http://repositories.cdlib.org/postprints/763/>

2. <http://www.blog.sethroberts.net/2006/12/28/science-in-action-procrastination-results/>

---

Phillip J. Eby (2007-12-25 22:13:11)

Procrastination is a tricky subject to study, precisely because the word itself is misleading. It describes a symptom rather than defining a disease – like trying to improve medicine by figuring out a treatment for "death". There are many causes of procrastination, just as there are many causes for death. It is also difficult to investigate treatments for procrastination in self-experimentation, because it can be hard to be sure whether testing one's idea is adding just enough novelty and interest to make the target activity motivating! To be sure, I have to find out if a method will work when I'm not interested in testing it. :) When I first worked with clients who were procrastinating, I had a few simple theories of what caused it. Now I know there's little point in theorizing; I just help them figure out what's causing it in the specific case and address that.

seth (2007-12-25 23:03:57)

Philip, what are some of the many causes of procrastination?

Phillip J. Eby (2007-12-26 09:11:12)

Broad-based, chronic procrastination (long term, across many subjects) in my experience is usually linked to one or more pervasive negative emotions such as despair (e.g. "what's the use of trying?"), fear (e.g. of being found inadequate), anger (e.g. "I shouldn't have to do this"), or rebellion (e.g. "I don't want to and you can't make me!"). These are the easiest to get rid of, since they involve a strong feeling and there are plenty of simple techniques that only need to be applied once to get rid of them. Sometimes, though, chronic procrastination is just the result of a poor motivation strategy. For example, some people motivate themselves by thinking about what disaster will result if they don't do something, and others motivate themselves by thinking about what it will feel like to \*do\* the activity (which means they'll be motivated to do fun and enjoyable things, but nothing else). There's an audio sample about some of this at <http://theownerscircle.com/sample-the-cure.html> if you're interested. Subject-specific and situation-specific procrastination are a lot more varied, though. I've worked with a person who put off their own projects simply because they didn't put them on their calendar, which was reserved for what \*other\* people wanted. I've had a person who put off learning new things because he would always think about what \*else\* he had to do. These sorts of things are also pretty straightforward to solve with one-time thought replacements. Then we get to self-image and identity conflicts: a person who can't consistently exercise because they got picked on in the past by people who were fit and liked to exercise. Thus, actually \*liking\* exercise would make them like the hated group. A person who has trouble being organized because of jealousy of organized people – and another who has trouble being organized because they can't bear to be near the chaos they've created. There are a whole bunch of procrastination causes that could be called "fear of success", but just like procrastination might be compared to "death" as an explanation, "fear of success" might be compared to "cancer" in how broad it is. The identity fears of success I just mentioned are one kind, but anything that creates a conditioned link between pursuing pleasure and receiving pain can produce avoidance behaviors that you could call "fear of success" without being in any danger of actually learning something about the problem. :) The approach that I use with my clients could be compared to guided self-experimentation: I have them think about a recent, specific situation where they experienced a block or problem, and to note their spontaneous responses: thoughts, images, feelings, etc. Then I begin having them work backward through their thought process so I can figure out what their brain is actually \*doing\* to produce those images or feelings or whatever. Then I try various techniques, and have them think about the original situation again, to observe what change(s), if any, have occurred in the spontaneous response. The idea of testing against the spontaneous response is that anybody can use willpower to override their conscious response to something, at least \*once\*. So it's not very useful to test whether they can \*make\* themselves act differently, especially since in the long term that just creates feelings of alienation

and restriction, not freedom. Oh, anyway, I'm digressing a bit, as there are still \*more\* forms of procrastination that are situation-specific. For example, not having a clear enough idea of what it is you intend to do, or having a clear idea about some problem with what you want to do, but no clear idea of how to solve it and no \*commitment\* to try solving it anyway. In short, "procrastination" is a pretty useless word: it simply describes the action of not doing something that's intended, without giving any useful information as to \*why\* or \*how\*. So, despite the fact that I sell a course called "The Procrastination Cure", there is really no \*single\* cure for procrastination, because procrastination is not one single thing. (The course deals almost solely with chronic feeling-based procrastination and chronic motivation strategy failures, as these forms are usually the most debilitating, and also the easiest to give straightforward procedures for fixing, that most people can use. In contrast, subject-specific and situation-specific procrastination varies so widely from person to person that it's easier for them just to have me spend 20 minutes asking questions to find out what's going on, than to try to learn about all the different possibilities.) By the way, I find it interesting that psychology works tend to have by far the \*least\* useful information about procrastination, when compared to say, economics papers. That is, economists seem to understand procrastination better than psychologists... and good direct marketers understand it even \*more\*. See, e.g.: <http://dirtsimple.org/2006/09/seven-self-help-secrets-you-can-learn.html>

seth (2007-12-26 10:50:34)  
Thanks, Philip

### **Hard Times and the Shangri-La Diet (2007-12-23 11:01)**

Life in Cuba:

In 1991, Mr. Castro declared a "special period" of drastic reductions in food and other rations. Average daily caloric intake fell by 40 %. . . . When friends got together during those times, Ms. S  nchez recalls, a single topic dominated conversation: food. To stave off hunger pangs, Ms. S  nchez gobbled spoonfuls of sugar.

If there were several cheap foods to chose from this suggests that sugar reduced hunger more than other foods. From an excellent [1]WSJ article about a Cuban blogger.

Thanks to [2]Santosh Anagol.

Tom (2007-12-23 11:30:29)

Seth, Not on-topic for this post, but this fits in nicely with your interest in the aquatic ape hypothesis: <http://www.drmmcleary.com/2007/12/21/BecomingABrain.aspx>

Peter (2007-12-23 13:53:54)

the first time i heard of 'the special period' was in this video, which is very good: <http://video.google.com/videoplay?docid=-5350731284170267256>

David (2007-12-24 09:37:17)

I don't think this implies that sugar is more hunger reducing. Sugar may just have been a very cheap or easily available source of calories.

seth (2007-12-24 11:12:18)

David, good point. I have added that qualification.

Euonymous (2007-12-26 17:47:49)

Perhaps off topic, but I recall reading years ago that said traditionally Chinese use honey to help with dieting and weight loss. Now I have always loved honey and have never found that it diminished my appetite in the least. But then I put it on top of toast. I find the SLD matches my observations and anecdotal experiences over the years. Our Western diet patterns clearly increase our appetites. The oil approach decreases my appetite and that is all I ask for. I'm reluctant to try the sugar water approach just yet. Honey may also work just fine if it's used in an SLD pattern, but I'm going to stay with what's working for the moment.

My Diet and Weight Loss » Blog Archive » Comment on Hard Times and the Shangri-La Diet by Euonymous (2007-12-27 03:08:08)

## How Doctors Tell Family Members that the Patient has Died (2007-12-24 12:44)

The last issue of the BMJ each year is a "Christmas issue" with humorous and seasonally-themed articles. [1] This year's Christmas issue has an [2] article about how doctors tell family members that the patient has died. The execution is very flawed; for example, it's hard to tell how fictional it is. I mention it because a study of how doctors actually do this and how it changes with experience – comparing young and old doctors, for example – would be fascinating.

## Speaking of Gifts (2007-12-25 10:29)

Yesterday I knocked something off a table and caught it before it fell very far. "Nice catch," said an observer. I too was surprised. Today the same thing happened. Something fell and I surprised myself by catching it. I think it's the omega-3. Tests showed that flaxseed oil reduces my "simple reaction time" – the time to push a button as quickly as possible in response to a signal.

Peter (2007-12-25 11:18:23)  
and it must throw off your spatial thinking, too.

Stephen M (Ethesis) (2007-12-25 23:01:37)  
BTW, how much fish oil and flaxseed oil does it take you to get the effects you get?

Willy (2007-12-26 17:19:27)  
Stephen M, 2 tbsp flax oil, from what I read in other posts.

Nansen (2007-12-26 17:28:20)  
Catching things that I used to dropâ€”for example, keysâ€”was the first effect that I noticed. (I take 2.5 grams of OmegaBrite fish oil capsules a day.)

seth (2007-12-26 20:28:23)  
Stephen, 2-3 Tbsp flax oil per day. Don't know how much fish oil.

Stephen M (Ethesis) (2007-12-26 23:43:29)  
Glad to know it is the same amount.

Aaron (2007-12-29 15:58:55)  
Seth, I know this may be covered elsewhere- but what type of balance between omega 3s and 6s do you strive for? Seems that with 2-3 tbsp of flax oil- you would need a lot of omega 6 oils to make up for the 3 or 4 to 1 ratio of omega3s to 6s in flax oil.

seth (2007-12-29 16:15:42)  
Aaron, I don't worry about getting enough omega-6. It's everywhere in our food system. Nuts, olive oil, other vegetable oils, etc. I don't know what the optimal omega-3/omega-6 ratio is.

Laura (2007-12-31 09:45:53)  
I think it is very easy to get enough omega-6, if you know that the average American consumes ratios of 1:25!!!

seth (2007-12-31 17:39:53)  
Thanks for supplying that missing piece of info, Laura.

Nathan (2008-01-22 19:28:15)  
Seth, What evidence do you have that the placebo effect is not the cause of your improved performance?

seth (2008-01-22 23:31:41)  
Nathan, three kinds of evidence: 1. The initial effects were surprising. They cannot be due to placebos. 2. The effect is dose dependent – different doses produce different effects. Placebo effects are not dose dependent. 3. When others tried the amounts of flaxseed oil I used, it produced surprising results. Again, placebos cannot produce surprises.

## **Everyday Humor (part 4) (2007-12-25 23:20)**

A collection of [1]mathematical jokes at Wikipedia includes some nice ones – such as

Why do mathematicians think Halloween and Christmas are the same?  
Because 31 Oct = 25 Dec.

- but inexplicably omits my favorite:

Why is six afraid of seven?  
Because seven ate nine.

Why is this funny (at least to a 5-year-old)? Because we enjoy seeing unexpected connections.

1. [http://en.wikipedia.org/w/index.php?title=Mathematical\\_joke&oldid=179995500](http://en.wikipedia.org/w/index.php?title=Mathematical_joke&oldid=179995500)

### **The Power of Placebos Over Health Journalists (2007-12-26 10:17)**

In the New York Times, Abigail Zuger, an M.D., recently [1]reviewed a book called Snake Oil Science: The Truth About Complementary and Alternative Medicine by R. Barker Bausell – the "truth" being, if I read Zuger correctly, that it's all baloney. Zuger calls the book "immensely educational". Not educational enough:

Dr. Bausell starts out with the story of his late mother-in-law, Sarah, a concert pianist who developed painful arthritis in her old age and found her doctors to be generally useless when it came to satisfactory pain control. "So, being an independent, take-charge sort of individual, she subscribed to Prevention magazine, in order to learn more about the multiple remedies suggested in each month's issue" for symptoms like hers.

What ensued, according to Dr. Bausell, was a predictable pattern. Every couple of months Sarah would make a triumphant phone call and announce "with great enthusiasm and conviction" that a new food or supplement or capsule had practically cured her arthritis. Unfortunately, each miracle cure was regularly replaced by a different one, in a cycle her son-in-law ruefully breaks down for detailed analysis.

Neither Bausell nor Zuger notice two problems here: (a) The alternative treatments worked better than the conventional ones. They didn't provide permanent relief, true, but apparently conventional medicine ("useless") didn't provide any relief. [2]Something is better than nothing – and something is wrong with Bausell's interpretation of this story. (b) Why didn't the conventional treatments benefit from the placebo effect?

That Zuger thinks this story supports her claim that the book is good suggests the power of pre-conceived notions, not the power of placebos.

The book is published by Oxford University Press. [3]Bausell has a Ph.d. in Educational Research and works as a methodologist.

Not only do Bausell and Zuger fail to see what the mother-in-law story means, they fail to grasp a larger point: Skeptics are a dime a dozen. The attitude in short supply is sophisticated appreciation.

Thanks to Dave Lull and Hal Pashler.

Willy (2007-12-26 17:16:21)

>Why didn't the conventional treatments benefit from the placebo effect? Maybe because the alternative treatments offer something conventionals don't: a sense of power, not a passive acceptance. People like to read about "natural" treatments in popular magazines that are written for the lay person (they get an explanation of the suffering) and they let one take charge of their problem and do something active apart from obeying a doctor.

LemmusLemmus (2007-12-26 21:53:01)

Are you saying homeopathy works?

LemmusLemmus (2007-12-26 21:53:22)

Beyond the placebo effect, that is?

seth (2007-12-26 22:58:34)

No, I'm not saying homeopathy works. Prevention magazine doesn't cover homeopathy, I'm pretty sure.

Stephen M (Ethesis) (2007-12-26 23:47:51)

Nicely said.

michael vassar (2007-12-27 08:59:09)

Of course, we all know that "Education Research" is just a placebo PhD.

Timothy Beneke (2007-12-27 14:18:14)

I think Seth's general point that we should be alert to new hypotheses is well taken; and in many domains new hypotheses can be readily tested through self experimentation – if we could have 1000 skilled self experimenters working together around the world, to judge from Seth's achievements, we could do a lot of good. Regarding "placebo": It's a concept that hides more than it reveals. It could reflect a dissonance effect resulting from intolerance of psychological contradiction. It's well known that if you can get people to choose to participate in a second experiment, after going through one already, that causes them to suffer more electric shocks or eat more salty foods that require enduring thirst, their act of choosing causes them not only to say that they are less stressed by the shocks or thirst the second time around, but physiological measures confirm this. And people in nursing homes live longer if they are given more choice over their environments. It may be that Sarah's own initiative and choice resulted in symptom reduction, which is real, but caused not by the agent she consumed but by her own positive attitude and belief. And we have to allow for reporting effects where someone says their pain is reduced and wants it to be when it isn't; I've done this. When I pay good money for something, it's hard to admit it's not working. Second, when is "placebo" just return to the mean? If people seek help when their suffering is bad and will get better on its own, a placebo effect may just be an effect of time and not an effect of "belief" or "expectation". As I recall, a meta-analysis of placebo effects done a few years ago found zero effects for blood pressure and cholesterol; and very small ones for pain. "Placebo" is a concept

that reflects a lack of precision and rigor in those who use it....

### **Irritability and Coca-Cola (continued) (2007-12-27 16:49)**

John Keltner, an M.D./Ph.D. at Oxford, guest-blogged [1]earlier about a self-experiment to measure the effect of Coke on his mood. Below he describes his results in more detail.

I did a self-experiment to measure the mood and hunger effects of consuming 30 oz of Coke, Diet Coke With Caffeine, and Diet Coke Without Caffeine. I used two numerical rating scales. For the mood scale 0 represented profound dysphoria, 5 neutral mood, and 10 profound euphoria. For the hunger scale 0 represented profound hunger, 5 no hunger or fullness, 10 profound fullness.

Each day before dinner (after 7 hours of not eating anything but water), I measured my mood and hunger/fullness at four times: right before drinking 30 oz of soda, right after drinking the soda, 10 min after, and 20 min after.

I collected the data in two ways: blinded and not blinded. The 3 drinks were consumed in a random order.

The experiment lasted 25 days - one drink per day.

At the end of the 25 days there were a couple of measurement categories with only 2 or 3 data points, so I have combined the blinded and not blinded data for the purposes of presenting the data here.

The figures below show means and standard errors.

Within 10 minutes (and stronger at 20 minutes) there appears to be a significant change in mood ratings for the sugar and caffeine coke drink compared to the non-sugar and non-caffeine coke drink. Furthermore, it appears that caffeine alone was able to cause an increase in mood at the 10 minute and 20 minute time points between diet+caf coke vs diet w/ no caf coke. Finally, it appears that effects of sugar and mood are additive.

There was not a large difference in the fullness ratings between the three different drinks.

It is also notable that mood and fullness were markedly increased for all drinks immediately after consuming the drinks. Presumably this immediate increase in fullness and mood has more to do with the immediate taste or volume affects of the drinks and less to do with the calories or caffeine in the drinks.

In my next experiment investigating mood effects of sugar and caffeine I will reduce the number of parameters in my experiment. I spent a month collecting this data and a fair amount of effort (blinded data are hard to collect). Because I chose three types of coke drinks (sugar+caf, no sugar but caf, no sugar and no caf), two parameters to examine (hunger and mood), and two conditions (blind and non-blinded) my data points were spread too thin over the categories. Next experiment I will choose just two drinks (caf vs no caf), one condition (blinded), and I would focus on mood instead of hunger.

This experiment leads me to believe that a number of smaller experiments are more effective than one large experiment - at least in the beginning.

I would like to thank Seth Roberts (a lot!) for his generous helpful suggestions as I pursued this self experiment. I

initiated the experiment on my own, but I would not have finished it without Seth's help.

1. <http://www.blog.sethroberts.net/2007/07/11/irritability-and-coca-cola/>

---

Tom (2007-12-27 22:48:29)

There's a variable I wish he would have measured (though I can understand why he wouldn't have thought to)... consuming colas, even diet ones, causes very strong carb cravings on the evenings of any day a cola has been consumed...even many hours after the soda consumption. ie, drink water all day long - minimal munchies at night. Drink diet coke with lunch - ravenous munchies at night. Bizarre, but true.

### **Academic Horror Story (Duke University) (2007-12-29 07:12)**

From [1]Until Proven Innocent by Stuart Taylor and [2]K. C. Johnson, about the Duke lacrosse case:

The Duke president addressed the [lacrosse] team for the first time since May a few weeks into its fall practice. . . . When Brodhead opened the floor for questions, Read Seligmann's former roommate, Jay Jennison, spoke up. He said that all of the team had learned much from the case . . . "What have you and the administration learned?" Jennison asked Brodhead. . . . Brodhead responded, "What do you think I should have learned?"

Head of a prestigious institution of higher learning resistant to learning or at least admission of learning. Curious.

[3]Tulane University.

1. <http://untilproveninnocent.com/>

2. <http://durhamwonderland.blogspot.com/>

3. <http://www.blog.sethroberts.net/2007/06/10/academic-horror-story-tulane-university/>

---

bobvis (2007-12-29 08:25:38)

I am curious as to how the conversation proceeded from that point. I hope the student said something like "I wouldn't be so presumptuous as to tell you what I think you should learn. I was hoping that you could let us know more about what the experience was from your position."

Dennis Mangan (2007-12-29 08:46:36)

What Brodhead should have learned, and hopefully will, is that he and his university can be sued to within an inch of their lives because of their actions in this case. Duke has apparently settled for an undisclosed sum, but to my knowledge Brodhead has yet to suffer any consequences. Nor have the 88 professors who signed a public letter condemning the students. I'd fire every one of them.

Stephen M (Ethesis) (2007-12-29 10:20:47)

Kind of what people should learn about diets. BTW, for an interesting perspective: <http://www.t-nation.com/readArticle.do?id=1392804> Mostly about more things wrong with normal diet efforts.

seth (2007-12-29 11:43:13)

bobvis, the book doesn't say in any detail what happened next, only that the team was stunned by Brodhead's response. Dennis, I agree, that Brodhead hasn't suffered any consequences speaks volumes. I take him as a good example of what's wrong with Duke because his view of the case wasn't politically slanted; the problem is not that faculty have political views and biases, it's their heedless certainty that's the problem. I wouldn't fire anyone for exercising freedom of speech, including the Duke 88. After the Duke 88 signed that public letter, the rest of the faculty (a few thousand professors) could have signed an anti-88 letter. They didn't. A handful complained, much less visibly. That says something not very pleasant about practically all Duke professors.

Tom (2007-12-29 11:53:31)

I dunno...I think all involved just did a meta-analysis of their personal experiences and private biases and reached a reasonable conclusion. People have turned Vegan for less. :-) More seriously, I agree with all of the above, and yet, while there are corrupt DAs, stupid DAs, and desperate DAs...a DA as corrupt, stupid and desperate as Nifong is a bit of a "black swan" event.

Peter (2007-12-29 12:51:54)

if the student insulted me like that i'd tell him to go eff himself. so, as far as i can see, the prez handled it a lot better than i would have.

### **An SLD Story for the Coming Year (2007-12-29 19:32)**

My dad has diabetes, and I casually got Amazon.com to send him the Shangri-La Diet book. I left him a message saying (still very casually) "I came across something that you might find interesting. The book is in the mail. Talk to you soon".

A few weeks later he (casually) mentioned that he had started the oil, and was now physically incapable of overeating.

A few more weeks later, and he reports that he is unable to finish his breakfast in one sitting - he has to eat half, go work for a few hours, then finish his breakfast.

I'm elated.

My father has been compared to Homer Simpson. Both in the "get thrown out of Pizza Hut on all-you-can-eat night" and in the "awwww, my stomach hurts... I shouldn't have eaten that packet of gravy that I found in the parking lot" departments.

From the [1]SLD forums.

1. <http://boards.sethroberts.net/index.php?topic=5893.msg62211#msg62211>

---

Paul (seeking weight loss solutions) King (2007-12-30 16:43:59)

Great story, I'll be sure to check out this diet plan. If it can work for Homer there's hope for me yet! : )

### Can Anti-Depressants Cause Suicide? (2007-12-31 14:15)

Many parents have said yes. David Healy, a Scottish psychiatrist, prompted by those stories, did a small experiment in which undepressed persons took anti-depressants. About 10 % of them started having suicidal thoughts. Drug companies and the University of Toronto (where Healy had been offered a job) reacted very badly to this information, as Healy describes in [1]Let Them Eat Prozac. An [2]article in the latest issue of the American Journal of Psychiatry by David Leon, a biostatistician on the FDA oversight panel, describes why he voted to extend a warning about this from children (< 18 years old) to young adults (18-24 years old). This was the main data:

X

What's shown is the odds ratio for a report of suicide ideation or behavior, comparing those who got anti-depressants with those who got placebos. An odds ratio of more than 1 means greater risk in those who got anti-depressants. The red bar is from a different study. When different ages are lumped together there is no increase in risk but that hides opposing tendencies at high and low ages.

The article contains this curious sentence: "The results did not provide definitive evidence of risk, yet they failed to demonstrate an absolute absence of risk." No possible results could "demonstrate an absolute absence of risk" so it is unclear what Dr. Leon meant. Later he writes: "My vote to extend the black box warning to young adults was based on concern that risk of suicidality could not be ruled out and, given the widespread antidepressant use, even a small risk must not be ignored." Yes, he has it backwards: The data do not "fail to rule out" suicide risk (no possible data could "rule out" such risk, i.e., show the risk is zero); they manage to overcome a barrier to show it's there. And yes, he's congratulating himself ("even a small risk must not be ignored") for doing his job.

Uh-oh. That someone – a biostatistician, no less – in such a powerful regulatory position fails to understand basic concepts is bad enough; to make things worse, Dr. Leon has received money from three of the companies (Eli Lilly, Organon, and Pfizer) he oversees.

---

NE1 (2008-01-01 00:00:40)

Finding ratios 5 sigma below 1 (for a well-reasoned study) would easily satisfy my definition for "absolute absence of risk". It means in a large sample of people, the risk just doesn't occur. The results do not provide definitive evidence of risk because...

the value isn't 3 sigma above 1. What's hard about this?

lasser80 (2008-01-01 02:10:00)

I don't doubt that anti-depressants help many people. But the question on if anti-depressants are necessary and if they are, in fact, better than other less abrasive treatment methods is still questionable to me. Messing around with one's brain chemistry does strike me as potentially dangerous. It might subdue the depression, but the side effects are unknown. If more organic means can provide the same benefits as the abrasive means, then it's an easy decision. Yet psychiatrist don't seem to be open to the organic means.

seth (2008-01-01 02:48:17)

NE1, what is the numerical value of a risk ratio "5 sigma below 1"? And why 5? why not 20? or 3?

Seth's blog » Blog Archive » Anti-Depressants, Suicide, and a Malfunctioning Legal System (2008-01-01 19:03:49)  
[...] Can Anti-Depressants Cause Suicide? [...]

NE1 (2008-01-01 21:05:53)

Seth, you must be joking. A value 5 sigma below 1.0 means that if we were able to commission 4000 independent studies like this, we would expect to find an increase in ideation over placebo in just about one. So that, unless this is \*that\* one horribly biased study, we can be pretty certain that the risk does not exist (and is most likely reversed!). Now, if you want to turn that around and say that's still not enough, that 2 excess children having suicidal ideas is too many, then sure, price in some reasonable precautions. The odds against a 20 sigma study would be so great as to require the inadequacy of the study on other grounds (systematic error). But no, at some point you have to say: These 3999 positively (!) reacting teens are good evidence for me, and the 1 other could very well be the product of some other unfortunate circumstance. This isn't even in the realm of this Commentary, though. The value is within 1sigma of 1 here, so there isn't sufficient evidence to draw any hard conclusion. He also explicitly says that the black box warning is not about discouraging use, but warning about the danger of not monitoring; the reality is unknown, doctors are encouraged to be perceptive. You say: "The data do not fail to rule out suicide risk (no possible data could rule out such risk, i.e., show the risk is zero); they manage to overcome a barrier to show it's there. This is certainly not true. I have been willing to give you the benefit of the doubt on many things, as this is not my field, but one thing I have learned is an appreciation for the depth of people such as Leon. I may not understand the analyses he walks us through, but I do know that such processes are created for a reason. I am amazed that you feel capable of dismissing them without any reasoning yourself. You must think he has not gone far enough in restricting these drugs, but the evidence you seek does not seem to be in this report. Lasser: it's not hard to imagine that some people have inappropriate levels of the basic neurotransmitters in the brain, a natural "chemical imbalance". In that case it seems perfectly reasonable to me to plan on replacing those chemicals with a pill, as opposed to suggesting they exercise or eat more ice cream. To insist otherwise, as say the Scientologists might, is to turn one's back on centuries of confidence building in science. I know you're not taking this stance, but I think much of the public is still attached to the stigma against anti-depressants.

Corrinne Levanovich (2009-01-25 21:29:05)

For the last person to respond- when I was 19 I was put on Paxil, and while it did not cause suicidal feelings I had a severe reaction to it. It actually made me manic and angry. I am not saying this is a common experience, but I have never had a manic episode in my life and I haven't had one since I stopped taking it. (I am 23 now) I don't doubt that there's some people that antidepressants react badly with.

## Dr. Dermatologist, Meet Governor Huckabee (2007-12-31 15:29)

Since the 1960s, this has been the [1]standard conversation in dermatology offices:

PATIENT I think Food X causes acne. After I eat Food X, I break out.

DOCTOR There's no link between food and acne, but if something bothers you, don't eat it.

Here is Governor Huckabee [2]campaigning for President:

"If you want to believe that you and your family came from apes, that's fine," Huckabee said after an early debate. "I'll accept that. I just don't happen to think that I did."

The dermatologists made a mountain out of a molehill (the diet/acne question hadn't been carefully studied). Huckabee made a molehill out of a mountain.

### **Academic Horror Story (Johns Hopkins University) (2007-12-31 18:14)**

I previously blogged about [1]ICU checklists. Atul Gawande has written another excellent article about them, this time an editorial in the New York Times:

A year ago, researchers at Johns Hopkins University published the results of a program that instituted in nearly every intensive care unit in Michigan a simple five-step checklist designed to prevent certain hospital infections. It reminds doctors to make sure, for example, that before putting large intravenous lines into patients, they actually wash their hands and don a sterile gown and gloves.

The results were stunning. Within three months, the rate of bloodstream infections from these I.V. lines fell by two-thirds. The average I.C.U. cut its infection rate from 4 percent to zero. Over 18 months, the program saved more than 1,500 lives and nearly \$200 million.

Yet this past month, the Office for Human Research Protections shut the program down. The agency issued notice to the researchers and the Michigan Health and Hospital Association that, by introducing a checklist and tracking the results without written, informed consent from each patient and health-care provider, they had violated scientific ethics regulations. Johns Hopkins had to halt not only the program in Michigan but also its plans to extend it to hospitals in New Jersey and Rhode Island.

The government's decision was bizarre and dangerous. But there was a certain blinkered logic to it, which went like this: A checklist is an alteration in medical care no less than an experimental drug is. . . . A checklist may require even more stringent oversight [than drug tests], the [OHRP] ruled, because the data gathered in testing it could put not only the patients but also the doctors at risk "by exposing how poorly some of them follow basic infection-prevention procedures. . . .

A large body of evidence gathered in recent years has revealed a profound failure by health-care professionals to follow basic steps proven to stop infection and other major complications. We now know that hundreds of thousands of Americans suffer serious complications or die as a result. It's not for lack of effort. People in health care work long, hard hours. They are struggling, however, to provide increasingly complex care in the absence of effective systematization.

Excellent clinical care is no longer possible without doctors and nurses routinely using checklists and other organizational strategies and studying their results. There need to be as few barriers to such efforts as possible. Instead, the endeavor itself is treated as the danger. . . . Scientific research regulations had previously exempted efforts to improve medical quality and public health "because they hadn't been scientific. Now that the work is becoming more systematic (and effective), the authorities have stepped in. And they're in danger of putting ethics bureaucracy in the way of actual ethical medical care.

Not "in danger of" – they have put "ethics bureaucracy" ahead of patient safety. In a big way.

David Hunter (2008-01-11 01:37:03)

Seth I don't see the problem here. Why did John Hopkins not simply apply for approval before they began what was clearly research? You seem to be siding with Hopkins because it worked, but what if it hadn't? What if their experiments had negative effects, would you then be condemning them? The job of research ethics committees is to ensure research is carried out ethically, and I don't see how bypassing them is laudable.

Royce Fessenden (2008-08-05 07:49:01)

I'm stunned at David Hunter's comment that elevates an administrative procedure to the same level as "medical research". This is the same type of medieval madness that objected to doctors washing their hands and cleaning up the bloody surgeons gowns. Who will protect us from the "ethics" protectors!

PJ Eby (2009-01-29 13:16:29)

FYI, a response from the OHRP is here: <http://www.hhs.gov/ohrp/news/recentnews.html#20080115> They seem to be saying that as long as you're not \*researching\* whether checklists actually WORK, it's okay to just go ahead and USE them. Which seems a bit weird, but oh well.

### 3.1 January

#### Why New Year's Resolutions? (2008-01-01 03:02)

[1]Justin Wolfers gives seven possible explanations for New Year's resolutions. Here's another: They improve self-image. A Catholic who has gone to confession and been granted some sort of absolution has a better self-image after confession than before. Likewise, a person who wants to do X but hasn't (a "sin of omission") feels better about him- or herself after making a New Year's resolution to do X.

[2]Mark Liberman's resolution – surely for a different reason. I can't imagine making a New Year's resolution – see busman's holiday – but if I did it would be . . . to blog less. I enjoy blogging too much.

Happy New Year!

#### An Excess of Caution at The New Yorker (2008-01-01 11:20)

From an otherwise excellent [1]article about Rudy Giuliani:

Many, perhaps most, politicians probably value competence and probity somewhat less than devotion.

Uh, how about

Perhaps most politicians value competence and probity less than devotion.

Too much hyper-editing or too little? During a visit to The New Yorker, I used the bathroom. In the next stall, there were page proofs on the floor. The occupant was studying them.

1. [http://www.newyorker.com/reporting/2008/01/07/080107fa\\_fact\\_kolbert](http://www.newyorker.com/reporting/2008/01/07/080107fa_fact_kolbert)

---

Peter (2008-01-01 14:25:35)

the two version read very differently. is the second version a response to a query? is the second version a rhetorical question? and the concept of competence vs. loyalty in politics is not very clear, i would argue - thus making the first version preferable on another count. the first version just reads easier - and that has value. the seeming watery-ness of the first version would be a problem in many/most other cases (probably), but not here, methinks. :)

seth (2008-01-01 14:58:15)

The second version is my edit of the 1st version.

Chris (2008-01-02 09:56:49)

I think it's underediting. Sad, cos line-editing is something the New Yorker used to do superbly. The writer obviously wants to add a tentative note to the blank statement "Politicians value competence and probity less than devotion", so he throws in a quibble, in fact he throws in three, then qualifies one by writing "Many, perhaps most" instead of just "Many". It makes him sound like a nervous Nellie. I'd rewrite as follows, with one quibble only only: "Many, perhaps most, politicians value competence and probity less than devotion." It's still not very good. "Probity" is a stuffed-shirt word - does he mean honesty? "Devotion" is also unclear - is it religiosity or loyalty? Anyway, if the 1965-era New Yorker somehow reappears and is looking for a line-editor, let'em know I'm available.

## **Anti-Depressants, Suicide, and a Malfunctioning Legal System (2008-01-01 19:03)**

[1]This sort of combines two recent posts of mine ([2]here and [3]here):

Unlike the possibility that anti-depressants may cause suicidal ideas, [addition of] the black box warning has been followed by the deterrence of non-psychiatric doctors from treating depressed people. The rate of hard outcome suicide, not just thoughts, shot up. It had been dropping prior to that.

[4]Supporting data. Related [5]FDA overreaction.

## The Best Way to Learn is to Do (Jonathan Schwarz edition) (2008-01-02 18:50)

"The best way to learn is to do," wrote the late [1]Paul Halmos at the beginning of [2]an article about how to teach college math that inspired me to start self-experimenting. [3]Jonathan Schwarz says [4]something similar:

America is so completely depoliticized that I support people doing pretty much anything (except forming neighborhood fascist gangs, and even that doesn't worry me too much). Perhaps I'm foolishly optimistic, but I believe people will learn from the horrendous mistakes they'll surely make. And even if they don't, giving it a shot is the only way they have even a possibility of doing so.

Well put.

A subtle defense of the Iraq War? If Halmos were alive I like to think he'd agree with this:

Lesson 1: The best way to learn is to do.

Lesson 2: And the best thing to do is something small.

[5]Halmos excerpts.

david (2008-01-02 20:28:39)

William Blake edition: "If the fool would persist in his folly he would become wise." from the \_The Marriage of Heaven and Hell \_

seth (2008-01-02 21:53:40)

Nice, David.

Peter (2008-01-02 22:47:25)

A subtle defense of the Iraq War? people will try anything to defend war crimes.

Aaron Brown (2008-01-03 12:02:15)

I'm reading the [1]collection of Halmos excerpts right now and it's great. This part hit home:

Despite my great emotional involvement in work, I just hate to start doing it; it's a battle and a wrench every time. Isn't there something I can (must?) do first? Shouldn't I sharpen my pencils, perhaps? In fact I never use pencils, but pencil sharpening has become the code phrase for anything that helps to postpone the pain of concentrated creative attention. It stands for reference searching in the library, systematizing old notes, or even preparing tomorrow's class lecture, with the excuse that once those things are out of the way I'll really be able to concentrate without interruption.

1. <http://www.ams.org/notices/200709/tx070901136p.pdf>

seth (2008-01-03 15:24:28)

Everyone procrastinates. Or almost everyone.

## **Interview with Gary Taubes (part 1) (2008-01-03 05:47)**

I interviewed Gary Taubes shortly after he gave a [1]talk about the main ideas of his new book – Good Calories, Bad Calories – at UC Berkeley. The interview lasted 2 hours.

INTERVIEWER I just spoke to someone who reduced the carbohydrate in his diet, for various reasons, including your book. He found that his performance on mental problems started improving again. It had stopped improving; it had been constant for a long time, and then it started getting better. So it may be that when you reduce the carbohydrate in your diet, your brain starts working better.

TAUBES Well, there is evidence that your brain works more efficiently on ketones, as does your heart. So if he reduced his carbohydrate consumption sufficiently, he probably increased the level of ketones in his blood. But I'm just speculating here.

INTERVIEWER: The book seems to have had an unusual beginning. You'd been writing about salt, and you learned that a scientist you didn't trust about salt was also talking about obesity?

TAUBES Well, I've spent over 20 years now writing about controversial science. In the mid-1980s, I lived at CERN for ten months, the big physics lab outside Geneva, watching physicists discover non-existent elementary particles. Then I wrote a somewhat infamous story about prions, the supposed causative agents of Mad Cow Disease. I wrote a book about cold fusion: I got obsessed with this question of how it happened, because it was so obviously wrong. After all that, I developed what I believe is a very good feel for who's a good scientist, and who's a bad scientist, just by talking to them. There are certain ways that good scientists describe their data, describe the caveats, and describe the conditions by which they may or may not be right. I had also, obviously, with cold fusion, interviewed some of the worst scientists in the world. I used to joke with my friends in the physics community that if you want to cleanse your discipline of the worst scientists in it, every three or four years, you should have someone publish a bogus paper claiming to make some remarkable new discovery – infinite free energy or ESP, or something suitably cosmic like that. Then you have it published in a legitimate journal ; it shows up on the front page of the New York Times, and within two months, every bad scientist in the field will be working on it. Then you just take the ones who publish papers claiming to replicate the effect, and you throw them out of the field. A way of cleaning out the bottom of the barrel.

INTERVIEWER I thought your NY Times article, "What if It's All Been a Big Fat Lie," sort of did that. The people who came out against it, they were the bad journalists. Just throw them out!

TAUBES Well, how I got onto that: I was doing this story for Science on salt and blood pressure, looking into the controversy about whether salt consumption plays any role at all in raising blood pressure and causing hypertension. One of the prime players in this salt/blood pressure controversy was obviously one of the worst scientists I'd ever met – one of the five worst" | you can't say, in that five, who is the very worst, but they're all pretty bad. This is a group that includes guys like Stan Pons and Martin Fleischman who claimed to have discovered cold fusion. While I'm on the phone with this guy, interviewing him, he takes credit for getting Americans to eat less fat and fewer eggs. I literally finished the interview, called my editor at Science, and I said "You know, one of the worst scientists I've ever interviewed just took credit for getting Americans to eat less fat and fewer eggs, and I don't know what the story is, but when I'm done with this salt story, I'm going to look into fat, cholesterol, and saturated fat." I had a great relationship with Science. My editors had faith in me. If I said there was a story there, they'd give me the support

I needed to pursue it. A year later, I ended up with that first story in Science, saying that there's no evidence that reducing the total fat in the diet makes a damned bit of difference in our health. The evidence that saturated fat and monounsaturated fats are players is, at best, marginal. And that led to the N.Y. Times article.

INTERVIEWER What did that scientist say that made you rank him so low?

TAUBES There are all kinds of signs. He told me there was no controversy, when there was obviously a controversy. His side might have been right, but to deny there as a controversy was ludicrous. He talked about the legitimacy of throwing out negative data. You measure salt consumption one way; you don't see any effect on blood pressure, and so you decide that's obviously the wrong way to measure it. The implication of everything he told me was that he knew what the answer was before he did his experiments, and then he adjusted his experimental techniques and methodology until he got the answer that he wanted. And he believed this was legitimate science. There are other signs. I'm a stickler about the use of words like "evidence"<sup>[2]</sup> and "proof"<sup>[2]</sup>. So if someone tells you there's no evidence for some controversial belief, you can be fairly confident that they're a bad scientist. There's always evidence, or there wouldn't be a controversy. If somebody says that "we proved that this was true"<sup>[2]</sup> or "we set out to prove that this was true"<sup>[2]</sup> that's another bad sign. The point here, as Popper noted, among others, is that you can never prove anything is true; you can only refute it. So researchers who talk about proving a hypothesis is true rather than testing it make me worried.

INTERVIEWER Yeah, I see what you're saying. They overstate; they twist things around to make it come out the way they want. They are way too sure of what they"<sup>[1]</sup>

TAUBES Yes, and the really good scientists are the ones, almost by definition, who are most skeptical of evidence that seems to support their beliefs. They're most aware of how they could have been fooled, how they could have screwed up, or how they might have missed artifacts in their experiment that could have explained what they observed. They're very careful about what they say. If you ask them to do play devil's advocate, and tell you how they could have screwed up, then at the very least, they'll say "Well, if I knew how I could have done it, I would have checked it before I made the claim"<sup>[2]</sup>. So when I'm talking about discerning the difference between a good scientist and a bad scientist, I'm talking about how they speak about their research, the evidence itself, it's presence or absence. My friends in journalism would often ask me this question: by what right do I think make decisions about who's a good scientist and who's not. I'd say "Well, when you're an English major, you can be confident that Norman Mailer was a better writer than John Grisham, even though John Grisham makes 10 to 100 times more money"<sup>[2]</sup>. It's just a feel for what you do; I don't know how else to describe it. I know a good scientist when I talk with one. I might be fooled, on occasion, but....

INTERVIEWER It's not particularly well-correlated with how famous they are, or how many Nobel Prizes they've won.

TAUBES My first book was about a Nobel Prize winner who discovered non-existent elementary particles.

INTERVIEWER Who was that?

TAUBES An Italian physicist named Carlo Rubbia.

[2]Interview directory.

sidereal (2008-01-03 13:12:50)

Funny juxtaposition:

There are all kinds of signs. He told me there was no controversy, when there was obviously a controversy. His side might have been right, but to deny there as a controversy was ludicrous... I'm a stickler about the use of words like "evidence" and "proof". So if someone tells you there's no evidence for some controversial belief, you can be fairly confident that they're a bad scientist. There's always evidence, or there wouldn't be a controversy.

My first book was about a Nobel Prize winner who discovered non-existent elementary particles

Rubbia won the Nobel Prize for discovering the W and Z bosons. Their existence is fairly well established in the Standard Model, to the degree that we can observe particles that minute. To call them 'non-existent' would be a profoundly hubristic scientific claim. Taubes might be referring to the Higgs boson, which is predicted within a fairly narrow range of parameters, but unobserved. This is again substantially different from 'non-existent'. I haven't read Taubes' book of course, so it's entirely possible he's referring to some other particles, but it certainly seems as if Taubes is failing to hold himself to the standard he requires of the scientists he interacts with.

taubes (2008-01-03 15:53:20)

With apologies for coming off like an egomaniac and writing in the third person, Taubes was indeed referring to some other particles. He was there when Rubbia won the Nobel Prize. He even accompanied him to Stockholm (something Rubbia probably regrets to this day) and had a great time. The first half of his book, *Nobel Dreams*, chronicles the work leading up to the observation of the W and Z bosons at Rubbia's experiment. The second half of *Nobel Dreams* chronicles the "discovery" of the non-existent elementary particles and the subsequent realization that it was, indeed, a royal screw-up. The book is a good read. I recommend it. (My advice to sidereal, which I try to follow as an investigative journalist, is always to begin from the assumption that someone is no more nor less idiotic than you might be, until proven otherwise.)

sidereal (2008-01-03 17:29:13)

Indeed. sidereal simply read the exchange about Rubbia, in the context of the impeachability of Nobel Prize winners, as being about the work *for which* he won the Prize. sidereal apologizes for the assumption and will, as a fan of scientific controversies, read the book if he gets a chance. Regarding idiocy, he's surprised Taubes though it was implied. Lack of scientific rigor in approaching claims is unfortunately the human condition, and hardly qualifies as idiocy.

[...] Interview with Gary Taubes (part 1) [...]

Bix (2008-01-04 11:25:09)

Taubes' response to the question, "What did that scientist say that made you rank him so low?", was, in my humble opinion, excellent. (I thought the asking of that question was also on target.) I especially liked, and agree with, his discussion about "proof." I was curious to see if Taubes would respond with an emotional argument. He didn't. In my eyes, this elevates his credibility. Just for a moment I'd like to come to the defense of scientists. I've worked with some, and I see that when someone becomes very excited about a finding, they, as if it was human nature, start to erect blinders to the alternative hypothesis. I think that's ok, as long as they can be reigned back in. Excitement is ok. But there are others who become progressively cemented to their idea. It's difficult to work with someone who has stopped listening, who can't see beyond their selected path. That's all! Nice job on the interview!

Seth's blog » Blog Archive » Interview with Gary Taubes (part 3) (2008-01-04 16:09:14)  
[...] Interview with Gary Taubes (part 1) [...]

Quantum Theory Man (2008-01-04 17:38:43)

I would have to agree, having been involved in various "hard" science projects over the years. When a new idea or discovery is thought up by the scientists, they often do put on blinders to any conflicting data or confounding hypotheses. This is what peer review is supposed to solve, but sadly since most of the peer reviewers also have their own set of blinders, things don't work out as they should. Paradigms change offly slow...

[...] Interview with Gary Taubes (part 1) [...]

Allen Oelschlaeger (2008-01-06 11:47:49)

I recently read Gary Taube's new book and believe he got a lot of things right (e.g., overstated role of salt and fat to health). However, I'm less convinced that the obesity epidemic has been caused by a decrease in fat consumption and that a low-carbohydrate diet is the best way to lose weight for everyone. Instead, I think there is equally strong evidence (if not stronger) that the increased incidence of obesity is due to an increase in dieting (one indicator – \$11 billion was spent on dieting in the early 1980s and over \$60 billion is spent today). In fact, there is a strong argument that the global obesity epidemic is due to the broader issue of an increase in food insecurity (for which dieting is just one example). To read a paper on this topic, you can download a PDF at this URL: [http://www.truthspublishing.com/Obesity\\_Epidemic\\_Public\\_Policy.pdf](http://www.truthspublishing.com/Obesity_Epidemic_Public_Policy.pdf) Allen Oelschlaeger Author of Finally, the Straight Scoop About Weight, Nutrition, and Fitness (learn more at <http://www.truthspublishing.com>).

tiara.org » links for 2008-01-11 (2008-02-25 12:43:36)

[...] Seth's blog » Blog Archive » Interview with Gary Taubes (part 1) First part of a lengthy interview with Gary Taubes, author of Good Calories, Bad Calories which indicts many nutritional studies from the last 60 years and concludes again: it's carbs, not fat, to watch out for. (tags: foodscience diet health) [...]

Ron Burk (2008-02-26 21:01:20)

"may be that when you reduce the carbohydrate in your diet, your brain starts working better." I gotta dollar that says that all mental effects of low-carb diets are the result of increased serotonin getting into the brain. I have (ahem) self-experimented on this extensively because I was experiencing circadian dizziness (falling-down dizzy if I got up at 4am to go to the bathroom) and mental foggiess that seemed to correlate with sugar intake. After the doctor ruled out the good stuff (tumor, diabetes, etc.) I realized that a) when you get circadian symptoms, you look at circadian hormones and b) dizziness and mental foggiess are well-known symptoms for people using drugs that try to tinker with serotonin levels in the brain. They are often circadian symptoms, but for some reason doctors are real likely to ignore the fact that symptoms occur only at a certain time of day. A good scan of the literature helped me form the hypothesis: eat too much sugar, get sugar malabsorption, excess sugar binds with tryptophan, increased carbs in blood competes with tryptophan at brain-blood barrier, and you get seriously lowered ability to make serotonin in the brain. If you have any interest, ya gotta read this grotesque experiment they did on athletes where they put a catheter in the jugular so they can directly measure how much tryptophan is getting sucked in to the brain when athletes do endurance exercise with or without drinking carbs. I swear, you can do experiments on athletes that prisoners would never sign up for. The experiment to test the hypothesis on myself was easy: pop a tryptophan pill and do extended aerobic exercise on an empty stomach at peak serum tryptophan time (say, 6-8pm). The result was stunning. Boom – the mental foggiess I had had for unknown months or years disappeared. It was like the feeling you get when you get new prescription glasses and you suddenly realize that you had been unable to see clearly for who-knows-how-long. I can reproduce the symptoms at will and make them disappear at will. When you cut those carbs drastically or eliminate them, yer gonna get more tryptophan in the brain, so more serotonin can be produced from it. More serotonin in the brain may also help decrease cravings and increase satiety. I believe it's impossible really understand the Atkins diet without understanding how carbs can compete with tryptophan, and without understanding the Harvard work on using protein to help raise brain serotonin levels. The Atkins diet tinkers with brain serotonin, but since it does so unconsciously, it doesn't always produce the desired result (and certainly isn't the only way to elevate brain serotonin).

Lauren Schiller (2008-02-27 12:29:54)

So Ron, Very interesting, where can I find this information? I've been reducing my carb intake but it still seems like I fluctuate between good days and foggy days. I'd love to have a better understanding of what to do to reduce the brain fog.

### **Advances in SLD: Easing the Burden of Sugar Water (2008-01-03 08:09)**

One way to do the Shangri-la Diet is to drink sugar water. This can cause your blood sugar to go too high if you don't drink it slowly. Dr. Edward Pooley, a UK doctor, has noted that in the UK you can buy [1]FibreSure, which is powdered [2]inulin, a flavorless soluble fiber. Adding it to the sugar drink should slow digestion of the sugar. It is also sold in the United States.

1. <http://us.fibersure.com/ca/en/about.shtml>

2. <http://en.wikipedia.org/wiki/Inulin>

Matthew (2008-01-03 09:42:40)

FYI, in the US it's called Fibersure. Thanks for the tip-I'll be trying this as soon as I can get my hands on it. Never could tolerate the oil.

Mike (2008-02-12 11:56:33)

Why is this sugar/insulin/diabetes issue dealt with so little detail. I wonder about the general warning being sufficient. If you're not diabetic and you use the sugar water religiously can you BECOME diabetic? What specifically happens when your blood sugar gets too high? How would one measure that? Drinking in 5 minutes, 10 minutes, 15 minutes? Now you suggest that one should use powdered insulin? Is it safe to be "eyeballing" or guestimating your sugar and insulin intake?

seth (2008-02-12 12:40:10)

There's no doubt that high blood sugar levels are damaging. This is why I used fructose instead of sucrose; fructose is digested more slowly. My A1C levels - which detect too-high levels - were fine. If you are worried about this, one thing to do is get your A1C level measured. Another (more time consuming) is to measure your blood sugar directly with a home meter for that purpose. There's too much variation from person to person and from one situation to another for me to make very concrete statements about what is best. You can post at [boards.shangriladiet.com](http://boards.shangriladiet.com) if you'd like more information.

### **Advances in SLD: Eating Lots of Nose-Clipped Food (2008-01-03 14:44)**

At the Shangri-La Diet forums, Heidi 555 [1]wrote (excerpts):

I highly recommend nose-clipping a high percentage of food. My weight has been steadily dropping down and my body is shrinking. But best of all I feel really good in my body. For the past five years I've been dedicated to getting in shape. I gradually built some muscles but found it impossible to lose those last 10 pounds of fat. Working out made me look stockier. Now I am in the enviable position of trying to figure

out what I want to weigh. Imagine that – pick what I want to weigh! I can't believe that I'm trying to figure that out.

For the most part, I don't mind nose clipping lots of food. I enjoy eating even with nose clips on. Yesterday, I made some delicious cream of mushroom vegetable soup. I raved about how delicious it tasted. My husband looked at me as if I was slightly nuts. I was wearing nose clips and couldn't taste a damn thing. Yet, I enjoyed every mouthful and raved about how great it "tasted". The healthy, creamy, warm, texture, umami elements were deliciously satisfying.

I have found the same thing – that there is a lot of pleasure to be gotten from the non-smell elements of food (creamy, sweet, salty, sour, etc.) and that the overall effect, when these elements are present in good amounts, is that the food tastes delicious, even without smell. When I have nose-clipped chicken, for example, I sprinkle it with salt, sugar, vinegar, and hot sauce.

I don't worry about a two hour window. I'm also flexible each day with what percentage of food I nose clip. I think in general I nose clip somewhere between 40 and 90 percent of what I eat. But it's not as bad as it sounds. With strong appetite suppression, I often don't care if I taste what I eat. I try to nose clip extremely healthy food. But sometimes I have a fridge to mouth nose clipped binge. The weirdest thing is that I always feel like I'm eating a lot. Maybe eating as much as you want, of whatever you want, always feels like a lot.

It's especially interesting she doesn't worry about a two-hour window.

With flavorless oil and unflavored sugar water, there is a dosage limit, of course: you'll probably want to stay under 400 calories/day so that the rest of your diet provides good nutrition. With nose-clipping there is no obvious calorie limit. Everything we know about nutrition suggests you could eat all your food this way. Given the right choice of foods – foods that are adequately creamy, salty, sweet, etc. – you'll still enjoy everything.

david (2008-01-03 15:55:29)

Ever since I read about the SLD, I've wondered if the real reason smokers lose weight (or gain it when they quit smoking) is because they can't taste/smell food as well when they smoke. IIRC, you mention in the original paper that smokers don't lose all that much weight because of smoking, but still they lose some. What if there were a pill that temporarily interfered with your ability to smell/taste food? Would that be the ultimate diet pill? Perhaps there is a drug already out that has that as a side effect.

lasser80 (2008-01-03 21:56:16)

I had difficulty swallowing food with my nose clipped.

Heidi 555 (2008-01-04 06:04:26)

I have difficulty swallowing liquids with my nose clipped. I have to drink slowly in small sips. Perhaps I also eat more slowly with nose clips. I'll have to pay attention and see.

## Interview with Gary Taubes (part 2) (2008-01-04 05:36)

INTERVIEWER What do you think about prions?

TAUBES Here's the problem with prions: the claim is that here's a radical discovery – an infectious agent that doesn't have nucleic acid – and it's based fundamentally on a negative result, which is that when researchers have gone looking for the nucleic acids they failed to find them. Therefore, so the logic goes, they must not be there. The original claim, by Stan Prusiner, another Nobel Prize winner, was premature. He made some claims in his early papers that were definitively wrong. Yet everything he's done since then supports his initial claim, which suggests he's was either remarkably lucky to begin with, or he's only capable of interpreting his results so that they agree with his preconceptions. One of the themes in all of my work is that if you go public on premature data, what happens is that the motivation to do really good science ceases. By "really good science", what you're supposed to do, as brutally as you can, is to try to come up with tests that would refute your own hypothesis. The idea is that if your hypothesis survives every rigorous test you can imagine, and all those that everyone else can imagine, then you can start believing it's true. But once you've staked a claim based on premature data – once you've gone out on a limb without doing any of those rigorous tests – now your motivation becomes to prove that you were right., which you can never do in any case. But the point is that you stop trying to refute your hypothesis, and you start trying to accumulate evidence that supports it and the latter isn't science. It's more like what happens in religions.

INTERVIEWER That's what happened with Peter Duesberg. He was a good scientist until he started making claims about HIV.

TAUBES When I wrote this prion article in 1987, the science was so bad that it was a joke. Still, I never said that the prion concept wasn't correct; I just said there was excruciatingly little evidence to support it, and there were plenty of reasons to believe it was wrong. How do you get strains of an infectious agent without nucleic acids (RNA or DNA) to encode the information in the strains? If you actually look today, even though Prusiner has won the Nobel Prize, if you go to the WHO website or the NIH website and you read up on prions, you'll see that it's still considered a hypothesis. There's still no way to explain how you can get strains without a virus. Prusiner has these ideas, but they're along the lines of now "a miracle happens". It's another long story, but one of the problems (and this is a theme in my book), when you let an untested hypothesis grow and infect the science to the point where people start to believe it's true, even though it's never been rigorously tested, the obstacles against ever overturning it get bigger and bigger. It's like the dietary fat hypothesis: you let it sit around for 40 years, and it evolves to the point that people consider it dogma; it's virtually impossible to overturn it. The situation with prions isn't so bad because the public

doesn't care about prions the way that they care about diet, but once the Nobel Prize is awarded, even though it's still considered a hypothesis, people tend to ignore the studies that suggest it's wrong. There's one researcher from Yale who is constantly publishing evidence in major journals that she's found the nucleic acids, and people just ignore her. They believe the question has already been answered.

INTERVIEWER What's her name?

TAUBES [1] Laura Manuelidis.

BarryBrolley (2008-01-04 14:10:29)

this sounds reminiscent of Smolin's critique of string theory in his book, "The Trouble with Physics" Smolin writes that string theory makes no testable predictions..

Joshv (2008-01-05 11:45:42)

"INTERVIEW That's what happened with Peter Duesberg. He was a good scientist until he started making claims about HIV." Unless I misunderstand your position, you are missing the parallels between the Dietary Fat/Obesity hypothesis and the HIV/AIDS hypothesis entirely. The "probable cause" of AIDS was announced in 1984 by press conference, not in a published, peer-reviewed paper. Since then there has always been ample evidence that either HIV does not cause AIDS, or that there are other causal "co-factors" involved. This evidence still exists, and has yet to be adequately explained. Instead most of this evidence is ignored, and the HIV-AIDS causal link is taken as a forgone conclusion - there is simply an opinion that "consensus" that HIV causes AIDS. Which is exactly the flawed misapplication of the scientific method that lead us to the current badly flawed dietary advice to avoid fat and replace it with carbs. Based on my reading of Taube's work, and my own extensive research on HIV/AIDS, I suspect that Taube's is most likely extremely skeptical of the causal link between HIV and AIDS. Duesberg is in fact an extremely careful and skeptical scientist, exactly the sort of researcher Taubes tends to respect based on my reading of his latest book, and other interviews/presentations. The parallels between the terrible science/scientists Taubes discovered in the field of dietary research, and what can be found in HIV/AIDS research are legion. I have not been able to find a public statement of his opinion on these matters, but I realize that for him to "come out" as an HIV/AIDS skeptic would most likely be an act of career interruptus. Note how he didn't answer the question you asked? He avoided it entirely (I am assuming his answer is unedited).

seth (2008-01-05 15:13:40)

I didn't ask Taubes what he thought about HIV and AIDS. My comment about Duesberg was an interruption.

Seth's blog » Blog Archive » Interview with Gary Taubes (directory) (2008-01-06 02:42:41)

[...] Interview with Gary Taubes (part 2) [...]

MacDonald (2008-01-06 07:08:25)

The comment on Duesberg and HIV certainly was an interruption. It would have been more interesting to compare Taube's and Duesberg's almost identical criticisms of prion theory.

joshv (2008-01-06 09:18:44)

"I didn't ask Taubes what he thought about HIV and AIDS. My comment about Duesberg was an interruption." I realize that, but your quip got it 180 degrees backwards. What Taubes is doing in dietary research is entirely analogous to what AIDS dissidents such as Duesberg, and more recently Culshaw are doing in realm of AIDS research. The parallels are clear, and if anything Taubes is most likely extremely skeptical of the conclusions reached by the last 25 years of HIV/AIDS research. I'd love to hear him comment on the subject.

Bob (2008-01-06 21:50:46)

"...now your motivation becomes to prove that you were right., which you can never do in any case. But the point is that you stop trying to refute your hypothesis, and you start trying to accumulate evidence that supports it and the latter isn't science. It's more like what happens in religions." Oh my goodness, the 2,000 pound elephant sitting in the living room, that nobody is remarking on, is named Al Gore. He's even got his own Nobel Prize, how apt. At the same time, Earth Day is replacing Easter, so the comment about religion is true in spades. Yet he and the hordes who insist that global warming is "proven" to be caused by man go unremarked upon in all of this discussion. Why? Does it depend on whose ox is being gored?

ryanwc (2011-04-04 21:05:18)

I'm awfully late getting here, via a search for Taubes critics to see what might turn up. But Bob, two things. One, Gore doesn't claim to be a scientist. If you even knew the names of actual scientists involved, rather than a guy who funded a movie, your own "skepticism" might seem better justified, rather than merely self-serving. Two, Taubes uses a large number of scientists whose views correspond in different ways to the things he is saying, and also cites many scientific papers whose results suggest different conclusions than those drawn by the high-carb folks. The climate science "skeptics" (as opposed to the genuinely skeptical scientists within the mainstream of climate science) have never been able to do either of those things. The very small number of people disputing that anthropogenic human warming exists (as opposed to the many who dispute exactly how much) are barely able to interact with the scientific papers that are published. They don't even attempt to explain or to integrate, instead, they've spent inordinate amounts of money trying to wish away the data. But the data itself has proven quite robust.

### **Interview with Gary Taubes (part 3) (2008-01-04 16:09)**

INTERVIEWER You wrote that New York Times piece, and from my take on it, you had a bunch of evidence, and then you got a book contract. Is it fair to say that you found out that what you wrote in the piece was mostly right?

TAUBES It's a difficult question. I had actually pitched the New York Times piece on fat as an attempt to determine the cause of the obesity epidemic. The proposal was very open ended. I had several ideas. I actually believed, going in to the story, that the answer was going to be that high-fructose corn syrup was responsible for Americans getting fatter over the last 30 years.

INTERVIEWER I'm glad to hear that.

TAUBES The thing about the obesity epidemic is that we can say when it starts, give or take five years: some-time between the mid-1970s and late 1980s. So we have a starting point, and that happens to coincide with the introduction of a type of high-fructose corn syrup known as HFCS-55, which was developed to taste exactly like sugar when it's put in sodas and juices. In fact, it is effectively identical to sugar, as far as the body is concerned – sugar (sucrose) is 50-50 glucose and fructose and HFCS-55 is 45 percent glucose and 55 percent fructose – although I didn't know that when I pitched the article. But I thought that high-fructose corn syrup is so cheap. Basically this is an idea that Greg Critser in a book called *Fatland* picked up on, and subsequently Michael Pollan, too, that high fructose corn syrup allows you to saturate the market with sugar, without any fear that price fluctuations will cause you to go out of business, or lose you a lot of money. If the international price of sugar suddenly spikes, as it did in the 70s, and

you're committed to fulfilling this enormous demand for sugar you've created, then you're in trouble. But if you have a cheap reliable source of sugar, at a price that won't change from year to year, then you can create an enormous market without fear. This was, more or less, my naive idea of how the economics of HFCS might have caused an entire nation to get fat. Once they had this dependable low-cost sugar substitute, the sugar industry and the soda industry could then expand their production and sell Big Gulps, etc. Then I did the reporting. I talked with industry analysts, and they said that was nonsense; that the primary cost of selling sodas and fruit juices is the bottling and the shipping, and that the cost of the sweeteners is such a tiny portion of the cost of the end product that it wouldn't have made any difference whether it was sugar or high-fructose corn syrup. So I moved to my next idea, which was based on the fact that the beginning of the obesity epidemic coincided with the institutionalization of the low-fat dogma. As I'm doing that reporting, I stumbled upon what was, at that time, five trials of the Atkins diet, all of which had been finished, but not yet published. At one point, when I was doing the reporting, I actually got worried that some other journalist would beat me to the punch.

INTERVIEWER What was it about the Atkins diet that made these trials so important to your article?

TAUBES: Well, remember, my background, as a journalist and in school, was more or less in physics. In the kind of physics I used to write about, you've got some complicated detector that's looking at particles and atoms smashing together inside it and you're looking for some byproduct of a collision that you've never seen before. A new particle. But the first thing you have to do is make sure you understand your detector. Can you believe what it's telling you. So you have to calibrate it. If you want to know how much you weigh, for instance, one thing you might do before you step on the scale is you calibrate that. You make sure that when you're not on it, the little arrow on the scale is pointing to zero. If it's registering one or two pounds when you're not standing on it, then it might be off by five or ten pounds or more when you are. So you want to calibrate your equipment. You want to know that when you set it to zero, it says zero. That's an idea that's always resonated with me. Measure what happens at an extreme, make sure you understand that, and then see what happens from there. So here's the Atkins diet: in theory, you're removing virtually all of the carbohydrates, but you don't tell people to eat less. You tell them to eat as much as they want. It's like you're setting the diet to zero carbohydrates, and as much fat as possible. According to conventional wisdom, you should certainly not lose weight and you might even gain it. But here were five studies saying that, lo and behold, people really do lose weight when you remove the carbohydrates from the diet, and they lose more weight than they do when you tell them to keep the carbohydrates but eat less calories. What's more, their cholesterol profiles actually improve, so how can fat or saturated fat be bad for your cholesterol, if these high fat, high saturated fat diets make your cholesterol levels better. To me that had to tell you something about the validity of the low-fat dogma and about the underlying physiology. What do carbohydrates do, and what does their removal do. So once I learned about those five studies, I was confident that I had a story that was now worth writing. As for your original question, about whether I found out most of what I originally wrote was right, obviously the book supports the message of the article, but I no longer believe a fair number of things I believed when I wrote that story. For instance, when I wrote the Times article I inherently believed that the key was still calories consumed.

INTERVIEWER You mean things that you believed then, that you don't believe now?

TAUBES Yes, that I don't believe now. In that original article, I discussed what David Ludwig has argued – that easily digestible carbohydrates cause these blood sugar and insulin spikes, and that in turn causes blood sugar to plummet, and the result is blood sugar so low a few hours later that this in turn makes you hungry. So you eat more and that's why you get fat with carb-rich diets. Ludwig works with obese children at Harvard and I believed that his hypothesis was probably true. Then I also talked about Michael Schwartz's research at the University of Washington. Schwartz believes that insulin's primary role is to suppress hunger in the brain, but that somehow we become resistant to that effect and so, once again, we eat too much and that's why we get fat. Both these theories are predicated on the notion that we get fat because we eat too much and that's what I believed. We consume more calories than we expend and we get fat; something about carbohydrates facilitates that excess consumption. Now I believe the causality is reversed, and that's what I discuss in the book and in the lecture. Carbohydrates make us

accumulate calories in our fat tissue, and that in turn makes us eat too much. It's all about the regulation of fat metabolism. All those things that Ludwig and Schwartz were talking about might have been true (I mean, they are true, on some level), but they're not the driving force of why we get fat, or why removing the carbohydrates makes us lean.

INTERVIEWER I see. So that's a good summing up of what was in your article that you believe, and what you don't believe anymore.

TAUBES There are other related facts, as well. I never imagined when I wrote that original article that I would come to believe that exercise won't make you lose weight, even though I've been an athlete my entire life and it's never helped me. So it's fair to say that when I wrote that New York Times article five years ago, I had an entirely different conception about the causes and cures of obesity and overweight. Carbohydrates were key, but my understanding of the mechanisms was completely different. That's the kicker with research and reporting: you don't know what you'll find until you do it.

---

Timothy Beneke (2008-01-04 20:07:56)

First, a huge thank you to Gary Taubes! He's opened my eyes more than once. But, regarding high-fructose corn syrup; the obvious issue for anyone who as lost weight using Seth's ideas - through bypassing taste, or eating weaker tasting foods: Was it the biochemical effects of the added sugar or the enhanced flavor effects that led to the obesity epidemic? I was shocked 2 years ago when I sampled junk food - chips especially - after years of not tasting them and saw how rich-tasting they were. We need a history of taste strengths in the US and rest of the world in the last 30 years. And don't forget all those swell Flavor Chemists(<http://www.flavorchemist.org/>) who are working studiously to enhance the taste of foods. Did their influence grow in the 70s? (I hope to test whether the low-carbs effect on weight loss is really a weak-taste effect by seeing if I can lose more weight consuming a low carb diet free of taste than I have on a high carb taste-free diet. My first attempt failed because I could not go tasteless on the low-carb mush - but I may have had too much protein and not enough fat.)

Di the Colon Cleanse Buff (2008-01-05 13:14:14)

Great post enjoyed reading the decade of info. Still think the most important change we can make is to decrease our simple carbohydrates completely. If we only choose whole grains products and complex carboydrates we wouldn't see those insulin spikes. Thanks for your info.

Cynthia1770 (2008-01-06 00:08:03)

re: "It (HFCS) is effectively identical to sugar, as far as the body is concerned" The chief difference between sucrose and HFCS is that sucrose is a disaccharide and requires the enzyme sucrase to cleave the molecule into its component sugars. Anytime you have enzymatic catalysis you have regulation at the site of the chemical reaction. In contrast, HFCS is just a mixture of fructose and glucose, and therefore the sugars are delivered directly to the bloodstream. Secondly, HFCS 55, the sweetener used for every national brand of non-diet soda is 55 % furtcose:45 % glucose. Although the Corn Refiners Assoc., claim that it is "very similar" to sucrose (50:50), this is patently misleading.  $55/45\% = 12.2\%$  excess fructose in every can of caloric soda. It is the fructose moiety that causes long term health hazard leading to lipidemia and heart disease; hyperinsulinemia and Type II diabetes. Considering that the average teen chugs one or two cans of soda a day that is a lot of excess fructose that the liver is forced to metabolize. No, as far as the body is concerned the industrial sweetener HFCS and sucrose are quite different. Why

is it that in France Coke, made with real sugar is still served in 6 oz glass bottles (quite refreshing) and in the US Coke is only sweetened with HFCS and we guzzle liters. Is it because HFCS is so inexpensive that we are awash in the sweetener or are the inherent differences, unbound sugar molecules and sugar ratios yielding >10 % excess fructose causing our obesity epidemic. I'll put my chips on the latter.

Seth's blog » Blog Archive » Interview with Gary Taubes (directory) (2008-01-07 03:35:34)  
[...] Interview with Gary Taubes (part 3) [...]

Bob (2008-01-07 09:49:59)

I was very tempted to read the book because I like the way that the author thinks. However, I've just read a few reviews on Amazon. People who've read the book are repeating the very misleading saw that refined carbs are high GI and whole grains are not. Does the author really think that? The truth is far from such a simple analysis, just as was the earlier misconception that simple carbs are high GI and complex carbs are low GI (which even some doctors still believe). Well, table sugar actually is medium GI (requiring a multistep enzymatic reaction to convert the fructose to glucose, as mentioned above). Table sugar is bad in a lot of ways, but it's not high GI. Glucose = 100 and fructose = 20, and so it's no surprise that sucrose is in the middle, roughly at 60. Brown rice is not much different than white rice as a general rule - it's the type of starch (amylose vs amylopectin) that matters. So Uncle Ben's converted rice is better than a high GI brown rice. Most whole wheat breads are not much better on GI than white bread. But \*coarse\* grain bread is lower GI. Most whole wheat breads are fine milled. White spaghetti will beat the pants off most any whole wheat bread or brown rice, because it's durum semolina wheat. Prunes are good (because of the soluble fiber), but raisins are not. Most of this is counter-intuitive. [Note that all of this has to do solely with the narrow field of GI, and not with any other health consideration such as benefits of fiber or phytochemicals, or other valid considerations such as dangers of high blood fructose levels or glycation or whatnot.] So, to bring it all back to the topic, those misconceptions about GI represent yet another area where the established "knowledge" is wrong. Anybody with a glucose meter can observe that.

greigt (2008-01-12 03:56:09)

Bob read the damn book and stop relying on others to inform you. That's what's wrong with us all in the first place we place trust in the info. we are given to be true and it's not in most cases! This book hasn't got much on the GI at all, I've read it 3 times over now and still dip into it for information. It is a fantastic read and the first part of the book about the history of nutrition is worth it by itself. I never use the GI, eating is simpler than that, and Gary Taubes emphasises this with the statements near the end of his book.

## Worried About Prostate Cancer? (2008-01-04 18:17)

Many studies have linked dairy consumption with an increased risk of prostate cancer. Two studies in a recent issue of the American Journal of Epidemiology looked at this connection in detail and reached the same surprising conclusion: it's low-fat dairy that is problematic. Here are their abstracts:

High intakes of calcium and dairy products have been suggested to be related to prostate cancer risk. Such associations were examined in the Multiethnic Cohort Study (1993–2002) among 82,483 men who completed a detailed quantitative food frequency questionnaire. During a mean follow-up of 8 years, 4,404 total cases of prostate cancer were identified. In Cox proportional hazards models, no association was found between calcium and vitamin D intake and total, advanced, or high-grade prostate cancer risk, whether for total intake, intake from foods, or intake from supplements, among all male participants or among nonusers of supplemental calcium. No association of calcium or vitamin D intake was seen across racial/ethnic groups. In analyses of food groups, dairy product and total milk consumption were

not associated with prostate cancer risk. However, low-/nonfat milk was related to an increased risk and whole milk to a decreased risk of total prostate cancer; after stratification, these effects were limited to localized or low-grade tumors. Although the findings from this study do not support an association between the intakes of calcium and vitamin D and prostate cancer risk, they do suggest that an association with milk consumption may vary by fat content, particularly for early forms of this cancer.

Calcium and dairy foods in relation to prostate cancer were examined in the National Institutes of Health (NIH)-AARP (formerly known as the American Association of Retired Persons) Diet and Health Study (1995/1996–2001). Diet was assessed with a food frequency questionnaire at baseline. Multivariate relative risks and 95 % confidence intervals were estimated by Cox regression. During up to 6 years of follow-up (n = 293,888), the authors identified 10,180 total prostate cancer cases (8,754 nonadvanced, 1,426 advanced, and 178 fatal cases). Total and supplemental calcium were unrelated to total and non-advanced prostate cancer. However, a statistically nonsignificant positive association with total calcium was observed for advanced ( $\approx 2,000$  vs.  $500 < 750$  mg/day: relative risk (RR) = 1.25, 95 % confidence interval (CI): 0.91, 1.71; ptrend = 0.06) and fatal ( $\approx 1,000$  vs.  $500 < 750$  mg/day: RR = 1.39, 95 % CI: 0.92, 2.09; ptrend = 0.10) prostate cancer. Skim milk, but not other dairy foods, was associated with increased risk of advanced prostate cancer ( $\approx 2$  vs. zero servings/day: RR = 1.23, 95 % CI: 0.99, 1.54; ptrend = 0.01). In contrast, calcium from nondairy foods was associated with lower risk of nonadvanced prostate cancer ( $\approx 600$  vs.  $< 250$  mg/day: RR = 0.82, 95 % CI: 0.68, 0.99; ptrend = 0.04). Although the authors cannot definitively rule out a weak association for aggressive prostate cancer, their findings do not provide strong support for the hypothesis that calcium and dairy foods increase prostate cancer risk.

Emphasis added. The differences between these two abstracts should interest people trying to learn how to write abstracts.

Richard Tamesis, M.D. (2008-01-06 03:39:29)

All that sugar in low fat or skim milk is feeding prostate cancer cells.

seth (2008-01-06 05:35:07)

You seem to be saying that people tend to consume the same number of calories of skim milk and whole milk and that the skim milk has a larger fraction of those calories as sugar. Very interesting idea.

Adam Becker Sr (2008-01-10 22:34:39)

Interesting, but. Observational data are like captured soldiers. If they're not confessing \what you want to hear, you can always torture them some more. Remember, it's an \*observational\* study (or a meta analysis of many observational studies.) Observations like this are excellent starting points for intervention studies (either animal or human.) Till then, apply grains of salt liberally.

Anna (2008-03-25 12:41:50)

I think there is a transcription error in this section of the interview. I think there are two separate incidences far down in the interview where insulin-resistant should really be insulin-sensitive. I noted them below in these: "TAUBES What I ask when I talk with these people. What I say is: Look at the regulation of fat tissue. The question is, how can you lose weight, or gain it — how can you gain weight without either increasing insulin secretion, or increasing the relative insulin sensitivity of the fat tissue to the muscle tissue. Basically, the way we work, at least if you believe the biology that I describe, is that as we secrete insulin in response to the carbohydrates we consume and the insulin works, among other things, to facilitate the movement of glucose into the cells of your muscles and other lean tissues. But blood sugar is kind of toxic, so your muscle tissue doesn't want the insulin pushing all this blood sugar in, and it becomes insulin resistant. Your fat tissue now remains , because your body doesn't like to waste fuel. So if you eat a high-carb diet, your lean tissue takes up some of the glucose for fuel, and the rest gets dumped in your fat tissue, and your fat tissue remains for a long time — far longer. Because once your fat tissue becomes insulin resistant, then you just become diabetic; you have no place to put the glucose. You just pee it out. That's the last resort, because your body doesn't want to waste fuel."

seth (2008-03-26 05:26:57)

## A Different Sort of Scientific Progress: Toward Utility (2008-01-05 16:41)

From a [1]excellent column by Tim Hartford:

Esther Duflo, a French economics professor at MIT, wondered whether there was anything that could be done about absentee teachers in rural India, which is a large problem for remote schoolhouses with a single teacher. Duflo and her colleague Rema Hanna took a sample of 120 schools in Rajasthan, chose

60 at random, and sent cameras to teachers in the chosen schools. The cameras had tamper-proof date and time stamps, and the teachers were asked to get a pupil to photograph the teacher with the class at the beginning and the end of each school day.

It was a simple idea, and it worked. Teacher absenteeism plummeted, as measured by random audits, and the class test scores improved markedly.

Another young economist, Ben Olken of Harvard, used a similar randomisation technique to work out whether corruption in Indonesian road-building projects was best fought top-down, using audits, or bottom-up, soliciting comments from local villagers about whether money was being embezzled. One challenge was to work out how much embezzlement was taking place. Olken enlisted engineers to take samples of the road's structure and to estimate how much it should have cost to build; he compared that estimate with how much spending was claimed in the project's accounts. The missing funds were a rough guide to the amount embezzled.

In contrast to Duflo's results, Olken found that the bottom-up monitoring was not effective – it shifted the embezzlement from something the villagers cared about (wages) to something they did not (building materials). The threat of a guaranteed audit – a threat that was later carried out – was much more effective, reducing the estimates of missing funds by a third.

[2]A chapter in *The Theory of the Leisure Class* by Thorstein Veblen is about academia and the tendency toward uselessness, which Veblen explained as a way of signalling that one doesn't need to work. As a general rule at research universities, useful = low status. A few years ago, I had lunch with an engineering professor. By far the most useful thing to come out of the UC Berkeley Electrical Engineering Department in the last 20 years, he told me, was a circuit analysis program ([3]SPICE). Used everywhere. A big contribution to the field. Who did it? I asked. He didn't know. That's how low-status it was – no professor wanted to be closely associated with it.

The curious thing about the two examples that Hartford describes is that they are happening at the same time. Is this a coincidence? Or is there an explanation?

[4]Peter Pronovost's research on ICU checklists is far more useful than one would expect from a medical school professor; likewise my [5]self-experimentation about everyday problems (e.g., poor sleep) was far more useful than one would expect from a psychology professor. So perhaps there is some sort of larger discipline-spanning force at work.

David (2008-01-06 09:44:54)

The two examples cited are part of a trend in economics to use field experiments to evaluate policy alternatives in developing countries. These techniques are also used to study more abstract, fundamental questions about economic behavior. The individuals mentioned are both part of the Cambridge, Mass. development economics communities and are stars in the field.

## Jonathan Schwarz, Philosopher of Science (2008-01-05 23:41)

In his [1]New Year's Resolutions, Jonathan Schwarz vowed to "accentuate the positive":

At all times in history, there have been zillions of people doing wonderful things with little recognition. 99 % of the attention goes to various monsters. Even when the attention is extremely negative (i.e., people like us yowling about Dick Cheney or Thomas Friedman) it suggests the monsters are the only ones doing anything important, and the rest of us have nothing better to do than talk about them.

This is empirically wrong. And it saps our capability for independent thought, because it orients us toward reacting to the powerful, rather than acting ourselves.

This is especially pernicious in a period when technology is opening up ways to build new and better institutions. While I understand the visceral appeal of dumping a bucket of pig excrement on Fred Hiatt, this takes time away from what will have a longer-term impact: nurturing our own fledgling efforts.

This is similar to [2]what I wrote – in the context of a NY Times review of a book about "pseudoscience" – about skeptics being a dime a dozen and what's really lacking is sophisticated appreciation.

## Interview with Gary Taubes (part 4) (2008-01-06 02:42)

INTERVIEWER I was impressed with the discussion in your book and lecture about obesity coexisting with poverty in all these different cultures and the implications of that. I'd never seen that before.

TAUBES I have this feeling, and I guess that all writers (or all neurotic writers) have to some extent, that my work is being ignored. It's my Rodney Dangerfield complex. Now that I've written the book, I occasionally get emails from friends saying that they had some discussion with some obesity researcher, and they said, "Are you going to read Taubes's book?" and their response was "Well, we know what Taubes thinks, so why should I bother reading the book?" What's more, the Atkins craze has come and gone, so these people believe it's old news. Why should they pay attention to the book or what I might have learned in reporting it? In fact, I got more reviews for my cold fusion book than I have for Good Calories, Bad Calories. And The cold fusion book came out three years after the fact. There was also this sense that my article started an Atkins craze, and then Atkins Nutritionals declared bankruptcy, and somehow it all went away, and it's just the same old diet crap that nobody wants to hear about.

Nobody is going to stay on the Atkins diet so who cares? Let's move on. The lecture you heard is an attempt to combat that attitude: I argue that the existence of these obese, impoverished populations living on high carbohydrate diets are counter-examples to the conventional wisdom. As I said in my talk, if you have an obese mother and a malnourished child living in the same family, and this is a common phenomenon, that should be perceived as a refutation of the calories in/calories out hypothesis. In any sort of healthy scientific endeavor, that's the kind of paradox you look for. Physicists have recently spent a few billion dollars building an accelerator that will, they hope, produce some kind of phenomenon that they can't explain by their current theory. If they get that, it's front page news and they now have some observation that they can use to improve their theory. These obesity researchers, they have malnutrition and obesity coexisting in the same impoverished population, and they don't see it as a challenge to their hypothesis. How do I get the word out that there are important issues here that have to be discussed? That's what that lecture is intended to do. When [the New York Times reporter] Gina Kolata reviewed my book in the New York Times Book Review, she swept right over these issues. She went right to the thing that bugged her – why don't people stay on these low-carb diets? – and ignored all the evidence that refutes the conventional wisdom about why we get fat. All she cared about in the end was why don't people stay on these diets if they work.

INTERVIEWER As if that's your fault! I thought that was a very unusual way to review a book.

TAUBES Well, she had written her own obesity book that came out five months earlier, and she blamed obesity, in effect, on genes, without bothering to acknowledge that the genes interact with the environment; we have an obesity epidemic; we have obesity associating with poverty, for instance, so there's obviously some lifestyle factor.

INTERVIEWER And obesity's gone way up in the recent past; it can't be genes.

TAUBES I felt her review was her way of saying "Look, this is why none of the stuff he discusses was in my book." One point I make over and over again is that obesity is a disorder of excess fat accumulation, so you have to look at the hormonal regulation of fat tissue. If you're discussing growth disorders – gigantism or dwarfism – you look at the hormonal regulation of growth. So why not do the same in obesity. Gina didn't, because nobody she interviewed brought it up. Then she turned her review of my book into an excuse for why she didn't mention any of these things. Anyway, that's life in the publishing industry. If you think about it too much, you just get angry.

[1]Interview directory.

1. <http://www.blog.sethroberts.net/2008/01/05/interview-with-gary-taubes-directory/>

---

Richard Tamesis, M.D. (2008-01-06 03:35:08)

Excellent interview! I just hope someone at the NIH will at least consider the alternative hypothesis presented in his book and fund a modest study to actually test the two hypotheses and settle the question of what makes us fat once and for all.

SusanJ (2008-01-06 14:36:33)

Thanks for the link to Taubes lecture (which was great) and also for the excellent interview. I've got his book on order. Meanwhile, is there a short answer to the question as to why Taubes' theory doesn't violate conservation of energy?

David Brown (2008-01-06 16:52:24)

Susan J, The short answer as to why Taubes' explanation of the disconnect between caloric intake and weight gain or loss involves two observable but difficult to measure phenomena. One is caloric excretion and the other is metabolic adjustment.

The body is not anywhere near 100 % efficient at absorbing calories from the gut. Also, the body will build or tear down organ tissue, muscle tissue, and brown fat tissue depending upon how completely and consistently its nutrient needs are being met. For further discussion I suggest you Google "calorie excretion" and "brown fat tissue."

David Brown (2008-01-06 16:57:47)

Correction: I meant to say The short answer as to why Taubes's explanation of the disconnect between caloric intake and weight gain or loss doesn't violate any physical laws of nature involves two observable but difficult to measure phenomena.

Stephen M (Ethesis) (2008-01-06 17:26:13)

Susan, the short answer is that his bottom line doesn't. It is like the SLD. Sure, I take in about 300 additional calories a day in extra light olive oil - but, I went from eating 5000 calories a day to eating less than 2000. So, a lot more went on that the part where I added calories (or, perhaps better said, the part where I changed some of my calories). Taubes comments merely point to retention and metabolism. Many people, with certain diets, will have their metabolisms alter. Kind of like saying, eat fat, your thermostat will be set to 80 degrees, eat carbs and your thermostat will be set to 60 degrees. (Speaking by analogy, but I would notice dramatic crashing of my metabolism on some diets. If I'm eating 1600 calories and using 1200 a day, I'll gain weight. If I eat 1800, but use 2000, I'll lose weight).

Wade (2008-01-06 20:10:52)

> Meanwhile, is there a short answer to the question as to > why Taubes's theory doesn't violate conservation of energy? Mainly because the "calorie is a calorie" argument is based on some naive assumptions about the conservation of energy, and a misplaced ideas of causality. Your total weight is a function of the total number of calories you've ever ingested, minus all the energy that your body has ever used. The second part of that equation is highly variable, and in fact is part of the body's self-regulation mechanism (with or without a setpoint). The body has ways to use energy more or less efficiently. For example, it can reduce energy and movement to conserve energy, or fill you with nervous energy to consume excess energy. Both of these will change the number of calories required substantially without changing your weight, the same as if you moved to a warmer or colder climate. There are also simply differences in metabolic efficiency so that some calories can be used more efficiently than others. What that means is that the idea that your weight is directly related to total caloric input minus total output, but it's not helpful because there are a bunch of other factors that have to be ignored to make the case that all weight loss must be from calorie restriction, or that reducing one kind of calories is the same as any other kind of calories. That's the Cliff's Notes version anyway.

SusanJ (2008-01-06 20:35:42)

Thanks. As a scientist, I was persuaded by the data Taube showed but didn't know the explanation. For an amusing recent paper that uses "energy balance" to [mistakenly, I believe] conclude that the reason low calorie diets don't work can only be that people don't really stick to them see Heymsfield, et. al, <http://www.ajcn.org/cgi/content/full/85/2/346>

Bob (2008-01-06 23:01:48)

As I remember things (as a casual observer), the Atkins diet turned out to be a calorie reduction diet - since people got so sick of all the tasty fat after a few days that they ate less of it while pining for simple things like bread. (Besides which, the body seems to know that it needs carbs in order to completely metabolize fat anyway.) ...and despite the talk at the time in the popular press that serum cholesterol improved, it was really triglyceride levels that fell - which is no surprise since it is the carbs that are rapidly assembled into triglycerides/chylomicrons. ...and that much of the weight loss under strict Atkins in the first week occurs from water loss - since intra-muscular and hepatic glycogen storage is accompanied by several times its own weight in associated water. Has any of that been disproved? Also, just for the heck of it, I'd speculate that the main danger of sugars to waistlines comes because it is so eminently easy to increase calorie consumption with sugar. Even after everybody is absolutely stuffed at a big feast and can eat no more of the actual meal, out comes the desert and most people manage to pack in more calories. There really is always room for Jello... or ice cream or chocolate or whatever. Besides, between meals nobody chews on a stick of butter, but those extra calories in soda or candy go down almost without thinking. Sugars, or sugars and fat, are the easiest & most effective ways to increase calorie consumption.

Seth's blog » Blog Archive » Interview with Gary Taubes (directory) (2008-01-08 21:54:36)  
[...] Interview with Gary Taubes (part 4) [...]

Charles (2008-01-20 00:00:57)

Bob: Read the book. Your arguments are answered there. These were quite common, and mistaken, perceptions.

None Given (2008-02-03 21:47:27)

Yeah, I lost 70+ pounds of water, sure. The first few pounds lost from all diets is water because even the low-fatters cut back on sugar. You don't get sick of all the fat, after the first 2-3 weeks, more of your body's processes convert to burning ketones instead of glucose. Then you need less protein to fuel gluconeogenesis so you feel less hunger. Also, fast carb is addictive and after the worst of the withdrawal is over you just don't crave it like you may have before. Now I know what it feels like to not be hungry all the time. Triglyceride levels do fall and so does the amount of VLDL which in turn leads to larger LDL particle size. Also, HDL levels increase. My HDL went from 45 to 54 in a few weeks.

Migraineur (2008-03-20 09:58:19)

I wrote a couple of blog posts that address some of Bob's and Susan's questions about calorie restriction and water loss:  
<http://migraineur.wordpress.com/2007/11/11/calories-in-calories-out/> <http://migraineur.wordpress.com/2007/10/12/its-all-just-water/>

Sam S.R (2008-05-18 03:23:37)

We have hundreds of case studies to prove that carbohydrate consumption and ensuring high insulin levels are primary driver in obesity. I found Gary Taubes book to corroborate the observations we made during four years. We did gain one crucial insight also from his book. Gary says that carb consumption encourages the kidneys to reabsorb and retain sodium. We found that interesting because many obese femals have low blood pressure in the presence of poly cystic ovarian syndrome. The paradox was solved when we looked at homestatic mechanisms in PCOS.

seth (2008-05-18 06:11:29)

If "carbohydrate consumption and ensuing high insulin levels are the primary driver in obesity" then how come I lost weight by drinking sugar water?

## **Interview with Gary Taubes (part 5) (2008-01-07 03:34)**

INTERVIEWER Well, I think your book is a great book, and I don't think its effect is limited to how many reviews it gets. What books do you think your book resembles? I think of it as a book showing that authorities can be seriously wrong, but what do you think?

TAUBES You know, I don't know, actually. I can't answer that question without sounding like a crazed egomaniac, so I won't. What the book does is try to explain why the paradigm of obesity and chronic disease has to change and then to offer the alternative paradigm. Although I don't use the word "paradigm" in the second half of the book, that's what it's trying to do. I want people to stop thinking about obesity as a disorder of overeating, calories in over calories out, and think about it as a disorder of excess fat accumulation. That's a classic paradigm shift, or at least so I think. I don't believe that you can understand obesity and its associated chronic diseases, without thinking of obesity fundamentally as a disorder of excess fat accumulation and asking this question: what regulates fat accumulation? That's going to be the thing that tells you what the cause of obesity is. If it's a paradigm shift, then you have to ask yourself how many paradigm shifts are there like this, and what kind of books have been written to directly shift those paradigms, and then I sound like I have some serious ego problems.

INTERVIEWER Then let me put the question differently. I think your book piles up an enormous amount of evidence that is hard to refute. The cumulative effect of all that evidence is not that weâ€™ve been lied to, of course, but that weâ€™ve been misled, badly misled, about something thatâ€™s really important, namely our health. So, are there other books like this?

TAUBES I really canâ€™t answer that question either. Iâ€™m not erudite enough and then I spent the last five years doing nothing but reading about fats and carbohydrates, so my memory of other subjects fades away. Hereâ€™s how I think of it, though: when I was talking with my editor about this book when we in the editing process – and heâ€™s a tremendous editor, who has edited maybe eight or nine non-fiction Pulitzers – I brought up a book called *Ashes to Ashes* as an example. *Ashes to Ashes* is by Richard Kluger and it won the Pulitzer and my editor edited it. Itâ€™s about the cigarette industry and not just the industry itself, but the science and the struggle to understand that cigarettes cause lung cancer. I said to my editor, â€œImagine if we lived in a world where the public health authorities were telling us that lung cancer is caused by saturated fatâ€. Kluger has got to write a different book, and thatâ€™s the situation that we are in.

INTERVIEWER Kluger has got to write a longer book? Was that your argument?

TAUBES Heâ€™s got to write a different book. His book was actually longer than mine, but it was a narrative, which mine isnâ€™t. If youâ€™re going to convince the entire public health community that theyâ€™ve made a horrible mistake – or many of them, in this case, whether about cigarettes or obesity and disease – then you have to build an argument as carefully and as rigorously as you can. Itâ€™s like arguing a legal case, more so than telling a story. And thatâ€™s one of the reasons why my book can be difficult to read, or challenging.

INTERVIEWER I found it easy to read.

TAUBES Well, good. See, I read the Amazon reviews. I shouldnâ€™t but I do. And for every three people who say itâ€™s tremendous, thereâ€™s somebody who says â€œItâ€™s boringâ€ and they couldnâ€™t get through 20 pages of it. One problem is that we gave it this diet-like spin, with the title *“Good Calories, Bad Calories”* and people buy it expecting a diet book. And itâ€™s not a diet book. I also have a lot of friends who tell me they bought the book and theyâ€™re jumping into it, and I never hear from them about it. It tells me, being a cynic, that they got to the section on VLDL and LDL or some such, and that was the end of that.

INTERVIEWER I think it has a lot of evidence. I think the book is harder to read than it might be, because you feel compelled to have a lot more evidence than usual, because youâ€™re saying something that everyone says is false. If what youâ€™re saying was more conventional or acceptable or went down more easily, you wouldnâ€™t need as much evidence.

TAUBES Well, thatâ€™s the thing. This is one of the ironies, again, of reviews like Gina Kolataâ€™s or some other that Iâ€™ve got. Theyâ€™ll say the bookâ€™s too long, it goes on and on, and then theyâ€™ll say â€œhe doesnâ€™t even mention X,” or â€œhe leaves out this evidenceâ€. Iâ€™m all too aware of the arguments I left out, the counter-arguments, the counter-counter-arguments, the counter-counter-counter-arguments. At one point I had a draft of the book that was 400,000 words, unfinished. For every section, like the section on salt and blood pressure, I would say â€œhereâ€™s why we believe what weâ€™ve come to believe. Hereâ€™s the counter-evidence implicating carbohydrates. Hereâ€™s how the authority figures treat that counter-evidence. Hereâ€™s why they can look at that evidence and think itâ€™s not a challenge to their beliefsâ€. And my editor, bless his heart, said â€œLook, you donâ€™t need this. If you get a chance to lecture on this material, then you can tell the people in the audience why their counter-counter-arguments arenâ€™t actually refutations of the carbohydrate hypothesis. You donâ€™t need fifteen different levels in the book.” But, youâ€™re right, Iâ€™m trying to convince people of something they donâ€™t believe. I was walking this tightrope between making it readable for the lay public, so that they could make their own decisions, and hoping that doctors, researchers, and authorities would read it, and they might say,

“Well, you know, Taubes has a point. Maybe we should take this seriously.” What I fear is that on one level, I lose some of the lay public, because it’s too difficult and advanced, and on the other level, the physicians and researchers aren’t going to read it anyway, because they don’t see that a journalist can tell them anything they don’t already know. And then there’s this effect where, after I challenge half a dozen of their most fundamental beliefs, and they’re only 150 pages into it, do they just burn out? The example that I use there is that if somebody came out with a really-well-reviewed book saying that extrasensory perception should be taken seriously as a scientific phenomenon, I wouldn’t be able to read it. No matter how good it was, or other people thought it was, I wouldn’t be able to read it. I might try, because I tell myself I have to be intellectually honest and rigorous, but I could imagine, after 50 pages, I’d just say “I can’t do it. Maybe he’s right, but I can’t process it. My brain won’t allow me to process what he’s saying.” I wonder if that’s going on here, too: “Saturated fat, OK, but salt, fiber? Give us a break.”

Dennis Mangan (2008-01-07 10:52:26)

Gary Taubes may be speaking in shorthand when he implicates “carbohydrates” in the genesis of obesity and disease, but it’s ludicrous to think that all carbs cause problems. The obesity epidemic is not, I submit, caused by a huge spike in broccoli consumption. Furthermore, as to looking at “calories in, calories out”, the plain fact is that calorie consumption in this country has increased non-trivially over the past 30 years, and calorie expenditure decreased.

Tom (2008-01-07 11:59:50)

It wouldn’t kill you to actually READ Taubes’ book, Dennis.

Varangy (2008-01-07 12:41:03)

@Dennis Check out the [1]Hyperlipid blog. Most notably this [2]post: *It is remarkably widely accepted that fruit and vegetables are good for you. Three a day, five a day, nothing but fruit and vegetables all day..... The problem is that all of the evidence of benefit is epidemiological, and **this never proves causation, merely association.***

1. <http://high-fat-nutrition.blogspot.com/>

2. <http://high-fat-nutrition.blogspot.com/2007/12/fruit-and-vegetables-re-post.html>

David Johnson (2008-01-07 19:33:54)

Who is to say that Dennis didn’t read the book? Everyone who has problems with this book is accused of not reading it—but the fact is, despite the mountain of tedious research he quotes, he has not laid out the truth. He’s chosen the studies that support his thesis—which he’s held for years, and for which he is paid handsomely—and ignored the studies that do not support his thesis. That is why not a single scientist in the field endorses this book. As we all know, Americans did not get fat eating whole grain bread and bananas—among the evil foods that Taubes sites. We got fat eating sweet, fat, calorie dense convenience foods—and not moving. If low carb diets work, they work because people can only eat a limited amount of fat and protein, and therefore decrease their total calorie consumption. That’s the truth, and that’s also the reason why low carb diets generally fail over the long term. (They do work for some people, as all diets work for some people—but not for most people.) The French, the Japanese, and the Dutch have very low rates of obesity, and each has a very high carbohydrate diet I know Taubes denies this, but this is absurd—anyone who has lived in France know they begin and end their day with bread. The Japanese eat large amounts of rice. The Dutch love their potatoes. These are starch lovers all, yet have very low obesity rates. Still, so many Americans believe what they want to believe—they WANT to believe that there is a conspiracy

of bad doctors and scientists making them fat—they want to believe that the French are thin because they don't eat carbs, when the real reason is because they walk everywhere, don't snack, and eat small portions. Taubes is brilliant in that he has caused so many people to let go of their common sense. He has actually convinced readers that exercise does not help maintain weight loss, that eating large quantities of fat is healthy, that calories do not count. But then again, Taubes went to Harvard and studied physics, of all things. He's a smart guy who knows how to spin a tale and make a buck. Good for him!

Tom (2008-01-08 00:11:41)

David, diatribes like yours are the reason Taubes took so many years writing his book, and why it's so damn long. You have spewed so much misinformation in that post, yet Taubes has deconstructed every hoary assertion in it. Read the book, and respond to the EVIDENCE. And the personal attack about "making a buck" is just asinine. No one writes an encyclopedic examination of the perversion of science to get rich!

Varangy (2008-01-08 01:06:40)

Wow. David, it sounds like you haven't read the book b/c Taubes very credibly backs up the fact **we don't know that:** *Americans did not get fat eating whole grain bread and bananas* "among the evil foods that Taubes sites. We got fat eating sweet, fat, calorie dense convenience foods" and not moving.'. He addresses most, if not all, your points either in the book itself or in subsequent interviews and presentations. You really should check it out. He might not be right (I personally think he is on to something), but he definitely employs reason and evidence in his arguments.

Dennis Mangan (2008-01-08 07:42:53)

Look at China: a diet based on rice; Peru, potatoes, West Africa, rice and sweet potatoes; India, bread and lentils; why aren't all those people fat, diabetic, and suffering from heart attacks? Oh, but it's "only" epidemiological evidence, of the sort that linked cigarettes to lung cancer. Correlation should make one suspect causation. That's the point of it.

Tom (2008-01-08 08:13:56)

Dennis, watch the video of Taubes that Seth linked to in an earlier post – Taubes discusses why this isn't so. He shows how a healthy, slender Native American tribe became horribly obese after the whites moved in and killed off the game the tribe had lived on for centuries. The tribe was forced to subsist on handouts of – surprise! – carbohydrates, and got massively obese. Once again, Dennis, Taubes exhaustively deconstructs all of these Vegan bullet points in *Good Calories, Bad Calories*.

michael vassar (2008-01-08 08:20:56)

It seems to me that the best format for this book would have been a hypertext. Then everything could have been left in without it becoming slow and pedantic.

Lancaster (2008-01-08 16:41:52)

White short-grain rice is not consumed bulk like potatoes or pasta. It is typically eaten as a side-dish to a high-fat, high-protein meal. A katsudon comes to around 1000 calories, of which less than a quarter is the rice. The rest comes from the deep-fried pork cutlet and egg. At least in Japan, this myth of "low fat" cuisine seems to be the product of cookbook authors writing for western audiences, not observations of what normal people actually eat. (Or how they eat—I seriously think chopsticks make a big difference.) White short-grain rice has no taste to speak of and is generally not consumed flavored. It does have a very definite "mouth feel." Eating it alone you quickly achieve a sense of "fullness." In fact, it would seem to meet Dr. Roberts' "tasteless calorie" criteria for appetite suppression. Moreover, the short-grain rice that predominates in Japan and China is an expensive source of calories. Before the 20th century, few farmers could afford to eat the rice they grew. Rice grown in Japan still costs twice what it does in the U.S., yet is being exported to China at extraordinary premiums.

Seth's blog » Blog Archive » Interview with Gary Taubes (directory) (2008-01-08 21:55:23)

[...] Interview with Gary Taubes (part 5) [...]

Lana Nelson (2008-01-09 20:48:09)

Dennis, Dennis, the highest rate of diabetes in the world is in India. The second highest rate of diabetes in the world is in China. People in India have been encouraged to replace their traditional cooking fat, ghee (clarified butter) with rape seed oil and to reduce the amount of oil used. They have no doubt been pressured to make other changes to their traditional diet as well. It would be interesting to know if they had such a high rate of diabetes in 1950 as they do now. For a country where half the country is vegetarian, reducing fat no doubt greatly increases carbs.

Gary (2008-01-13 09:35:05)

Dennis writes: "Look at China: a diet based on rice" I have a woman friend who grew up in Chunking, and was training for the Chinese gymnastic team in her adolescence. We spoke about my change to the paleo diet a while ago. I don't eat rice any more. I had this exchange in e-mail: "I see in my readings that many people ask why are Asians not obese and they eat all that rice, very high carbohydrate. I'm guessing that rice is eaten for sure, but what percentage of the diet is it, your best guess for the average person in Chun King? And is it white or brown rice?" "Yup, rice was considered fattening and it is known among athletes. The coaches often exclude white rice, or limit the quantity of it in players' diet. I think Asians are not fat partially due to the genetic reasons and also the food in Asian countries is still a lot more organic and balanced compare to the western diet where a lot of processed food is being used everywhere including home-cooked food. Carb is not all that bad if your meals are combined with vegetables and meat instead of white bread plus processed beef and processed cheese. Some crap is better than all crap I guess. As of percentage of the white rice, rice is the equivalent of bread in Western diet. I would say 1/3 of a meal on average?" There goes your "diet based on rice" canard. It's really a low-refined food diet. I disagree about the genetics, for as Taubes points out, Asians who adopt Western eating habits get fat too.

None Given (2008-02-03 21:58:28)

The French eat smaller portions because they eat more fat than Americans.

Migraineur (2008-03-20 10:14:28)

"The obesity epidemic is not, I submit, caused by a huge spike in broccoli consumption." Broccoli is very low in carbohydrates. "As we all know, Americans did not get fat eating whole grain bread and bananas" among the evil foods that Taubes sites." I did. Steel cut oats, one of the wholest of the whole grains, spike my blood sugar to near diabetic levels, even though I've never had a diabetes diagnosis. "Look at China: a diet based on rice; Peru, potatoes, West Africa, rice and sweet potatoes; India, bread and lentils; why aren't all those people fat, diabetic, and suffering from heart attacks?" There's at least one study - a correlation study, which means it is not the highest standard of evidence, but correlation studies are great for raising questions - that shows that the Chinese women who eat the most rice are most likely to be diabetic. (<http://weightoftheevidence.blogspot.com/2007/11/higher-carb-higher-gi-and-high-gl.html>) "Oh, but it's only epidemiological evidence, of the sort that linked cigarettes to lung cancer." I'm not quite certain about this, but I believe the epidemiological evidence that links smoking to lung cancer shows that smokers are something like 3,000 times more likely to have lung cancer than non-smokers. That means for every non-smoker who gets lung cancer, there are 3,000 smokers who get it. In dietary studies, you're hard pressed to find an effect that shows a 2:1 ratio. If you are studying 2 groups of 1,000 people, one on a high-fat diet and one on a low-fat diet, and 2 high-fat eaters kick the bucket and only one low-fat eater kicks it, that's not a very impressive correlation, is it? "Correlation should make one suspect causation." Yes, emphasis on *suspect*. But people in countries with more telephone poles have more heart disease than people in countries with fewer telephone poles. Do telephone poles cause heart disease? Weak correlations like the one I described above are good, at best, for generating hypotheses, but they don't prove anything.

Michael Cohen (2011-09-25 08:35:44)

I DID get fat eating whole wheat bread and bananas, as well as brown rice legumes and other fruits. I was a life long avoid-er of sugar, processed and refined foods. I avoided all dairy and fats as best i could especially saturated fats. Most of my calories came from whole grains and legumes. My job involved walking 3-5 miles a day and I was a competitive fencer and coach. In middle age I found myself 40lbs overweight with high triglycerides and cholesterol. I also developed severe GERD and arthritis in my neck and shoulders. My doctor a gastroenterologist was puzzled because my "low fat, whole grain" diet was supposed

to be an ideal one for health. All he could offer me was a lifetime of drugs like nexium, celebrex and statins. This was not acceptable to me and I started my own research. After reading Taubes GCBC and other books and articles I eliminated ALL grains, concentrated carbs and vegetable seed oils from my diet and increased the animal fats. The GERD disappeared in two days, the arthritis in ten days. So far i have lost over 25lbs without hunger or increasing my exercise.

### **"This is Not Science As We Know It" (2008-01-07 19:51)**

Therefore it must be wrong. This was the reaction of several prominent anthropologists when Chuck Millikan, a California policeman, wrote to them to ask what they thought of the aquatic ape hypothesis, according to [1]Elaine Morgan. Millikan was "a compulsive letter-writer," said Morgan. He had been impressed by her ideas and wrote her to ask when her next book was coming out. There won't be a next one, Morgan had replied, I've said all I have to say. Millikan's response to this was to write prominent anthropologists asking them what they thought of her theory. When he sent Morgan their replies, she saw they had no good reasons for ignoring her. Emboldening and irritated, she wrote another book.

Let me invent a verb: to elaine morgan something is to have a big effect on something you shouldn't have been able to influence. Elaine Morgan elaine morganed the study of evolution. She was far outside anthropology; she shouldn't have been able to successfully promote a radical new view of evolution, but she did. Chuck Millikan elaine morganed Elaine Morgan; he shouldn't have been able to persuade her to start writing again, but he did.

A excellent BBC documentary about the aquatic ape theory ([2]part 1 of 6).

Chris (2008-01-08 06:54:57)

I read on of Morgan's books years ago, and she struck me as a truly original thinker, another Jane Jacobs. I expect that the aquatic-ape hypothesis will eventually accepted in some form. Looking around the web, it seems that Morgan is a pariah in academic circles, and has suffered for this emotionally. Some academics seem to feel almost a revulsion for her. I'm not sure why. The cheerful, commonsense tone her books radiate may drive some batty; perhaps they prefer things mysterious and deep. Sometimes she gives the impression of throwing every conceivable scrap of evidence into her argument, which is a hallmark of crank arguments. She sometimes has gotten emotional in her online responses - that's hardly unusual for academics, but is especially damaging for people who already carry the stigma of crankdom. But in the end I think it comes down to her lack of academic credentials and the fact that she is challenging a hegemonic theory. Other examples occur to you no doubt.

anthrosciguy (2008-01-11 06:59:36)

The reason academics didn't take to Elaine Morgan's ideas, and to her to some extent, is that they don't tend to like ideas, and people, which depend on distorting what people say, claiming they said the opposite of what they did, people who alter quotes to suit their purposes, people who use bogus claims as data. All this describes her methods in her books and articles, and much of it describes all the work done by AAT proponents. My site, [1]Aquatic Ape Theory: Sink or Swim?, has many examples of these and other problems with the AAT in its various forms. Chris, it's ironic that you compare Morgan to Jane Jacobs because Morgan also wrote a book following Jacobs' thesis, and it really shows the difference between the two. Jacobs was a brilliant thinker who had original and thought-provoking ideas, Morgan's book was merely a weak imitation of Jacobs' work. Sad, really, because Morgan is a talented TV writer, but falls down badly when she stretches outside it.

1. <http://www.aquaticape.org/>

DDeden (2008-01-14 23:18:06)

Seth, she certainly did. So did Chuck.

### Interview with Gary Taubes (part 6) (2008-01-08 21:53)

INTERVIEWER When I started your book, I already kind of believed all of your main points. Not all of them, but I was sympathetic. I knew where it was going. I thought "œOh, good. More evidence. This is interesting, and that's an interesting way to tell that story".

TAUBES The way I see it is that the establishment has an immune system to protect itself from challenges. Every science needs that kind of immune system to protect itself from quacks and easy-to-swallow but erroneous ideas that might infect the good science in the field. My question is whether I can infect enough people, enough serious scientists, that I can pose a threat to this immune system, that I could compromise the immune system of the establishment and make them take this idea seriously. Because some times these immune systems work against challenges that are legitimate. I honestly don't know if I can. It's going to be an interesting year. I hope I don't become one of those bitter old men who, when I fail to do so, who can't let it go.

INTERVIEWER How did you end up giving your recent [1]talk at Berkeley? Obviously someone in the establishment was willing to invite you?

TAUBES Yes. It was actually epidemiologists at the School of Public Health who invited me initially to talk about epidemiology after I had a cover story called "Unhealthy Science" in the New York Times. I told them that the subtext of that story was my book. If what I say in the book is correct, then an observational epidemiology has done an enormous amount of damage. One line that was taken out of the New York Times article said that this was a story about the risks and benefits of observational epidemiology. There are certainly some successes in that endeavor, but if we're living through an obesity and diabetes epidemic because of its failures, then it's conceivable that more people have died because of observational epidemiology than have been saved. You always have to look at the negatives, the false negatives and the false positives. You can't just look at the true positives and say that this is a valuable field of science. We're digressing again, but the game of poker is relevant here. Are you a poker player?

INTERVIEWER I've played a lot of poker, yeah.

TAUBES Bad poker players base their methodology, their strategy, only on what happens when they win. They don't notice that that strategy is making them lose more money when they're losing than they win when they're winning. The best strategy, of course, minimizes the losses and maximizes the gains. But they don't think like that; the wins are so seductive that that's all they pay attention to. Anyway, getting back to the question, these Berkeley epidemiologists invited me to lecture on epidemiology; I said "œlet me talk about the book"; it gives me a chance to sit down and try to convince some unbiased observers, I hope, that their beliefs about calories-in/calories-out has to be questioned.

INTERVIEWER What effect do you think your lecture had?

TAUBES I don't know actually. I don't know how many of the people I was preaching to are already converted. I thought it went over well. I mean, I couldn't believe that I had spoken for almost two hours and had 90 % of the audience awake. There were a few people I lost (you know, you focus on the girl in the seventh row on the right, who's asleep). But most people seemed pretty attentive. But when I say I'm trying to infect others with these beliefs, if I convinced even a few of the faculty Berkeley that these ideas have to be taken seriously I've made progress. OK, now I've got a little infection growing at Berkeley. Indeed, I asked one of the epidemiologists who

invited me to e-mail, say, ten of his colleagues and say, "You should get Taubes to come lecture, because it's fascinating, and you might think his book is a little dubious, but when you hear his lecture, you'll see if it has any effect or if they've found it compelling enough that they went through with it. I hope so.

INTERVIEWER I'm just surprised that they found your book dubious. I think they might disagree with your interpretation of the evidence, but I don't think they would find the reporting dubious.

TAUBES I've got to get to the people who take this knee-jerk response that they know what I think, and they don't have to read the book. For instance, I had lunch with a Berkeley obesity researcher that I'd interviewed five years ago. We spent a couple of hours together five years ago and I sent him a copy of the book when it came out.

INTERVIEWER Who is this?

TAUBES A guy named Marc Hellerstein. He's a runner and, of course, he believes that sloth is the cause of overweight. He joined us for lunch on Wednesday, but he didn't eat, and I had about 35 minutes to try and convince him to read the obesity section of the book. The way he sees it, he's got a lot to do; he's a busy man, doing all of these experiments, trying to get funding, what could he possibly learn from reading the book and it's a big book? So I was basically sparring with him for 35 minutes trying to inflict enough damage that he might conclude that he might actually learn something about his own subject of expertise if he reads it. And he actually said "OK, OK, OK, I'm going to read it, I'm going to read it." (If he does, I'd be surprised, because after the lecture I e-mailed him a few follow-up notes, and he never bothered to respond.) I believe his initial response is probably common among obesity researchers, and even if they're tempted, they first have to wade through 200 pages on chronic disease that try to convince them that everything else they believed is wrong. The exceptions are those people like you, who already had reason to agree with me.

[...] Interview with Gary Taubes (part 6) [...]

## How Much Fish Oil Should You Take? (2008-01-09 11:50)

A [1]WSJ article doesn't reach much of an answer:

Hardly a month goes by without a study suggesting that the omega-3 fatty acids in fish oil can fend off disease – including heart attacks, strokes, Alzheimer's disease, depression, rheumatoid arthritis, asthma, psoriasis and even attention-deficit hyperactivity disorder.

The problem is, to get the health benefits seen in clinical trials, you probably need to take fistfuls of capsules.

"The kind of benefits seen in most of the clinical trials with omega-3 generally have involved much higher

doses than you see recommended on supplement labels,” says Charles Serhan, a Harvard Medical School expert on omega-3’s activity.

Which raises a little-discussed point. For practical purposes, it’s not enough to show that a drug works; you also need to find out the minimum dose that produces near-optimal results. In layman-speak, you need to find “the right dose.” Studies that compare drug and placebo are no help; much better would be studies that compare dosages (e.g., Group A gets one dose, Group B gets a different dose).

Here are three more useful comments:

1. [2]I found that about 3 Tablespoons/day of flaxseed oil was enough to produce the best brain performance. As I’ve said, the amount that optimizes brain performance is likely to be a good amount for everything else. For the same reason that the best voltage pattern for your TV is likely to be a good voltage pattern for your other electrical appliances.
2. You can choose the minimum dose of fish oil that makes your gums perfectly pink. The transition from reddish gums (a sign of inflammation) to pink gums (no inflammation) takes about a week.
3. You can do mental tests to choose your dose, as I have done. The big problem here is practice effects – you will get better at the test just from doing it. So you will need several weeks of doing the test before the practice effects become small. You have to be a little bit sophisticated at data analysis – at least, able to plot your data – to take this approach.

In the future I can imagine people repeatedly measuring their mental ability with short (2-3 minute) tests, just as diabetics measure their blood sugar today.

Thanks to Santosh Anagol.

Loweeel (2008-01-09 13:06:00)

*For the same reason that the best electrical current for your TV is likely to be a good amount for your other electrical appliances.* Seth, let me preface by saying that I have an enormous amount of respect for you, love your writing, and think that you’re right over 99 % of the time. However, at least part of this statement isn’t one of them (as you don’t have a Physics/EE background). In fact, appliances DO NOT draw the same amount of current (i.e., electrons/second). What is standardized, at least from the outlet, is voltage, or at least the voltage pattern (120V, 60 Hz), which is roughly equivalent to the amount of momentum each electron has, or, to analogize to water flow, the vertical drop of the pipe in a section. Various appliances all have different wattages (e.g., Computer power supply at 300-500 W, Gen1 Foreman Grill at 1500, lightbulbs at their rating), but they achieve this by drawing different amounts of current at the given voltage, not by varying the current. So no, the amount of current that a TV requires will be vastly different than the amount of current that everything else draws – largely because power systems are designed to have a standard voltage and have the current be variable. It’s much easier to get more electrons when you

need them than it is to alter their potential energy. A TV will operate at the same voltage input as other appliances because they are all designed to operate from that 120V 60 Hz source voltage.

Loweel (2008-01-09 13:06:36)

"... not by varying the current" should be "not by varying the VOLTAGE and keeping the current constant."

seth (2008-01-09 13:16:29)

Thanks, Loweel. By "current" I meant "voltage pattern". I should have at least said "type of current" rather than "current". I will correct my post.

Varangy (2008-01-09 15:14:20)

*In the future I can imagine people repeatedly measuring their mental ability with short (2-3 minute) tests, just as diabetics measure their blood sugar today.* This is very thought-provoking. By what sort of mechanism do you posit this sort of testing?  
1) An automated test, similar to the ones you have experimented with? 2) A blood test to check for levels of XYZ?

seth (2008-01-09 18:41:39)

The test of mental ability would be automated. A series of problems, measuring how fast and accurately you response.

sj (2008-01-09 20:43:59)

i tried the flax seed oil Seth, I really did. It was awful - I felt as though I had just gargled furniture polish for 10 minutes after taking 1 tablespoon. I am using one that requires refrigeration - heard that is really the only way to get the "real benefit". Is your flax seed oil refrigerated? Is there a particular brand that has a more mild and tolerable taste? Otherwise I am going to have to bypass these benefits due to my gag reflex.

Doshia Wall (2008-01-09 22:14:41)

Texas Rep-Carlson Labs Is flaxseed oil a risk for men? Dr. Andrew Weil Calgary Herald Monday, June 18, 2007 CREDIT: Richard Arless Jr./Montreal Gazette Dr. Andrew Weil says men should avoid flaxseed oil, unless it has added lignans. Q: Several years ago you indicated that you do not recommend flaxseed oil for men due to potential for prostate tumour growth. Does this research still hold? A: Freshly ground flaxseeds are an excellent source of alpha-linolenic acid (ALA), a type of omega-3 fatty acid. The human body needs long-chain omega-3s (EPA and DHA), which are found in salmon and other oily, cold water fish. It can make them from ALA, but the conversion is not efficient and is inhibited further if the diet is rich in the omega-6 fatty acids, which are found in most vegetable oils and processed foods. As you know, omega-3s are associated with reduced risks of heart attacks and stroke and also may decrease the risk of macular degeneration (a leading cause of age-related blindness) as well as breast, prostate and colon cancers. If you don't like fish (and don't eat the recommended three servings of cold water fish per week), ground flaxseeds can help fill the gap. I recommend buying whole flaxseeds, storing them in the refrigerator and grinding a half-cup (125 mL) at a time in a coffee grinder. You can then sprinkle a tablespoon or two (15 to 25 mL) over salads, cereals or potatoes or add them to baked goods such as breads and muffins. In addition to providing some omega-3 fatty acids, flaxseeds are an excellent source of fibre, which helps prevent constipation, and of lignans, compounds with beneficial estrogen-like effects that offer protection against breast and prostate cancer. I often recommend supplementing the diet with fish oil as an omega-3 source, but I'm less enthusiastic about flaxseed oil. One tablespoon (15 mL) flaxseed oil daily will give you seven to eight grams of ALA, but little of that will be converted to EPA and DHA. Flaxseed oil spoils easily, so be sure to keep it refrigerated (it should be refrigerated when you buy it). If you notice that it tastes like oil paint, throw it away. Rancidity is oxidation, and oxidized fats are toxic. Although flaxseed oil seems to be safe for women, I still haven't seen any data showing that it is safe for men. In October 2004, Nutrition Journal published an analysis of nutrition and cancer. One meta-analysis included in that publication reviewed nine studies that revealed an association between flaxseed oil intake or high blood levels of alpha-linolenic acid and increased risk of prostate cancer. The author speculated that the lignans in flaxseed are a major component of its anti-cancer effects and that the lack of lignans in most brands of flaxseed oil may explain why flaxseed oil is not beneficial. Until we know more about the risk flaxseed oil appears to present, I recommend that men avoid it, or at least stick to brands that put the lignans back in. Flaxseeds, however, present no danger to men.

Timothy Beneke (2008-01-09 23:53:52)

SJ: I find Barleans quite tolerable, the high lignan kind. I just mix two tablespoons with about 3 ounces of water and put my tongue outside of the glass at the bottom and swallow it; then drink more water or have some tea to get rid of any lingering taste. The taste is not so bad anyway, but I want to do it tasteless, so I can get the benefit of calories without taste, and lower hunger levels. I have not done any precise self experimentation but I can say that I am quite happy with my mental abilities since I've been on it... And there seems to be powerful effects on my gums — this based on comments from my dentist and periodontist.

Stephen M (Ethesis) (2008-01-10 20:58:13)

"The test of mental ability would be automated. A series of problems, measuring how fast and accurately you response." There are game collections for portable game players (like the PSP) that are quite popular in Japan that are intended to improve mental acuity, but that would work well to test it. I'll note that the WSJ article noted that a fairly small amount of fish oil in elderly men protected brain function – about two capsules worth. Triglyceride suppression varies, some people are more sensitive than others. I dropped mine from 300 to 100 pre-SLD on a capsule a day for six months. Surprisingly, my mother on more, over a longer time, got much milder results (though measurable ones). For a humor article on Applied Nutrigenomics (the science of calculating how different people react differently to the same input) see: <http://www.t-nation.com/readArticle.do;jsessionid=F32229025A924E1A2D4F0469D93754FE.hydra?id=1885110> Ok, parts of the interview are serious, e.g.: "I first became interested in this field about 10 years ago, which is before the term "nutrigenomics" was actually coined. At the time, I was working on my PhD in nutritional sciences and was researching the effects of cholesterol on cancer using rodent models. One of my experiments gave totally unexpected results. In fact, they were completely the opposite of those published by other researchers. It turned out, however, that the strain of rat that I used metabolizes cholesterol quite differently than other strains that were used in previous experiments. The study design was virtually identical to previous ones, but the only real difference was the genetic background of the animals. I realized the importance of considering genetics when studying nutrition and it occurred to me that genetic differences between humans could also explain why some people respond differently than others." I'll have to look at the flax seed oil I bought, it hasn't resonated for me, so I've been just using the ELOO and taking a few grams of fish oil and flax oil with my vitamins, though I really enjoy the flaxseed bread I've taken to eating. I might try to find the seeds some place and eat them (or mix them into a morning smoothie).

Chris (2008-01-10 21:14:56)

I would try looking for Japanese Shiso (a.k.a. Perilla or Beefsteak) oil if you can't stomach flaxseed oil. The omega-3 levels are equivalent and the flavor isn't as strong. I've found it to be easier on the stomach as well.

Anthony (2008-01-11 00:59:24)

You can mix flaxseed oil with all sorts of stuff (two examples: yogurt and guacamole) if the taste bothers you. If you are trying to have it alone because of the SL diet, then I feel for you.

DdK (2008-01-11 01:05:17)

I take 'Udos choice' and mix it in a smoothie or some sort of vegi or fruit juice; and can't taste it at all.

Ruth Heasman (2008-01-12 04:48:45)

I use hempseed oil personally. And I try to take it tastelessly as per the SLD, but if you don't then I think it probably has a better flavour than flaxseed oil. As for the mental benefits of reduced inflammation, I can agree with that wholeheartedly. I have rheumatoid arthritis and so have high levels of inflammation on an ongoing basis. I've been playing the Nintendo DS brain training game daily recently and it graphs your progress. I've been altering my daily dose of prednisolone (a powerful anti-inflammatory) lately as I've been trying to taper my dose, and it's absolutely obvious that on my high dose days my brain training scores are higher and on my low dose days, my brain is functioning considerably less well, with lower scores. I received this gadget as a Christmas present, so this is a fairly recent discovery for me, but ties in with my subjective experience that my brain fog is significantly lessened when my arthritis is controlled. It sounds like common sense I know, but doctors don't tell you this. Also, I read an article this week that claims that etanercept (aka enbrel), an anti-tnf rheumatoid

arthritis drug, made miraculous improvements to an alzheimer's sufferer when injected into his spinal column. He went from not knowing the day or date, to knowing these things in under 10 minutes! Here's the link to the story on the BBC: <http://news.bbc.co.uk/1/hi/health/7179060.stm> So perhaps reducing inflammation in the brain is the key to improved mental ability, in healthy people as well as in alzheimer's and rheumatoid arthritis sufferers. And maybe in healthy people, a daily dose of omega 3 via flaxseed oil or similar is enough to do that.

### **Interview with Gary Taubes (part 7) (2008-01-10 03:24)**

INTERVIEWER I was a member of the Center for Weight and Health. But the other members didn't know what I was up to, and had no idea it could have anything to do with actual weight loss.

TAUBES That's one of the things I've found most amusing about obesity research, that you have this disconnect from pre-World War Two, when the people doing it were clinicians who were treating obese patients, to post-World War Two, where first, it's nutritionists, who do rat experiments. Then, by the 1960s, obesity is considered an eating disorder and it's being treated by psychologists and psychiatrists. So today, if you looking at some of the major obesity centers in the country — at Yale, at University of Cincinnati, they're all run by psychologists or psychiatrists. Here's a physiological disorder of the body, and it's being studied by psychologists and psychiatrists. They're not interested in anecdotal evidence, unless it agrees with their preconceptions.

INTERVIEWER In my department, we don't have any of that. Obesity is not handled much on the Berkeley campus.

TAUBES But think about it: it's a physiological disorder.

INTERVIEWER Well, hunger is controlled by the brain.

TAUBES I know, I know, but you know, diabetics get hungry. Type I diabetics are starving. Literally starving, without insulin. But it's not psychologists who treat diabetics.

INTERVIEWER I think that with Type I diabetes, you can say, "look at this problem; it's not in the brain". But I think with most obesity, it's not so obvious that the problem isn't in the brain. Sure, they're fat, but maybe they're fat because they're hungry too much. That could easily be a brain disorder. It could easily have something to do with the brain.

TAUBES It could have something to do with the brain, but the problem is in the body. This is the paradigm problem. If you just think of it as hunger, then

INTERVIEWER I'm not saying you just think of it as hunger, but you wouldn't want to rule it out.

TAUBES Yeah, I know. That's why the book is so long, because I'm trying to do it — I'm trying to say "Look, your fat tissue is trying to get fat. Hunger and gluttony and sloth are side-effects of what's happening at a hormonal level in your fat tissue."

INTERVIEWER Right. What effect did Weston Price have on you?

TAUBES Price was interesting. It's funny. He got cut from the book for reasons of length and narrative, but reading Price was a revelation to me, as I say in the acknowledgments. I think that Price should be required reading for every nutritionist in the world. And then, "Nutrition and Physical Degeneration" is a great read, as well.

INTERVIEWER How did you come to read his book?

TAUBES How did I come to Price? I don't remember, actually. Somebody in the field must have recommended him.

INTERVIEWER It was after your New York Times article?

TAUBES Oh, yes, definitely. I did not read Weston Price prior to that. I have to say, by the way, that I was trying to decide how much to believe of Price's stories. I decided that if his story about migrating, tree-climbing crabs in the South Pacific was true, I would believe everything Price said. This was my calibration. Because some of his stories are wild: about how pygmies, for instance, kill elephants by slowly hamstringing them over the course of a few days. Even with his photos as evidence, they're still hard to believe. So, anyway, this being the 21st century, I googled the tree-climbing crabs, and indeed, there are migrating, tree-climbing crabs in the South Pacific. The article I found didn't say whether the local natives hunted them by putting nets under the trees and making the sounds of coconuts falling, so that the crabs would climb back down into their nets, which is what Price wrote, but the crabs definitely exist. I decided that's it. As far as I'm concerned, Weston Price is an unimpeachable source.

INTERVIEWER That's good to know. I really like his work, too.

TAUBES And those photos of the teeth of populations that do and do not eat sugar and white flour. Compelling stuff. I have a 2 year old and I try to keep him away from sugar and white flour just because of Price's photos. And you know, in this day and age, it's not easy to keep a child away from sugar and white flour. But it's the photos in Price's book that keeps me motivated: we've got to survive in Manhattan on a science writer's salary. It would be nice to save the \$6,000 for braces, if I could keep him off sugar and white flour. I still don't understand how the sugar and flour can effect how the teeth actually grow in, but Price makes a compelling argument that they do.

INTERVIEWER There's disagreement about that. Weston Price thinks it's one thing. A professor in Illinois thinks it's that that people who eat the urban diets have soft food, and the people who eat the rural diets have chewy food. The chewy food makes the kids' jaws grow to be the right size.

TAUBES My problem with that is that he's making the assumption that the addition of sugar and flour removes some significant portion of the baseline diet. It could be true, but again, it's an extra assumption. Take the Inuits, for example: one of the things I did in the course of my research was try to refute this notion that cancer didn't exist in the Inuits until the 1930s. So I tracked down whatever memoirs I could find from physicians working with the Inuits to see if any of them mentioned cancer prior to the 1930s. And one of the things I found fascinating was that at the turn of the early years of the 20th century, the Inuit were eating mostly their native diet. By the 1950s, they were eating tons of sugar and flour and drinking beer and other alcohol, and tuberculosis had decimated them, but they were still eating their baseline diet; it's just that all these other things had been added on top. So they're still eating seal and whale and caribou, but they're also eating these Western foods. In general, it's never a good idea to add that extra assumption until you absolutely have to – that something else critical changes with the addition of sugar and flour. Maybe it's just the addition that's the cause. That's the one thing you know for sure that happened. This is Occam's Razor. The key thing is that cavities are caused by the sugar and flour. The simplest hypothesis is that the orthodontal problems are too. It is possible that the sugar and flour affect growth hormones – insulin-like growth hormone, for instance – which could have local effects on how the teeth grow in. The sugar and flour could affect bacterial growth locally and that could have some effect. Either way, I find the evidence sufficiently compelling

to wonder whether my son will grow up with nice teeth if he doesn't eat a lot of sugar and candy and white flour.

INTERVIEWER Changing the subject slightly, you mentioned that the obesity center at Yale is run by psychologists. Did you ever ask Kelly Brownell how he reconciles his toxic environment view with the fact that many people in poor countries are fat?

TAUBES Not yet. I would like to lecture at Yale some day, and I'm hoping that I don't have to invite myself. You know, I'm fairly confident that if I were to ask many of these people if they'd get me a lecture – call them and say I'd like to come and talk – they'd arrange it. They're intellectually honest enough on that level. But again, it's people like Kelly Brownell that I was thinking of when I was compiling that list of populations. And what boggles my mind is that people have been peddling this nonsense for 30 years, and they never bothered to look. They never bothered to do their research, to see if there was evidence that refuted their hypotheses. Again, this is what you do in science; you get a hypothesis, and you try to test it. So how would you test the hypothesis that prosperity causes obesity, or that our modern toxic environment, as defined by Brownell, is the cause. Let's see if we can find examples of non-toxic populations, you know, poor populations without McDonald's, without televisions, without remote controls, who are obviously physically active, at least by our standards. It's funny, I was talking with Hellerstein at Berkeley. When I told him about the Pima and the Sioux Indians, and he said "Well, do they live on reservations?" Like, if they live on reservations, then that means they're sedentary, at least relatively, compared to their previous lives, and so you can evoke sedentary behavior as the cause of their obesity. So now you have this idea that it's not how sedentary you are, it's how sedentary you are in comparison to how active you used to be. So like, Sioux Indians, who rode along the Great Plains and chased after Custer — they were so active that if they only have to move onto reservations and stop riding their horses all the time, they get obese. So it can actually be a detriment to be extremely active, because then being only mildly active causes obesity.

michael vassar (2008-01-10 07:47:54)

Does Gary read this blog? It's interesting to know that he's in NYC and I was wondering if he would be interested in getting together with some of us readers in the city some time to discuss his conclusions.

seth (2008-01-10 08:22:46)

Michael, I'll refer him to your comment.

Varangy (2008-01-10 13:22:14)

Seth, While you are it, would you mind seeing if he will be in Southern California anytime soon? The entire paradigm shift and how he applies his findings to his own life is absolutely fascinating.

Tom (2008-01-10 15:31:41)

Great interview, Seth.

Michael Blowhard (2008-01-10 17:02:25)

Great interview. Many thanks to both of you.

Stephen M (Ethesis) (2008-01-10 20:45:31)

I really enjoyed the interview segments, and I'll note his book is doing well enough that the used copies on Amazon have a price very close to the Amazon price – always a good sign as to actual demand.

Dennis Mangan (2008-01-10 22:27:25)

Pima Indians in Mexico have far less obesity and diabetes than their American cousins. "This preliminary investigation shows that obesity, and perhaps NIDDM, is less prevalent among people of Pima heritage living a "traditional" lifestyle than among Pimas living in an "affluent" environment. These findings suggest that, despite a similar potential genetic predisposition to these conditions, a traditional lifestyle, characterized by a diet including less animal fat and more complex carbohydrates and by greater energy expenditure in physical labor, may protect against the development of cardiovascular disease risk factors, obesity, and NIDDM." The Mexican Pimas' traditional diet largely consists of beans and corn, i.e. carbohydrates. If Taubes wants to say that white flour and sugar makes people fat, he ought to be more specific, because clearly not all carbohydrates have that effect, even when they make up 3/4 or more of calories. Sorry to rain on the parade.

Dave Lull (2008-01-11 06:19:02)

"You're not talking about a diet with no carbs, just a reduced amount?" [Gary Taubes]: The underlying philosophy is this kind of Paleolithic diet theory. It's what we ate during the 2 million years that we were hunter-gatherers on this planet. The fact that we were hunter-gatherers for 2 million years suggests it was an extraordinarily successful evolutionary adaptation. The question is: What did we eat during these 2 million [years] when we left the jungle, the trees, went down into savanna and started surviving on whatever we could hunt or gather? That's the philosophy. The answer is, probably considerable meat, very low glycemic index, hard-to-digest roots and starches, and fruits and berries that look nothing at all like the beautiful Fuji apples you can buy at your local market now. Some carbohydrates, but whatever it was, it wasn't refined. It wasn't sugar. It wasn't flour. It wasn't easy to digest. That's my going theory. If this theory's right, the diet we evolved to eat is probably the correct diet." Frontline interview of Gary Taubes: <http://www.pbs.org/wgbh/pages/frontline/shows/diet/interviews/taubes.html>

taubes (2008-01-11 10:40:39)

Dennis, To echo several other comments, Taubes (again speaking pretentiously in the third person to identify the author) thinks you'd benefit by reading the book. Taubes is always specific about the type of carbohydrate he's discussing – often to the point of slowing the narrative to a crawl – because such specificity, as Dennis notes, is critical to understanding what might be happening in these populations. That said, the argument is that the quality and the quantity of the carbohydrates have to be taken into account (which you would know if you read the book.) as well as the time that a population has had to adjust to carbohydrates in new forms. It could be true that the difference between the two Pima population is that the Mexican Pima eat less animal fat, more complex carbohydrates and expend more energy, as the NIH report suggests. It could be true that the relevant factors are that they consume far less sugar, and less refined easily-digestible carbs, in which case any differences in animal fat consumption and physical activity would be canards. This is why observational studies are so difficult to interpret. They don't tell you what factors cause the difference in disease rates, only what factors differ between the populations. And if the researchers have blinders on, as the NIH researchers in this case did, they don't even tell you all of those. Only those that the researchers chose to look at the time. My advice: read book first, rain on parade second.

Lancaster (2008-01-11 11:55:36)

No one argues that low-fat, high-carbohydrate diets don't "work." Only that they require great discipline to be effective. In large parts of the world, this discipline continues to be supplied by scarcity and work. In economic terms, the steep marginal costs in time, money and labor of each additional calorie. That marginal cost in the U.S. is the lowest in history—close to zero—which is why it is so profitable to "supersize." However, the modern high-carb, high-calorie diet is a quirk created only in the last century or so. Prior to the mechanization of agriculture, processing grains into food took enormous amounts of time and labor. Grains stores had to be rationed or people starved. One hard drought and you were all dead. Even avid gardeners don't plant rice or wheat as a hobby. People plant corn as a hobby, but not to eat as corn meal. (Modern sweet corn is organic candy.) People bake bread, but few in the first world grind flour from wheat and bake a half-dozen (big) loaves a week (like my parents did, though they did use an electric grinder). Because it's hard, time-consuming work. Especially without the electric

grinder. I believe the hundred-thousand years of human evolution prior to the agricultural revolution programmed a simple instruction into the metabolism: "If you encounter a carbohydrate surplus, rather than letting it go to waste, chow down and convert into fat, because it comes dear and won't last."

Tim Lundeen (2008-01-11 12:09:26)

Great interview series, thanks! The Weston A Price Foundation web site is at <http://www.westonaprice.org/> and is a good resource. And I just ordered a copy of Nutrition and Physical Degradation :-)

Varangy (2008-01-11 16:11:45)

Kudos to Seth for giving space to Taubes' ideas.

Seth's blog » Blog Archive » Interview with Gary Taubes (directory) (2008-01-11 16:39:45)

[...] Interview with Gary Taubes (part 7) [...]

Andrew Gelman (2008-01-11 18:27:20)

Seth, I'm confused. There's all this talk about the paleolithic diet or whatever, but people didn't eat burgers in paleolithic times either.

seth (2008-01-12 15:54:52)

Andrew, during Paleolithic times people ate zero refined carbs. No bread, no soft drinks, no pasta, etc. The Atkins diet consists of eliminating these foods (while, yes, leaving cheese and eggs, which were also absent in those days). So you can think of the Atkins Diet as a semi-Paleolithic diet.

Andrew Gelman (2008-01-13 12:49:20)

Seth, Yeah, but that's a much weaker statement. Taubes appears to have lots of data supporting his claims, which is great, but then he makes statements implying that his ideas make sense because of the paleolithic diet. But unless he's talking about climbing trees and chasing down weak gazelles or whatever, his lifestyle does not seem particularly paleolithic. If he wants to cut out white flour and keep burgers, rather than the other way around, that's fine, but I don't see the "paleolithic" argument to be very relevant to that choice.

LCforevah (2008-01-16 11:32:55)

A bit of bad news for Taubes as a Dad. I believe the future shape of the jaw and the tooth buds are pretty much laid down in utero. Just he found evidence that shows that overweight mothers with diabetic/insulin resistance problems give birth to children who then develop the same problems more easily, it's his wife who had to give up the sugar and white flour so her infant would have strong jaws and straight teeth. Of course keeping his son away from refined junk will help his overall development on many other levels anyway.

Mamas, Don't Let Your Babies Grow Up To Need Braces « Sacred Appetite (2009-10-23 21:08:44)

[...] <http://www.blog.sethroberts.net/2008/01/10/interview-with-gary-taubes-part-7/> [...]

## **Interview with Gary Taubes (part 8) (2008-01-11 16:38)**

INTERVIEWER Marc Hellerstein thought that the obesity epidemic was caused by people being sedentary?

TAUBES He believed that the key is whether you're sedentary compared to how you used to be. When I told him about the Pima and the Sioux Indians and this 1981 study of obesity in oil field workers, he had an excuse for everything. So the Pima and the Sioux Indians, they lived on reservations, so they could be obese because they were relatively sedentary, at least more sedentary than they used to be. And the oil field workers, well, they're

Mexican-American, so they have some kind of “thrifty” gene going. You know, this is what pathological science is: a field in which you can find a reason to explain away all negative evidence. In pathological science, it’s no longer possible to refute the hypothesis. Remember, science is about trying to test your hypothesis and refute it, but in a field like this, if you test it and come up with a counter-example, the counter-example is just explained away with whatever comes to mind. Negative evidence never means anything. So you have an obese person who’s sedentary, that’s proof of my hypothesis. If you have an obese person who’s very active – at least, compared to most people today – the Sioux Indians, for instance, who were so poor they had to walk down to the river to get their drinking water; who had no televisions, no cars; they had to walk outside to evacuate their bowels – those people are obese because they used to be more active than they are now.

INTERVIEWER I’ve never heard that before: “They used to be more active.”

TAUBES But that’s the implication of Hellerstein’s knee-jerk reservation hypothesis. They may be poor, and they may be out working in the fields, so compared to us, they’re active, but compared to their former life, they’re sedentary. See what I’m saying?

INTERVIEWER Yeah, I understand the logic. I’ve just never heard it before.

TAUBES Well, the reason you’ve never heard it before is because you’ve never heard anyone have to explain why obesity was common in an impoverished Native American tribe in 1902 or in 1928. When confronted with that observation, they have to come up with an explanation so that they don’t have to question their hypothesis. I happen to challenge someone who believes the conventional wisdom unconditionally, and that’s the response I get: “Well, they’re living on reservations”.

INTERVIEWER Does he do research on weight, on obesity?

TAUBES Absolutely, he does.

INTERVIEWER That’s unfortunate.

TAUBES This is why the field is in the position it’s in. These people believe so strongly in the calories in/calories out/gluttony/sloth combination that they no longer function as scientists. They can’t imagine the existence of an alternative hypothesis. So everything they see, they have to find a way to interpret it so that it supports what they already believe to be true.

INTERVIEWER They don’t see that they’re operating differently

TAUBES than other scientists.

INTERVIEWER Do they see that they’re not making progress?

TAUBES No, because that gets blamed on the obese. If you believe that obesity is caused by sloth, then the reason fat people are fat is because they don’t have the moral fortitude to go run ten miles every day the way you do.

INTERVIEWER Well, people have been saying that for 50 or 60 years. So the fact that they’re saying the same thing now as they were saying 60 years is a sign, to me, that they’re not making progress.

TAUBES Yes, that’s a very good sign, but these people don’t realize they’re saying the same things and doing the same experiments and making the same mistakes that their predecessors made a century ago because they don’t bother reading that literature. For reasons I still don’t really understand, these people see no reason to pay

attention to the history of their field. Imagine if physicists saw no reason to pay attention to Einstein and Plank and Maxwell and Heisenberg? I mean, these guys all lived a century ago, why would anyone want to know about them or the experiments they did? But in physics, mathematics and even biology, the history is carried along with it. As the science progresses, it takes with it the successful ideas and the students learn about the history along with the science. In obesity research, World War II just cut all of that off. For whatever reason, several generations of researchers grew up with this belief that the history of the field doesn't matter. And so they don't even know or care that they're saying the same thing and doing the same experiments that their predecessors did 100 years ago. And then this latest generation is full of young molecular biologists, and they start the clock in 1994, when leptin was discovered. They're not aware that they're not making progress, because they believe that nothing of value was done until 1994.

INTERVIEWER The birth of a new world. In your book, you seem to place weight on the fact that Atkins was disliked by people he went to school with. Did I read that wrong?

TAUBES I think that was part of it. I think the fundamental problem with Atkins is that his book emerged in 1972, when the low-fat dogma was really beginning to be taken seriously, not just by the heart disease researchers, but by physicians and public health authorities. It was viewed as a great triumph of modern medicine. We finally understand what causes heart disease. Then Atkins goes out of his way to throw the high-fat nature of his diet out there: "You can eat Lobster Newberg, double cheeseburgers, and porterhouse steaks" (like my New York Times Magazine cover). The AMA always had this philosophy that even if people wanted to lose weight, they should go to their doctor and discuss it with them. You shouldn't go on a diet without your physician's guidance. So here Atkins was end-running all of that. Then he was saying "eat a high-fat diet. It's harmless". He actually said "it's good for you." If you read Atkins, he read a lot of the papers I read. His understanding wasn't tremendously sophisticated, but he didn't have the advantage I had, of coming along 40 years later. For the time, he was doing pretty damned good. He believed that triglycerides were the problem, not cholesterol. He believed that insulin was a problem. He was a working physician; he didn't have the time that I did to read all of the research, and to have the internet available to allow him to track down all of the references. But the establishment thought his diet was dangerous. And then Atkins made these claims that he had patients who consumed 5000 calories a day and still lost weight, so they also believed Atkins was a quack, a shyster trying to sell impossible dreams. And they thought this because they believed that calories in/calories out was all that mattered. They had this inherent belief that in order to lose weight, you have to restrict calories; Atkins said you didn't. So, to these establishment nutrition types, Atkins was saying that the laws of thermodynamics can be ignored. So they had reason to think that Atkins's diet couldn't possibly work, on the one hand, and that it would kill you, on the other. So these "responsible physicians," as they perceived themselves to be, felt an obligation to suppress this threat to the public health. The fact that they knew Atkins personally, that some of them had worked with him and gone to medical school with him and didn't particularly like him, made it all that much more . . .

INTERVIEWER Irresistible.

TAUBES Yes, irresistible. One of the things I mentioned in my lecture was something I didn't realize this when I wrote the book. Atkins proposed that one reason carbohydrates-restriction worked is that it stimulated the secretion of something that British researchers in the 1950s had called Fat Mobilizing Hormone. The joke is that you didn't need a Fat Mobilizing Hormone; the thing you have to do to mobilize fat is lower insulin levels and the way to do that is to remove the carbohydrates from the diet. That's what mobilizes fat from the fat tissue. But Atkins was doing what a lot of diet book authors do, which was combing the literature for everything and maybe anything that might support his argument. He talked about insulin, but he also talked a lot about Fat Mobilizing Hormone, which was controversial at the time but not an outrageous idea. At the time Atkins wrote the book, this Fat Mobilizing Hormone had yet to be nailed down, and it never would be. The fundamental requirement to mobilize fat, as I said, is to lower insulin. So, the American Medical Association publishes this famous article dedicated, effectively, to establishing that Atkins has no credibility and one of the ways they do it is to discuss how Atkins was wrong about

this idea of Fat Mobilizing Hormone. Then in the same paragraph they also say “in order to mobilize fat, you have to lower insulin”<sup>[2]</sup>. Then they go back to talking about how Atkins jumped the gun on Fat Mobilizing Hormone . So they know that insulin controls fat accumulation, and they say actually acknowledge it in the article, but only in the context of it supporting the argument that Atkins has no credibility. They never mention that the way to lower insulin – and so, apparently, to mobilize fat from the fat tissue – is to eat less carbohydrates, which is exactly what Atkins was recommending. I was writing my response to Gina Kolata’s review when I first really noticed that sentence, and it jumped out at me. “Holy shit!” These people knew what regulates fat tissue, and they know what regulates insulin. They just don’t care. That’s how dedicated they were to trying to squash Atkins.

INTERVIEWER It didn’t matter whether evidence supported them or that there was something there that they couldn’t explain. It just mattered that he was wrong about something.

TAUBES All they wanted to do was establish that Atkins was not a credible source, and people shouldn’t follow these bizarre practices of nutrition, or whatever they called it. One of the things I’m curious about is whether, from here on, the American Heart Association and other health authorities will continue to refer to low-carb diets, the Atkins diet, as these fad diets. Even though, if nothing else, as I point out in the book, these diets constituted the preferred medical treatment of obesity for 150 years, or 100 years, until the low-fat diet came along. It’s the low-fat diet that’s the fad.

INTERVIEWER That’s an interesting point. What is the fad diet? Is it the absence of the Atkins Diet, or its presence? Which is temporary?

TAUBES The idea that you could somehow lose weight by removing fat and increasing carbohydrates is as ludicrous as the idea that you could do it by eating ice cream for any extended period of time. I’m sure there’s something about the ice cream diet that works in the short term. I’m not sure, but I wouldn’t be surprised.

INTERVIEWER Was your response to Kolata’s review published?

TAUBES Yes. If you search me in the Times, you can read [1]my response.

Dennis Mangan (2008-01-11 18:31:15)

“The idea that you could somehow lose weight by removing fat and increasing carbohydrates is as ludicrous as the idea that you could do it by eating ice cream for any extended period of time.” Overreaching, to put it mildly. People lose weight that way all the time. For example, at places like Dr. McDougall’s clinic, which practices low fat/high carb in the extreme, with no limitations on intake, massive weight losses are common, not to mention reducing or eliminating insulin and blood pressure medications.

Tom (2008-01-12 00:43:44)

Any studies to back that up? Taubes has references for every statement he makes. Which you would know. If you READ THE BOOK !

Dennis Mangan (2008-01-12 09:01:31)

"Our patients' average weight loss is 4 pounds (2 Kg) in 7 days; that's half a pound a day while eating unlimited amounts of delicious foods, served buffet-style. Significant improvements in blood pressure, cholesterol, triglycerides, and blood sugar are seen. [...] Most (over 90 %) people are able to stop their medications for hypertension, type-2 diabetes, arthritis, indigestion, and constipation. Those who must stay on medications are often able to switch to simpler, safer, more effective, and less expensive ones." [http://www.drmcDougall.com/health\\_10\\_day\\_program.html](http://www.drmcDougall.com/health_10_day_program.html)

Dennis Mangan (2008-01-12 09:05:39)

By the way, Tom, have you read any book or paper on nutrition other than Taubes or garden-variety diet books? Just wondering.

Tom (2008-01-12 09:37:03)

That would be a personal attack, Dennis. I believe it's been made clear that those are inappropriate.

Lauren Schiller (2008-01-12 10:04:09)

Gary Taubes (If you read these posts), Since the medical and scientific communities seem hopeless regarding nutrition, why not try to sell your book to Oprah. I say this not only because she can make a book a bestseller, but especially because she has had an epic struggle with her weight all of her life. I would guess that it's those of us who've struggled with food and have the most to gain from your insights, who are your biggest fans. Since reading your book and everything else I can find related to it, I've come across information linking insulin/blood sugar with eating disorders, mood disorders, alcoholism and addiction, night eating syndrome and more. I'm not overweight but have struggled with food and various disorders all of my life and reading your book gave me the motivation to try something different. I'd been fat-phobic and ate little protein or fat for years and I can only wonder what havoc that wreaked on me. Anyway, I'm a huge fan of the book and hope that it breaks through the mental fog of the mainstream nutrition field. I understand that you don't want to spend time on a website but something simple just to alert people about new events/interviews would be great.

Dennis Mangan (2008-01-12 10:39:57)

In no way is it a personal attack; I'm merely turning the tables regarding your repeated query about my reading Taubes' book. You seem to be questioning my qualifications (when of course, the only thing that matters is whether one's statements are true or plausible and whether they can be backed up). So, for the record, my background is in microbiology, biochemistry, and pharmacology, the last at the grad level. What's yours? I'll also take your response to my question about reading in nutrition to be "no".

Tom (2008-01-12 11:39:41)

Of course it's a personal attack; the subject is Taubes' writings. I could remark that it's amusing that you're trying to engage **me** in debate while ducking one with Taubes himself (in the part 7 comments), but that too would be a personal attack. So I'll refrain. :-) So I'll just advise everyone (that includes you, Dennis) that Good Calories, Bad Calories is a groundbreaking work. Read it – even if you never read another book. :-)

Dennis Mangan (2008-01-12 13:01:40)

Tom, you seem to be blind to the fact that every time I write something critical of Gary Taubes, you bring up me. Look at your first comment: "Which you would know. If you READ THE BOOK ! " Anyone who reads my blog or my comments here can see that I'm a complete ignoramus who never reads anything. In any case, I'm responding to words on this page, not somewhere else, and I've backed up my claims wherever I've made them. So, Tom, do us all a favor, and unless you've got something substantive to say, that is something that isn't about me or my reading habits or my qualifications to comment on Gary Taubes' bad science and misleading statements (like the one above)... I notice that Taubes himself makes a number of insinuations about other peoples' motivations, e.g. "They just don't care. That's how dedicated they were to trying to squash Atkins. [...] All they wanted to do was establish that Atkins was not a credible source, and people shouldn't follow these bizarre practices of nutrition, or whatever they called it."

Tom (2008-01-12 13:22:37)

Again, Dennis, why not take it up with Taubes himself? I will repeat that anyone who wishes to comment intelligently on Taubes would be well served to read him first.

David Brown (2008-01-12 14:37:55)

Tom and Dennis, I imagine differences of opinion regarding what constitutes the "proper" approach to weight control could be resolved if more experts understood the importance of "Biochemical Individuality." That's the title of a book by Roger J. Williams that was published more than 30 years ago. Mainstream science is only now beginning to appreciate the range of variation in human metabolic makeup as manifested in individualized responses to food intake. Some people are really not all that sensitive to carbs. Others must strictly limit their intake to keep from gaining weight. There's some excellent discussion of this on pages 85-86 of "Nutrition Against Disease," also authored by Dr. Williams. For example: "Kuo and his coworkers found that the liver tissue of individuals with high blood fat levels took up fructose five times as rapidly as individuals whose blood-fat levels were lower. Fat tissue from individuals with high blood fat levels also took up fructose seven to eight times more rapidly than the fat tissues of individuals with low blood fat levels. This shows how biochemical individuality comes into the problem and gives us a lead as to how some individuals may be adversely affected by the fructose content of sucrose." The notes at the back of the book contain further comment: "In their study of eight 'hyperlipidemic' patients, Kuo and colleagues found that dietary sugar (sucrose) administered to patients causes blood fats to increase, while starch tends to lower them. They found that individuals who had low blood fat levels were relatively resistant to the effects of sugar, and that 85 to 90 percent of the total calorie intake in sugar was required to produce hyperglyceridemia." Notice the difference between metabolic response to starches and sugar. For some, just reducing sugar intake while consuming all the unrefined carbs they want will result in weight loss. So Dr. McDougall's approach does work for some but not for others. I suggest you guys read a December 10, 2007 article by Carmen Drahl published in CE & N subtitled "The maturing field of metabolomics is taking steps toward guiding personalized nutrition." David brown Nutrition Education Project

David Brown (2008-01-12 14:40:57)

Oops: Forgot to include the address for the article. Here 'tis: <http://pubs.acs.org/cen/coverstory/85/8550cover.html>

Seth's blog » Blog Archive » Interview with Gary Taubes (directory) (2008-01-12 16:57:18)

[...] Interview with Gary Taubes (part 8) [...]

Varangy (2008-01-13 11:03:35)

Does anyone else think that Dr. McDougall's clinic's claim of weight loss seems totally, well, ridiculous? \*\*\*\*\*Our patients' average weight loss is 4 pounds (2 Kg) in 7 days; that's half a pound a day while eating unlimited amounts of delicious foods, served buffet-style. \*\*\*\*\* 1/2 pound a day? No f--- way! (Apologies for the unintentional rhyme).

Kevin C (2008-01-13 22:01:51)

Actually, Varangy, I don't think it's outrageous at all. I experienced a similar rapid weight loss years ago, and it was on a very low fat diet. At the time I was following a plan very similar to the low-fat diet outlined in "Eat More, Weigh Less" by Dr. Dean Ornish. 4 pounds a week for an extended period of time seems unlikely, but 4 or 5 pounds during the first week of a program is not unusual. Of course, much of that weight might be from water loss and from your bowels and not really body fat loss.

Neil Wilkinson (2008-01-18 14:30:23)

Whatever the diet, a loss of 4lbs of fat equates to a 'loss' of approx 14000 calories. Much of initial large scale loss has to be more than just fat loss(which is the only thing that people actually want to lose) Losing even a pound of fat (3500 cal) over the long term would seem a pretty demanding target.

Eric (2008-06-23 19:57:10)

Varangy, It's not far-fetched at all. I lost 50 lbs over 5 months following McDougall/Esselstyn's plans, with much of the loss coming in the first 3 months. I've kept it off for over a year and a half and have never counted a calorie. If you take out

extremely calorie dense foods (oils, meats, dairy) and substitute them with bulky less calorie dense foods, you will feel full on far fewer calories than ever before. If you doubt it so much, why don't you just try it for a month and see? Don't worry, eating lots of veggies and whole foods won't hurt you.

Varangy (2008-06-24 11:32:48)

@Eric I find .33 to .5 lbs of fat/day extremely hard to believe. I suspect a not insignificant portion was initial water weight. Regarding my diet, I do eat so-called 'whole foods' as I have recently started eating hyperlipid\* (majority of calories from fat, moderate amount from protein, little from carbs) and have had fantastic results. My average weight loss per day was about .12 lbs per day. My sleep has dramatically improved as well. \*And no, I don't believe the lipid hypothesis ( [http://en.wikipedia.org/wiki/Lipid\\_hypothesis](http://en.wikipedia.org/wiki/Lipid_hypothesis) ). :)

Sue (2008-07-03 03:45:18)

Must have been a lot of lean body mass loss with the McDougall diet as low-carb is muscle sparing.

Eric (2008-09-10 07:42:43)

Well, after 2 years on the Esselstyn diet, not counting calories at all, and eating as much as I want, I'm still 50 pounds lighter than I was when I started, my exercise endurance is better than it was 20 years ago, and I'm off all medicines. Lipid panel for those who believe in these numbers are well below Esselstyn's target of sub 159 TC. I have no idea if Taube's and the low carb crowd are on to anything, but I see no reason to question whether Esselstyn's diet works or not when it's been so easy to maintain results. Really, if you doubt that this kind of weight loss is possible, just try it for a month and see what happens.

## **Academic Horror Story (Podesta State) (2008-01-12 16:26)**

From [1]Inside Higher Ed:

T. Hayden Barnes opposed his university's plan to build two large parking garages with \$30 million from students' mandatory fees. So last spring, he did what any student activist would do: He posted fliers criticizing the plan, wrote mass e-mails to students, sent letters to administrators and wrote a letter to the editor of the campus newspaper. While that kind of campaign might be enough to annoy university officials, Barnes never thought it would get him expelled.

Rather than ignore him or set up a meeting with concerned students, Valdosta State University, in Georgia, informed Barnes, then a sophomore, that he had been "administratively withdrawn" effective May 7, 2007. In a letter apparently slipped under his dorm room door, Ronald Zaccari, the university's president, wrote that he "represent[ed] a clear and present danger to this campus" and referred to the "attached threatening document," a printout of an image from an album on Barnes's Facebook profile. The collage featured a picture of a parking garage, a photo of Zaccari, a bulldozer, the words "No Blood for Oil" and the title "S.A.V.E.-Zaccari Memorial Parking Garage," a reference to a campus environmental group and Barnes's contention that the president sought to make the structures part of his legacy at the university.

1. <http://www.insidehighered.com/news/2008/01/11/valdosta>

---

Peter (2008-01-13 00:03:38)

i don't understand why it's being published just now. the article seems to let us know that Barnes did actually have a personal/private psychologist - was that knowledge the university was allowed to divulge? it's obviously a trashing operation run by the President, Ronald Zaccari. I'll drop a call in there on Monday, for sure. and it reminds me that I should do something to get myself and all alumni of my schools organized for when something like this happens. uh-oh - a new website - here it comes....

Peter (2008-01-13 00:10:40)

well, i left a voice mail and sent an email. that should start things nicely.

Peter (2008-01-13 00:56:09)

I did a little more research on that FIRE institute - I was alerted when I saw that Cato was involved (Cato being a libertarian right-wing think tank). It appears that FIRE is, indeed, a right-wing hack group: [http://en.wikipedia.org/wiki/Foundation\\_for\\_Individual\\_Rights\\_in\\_Education](http://en.wikipedia.org/wiki/Foundation_for_Individual_Rights_in_Education) #FIRE.27s \_political \_orientation They're using this case to try and up their street cred. It's why you won't find any mention of their funding sources on their website. It's a good cause - defending this kid - but it's shameful that FIRE is using the case in a cynical fashion. But would you expect anything else from a right-wing hack group? They're part of that whole David "I used to be a left-wing Marxist" Horowitz's campaign to intimidate professors into teaching 'state capitalism for the rich'.

Stephen M (Ethesis) (2008-01-13 22:18:13)

FIRE is more than that (and less). They aren't hacks, but they are ideologically driven, much like the ACLU, and sometimes the drive takes them strange places.

## **Interview with Gary Taubes (part 9) (2008-01-12 16:56)**

TAUBES Kolata's response to me reminds me a little of Mike Fumento's response to me. Did you read that back-and-forth?

INTERVIEWER Yes. This is an example of the litmus test for who the good journalists are and who the bad journalists are. In your Berkeley talk, you quoted Jane Brody: "eating pasta is a good way to lose weight." There seems to have been some sort of journalistic failure. What was the journalistic failure; what is it?

TAUBES Beginning in the 1960s, when newspapers institutionalized this idea of having diet and health/nutrition writers on newspapers, and it's still the case, for the most part, today, the people who got those jobs weren't the shining intellects on the newspaper, and the shining intellects didn't want to be diet and health writers. If you're a whip-smart young guy or girl who wants to go into journalism, you want to be an investigative reporter, a political reporter, or a war correspondent; you don't want to write about diet and health. Or at least you didn't. So I think that was one of the problems. You got not very smart people; truly mediocre reporters, doing jobs that turned out to have remarkable significance and influence. I do think that Jane Brody is as responsible as anyone alive for the obesity epidemic. She just bought into this idea of the low-fat diet as a healthy diet, and her sources in New York told her that Atkins was a quack, and that fat was bad, and she never questioned any of it. I don't know if she had the intellectual wherewithal to do it. In any other field of reporting, as far as I know, reporters are supposed to be as skeptical of their sources as scientists are supposed to be skeptical of their data. Certainly, if George Bush tells a political reporter something, that political reporter doesn't treat it like it's true. He might faithfully report what George Bush said, but you're supposed to be skeptical of what government institutions tell you. So now it's 1977, the McGovern Committee and the USDA make these proclamations about what constitutes a healthy diet, and there's simply no skepticism. (With the possible exception of Bill Broad writing in Science magazine, which no one outside the field of science was reading.) So the government tells us that we should eat low-fat diets - and

not even learned authorities in the government, but Congressman and USDA bureaucrats channeling 30-year-old congressional staffers – and lo and behold, all these health reporters decide it must be true. That’s the failure. In my fantasy life, I get a call from the managing editors of the New York Times and the Washington Post and the Wall Street Journal and they say they’ve read my book and they want to know how they can improve their health and diet reporting. Because they can see, whether or not I’m 100 % right, or 80 %, or only 50 %, surely their reporters did something wrong. Now there’s a fantasy for you.

INTERVIEWER Yeah, I agree. That makes sense. So, what would you say?

TAUBES I haven’t figured that one out yet. Get some of your political reporters to do the health writing. Get the smarter people on the paper to do it.

INTERVIEWER Well, I always thought of you as one of the very few science writers who was sufficiently skeptical. Practically none of them are.

TAUBES That’s basically the problem. This lack of skepticism. But I had an advantage. . . . You’ll remember, in my first book, I got to live at a physics laboratory and I was lied to regularly by a Nobel Prize-winning physicist. His conception of truth was what he needed to be true at the moment, and what he could get people to believe. So if you called him on the lie, and he was kind of a charming fellow, he would acknowledge that he might have misled you, and then he would step back and try another lie, because it wasn’t in his best interest to tell the truth. Then I did this book on cold fusion where I spent three years, basically, getting lied to constantly by anyone who thought it was in their best interest. There was a period in my life where it was hard for me to trust anyone, because I’d just been around too many people who believed that the truth was what was convenient. I also knew, by the time I got into public health reporting, I knew what it took to do good science. So, if somebody wasn’t doing it, I knew there was no reason to put them on a pedestal. The first article I ever wrote for Science magazine was an investigative piece of an alleged fraud that had happened in the cold fusion episode – a fundamental result that kept the field alive for another few months couldn’t be explained by nuclear physics. That alone was so remarkable – as one of the smartest men in the world suggested to me, a physicist named Dick Garwin at IBM – that it should have made everyone suspect fraud. If something can’t be explained by a very well-tested theory, you would question the ethics of the researcher who did the work before you’d question the theory. This is Hume’s idea that eyewitness testimony is never good enough to make you believe in the existence of a miracle, because a miracle is, by definition, something that’s impossible, by all our accepted theories. It’s easier to believe that 10, 100, or 1000 people were deluded or dishonest than it is to believe that the Virgin Mary really did appear in Times Square or whatever your miracle of choice is. Anyway, I’m writing this story for Science about an alleged incidence of fraud that took place at Texas A & M, and the editor had a Master’s degree in mathematics from Texas A & M. He took it upon himself to call some of the professors I interviewed, and he would ask them if they really believed what I said they believed, which was not completely unreasonable, considering I’d never written for the magazine before. But then he would say to me, “Well, I talked to professor so-and-so, and he says he doesn’t believe what you said he believed.” And I would say, “Well, this is six months after the fact. Let’s go look at the lecture he gave six months ago, and here’s the paper he wrote on the lecture, and here’s the sentence where he says what he believed then, which is what we’re writing about.” And this editor’s response was “how could you question him? He’s a PhD, and you’re not.”

INTERVIEWER That’s rather unfortunate.

TAUBES This was around 15 years ago; it’s still one of those memorable moments in my life.

INTERVIEWER This guy was an editor at Science magazine?

TAUBES An editor for the journal Science.

INTERVIEWER Oh yeah — that's really bad. Really, really bad.

TAUBES It's a common response you see -- what right does Taubes have to say this stuff? He's not a scientist. It's like "The Wizard of Oz," where in order to be a scientist or be taken seriously in science, somebody has to first give you the piece of paper?

INTERVIEWER On a scale of sharpness of criticism, from one to a hundred, that ranks about a zero.

[1]Interview directory.

1. <http://www.blog.sethroberts.net/2008/01/05/interview-with-gary-taubes-directory/>

---

Varangy (2008-01-13 11:07:38)

\*\*\*\*\*And this editor's response was "how could you question him? He's a PhD, and you're not."\*\*\*\*\* Ah yes, the classic logical fallacy of argumentum ad verecundiam rears its hideous head.

Seth's blog » Blog Archive » Interview with Gary Taubes (directory) (2008-01-13 18:08:14)

[...] Interview with Gary Taubes (part 9) [...]

charles (2008-01-13 20:09:12)

My wife recently lost 40 lbs. She is 40, and she has a bad hip, so she has extreme difficulty exercising, esp. cardio. She is lactose intolerant, and she is a vegetarian. So, that leaves vegetables, and to top it off, she does not like sweets. Whew! So she eats a hi carb diet. She lost 40 lbs in a year, has kept it off. I am very proud of her, and her doctor's visits have shown her health and tests to be very good. So I guess she's a case where she is the opposite of an Atkins type diet. I, for one, expected her to fail, but of course did not say this! Her case is very atypical, I would imagine. She is very disciplined.

marge (2008-01-13 20:20:24)

I just watched Taubes on Charlie Rose. Dr. Ornish raised a good point - that Taubes is very good at poking holes in others' research, but there hasn't been many studies to show that Atkins own diet is actually healthy. On a side note, Taubes didn't really come off too well; he interrupted too much and Ornish's point (my point above about poking holes) rang true. Taubes wasn't rude, but Ornish seemed too mild mannered and nerdy, and Taubes too impatient and testy, unwilling to let either of these actual researchers even finish a sentence. Unflattering. Taubes is a bright man, no doubt - Harvard, etc. I also don't doubt his honesty or his zeal (certainly not the latter! I just read his response to Fumento at Reason!). I would just offer unsolicited advice that his ideas are exciting and he is an articulate, forceful advocate - he can rest a little bit; the average reader/viewer will, however, constantly be thinking "But he's not a doctor, let alone a researcher himself", unfortunately. No journalist can match an actual researcher, no matter his or her zeal. A good narrative is still different than good science. I am all for paradigm shifters and new Copernicuses. If Taubes helps Americans be healthier and provides an epistemological slap in the face of the AMA, hot dog, as long as the evidence is there. But it's so much fun to be sexy and an outsider, and no fun at all to be a scholarly drudge affirming the platitudes of dietary common sense.

marge (2008-01-13 20:25:57)

Sorry, I hit return too early! As far as the interview here, I found the entries on Rubbia fascinating! I realized while reading the interview I had bought that book years ago and read it! I had forgotten the author's name. The cold fusion portion is also fascinating - what a great opportunity to develop one's scientific intuition. I would love to hear more about that BS detector,

whether that was generalizable to other people, circumstances, and if it helped him in his daily life. In the spirit of Seth Roberts, the intriguing idea to me is that everyone has intuitions, but to be able to TEST the intuitions, and to verify or disconfirm them, is very exciting. The idea of calibrating one's intuition is great. I work with patients and they often fib or lie, and I often wish I could find out if my hunches are accurate, and to what extent. Taubes' experience in this dept is an interesting lead...

Mickey (2008-01-15 23:56:37)

> I just watched Taubes on Charlie Rose. Dr. Ornish raised a good point - that Taubes is very good at poking holes in others' research, > but there hasn't been many studies to show that Atkins own diet > is actually healthy. Marge, I'll have to point out now that the Charlie Rose show with Barbara Howard, Gary Taubes, Dean Ornish was in 7/2002 - that is almost six years ago. At that time Gary Taubes hadn't even started the 5 years of full-time research for his book. I also found the discussion and was a little disappointed because Gary didn't give the arguments that he so very clearly presented in his book until I realized that the video was from 2002 when Taube's 'Big Fat Lie' article was published. After 2002 there have been a lot of studies showing that the Atkins type of diet is in fact very healthy! Unfortunately there are no major long-term studies - the longest I heard of being 44 months (a Swedish study on diabetics on low carb). But there are dozens of studies that are 6 or 12 months long already. I'm staggered by the amount of studies that come out nowadays - nearly every week there is a new low carb study published in some of the big nutritional / medical journals all of the results have been very good. Luckily a lot of things have changed in the last 6 years.

Stephen M (Ethesis) (2008-02-25 19:43:24)

**I do think that Jane Brody is as responsible as anyone alive for the obesity epidemic. She just bought into this idea of the low-fat diet as a healthy diet, and her sources in New York told her that Atkins was a quack, and that fat was bad, and she never questioned any of it. I don't know if she had the intellectual wherewithal to do it. Kismet.**

## **Interview with Gary Taubes (part 10) (2008-01-13 18:07)**

TAUBES I'm definitely more skeptical; even the science journalists I really respect, some of my friends, sometimes I read their stuff and I say, "They just weren't skeptical enough".

INTERVIEWER Yeah, that's my reaction to at least half of the science journalism I read. One of my next questions is, did writing your book radicalize you? But it sounds like you were already radicalized!

TAUBES What do you mean by "radicalize me"?

INTERVIEWER Did it make you even more skeptical of the establishment? Obviously, you were skeptical to begin with.

TAUBES Again, the obesity stuff, in retrospect, is mind-blowing to me. Until I did the research for the book, I never questioned the idea that obesity wasn't about calories in/calories out. That it wasn't about overeating. Then you realize that there's no arrow of causality in the law of energy conservation. That the correct interpretation is that we overeat because we get fat, we don't get fat because we overeat. Now that's a remarkable shift in causality, and yet nobody picked up on that for fifty years. And nobody seems to care even now. There's one guy I know of - Robert Lustig at UCSF - who has written papers discussing this causality issue and getting it right. And nobody else seems to care. It blows my mind that an entire field of research could get it so wrong.

INTERVIEWER But you'd seen Nobel-Prize-winning physicists get it very wrong.

TAUBES But what they were getting wrong were subtle; yes, they'd believe incorrectly that they'd discovered elementary particles, but what they were doing was a real subtle game. What they were misinterpreting

were extraordinarily subtle aspects of the data. This obesity screw-up is fundamental; it's like a grade school error in the interpretation of the laws of thermodynamics. And I made it as well, up until five years ago. I never thought differently. But what radicalized me is that they don't care. If they successfully ward off my threat to their beliefs, then I'm in a very dangerous place. Then it's, like I said, where I end up a bitter demented old man, one of those guys who's muttering to himself all the time that they, the establishment, didn't listen to him...

INTERVIEWER I wondered, too, what other books your book resembles. To me, that's an interesting question. But there's many possible answers, and one is "Well, there's been a long list of books that talk about this scam or that scam, and some of them are awful and some of them are pretty good. One of the ones that's good is that great cholesterol scam, *The Great Cholesterol Con*. That's a good book. But your book is different, because unlike the author of that book, you really had something to lose. You were a respected science writer who could expect to receive many more assignments in the course of a lifetime and write many, many more times for the *New York Times* in science, and so forth, and might write other books. For a writer in that position — this is an incredible book, because

TAUBES I actually didn't think — and this may be my own ignorance — I didn't ever think of it as endangering my career.

INTERVIEWER But you clearly have more at stake

TAUBES I always knew I could write about other subjects. I could go back to writing about high-energy physics; I like it. There's a new accelerator turning on; there'll be something to write about. I would have to compete with the whole new younger generation of whiz kids who may be better prose stylists than I am, but I could do it. What stuns me is that people may not take me seriously enough to refute me, to ruin my credibility. That's what bothers me, not that they could ruin it. Here's a book that might be similar, OK? Not in terms of prose style, or beauty of presentation, but like *The Best and the Brightest*. A book that came out during the Vietnam War and exposed the sort of irrationality of it. When I was writing my cold fusion book, I read *A Bright and Shining Lie* and I read Randy Shilts's *And the Band Played On*. I thought we're all writing about human idiocy. Shilts's book was particularly important, because it came out at a time when it could still make a difference, when people still had to change their beliefs. So Shilts actually accomplished something. And *A Bright and Shining Lie* was an extraordinary book. In my fondest dreams, I couldn't imagine writing such a book. But maybe my book may be akin to book *And The Band Played On* and *The Best and the Brightest*. Those are books that revealed the establishment's erroneous beliefs and how they were misleading us, and they did so at a time and in a way that could actually help set us on the right path. You use the term "We were misled"; we were literally misled. Not deceived; we were just led down the wrong path. Often, when I think about this, I imagine this situation in the 50s and 60s, when there were these dual paths that could be followed; two paths through the woods, and the establishment took us on this low-fat path. What I had to do when I did this research is I had to back up, back up, back up until I got back to the woods, to the point where the two paths diverged, and see the existence of the other path, and see where that one led us. Did that get to a place where we could actually understand what was going on, and maybe prevent and cure these diseases.

INTERVIEWER Well, when I think about precedents for your book, sometimes I think of *The Jungle* [by Upton Sinclair]. In the sense that there's this awful thing going on, and it's in the interests of many people to keep it going on, but it's really outrageous. It's very different, in a way, because the meat-packing industry was very obviously horrible, whereas what you're saying went on isn't obviously horrible; it's more complicated than that. But on the other hand, your thing is kind of a bigger issue; it's everyone's health. It's not just everyone's health, it's everyone's mental health; it's horrible, being fat; it's awful every day, not just when you die.

TAUBES I have friends and acquaintances who will often say to me at dinner parties, "Well, who really cares about this stuff, because you want to live well, not just eat the healthiest possible meals." But they're

not overweight, they don't have cancer running in their family. Their life, rightfully, is a balance between living healthy and living well. But the problem always is that even though those people want to live well, they eventually get to the point where now they're sick. Inevitably, when you get to that point, you wish maybe you hadn't lived quite so well. Unless you're lucky and you have that massive coronary on the golf course, or on your lover, so you don't have time to think about it. But both my mother and my father died from long, extended, horrible illnesses. There's a point at which you think, "Maybe if, 30 years ago, I had lived less well and more healthy, I wouldn't have to go through this," but I guess we all have to die of something.

INTERVIEWER Well, I think understanding what causes obesity is a big, big issue. For the medical establishment to be misled, or deluded, to get the wrong answer and insist on it, is a tragedy. It's a gigantic tragedy, because of all of the people who are overweight. Not the people who are 5, 10, or even 20 pounds overweight. The people who are 50 or 100 pounds overweight.

TAUBES We're drowning in diabetics; we're drowning in obese patients. Obviously, physicians and obesity researchers and public health authorities haven't got a clue. By what right does anyone flippantly discard an alternative hypothesis that can explain the evidence? You would think they'd be desperate for such a thing. You know, this guy presents a compelling argument that we got it wrong. Well, Jesus, we obviously got it wrong. We haven't cured a person in 100 years! Let's take him seriously!

INTERVIEWER Let's praise him for raising an idea that hasn't yet been proved wrong.

TAUBES We'll see how it goes. Again, I'm obviously impatient. I expected people to read the book immediately and to send me emails; somebody at NIH saying "Come on down here! Talk to us about what experiments we should do." If the book has any effect over five years, ten years, that probably would be a great accomplishment. In a sense, I wrote the book for graduate students and post-docs, so that when their professors utter nonsensical statements, like the only that matter is calories in/calories out, these kids will challenge them. It could take awhile; it's only been a few months.

INTERVIEWER When their ideas failed to produce better ways of losing weight, and fifty years had passed, it was understandable, but not for scientific reasons.

TAUBES As I say in the book, they're not scientists. The funny thing is, they're not trained as scientists; a lot of the people involved in this field are nutritionists, medical doctors, public health people, and that's a different way of thinking. I had an apprenticeship in science; I got to spend my ten months at this physics laboratory; I got to delve into cold fusion for three years. In a way, you have to get an apprenticeship in how to think like a scientist. You have to be mentored. It's not how we naturally think. These people, it's not part of their training in any way. Not that there aren't scientists who started as MDs. There are these yellow berets, the guys who went to NIH instead of Vietnam in the late 60s and early 70s, so suddenly, they're MDs who were working around biologists and PhDs, and they were taught how to do good science. But it's not how we naturally think; these people just didn't do it. Then there's this whole world of nutritionists and epidemiologists who, for whatever reason, far too many of the senior figures in those fields don't have a clue how to do science. So they passed on this sloppy way of thinking to their students, and the whole field is permeated with less-than-rigorous thinking.

Aaron Brown (2008-01-13 20:34:46)

This is a fascinating interview. A couple typos in this installment: "we get overeat" "getting it write" Did you conduct the interview with voices or email?

Aaron Brown (2008-01-13 20:39:53)

Sorry for the bogus formatting in my last comment. (But hey, if there's no preview button...)

Tim Lundeen (2008-01-13 21:15:48)

I do think science gets it right in the end, and that good science displaces non-science in the end. And I think Taubes' book will accelerate this process re carbohydrate metabolism. The book has been incredibly useful for me, and has started me down a number of good/interesting paths. Since lowering my blood sugar down another level, to try to keep it close to 83, I've lost 10 more pounds and my arithmetic performance tests look better.

Tom (2008-01-13 21:30:12)

This interview continues to amaze me, Seth. Fantastic. And there is deafening silence on Taubes from the top obesity authorities - a far cry from the howls of outrage that greeted his NY Times piece. The book is just too authoritative. I think they know he knows their field better than they do...so they're hiding in their foxholes, waiting for it to blow over. The blogs know about the book, though, and Google ain't forgetting it any time soon. It may be my imagination, but I have seen a skepticism re: the Ancel Keys/low-fat dogma beginning to percolate through the memes out there. A work of this quality and range simply cannot be denied.

Stephen M (Ethesis) (2008-01-13 22:16:24)

"but I have seen a skepticism re: the Ancel Keys/low-fat dogma beginning to percolate through the memes out there. A work of this quality and range simply cannot be denied." I hope so. I'm a hoper in the percolate theories ... BTW, went to Washington over Christmas (State, not D.C.) started four people on SLD. Now that I've kept the weight off, they are interested. Was an interesting visit. I'm really curious to hear how it goes for them.

Tom (2008-01-14 08:57:53)

Another result that is 'impossible' according to low-fat, low-cholesterol dogma - Cholesterol drug lowers cholesterol, clogs arteries faster: [http://www.nytimes.com/2008/01/14/business/14cnd-drug.html?\\_r=1&hp&oref=slogin](http://www.nytimes.com/2008/01/14/business/14cnd-drug.html?_r=1&hp&oref=slogin)

Heidi 555 (2008-01-14 09:37:03)

Seth, great interview. I've been enjoying it, and am looking forward to reading Taubes' book. (These are the typos that I noticed: "is that we get overeat because we get fat," "who has written papers discusssing this causality issue and getting it write" "But what they were getting wrong were subtle" "like the only that matter is" Please delete this portion of my comment, after you read it.)

seth (2008-01-14 15:13:15)

Aaron, this interview was by phone.

Seth's blog » Blog Archive » Interview with Gary Taubes (directory) (2008-01-14 16:18:49)

[...] Interview with Gary Taubes (part 10) [...]

losing-it (2008-01-15 09:15:36)

"...the correct interpretation is that we overeat because we get fat, we don't get fat because we overeat." Whoa. Brilliant. This perception clicks; echoes clear and true somewhere in the unplumbed Depths of Recognoscere.

Mickey (2008-01-16 00:10:13)

â€œthe correct interpretation is that we overeat because we get fat, we don't get fat because we overeat.â€ Yes. The slightly longer version: When our insuling levels are high (either from eating a lot of carbs or from having metabolic syndrome and hyperinsulinemia) all energy is directed to the fat tissue. All the energy (fatty acids and lipoproteins) get's sucked up in our fat tissue and our muscles and other organs are deprived of evergy which will make us hungry and causes us to eat again. So the above sentence is literally true even if it doesn't seem to make sense at first.

## Interview with Gary Taubes (part 11) (2008-01-14 16:17)

INTERVIEWER What happened when you met with the [UC Berkeley School of Public Health] epidemiology students?

TAUBES Again, it was a little discouraging, only because these kids really want to do good, they want to make a difference in the world. That's why they go into the field. They want to have an effect. But as I say at the end of the book, to do science right, your primary motivation has to be to learn the truth, and if you're infected with this desire to change the world, to save lives, it takes you away from the fundamental motivation, which is to get it right. If you want to save lives, then you want to get the word out as quickly as possible. You don't want to wait ten or twenty years or more for definitive evidence, for the rigorous tests to be done; you want to give advice and tell people what you've learned, even if you only think that you've learned it. Doing science right takes a long time. So does good journalism. You can say the difference between my book and Gina Kolata's book is – not counting whatever difference in intellect we begin with– my book took five years, more than full time, because I wasn't going to say anything until I was certain that what I was saying was sound. She wrote her book in two years, part-time, while still working full-time as a New York Times reporter.

INTERVIEWER Yeah, they're very different.

TAUBES Even when I was writing magazine articles, if I was in danger of missing a deadline, which was often the case, I would ask my editors, â€œDo you want it on time, or do you want it right?â€.

INTERVIEWER There was a managing editor at The New Yorker, one of the first, whose motto was â€œDon't get it right, get it written.”

TAUBES When I was a young journalist working for Discover, which was owned by Time, Inc., the philosophy was that one of the worst things anybody could do was over-report a story. Just get the facts and get it out. Except science doesn't work like that. Science, you've got to get it right, and that takes time, and you can't do it on deadline. Along those lines, I did read one of your blog entries about settling points versus set points, and I thought it might be. You know, I Google myself, as all writers do fairly regularly, so first you read all news stories that day, hoping that the Google Alert might have missed something, and then you go to the blogs.

INTERVIEWER So you read my post about the most surprising thing in your book?

TAUBES What was the most surprising thing?

INTERVIEWER That you didn't agree that set points play a role in homeostasis.

TAUBES It's funny â€“ the more I think about it, the more Claude Bernard was brilliant. (I'd like to do a book on Claude Bernard, but probably can't because my French is terrible.) In particular, this idea of the milieu interieur? The fundamental idea of homeostasis is that the body works to maintain the stability of what he called the milieu interieur, which gets translated to â€œinternal environmentâ€. What he meant by that is the conditions

right outside the membrane of the cell, every cell in the body. So the body wants to maintain stable this internal environment – the pH, the blood pressure, the ionic potential, everything – of the cell itself. So it wants to make sure that the environment the cell lives in – every cell – remains relatively stable. In that sense, we're this huge symbiotic organism made up of billions of individual cells, and homeostasis functions to keep the conditions that these cells live in stable. So each cell lives in this little isolated world, and it's got to see stable conditions, or it's going to die. The idea of the set point is that there's some central controller in the brain that maintains homeostasis, but that's naive. Rather, there's an unbelievably complicated mechanism composed of individual settling points. Like the fatty acid concentration on the interior, and exterior of the fat cell. If there's more fatty acids on the outside of the cell membrane than the inside, then fatty acids flow into the cell, and you get slightly fatter. There's no brain in charge. The brain may respond, and the hypothalamus sends signals back and forth, and effects changes in hormones in response to changes in the environment, but there's so many different interrelated, interconnected feedback loops involved that to refer to a set point is to grossly oversimplify this beautiful homeostatic system, and it directs attention away from the body, where all these feedback loops interact, to the brain. Did you ever read any books on chaos theory?

INTERVIEWER No, I haven't.

TAUBES Well, to understand homeostasis you have to understand this concept of dynamic equilibrium, where there can be hundreds of forces acting simultaneously. And the point is, you've got these negative feedback loops all over the body, and they involve the brain, but on some level, the dynamic equilibrium you're looking at is right at the cellular level. That's where the forces converge to make us leaner or fatter. And the brain is part of these loops, but to concentrate on the brain misses the big picture.

INTERVIEWER The brain is sensitive to the environment — sure, the set point doesn't really exist anywhere, and sure it's a function of about a zillion things, not all of them in the brain, sure. But the reason I like that idea of a setpoint is that it's easy to imagine something going up and down, rather than a million things going up and down.

TAUBES But the problem is once you oversimplify, there's a tendency to believe the oversimplification. You should go back and read the papers on settling points. There were a couple, if I remember correctly, written by psychologists from the University of Chicago. You should go back and read those original papers. They're fascinating, and the point they make, is that you don't need the brain involved. Like we don't think of the brain regulating blood pressure. You don't really think of your brain regulating blood glucose. Those cycles I described in my lecture, you know, the triglyceride fatty acid cycle and the Randall cycle, serve to regulate blood sugar. Then hormones are layered on top of those cycles, and the hormones are determined, in part, by the hypothalamus, so you get the brain involved, and the sensing of the environment, but there are other ways to sense the environment, like temperature sensing of the skin, evaporation. There are other ways that we adjust to the environment without the involvement of the brain. One of the things I left out of the book, for instance, is this theory that hunger is perceived by the liver.

INTERVIEWER Perceived, or controlled?

TAUBES Perceived. Or sensed by the liver. You know, your eyes collect photons, and then they send the signal back through the optic nerve. The perception of the universe is done in the inside of the brain, but the eyes are the sense organ that collect the photons. Your ears detect sound waves, but your perception of what you're hearing is inside of the brain. This theory says that your liver senses fuel availability and then your brain integrates the signals from the liver and registers them as hunger or the absence of hunger.

INTERVIEWER Hunger is internal. It's like the recognition. Hunger is not something external to the body.

TAUBES Let me re-phrase it. It senses fuel ability. Then your brain perceives it as hunger and initiates — that would be a better way of putting it. But the sense organ of fuel availability is your liver. I had some discussions with Mark Friedman, a fascinating guy, really smart. He's at the Monell Institute.

---

Timothy Beneke (2008-01-14 17:07:37)

This interview gets more fascinating with each installment. You guys should talk forever!

NE1 (2008-01-14 18:16:54)

I haven't been reading these interviews (I read blogs for the value-added), but I'll once again take the contrarian position. Science done right is science that *\*works\**. I see nothing wrong with straining at the bit to counteract disease before it is fully formed and overblown. Surely this is what the study of epidemiology is—else it's medicine or biology. Leave it to the Historians of Science to be cautious and right.

Tom (2008-01-14 18:41:28)

Well, do you see anything wrong with creating epidemics of obesity, diabetes, and heart disease because a nation's diet was completely changed on the basis of a few misunderstood findings?

NE1 (2008-01-14 20:19:58)

Well, I still don't know much about the world of epidemiology, and had assumed there were tests for significance as in most of science, but perhaps things get carried away when they are handed off to policymakers. Anyways, I actually ran into an epidemiologist today, and she echoed general frustrations with the half-assedness of many in the field, and not just in the issue of competency.

Wade (2008-01-14 20:47:51)

Seth, Did you get a chance to ask Taubes to comment on the "China Study". It seems like a well reasoned, well researched tome that comes to the exact opposite conclusions he does. It agrees that refined carbs are bad (is there anyone who doesn't), but advocates an all whole foods plant based diet.

Chris (2008-01-15 12:15:13)

I'm sympathetic to NE1: we have finite lifetimes, so it makes sense to act on partial or preliminary evidence rather than wait a couple of decades for the science to firm up. Sure, I may have wasted a few bucks on beta-carotene supplements back when they were being hyped - and maybe the Vitamin D I'm taking now will fail to live up to the claims being made for it. Still, I think the risks and benefits, based on the information available at the time, made it rational to take these supplements. As for the low-fat fiasco, the problem there was not in initially promoting the hypothesis, but in continuing to promote it - hegemonically - despite negative results. For someone fighting a weight problem, it made perfect sense to try the low-fat approach in 1978, but not in 1988 or 2008.

Jen B. (2008-01-16 12:05:59)

What is puzzling to me is that the low fat theory took hold so fast and so hard. Even after reading GCBC it is hard for me to see why this happened. However, Gary, be of good cheer. I have convinced both of my parents to go low carb, and I gave each of them your book. I know you'd rather *\*scientists\** were rethinking this stuff, but perhaps it will percolate in from the outside

instead of the other way around.

Stephen M (Ethesis) (2008-01-16 17:44:30)

I like the concept of dynamic balance, would explain some things about why I can make sugar or oil work for weight loss, but if I take them together (not split am/pm, but a combined dose) or use protein powder SLD doesn't seem to work over the long run as well.

Neil Wilkinson (2008-01-18 14:48:34)

Wade, for a counter argument to T Colin Campbell who wrote about the China Study, try this review by of the book by Chris Masterjohn at <http://www.cholesterol-and-health.com/China-Study.html> Cheers

Seth's blog » Blog Archive » Interview with Gary Taubes (directory) (2008-01-19 18:46:18)

[...] Interview with Gary Taubes (part 11) [...]

Wade (2008-01-27 20:07:47)

Neil: Thanks for that link... very interesting reading, particularly the stuff about Price who seems well worth reading. After going through the rebuttal, the counter rebuttal, and the counter-counter rebuttal my head's spinning, but it certainly takes quite a bit of shine off of the China Study. Doesn't mean it's all wrong, but in the end it seems to me that you can quite reasonably shoot down the China Study's conclusions, or at least that there isn't enough information in the book itself to really justify its conclusions. Wade

### **Most. Frustrating. Party. Ever (2008-01-16 02:47)**

I attended the [1]Electronic Freedom Foundation's [2]17th birthday party.

It was a highly frustrating party because (a) there were many fascinating guests and (b) the music was so loud it was hard to talk to them. Every conversation was at least a little difficult. Still, I learned a few interesting things:

1. Around 5 p.m. that day, as a BART train pulled into the 16th Street stop, the driver announced, "16th Street, EFF."

2. Every EFF employee was required to wear a name tag that said "Hello, my name is" along with their name. Underneath the name box it said "Don't ask me about XXX" where XXX was about 30 or 40 possibilities, including "drugs", "P2P", and "Open Government". This was so amusing it would have been nice if the room had been a little bit brighter so I could have read more of them. The "Open Government" one was worn by a woman named Marcia, who was responsible for the FOIA request that caused Attorney General Alberto Gonzales to resign. "The straw that broke the camel's back," said Marcia. In a little speech by one of EFF's leaders, this was mentioned as one of the year's two biggest accomplishments. The other was the success so far of their lawsuit against AT & T for allowing the government to tap everyone's phone without a warrant.

3. Marcia was impressed that I knew Aaron Swartz. She didn't know him personally but she admired the breadth of his activities. "Like what?" I asked. "The [3]12-part novel he's writing," she said. This was a surprising answer. "You read his blog?" I asked. "No, I just heard about it," she said.

4. [4]Graffiti Research Lab exists.

5. I met a guy named Jason who had recently graduated from the University of Rochester and is now working at a small (12-person) start-up in San Francisco. He had wandered over to the EFF party from another get-together. We

talked about working conditions. Most people don't like their jobs, I said. That was a strange concept to him, he said, since he had enjoyed the two jobs he had. "It's a job, you're not supposed to like it, my friends tell me," he said.

6. When I was a grad student, I studied how rats measure time on the order of minutes and seconds. (They have a clock that resembles a stopwatch, I found.) Surely humans have a similar clock, but why? One use of such a clock, I realized, is to measure how long it's been since the last good conversation. When that time gets large enough, you leave the party.

Addendum. Me comparing chocolates: [5]Photo 1. [6]Photo 2. [7]Photo gallery.

Mike Kenny (2008-01-16 09:19:24)

Regarding item six—that reminds me of when one speaks with others, a silence of too long a duration feels like a prompt to 'say something'. Or when someone is talking for too long (I wonder why we have this intuitive standard), one feels like 'Okay, okay, you've gone over your time limit' as if you were at a debate. Do we have mechanisms that induce us to share information in conversation, but not to monopolize or allow others to monopolize so multiple sources can be considered? This might be useful to people in a stone age environment.

Akhdar (2008-01-22 00:43:58)

Why, in arenas promoting talk with fascinating people, do they play the music so loud? I do not get this. I find it frustrating as well! I went to a party recently with a lot of older (my age) people of varied interests and affiliations. We began to have a chat and became tremendously involved in our conversation. The host then put on some ear-splitting electric guitar filled screaming music. Mid-life crisis, I wondered. How conducive to good conversation is music when one has to shout? Call me a fuddy-duddy, but I feel constantly assaulted by loud music in many places. I don't get it at all. A discotheque ambiance in a store is not going to encourage me to peruse, but to get the heck out of there as fast as I can make it. Number 6: very funny.

Piracy EFF » Blog Archive » Most. Frustrating. Party. Ever (2008-03-22 08:28:39)

[...] Laura McGann wrote an interesting post today on Here's a quick excerpt Every EFF employee was required to wear a name tag that said "Hello, my name is" along with their name. Underneath the name box it said "Don't ask me about XXX" where XXX was about 30 or 40 possibilities, including "drugs", "P2P", ... [...]

## A Cautionary Tale about Salt (2008-01-17 00:20)

From the [1]SLD forums:

Thinking that I was doing a good thing, about twenty-two years ago, I stopped buying salt to keep at home – believing the hype about Americans eating too much salt, etc. I suppose that, in my younger years, it was not too dangerous as I was eating out a lot, and, at times, eating from packaged foods. Also, Pre-SLD, I would get cravings for popcorn (with a little salt added) and give in – so I did get salt at times.

But, for years, I have mainly cooked at home and have eaten foods high in potassium (garlic, onions, et al). Potassium depletes sodium further – and I was even taking potassium pills in order to ease a separate condition. I rarely go out and do not eat packaged foods. I had no idea that sodium was essential (stupid me). I thought that it was like sugar – best to cut it out completely.

On SLD (not that this is SLD's fault, of course!), I could rein in my cravings for popcorn. And so I was getting no salt. At the end with SLD (and for many, many months, afterwards), I began to have an issue that if I ate anything sweet, I would begin to stutter, feel like I could not breathe, feel faint, dizzy, etc. It was like the sugar bypassed the blood-brain barrier and went directly to my head. Honestly, it was terrifying and I was fairly sure that I was becoming diabetic.

The doctors, noting atypical symptoms and a frightened, teary woman, naturally diagnosed panic attacks. Then low iron. And a million other things which had no effect. Of course they really thought that I was a hysteric (an hysteric?). The irony is that they thought that maybe I was dehydrated so I increased my water intake. The worst possible thing.

And then I began to faint, to black out. And then had two seizures.

A friend of mine who is a chef (my ex, actually) figured it out. I bought some sea salt and the minute I ate it, my body lunged! Like this was exactly what I needed. After three heavily salted meals, everything normalised – even things which I had not noticed as abnormal. My eyesight sharpened, my balance improved, and I felt sane – like I wasn't drowning anymore. Overnight I felt better than I had in years.

Later neurological consultations confirmed that I probably injured my brain as badly as I did in the car accident I was in as it may have been chronically swollen from the lack of salt. Who knew? I had no idea how important – vital – salt was to the diet.

Ed (2008-01-17 11:37:24)

Interesting, how is one to know what the "right" amount is for salt and or sugar? –Ed

### **Loss of a Child and ALS (2008-01-17 05:03)**

This is one of the most unusual research findings I have ever encountered. From the [1]American Journal of Epidemiology:

Between 1987 and 2005, the authors conducted a case-control study nested within the entire Swedish population to investigate whether loss of a child due to death is associated with the risk of amyotrophic

lateral sclerosis (ALS). The study comprised 2,694 incident ALS cases and five controls per case individually matched by year of birth, gender, and parity. Odds ratios and their corresponding 95 % confidence intervals for ALS were estimated by using conditional logistic regression models. Compared with that for parents who never lost a child, the overall odds ratio of ALS for bereaved parents was 0.7 (95 % confidence interval (CI): 0.6, 0.8) and decreased to 0.4 (95 % CI: 0.2, 0.8) 11–15 years after the loss. The risk reduction was also modified by parental age at the time of loss, with the lowest odds ratio of 0.4 (95 % CI: 0.2, 0.9) for parents older than age 75 years. Loss of a child due to malignancy appeared to confer a lower risk of ALS (odds ratio = 0.5, 95 % CI: 0.3, 0.8) than loss due to other causes. These data indicate that the risk of developing ALS decreases following the severe stress of parental bereavement. Further studies are needed to explore potential underlying mechanisms.

I would love to learn how the authors decided to look into this. There are a variety of "stress is good for you" results (e.g., low calorie intake increases rat longevity) but this is the most puzzling.

1. <http://aje.oxfordjournals.org/cgi/content/abstract/167/2/203?etoc>

---

Joe (2008-01-17 09:19:24)

It would just seem that there are different kinds of stress, which may even release different hormones. The stress of hunger can actually be beneficial to the body, while the stress of grief for a loved one can be harmful. It would seem to make sense.

Timothy Beneke (2008-01-17 09:59:19)

Fascinating. If there's research on this, one would expect there to be research determining the overall mortality and morbidity effects of losing a child. Everything I've ever seen, from literature to clinical observations says losing a child is the most painful grief one can experience. Surely it correlates with depression, which is known to correlate with heart disease... But all this correlation stuff is one big guessing game...

Tom (2008-01-17 10:29:11)

Perhaps the death of a child causes an increased focus on the body's fragility, leading to better care of one's health, diet, exercise?

Stephen M (Ethesis) (2008-01-17 18:20:02)

"Perhaps the death of a child causes an increased focus on the body's fragility, leading to better care of one's health, diet, exercise?" All I can say is "not hardly." I've known a lot of parents who went through the death of a child. None of them took better care of themselves for years, if ever. Took me, I'd say almost ten years from the last death before I really started to take care of myself at all, I'm still not to pre-death levels of care.

Tom (2008-01-17 18:25:00)

I should have been able to figure that out...apologies for the witless remark.

donnyrosart (2008-01-18 20:14:14)

Calorie restriction makes just about every degenerative disease less common—except for ALS. So maybe something that increases the genetic risk of cancer decreases the risk of ALS?

Stephen M (Ethesis) (2008-01-19 12:25:28)  
No apologies necessary.

Sheila Buff (2008-01-19 17:05:51)

Hi Seth– I think this ALS/stress study is related to a long series of similar studies that have been conducted in Scandinavia. For example, Cancer incidence in parents who lost a child: a nationwide study in Denmark (Cancer 2002;95:2237-42). The conclusion was that the death of a child is associated with a slightly increased overall cancer risk in mothers, mostly due to smoking-related malignancies. Since people often smoke as a way to reduce stress, that's not surprising. A follow-on study showed that cancer survival in the child-loss cohort isn't impaired. Separate studies have looked at heart disease, rheumatoid arthritis, inflammatory bowel disease, multiple sclerosis and some others. The bereaved cohort had a greater risk of myocardial infarction, again mostly due to stress-related behaviors such as drinking alcohol and smoking. They also had a greater risk of MS, but for RA and IBD there was no difference. The ALS finding is especially interesting compared to the increased MS risk. The expectation would be that if stress increases the risk of one neurodegenerative disease it would increase the risk of others, but maybe not.

## **Obesity and Refrigerator Design (2008-01-18 02:24)**

In the last chapter of The Shangri-La Diet, I discussed what environmental changes my theory of weight control suggested. An [1]article in the LA Times about how to reduce obesity by changing the environment contains some ideas that strike me as unwise:

laws regulating portion size

but also a good one, from Brian Wansink.

A 2006 study in the International Journal of Obesity [by Wansink and colleagues] found that when candy was placed in a clear dish, people ate 71 % more than when it was in an opaque dish. The same study found that the closer the food, the more likely it would be eaten. . . . "We need to make small changes in our environment. That can be as small as moving fruits and vegetables to the middle shelf in the refrigerator" [said Wansink].

In Japan – where portion sizes are smaller without the need for legislation – most new refrigerators have three compartments separately accessible from the outside. Two are above freezing, one is below. Wansink's comment suggests not only that such refrigerators are a good idea but also that one of the above-freezing doors should be transparent. Behind the transparent door you'd put fruits and vegetables.

Thanks to Dave Lull.

### Does Cholesterol Cause Heart Disease? (2008-01-18 05:24)

The first links between cholesterol and heart disease were correlational, of course. Then statins, which improved cholesterol levels, turned out to reduce heart disease – experimental evidence of a connection. This strengthened the case for causality, but [1]Malcolm Kendrick argued, based on lots of other evidence, that the heart-disease lowering effect of statins was due to other effects of the drugs, not their cholesterol-lowering properties. Now we have [2]this:

Pfizer stopped development of its experimental cholesterol drug torcetrapib in December 2006, when a trial involving 15,000 patients showed that the medicine caused heart attacks and strokes. That trial “somewhat unusual in that it was conducted before Pfizer sought F.D.A. approval” also showed that torcetrapib lowered LDL cholesterol while raising HDL, or good cholesterol.

This supports Kendrick’s argument. It shows that drugs can have two effects: (a) on heart disease and (b) on cholesterol.

Thanks to Dave Lull.

Addendum. [3]Do cholesterol drugs do any good?

1. <http://www.blog.sethroberts.net/2007/11/29/what-causes-heart-disease-malcolm-kendricks-views/>

---

Timothy Beneke (2008-01-18 09:42:45)

I am on statins, blood pressure meds and baby aspirin. When I asked my doctor if we really had good scientific evidence that the statins were reducing heart disease, he said that something was but that we really didn’t know what. People were definitely living longer; he said it could be statins, blood pressure meds – it could be that people are exercising more. No one could be sure. I appreciated his frankness. I’d place my bet on exercise, but I’m continuing with the other stuff to be safe...

## Eggs are Good for You (2008-01-18 21:51)

A generation of Americans reduced their egg intake because eggs contain cholesterol and cholesterol = bad. Now comes [1]this study from the Journal of Nutrition of the effect of 3 eggs/day:

In this study, 28 overweight/obese male subjects (BMI =  $25 \pm 37 \text{ kg/m}^2$ ) aged  $40 \pm 70 \text{ y}$  were recruited to evaluate the contribution of dietary cholesterol from eggs in a CRD [calorie-reduced diet]. Subjects were counseled to consume a CRD ( $10 \pm 15 \%$  energy from carbohydrate) and they were randomly allocated to the EGG group [intake of 3 eggs per day ( $640 \text{ mg/d}$  additional dietary cholesterol)] or SUB group [equivalent amount of egg substitute ( $0$  dietary cholesterol) per day]. Energy intake decreased in both groups from  $10,243 \pm 4040$  to  $7968 \pm 2401 \text{ kJ}$  ( $P < 0.05$ ) compared with baseline. All subjects irrespective of their assigned group had reduced body weight and waist circumference ( $P < 0.0001$ ). Similarly, the plasma TG [triglycerides] concentration was reduced from  $1.34 \pm 0.66$  to  $0.83 \pm 0.30 \text{ mmol/L}$  after 12 wk ( $P < 0.001$ ) in all subjects. The plasma LDL-C concentration, as well as the LDL-C:HDL-C ratio, did not change during the intervention. In contrast, plasma HDL-C concentration increased in the EGG group from  $1.23 \pm 0.39$  to  $1.47 \pm 0.38 \text{ mmol/L}$  ( $P < 0.01$ ), whereas HDL-C did not change in the SUB group. Plasma glucose concentrations in fasting subjects did not change.

I want to raise my HDL. I am going to eat more eggs. Perhaps nose-clipped.

1. <http://jn.nutrition.org/cgi/content/abstract/138/2/272?etoc>

---

Chris (2008-01-19 09:15:31)

Cripes, you mean no-one undertook studies like this before they started demonising eggs? How unsurprising.

Stephen M (Ethesis) (2008-01-19 12:31:21)

Darn, I knew there was a reason my Cholesterol numbers have always been low. ;)

craig (2008-01-19 13:30:53)

Now I can eat that "The Incredible Edible Egg" again.

losing-it (2008-01-20 10:40:35)

Don't know if you've cited this on your blog, but here is an older study concerning eggs & cholesterol: <http://jn.nutrition.org/cgi/content/abstract/131/9/2358> Excerpt from related web article on Unisci.com <http://www.unisci.com/stories/20014/1029013.htm> Why Eggs Don't Contribute Much Cholesterol To Diet "Nutrition researchers at Kansas State University have published the first evidence that the absorption of cholesterol is reduced by another compound in the egg, a lecithin. "The research by Sung I. Koo, Yonghzi Jiang and Sang K. Noh has resulted in the issue of U.S. Patent No. 6,248,728, "Compositions and methods for lowering intestinal absorption and plasma levels of cholesterol." The patent was issued June 19 to the KSU Foundation. "A peer-reviewed research paper by the three researchers, "Egg

phosphatidylcholine decreases the lymphatic absorption of cholesterol in rats," appears in the September issue of Journal of Nutrition. ..."

Dennis Mangan (2008-01-20 20:15:07)

"I want to raise my HDL. " Why? I thought you were of the opinion that cholesterol doesn't matter. Also, feeding eggs to someone on a 10 to 15 % carbohydrate diet couldn't make a lot of difference, good or bad, because they're bound to be consuming huge amounts of fat and protein already. Adding a few eggs to a horrible diet doesn't make it much more horrible, and hey, it even raises HDL, so party on!

Dave Lull (2008-01-21 07:43:53)

Peter, posting at his blog, Hyperlipid: "Well, elevated HDL cholesterol appears to be a marker of a high fat, low carbohydrate diet and its associated beta hydroxybutyrate. So it is a marker of good things happening in the metabolism. As such I welcome it, but not if it is an effect of some drug." <http://high-fat-nutrition.blogspot.com/2007/10/niacin-and-beta-hydroxybutyrate.html>

### **Interview with Gary Taubes (part 12) (2008-01-19 18:45)**

INTERVIEWER Did you ever hear of Israel Ramirez? He was one of Mark Friedman's colleagues.

TAUBES That's the Ramirez you quoted. I forgot that. I didn't put it together, because I always knew him as I. Ramirez. I saw that, too — here's my other carp, and then I'll stop. It doesn't do any good to have somebody discuss my arguments who hasn't read the book.

INTERVIEWER I asked him to, so it's my fault.

TAUBES Then other people see someone refuting me, and they don't care whether they read the book or not. You know what I mean?

INTERVIEWER Well, I appreciate that it would be irritating.

TAUBES The problem is, you can't ask Mark, because I know what Mark thinks of the book. He's read it — he read it in draft and critiqued it for me. He's in the book, so you can't ask him, either, even though he would probably say tremendous things about it. You have to find people whose research I don't discuss. I'll tell you one guy who would be worth knowing what he thinks: George Wade. He's at U. Mass Amherst. He did these rat experiments. He's an expert on animal reproduction and I sent him a draft of the book, and I didn't ask him to critique it, but I was asking him a fact-checking question and I sent him a copy of the book and he never got back to me. I don't know if he read it or not. I'd be curious what he thinks, because he was my revelation, Wade. He shifted my paradigm.

INTERVIEWER You said something about that in your Berkeley talk.

TAUBES He was the one who got me to realize that we overeat because we get fat; we don't get fat because we overeat. That's the paradigm shift, the literal paradigm shift. He's describing his ovariectomized rat experiments to me. That's how he did it.

INTERVIEWER Do you know about someone named Michel Cabanac?

TAUBES Yeah, I read a lot of Cabanac's stuff. I forget what the details were. I only remember that I was disap-

pointed and decided that he was missing the point.

INTERVIEWER Well, he had a big effect on me, at least. His idea is that I'm sure there's a set point, but that's an old idea. The new idea is that the set point depends on what you eat. He had some ideas about that.

TAUBES Well, that's the thing. There is a settling point, whatever you call it. The weird thing is that insulin regulates the settling point. It obviously goes up and down. It obviously goes up, anyway.

INTERVIEWER He might not disagree with your book. I asked him "Can insulin regulate the settling point?" I thought that was unlikely, but he didn't; he thought, "Why not?"

TAUBES Insulin levels correlate with weight, with fat. The question is whether insulin goes up because we get fat, or we get fat because insulin levels go up. There's always two ways of interpreting the observations in this business. So the establishment viewpoint is that insulin goes up because we get fat. I tracked that belief down to see if there was evidence for it, and indeed, there's not; there's a sort of misinterpretation of these experiments done by Ethan Sims 40-odd years ago. On the other hand, it's easy to show that you can manipulate insulin levels by manipulating the carb content of the diet. If you manipulate the carb content of the diet, then the question becomes, does insulin and the weight still track? So the hypothesis is insulin regulates the settling point and the question is how do we test that rigorously to find out if that's indeed what's happening.

Seth's blog » Blog Archive » Interview with Gary Taubes (directory) (2008-01-20 21:44:56)  
[...] Interview with Gary Taubes (part 12) [...]

### **Interview with Gary Taubes (part 13) (2008-01-20 21:43)**

INTERVIEWER My book came out of an accidental observation, which is that I lost weight when I drank sugar soft drinks. Lost weight, not gained weight. That happened in Paris, and I came back to Berkeley, and I found out it was the sugar. In other words, if I drink unflavored sugar water, I lost weight. Not so obvious, right? But Israel Ramirez, who I mentioned a few minutes ago — his experiments with rats are what led me to this discovery. Because I don't think most people would have thought it was possible to lose weight by drinking Coke, or whatever. But it has to be unflavored. Anyway, the effect never wore off. I drank sugar water for three years, and my weight went down and stayed down. There was no sign that it was ever going to wear off. So this seems to me to be a big problem with your theory, which is that I drank something which obviously raised my insulin level, sugar water. I didn't measure it. I lost weight and not only did I lose weight, but I kept the weight off, and I lost it without being hungry; I was less hungry than usual. I mean, you're right, you know, set points, settling points, who cares. . .

TAUBES It's important to think of it as a settling point. Because it's important to have this concept of dynamic equilibrium. As long as you're thinking about what's happening in the brain, which is what set point implies. My question is, what did the sugar water do to your fat tissue? It should have caused you to accumulate fat, or at least hold on to the fat you had, according to what I know of the underlying regulation of fat tissue. The

question is, why did it do what it did?

INTERVIEWER I was less surprised than you are, or than most people are, let's put it that way, because I was led to this observation by a theory. I had a theory which pre-dated all of this. I was kind of surprised my theory was so helpful, because it hadn't been that helpful before. But, lo and behold, it really turned out to be helpful and it led me to other ways to keep my weight off, and I'm still way down from where I was.

TAUBES What I ask when I talk with these people. What I say is: Look at the regulation of fat tissue. The question is, how can you lose weight, or gain it — how can you gain weight without either increasing insulin secretion, or increasing the relative insulin sensitivity of the fat tissue to the muscle tissue. Basically, the way we work, at least if you believe the biology that I describe, is that as we secrete insulin in response to the carbohydrates we consume and the insulin works, among other things, to facilitate the movement of glucose into the cells of your muscles and other lean tissues. But blood sugar is kind of toxic, so your muscle tissue doesn't want the insulin pushing all this blood sugar in, and it becomes insulin resistant. Your fat tissue now remains insulin-sensitive, because your body doesn't like to waste fuel. So if you eat a high-carb diet, your lean tissue takes up some of the glucose for fuel, and the rest gets dumped in your fat tissue, and your fat tissue remains insulin-sensitive for a long time — far longer. Because once your fat tissue becomes insulin resistant, then you just become diabetic; you have no place to put the glucose. You just pee it out. That's the last resort, because your body doesn't want to waste fuel.

The thing that Rosalyn Yalow and Solomon Berson reported forty years ago is that organs respond differently to high levels of insulin, and they get insulin resistant at different periods. One of the things I put into a paragraph in the book is that I can imagine a scenario where fat tissue becomes insulin resistant prior to muscle tissue, and the result would be anorexia or bulimia. The person would eat a meal and would have no place to store the calories temporarily. So they would either lose their appetite and not be interested in eating at all (anorexia), or they might just throw it up afterwards. Because they have no place to temporarily store the calories that aren't being used immediately. Bulimia would be another option. A third option would just be to get on an exercise bicycle and ride for three hours and burn the calories off — be Lance Armstrong, in effect. So what I'm trying to figure out is what did the sugar water do, unflavored? And it's interesting — the idea that it's unflavored might disconnect some of the sort of Pavlovian responses that you've developed.

INTERVIEWER Yeah, I think that's what was key. The reason I lost my appetite in Paris was that I was drinking unfamiliar sugar water. I think this is the reason that so many diets work in the beginning: because people eat unfamiliar food. Once the food becomes familiar, the diets don't work so well.

TAUBES This is the problem with anecdotal evidence. The idea that oil could suppress your appetite I could understand, because, as I said in my lecture, you need alpha glycerol phosphate to fix fatty acids as triglycerides. You get the alpha glycerol phosphate from eating carbohydrates, so if you only ate oil it would be shipped off to the fat tissue as triglycerides, then broken down by lipoprotein lipase into fatty acids, but those fatty acids couldn't be stored in the fat. So it would raise the fatty acid level in your blood, and your body would switch over to burning fatty acids, and this would effectively suppress hunger. That makes sense. But I can't see why unflavored sugar water would be any different than say, Coca Cola itself, which is just flavored sugar water, for all intents and purposes.

INTERVIEWER Well, when I talked about it in the beginning, I was using fructose.

TAUBES Well, pure fructose, I can also understand. Friedman and Ramirez did an experiment showing that fructose suppresses hunger apparently because it is metabolized in the liver and they believe that the liver monitors fuel status in the body.

INTERVIEWER This is very interesting: someone who is not dedicated to my being wrong.

TAUBES I'm open-minded.

INTERVIEWER Your book proved that.

TAUBES The experiments that Freedman and I think Ramirez did to demonstrate that the liver must sense hunger, must sense fuel availability, is they did intravenous infusions of fructose, Fructose is metabolized only in the liver. It's not metabolized in the brain. So they infused fructose into the blood stream of rats and it suppressed eating behavior. That's one of many experiments they did that suggested that somehow what we sense as hunger is being communicated by the liver. It's always made sense to me. So if you only use fructose, and you don't get an insulin response to fructose, it would make sense that it suppresses hunger. In my book, I discuss the hypothesis that whatever prompts an insulin response is what causes us to get hungry. So, the fructose, I can understand. Actually, if you're now eating real sucrose, that's where it gets complicated, because with sucrose, you're going to get an insulin response. Unless the fructose component outweighs the glucose, but then, what is it about the absence of taste? Why would Coke make you fat, and sugar water not?

INTERVIEWER Well, first it was it was that flavorless fructose worked. Then it was flavorless sucrose worked. Then it was flavorless oils work. Then it was flavorless any food worked, in particular flavorless protein.

TAUBES When you talk about flavorless protein, what do you mean? The oils, I understand; the fructose fits with everything I know. The sucrose starts getting tricky. What do you mean by flavorless protein? Give me an example.

INTERVIEWER Oh, for example, eating chicken holding your nose clipped. It's flavorless in the sense that you don't smell it.

TAUBES That's interesting. Remember I told you that Jaques Le Magnen started his career studying olfaction (because he was blind). He was curious why the smell of a particular food can go from being very pleasurable when you're hungry to being nauseating when you're full. The example I used in the book was the smell of a cinnamon bun cooking. You can imagine that being unbelievably enticing when you're hungry, and then nauseating if you've already eaten three cinnamon buns. Le Magnen moved from that to asking similar questions about the taste of a food, which he thought was determined by our level of hunger. It's conceivable that if you don't taste a food it somehow works to suppress hunger, but I have no idea why.

[1]Interview directory.

1. <http://www.blog.sethroberts.net/2008/01/05/interview-with-gary-taubes-directory/>

---

SusanJ (2008-01-21 11:39:01)

I've thought a lot about how consuming tasteless food could suppress hunger. My favorite theory is that it is similar to what happens when an animal is hibernating. The "magical" appearance of calories fools your body into thinking it is living off its fat and then it actually does so.

Seth's blog » Blog Archive » Interview with Gary Taubes (directory) (2008-01-21 22:45:12)  
[...] Interview with Gary Taubes (part 13) [...]

Charles (2008-01-22 09:43:07)

While eating without taste may be effective, it seems to me to be a very unnatural approach, that cuts out a whole heck of a lot of built-in safety and feedback mechanisms that taste is involved in. Don't get me wrong. I have been fat, and "effective" beats "powerlessness." So if one has tried everything else, like low-carb, then I understand the appeal. But for the long term, it seems to me you're losing a lot of important information, information that is important for health and even survival. You are eating entirely based on your rational beliefs about what your body needs, and not training yourself to listen to important messages, and not rebuilding or improving the body's messaging systems. And I have found that to be a really valuable part of the process of normalizing weight.

SusanJ (2008-01-22 16:11:41)

If you are talking about food safety such as identifying rotten food by its smell or taste I don't think SLD advocates eating something you aren't sure about. For example, you'd smell and taste the first bit from a new bottle of oil and then store it properly. If Taubes is correct, fat people's bodies send them messages that they are hungry because they actually are hungry. The body is starving internally because of its inability to utilize its fat stores. Taubes provides lots of data to explain how a low-carb corrects this inability. If SLD makes your body send the message that you aren't hungry and you know you are overweight, this seems good, not bad. You wouldn't want to stay on SLD if you got too thin.

Charles (2008-01-22 17:47:03)

I guess I was talking about more subtle stuff than just whether the food was going to kill you or not. My experience is that there are a lot of messages that come from our bodies about the food we eat, or more interestingly, are hungry for. When we are tuned into our bodies, and our bodies are tuned up by a generally good diet, I think we tend to crave what we need. One thing I see with people struggling with overweightness is that both the messaging system and their interpretation of the messages has gotten out of whack. Now one explanation for that is that we just don't have a physiology that has historical experience with the kind of dense, high-carbohydrate foods we find ourselves surrounded with. So our messaging system just doesn't have the built-in experiential intelligence to deal with these kinds of foods. Yes, the SLD short-circuits the problem entirely. I'm not saying it's awful because of that. I am very pragmatic when it comes to fat control. All I'm saying is that there is value to improving the messaging system and the messaging receptors in our thought processes, so that someone stops the SLD-eating, the body/mind has a clue about what to do next to maintain where it's gotten.

Tom in TX (2009-01-02 18:15:22)

Gary Taubes: "Actually, if you're now eating real sucrose, that's where it gets complicated, because with sucrose, you're going to get an insulin response. " Forgive me for asking what may be a very dumb question, but do we know this for sure? Has anyone measured insulin response when people eat unflavored fructose/ sucrose/glucose to see if it is any different from flavored fructose/sucrose/glucose?

Darrin Thompson (2010-01-11 17:00:36)

Yes someone did measure blood glucose response to sucrose! The work of Dr. Jennie Miller-Brand on constructing a glycemic index might be useful. Their testing method for foods seems reasonable. They measure blood glucose response to eating specific things using 10 volunteers in the morning who apparently don't mind a lot of finger sticking. Their website still promotes the usual wisdom concerning fat, but they do acknowledge that fat does lower food GI. So they appear to at least be honest about their measurements. They measured sweeteners. Here are some useful numbers from their shopping guide: Fructose: 19 low Sugar, white: 68 med Glucose syrup tablets or powder: 100 high So the surprising fact is that sucrose (presumably Sugar, white above) in isolation isn't terribly harmful to insulin. Other things normally consumed with sucrose probably are worse. That said, it would be worth testing SLD vs. glucose. I'd be willing to propose that corn syrup will \_never\_ work.

Tom in TX (2010-01-12 08:19:56)

My question was: Has anyone measured insulin response when people eat \_unflavored\_ fructose/ sucrose/glucose to see if it is any different from \_flavored\_ fructose/sucrose/glucose? I want to know if the flavor has anything to do with the response.

It would seem obvious that it doesn't, but sometimes obvious things aren't true, and vice versa. 8-) I am told that the standard glucose tolerance test is given with some kind of flavored glucose solution. But I have never taken the test myself.

Darrin Thompson (2010-01-12 09:01:47)

Oh, my bad. That would be a good test. I'm a little suspicious of the favor hypothesis, but that's probably because I'm not a psychologist and I don't understand those mechanisms. And I'm partial to Taubes view that it's safe, for us laymen, to simplify the obesity model to "it's the insulin, stupid" since given all the factors acting on fat balance, that seems to be the biggest. And it's really simple to understand. And as a matter of saving the world, converting people's opinion from "it's the calories, stupid" to "it's the insulin, stupid" would be an easier sell than "it's the flavor, stupid." Seth, great work. Thanks for publishing this interview.

Seth Roberts and the Shangri-La Diet | the Justin Owings page (2011-07-25 09:40:08)

### **How Things Begin (a surprising ALS result) (2008-01-21 13:41)**

I [1]recently blogged about a surprising association between ALS and loss of a child: Losing a child reduces your chance of getting ALS. I wrote to the lead author of the study, Dr. Fang Fang, to ask how this study come to be. Here is his reply:

Severe emotional stress, as in the case of loss of a child, has previously been associated with health consequences such as psychiatric hospitalizations, cardiovascular morbidity, etc. Our initial hypothesis was that severe emotional stress might also contribute to the development of ALS. We thus used the unique settings in Sweden including the population based registration of in-patient hospitalizations and familial link registration to explore the relationship between loss of a child and the risk of developing ALS. It was surprising for us to see an inverse association between loss of a child and the risk of ALS. After a series of careful checks on data quality, we came to believe this association was not due to systemic errors.

In other words, they did the study because they expected the opposite result.

1. <http://www.blog.sethroberts.net/2008/01/17/loss-of-a-child-and-als/>

---

Stephen M (Ethesis) (2008-01-21 18:48:06)

And, they did the study because they had an easy to use database. That answered my real question, and was what I supposed. Interesting.

## Why I Like HDL (2008-01-21 15:16)

In the comments, Dennis Mangan asked why I wanted to raise my HDL cholesterol levels. The answer is simple: Because Eddie Vos told me a few years ago that "it's unanimous that having a good amount of HDL is a good thing." Eddie Vos is a Canadian engineer who runs a [1]diet-and-health website as a hobby.

1. <http://www.health-heart.org/acceuil.htm>

---

Tom (2008-01-21 16:11:43)

If you really want to boost HDL (a great idea, btw) consider 4,000 - 5,000 IU Vitamin D3/day. (And the linked blog is highly recommended for a very in-depth discussion of cholesterol, which even most doctors do not understand.) <http://heartscanblog.blogspot.com/2007/02/hdl-and-vitamin-d.html>

Tom (2008-01-21 16:25:54)

btw, Seth, I notice your blog has a Page rank of 5...you can make a lot more money if you offer the space you're giving to Google ads directly to advertisers...usually 5x more. (Yes, Google's standard cut is they take an 80 % commission....there's a reason they're taking over the world.) Suggestion...create an "advertise here" link under the google ad tower, offer the same size tower ad for 5x what you made last month from Google, and field the offers. Someone will meet your price and your standards.

## Interview with Gary Taubes (part 14-the end) (2008-01-21 18:32)

TAUBES Now here's one question for you, you know the Freakonomics guys, right? Did you read their last column on obesity?

INTERVIEWER About bariatric surgery?

TAUBES Yes. In particular, the last two paragraphs, about their recommendation that fat people, in effect, carry around something nauseating. I felt like I was reading something from 150 years ago, where they were using anal suppositories to try to cure obesity. Do you remember those paragraphs?

INTERVIEWER Yes, I do.

TAUBES They're saying, "let's get fat people to have willpower, like we do." Here's a way they could do it, they could carry some nauseating-smelling thing in a pouch around their neck, and whenever they find themselves going to the refrigerator, they could open it up and smell it.

INTERVIEWER I think they were trying to illustrate the concept of commitment device.

TAUBES I got what they were trying to do, but

INTERVIEWER You're saying that trivializes the problem.

TAUBES More than that. I'm saying it misses the point entirely. It's not about how much they eat. Remember, you can starve fat animals, for instance, and they'll die with their fat tissue intact. It's not about how

much theyâ€™re eating; itâ€™s about the regulation of their fat tissue. And if you don't understand that, you're not doing anyone a favor by discussing it publicly. If these guys are going to write about this subject, and they're so now so influential and noticeable, they should have some understanding of what's actually going on physiologically. We talked earlier about how I can become flabbergasted – your words was "radicalized" – by the idea that people can write about obesity without stopping to think â€œwhatâ€™s the mechanism? Should I know anything about the underlying biology?â€ And again, I never did until the last five years. It was only when I did the research for the book that I realized that you have to actually pay attention to the underlying biology – the hormonal and enzymatic regulation of fat tissue – or you can't understand what's going on. Imagine writing about growth defects, about gigantism or dwarfism, without caring about the hormonal regulation of growth. If the Freakonomics guys are going to write about obesity in the New York Times, then maybe they should read my book (he said, ego-maniacally), so they know what they're talking about. And since I don't know them personally, maybe you could...

INTERVIEWER Iâ€™ll recommend your book to them. Itâ€™s great that you were invited to Berkeley; that shows people trust you. The fact that they invited you means youâ€™re not a heretic, youâ€™re not off the reservation, youâ€™re a respectable person. The fact that you continue to write for the New York Times, thatâ€™s very good. Every article you publish from now on will push your book forward, will push your case forward, will say that you are a serious person who is respected by serious people. Just maybe, just maybe, this is one of the cases where the authorities were wrong. Weâ€™re all familiar with this happening in the past, and maybe this is just another case. For everybody but the tiny faction of people at the top of the health establishment, I think theyâ€™re perfectly fine with the idea that the authorities are wrong. I think that the lack of progress on the obesity epidemic is making more and more people dissatisfied. Thatâ€™s just a guess. More and more people, outside of the people who are responsible for the current policies.

TAUBES I think that's true, but thereâ€™s this contrary effect that happens. I said this in my lecture. The science I'm trying to get across can be accepted up until the point at which I say the the word carbohydrate, and then people shut down, and they think â€œOh, itâ€™s that Atkins stuff again." Their minds close and they turn around and go back to their lives. Anyway, I look forward to seeing the interview and getting your book and reading it. I enjoyed this. Again, I like nothing better than talking about this stuff.

INTERVIEWER I learned a lot from our conversation. Iâ€™m sure my blog readers will enjoy this.

[1]Interview directory. [2]The whole interview.

Andrew Gelman (2008-01-22 00:35:51)

Seth, Thanks for doing this. But I love bread, so I hate hearing this stuff about carbs being bad for you!

Niko (2008-01-22 06:34:55)

Thanks for conducting the interview! It was a feast to read an honest exchange not being spoiled by vanities and preconceptions.

Stephen M (Ethesis) (2008-01-22 06:52:10)

"Remember, you can starve fat animals, for instance, and theyâ€™ll die with their fat tissue intact. Itâ€™s not about how much theyâ€™re eating; itâ€™s about the regulation of their fat tissue." That is something that belongs on the front of a book, as the

money quote.

Stephen M (Ethesis) (2008-01-22 06:54:38)

One other comment. I noticed that my metabolism was dramatically different at somewhere between fifteen and twenty hours a week of exercise. When I hit the break point, what caused me to lose weight and the kind of food that worked well for me changed. I've always thought that a significant problem with weight loss advice is that too much of it comes from people who exercise a lot and from competitive athletes. I think what we are finally getting is an approach to weight and weight loss that involves science and a data set of normal people.

Trina (2008-01-22 09:54:57)

Thank you for this. I have copied the whole interview-35 pages. I love you guys!

Timothy Beneke (2008-01-22 10:05:57)

Fantastic interview. If Gary Taubes ever reads (or has now read) "The Shangri-La Diet" I'd love to hear more about his reactions.

Stephen M (Ethesis) (2008-01-22 12:04:07)

One last comment, I knew Clyde Filmore, a Bataan Death March survivor, and he remarked that they all thought the fat guys would do best, having the extra reserves, but that they died the soonest. Fat humans died with a good deal of fat tissue intact. Not just animals.

Always INquisitive (2008-01-22 15:47:35)

A fantastic interview. Thank you, Seth, for publishing and thank you, Gary, for participating.

Tom (2008-01-22 19:16:29)

Next step: *Surgery* so people don't have to give up their carbs. Aren't you looking forward to having your premiums raised so they can keep hitting the Mallomars? :- ) <http://www.nytimes.com/2008/01/22/health/research/23cnd-diabetes.html>

Tom (2008-01-23 13:47:35)

More interesting science: Does taking calcium cause heart attacks? [http://heartscanblog.blogspot.com/2008/01/calcium-chaos\\_22.html](http://heartscanblog.blogspot.com/2008/01/calcium-chaos_22.html)

Sandy (2008-01-23 20:05:59)

Thank God Gary's book was sitting in my public library on the day 3 weeks ago when I learned that I was officially diabetic. I am not obese at 140 pounds but could lose a dress size or maybe even two, which would bring me back to my lifetime approximate weight of 125 pounds. So - 15 or so pounds would be good, diabetic or not. I am a 65 year old woman. My doctor's few words of advice began with 'Limit your carbs drastically - no sugar - talk to our nutritionist (appt. scheduled) - and go to the American Diabetes Association website and educate yourself as to their recommendations' and I'll see you in a month after you've seen the nutritionist'. So first off I went to the ADA website - and I was SHOCKED! The ADA food pyramid is completely contrary to a low carb diet. (Look it up!) They in fact recommend that a diabetic 'choose 6-11 servings a day' of carbohydrates. They furthermore do not distinguish between highly refined carbs and complex carbs. In their pyramid rice is merely 'rice' and pasta is 'pasta' and bread is 'bread' (not even whole grain or whole wheat bread.) They encourage 2-4 servings of ANY kind of fruit a day (even canned fruit, no mention of low or no sugar). They advise very limited meats, very small portions, all fat removed, they do not bother to even mention eggs, give cheese no particular importance, and no mention of butter at all. It's a 'fat' which is not advised and is included with 'fats, oils, and sweets'. They even suggest that sweets such as cookies, ice cream or cupcakes should be used 'in small servings, to be eaten as a 'special treat'. Are they TRYING to get me on insulin? Are they TRYING to kill me? So then I went to the NIH diabetes advice. They say 'Grains, beans and starchy vegetables - 6 or more servings a day. Mayo Clinic: (Diabetics should... aim for:) 45 % to 65 % of daily calories from carbohydrates. They are ALL trying to kill me! So..... I read Gary's book twice all the way through. I am reading selected chapters again. The book will be overdue soon so I am going to buy it. And every time someone, maybe this nutritionist even, says to me 'You really need to eat

a lot of carbohydrates for a balanced diet' I am going to say 'uh huh, thanks, I will' and go home for dinner, which might be a steak with 2 eggs fried in butter, a small salad with bleu cheese dressing, water, and for dessert some dry roasted almonds. In the morning there will be cream in my coffee and then I will think about something fatty like bacon for breakfast. If my labs come down, and I am positive they will, I will send Gary a Christmas card next year because unless I get run over by a truck, I will possibly still be alive. Thx for a voice of reason in the babble of the medical community.

Tom (2008-01-24 00:22:14)

Sandy, Taubes is great and you're well on your way, but with a diabetic Dx you owe it to yourself to get a copy of "Dr. Bernstein's Diabetes Solution" in the newest edition.

Pete (2008-01-25 13:03:28)

I was excited to hear about the book, and am completely open to new possibilities, but I was pretty disappointed with the interview. It seemed to me Taubes exhibited the same human biases that he was railing against during the interview - he seems to have lost his own skepticism in the process. And to simply suggest that he is right because he is smarter than his colleagues isn't really going to get him anywhere. It is too bad, because I sure hope people take his book seriously. I will be a bit more suspicious due to this interview. Perhaps his next book should be on human influence and persuasion (Cialdini is a good starting point).

Stephen M (Ethesis) (2008-01-26 09:36:53)

I ordered the book a while back, must be selling well because it hasn't arrived yet.

None Given (2008-02-05 11:51:34)

*Surgery so people don't have to give up their carbs.* I've heard that the post op diet is low carb and low fat.

Migraineur (2008-03-20 10:45:58)

"If my labs come down, and I am positive they will, I will send Gary a Christmas card next year because unless I get run over by a truck, I will possibly still be alive. Thx for a voice of reason in the babble of the medical community." That's exactly how I feel. "What If It's All Been a Big, Fat Lie?" saved my life. I owe the fact that I am not yet diabetic (and hope never to be) to that article. So, Mr. Taubes, if you're reading, I owe you a Christmas card, too.

Paul Johal (2008-12-17 10:38:51)

I Read Gary's NYT Magazine article on July 7 2002 on a plane from Chicago to Calgary Canada. Then I bought the Atkins Book. From July 8 2002 to August 11 2002 (1 Day before my Birthday) I went on the program. I lost between 30-35 Lbs of body fat. I worked out 3-4 times a week. My allergies disappeared. I woke up without an alarm every morning by 7 AM. Having been a chubby kid, adolescent and adult - what I had gone through was truly a metamorphosis. I am still amazed at the mainstream media, health authorities and groups like the AMA, Diabetes association still maintaining their adherence to the low-fat dogma. I think with the Internet - the truth will finally start to spread. Thank you so much guys!

## Helping Students Find Their Way (2008-01-23 14:06)

At the [1]EFF party, the friend of a friend made a vivid statement about the value of helping high school and college students figure out what job fits them best. When I asked if I could quote him in my blog, he said he preferred this way of putting it:

I believe a large fraction of people around ages 16-22 are ignorant of what kinds of work environments and activities will make them happy and productive later in life. Current classroom-based training structures do not provide exposure to work environments. The cultural and social pressures from media, family and friends can be overwhelming and can often lead to people being very confused, and hence, making poor choices. I've seen that people tend to get very limited and highly biased information that leads to making training choices and work choices early in their life that are often not well matched for the person's individual genius. By mid 20's and 30's, getting out of these poor choices is extremely difficult, as financial requirements as one ages grow and available time to retrain diminishes. Expectations of experience grow as one gets older, and the neural ability to quickly learn and master new skills diminishes, especially much later, after 40 or 50 years. All of these factors point toward a critical need to have experienced, outside input into making early choices about career paths, and what types of experiences individuals would benefit from most. Such advice is available, and can be found - but it is not commonly accepted that expert outside opinion is the best source for career and training choices for young people. Kids get it mostly from their parents and friends - neither of which are consistently accurate, trained in normal psychology, or unbiased in their assessments. While many schools have "guidance counselors", I have seen most of the service offered as severely lacking (like much of public education) when compared with the needs of students, both in quality and quantity. I think there is are enormous unmet needs in many cultures, the US in particular, to provide more assistance to people in their late teens and college years to deeply explore what career options best fit their personality, and provide assessment and testing with definitive recommendations for majors, mentors, internships, and work choices.

Furthermore, when viewed on the societal level, there is an obvious argument that a society will function better when higher percentage of the population finds work/life situations that leave them happier and more productive. This I feel is even more important than providing education looking out on the 10-20 year technology horizon. In a world where most educational materials and social connections will be portable, open source, and available online - the problem will not be as much about getting information, skills, or training, but in individuals being tracked toward education options, career paths, and work environments that work best for them: a problem not easily solved with mass distribution of content or any technology solution.

This view arises partly from his own experience. He majored in Chemistry and Physics, then got a Ph.D. from Stanford in Biomedical Informatics. After working in that area for several years, he discovered that what he really enjoyed

was building communities, and moved in that professional direction. Currently he is building an online community to share digital media content.

1. <http://www.blog.sethroberts.net/2008/01/16/most-frustrating-party-ever/>

---

Peter (2008-01-23 15:13:42)

i don't think there's much rocket science to it, really. Like they say, you can paint a turd gold...put lipstick on a pig...etc. I have always hated the word 'career' and still do - I'm 34, now. A career means you've sold out - you've stopped caring about the world and have bought into the 9-to-5 and a mid-level management position and an occasional lunch at the Cheesecake Factory. Forget that. People don't hate their jobs because they are 'not a good personality fit' for them. People hate their jobs because people are not automatons. Adam Smith said division of labor led to productivity gains, but he also said it made people "as stupid and ignorant as it is possible for a human creature to become". He goes on to say that governments needed to prevent this from happening - well, if we would want to consider ourselves an 'improved and civilized' society, that is. Other economists went much further - decrying wage labor because it deprives us of our humanity. I think i'd agree with these other economists. I'm sure most Americans do, too. The solution, then, is not to help children to decide which position they would best be able to withstand this mental, physical, moral, and emotional dumbing down with - the solution is to help children escape this awful world we've created for them by restructuring society so that they don't have to perform mind-numbing work just to have access to health care - just to have a roof over their heads - just to be considered 'respectable'. At a minimum, we need to be honest with them about the world they are going to enter - they will rent themselves to some corporation for 40+ hours a week, push paper, take orders, attend meetings, and other assorted meaningless tasks. And when they're sufficiently brain-dead and have learned to not challenge authority, they'll be promoted. Then they'll buy more stuff and repeat the process. They'll be miserable, so they'll have kids, and those 20 years will slide by with some sense of purpose, and then they're back in the crapper - visiting websites on anti-depressants, wondering if they can just end it all without hurting too many people they care about. We need radical democratic reforms at the lowest levels of society - in the home, in the workplace, etc. Don't try to tell kids that they're supposed to fit into some godforsaken 'career' - it's not fair. Tell them the truth - "We messed up really bad. It's unforgivable, but that's the truth. You will probably never be happy renting yourself to some corporation - an immortal person - a god, if you will - so you need to think about ways you can stay alive without submitting yourself completely to this way of life. Here are some ideas. Oh yeah - now you have a responsibility to help us change things for kids behind you."

Stephen M (Ethesis) (2008-01-23 18:21:19)

Interesting, I was blogging about parts of that at: <http://ethesis.blogspot.com/2008/01/now-she-has-life-chosen-for-her-by-high.html> obviously heavily influenced by the links I included.

donnyrosart (2008-01-24 11:14:26)

<http://pharmaco-nutrition.net/2007/02/02/is-smelling-a-matter-of-life-and-death/> Nothing to do with helping students, but I was just wondering if you'd seen this?

Andrew Gelman (2008-01-24 19:17:59)

Seth, I chose my career (scientific research) by looking around, when I was 20 years old or so, at what various guys in their 50s whom I knew were doing. My impression was that the guys doing scientific research were happy with their jobs, even into their 50s and 60s, but people in other jobs weren't so happy. Just about all the researchers—including those who weren't doing interesting work—seemed to like their jobs. To me, at the age of 20, a business-type job seemed more glamorous, but I thought it would make more sense to do work that, statistically speaking, would be likely to leave me happy in 30 or 40 years.

Stephen M (Ethesis) (2008-01-26 09:35:54)

Andrew, looks like you made an excellent choice. My wife did something similar and is happy with her work.

Greg S (2008-02-07 09:36:14)

Help!!! I have three kids, ages 24, 22 and 19, and I know they need this type of career counseling. The colleges are pretty useless at this too, especially liberal arts. But I don't know who to go to (Mpls area). Any suggestions? And how do you tell the "good" counselors from the bad?

## **Jane Jacobs and the Drug Industry (2008-01-24 16:40)**

At the Freakonomics blog there is a [1]fascinating "quorum" (four people answer the same question) about the drug industry. "What can you tell us – good or bad – that we don't know about drug companies?" was the question. Three of the answers were bad things, one was a good thing – pretty predictable given who was asked. What interested me was how bad were the bad things (very bad) and how good was the good thing (barely good). The answers make the drug industry look very bad, in other words.

You are reading this because of my fear and dislike of pharmaceutical drugs. Long ago, I had trouble sleeping through the night. If I went to a doctor, I knew I would be given a prescription for a drug that would be ineffective (long-term) and dangerous (due to biases in the way drugs are tested). So I struck out on my own and via self-experimentation eventually [2]found several solutions that did not involve drugs. (The first was to stop eating breakfast.) This is how I realized the power of self-experimentation to find unusual solutions to everyday problems.

Why does an industry entrusted with something so precious – our health – come across so badly? In [3]Systems of Survival, Jane Jacobs pointed out two moral "syndromes" (sets of values): the commercial syndrome and the guardian syndrome. The commercial syndrome (e.g., be honest) was appropriate for businesses; the guardian syndrome (e.g., be loyal) was appropriate for governments. Why just two? Because there were two fundamental ways of making a living, Jacobs said: trading (business) or taking (government). She pointed out the trouble that arises when governments act like businesses or businesses act like governments. It is bad news, for example, when policemen are given ticket quotas. Quotas are a business tool.

I recently experienced the problem Jacobs pointed out when my scooter was towed by Avenue Tow Service (Berkeley, CA) – using power given them by the city government. They broke the windshield. No surprise they lied about it. Why should they bother telling the truth? Unlimited power is a government tool.

The drug industry is a much larger example of the same thing. What is trading? You trade voluntarily. The two parties are roughly equal in strength. What is taking? The powerful take from the weak. Although drug companies are businesses, they deal with people who are weak (sick) and have no other choice. So in essence, they take rather than trade. One of the Freakonomics examples of bad behavior was price gouging.

The federal government has given drug companies this power, just as the Berkeley city government gave Avenue Tow Service the power to tow my scooter. The federal government has done so because it has failed to effectively support research into non-drug solutions. ([4]Norman Temple and I wrote about how almost all research money goes in the wrong direction.) This leaves the drug industry, like the company that towed my scooter, with a monopoly. Unlike a conventional monopoly (a single company) it is industry-wide. But the effects are the same – a business starts to take rather than trade. And they do things that, when exposed, make them look very bad.

---

Dennis Mangan (2008-01-24 19:42:51)

Seth, it would be hard for me to disagree more with you. You say that drug companies deal with a weaker party (the sick), who "have no other choice". But if decent profits - and drug companies in general are hurting these days - are not available, the drugs they develop wouldn't be there in the first place. Then the sick would have no choice whatsoever. "Price gouging" is a euphemism for "I think you charge too much, and I want it at a lower price... my price". I do agree with regard to your ideas on sleep, but if you think that the average person is going to laboriously try different methods for getting decent sleep, rather than quickly and easily take a pill, you're dreaming. If people operated like that, there wouldn't be any obesity problem, to take one example. The pharmaceutical industry has done more good for more people than any equivalent government source, and without stealing money in the form of taxes like the government does.

seth (2008-01-24 21:52:06)

Two questions, Dennis: 1. What other choice do most people have than take the pill their doctor prescribes? 2. The Freakonomics example isn't price-gouging? (If you don't like the term price-gouging, call it something else.) You don't think that sort of pricing is widely seen as offensive?

lasser (2008-01-24 22:34:26)

What about doctors? for some reason, no one wants to criticize them. It's taboo. It's easier to criticize drug companies. But Doctors are directly responsible for our health care mess. The AMA has lost its soul.

Tom (2008-01-24 23:41:39)

Doctors? Have you seen a doctor in the last fifteen years? They have miserable lives. I would say the insurers have made whores out of them, but whores make good money and don't need to see forty clients a day to make ends meet. See "Sicko" and get back to us. (I wish Moore would do a film on Big Pharma - imagine the sequence he could create on the procession of Homecoming Queens the drug co's keep pumping through every medical office building in the country.)

Dennis Mangan (2008-01-25 07:33:21)

Seth: You ask about the choices of the sick, but thanks to "Big Pharma" they've got more choices than ever. And at any rate, poor health does not give anyone a claim on others' resources, at least not in my moral universe. "Price gouging" is indeed seen as offensive, but Americans have never shied away from having the government force others to give them free goodies. Personal responsibility is so last century.

Tom (2008-01-25 10:05:44)

The issue is a company's conspiring for years to hide evidence that their drug was useless - if not dangerous - while billions rolled in from people who believed their promises of better health and longer life. Is there a right not to be defrauded? The law says so.

Stephen M (Ethesis) (2008-01-25 11:31:32)

Tom, I deal with some doctors who have lunch catered four times a week, week after week, by the pharmaceuticals reps and who are making more than \$600k a year. Most prostitutes net a great deal less, and get far fewer free lunches.

Tom (2008-01-25 11:53:11)  
lol Point taken.

Timothy Beneke (2008-01-25 12:21:52)

The disparity between neuroscientific knowledge and drug efficacy is striking. The causes of Alzheimer's are well known, but no drug can treat it. The neurological causes of depression are not well known, but lots of drugs and even ECT can treat it well, much of the time, though probably not as well as the drug companies would have us believe. It's worth being reminded that a lot of the drugs Big Pharma creates do help people a lot.

Tom (2008-01-25 15:35:52)

Well...if a drug is under patent, we'll hear about its benefits – a lot. I was startled by the study a few days ago that appears to show that pregnant women who drink a lot of caffeine have a 25 % chance of mis-carrying (up from 12.5 % of women who don't drink much caffeine) - a **doubling** of risk. After all the ferocious battles in this country over abortion, I really don't understand the silence on caffeine, which is clearly aborting far larger numbers of children every day. (The story got some play, but it's already faded and will be forgotten in a month.) But can you imagine if Merck owned the patent for *Vivasurin* **ad**rug that could reduce miscarriages by 50 %? They could charge \$10/day minimum, and every pregnant woman in the country would be on it. Merck would make a couple of grand off every baby born, and the ads would be everywhere.

Tony (2008-01-25 16:07:49)

"The neurological causes of depression are not well known" Has anyone here read work by Griffin and Tyrrell on the causes of depression (incidentally, some of it stemming from Griffin's self-experimentation)? If so, what do you think about it?

Stephen M (Ethesis) (2008-01-25 17:13:15)

**s there a right not to be defrauded? The law says so.** The entire research thing and the buried studies is a real crime. There are real problems with drugs that work but that can't be patented, such as the Chinese herbal remedy for malaria that turns out to actually work, is cheap and not worth the trials. The UN has been working out a protocol for approving financing for it (but not opening the floodgates to tapping funds for worthless folk remedies at the same time). Tom, you and Tim make excellent points.

Dennis Mangan (2008-01-25 19:21:45)

"Merck would make a couple of grand off every baby born, and the ads would be everywhere." Yeah, and we'd see the Merck executives holding guns to people's heads to force them to fork over the money, just like they're doing now. What a bunch of whining socialists everyone in this country has become.

lasser (2008-01-25 23:30:06)

"Tom, I deal with some doctors who have lunch catered four times a week, week after week, by the pharmaceuticals reps and who are making more than \$600k a year." I worked at a doctor's office in a rural town hundreds of miles from a large city. Every lunch was catered at the most expensive restaurants in town. The doctor did not have an objection. The drug companies' sales representatives were likable people. The doctor, making much more money than everyone else in the office, was an outsider socially. As a result, the doctor loved to talk with the drug company rep. I can't honestly blame the doctor. The lunches were a great opportunity to get the bitter office employees together to share a meal. And like I said, the sales reps. were extremely likable. The bottom line: The American Medical Association needs to look into this. But I don't have a lot of faith they will.

## The Mystery of Bilboquet (2008-01-25 10:46)

A [1]bilboquet is a toy: a ball and stick. The ball has a hole and is attached by a cord to the stick. You toss the ball and impale it with the stick. A friend gave me a Japanese version:

It seemed impossible to reliably catch the ball on the stick but here is someone who can do it:

[EMBED] Even better: [EMBED] How do people get so good at this? I have part of the answer: it is a lot of fun to practice. I have been tracking my progress and I have to restrain myself from doing it more often. Why is it so much fun to practice? To be continued.

1. <http://www.gamesmuseum.uwaterloo.ca/VirtualExhibits/bilboquet/pages/index.html>

---

Timothy Beneke (2008-01-25 12:31:06)

I'd explain the toy's attraction in terms of the induction of "flow" ([http://en.wikipedia.org/wiki/Flow\\_\(psychology\)](http://en.wikipedia.org/wiki/Flow_(psychology))) as Cs kszentmih lyi (sheek-sent-me-high) calls it. In his research people are happiest in such states; states where they are absorbed in activity that is hard enough that they are not bored, not so hard that they are totally overwhelmed and frustrated and helpless, where they get feedback as to how they are doing, and that preferably have some meaning for them, though the latter may not even be necessary. We are happiest when we are engaged and lose awareness of ourselves; of course if we are getting paid for it, that's even better... We evolved to find the use of our abilities pleasurable... The Japanese are very good at creating entertainment..

Seth's blog » Blog Archive » The Mystery of Bilboquet (continued) (2008-01-29 10:46:17)  
 [...] The Mystery of Bilboquet [...]

OdileS (2012-03-25 16:26:44)

Yeah, I use to play this as a teen while living in France...I constantly practiced and got very good at it..I would challenge myself as to how many times I could get the ball in the peg... I am looking around the web to buy one...Got any suggestions?

## Clavell's Law (2008-01-26 10:04)

Andrew Clavell writes a blog called [1]Financial Crookery. A [2]recent post about bonuses included this:

Due to the apparent ease of this management game ["managing upward" = convincing your superiors you are doing a good job without actually doing so] compared to the grisly business of finding actual customers and making them want to do profitable business with you, it is no wonder foot soldiers vie to join management ranks.

What is the scientific equivalent, I wonder?

1. <http://crookery.blogspot.com/>
2. <http://crookery.blogspot.com/2008/01/at-bonus-time-no-one-can-hear-you.html>

---

David (2008-01-26 11:35:54)

Focusing your work on what will bring top publications and grants, on low-risk small steps rather than high-risk big steps?

seth (2008-01-26 11:46:18)

It's about creating the illusion of progress rather than actual progress. It's a variant of Gresham's Law (bad money drives out good).

Stephen M (Ethesis) (2008-01-26 21:20:59)

OB guys study things like this. For example, effective managers (ones who get things done) actually network less than the average. Successful managers (those who get promoted and make money) spend almost half their time networking. Interesting.

## Does Mercury Cause Autism? (2008-01-27 07:59)

A [1]2003 paper in the International Journal of Toxicology suggests the answer is yes. A Baton Rouge doctor named Amy Holmes, who herself had an autistic child, wondered if mercury was involved. She tested the hair of a series of autistic children from her practice and found, to her surprise, that they had less mercury in their hair than other children. Then she and two other scientists did a well-controlled comparison of normal and autistic children that confirmed her original observation. These are the data in the 2003 paper. Here is its abstract:

Reported rates of autism have increased sharply in the United States and the United Kingdom. One possible factor underlying these increases is increased exposure to mercury through thimerosal-containing vaccines, but vaccine exposures need to be evaluated in the context of cumulative exposures during gestation and early infancy. Differential rates of postnatal mercury elimination may explain why similar gestational and infant exposures produce variable neurological effects. First baby haircut samples were

obtained from 94 children diagnosed with autism using Diagnostic and Statistical Manual of Mental Disorders, 4th edition (DSM IV) criteria and 45 age- and gender-matched controls. Information on diet, dental amalgam fillings, vaccine history, Rho D immunoglobulin administration, and autism symptom severity was collected through a maternal survey questionnaire and clinical observation. Hair mercury levels in the autistic group were 0.47 ppm versus 3.63 ppm in controls, a significant difference. The mothers in the autistic group had significantly higher levels of mercury exposure through Rho D immunoglobulin injections and amalgam fillings than control mothers. Within the autistic group, hair mercury levels varied significantly across mildly, moderately, and severely autistic children, with mean group levels of 0.79, 0.46, and 0.21 ppm, respectively. Hair mercury levels among controls were significantly correlated with the number of the mothers' amalgam fillings and their fish consumption as well as exposure to mercury through childhood vaccines, correlations that were absent in the autistic group. Hair excretion patterns among autistic infants were significantly reduced relative to control. These data cast doubt on the efficacy of traditional hair analysis as a measure of total mercury exposure in a subset of the population. In light of the biological plausibility of mercury's role in neurodevelopmental disorders, the present study provides further insight into one possible mechanism by which early mercury exposures could increase the risk of autism.

The abstract omits the most important piece of information: There was little or no overlap between the hair mercury of the control and autistic groups. (It is hard to tell exactly, the data are badly plotted.) Given the size of the two groups, this is highly persuasive. The abstract also omits the basic conclusion: In autistic children, a mechanism that gets rid of mercury is broken. As a result, they get poisoned by levels of environmental mercury that would otherwise be safe.

Holmes started treating autistic children by (a) giving them a compound that tends to bind to mercury and form a compound that is excreted and (b) reducing their mercury exposure. The results of this treatment have been very impressive. As children get older, it becomes less effective. Here are details:

We currently have over 500 autistic patients under treatment with DMSA ranging in age from 1 to 24 years old. In general, we do not expect to see any behavioral, language, or social improvements until at least some of the CNS mercury has been removed. As of 1/15/01, we had 85 patients who had finished DMSA alone and had completed at least 4 months of DMSA + lipoic acid. The results of treatment in these patients are presented below:

n = 85 Improvement ( % )  
 Age Number Marked Moderate Slight None  
 1-5 40 35 39 15 11  
 6-12 25 4 28 52 16  
 13-17 16 0 6 68 26  
 18+ 4 0 0 25 75

Once lipoic acid is added, we usually track mercury excretion via tests of fecal mercury. We have noticed a large dependence of excretion on age of patient with the younger patients excreting much more mercury than the older patients. We think this difference in rapidity of excretion may explain the differences in response between the various age groups.

We have 6 patients, all 1 to 2 years of age who are finished with treatment by measurements of urinary and fecal mercury excretion. These 6 patients are "normal" by parent reports and repeat psychological testing. We have no children over the age of 2 who are finished with treatment. The rapidity of excretion seems to decrease markedly with each additional year of age. There are several children, mostly in the

younger age groups, who have made remarkable progress to the point of being able to be mainstreamed in school, but who are still have some "oddities" of behavior – none of these children have completed treatment yet.

Unfortunately I cannot find later results. An [2]undated announcement says "due to health reasons, Dr. Amy Holmes is no longer able to continue in her practice." [3]Miscellaneous comments by Holmes. [4]SafeMinds, a Cambridge, MA nonprofit devoted to this issue.

Addendum. A [5]new TV series (Eli Stone, rated B+ by Entertainment Weekly) will consider this issue. According to the NY Times TV reporter, "Reams of scientific studies by the leading American health authorities have failed to establish a causal link between the [mercury-containing] preservative and autism."

beagle (2008-01-27 17:49:57)

A quick google search brought these up: <http://autismdiva.blogspot.com/2005/12/dr-amy-holmes-was-just-trying-to-help.html> <http://autismdiva.blogspot.com/2007/08/dr-amy-holmes-and-mikes-story.html> Haven't had time to read either the original docs too deeply myself, nor these links.

B Campaigne (2008-01-27 18:45:16)

Hair analysis is inconclusive. Thy a live blood cell anaysis. I guarantee a different result. Please stop this propaganda. Why is the focus always only on thimerosal? Included on this list of chemical concerns should also be formaldehyde, M.S.G., aluminum, Butylated hydroxytoluene or B.H.T. and many others. Don't let the mainstream media and pharma spin doctors lull you into only focusing on the thimerosal. Remember these corporations would no doubt lose everything if a connection is made between the preservatives and the world wide vaccine programs. I saw my 5yr old son's live blood analysis taking place. I saw live candida yeast in his blood. I saw the heavy metals as well. Where do you think it came from? Leaky gut syndrome comes from the M.M.R jab.

Kathleen (2008-01-29 16:46:27)

Frankly Seth, I'm stunned. Shocked. That you'd even find the topic worthy of consideration much less come to these conclusions. This tired old argument is what I expect from wild-eyed curebies -not you- and it causes me to question the caliber of the content you've been publishing. I am sad and disappointed. Or maybe that's just my mercury poisoning talking...Odd how mercury poisoning seems to run in families. Perhaps you'll tackle that next.

seth (2008-01-29 18:25:41)

Kathleen, do you have an alternative explanation of the data of Holmes et al.? As for "tired old argument" I haven't seen anyone else say how persuasive the Holmes et al. data are. Even their abstract fails to make this clear.

Seth's blog » Blog Archive » New York Times vs. Reality (2008-02-02 17:05:50)  
[...] Does Mercury Cause Autism? [...]

Charles (2008-02-03 01:22:20)

Seth, I lean towards the mercury-autism link, but only lean, because the data seems contradictory. When I mentioned this article/study to a statistician friend of mine (he had just blogged about this) his response was that since the mercury was removed, we haven't seen any changes in the rate of autism, therefore it couldn't have been the mercury. I still haven't been able to find a way around that argument. I would suggest that some children are more susceptible than others, and the vaccinations might send them over the edge. I would also suggest that the rise has a lot to do with the essential fatty acid imbalances (Omega-6 vs. Omega 3) that have been increasing significantly over the past couple of decades. A book I read 10 years ago predicted a rise in autism, ADD, MS, Alzheimer's and other nervous system issues as a result. And as to your commenters who just can't bare the thought of someone bringing this issue up again, get a life. You speak as if all of these questions have always been dealt with purely dispassionately and scientifically. Your willful ignorance of the politicization of science and public health does not speak well of your intellectual capacity. The idea that mercury could have been a cause of the rise of autism was not unreasonable, and while the question seems to have been answered at this point, it was not always so clear. It would be wonderful if you could save your passion for helping to figure out what's happening, rather than getting your rocks off by reacting so indignantly.

Kev (2008-02-03 02:06:48)

Speaking as the parent of an autistic child, Seth and Charles will just have to get over their continued outrage that people should be outraged that this study is still being discussed as viable. You would both do well to read the following: 1) [1]Prometheus Part II 2) [2]Autism Street 3) [3]Not Mercury 4) [4]Autism Diva The above authors and scientists are also parents of autistic kids. We share an opinion that it might be good for our kids if people would move on, actually LEARN about the science involved instead of regurgitating abstracts like they think they know what they're talking about and hey - maybe some of that good old research money might start going to ways that will improve the lives of our kids. Y'know - education, housing for autistic adults, silly little things like that.

1. <http://photoninthedarkness.blogspot.com/2005/07/perfect-example-of-how-not-to-do-study.html>
2. <http://www.autismstreet.org/weblog/?p=61>
3. <http://notmercury.blogspot.com/2006/03/glutathione-what-is-it-and-why-should.html>
4. <http://autismdiva.blogspot.com/2005/08/ pernicious-is-word.html>

seth (2008-02-03 06:31:57)

Charles, "I haven't been able to find a way around that argument." I suggest you look at <http://www.jpands.org/vol11no1/geier.pdf> which shows that the autism rate HAS started to fall, exactly when you would expect from the mercury/autism hypothesis. Kev, Thanks for the links. I read the comments of Autism Diva before my post. I've now read the rest. They don't make any good points. For example, Prometheus gives three possible explanations - explanations he or she thinks are plausible - for the Holmes et al findings. Here is one of them:

The low hair mercury level is the result of a laboratory or specimen collection error that was systematically applied to only the autistic subjects. There is not enough information in the paper to address how this might have happened, but it is my personal favorite.

With no supporting data. This is like saying "then a miracle happens" or "I just don't believe it". It isn't persuasive.

Charles (2008-02-03 09:09:34)

Seth: Thanks for the .pdf. Interesting stuff. And I think your excerpt above, "...but it is my personal favorite," perfectly illustrates why people might be generally skeptical. I'm no longer shocked when I read various scientific studies in which the conclusions aren't at all supported by the data because it happens so often.

Kev (2008-02-03 10:19:18)

If you're relying on JPANDS papers for good science then I understand why you are having a problem. Good luck, but don't expect people not to take issue with you when you express your dissatisfaction with their criticism of your credulousness.

Autism News Beat (2008-02-03 10:50:20)

Kev's right - JPANDS gives a bad name to junk science. A recent paper (Gundacker et al , 2007) shows that genuine poor Hg excretors have elevated hair mercury levels. Hair reflects blood mercury level, so if you can't excrete it, the mercury builds up in the blood and the hair. Hair has high levels of cysteine (a sulfur-containing amino acid), that draws out and retains blood mercury. That's why we use hair mercury levels to track long term exposure. But hair also attracts and hold on to environmental mercury, which makes hair mercury levels in urban environments unreliable.

seth (2008-02-03 16:50:14)

Kev & Autism News Beat, Do you have an alternative explanation for the very clear declines in autism rates shown in the JPANDS paper?

Autism News Beat (2008-02-03 19:44:48)

There were a few quarters in late 2004 and early 2005 when the Calif. numbers seemed to trend downwards, but it didn't last. Over the longer term, case loads are not going down. Figure 3 in the Geier's non-peer reviewed article tracks CDDS numbers. Look at the data point for the third quarter of 2002. It's a huge out-lier, due to a programming error that was discovered in July 2002, in addition to changes to the reporting system effected in the same month, that added a large number of clients that had previously gone unrecorded. The hugely inflated number and subsequent "decline" is an anomaly that the Geiers passed off as real. A legitimate journal would have caught the deception. The Geiers presented the data point like any other. It is inconceivable that any honest, skeptical researcher could look at that data and not wonder about the outlier. The answer is readily available on the CDDS website. It is obvious that the Geiers deliberately used skewed data to further their agenda. That's not science.

B Campaigne (2008-02-16 03:58:57)

Blood Levels of Mercury Are Related to Diagnosis of Autism: A Reanalysis of an Important Data Set M. Catherine DeSoto, PhD Department of Psychology, University of Northern Iowa, Cedar Falls, Iowa, cathy.desoto@uni.edu Robert T. Hitlan, PhD Department of Psychology, University of Northern Iowa, Cedar Falls, Iowa The question of what is leading to the apparent increase in autism is of great importance. Like the link between aspirin and heart attack, even a small effect can have major health implications. If there is any link between autism and mercury, it is absolutely crucial that the first reports of the question are not falsely stating that no link occurs. We have reanalyzed the data set originally reported by Ip et al. in 2004 and have found that the original p value was in error and that a significant relation does exist between the blood levels of mercury and diagnosis of an autism spectrum disorder. Moreover, the hair sample analysis results offer some support for the idea that persons with autism may be less efficient and more variable at eliminating mercury from the blood.

seth (2008-02-16 06:30:44)

The article by DeSoto and Hitlan is here: Journal of Child Neurology, Vol. 22, No. 11, 1308-1311 (2007)

Ashley (2008-03-24 19:54:48)

Hi, I'm a student at a college in New England majoring in Psychology. For my Research Methods class I need to do a study and I chose to do Mercury causing Autism. I have a few questions that I would be very grateful if anyone would answer them and maybe give me an idea of how you feel about the subject. Thank you for taking the time. 1. Do you personally know anyone that has Autism? 2. Do you know a lot of information about Autism? Would you consider yourself an expert? 3. Do you believe mercury causes Autism? 4. Do you believe that thimerosal has made Autism increase? 5. Why do you think that the rate of Autism is at 1 out of 150 children? 6. Why do you believe that that number varies from state to state? Is it the environment? The mercury in the environment? 7. Do you believe that testing childrens' hair is an accurate test of mercury causing Autism?

Agerserve (2008-10-23 09:32:23)

There was this guy see. He wasn't very bright and he reached his adult life without ever having learned "the facts". Somehow, it gets to be his wedding day. While he is walking down the aisle, his father tugs his sleeve and says, "Son, when you get to the hotel room...Call me" Hours later he gets to the hotel room with his beautiful blushing bride and he calls his father, "Dad, we are the hotel, what do I do?" "O.K. Son, listen up, take off your clothes and get in the bed, then she should take off her clothes and get in the bed, if not help her. Then either way, ah, call me" A few moments later... "Dad we took off our clothes and we are in the bed, what do I do?" O.K. Son, listen up. Move real close to her and she should move real close to you, and then... Ah, call me." A few moments later... "DAD! WE TOOK OFF OUR CLOTHES, GOT IN THE BED AND MOVED REAL CLOSE, WHAT DO I DO???" "O.K. Son, Listen up, this is the most important part. Stick the long part of your body into the place where she goes to the bathroom." A few moments later... "Dad, I've got my foot in the toilet, what do I do?"

Plavuse (2011-03-06 13:53:12)

Ues, but not everthing black and white, something is gray :) Miranda

### **Gary Taubes on Cholesterol and Heart Disease (2008-01-27 17:25)**

[1]He interprets recent results with a cholesterol-lowering drug called Vytorin much like [2]I interpreted similar news about a different cholesterol-lowering drug (torcetrapib).

### **Interview with Susan Allport (2008-01-28 11:07)**

[1]Susan Allport is the author of [2]The Queen of Fats: Why Omega-3s Were Removed from the Western Diet and What We Can Do to Replace Them, which for me was the best source of introductory information on the subject. Chapter 1 is [3]here. A [4]video.

What have been the main reactions to your book?

The best reaction has been from scientists and the American Oil Chemists Society (AOCS), whose members were happy to have the history of this important research laid out for the public and for themselves. The book hasn't yet caught on with general readers – in part because the material is somewhat difficult and in part because most people think that the problems with fats are with trans fats or saturated fats or cholesterol: three long detours on the road to dietary understanding, in my opinion.

Learned anything since you wrote it that you would include in a revised/expanded edition?

I would certainly include a key piece of evidence that has been available for some time but not brought to light. It has to do with the argument that we don't elongate and desaturate the parent essential fatty acids very

well (the omega-3 fat: alpha linolenic acid and omega-6 fat: linoleic acid). Therefore, the argument goes, it doesn't matter about the quantities of these parent fats in the diet. What matters is the amount of long chain fats (in fish, etc.)

But here's the rub and the lie to this argument.

According to the Nationwide Food Consumption Survey and other data, Americans consume more long chain omega-3 fatty acids than they do long chain omega-6 fatty acids (See "Polyunsaturated fatty acids in the food chain in the US", Am J Clin Nutr 2000;71 S 179s-88s.) Yet their tissues are full of these highly inflammatory omega-6 fats.

How did this happen? There is only one way. The large amount of linoleic acid in the diet (about 7 % of energy) overwhelms and outcompetes the much smaller amount of alpha linolenic acid (about .7 % of energy). So it does matter how much linoleic acid we consume. Linoleic acid is the elephant in the living room and the reason we are experiencing the many chronic illnesses that are associated with an insufficiency of omega-3s.

I like to think that anyone who has read [5]my flaxseed oil results (flaxseed is high in alpha linolenic acid, the short-chain omega-3 fat) would agree. Next question: My impression is that the optimal amount of omega-3 is highly unclear. Do you agree?

The optimal amount of omega-3s in one's tissues does seem to vary, somewhat, according to where one lives. In the cold Arctic, humans benefited from a very high proportion of omega-3s in their tissues, and there they weren't penalized for having a lower proportion of omega-6s b/c there are few infectious microorganisms in the Arctic. (Omega-6s, remember, are important in mounting a good immune response.) In more temperate and tropical regions, we need a more balanced amount of 3s and 6s in our tissues. We'll be learning a lot more about these optimal amounts in the future.

What's most critical to understand, though, is that omega-3s and omega-6s compete for enzymes and for positions in our cell membranes. So the amount of omega-3s you need to eat in order to achieve a given (optimal) amount in your tissues depends entirely on the amount of omega-6s you're eating. If you're eating small amounts of omega-6s, you need to eat only small amounts of fish and greens. If you're eating, as most Americans are, large amount of omega-6s, you'll need to eat large amounts of fish and greens – more fish than there are in the ocean!

Which widely-listened-to nutrition expert or group of experts has best appreciated the importance of omega-3s? Which has worst appreciated them?

I've had very good conversations with Dr. Mehmet Oz, and I know that Andrew Weil has a very good understanding of the issues. Epidemiologists seem to have the least appreciation because they have little knowledge and appreciation of biochemistry, in general.

In that last question I was thinking of Walter Willett, whose book Eat Drink and Be Healthy fails to clearly distinguish omega-3 and omega-6 fats. Since he's an epidemiologist, that agrees with what you say. Can you say more about the reaction of epidemiologists?

For Willett to observe the difference between the two families of fats in his type of research, he would need subjects with very different proportions of these fats in their tissues. He doesn't have that since all of his subjects eat a similar American diet. He also doesn't see it because he doesn't control for the two families and their competitive interactions. What we need to do to achieve a good understanding of the role of the two families of essential fats in health and disease is to take experimental work (which clearly shows important differences b/n the two families) and use it to frame our prospective studies. (And because of the competitive interactions, we can't use fish intake as

an indication of omega-3 status; we must use tissue levels of the two families!)

Stephen M (Ethesis) (2008-01-29 18:41:49)  
Thanks, that was interesting.

Tom (2008-01-30 00:49:49)  
Seth, think you'll find this interesting: <http://heartscanblog.blogspot.com/2008/01/high-dose-fish-oil-for-lpa.html>

Susan Allport (2010-07-28 04:25:51)  
Hi Seth, Did you see this piece of self experimentation? It clearly shows how hard it is to have good omega-3s on a high omega-6 diet. <http://omega-6-omega-3-balance.omegaoptimize.com/2010/07/25/case-study-30days-of-high-omega6-dietstiffens-arteries-and-increases-belly-fat.aspx>

## **Blog Power (2008-01-28 15:57)**

[1]Philip Weiss:

It's not just that the Times is spot-on about Giuliani's character. It's great to see a big newspaper take the gloves off and really let someone have it and not worry about sinking the guy's campaign. The editorial wasn't fair or balanced, but it for-damn-sure knew what it was talking about. I feel that the Times was influenced by the blogosphere in those rhetorical liberties, and I hope the trend continues. Can you imagine someone saying what they really think about the Israel lobby on the Op-Ed page, instead of saying what they're supposed to be saying? Now that would be progress.

[2]  
New Yorker abstract:

On September 8th, two million people in two hundred and twenty cities across Italy celebrated V-Day, an unofficial new national holiday, the "V" signifying victory, vendetta, and, especially, "Vaffanculo" ("Fuck off"). The event had been organized by Beppe Grillo, Italy's most popular comedian, to protest endemic corruption in the national government. . . . Grillo has galvanized Italians by talking about corruption with irreverence and humor"indeed, by talking about it at all. The country's mainstream press is controlled,

or owned outright, by political parties and corporations. Since 2005, Grillo has addressed the public primarily through his blog. . . V-Day grew out of Clean Parliament, which Grillo launched in 2005, when he posted on his blog the names of the convicted criminals serving in parliament.

2. [http://www.newyorker.com/reporting/2008/02/04/080204fa\\_fact\\_mueller](http://www.newyorker.com/reporting/2008/02/04/080204fa_fact_mueller)

---

Andrew S. (2008-01-28 17:34:30)

The irony in the first quotation, though, is that a New York Times endorsement in the GOP primaries does more harm than good. Rudy rushed out a web add touting the NYT's attack on him. <http://blip.tv/file/629683>

### **The Mystery of Bibloquet (continued) (2008-01-29 10:46)**

Bibloquet appears impossibly difficult, I [1]posted recently. Yet people become very good at it, no doubt through huge amounts of practice. Why?

Now and then I hear about somebody getting very good at a physical skill: A basketball player is very good at free-throw shooting, for example. No doubt the reason is lots of practice. I'm not surprised because explanation is easy: He played a lot of basketball (social, fun to move around), he wanted to be a pro (aspiration). Professional musicians have practiced a lot – sure, music sounds good, it's their job. Most cases of extreme practice that I know of have plausible common-sense explanations.

Bibloquet skill does not. It leads nowhere, is completely useless (I suspect), isn't social, and isn't promoted by the environment (there are no bilboquet rooms, for example). Some people spend a huge amount of time playing video games (also useless, etc.), but video games are complicated. Bibloquet is simple. You can see this in the price. A video game might cost \$40, not counting the price of the computer it runs on. My bibloquet probably cost about \$1. No computer needed. For that \$1 I am going to get a huge amount of enjoyment. Hard to think of something else for \$1 that would provide so much pleasure.

As Michel Cabanac has argued many times, our brains use pleasure to guide our actions: What we should do is more pleasant than what we shouldn't do. Sometimes this system misfires because something man-made resembles what we should be seeking. If your iron level is very low you may suffer from pagophagia – too much ice chewing. Ice chewing brings persons with pagophagia great pleasure. I'm sure that the evolutionary reason is that ice chewing is producing the same sensations as bone crunching. Bone crunching would be a good source of iron because bone marrow is iron-rich. The mechanism that causes pagophagia evolved because it promoted bone crunching. Chewing ice resembles bone crunching. What biologically-useful activity does playing bibloquet resemble?

My guess is that bilboquet is addictive because:

1. Success is sharply defined. You catch the ball (success) or not (failure). Other addictive games have this feature. Tetris: you fit the falling shape into the pile at the bottom. Sudoku: You fill in all the squares correctly.

2. Success is not easy. We like a challenge. Most video games, such as Tetris, get harder and harder.

### 3. Hand-eye coordination is involved.

At the core of human evolution is occupational specialization and diversification. It started with hobbies. To get diversity of hobbies you need diversity of reward; a wide range of skilled activities must be rewarding. Rather than evolve a separate mechanism for each hobby, this was accomplished with a mechanism that is quite flexible and can operate with lots of different activities. Thus the reward system can be transferred to something completely useless, such as bilboquet. The not-too-easy feature caused hobbyists to become more and more skilled because only by continually challenging themselves could they keep enjoying it. Hand-eye coordination was required because the goal was to get people to make things. Why success had to be sharply defined I'm not so sure. (In art, a similar human activity, success is not sharply defined.) Maybe it serves to focus effort.

The lesson for me is that if I want to produce a task that will measure how well my brain is working and be so much fun it's addictive, it should involve hand-eye coordination. (It will be easier to make the many measurements [2]my omega-3 research requires if I have such a task.) This is consistent with what I've observed so far: None of the tasks I've used have been addictively fun. The balance task had a fairly sharp and difficult measure of success (staying balanced for more than a few seconds) and was physical but didn't involve hand-eye coordination. The digit-span task had a sharp measure of success (perfect recall) and could be made more and more difficult but didn't involve hand-eye coordination. Three other tasks I've used had less sharply-defined success and didn't involve hand-eye coordination.

Addendum. A [3]Japanese website. In Japan bilboquet is kendama. Thanks to Pearl Alexander.

---

Kjrsten (2008-01-29 16:38:28)

"success is sharply defined" ... that's why I moved from being a graphic/web designer (limited to visual presentation) to being a developer/programmer. I get a much bigger kick out of making a piece of code work – difficult to do sometimes, but when you get it right, you KNOW it. Design involves subjective value judgments, and "success" is in the eye of the beholder.

Kjrsten (2008-01-29 16:40:18)

I had to look up bilboquet. I had thought it might be "ball in cup" but it's "spike in ball". Female vs. male? ; )

Stephen M (Ethesis) (2008-01-29 18:39:07)

<http://www.independent.co.uk/news/science/scientists-discover-way-to-reverse-loss-of-memory-775586.html> You might find that interesting, an intersection of brain function and obesity research.

NE1 (2008-01-29 18:45:17)

Video games are very social, if mostly only between males. You might imagine it's a way to establish a hierarchy like hunting is for the Ache, even though it's not necessary anymore. Sounds like bilboquet would be useful if anything as party trick, like solving the Rubik's cube, playing the harmonica (these days), or other things kids routinely and amazingly master in their spare time. I don't see why you should want a particularly fun game, that would encourage you to want to improve personally. You want something where it's very clear what your limitation is, and not personal technique. Something that takes the data for you, so that you aren't able to bias the value, sure. The few you list sound fine, if they reflect something. Really, it seems like

with most games/tests you're screwed, because of learning. Maybe it's best to have a game you've reached a near permanent plateau with, so that transitory omega-3 status shows clearly against the residual learning background.

KenF (2008-01-29 18:51:45)

"Stacks" is very popular in my house, where you stack up these cups and then unstack them.

seth (2008-01-29 19:59:32)

NE1, I want a particularly fun test to make it easier to collect the data.

Jeff Winkler (2008-01-31 12:26:20)

My morning routine includes: 1 - 20 minutes of a driving game, Burnout Revenge, an Xbox video game, using a Kilowatt game controller ([http://kotaku.com/gaming/live-blogging/kilowatt-kills-my-girly-muscles-110\\_058.php](http://kotaku.com/gaming/live-blogging/kilowatt-kills-my-girly-muscles-110_058.php)) This meets your criteria in spades - hard, fast paced, visual. Wakes me up physically, gets blood flowing to the brain. 2 - Mindhabits, <http://mindhabits.com/> . The goal is to click on smiling faces. Hand-eye coordination...and a tie-in with your faces in the morning idea. It's shown to reduce cortisol (paper - [http://selfesteemgames.mcgill.ca/research/dandeneau\\_etal\\_07.pdf](http://selfesteemgames.mcgill.ca/research/dandeneau_etal_07.pdf)) Mindhabits meets your 3 criteria.. though I don't obsess over score. I do it because it's fun and improves my outlook. 3 - Typing practice: recently switched to the Dvorak keyboard layout so I practice 15 minutes a day. The software tracks speed and error rate. All 3 are electronic games which record results. They're fun and get me "warmed up" for the day.

The Doctor What (2008-02-01 12:30:45)

You keep saying it's hard to do, but it isn't once you know the trick. Both the cup-and-ball and the spike-and-ball have a trick that let anyone with a little eye-hand skills do it successfully. cup-and-ball: When you throw the ball in the air (by tugging on the cup) it forms an arc. You want to catch the ball as it approaches the apex (top) of the arc. If you catch it too far below the apex it bounces and won't stay in the cup. Ideally, you get the cup right under it as it hits the apex. spike-and-ball: Take the ball and set it spinning at the end of the string. Then do the same thing as with the cup-and-ball. The spinning keeps the hole pointed downwards. It's actually easier because you have more "bounce" room because the spike is so tall. Ciao!

Seth's blog » Blog Archive » The Lessons of Bilboquet (2008-02-07 12:37:20)

[...] The Mystery of Bibloquet (continued) [...]

Mark (2008-12-28 10:01:00)

If you're still doing the kendama, let me know. I'll send you an official one, licensed by a nonprofit that certifies them. They have patents and design patents on the particular design used in competitions, and three companies currently make them. Spinning the ball isn't necessary. You just need to jerk the ball straight up from a dead hang when it is still and not jiggling so that the hole stays on the bottom. Spinning accomplishes that by making the ball a little gyroscope, but you can just stop the wobbling with your hand also. When catching the ball in the cup, you put the cup under the ball at its apex, but you should pull it straight up, not in an arc, although the arc version is also one of the tricks you can do. There are over 100 tricks. There are kyu and dan levels, just like in karate. This page has the tricks for all the kyu levels of [1]kendama. Check out the "lighthouse" if you really want to see something that seems impossible (but is not so hard if you blow several hours practicing it).

### **Academic Horror Story (UC Berkeley) (2008-01-31 10:44)**

Two years ago, a University of California Berkeley undergraduate was a subject in an MRI experiment at the Henry H. Wheeler, Jr. Brain Imaging Center on the UC Berkeley campus. She did it for the money: It paid \$200 for two two-hour sessions, during which you lie motionless inside a large loud machine. During the first session, the persons monitoring the experiment could see that something was seriously wrong: The subject had a large mass in her brain. Clearly her life was at risk. But they didn't tell her immediately what they had seen. (Later they claimed they "couldn't" have told her, for legal reasons. A friend of hers who was present at the experiment was threatened with serious legal action if he told her.) Instead, they sought outside opinion about what the mass was and what to do about it. A few weeks later, they told her about it. "Sometimes unusual things show up on these scans" she was told. This was incorrect: Nothing like this had happened before at UC Berkeley.

In a way, the story has a happy ending. The large mass turned out to be benign (but at the time of the experiment they had no way of knowing that). It was removed. A year and a half after the operation, there are no signs of recurrence.

The experimenters not only (a) withheld what might have been life-saving information, (b) they persisted in this behavior after having time to think about it; and (c) they threatened someone who wanted to do the right thing. This is no momentary lapse in judgment. The experimenters – including the professor in charge and who knows what other powerful people at UC Berkeley – actively did the wrong thing. They carefully decided not to tell her info that might have saved her life.

More. After I wrote this post, I learned that the person in charge of the Wheeler Brain Imaging Center at the time was Professor Mark D'Esposito. By email I asked him if he disputed any of the facts in this post and if the Center had done anything to keep such a thing from happening again. He didn't reply.

---

NE1 (2008-01-31 11:27:21)

When I have done those experiments in the past, the grad students running it have offered to give them the MRI's for free. They'd do anything to get people to just show up.

Chris (2008-01-31 12:07:42)

Privacy rules have proliferated so much in recent years that I expect many institutions have developed a culture of not releasing any information to anyone, ever, common sense or humanity be damned. In this case, there may be some mindless spillover from experiment protocols that obsess over double-blindness. Not that that there's a logical case for it - compare it to the reporter's reflex to scatter "alleged" throughout any crime story, even where the risk of libel is laughably absent: e.g., "The alleged assassin felled the long-time dictator with one shot to head." Needless to say, the experimenters' behaviour was inexcusable.

CD (2008-01-31 12:27:25)

Why not tell us the experimenters' names?

Stephen M (Ethesis) (2008-02-01 11:43:52)

btw, for a funny post on salt (and the sodium lack most people have): [http://www.t-nation.com/article/most\\_recent/sodium\\_your\\_secret\\_weapon](http://www.t-nation.com/article/most_recent/sodium_your_secret_weapon)

Emily M (2008-02-08 21:36:47)

A friend of mine participated in an MRI experiment at Minnesota about a dozen years ago. When the researchers saw his scan, which showed a large tumor, they IMMEDIATELY referred him to a neurologist. His tumor also proved benign although it was large enough to be quite threatening (despite having up till then produced no symptoms he'd noticed).. There has been no recurrence. Happy ending. I find it really shocking that researchers would withhold information like that from a volunteer about their scan.

seth (2008-02-09 12:51:49)

Thanks, Emily, that's good to know.

## 3.2 February

### Everything Old is New Again: Pick-Up Lines (2008-02-01 18:30)

Long before Atkins, there was Banting. The first low-carb diet was the creation of William Banting's doctor. A pamphlet about it titled [1]Letter on Corpulence, published in 1864, was a huge best-seller. The verb to banting meant to diet.

And long before The Game – albeit less well-known for teaching pick-up lines – there was Jane Austen. The lessons of The Game were [2]a subplot of a recent episode of Ugly Betty in which Betty interviews an author of a similar book that says the best way to get a woman's interest to follow praise with criticism. Later in the episode, we see this advice in action: Henry tells a woman that she has a lovely face – "your doctor did an excellent job."

Here's Austen, from [3]Northanger Abbey:

"I have sometimes thought," said Catherine, doubtingly, "whether ladies do write so much better letters

than gentlemen! That is – I should not think the superiority was always on our side.”

”As far as I have had opportunity of judging, it appears to me that the usual style of letter-writing among women is faultless, except in three particulars.”

”And what are they?”

”A general deficiency of subject, a total inattention to stops, and a very frequent ignorance of grammar.”

A little later:

”And pray, sir, what do you think of Miss Morland’s gown?”

”It is very pretty, madam,” said he, gravely examining it; ”but I do not think it will wash well; I am afraid it will fray.”

Ugly Betty Writers Inspired By Jane Austen? (2008-02-02 08:47:01)

[...] Well, Seth Roberts has found an interesting parallel in Jane Austen’s writing.Â Roberts, professor emeritus of psychology at the University of California at Berkeley, gives these two excerpts from Austen’s Northanger Abbey: “I have sometimes thought,” said Catherine, doubtingly, “whether ladies do write so much better letters than gentlemen! That is – I should not think the superiority was always on our side.” [...]

## **Jane Jacobs and Self-Experimentation (2008-02-02 05:03)**

In answer to a question about what Pittsburgh should do to revive itself, Richard Florida [1]answered:

I asked Jane Jacobs once, ”What would you do – as a person who lived in New York in the Village – to rebuild the World Trade Center site? She said, ”Well, Richard, you asked the wrong question. What would the people who used that site do? What would the people who used to work there do? What would the people who owned shops there do?”

The people who used the site know the most about the site. And they care the most about it.

This is one big reason self-experimentation is a good idea: The people with a problem know the most about the problem and care the most about it. People with acne know more and care more about acne than people without it.

People with insomnia know more and care more about it. And so on. It's a huge resource that conventional research almost completely ignores.

1. [http://www.pittsburghlive.com/x/pittsburghtrib/opinion/columnists/steigerwald/s\\_550387.html](http://www.pittsburghlive.com/x/pittsburghtrib/opinion/columnists/steigerwald/s_550387.html)

### New York Times vs. Reality (2008-02-02 17:05)

In a recent NY Times [1]health blog by Tara Parker-Pope was the following:

Dr. Parikh says it is a lesson pediatricians have already learned. He notes that doctors weren't paying attention in the late '90s, when patients were just beginning to go online en masse and theories about vaccines and autism were first circulating.

"We weren't paying much attention until parents started to refuse vaccines. When we looked, we realized that many parents were exposed to story after story on autism Web sites and in chat rooms about the dangers of vaccines. That echo chamber of opinion became a reality despite our best efforts to prove otherwise. Would things have been different if we had engaged our patients from the get-go by providing them with alternative Web sites, scrutinizing and rebutting anti-vaccine 'science,' or posting studies demonstrating vaccine safety in the public domain? I would answer, emphatically, yes."

To Parker-Pope, in other words, everybody knows – or at least every sensible person knows – that "anti-vaccine 'science'" wasn't really science and that vaccines were safe. [2]Not quite. Further examples: [3]NYT vs. business reality. [4]NYT vs. political reality.

1. <http://well.blogs.nytimes.com/2008/01/11/medical-googlers-part-two/>
2. <http://www.blog.sethroberts.net/2008/01/27/does-mercury-cause-autism/>
3. <http://feeds.feedburner.com/~r/pmarca/~3/227737846/inaugurating-th.html>
4. <http://www.tinyrevolution.com/mt/archives/002038.html>

Dennis (2008-02-02 21:57:11)

Nothing is completely safe. Vaccines have risk. Having a significant portion of the population unvaccinated has risk. The optimal situation for parents is not to vaccinate their child, so they bear no risk from the vaccination, and for every one else to vaccinate their child, so there is no one to catch the disease from. Of course, if many parents try to choose the optimal situation, the disease can infect many unvaccinated children.

seth (2008-02-03 05:54:55)

The choice isn't between vaccine and no vaccine; the choice is between different methods of preserving vaccines: with or without mercury.

Andrew Gelman (2008-02-03 08:47:52)

Seth, I respect your concerns on this issue, but I think you're presenting it a bit strongly: rather than "NYT vs. Reality," it seems the situation is really "NYT and the Expert Consensus vs. A Minority of Scientists (that happens to include Seth)." Disagreement is not the same thing as denying "reality."

seth (2008-02-03 09:17:47)

If you ignore the data, that's a fair statement. Yes, a majority vs. a minority. I don't think the data should be ignored. They paint a very different picture. Not only the paper I mentioned earlier but also this: <http://www.jpands.org/vol11no1/geier.pdf> Lo and behold, when mercury is removed from vaccines autism rates decline, at the predicted time. Nothing prevented Parker-Pope from reading this paper. I believe NYT journalists should do more than simply repeat what experts tell them; they should actually look at the research. Had Parker-Pope done so, she might not have been able to figure out that "the expert consensus" was wrong; but she could have surely realized it might be wrong.

Stephen M (Ethesis) (2008-02-03 12:47:17)

*I don't think the data should be ignored. ;)*

Tom (2008-02-03 13:06:10)

Good point, Seth, and yet Tara Parker-Pope is so much better than Kolata and Brody that it's not even funny. In TPP's recent blog on Cholesterol, you can actually see her POV shifts as the comments spur her to do more reading on what she's writing about. <http://well.blogs.nytimes.com/2008/01/28/will-cholesterol-pills-save-your-life/> #comments And TPP clearly respects Dr. (Malcolm) Kendrick, who will not be appearing in Brody's blog, I guarantee you. In a recent post in her Times "science" (!) blog, Brody covers a similar subject with absolute Ancel Keys-rigidity. <http://science.blogs.nytimes.com/2008/01/28/a-new-you-jane-e-brody-on-nutrition/> One thing that's fascinating about Brody's blog entry is that she concludes her final comment by defensively discussing what has clearly been a blizzard of comments about Gary Taubes...yet, if you look at comment's she's approved for posting, only ONE of them mentions Taubes. In other words, she's gotten an onslaught from readers demanding she respond to Taubes' research, and has censored it all! And then she forgets that she has done so!

Stephen M (Ethesis) (2008-02-03 20:38:26)

Quote: And since so many queries and comments concerned Gary Taubes, I think a final word is needed. While it is true that the saturated fat/cholesterol hypothesis about heart disease has never been put to an incontrovertible clinical trial, there is at least decades-long experience with it that has found absolutely no hazardous effect and strong indications of benefit. The idea that carbs (and I don't mean the refined and sweet ones, at least) are the real cause of obesity and heart disease is thus far just an idea. Although in short-term tests about a year the high-fat, low-carb diet has improved measurements of cholesterol and diabetes control, it has never been followed for decades in any population group except the Eskimos and some Greenlanders, whose main source of fat is not from red meat and dairy but from creatures from the sea. So, to my mind, the jury is very much still out on the long-term safety of a diet that gorges on red meat, high-fat cheeses and other sources of saturated fat and dietary cholesterol. End Quote Sure enough, she hardly let any of those through moderation (though she did let lots of "pat on the back, requires no response" err "questions"). I'd have posted a link back to this thread, or a copy of the above post, but comments were closed.

SusanJ (2008-02-03 22:01:27)

Seth, It is extraordinarily difficult to disentangle what is going on in the autism field. You could easily spend several months full-time just trying to sort out the players and agendas. It makes Taubes' book look simple by comparison. You might want to read this article: <http://quackfiles.blogspot.com/2005/03/mark-geier-untrustworthy-autism.html> Bear in mind that at least some autism is hereditary and any theory would need to explain that. FAAASS (Families of Adults Affected by Asperger's Syndrome) has a number of stories of parents (typically fathers) who were only diagnosed as a result of their child's diagnosis since AS wasn't well-recognized a generation ago. <http://www.faaas.org/>

Tom (2008-02-04 15:11:26)

Another note in Tara Parker Pope's favor – in the comments for the blog entry I linked to above, I urged her to look into the Cochrane Collaboration, and just days later it figures prominently in today's article. <http://well.blogs.nytimes.com/2008/02/04-/antidepressants-dont-ease-back-pain/> IMHO, a policy of engagement is probably in order with most journalists, who are very harried and doing their best in most cases. There will certainly be exceptions like Brody who are actively censoring science out of their papers (even the paper of record!), but most will want to hear the truth. Unfortunately, they are not hearing the truth, and if they need a quote on a deadline, they have a long list of rent-a-docs on big pharma's retainer who are ready to return their "I need a quick quote" calls immediately. But if we want better science reporting, rather than deploring first, why not at least try to educate first?

pam tigre (2008-03-24 08:33:56)

I am a producer with WCBS TV working on a story about vaccination controversy...would love to speak to some parents who are not vaccinating their children... Call 212 975-7953 or e-mail...[ptigre@cbs.com](mailto:ptigre@cbs.com) Thank you! Pam Tighe

### **Interview with a Connector (2008-02-03 11:42)**

One of Malcolm Gladwell's best articles is "[1]Six Degrees of Lois Weisberg", about a Chicago woman who seemed to know everyone and enjoyed introducing them. In *The Tipping Point*, Gladwell called such people Connectors. When I met a Connector, a Berkeley psychologist named Karine S., at a Los Angeles party, I wanted to know more.

You like to connect people? How do you do that?

I think the root of my desire to connect people stems from being from a collectivistic culture (Israeli). Also, friendship means a lot to me and I take it very seriously. So I like to bring friends together when I know that they will get along. I do have to say that I'm very selective about which friends I combine though. And often times people connect because they meet over and over at events/outings that I plan/initiate. But ultimately I have to say that I think that people in my life connect because of a common experience. For example, when I moved up north [the Bay Area] I spent a lot of time with friends in the time before at "going away" outings. So I think there was a common emotion experienced which led to them bonding. So now some of my friends back home and are now friends because they met through me. Of course when I come down we all get together again. I think it just comes down to making a plan and inviting a bunch of people that are my friends which leads them to connect and get along.

You say you're selective about "which friends [you] combine". Can you say more about this? Such as how you decide?

I guess it stems from being so sensitive and attuned to people's feelings and experiences that I know who will hit it off and who won't. It's also somewhat selfish because I will end up "babysitting" people if they do not blend with others and engage. I'd like to say that most of my friends get along with each other, but there are some who have not hit it off. I think I combine those who are open to diversity and are not judgmental much more easily. Come to

think of it, in big settings I combine mostly everyone. But let's say it's a Sunday on Melrose...window shopping, eating lunch...I invite those that I know like each other. It's basically a personality assessment. Some people are very open to being around others and there are some people that are so uncomfortable in their own skin that they cannot be around others comfortably and it shows. And when you have known people for a long time, it doesn't require much thought. I know I'm pretty good at doing this because there are people who share me as a friend, and now hang out because they met through me.

Can you think of a mistake you've made bringing people together?

One time I brought two people together who I thought would hit it off and didn't! It was like a bad accident! I thought they would bond about things and enjoy each other and it turned out that the "philosophical" conversation turned into a battle of egos. They verbally attacked each other and it was so bad. This all happened at a restaurant and carried over to my house. One of them reassessed whether she wanted to be friends with me if I was to have this other friend in my life. I think now when someone has as strong a personality as this friend did, I make sure to talk to that person about how expressive they will be about their viewpoints. I think this issue only comes up with certain people in my life...meaning there are certain friends that I cannot bring around just anyone because they are fragile and/or not as mentally sophisticated/intelligent as the other people in my life.

A [2]nice article critical of Gladwell's thesis.

1. [http://www.gladwell.com/1999/1999\\_01\\_11\\_a\\_weisberg.htm](http://www.gladwell.com/1999/1999_01_11_a_weisberg.htm)

---

Varangy (2008-02-04 13:45:39)

Your interview is interesting b/c Karen S. seems to be self-aware that she is a Connector and appears to work at it. All the Connectors I have met do their connecting/networking effortlessly, fluidly and without conscious thought, or at least exude the appearance of effortlessness.

### **Does Mercury Cause Autism? (continued) (2008-02-03 23:20)**

A [1]2006 paper reported that autism rates have started to decline, according to a California reporting system and a nationwide one. The declines, you will see if you look, are very clear. They started soon after mercury began to be removed from childhood vaccines. Richard Herrnstein, the psychologist, coined a useful phrase: to praise with faint damn. I thought of it when I read comments ([2]here and [3]here) criticizing this study because of the journal it is in.

According to the [4]Sacramento Bee,

Experts said, however, that they don't know what's causing the numbers to fall off.

“Perhaps whatever caused (the number of cases) to go up ... is no longer present,” said Dr. Robert Hendren, executive director of the University of California, Davis MIND Institute, which researches neurodevelopmental disorders.

No kidding.

NE1 (2008-02-04 08:34:12)

They do more than criticize it for the journal it's in (which seems low-rent even by inspection). They criticize it because of the lack of peer review, cite shoddy methods, and provided more recent data. How can you read this and still be indignant at the vaccine makers? The reality is, this is a 2006 paper, from even earlier data. If there was anything to it, the trend would have continued and it would be all of the news, and vaccine makers would be hauled off to court in droves. So tell us, what is Big Pharma doing to hide the True drop in autism cases that has occurred because of the removal of that nefarious chemical thimerasol?

seth (2008-02-04 09:08:09)

NE1, To answer your question: I don't know. Perhaps you have read "The Emperor's New Clothes"? Do you have an alternative explanation of the declines?

Charles (2008-02-04 09:59:14)

I really can't imagine why anyone would question the integrity or reliability of the pharmaceutical industry. Their record of honesty and transparency is unassailable. I am certain that if they had any information regarding the safety or danger of any of their products, they would move heaven and earth to reveal that information immediately. And skepticism about their motives is clearly unwarranted and unfair.

SusanJ (2008-02-04 10:10:29)

"Do you have an alternative explanation of the declines?" Why do you trust these authors? You are stepping into the middle of a very politicized situation without knowing the history or the players.

Rich (2008-02-04 10:21:35)

I think an alternative explanation of the adverse events data (figs 1 and 2) is pretty easy. they're using an exceptionally poor sample that is subject to a bias that, i would predict, would mimic their results. the data set is one maintained by the cdc and contains adverse events reported to the cdc following vaccinations. some adverse events are legally required to be reported (as the authors note), but most are not. Autism is not required to be reported, and i didn't see that the authors mention this (but i only skimmed the paper). medical professionals are rather busy and reluctant to report things that are actually legally mandated, let alone optional. Further, the other adverse events that are required to be reported are things like anaphalaxis (see <http://vaers.hhs.gov/pdf/ReportableEventsTable.pdf>) which happen almost instantly after immunization. So this raises the questions of what physician in his/her right mind submits non-mandatory adverse events information about a vaccine many years after that vaccine was given. physicians who are already convinced that vaccines cause autism. why did the number increase over the late 90's? likely because 1 or 2 physicians became increasingly convinced of the link and began reporting it. why did it decline after use of thimerisol stopped? because they were convinced of the link and therefore stopped reported

their cases after thimerisol use stopped. i actually don't know anything about the CDDS data, but it also seems to be self-report and is probably non-mandatory and could be subject to any manner of reporting bias. i also recall seeing data presented at a meeting a few years ago from an autism study in california that did not show this trend at all. further, if my memory is correct, japan switched off thimerosal before the US did and didn't see any decline. you seemed to indicate the NYT acted inappropriately in not reporting the results of this article. but a cursory glance at the first half of the data indicates an analysis so flawed that they would have been (rightly) ridiculed had they reported it.

SusanJ (2008-02-04 10:38:54)

Perhaps you have access to this article and can review it for us. "Thimerosal Disappears but Autism Remains" Arch Gen Psychiatry. 2008;65(1):15-16.

seth (2008-02-04 12:25:47)

Rich, thanks for the alternative explanation. I don't find it plausible that the reduction in cases occurred because 1 or 2 physicians stopped reporting their cases after thimerosal stopped. Of course the measurements are flawed; all measurements are. SusanJ, thanks for the citation. I'm going to wait to see what people who know more about this than me say. I do have one comment, however: The author has apparently received a lot of money from pharmaceutical companies for defending them in court. He tried to downplay this by including a lot of irrelevant detail in his financial disclosure, including the statement "None of his research has ever been funded by the pharmaceutical industry." He is far from unbiased – yet he tried to appear so. Not a good sign.

Steve Grathwohl (2008-02-04 13:56:57)

If you are worried about the credibility of the author of the Arch Gen Psychiatry article, then you should do a bit more research about the Geiers before betting on their horse. There is a wealth of research showing no association between thimerosal and autism. It would be difficult to dismiss all that research as being big pharma funded and useless. In a recent court case (Blackwell v. Sigma Aldrich, Inc. et al. (Circuit Court for Baltimore City, Case No. 24-C-04-004829)), the Court held that "The 2004 IOM Committee found that '[e]pidemiological studies examining TCVs and autism, including three controlled observation studies (Hviid et al., 2003; Miller, 2004; Verstraeten, et al. 2003) and two uncontrolled observational studies (Madsen, et al., 2003; Stehr-Green, et al., 2003), consistently provided evidence of no association between TCVs and autism, despite the fact that these studies utilized different methods and examined different populations (in Sweden, Denmark, the United States and the United Kingdom).' " The Court also had harsh words for Mark Geier: "Dr. Geier is not qualified by his knowledge, skill, experience, training or education to render the opinions he proffers in this case... [T]his Court does not find that there exists a sufficient factual basis to support [Dr. Geier's] proffered testimony..." and "Dr. Geier's epidemiological studies purporting to show an association between thimerosal-containing vaccines and autism were not conducted in accordance with generally accepted epidemiological methods." "...Dr. Geier's methodology of differential diagnosis is fundamentally flawed, because he improperly "rules in" thimerosal as a potential cause of autism, and he cannot rule out the high likelihood that autism in any given individual was caused purely by genetic factors that do not require an environmental trigger." You should browse the archives of <http://scienceblogs.com/insolence/>. If you want to see bias, the Geiers are your men.

Igor Carron (2008-02-05 02:38:11)

Seth, As SusanJ points out, you really need to do your homework as the various actors of this tragedy have various angles to this. It is easy to say that big pharma is trying to hide something. However, I am overly skeptical of this type of conspiracy. To get a better perspective, I went to a presentation of Eric Fombonne (McGill) and he has shown (with peer-reviewed publications) in Canadian studies that the removal of mercury in vaccines has not changed the numbers of cases in autism. His point is simple, tax-payers money in every country is somehow diverted in these type of statistical exercises even though other stats in other countries have shown it was negative. He has also shown that the change in the definition of autism from DSM-II to DSM-IV has changed the number of kids diagnosed with the disease but going back to 1970's and recategorizing some of the diagnostics, one eventually gets about the same number : 1/166 kids is affecting with the disease. So it is easy to see a jump into some epidemics bandwagon if most of the people you used to put in different categories now fall into this new autism spectrum disorder (ASD). Now, the worst thing that I think is really happening is that this diagnosis of ASD

comes generally very late and that there is no simple way to find out that there is something wrong. As somebody asked me once, "so what, you learn your kid has ASD, there is no cure, it doesn't matter if you learn about it sooner rather than later". It so happens that ASD is actually a very broad term and it includes, it seems, about three different subgroups (still not very well defined). One group has major problems and our current health care system will have to take care of them for a long time. For the rest two other groups, it looks as though by aiming at the capabilities that are missing that some type of re-education program does OK. Please note that there is not even a substantial work on the evolution of the disease/condition as witnessed by the inability to interpret well the graphs we studied here: [http://www.stat.columbia.edu/cook/movabletype/archives/2007/09/redoing\\_venn\\_di.html](http://www.stat.columbia.edu/cook/movabletype/archives/2007/09/redoing_venn_di.html) [http://www.stat.columbia.edu/cook/movabletype/archives/2007/10/venn\\_diagram\\_ch.html](http://www.stat.columbia.edu/cook/movabletype/archives/2007/10/venn_diagram_ch.html) [http://www.stat.columbia.edu/cook/movabletype/archives/2007/10/venn\\_diagram\\_ch\\_1.html](http://www.stat.columbia.edu/cook/movabletype/archives/2007/10/venn_diagram_ch_1.html) Your interest in rigorous self-experimentation is exactly what families should go through in order to see the things that work and the ones that do not. For instance, in the detection of autism, we already know that the cranial perimeter of the infant goes above the 95 percentile for the first two years of his life (with a specific jump in the first six month). How come there is no universal way of measuring the head perimeter of infants ? Also, some groups have dedicated psychologists going through hours of family movies to see if, at the age of 6 months, one could already see something amiss (generally it's the eye tracking business). Hence how come more money is not spent on having an automated system that evaluates this condition right on the spot instead of doing it 3 years later when people are seeking a diagnosis. Not only could it be used for diagnosis but more importantly it could be used to assess the day-to-day effects of the therapy. One more thing, I think it is unfair to say that if you are funded by big pharma your studies are suspicious. If you make your data available and do the peer-reviewed thing, I don't see how the funding affects the findings and subsequent re-analysis of it by others. Igor.

seth (2008-02-05 09:04:34)

Igor, thanks for your comment. There is one thing I don't understand. You write: "tax-payers money in every country is somehow diverted in these type of statistical exercises even though other stats in other countries have shown it was negative." I think I understand the first part of the sentence about taxpayer's money but certainly don't understand what you mean by "even though other stats in other countries have shown it was negative." What's "it"?

Igor Carron (2008-02-05 11:40:25)

Seth, In all developed countries, the same rumors about the vaccine causing autism have abounded and in every country, local governments had to fund the same studies using their own data to eventually come to the same conclusion. The "it" was referring to the statement "vaccine cause autism". One more note in case I was not clear, the head perimeter study from Couchesnes and the less "peer-reviewed" studies on family movies are pointing to an autistic syndrome that was already there from birth. It so happens that the disease is so badly detected/diagnosed that the first time people worry about it, is when their kids don't start speaking at about 2-3 years old. It so happens that this is also the time when some vaccines are being inoculated thereby producing this never ending wave of "mercury causes autism". Let me also state that I am clearly not saying that vaccines are not exacerbating a condition that was already there. If there is, the studies have shown it is not a mercury issue. Igor.

SusanJ (2008-02-05 15:35:06)

This looks to be a good starting point explaining why the study by Dr. Amy Holmes has been discredited. <http://photoninthedarkness.com/?p=142>

## Recent Reading (2008-02-04 15:37)

Random paragraphs from two books I've recently read.

By 1853 Riemann was twenty-seven and on the last stretch of the long road to a lectureship at Gottingen.

In Germany at that time, such an academic position did not pay the modest salary it does today. It did not pay any salary. To many of us, that would be a bit of a drawback. To Riemann, it was a coveted position, a stepping stone to a professorship. And students gave tips.

From Euclid's Window: The Story of Geometry from Parallel Lines to Hyperspace (2001) by [1]Leonard Mlodinow.

“Tastes great, less filling!” could be the motto for most processed foods, which are far more energy dense than most whole foods: They contain much less water, fiber, and micronutrients, and generally much more sugar and fat, making them at the same time, to coin a marketing slogan, “More fattening, less nutritious!”

From In Defense of Food: An Eater's Manifesto (2008) by [2]Michael Pollan.

1. [http://en.wikipedia.org/wiki/Leonard\\_Mlodinow](http://en.wikipedia.org/wiki/Leonard_Mlodinow)

2. <http://www.michaelpollan.com/>

Diety (2008-02-05 04:02:43)

It's my 1st comment here so I say Hi! :) I was looking for some different and strange diet and I found this. Starting to read right now. I'd like you to improve navigation a bit, I had real trouble to find the Shangri-La diet.

Stephen M (Ethesis) (2008-02-06 12:10:37)

"And students gave tips." That would really make the life of an adjunct hard.

### How to Be Wrong (2008-02-06 22:07)

There are two mistakes you can make when you read a scientific paper: You can believe it (a) too much or (b) too little. The possibility of believing something too little does not occur to most professional scientists, at least if you judge them by their public statements, which are full of cautions against too much belief and literally never against too little belief. Never. If I'm wrong – if you have ever seen a scientist warn against too little belief – please let me know. Yet too little belief is just as costly as too much.

It's a stunning imbalance which I have never seen pointed out. And it's not just quantity, it's quality. One of the foolish statements that intelligent people constantly make is "correlation does not imply causation." There's such a huge bias toward saying "don't do that" and "that's a bad thing to do" – I think because the people who say such things enjoy saying them – that the people who say this never realize the not-very-difficult concepts that (a) nothing unerringly implies causation, so don't pick on correlations and (b) correlations increase the plausibility of causation. If your theory predicts Y and you observe Y, your theory gains credence. Causation predicts correlation.

This tendency is so common it seems unfair to give examples.

If you owned a car that could turn right but not left, you would drive off the road almost always. When I watch

professional scientists react to this or that new bit of info, they constantly drive off the road: They are absurdly dismissive. The result is that, like the broken car, they fail to get anywhere: They fail to learn something they could have learned.

Addendum. By "too little belief" I meant too little belief in facts – that this or that new observation has something useful to tell us. Thanks to Varangy, who pointed out that there is plenty of criticism of too little belief in this or that favored theory. You could say it is a kind of conservatism.

---

Matthew (2008-02-06 22:28:51)

This post makes you sound a lot more like Aunt Dierdre than your recent spat would suggest. You two should kiss and make up; you'd make good intellectual allies.

seth (2008-02-07 00:46:29)

Matthew, You mean McCloskey made similar points somewhere? Where?

Two mistakes you can make when reading a scientific paper « Entertaining Research (2008-02-07 08:56:09)

[...] Two mistakes you can make when reading a scientific paper Seth in his blog tells what they are: There are two mistakes you can make when you read a scientific paper: You can believe it (a) too much or (b) too little. [...]

Chris (2008-02-07 11:40:53)

What do you think of Rupert Sheldrake? This episode of CBC Radio "Ideas" program put a lot of emphasis on the way the scientific establishment (notably, the editor of Nature) ostracised him after he published *A New Science of Life* in 1981 – admittedly, a book with some fairly far-out ideas. Here's a podcast: <http://www.cbc.ca/podcasting/pastpodcasts.html?45#ref45> The whole How To Think About Science series that Ideas has been broadcasting is well worth a listen.

Tom (2008-02-07 12:45:00)

In other words, correlation is strongly correlated with causation.

NE1 (2008-02-07 17:33:20)

Too little belief is always preferable to too much. If someone else comes along and does it again, there's your second chance. If you start acting on every Tom, Dick and Harry's theory, you'd be taking 5 types of Tibetan berry juice by now. Failing to learn something you could have learned is not a mode of failure for modern scientists. There will always be more than you could ever learn. You're never alone. On the other hand, building a bridge on a foundation that will eventually have to be removed is pretty much a complete waste. Your car example doesn't make sense, but professional scientists react by considering results false first because important new results are rare. Any graduate student can tell you this, because while to them every new feature is a mystery the post doc remembers you get crazy results with only one crossed wire.

Varangy (2008-02-07 17:41:40)

*The possibility of believing something too little does not occur to most professional scientists, at least if you judge them by their public statements, which are full of cautions against too much belief and literally never against too little belief.* I couldn't disagree more. Look at the theory of anthropogenic global warming. The second anyone professes too little belief, they are ostracized and branded a heretic – whoops – I meant to write skeptic. Which, ironically, has become a pejorative in the scientific community.

Matthew (2008-02-08 00:08:58)

Seth, It's not the same, but it reminded me of some of the methodological issues she has written about over the years. Check out her paper "The Secret Sins of Economics." You can find it here: <http://www.prickly-paradigm.com/paradigm4.pdf> Read the discussion of statistical significance and the mammogram example starting at the bottom of page 48 and following.

Pedro J. (2008-02-08 08:20:43)

In his book *The First Three Minutes*, Steven Weinberg explains his earlier rejection of the Big Bang Theory: "Our mistake is not that we take our theories too seriously, but that we do not take them seriously enough. It is always hard to realize that these numbers and equations we play with at our desks have something to do with the real world. Even worse, there often seems to be a general agreement that certain phenomena are just not fit subjects for respectable theoretical and experimental effort." So it is not quite true scientist do not think about what happens when we do not trust quite enough on scientific results. Another recent example is Max Tegmark complain about not taking MWI interpretation of quantum mechanics seriously enough or Robin Hanson complain about not taking seriously enough what most studies show: there is not a clear relationship more medicine-more health.

seth (2008-02-08 10:24:13)

Rather than "too little belief" in general, I should have said "too little belief in new facts." I should have said that no scientist warns against under-inference – not inferring enough from new facts. Although since I wrote that I thought of an exception: In 2007, Bruce Ames et al. wrote a letter complaining that the committee behind a report of nutrition recommendations failed to take seriously enough the evidence before them. The committee wanted better evidence before doing anything. In the case of theories, as Varangy says, it is different. Matthew, thanks for the reference. Pedro, yes, in individual cases scientists complain that this or that evidence isn't taken seriously enough. "Too little belief is always preferable to too much." It took doctors a long time to realize that smoking causes lung cancer. Their objections to the evidence in front of them were often absurd. That is a case in which too little belief was harmful and too much belief would not have been harmful.

Pedro J. (2008-02-08 10:58:38)

By the way, excellent recommendation, Mathew. The joke about double positive sentences enjoyed my afternoon.

seth (2008-02-08 15:53:21)

"Too little belief is always preferable to too much." What if the new idea is correct?

Eliezer Yudkowsky (2008-02-09 11:07:43)

Well, I've been going around for a while now saying that Bayesian probability theory tells us that there is an exactly correct update which you should make upon new evidence, neither more nor less; and even in cases where we can't calculate the math exactly, the mere fact that math exists tells us that there is a correct update which has no room in it for our whims, or for "conservatism" if you feel like being conservative. Judea Pearl has written extensively on the correlation/causation business. You can actually extract some damned impressive evidence off of even noninterventionist experiments, though it takes a sophisticated theory of causation to do it. The heuristics and biases community has investigated "motivated skepticism". So, no, you are not quite a lone voice in the wilderness here - though I agree that it is one of the most important ways that old-style pre-Bayesian Traditional Rationality goes astray. But the Bayesians have noticed the mistake, analyzed it mathematically, investigated it experimentally, etc.

James Annan (2008-02-10 02:17:43)

IMO this conservatism is a natural and reasonable correction for the undeniable fact that the majority of new and striking "results" are simply wrong. I've noticed a significant number of these in my own field (climate research) in the last couple of years (examples available if you want), they got a lot of publicity but basically every knowledgeable scientist realised (correctly) they were probably wrong at the outset. In fact it seems to me that the professional scientists are being (approximately) Bayesian in requiring strong evidence to overcome (well-justified) prior beliefs that the "new" results seek to overturn.

seth (2008-02-10 05:32:17)

James, I am surprised to hear that "the majority of new and striking 'results' are simply wrong." I'm not sure what you mean by "results". Theories, methods, data, conclusions drawn from data? I was referring to data – that is, observations. Upon encountering new data, the reaction of the average scientist is much more about what you can't learn from it (e.g., "correlation does not imply causation") than what you can. You believe that most new data is "simply wrong"? Wrong in what sense? And why do you believe this?

Seth's blog » Blog Archive » How to Be Wrong (continued) (2008-02-10 07:57:01)  
[...] How to Be Wrong [...]

James Annan (2008-02-10 16:16:23)

"Wrong" in that it does not represent the theory that is attributed to it. In climate change, we have: Plants emitting methane (AIUI no-one knows yet where this result really came from, but no-one thought it was reasonable and several replications have contradicted it). Oceans cooled over the last few years (now clearly understood as an artefact of measuring error due to a large number of buoys with a bias). Ocean circulation slow-down (combination of a rather simplistic analysis and perhaps intrinsic high-frequency natural variability being larger than we thought). These all had a \*lot\* of press coverage, and it was IMO entirely correct of scientists to warn against believing them too strongly. I don't think most new data is wrong - much data is confirmatory in nature, uncontroversial and right. I think much or most new and striking data are wrong. It's basically publication bias. But these are the cases where you hear scientists commenting, precisely because they are highly talked-about.

seth (2008-02-11 01:16:25)

Thanks for the explanation, James. As I say in a later post, <http://www.blog.sethroberts.net/2008/02/10/how-to-be-wrong-continued/> I see the same bias in areas much different than science. Therefore I don't think it is caused by science-specific things such as publication bias or press coverage.

Charlie (Colorado) (2008-02-12 07:53:41)

My grandfather used to tell me "If the bird book and the bird disagree, believe the bird." This is a lesson I have to teach new baby engineers pretty well every year.

Gustavo Lacerda (2008-04-07 12:34:50)

Eliezer, " though I agree that it is one of the most important ways that old-style pre-Bayesian Traditional Rationality goes astray. But the Bayesians have noticed the mistake, analyzed it mathematically, investigated it experimentally, etc. " This has nothing to do with Bayesianism. Spirtes, Glymour and Scheines are not Bayesians. I have no idea about Pearl. Gustavo

Nathan Myers (2008-04-17 13:52:26)

I like this term "twisted skepticism". It's more palatable than "dishonest skepticism". Justifications for the habit of twisted skepticism, and for specific examples of it, always sound plausible, but are often revealed as rationalization when the same individuals fail to be similarly skeptical of ill-supported notions favored within their community. E.g., no astronomer can remain in good standing while expressing any skepticism that 98 % of the universe's mass/energy is composed of stuff of which no hint has ever been detected in a laboratory. Likewise, none may be skeptical of the faith that gravitation must be the entire explanation for any large-scale phenomenon, or that the Doppler effect must explain all observed red shift, without exception. Different fields of science have different levels of dogmatism; astronomy's may be higher than most, paleontology perhaps lower. I have identified two systematically irrational behaviors common to scientists. First, there is commonly an established theory which is inconsistent with new data. (Perhaps no diagnostic data ever supported it; it may have originated as an honest speculation by a respected elder.) An alternative theory is simpler, accounts equally well for old data, but also predicts the new data. A rational scientist would accept that there are now two theories on possibly equal footing, but this never happens. Instead, the new theory must pass overwhelmingly more stringent tests than the old theory ever did before it may even be considered as a reasonable alternative. Until this occurs, the contradictory data is ignored or discounted. A related systematically irrational behavior occurs when new data conclusively falsifies a commonly-held theory (or received

speculation), but no one has advanced a palatable alternative. The typical response is to ignore, discount, or even actively suppress the new data. Systematically irrational behavior by scientists has seemed odd enough that I have puzzled over it for years. The best explanation I have identified is that scientists are self-selected from among the population as those who feel a need to know, and to feel that they do know. To go from relying on one theory to considering two feels like going from knowing to only half-knowing. To discard a theory one has lived with feels like going from knowing something to knowing nothing. Both are, evidently, intolerable to most people who choose to become scientists. The above does not suffice to explain the condition of astronomy.

## The Lessons of Bilboquet (2008-02-07 12:37)

There are lots of omega-3-related self-experiments I'd like to do: 1. What about fish oil? 2. Is omega-6 bad for the brain? As my olive-oil results suggested. 3. "Blind" experiments where I don't know what I've ingested. I wanted to use a design that involved many tests/day. This would be easy if the tests were fun, hard if they weren't. Games are fun—could I figure out why and make a mental test that was like playing a game?

After talking with [1]Greg Niemeyer, I decided that color, variety, feedback, and appropriate difficulty (not too little, not too much) were possible reasons games are fun. I constructed a letter-counting task with all of these attributes – and it wasn't fun. I had to push myself to do it. These attributes may help, but not a lot.

Then, [2]as I've posted, a friend gave me a bilboquet. For such a simple object, it was surprisingly fun and slightly addictive. Thinking about other addictive games, such as Tetris (I once played a lot of Tetris), I [3]guessed that the crucial features of a game that make it addictive are: 1. Success is sharply defined. 2. Not too easy. 3. Hand-eye coordination. (Not any eye-body coordination: I did thousands of balancing tests but had no trouble stopping.)

I constructed a new task with these attributes: Click the Circle. A circle appears on the screen, you move the pointer to the circle and click on it; a new circle appears somewhere else, you move the pointer to click on it, etc. At the end there's a little feedback: how long it took. Very simple.

This task, at least so far, is addictive. I think something else may be going on in addition to the three factors: we enjoy completion, especially visual completion. (Which Tetris had a lot of.) In this case the visual completion is the blank space that appears when I click on a circle. If I have a few dishes to do, it's easy to do them—the promise of an empty sink (= visual completion) draws me to the task. In contrast, if there are a lot of dishes to do, it's much harder to do a few of them. I'll probably do none of them or all of them. If you have 20 dishes to do, doing them will generate a lot more pleasure (and thus will be easier to do in the future) if you can manage to create 20 completion moments than if they get piled up and there is only one completion moment.

## **Ranjit Chandra: A New Position (2008-02-08 11:21)**

The Indian health tourism company [1]Indicure has appointed Dr. Ranjit Chandra, whose story is told [2]here, to be one of its panel of experts. Few scientists have a more impressive [3]resume:

Dr. Chandra has received 16 honorary degrees including DSc honoris causa recently from Panjab University. He has received over 100 awards worldwide. In 2003, he was given the Jubilee Gold Medal by the Queen and the title of Honorable Baron of Blackburn. Prof. Chandra is an Officer of the Order of Canada, the highest award given to Canadian citizens.

[4]More about Chandra. His work [5]remains influential.

## **Science in Action: Flavor-Calorie Learning (another simple example) (2008-02-09 09:52)**

At the heart of the Shangri-La Diet is the idea that we learn to associate flavors (smells) with calories. This learning was first shown in rat experiments. There's some human evidence, but not much. If I could discover more about what controls this learning, I might be able to improve the diet. For example, maybe I could say more about what the flavor-free window should be.

My earlier self-experimentation on this subject - I used tea for flavor and sugar for calories - was helpful. To my surprise, I found that really small changes in flavor made a noticeable difference. If I switched from one canister of Peet's Gunpowder Tea to a new canister, the ratings went down, although everything else stayed the same. From this came the notion of ditto food: Foods with exactly the same flavor each time are especially fattening. I hadn't realized what a difference it would make if you kept the flavor exactly the same each time.

It's been hard to learn more. After Christmas dinner, my mom gave me the leftover brandy (A. R. Murrow). I used it for a very simple experiment in which I learned to like it. I've never drunk brandy in any quantity and I started off not liking it. Every day for a few weeks, I drank one tablespoon. I drank it in a few sips over a few minutes. I didn't eat anything else for at least 30 minutes. I rated how good it tasted on a 0-100 scale where 10 = very bad, 20 = quite bad, 25 = bad, 30 = somewhat bad, 40 = slightly bad, 50 = neutral, 60 = slightly good, 70 = somewhat good, 75 = good, 80 = quite good, 90 = very good. The overall rating was the maximum of the ratings of the several sips. (The first sip usually tasted the best.)

Here are the results.

I've observed similar results five or six times. They are more support for the most basic conclusions: 1. The effect is very clear. One tablespoon of brandy has only 30 calories. 2. A really simple experiment is easy.

That's a promising start but then it gets hard, or at least non-obvious. As a way to study flavor-calorie learning, this little example has several flaws: 1. Slow learning. 2. Expensive materials. 3. Little control of flavor. The best I can do is choose which liquor to buy. Soon I will run out of ones I haven't used. 4. No way to separate flavor and calories in time. 5. No way to change the calorie source.

An [1]earlier demonstration used a soft drink. It's really Science in Inaction: I've made zero progress in a year.

1. <http://www.blog.sethroberts.net/2007/06/01/science-in-action-flavor-calorie-learning-simple-example/>

---

Socketopi (2008-02-09 13:56:28)

Could part of the French paradox be that they drink a lot of wine, and each bottle is a unique mix of flavors, resulting in a suppressed appetite?

August (2008-02-10 12:22:41)

What about an attempt to de-associate a flavor with it's calories? It seems to me you could use nose-clipping to add calories to any flavor, thus causing the flavor/calorie association to be adjusted. If the body kept getting random levels of calories for a particular flavor, wouldn't the flavor/calorie association be weakened?

Killer Bees (2008-02-11 19:04:11)

Does that apply to coffee? I really like a latte with a little sugar or a vanilla late. Can you really gain weight from drinking a white coffee with one sugar every day?

seth (2008-02-11 21:39:04)

Socketopi, yeah, something like that. In The Shangri-La Diet (the book) I mention a "culture of connoisseurship" as a likely reason the French weigh less than you'd expect. August, you can weaken a flavor-calorie association if you experience the flavor without the calories. Randomly varying the calories won't do it. I think Tim Beneke has tried the flavor-no-calorie approach. He tastes the food and then spits it out. If I remember correctly, it works: the flavor becomes less pleasant. Killer Bees, one sugar doesn't have a lot of calories.

## **How to Be Wrong (continued) (2008-02-10 07:56)**

I asked a friend of mine why she was a good boss. "I was nurturing," she said. [1]A big study of managers reached essentially the same conclusion: Good managers don't try to make employees fit a pre-established box, the manager's preconception about how to do the job. A good manager tries to encourage, to bring out, whatever strengths the employee already has. This wasn't a philosophy or value judgment, it was what the data showed. The "good" managers were defined as the more productive ones – something like that. ([2]My post about this.)

The reason for the study, as Veblen might say, was the need for it. Most managers failed to act this way. I [3]posted a few days ago about a similar tendency among scientists: When faced with new data, a tendency to focus on what's wrong with it and ignore what's right about it. To pay far more attention to limitations than strengths. Here are two examples:

1. Everyone's heard "correlation does not imply causation". I've never heard a parallel saying about what correlation does imply. It would be along the lines of "something is better than nothing."
2. Recently I attended a research group meeting in which a postdoc talked about new data she had gathered. The entire discussion was about the problems with it – what she couldn't infer from it. There could have been a long discussion about how it added to what we already know, but there wasn't a word about this.

Some of the comments considered this behavior a kind of Bayesian resistance to change in beliefs. But it occurs regardless of whether the new data support or contradict prior beliefs. There's nothing about prior beliefs in "correlation does not imply causation." The post-doc wasn't presenting data that contradicted what anyone knew. Also, similar behavior occurs in other areas besides science (e.g., how managers manage) in which the Bayesian explanation doesn't fit so well.

I think it's really strong. I was guilty of it myself when discussing it! I made very clear how this tendency is a problem, giving the analogy of a car that could turn left but not right. Obviously bad. I said nothing about the opportunities this tendency gives everyone. My self-experimentation is an example. The more that others reject useful data, the more likely it is that useful data is lying around and doesn't require much effort to find. I have called this behavior dismissive; I could have called it generous. It's like leaving money lying on the ground.

A [4]related discussion at Overcoming Bias. [5]What should "correlation does not imply causation" be replaced with?

Addendum. Barry Goldwater [6]weighs in: "I'm frankly sick and tired of the political preachers across this country telling me as a citizen that if I want to be a moral person, I must believe in 'A,' 'B,' 'C,' and 'D.'" Indeed, preachers spend far more time on what we are doing wrong (and should do less of) than on what we are doing right (and should do more of). The preacher Joel Osteen has taken great advantage of this tendency. "I think most people already know what they are doing wrong," he [7]told 60 Minutes.

Andrew Gelman (2008-02-10 12:52:17)

Bill James wrote about baseball managers that the important skill was to make use of what your players can do, rather than focusing on what they can't. He used Earl Weaver as an example of someone who made good use of his players. Weaver discussed this in his books, too, I think. Something about not having players on your bench unless you're willing to send them up to bat (or to pitch). But Weaver didn't do much "nurturing," at least not how that term is generally construed.

Notional Slurry » links for 2008-02-18 (2008-02-17 23:26:58)

son2 (2008-02-18 08:18:09)

I made very clear how this tendency is a problem, giving the analogy of a car that could turn left but not right. Obviously bad.

There were a lotta cars in Daytona Beach this past week that could only turn left. Ryan Newman won \$1.6 million with one of those cars. Which is a lot more than my car ever made *me*.

## Amy Winehouse and Nassim Taleb (2008-02-11 21:28)

Will Amy Winehouse – who won five Grammys last night – help or hurt the music industry? A few years ago, I went to a tasting event called The Joy of Sake. There were about 100 of the best sakes from Japan. A pre-event talk for retailers discussed the decline of sake in Japan. (Soju is cool; sake is old-fashioned.) That was the reason for the show. I loved tasting 30-odd high-quality sakes but the overall effect on me was the opposite of what the promoters wanted. I [1]quickly became a connoisseur. I no longer liked the cheap stuff – ugh! But the stuff I did like was too expensive. I stopped buying sake.

Before last night I had heard of Amy Winehouse and I had heard Rehab, but hadn't put the two together. Her Grammy performance blew me away. I watched a bunch of YouTubes of her. Back at the Grammys, I listened to an orchestra play Rhapsody in Blue. I used to like it; now it sounded awful. I listened to a few more group performances; they too sounded bad. Just as The Joy of Sake had made me no longer enjoy cheap sake, listening to a lot of Amy Winehouse had made me no longer enjoy "average" music – music where several individual performances are combined.

I thought of The Black Swan by Nassim Taleb. Taleb defined Mediocristan as situations where no one datum can have a big effect on the result. The average height of 100 people, for example. In Extremistan, by contrast, a single datum can make a big difference. The average wealth of 100 people, for example – one person can have much more money than the other 99 put together. Orchestras are Mediocristan, I realized; individual singers are Extremistan. In art, emotional impact is everything. Extremistan allows really big impact; Mediocristan does not. Maybe this is why classical music is dying.

I felt like throwing away half my CDs. I could use the space. Thanks, Amy!

---

Loweel (2008-02-11 23:19:26)

Seth – <http://www.sakeone.com/sakeone/index.jsp> Try the G, the Momokawa, and the Murai family series. Great sake at a reasonable price. And check the reviews at [cellartracker.com](http://cellartracker.com)

Varangy (2008-02-12 01:39:50)

Seth, Same exact thing happened to me with fish. After I started free-diving in Southern California, shooting fish (White Sea Bass, Halibut Yellowtail, and the occasional Calico Bass) as well as gathering Scallops and Lobster and then eating them literally within hours — eating fish at a restaurant, even a 5-star restaurant on a corporate expense account...seemed to be nothing but a brutal exercise in futility. I quickly realized even the best restaurants in the world cannot get fish of the same quality as my friends and I could on a good day in the water. (BTW my friends don't like to believe me, but it is true. None of my spearfishing buddies ever order fish at a restaurant unless it really doesn't matter e.g. Baja fish taco) And my sushi intake also slackened dramatically. Great fish ruined me forever for anything less than the absolute freshest and best. To this day, I never eat fish in a restaurant b/c I know it will be un-fresh and most often overdone. I usually opt for the steak cuz I haven't figured out how to slaughter a cow at home. :) And a steak can benefit from aging.

seth (2008-02-12 06:07:14)

Excellent story, Varangy. Curious that it involves sushi. Maybe Japanese cuisine, with its relative absence of strong flavors and sauces and spice-heavy recipes, is Extremistan, and other cuisines are not.

Tom (2008-02-12 12:39:34)

Yes, I think Japanese cuisine really needs to be good. American cuisine, not so much. A mediocre cheeseburger with mediocre fries is a filling lunch and we won't even notice there's anything wrong. But sushi, for example, is different. Very few people have ever had good sushi. Living in a city with a large Japanese community, I've had the opportunity to do so. Result: I rarely eat sushi now. And even though there are at least a dozen sushi places in my immediate neighborhood, I will get on the highway and drive for half an hour to the place I know is good.

Varangy (2008-02-12 15:53:15)

Yep, I agree. An average burger is totally edible and okay. Sure, it is not a Father's Office burger. (If you haven't had one, demolish one ASAP) But 'average' sushi is just horrible. (My friends think I am an intentional-snob-elitist-bastard, but I swear I am not.) Like you say Seth, sushi could be Extremistan where the mean and median are entirely meaningless, and the distribution is characterized by the extremes at either tail.

mike kenny (2008-02-12 16:11:48)

this post makes me think of the auteur theory of film. it seems like auteur films are better than the average film. one guy has a strong vision that is followed, versus a film made by a lot of collaboration by many-writers, director, actors. maybe this is the difference between extremistan and mediocristan. of course, there are good non-auteur films!

Tim Lundeen (2008-02-12 17:51:06)

Great post! I normally listen to popular music and like Amy Winehouse a lot, but recently found a classical piece that I love, Dvorak's Stabat Mater by Shaw ([http://www.amazon.com/Dvorak-Stabat-Goerke-Simpson-Atlanta/dp/B00001QGKI/r\\_ef=pd\\_bbs\\_sr\\_1?ie=UTF8&s=music&qid=1202863660&sr=8-1](http://www.amazon.com/Dvorak-Stabat-Goerke-Simpson-Atlanta/dp/B00001QGKI/r_ef=pd_bbs_sr_1?ie=UTF8&s=music&qid=1202863660&sr=8-1)). Extremistan for the orchestra and chorus. (Not really fair, because there are a lot of solos, but see what you think.)

Danny (2008-02-13 05:18:22)

You're absolutely right. It's always bothered me that that egotistical composer only had the same impact as the 5th chair, first seat second violin. And when it's a piece for solo piano? Each of the 88 notes can't stand above any of the others. Those damn classical musicians may as well be communists, but that's why they're all dying, so it'll be all good soon enough anyway.

Tony (2008-02-13 05:33:39)

"Orchestras are Mediocristan, I realized; individual singers are Extremistan. In art, emotional impact is everything. Extremistan allows really big impact; Mediocristan does not. Maybe this is why classical music is dying." This is the opposite for me. After developing my ear to better understand classical music, most of the pop I grew up on seemed like a distance echo of really emotional music. Second, to equate "classical" music with orchestral music seems puzzling. There is probably more classical music being produced now than at any time before, and classical music has spread to large parts of Asia. I'd be interested in data which suggest that classical music is dying, though.

seth (2008-02-13 07:55:04)

Tony, after reading this article <http://www.artsjournal.com/artswatch/aw-deathofclassical.htm> I agree with you, it's not obvious that classical music is dying. I was thinking of the current situation vs 100 years ago when classical music was a much larger fraction of all music. I forget which composer was the first rock star.

Norcross (2008-02-13 08:49:07)

Agreed. I've basically stopped listening to commercial "over the air" radio, since 99 % of what they play just isn't good music. It's crap. While it pens me as a music snob, it also means I don't have to subject myself to inferior music.

Pearl (2008-02-13 09:16:10)

I'm with Tony. Listening to Amy Winehouse for the first time makes everything ELSE sound better. Especially centuries of classical music. Listen to Jaqueline Du Pre playing Elgar here: <http://youtube.com/watch?v=L5C99JyP2ns> She was a rock star and a classical musician. Incredible.

Tony (2008-02-13 15:46:49)

Seth, thanks for the link. Interesting.

Nansen (2008-02-15 18:16:53)

Here's an experiment: You can compare an orchestral version of Beethoven's symphonies with Liszt's arrangements of them for solo piano. See, for example: [http://www.musicweb-international.com/classrev/2004/Jan04/Beethoven\\_Katsaris.htm](http://www.musicweb-international.com/classrev/2004/Jan04/Beethoven_Katsaris.htm)

Consuming good art decreases your overall art consumption « N=1 (2009-07-10 14:20:14)

[...] July 10, 2009 by jason After reading a lot of Charles Bukowski's writing, I've lost interest in reading a lot of other authors. Â They just don't seem good enough anymore. Â This reminds me of something that Seth Roberts wrote about: Before last night I had heard of Amy Winehouse and I had heard Rehab, but hadnâ€™t put the two together. Her Grammy performance blew me away. I watched a bunch of YouTubes of her. Back at the Grammys, I listened to an orchestra play Rhapsody in Blue. I used to like it; now it sounded awful. I listened to a few more group performances; they too sounded bad. Just as The Joy of Sake had made me no longer enjoy cheap sake, listening to a lot of Amy Winehouse had made me no longer enjoy â€œaverageâ€ music â€” music where several individual performances are combined. ### **My Theory of Human Evolution (Civil Rights Movement edition) (2008-02-12 23:32)**

From [1]Eyes on the Prize, about an Easter boycott of Nashville stores:

Easter was a most important time to buy. All blacks had to have a full, brand new outfit at Easter, no matter how poor you were, right? You may start three months ahead of time paying for that Easter outfit, and you may be paying for it for three months later.

There is a similar tradition in China: At the start of the new year you buy new clothes. I've [2]blogged before about how rituals, ceremonies, and holidays promoted technological development: They increased the demand for high-end items. This helped skilled craftspeople make a living.

Ryan Holiday (2008-02-15 13:43:20)  
Did you like The Power Broker?

seth (2008-02-15 16:58:59)  
yes, very much.

Julia Lupton (2008-02-15 21:31:56)  
I have heard about Robert Moses' response to Jane Jacobs' book, but I've never seen the document. That's great – and I will incorporate it into the set of lectures that you so kindly reference.

Stephen M (Ethesis) (2008-02-16 14:14:16)  
Thank you for this link, it suddenly helped me understand why Paris works as a city compared to Dallas which is just a place.

Anthony Flint (2008-02-16 15:55:00)  
The letter is vintage – "sell this junk to someone else" – and is from the Jane Jacobs papers at the Burns Library at Boston College, where MAS got most of its material. Far as I can tell, Moses made no public comment about Death and Life; he only wrote this private letter, and let others bash her in the weeks and months following publication October 1961 ... a staggering 47 years ago.

### **In Science, What Matters? (2008-02-16 07:28)**

And how do you learn what matters?

When I was a grad student, I read Stanislaw Ulam's memoir [1]Adventures of a Mathematician. I was impressed by something Ulam said about John von Neumann: that he grasped the difference between the trunk of the tree of mathematics and the branches. Between core issues and lesser ones. Between what matters more and what matters less. I wanted to make similar distinctions within psychology. Nobody talked about this, however. Not even other books.

Some research will be influential, will be built upon. Some won't. To put it bluntly, some research will matter, some won't. I once thought of teaching a graduate course where students learn to predict how many citations an article will receive. You take a 10-year-old journal issue, for example, and try to predict how many citations each article will receive. I like to think it would have been a helpful class: The key to a successful scientific career is writing articles that are often cited. I even had a title: "What Will You Do After You Stop Imitating Your Advisor?"

When I was a grad student the short answer to "what matters?" in experimental psychology was clear enough:

1. New methods. The Skinner box, for example, was a new way to study instrumental learning. Skinner didn't discover or create the first laboratory demonstration of instrumental learning; he simply made it easier to study.
2. New effects. New cause-and-effect linkages. For example, John Garcia discovered that if you make a rat sick after it experiences a new flavor it will avoid foods with that flavor.

My doctoral dissertation was about a new way to study animal timing.

A few months ago I had coffee with [2]Glen Weyl, a graduate student in economics at Princeton. We discussed his [3]doctoral research, which is about how to test theories. One of Glen's advisors had told him about a [4]paper by Hal Pashler and me on the subject. Hal and I argued that fitting a model to data is a poor way to test the model because there is no allowance for the model's flexibility. The first reviewers of our paper didn't like it. "You don't realize how hard it is to find a model that fits," one of them wrote.

Glen's interest in this question began during a seminar in Italy, when he realized the speaker was more or less ignoring the problem. The speaker was comparing how well two different theories could explain the same data without taking into account their different amounts of flexibility. Glen's thesis proposes a Bayesian framework that allows you to do this. His main example uses data of Charness and Rabin from choice experiments. ([5]Matt Rabin is a MacArthur Fellow.) Taking flexibility into account, he reaches a different conclusion than they did.

I wondered how Glen decided this was important. (It's a method, yes, but a highly abstract one.) I asked him. He replied:

Sadly, despite my interest in the history of economic thought, I don't have a lot of insight about why I came upon these thoughts. But one thing: my interests are very interdisciplinary . . . My work is based on drawing connections between economics, philosophy of science, and computer science (and meta-analysis from psychology and bio-statistics). Most of my work takes this form: as you'll see on my website, I've used theoretical insights from economics and computer science as well as evidence from neuroscience, psychology and biology to critique the individualist foundations of liberal rights theory; I've used ideas from decision theory to lay firmer foundations for goals set out by computer scientists designing algorithms; I've used tools from information theory to instantiate insights from psychology to help understand the design of auctions; and I've used computational neuroscience to model biases in economic information processing. Broad interests are hard to have, because they limit the time for learning a particular area in depth, but I prefer to read broadly and draw connections rather than to read deeply and chip away at open questions.

That was interesting. I read broadly, and so does Hal, who knows more about the philosophy of science than I do. I wrote to Glen:

The usual comment about interdisciplinary knowledge is that it's good because you can bring ideas from one area, including solutions and methods, to solve problems in another area. . . . But maybe it's also good because by learning about different areas you absorb a range of different value systems and this makes you less sensitive to fads (which vary from field to field), more sensitive to longer-lasting and more broadly-held values.

The more trees you know, the easier it is to see the forest.

Stephen M (Ethesis) (2008-02-17 13:08:16)

Seth, I've really been enjoying your blog recently. Just wanted to encourage you to keep posting.

Stephen M (Ethesis) (2008-02-17 18:49:00)

BTW, on finding something that matters: [http://www.newyorker.com/reporting/2007/12/10/071210fa\\_fact\\_gawande?currentPage=4](http://www.newyorker.com/reporting/2007/12/10/071210fa_fact_gawande?currentPage=4)

model fits and surprising predictions « the pulchrifex papers (2010-04-01 15:42:07)

[...] 1, 2010 · Leave a Comment I just attended a talk by a very famous quantitative psychologist. It was a good talk, all about modeling some fairly fine aspects of the interactions between information and reward in a decision-making paradigm, and there was a lot of mathematics in it that will forever elude me. Since I don't do this kind of work and am not well-equipped to understand it, I am probably undersensitive to how hard it is. Owing in part to these deficiencies, I've always appreciated Seth Roberts and Hal Pashler's points about model-fitting (here's a relevant post from Seth's blog, referencing a classmate of mine from a neural networks course), and in particular the point that fitting a lot of data with a few free parameters isn't always the coup it seems to be. I think there's an issue of denying the antecedent at work. Everyone knows that, if your observations aren't much more numerous than your parameters, a model fit is unimpressive; the easy inference is that, if your observations are much more numerous than your parameters, a model fit is impressive. But that's invalid and, more to the point, not always true. Roberts and Pashler bring up the point that "psychological data is often not surprising"; in many situations, including the ones addressed in this talk, it's predictable that the data will take the form of, say, a logistic function. (In fact, I'd guess that psychologists tend to prefer experiments that can be easily modeled by simple functions.) If there's a strong prior for a logistic function, the fact that you can fit a lot of data with a couple of parameters is not impressive; all it shows is that you know how to fit a logistic function. [...]

## **Blog Power (continued) (2008-02-17 22:26)**

What Jonathan Schwarz calls "the Lost Kristol Tapes" is a [1]taped debate between William Kristol (the new NY Times columnist) and Daniel Ellsberg about the invasion of Iraq. The debate was on C-Span's Washington Journal, of which I have fond memories; I watched it for years to get morning faces for my self-experimentation. [2]Schwarz called Kristol's comments "a double album of smarm, horrifying ignorance, and bald-faced deceit."

The debate has been watched about 5000 times. Three days ago, just before Schwarz's piece, it had been watched four times, three by Schwarz himself. [3]My long self-experimentation article would have been read by almost no one had not [4]Andrew Gelman blogged about it. Now it's been downloaded thousands of times.

More blog power: [5]here and [6]here.

Addendum. Funny coincidence: The day after I posted this, the formerly-obscure [7]Wikileaks hit the news for a super-charged version of the same thing. Wikileaks exposed Cayman Island tax shelters.

### **Forensic Means ... (2008-02-17 23:40)**

1. Forensic science = science relevant to the judicial system. Like CSI.
2. Forensic psychology = legal-system-related psychology. Like the personalities of serial killers.
3. Computer forensics is about using computers in the legal system.
4. Yet forensics by itself = public speaking.

Huh?

---

Varangy (2008-02-18 00:41:35)

*The first teachers of oratory were the ancient Greeks and Romans, namely Aristotle and Cicero. When they were classifying "kinds" of oratory, they termed the kind of argument used in a court of law to prove or disprove past events "forensic" argumentation. Centuries later while universities were still teaching all the forms of argument, students decided to take it to the competitive level and began debating for sport in an activity they named "forensics." Today forensics includes competitive dramatics and public speaking.* <http://www.morainevalley.edu/forensics/etymology.htm>

Benquo (2008-02-18 05:43:38)

The root is *forum*, which I think is used in the sense of a public place for discourse, where decisions might be made based on speeches. #4 is clearest – public speeches are proper to the forum. Similarly, anything to do with legal pleading is a public and thus *forensic* matter.

seth (2008-02-18 08:01:56)

Thanks for the explanations, Varangy and Benquo.

## The Greatness of Behind The Approval Matrix (2008-02-18 07:03)

What I like most about magazines is their ability to open new worlds to me. Books – unless by Jane Jacobs – rarely do this. Music, TV, and movies almost never do this. Paintings and other visual arts never do this (to me). Magazines do this regularly. Entertainment Weekly – the best magazine with a dull name – tries to do this (and succeeds). I am now reading The Golden Compass because of EW. An issue of Colors made me visit Iceland. Spy made New York fascinating. (E.g., an NYC map of smells.) It's the best kind of teaching: you open a door and make what's inside seem so interesting and wonderful that the student voluntarily decides to enter and explore.

Which is why it isn't completely surprising that Abu Ayyub Ibrahim, who writes [1]Behind the Approval Matrix, is a teacher. New York magazine's Approval Matrix has a wonderful way of introducing new things: with humor, poetry (if well-written short captions = poetry), a dash of outrage (calling stuff "despicable"), and an attractive layout. When it calls something Brilliant, I'm instantly curious – thus fulfilling the best function of magazines with remarkable ease. The problem for me, and I assume many others, is that the captions are often obscure. Behind the Approval Matrix – which might have been called The Annotated Approval Matrix – explains each item.

The creators of The Approval Matrix had a great idea and didn't quite pull it off. It's often too hard to figure out what they're talking about. Ibrahim has supplied what is missing.

It's a bit like my self-experimentation. Previous (conventional) research, for various reasons, couldn't quite reach practical applications (e.g., omega-3 research couldn't figure out the best dose); my self-experimentation, building on that research, was able to cover the final mile.

1. <http://behindtheapprovalmatrix.blogspot.com/>

---

barjac (2008-02-18 13:53:53)

I enjoy reading your blog. But I find infuriating the frequent non sequitur congratulatory insertions about your research on omega-3s in posts otherwise about other topics. It does not serve you well as a scientist and as a blogger. As to the correct dosage, I looked at my file in which I keep references for future use. The portion devoted to omega-3 goes on for 42 pages. A percentage of these studies are clinical trails (at least 900 have been done) or animal research and do talk about dosage. Dosage for what? A relatively low dose of EPA/DHA has been used in coronary heart disease studies. But one gram per day shows significant reductions in a variety of bad outcomes. Want to reduce triglycerides, 2 to 4 grams a day. Elevated blood pressure, at least 3 grams per day, but higher doses for higher blood pressure. Rheumatoid arthritis, 2 to 6 grams daily, but with greater percentages of EPA which is a major precursor to anti-inflammatory eicosanoids (DHA is not). And so on. What else is one consuming? Overconsumption of Omega-6 EFAs in the American diet is part of the problem. For example, there is some suggestion that maximum conversion of the 18 carbon Omega-3 (ALA, the Omega-3 in flax oil) to EPA occurs when the consumption of Omega-6 to Omega-3 is 2.3 to 1. But are Omega-6 EFAs bad? We have known that complete elimination of Omega-6s from the diet results in serious disease since the 1930s. There are only a handful of recognized such cases for Omega-3s. Can one take too much? Omega-3 EFAs reduce the ability of the blood to clot. For someone on the modern American diet, that first step of reduction is probably good for almost everyone. Somewhere around 13 grams of daily consumption of EPA/DHA probably gets dangerous. I like the idea of self-experimentation. But it is suggestive. As science, it tells us where it might be fruitful to look further, but it does not establish the "truth" of anything. I find your results of the effect on cognition from the consumption of ALA intriguing. I cannot account for it. I have some ideas why it might work, but I do not know. And almost certainly, if true, it is different from the ways EPA/DHA work in multiple different ways throughout the body.

seth (2008-02-18 14:24:40)

barjac, if you think I didn't figure out the optimal dosage for myself, I'd be curious to know why. I gave a reason for generalizing from my measurements of cognitive function to other measures. If you think the optimal dosage has been figured out in other studies, can you give a citation for this claim so I can look at the evidence for it? You seem to be giving the ranges of dosages used in published studies; they may all be too low or too high.

Ibrahim (2008-02-18 16:57:25)

Seth, Thanks so much for the kind compliments! I've been meaning to email you since I switched to the new format. Please send me an email, and let me know what you think. I'm going to start checking out "Entertainment Weekly", and "Spy." Wait, is "Spy" still in circulation? Thanks again! Ibrahim P.S. I can't believe the magazine didn't come out today.

barjac (2008-02-18 18:51:55)

Indulge me with a part of a story from New Scientist, 9 February 2008. "Dingemanse and his colleagues have established that there is genetic variation underlying exploration behaviour in small birds called great tits" some individuals inherit a highly exploratory personality and others a more cautious one. The researchers measured this trait in wild great tits and related it to their survival over three years. For females, the higher the exploration score, the more likely they were to survive in 1999 and 2001. However, in 2000, when resources were abundant, low-scoring females were more likely to survive. For males this pattern was reversed, reflecting the different survival pressures that they face. This study and others like it make a powerful point: the optimum level of a personality trait depends on the details of the local ecology. As humans we want a simple story. As scientists, one wants to say all other things being equal. (I chose the above story for how important all other things being equal is. I am a parable kind of guy, I realize some may read it and think how bizarre, but for me it is salient to the issue.) But things are complicated. Small changes in one dial can make the optimum setting of another dial different. Take acetaminophen toxicity. Assuming one does not have liver disease or has not drunk some alcohol recently, one can probably take 4 or 5 grams of acetaminophen safely. Not a good idea, but it will probably not kill or damage most people. The liver uses glutamate in metabolizing the toxic ingredient. Somewhere north of 7 or 8 grams, there is a cliff effect. Glutamate runs out and now things go south for the liver quickly. So no one should take, say, 20 grams of acetaminophen at once and almost all normal people can take 700 mg and a fair percentage will get pain relief. But what about 700 mg every four hours, is that okay? That is only 4.2 grams a day. What about day after day? What is the optimum dose for pain relief? What is the maximum safe dose? Both vary from person to person and importantly, both vary for the same person from time to time. (Most non-prescription drugs have a much higher ratio of toxic to therapeutic effect.) These examples are chosen for dramatic effect. The bullet point is that there is no such thing as an optimal dosage. Just a pretty good therapeutic dosage for a particular desired effect. One hopes the side effects are minimal. One hopes it remains a pretty good therapeutic dose, but a lot of the time it does not. Things change over time. Dosage for what? From the University of Maryland Medical Center web site: <http://www.umm.edu/altmed/articles/omega-3-000316.htm> "Macular Degeneration" Another larger clinical study confirms that EPA and DHA from fish, 4 or more times per week, may reduce the risk of developing macular degeneration. Notably, however, this same study suggests that ALA may actually increase the risk of this eye condition. (So ALA is bad?) "Inflammatory bowel disease (IBD)" In animals, it appears that ALA works better at decreasing bowel inflammation than EPA and DHA. (So ALA is good, better even?) Stroke: "Strong evidence from population-based clinical studies suggests that omega-3 fatty acid intake (primarily from fish) helps protect against stroke caused by plaque buildup and blood clots in the arteries that lead to the brain. In fact, eating at least 2 servings of fish per week can reduce the risk of stroke by as much as 50 %. However, people who eat more than 3 grams of omega-3 fatty acids per day (equivalent to 3 servings of fish per day) may be at an increased risk for hemorrhagic stroke, a potentially fatal type of stroke in which an artery in the brain leaks or ruptures." (Less one thinks that this example provides brackets for an optimal dose, note that for Americans a lot of therapeutic effects for other diseases start around 3 grams per day.) "Depression" In a clinical study of individuals with depression, those who ate a healthy diet consisting of fatty fish 2 - 3 times per week for 5 years experienced a significant reduction in feelings of depression and hostility. (Probably mostly the DHA. Note the effect is over years. I got to retrofit all those cell membranes. Also note that even at a healthy level there is more arachidonic acid (omega-6) in brain cell membranes than DHA. It would probably be impossible to get this effect with just ALA and certainly not with just ALA in a diet high in Omega-6 alpha-linoleic acid. So the time effects range from the short-term in the self-experimentation that you did to days to weeks to a few months

for anti-inflammatory effects – the gum disease example, but also other things such as sudden death from heart disease to years in the case of DHA in brain and eye cell membranes.) Could a dose of 3 grams or more of EPA/DHA just be too high, but the only one that will work to counteract the effects of a lifetime diet low in omega-3s and high in omega-6s? You have shown that ALA has an effect on a particular type of cognitive function in the short term in one person. Speculation is that it worked as a fat metabolized for energy. But it really tells us nothing about a good quantity for omega-3 in your diet over the long-term and even less about what might be good for other people. I am not trying to belittle the self-experiment that you ran, but it just doesn't.

barjac (2008-02-18 18:59:23)

Consider that it might be an fat metabolism providing a source of energy effect. Does it matter if you are somewhat ketotic after fasting or if you have recently ingested glucose. It has been a while since I read your stuff, maybe you considered this.

seth (2008-02-18 20:49:01)

I doubt that omega-3 brain effects are due to its being a source of energy. The brain is more than half fat – structural fat – and a lot of that is omega-3. Other fatty acids, as far as I can tell, do not produce the same effect. The studies you mention do not indicate optimal dosage. Such a study requires testing several doses and mapping out a dose-response function. Because self-experimentation is so easy and fast and the effects so clear, I was able to do a fair approximation of such a study. Of course my data is imperfect, of course it's unclear how far to generalize, but to say "it really tells us nothing about a good quantity of omega-3 in your diet over the long-term" is an overstatement.

barjac (2008-02-19 01:33:49)

By the way, I was typing fast and there is more DHA than arachidonic acid in brain membranes. About a quarter of the fat by weight in the brain is DHA, 10 percent AA. 50 % of the weight of the neuron's plasma membrane is composed of DHA. There is only a small amount of EPA in the brain. Only a small amount of ALA is converted to DHA, so even if your daily flaxseed consumption resulted in the consumption of, say, 7 or 8 grams of ALA, the amount of DHA resulting would be no more than a few hundred mg of DHA, probably a lot less. So overnight the consumption of a lot of ALA probably cannot effect the main ways that DHA effects cognition. Not enough DHA and not enough time to incorporate significant amounts into membranes. But I can quickly run out of fingers (a couple of times) just off the top of my head listing ways DHA is used in the body in addition to phospholipids. One or more of them may have an overnight effect. Yeah, the energy metabolism comment was the result of an impish impulse. Not absolutely, completely to be ruled out however. My impulse to comment here has run its course, so I will stop. But remember, we know a LOT about the biochemical processes these chemicals are involved in. And there is even more we don't yet understand. Especially in the complexity, the interactions, the emergent properties. It would be quite amazing if one guy experimenting on himself standing on one foot learned something astounding. That he learned something quite admirable, we learn a little something every time we do science even if it is that we don't yet understand.

Stephen M (Ethesis) (2008-02-19 17:08:56)

I have to say I always read Seth on Omega 3 as more happy about it than anything else. If you've ever talked to him, you can just hear his voice. More of a "gee, this reminds me of" than "non sequitur congratulatory insertions." Omega 3 dosages, and I've read a number of studies, are something that have a pretty wide range – more than 100 % (2-5 grams, as in the one study, is 150 % range – that's like saying maybe this, maybe twice this, maybe more), depending on what you are seeking to accomplish. I like the perspective of "covering the final mile" in the post. Honestly, the blog has gotten more interesting over time.

DW Bender (2008-02-21 11:19:38)

...It's the best kind of teaching: you open a door and make what's inside seem so interesting and wonderful that the student voluntarily decides to enter and explore. Which is why it isn't completely surprising that Abu Ayyub Ibrahim, who writes Behind the Approval Matrix, is a teacher. New York magazine's Approval Matrix has a wonderful way of introducing new things: with humor, poetry (if well-written short captions = poetry), a dash of outrage (calling stuff "despicable"), and an attractive layout. When it calls something Brilliant, I'm instantly curious – thus fulfilling the best function of magazines with remarkable ease." Those are interesting and sharp observations from you, a professional teacher and especially a learner through experiment, yourself. I had just finished blogging a bit on a science project my second grandson is engaged in,

touching on a long-standing concern about the interconnectedness of giftedness (primarily in the arts, including humor) with academic learning and enjoyment. [1]Leeches, Amoebas & Algae (Oh My!) . I believe that children and adults who exhibit such gifts (and those who may not exhibit them) develop them primarily as learning-tools, while the enjoyment and entertainment we derive from them may be secondary benefits.

### **Want to Self-Experiment? A Special Offer (2008-02-20 00:27)**

I'd like to increase the ability of self-experimenters to tell others what they've done and get feedback. Blog software can be used to do this.

Instead of posting again and again, as in the usual blog, you just post a few times then edit those posts as you collect new information. Instead of post = diary entry, the concept is post = section of scientific paper. You might have posts corresponding to Introduction, Equipment, Procedure, Raw Data, Data Summary, Interpretation, Strengths, Weaknesses, and Comparison to Other Work. You start by writing the Introduction. As the raw data comes in, you add it to the Raw Data post. After you finish collecting the raw data, you write the Data Summary post. And so on.

[1]Here is the start of an example.

The special offer is that if you want to do a self-experiment and are willing to communicate your results in this form, I will – time permitting – help you do it and write it up and will link to the blog you create. To take advantage of this offer, write me at twoutopias at gmail dot com. Tell me what you want to do and your relevant background. Deadline: Sunday, February 24.

1. <http://www.blog.sethroberts.net/2008/02/20/calorie-learning-introduction/>

---

josh (2008-02-21 08:07:54)

The sounds a bit more like something you would put in a wiki to me. Have you seen scholarpedia.org? I suppose scholarpedia is a little more formal since it is peer-reviewed.

How to Stop Procrastinating So that I Am Not a Bum - A Self-experiment | FlowingData (2008-03-02 22:55:32)

[...] In an attempt to work more efficiently, I am going to take up Seth's self-experimentation offer that I found via Andrew's post. I am going to self-experiment; I am going to collect data about myself; and I am going to find out if my two-pronged method to stop procrastination works. Here's my plan: [...]

### **Calorie Learning: Introduction (2008-02-20 08:40)**

In a series of posts, each titled Calorie Learning: [something], I'm going to use a blog to communicate self-experimentation. To see the whole series, look in the category Calorie Learning (under Self-Experimentation).

This research will be about how we (or at least I) learn to associate flavors with calories – more precisely, smells

with calories. This learning is at the heart of the Shangri-La Diet, which derives from [1]a theory that says the flavors of your food increase your set point if they are associated with calories. The stronger the association, the bigger the increase.

Why study this? 1. Maybe I can improve the diet. 2. It matters. It happens with every bit of food you eat. It controls what you eat and your appearance (assuming my theory is right). 3. Little is known about it. As I wrote in the appendix to The Shangri-La Diet, Anthony Sclafani has studied this learning extensively in rats. No one has studied it extensively in people. 4. The experiments can be simple and easy – or at least that's what I think now.

A few weeks ago, a friend told me how much she liked those cellophane-wrapped white-bread sandwiches sold in delis and bodegas. Egg salad sandwiches, for example. They were addictive, she said. That sounded about right: White bread (and bread in general) is digested very fast, witness its very high glycemic index. Fast digestion means the calorie signal it generates in the brain overlaps a great deal with the flavor signal it generates in the brain. The more overlap of the two signals, the stronger the association created. The stronger a flavor's association with calories, the more you like it.

Her comment gave me an idea: I can create a random new flavor by randomly combining many spices, mixing them into butter, and spreading the butter on white bread. The spices supply the flavor, which I can reproduce as often as I want by making a big enough batch of spicy butter when I start. Spice mixtures are cheap. I can easily and cheaply make a huge number of flavors that should taste entirely new. This means I can start fresh – which is where you want to start when doing a learning experiment – as often as I want. White bread is cheap, easily available, has little flavor, and provides a strong signal per calorie. If I want to increase the time between the flavor and the calories, maybe I can spread the butter on crackers, which have few calories, and eat the bread later.

Will it work? Stay tuned.

1. <http://sethroberts.net/about/whatmakesfoodfattening.pdf>

---

Jeff Winkler (2008-02-20 10:19:13)

Hi Seth- I meant to reply to your original brandy post, but see you're expanding on this (th/m)eme. Would the association be accelerated if you took flavorless calories along with the flavor? (Flax capsules, totally flavorless). Anything wrong with exaggerating the association in this way? Jeff

seth (2008-02-20 12:15:08)

Jeff, yes additional calories should strengthen the association. as for your "anything wrong?" question I don't think I understand what might be "wrong". in these experiments I will probably try flavorless calories – e.g., eating plain bread with my nose closed.

Trina (2008-02-20 14:41:16)

This is as interesting as being an undergraduate again, at the start of a new semester, in an exciting class with a dynamic professor, sitting at the edge of my chair with sharpened pencils in both hands–without the angst. Thanks, Seth.

seth (2008-02-20 15:10:46)

Thanks, Trina. That's a vivid and satisfying picture.

spacenookie (2008-02-20 19:43:07)

somewhere in the Taubes tome, Taubes talks about insulin release in \*anticipation\* of eating. He says that if you think about eating, there is an initial release of insulin that precedes consumption and then a later release after consumption. I wonder if the initial release could be a learned effect based on what types of food you expect to eat. Taubes argues strongly that if you don't have insulin in your system, you can't gain or maintain fat.

Jeff Winkler (2008-02-21 10:38:02)

Exaggerating the caloric content seems like a [1]Useful Lie, if the goal is to learn to like a food. Now how can I get my wife to like veggies? :) (This is a social engineering problem, she has an aversion to things that taste "green") [http://www.keepkidshealthy.com/nutrition/kids\\_vegetables.html](http://www.keepkidshealthy.com/nutrition/kids_vegetables.html) says - "What if you didn't teach your toddler to eat a lot of fruits and vegetables? Is it too late? Probably." The old trick of mixing veggies in with calorie-rich companions seems like it should not work if taste sensitivities are ultraspecific- "Creative ways to get your kids to eat more vegetables can include camouflaging them in with other foods, like chopping up and mixing vegetables in with pasta sauces, lasagna, casseroles, soup, chili, omelets, etc. or adding veggie toppings to pizza. You can even find recipes for things like banana raisin pancakes, carrot beef meatballs or zucchini cookies, that your kids might enjoy."

1. <http://c2.com/cgi/wiki?UsefulLie>

Aaron Blaisdell (2008-02-21 13:05:45)

Hi Spacenookie, Taubes discusses the anticipatory release of insulin resulting from thoughts about food, or exposure to the smell of food, in the last or second-to-last chapter of his book. I just finished reading the tome last night, so this section is still quite vivid in my mind. Now that I've finished the book (one of the best books I've read in my lifetime - ever!), I am going to re-read Seth's interview with Taubes. Btw, I've haven't done the SLD diet in quite a while (I'm 5'11" and 142 lbs., an ideal weight for my height), but I've been cutting way back on carbs and increasing my intake of protein and fats, especially red meat, eggs, whole milk, and cheese. I also take 2400 mg of fish oil in capsule form daily. I can honestly say I've never felt better both physically AND mentally in my whole life. I just had a dentist visit two days ago and the dentist was impressed at how good my oral health was. I used to suffer have one or two cavities filled almost every year, and my gums always had swelling. My gums are doing much better and I haven't had a cavity in almost two years.

Varangy (2008-02-21 23:56:14)

*Ticket cameras increase crashes.* Of course they do — why? Contrary to popular opinion, sometimes, not often, it is better/safer to run a red light than to stop for it. When you are driving in that uncertain netherzone, you don't know long it has been the yellow, and but you know that you cannot safely stop for the red w/u surprising the people behind you. Better to punch it. I am not advocating running reds by any means, but we all know that there are situations where it is very literally safer. But here is the irony and second reason that traffic cameras increase crashes: if a cop sees you run a red, your chance that you get a ticket is almost indistinguishable from 100 % (unless you are a highly attractive female). If you stop for every red, even in the unsafe situation described above, you will not get a ticket, almost no matter what happens, provided you weren't speeding. After all, you obeyed the law and stopped for the red. Sort of like the unseen hero that NNT describes in the Black Swan, you don't get credit for preventing an accident, b/c no one saw the accident.

seth (2008-02-22 00:57:28)

Very interesting. I thought the reason those cameras cause crashes is that they are distracting. I don't understand your second reason.

Stephen M (Ethesis) (2008-02-22 18:36:50)

Locally the cameras seem to have reduced accidents. Interesting. BTW, I've been really enjoying the various posts and material at <http://www.ted.com/talks/view/id/142> Fascinating.

Varangy (2008-02-25 12:08:25)

Hi Seth, I guess my second reason isn't really separate from my first. The point is that, while it may be safer in some instances to run a red light, the law doesn't recognize such an instance i.e. you will always get a ticket for running a red. Therefore, you are incented to stop for every red, even if you know it might cause an accident. You are not rewarded for preventing an accident — because no one will reward you for avoiding an accident that didn't occur b/c you prevented it. It is invisible (and probably) incomprehensible to 99.99 % of people.

## **Flaxseed Oil: Beware of Lignans (2008-02-21 22:03)**

When I buy flaxseed oil, I have a choice: with or without lignans. I almost always choose without. Apparently that's the right choice, witness [1]this from the SLD forums:

I've been trying to figure out what besides overeating might cause these flare ups with my gallbladder. It seems clear from the last few days that one of the things that can set it off is Flax Seed Oil with lignans. When I consume 2-3 tablespoons a day of FSO without lignans, I don't notice any problems. The FSO goes down easy and I don't feel nausea or pain. But with the lignans I often do. To be sure, I decided to switch from FSO to ground up flax seeds mixed into my oatmeal. And today, the first time I tried that, an hour later the familiar nausea is back.

1. <http://boards.sethroberts.net/index.php?topic=5995.msg63455#msg63455>

lasser83 (2008-02-21 23:33:46)

I purchase and intake flaxseed with lignans. But only because that is all that's offered at the health food stores in the midwest.

Caleb Cooper (2008-02-22 07:24:47)

huh. i've heard that men should take flaxseed w/ lignans, because without lignans there's increased risk of prostate cancer, which my family has a history of. For the record, at doses > 2tbsp I've experienced headaches with lignans flaxseed. Cutting back my dosage to

Caleb Cooper (2008-02-22 07:27:18)

oops, got cut off. [continued]...cutting back my dosage to

lasser83 (2008-02-22 16:16:11)

Yeah, the cancer thing freaks me out. I read a couple articles by doctors who would not recommend taking flaxseed oil without lignans due to the cancer risk. But both doctors also concluded that more research needed to be done on the matter.

Kristen's Raw (2008-02-22 18:57:02)

Anyone ever use hemp seed oil for getting the appropriate ratio of omega-6 to omega-3 essential fatty acids?

KevinK (2008-02-23 12:54:21)

The connection between prostate cancer and non-lignan FSO seems pretty weak to me. But I do want to do more. The [1]Mayo Clinic has a page on FSO and it's potential benefits and problems. The biggest takeaway from that page seems to be that there is a lot of room for more research. The prostate cancer/FSO connection seems the weakest.

Kevin Mullaney.com » Blog Archive » When Gallbladders Attack (2008-04-10 07:34:18)

[...] Now these attacks are infrequent. I had several last fall, but I think I've only had two this year. The hypothesis that I'm currently working under is that starches in my diet aggravate it. The first few attacks I had were after large meals with lots of rice. I also noticed that the lignans that accompany flax seed oil also irritate it, as do ground flax seeds themselves (the oil without lignans seems to be fine). [...]

## **Calorie Learning: Background (2008-02-22 01:02)**

The discovery of flavor-calorie learning (in rats) was no surprise. It was another example of flavor-consequence learning, which was well established. In the 1950s, John Garcia had found that if you make a rat sick after exposing it to a new flavor, it will avoid that flavor. Flavor-consequence learning belongs to the larger category of Pavlovian learning (also called classical conditioning), the sort of learning where an animal learns that an unimportant event (such as a bell) predicts an important event (such as food). Pavlovian learning belongs to the larger category of associative learning, which also includes action-event learning, such as a rat learning that bar presses produce food pellets. The action is pressing the bar; the event is getting a food pellet.

My Ph.D. was in the field of animal learning. Almost all animal learning research is about associative learning. When I taught introductory psychology, however, I found it hard to take advantage of my expertise because most of the research had little real-world relevance. The big exception was [1]Shepard Siegel's work on drug tolerance and craving. Tolerance and craving are due to Pavlovian learning, Siegel argued. Flavor-calorie learning, happening at every meal, might have been another exception had anything interesting been known about it – but nothing was.

The usual terminology is to say that in a Pavlovian-learning experiment, the animal learns to associate the CS (conditioned stimulus, such as a bell) with the US (unconditioned stimulus, such as food). In flavor-calorie learning experi-

ments, the flavor source is the CS, the calorie source the US.

1. <http://www.science.mcmaster.ca/psychology/ss.html>

---

Tim Lundeen (2008-03-16 22:40:10)

This Siegel & Ramos paper is just superb (finally made it to the top of my reading list). Thanks for linking to it, fascinating and useful information. It certainly looks like one factor in food binging is the insulin spike (the conditioned compensatory response) that your brain learns to generate when you smell or eat familiar food, which happens before the carbohydrates are absorbed into your bloodstream. This causes a need for carbohydrate to balance the insulin, making it very hard to stop eating.

### **Lewis Carroll on Mercury and Autism (2008-02-23 08:09)**

From [1]an article in Rolling Stone about mercury and autism:

The CDC "wants us to declare, well, that these things are pretty safe," Dr. Marie McCormick, who chaired the [Institute of Medicine's] Immunization Safety Review Committee, told her fellow researchers when they first met in January 2001. "We are not ever going to come down that [autism] is a true side effect" of thimerosal exposure. According to transcripts of the meeting, the committee's chief staffer, Kathleen Stratton, predicted that the IOM would conclude that the evidence was "inadequate to accept or reject a causal relation" between thimerosal and autism. That, she added, was the result "Walt wants" – a reference to Dr. Walter Orenstein, director of the National Immunization Program for the CDC.

From Chapter 12 of [2]Alice's Adventures in Wonderland:

'No, no!' said the Queen. 'Sentence first—verdict afterwards.'

'Stuff and nonsense!' said Alice loudly. 'The idea of having the sentence first!'

'Hold your tongue!' said the Queen, turning purple.

Eerily prophetic, no?

---

B Campaigne (2008-02-23 20:18:42)

You are a human being. You are not a person, you *have* a person. A person is your agent in commerce,. A fictitious entity to which rights and duties are ascribed. To the government and industrialists you are an indentured slave or as the media refers to us, *consumers*. Before you enter into the world arena let alone the Autism arena you must see where, as an individual, you stand. Here in Ontario Canada there are over 1000 citizen children on a shameful waitlist to receive funding for ABA/IBI therapies. Time is their enemy. After four years and the Senate / Eggleton paper *Pay Now or Pay Later* and the Canadian National Autism Strategy lies dormant. (Although it is a good document , worth reading) Canada is founded upon the principles that recognize the Supremacy of God and the Rule of Law. Both of which are being broken by the Canadian governments both Federal and Provincial. The Magna Carta, the British North American Act, The Canadian Charter of Rights and Freedoms and the U.S. Constitution were all written to protect us from the Sovereign. To all of us parents in the front lines all over the world *Hallelujah to Ya !* At the end of the day it's just us, our little team and the clinic we run from our homes. Why is the focus always only on thimerosal? Included on this list of chemical concerns should also be formaldehyde, M.S.G., aluminum, Butylated hydroxytoluene or B.H.T. and many others. *Don't* let the mainstream media and pharma spin doctors lull you into only focusing on the thimerosal. Remember these corporations would no doubt lose everything if a connection is made between the preservatives and the world wide vaccine programs. Our great grandparents our grandparents and our parents were all infected with toxic preservatives through the inoculation programs. I saw my 5yr old son's live blood analysis taking place. I saw live candida yeast in his blood. I saw the heavy metals as well. *Where do you think it came from?* *Leaky gut syndrome comes from the M.M.R jab.* We saw the change in our child right after the second round of vaccinations. Freedom of the person requires not only, or not even especially, the absence of legal constraints but the presence of alternative thoughts. The most successful tyranny is not the one that uses force to assure uniformity, but the one that removes awareness of other possibilities. I have come to the conclusion that those who benefit from any societal mechanism rarely wish to understand that mechanism, especially if it appears to grant them power or authority and understanding it or any alternatives would restrict, diminish or destroy that power apparently granted. They live in a vapid world of learned assumptions. Lets face it if you have acronyms after your name your whole goal is to get published and funded no matter how ridiculous your position is. Most if not all of the researchers and their research are in the pocket of Big Pharma. They have lobbied their way into the core of our societies. I feel sorry for the caregivers who actually administer the jab and wonder how they are going to live with themselves after the truth comes out. If we put up with this our children will be next. It's not the vaccines it's the toxins therein. A child on the spectrum is born every 20 minutes. What do they all have in common? Wake up people.

### **My Theory of Human Evolution (gift card edition) (2008-02-23 13:27)**

The Sharper Image has gone bankrupt and will [1]no longer honor gift cards. In the comments section of the Consumerist post about this, several people apparently fail to understand why gift cards exist:

Another reason why cash is a better gift than gift cards.

This is just a good example why you should never buy a gift card.

Did anyone ever NOT know that gift cards are stupid?

The real lesson here, as Consumerists know, is don't buy gift cards. They are a bad deal even if the issuer doesn't go bankrupt.

This is the low-rent version of the [2]deadweight cost of Christmas idea, which I [3]discussed earlier. At the risk of stating the obvious, the perfect gift shows you know a lot about the recipient; cash shows you know nothing. A gift card shows you know a little – where the person likes to shop. They are less wasteful but less gift-like than ordinary gifts, more wasteful and more gift-like than cash. Gifts are supposed to be wasteful. This is why they are nicely wrapped. (Curiously no commenter called gifts stupid, a scam, etc.) In evolutionary terms, gift-giving traditions evolved because they increased demand for seemingly "useless" stuff. Gifts that went unused and expensive wrappings weren't actually useless; they helped artists and artisans make a living. They were research grants for material science.

1. <http://consumerist.com/359574/the-sharper-image-suspends-acceptance-of--gift-cards-due-to-bankruptcy?>

[...] My Theory of Human Evolution (gift card edition) [...]

Giftcardblogger (2008-03-19 19:38:01)

I hope the sharper image situation will remind consumers to pay attention to what is going on with the company before buying a gift card, especially since many people hold on to gift cards for an extended period of time.

Jamie Lentzner (2008-03-30 21:05:20)

Low rent - I just learned that "expression" this past year - I love it! Anyhoo, good post - shame on Shaper Image.

## **Calorie Learning: Materials (2008-02-24 10:18)**

These are the supplies I used in my calorie-learning experiments:

1. Wonder bread. I wanted bread with as little flavor as possible
2. Unsalted butter. Unsalted because the spice blends have salt.
3. Eleven [1]Penzey's Spices spice blends. In particular, Baking Spice, Cake Spice, Chicken Taco Seasoning, Jerk Pork Seasoning, Poultry Seasoning, Mural of Flavor, Sate Seasoning, Southwest Seasoning, Sweet Curry (regular), Tuscan Sunset, Venison Sausage Seasoning. Each has 5-15 different spices. For example, Jerk Pork Seasoning contains paprika, allspice, ginger, cayenne pepper, sugar, nutmeg, black pepper, garlic, thyme, lemon grass, cinnamon, star anise, cloves, and mace. Baking Spice is a mixture of two kinds of cinnamon, anise seed, allspice, mace, and cardamom. Combining a few of them should produce a flavor unlikely to resemble any familiar flavor.

Stephen M (Ethesis) (2008-02-26 11:45:41)

Self control is a fun thing, isn't it ;)

### **Omega-3 and Sports Injuries (part 4) (2008-02-26 20:36)**

Anonymous writes again:

I got caught in a nasty achilles lock the other day—it's an MMA [mixed martial art] submission move—and while trying to escape, I accidentally dislocated my fibula at the knee. It made a LOUD popping noise, to the point where everyone in the gym stopped. It popped it back in immediately, and other than some instability, it felt OK. Thankfully there was a doctor there (by chance—he does MMA and was in my class). He spent like 15 minutes examining my knee and said that other than some stretched ligaments, it was fine. His quote (I'm paraphrasing):

"That's amazing. You should need reconstructive surgery right now. I don't know how that happened, you must have rubber ligaments."

I told him about taking 4 tablespoons of flax seed oil every day, and he was shocked, and said he was going to research it to see if that could be why I got so lucky. Told him to Google you, it's all there.

The injury happened Friday. Today (Tuesday) the doctor looked at my knee again in class, and he was amazed not only at the lack of swelling, but that I was able to roll today (not full speed, just lightly).

I have played sports my whole life and have had at least half a dozen various knee injuries. Things like minor cartilage tears, hyperextensions, strains, etc.—none that were this major (a dislocation of a bone at the joint). Of those injuries, I was out longer and recovered much slower than I have with this one. I know this isn't proof of anything, and I don't know how much the flaxseed oil has had to do with what happened, but even the doctor is shocked.

More about omega-3 and sports injuries [1]here and [2]here and [3]here.

Addendum. He uses Whole Foods flaxseed oil without lignans.

2. <http://www.blog.sethroberts.net/2007/11/25/omega-3-and-sports-injuries-more/>

3. <http://www.blog.sethroberts.net/2007/11/16/omega-3-what-happens-when-you-stop/>

---

Stephen M (Ethesis) (2008-02-26 20:58:00)

Wow, that is very, very impressive. Interesting what you discover when you pay attention.

Varangy (2008-02-26 22:58:58)

As a skeptic of largely everything, I think this might be an example of post hoc ergo propter hoc fallacy as the anonymous alludes to at the end of his comment. That noted, it clearly warrants further research.

MT (2008-02-27 02:24:02)

Any way to find out what type of flax oil Anonymous is taking? I'm curious about the lignan content comments from other posts which suggested lignans might be a source of nausea, and wondering whether they may have other effects on the benefits, or lack thereof, of flax. I've always taken flax with lignans and haven't experienced such benefits.

Charles Richardson (2008-02-27 16:15:19)

As per Roger Williams's "Biochemical Individuality," there is an incredibly wide range of responses to everything, including nutrients. Having owned a health food store for a lot of years, it was obvious to me that some things were miraculous for

some people, neutral for others, and harmful to another group. That's why Seth's approach is so important. It's all about experimentation and learning what things do to your body, and learning how to be objective about that (as far as that's possible). I was taking flax seed oil at one point for weight loss, and then I realized that it was improving my mood. Unfortunately I didn't trust that observation (about fatty acids) until years later, when it was validated by reading some studies about fatty acids and the brain. So again, Seth's approach to all these things, and the rigor with which he approaches them, is something to emulate.

seth (2008-02-27 21:44:10)

Charles, I agree, biochemical individuality is one big reason self-experimentation is important. So you can figure out what works for you. Self-experimentation is a bit like the two sides of a bridge, the on ramp and the off ramp. Self-experimentation (on ramp) will often be the only way to come up with a new idea worth testing conventionally. And even after this or that treatment is shown to work via conventional research (bridge), individuals will still need to use self-experimentation (off ramp) to make sure it is working for them.

JohnN (2008-02-28 14:37:19)

I suspect the idea of biochemical individuality will never be proven. I'm reminded of the popularity of "Eat Right for Your Type" several years ago. Both seem plausible but a long way from truth and of course, not testable as a hypothesis. What should be recognized, however, is that the body is a complex system, its output expressed by the myriad rules that govern it and the initial conditions. Different initial conditions yield different results. When it comes to the efficacy of omega 3 we can not isolate the daily dose of fish oil/flax seed from our current and past diets (omega 6: omega 3 intake; types of omega 3 - ALA, DHA or EPA; low-fat Vs low-carb; saturated fat: MUFA/PUFA; other supplements that may work for or against omega 3, etc.) and your physical & psychological environments (high intensity Vs endurance exercise; how you manage stress). The permutation is endless with endless possibilities without ever resorting to biochemical individuality as an explanation. Self experimentation may be the only way to settle some hard cases.

Seth's blog » Blog Archive » Omega-3 Greatest Hits (2008-03-01 08:21:53)  
[...] Omega-3 and Sports Injuries (part 4) [...]

jackson12 (2008-06-28 05:48:58)

Seth .. this may be a strange question, but I'm wondering how your hair is doing? I've experimented with flaxseed oil myself, but I noticed my hair got thinner as a result of using flax-oil. On the net I also found a lot of reactions from people who also experienced hairloss because of flaxseed oil. Thanks for your reaction

seth (2008-06-28 18:27:28)

I haven't noticed any effect on my hair other than it is much softer.

## **Calorie Learning: Procedure (2008-02-27 07:37)**

In the first experiment, I created a butter mixture with a random flavor and spread it on two pieces of bread, which I ate and rated.

To create the butter mixture with a random flavor, I took 1/2 stick of butter and heated it in a microwave until it was soft. Then I randomly selected four of the 11 Penzeys spice blends and mixed 1/2 tsp of each into the butter.

For each trial, I spread a thin layer of the butter on two pieces of the bread, which was at room temperature. I ate them in a minute or so. I rated how good they tasted on a scale where

90 = very good

80 = quite good

75 = good  
70 = somewhat good  
60 = slightly good  
50 = neutral  
40 = slightly bad

I've used this scale to rate food dozens of times. Sometimes the rating changes with successive tastes; if so, the assigned rating is the maximum.

After eating the bread I waited at least an hour before eating anything else or brushing my teeth in order to to eliminate interference from other smells.

I did no more than one trial per day. On most days I did a trial.

To find other posts in this series, use the Calorie Learning category.

---

SusanJ (2008-02-27 15:15:13)

Have you considered extracts for another set of flavors? You would be amazed at the number of different extract flavors they sell at cake-decorating stores.

seth (2008-02-27 21:45:54)

I do have about 20 flavor extracts. Good point, maybe I should consider using them in some experiments like this.

### **How Many Calories are in Your Blood? (2008-02-28 20:28)**

Any idea? Here is a [1]helpful comment by SixtiesLibber on the SLD forums:

When you get your fasting blood sugar tested, it's supposed to be below 100. And it should almost never go above 200. Well, I finally checked and found what those numbers mean, that's 100 milligrams per deciliter. That's kind of a weird measurement but it's actually the same as 1000 milligrams per liter or 1 gram per liter. In other words, normally your blood has only 1 gram of glucose (sugar) per liter. (A liter is almost the same as a quart.) Adults have something like 5 quarts of blood in their bodies. So at any one time you only have about 5 grams of glucose circulating in your blood. That's the equivalent of about 1 teaspoon of sugar or one-third of a piece of "squishy white bread."

Answer: Not many.

---

Charles Richardson (2008-02-28 22:37:28)

So a 24-ounce Starbucks Caramel Frappuccino Blended Coffee with whipped cream (530 calories, 17 grams of fat, 71 grams of sugar) shouldn't really affect that too dramatically, right? Right?

Andrew S. (2008-02-29 01:44:40)

Though there's also some fat in the blood, being shuttled to and from adipose tissue, right? (I seem to remember once when I gave platelets, they showed me the fat that had been skimmed out of my blood along with the platelets.) And, of course, there's lots of protein in the red blood cells themselves—but I assume we aren't counting that, because we're just considering how much fuel is being carried by the bloodstream, not the energy locked up in the blood itself (which isn't really available, unless you're starving).

seth (2008-02-29 09:14:30)

Good point. I wonder how many calories of fat.

Dennis Mangan (2008-02-29 10:24:10)

At a triglyceride level of 150 mg/dl, that comes to 1.5 g/l, times 5 l, equals 7.5 g. At 9 Kcal/g, a grand total of 67.5 Kcal of fat in your blood. Cholesterol at 200 mg/dl would more than double that.

Stephen M (Ethesis) (2008-02-29 11:59:15)

Gee, only five grams of sugar, compared to 71 grams of sugar in a standard extra large drink. No wonder low carb diets, as long as they are ultra low carb, don't seem to have effects. I'm trying one now. I realized that when I couldn't tolerate Atkins I was cutting carbs to a gram or so a day and cutting calories to those in 60 grams of protein. On a more Taubes like limitation, it isn't so bad at all. It is kind of fun to experiment. SLD makes that possible. BTW, kind of interesting: <http://www.nytimes.com/2008/02/26/science/26tier.html?em&ex=1204434000&en=2ed3c327ef3d4df4&ei=5087%0A>

anon (2009-11-17 17:22:31)

That's the amount of sugar (glucose) in the **serum** not the whole blood. If you counted the intracellular glucose, we'd be talking totally different numbers (but not exponentially more). I promise your W/RBCs have to have glucose IN the cell to do all the work they need to do, but w/o looking it up I don't know how what that quantity would be. More food, er, sugar, for thought. ;)

LW (2010-03-17 19:31:23)

I was told by the Inland Northwest Blood Center than one pint of blood is equal to 3000 calories being taken from you.

AnotherAnon (2010-04-07 14:59:03)

That's most likley how many calories it takes for your body to replace that pint, i.e. manufacturing new blood cells, producing plasma, etc. Probably not the healthiest way to burn calories though...

David\_notMD (2010-09-09 18:47:56)

Seth - I've written up a show-the-math answer for eHow that has been accepted but not yet posted. Once it is up a search on "calories human blood" will find it. You contributors are on the right track by adding up components. Calculating for a unit of donated blood (500 ml), it would contain between 400 and 500 calories (men average higher than women). It's mostly protein in the red blood cells and plasma, smaller amounts for contributions from white blood cells and platelets.

Boot Camp Calgary (2011-03-23 13:14:24)

I definitely have to give you a lot of credit for this post. I am writing an article on what to eat before a workout and trying to figure out how long it takes to deplete your blood sugar. I was surprised to learn that blood lipid levels are also important to consider in this equation. I know with cardiovascular training the primary source burned is fat and for muscular endurance it is carbohydrates. I suppose if you are going to do a boot camp style of workout with cardio and resistance training it is best to eat something with complex carbs and perhaps a small amount of fat. I have talked to triathletes who actually concern themselves with eating enough fat the day of the event. Beyond that I have never heard of anyone concern themselves with eating enough fat.

### **The Fate of Laura (2008-02-29 23:31)**

[1]This sounds promising. I have read more words written by Vladimir Nabokov than by anyone else, by a large margin. A few days ago I was watching American Idol and thinking about how I have come to enjoy singing more because of the judges' evaluations. It reminded me of reading Nabokov's commentary to Eugene Onegin when I was in college. In his commentary, Nabokov passed judgment on many lines of poetry – "this is beautiful," "that is awful." Studying those remarks – what did he see? – made me read in a new way forever.

## **3.3 March**

### **Why Are Games Powerful? (Part 1) (2008-03-01 08:15)**

Drug addiction, sure. The first pleasurable drugs were probably discovered hundreds of thousands of years ago, if not much earlier. All cultures use drugs. Drugs physically reach the brain. But video game addiction? Video games are a millisecond old, compared to drugs. How did they get so potent so fast?

Self-experimentation made me ask. Using an ordinary psychological test and a speeded arithmetic task, I [1]discovered a fast-acting effect of flaxseed oil. About two hours after ingestion of 4 tablespoons, my brain worked detectably better. The effect wore off over several hours. To properly study this effect, and exploit it to learn more about what fats we should eat (which has been very hard to figure out), I would have to test myself many times per day for many days. Thousands of tests. It would be a lot easier if the tests were fast, portable, and fun – especially fun. Many computer games have these traits. But they don't provide the data I need, which is a measure of how well my brain is working, and they take too long.

After talking with [2]Greg Niemeyer, I came up with four properties, shared by many games, that might be why they are fun: 1. Right difficulty level. Neither too easy nor too hard. This is a variable emphasized by Mihaly Csikszentmihalyi in [3]Flow. 2. Feedback. You learn how well you are doing. 3. Variety. Not the same thing over and over. 4. Color. I constructed a task with all four features. To my dismay, it wasn't fun! (So much for the placebo effect.) I had to force myself to do it.

I had no idea what was wrong. Then, [4]as I've written, a friend gave me a bilboquet, which led me to think that there were two principles of fun-making I'd left out: 1. Hand-eye coordination. We enjoy tasks that involve this. 2. Completion. We enjoy tasks where something is cleared up or put neatly together.

I used these ideas to construct a new test. It consisted of moving the cursor around the screen from one colored circle to the next. I move the cursor to a circle and click on it. That circle disappears and a new circle appears somewhere else. It's a bit like shooting one circle after another. Aim, click, aim, click. Each circle is effectively a new trial. The speed at which I moved the cursor to the new circle and click on it is the main measure. There is trial-by-trial feedback: the color of the next circle depends on how quickly I got to the last circle. Here's a screen shot (cursor not shown):

I did this on a Thinkpad. I used the trackpoint to move the cursor. This had the pleasant feature that there was no obvious learning curve – I didn't improve with practice. Presumably because I have years of practice with the trackpoint

Eventually I got around to the big question: Was this test sensitive to the effects of flaxseed oil? I've done two series of measurements to answer this. Here are the results from the first series:

The green line shows when I drank 4 tablespoons of flaxseed oil (without lignans). Here are the results from the second series:

Again, the green line shows when I drank 4 tablespoons of flaxseed oil.

Both times the results resembled my previous results. The flaxseed oil appeared to cause a decrease (= improvement), which reached a maximum around 2 hours after ingestion and declined. The results were far from beautiful but because of the similarity to earlier results ([5]here, [6]here, and [7]here) I found them fairly persuasive. They certainly suggest doing more with this test.

Then I made a different game...

[8]My visit to Greg's class.

---

Stephen M (Ethesis) (2008-03-01 08:57:46)

Have you thought of selling the game? As either a direct release or shareware?

peter (2008-03-01 14:53:58)

are you ever going to conduct tests with fish oil or DHA?

seth (2008-03-01 19:59:38)

No I'm not going to sell the game. It's easy to program. Yes, I will eventually test fish oil and other omega-3 sources. Before I do so, I want to make the flaxseed oil effects as clear as possible.

Seth's blog » Blog Archive » Why Are Games Powerful? (Part 2) (2008-03-01 20:43:29)

Seth's blog » Blog Archive » Why Are Games Powerful? (Part 3) (2008-03-02 09:01:46)

[...] Why Are Games Powerful? (Part 1) [...]

## **Why Are Games Powerful? (Part 2) (2008-03-01 20:43)**

After I saw that flaxseed oil probably affected my circle-game performance, I wondered how to make its effect clearer. One possibility was to change the input device. I was using the trackpoint on my Thinkpad to move the cursor; what about the touchpad? Might be a more natural task. So I played the game several times using the touchpad. I was a lot slower, presumably because in ordinary usage I've used the trackpoint.

I wondered: Could I get better on the touchpad? I made a little game to practice. Here is the initial screen.

You begin by moving the cursor to the green circle. Then with one movement – one fingerstroke – you move the cursor as close as possible to the blue circle. You "toss" it at the blue circle. You click where it ends up. It's a lot like free-throw shooting and darts. You do that again and again; at the moment each test session consists of 35 "tosses".

The outer circle around the blue circle is based on the previous 200 trials; the radius of that circle is the median distance. If I'm improving, I'll be within the outer circle more than half the time.

Here are sample results (from the most recent session).

Here is my learning curve. The y axis is the average distance from where the cursor landed to the middle of the blue circle. The bars show standard errors.

I have collected a lot of data in my life. This particular dataset (data from about 1700 trials) was the easiest. To my great surprise, this exceedingly simple game is great fun! I have to push myself to not do it.

What makes games addictive? This game has 1. Hand-eye coordination. 2. Feedback. 3. Difficulty. It doesn't have 1. Variety. 2. Action.

[1]Part 1. Part 3: Interpreting the results.

Addendum. A poem called "[2]Needle's Eye" in this week's New Yorker ends like this:

what does it matter how big  
a target you are? Someone somewhere  
will invent a game to make you hard to hit.

1. <http://www.blog.sethroberts.net/2008/03/01/why-are-games-powerful-part-1/>
2. [http://www.newyorker.com/fiction/poetry/2008/03/10/080310po\\_poem\\_chiasson](http://www.newyorker.com/fiction/poetry/2008/03/10/080310po_poem_chiasson)

## Why Are Games Powerful? (Part 3) (2008-03-02 09:01)

My observations:

1. The first task I used to measure my mental function at frequent intervals (e.g., every 30 minutes) resembled an typical cognitive psych task. It wasn't fun and I had to push myself to do it.
2. I [1]made another test to do the same thing based on the [2]lessons I drew from bilboquet. It consisted of tracking circles around the screen. It was mildly fun.
3. Trying to improve the second test, I made a [3]third test, which consisted of "tossing" the cursor from one point to another – like throwing darts. In spite of its simplicity, it was/is a lot of fun. Slightly addictive.

[4]My theory of human evolution places great emphasis on hobbies (which at first were varieties of tool making) and job specialization. Hobbies must be fun. So that we will do them – or at least so our Stone Age ancestors would do them – they must provide pleasure. Where does this pleasure come from? The third task suggests a source: We enjoy simple hand-eye tasks with feedback where there is plenty of room for improvement. The Stone-Age hobbyist is trying to get this or that stone or piece of wood to do what he wants. The importance of job specialization – people must be able to enjoy a wide range of jobs, and the first jobs derived from hobbies – implies that the pleasure derived from hobbies must be "free-floating." It cannot be closely tied to any particular hobby; to encourage a wide range of hobbies (= a wide range of tools) it must be generated by a wide range of hobbies. Because it is free-floating, we should be able to generate it from something quite different from a Stone-Age hobby, such as my third test. The Stone-Age hobbies we're talking about, ur-technology, involved making things – which involves hand-eye coordination. The third test was more fun than the first two because it was closer to a Stone-Age hobby.

I don't yet know if the third test is sensitive to flaxseed oil. I have doubts because it seems to involved only a small amount of mental computation per minute of testing. I believe flaxseed oil improves all brain function, but this test may require too much time (e.g., 20 minutes per session) to see the effect clearly. The other tests show the effect and take about 3 minutes per test. One reason balance clearly showed an effect of flaxseed oil is, I think, that it is computationally very intensive. A huge amount of computation goes on at once. A kind of averaging goes on, making systematic differences larger relative to noise.

Stephen M (Ethesis) (2008-03-03 20:05:25)

Seth, Askimet decided I was a spammer for a bit, something on a group blog where I'm one of the admins set it off. Got that fixed, but it ate my comment on your game. I used to program in machine code, a long time ago. Now I'm far away from doing that (since it was back in the early 70s and my last coding was in the late 70s). I'd like to try the game you invented, was

wondering if I could have a copy to try, even if you've decided it isn't difficult enough to be worth releasing. Let me know. Thanks.

### **Self-Experiment on Procrastination (2008-03-02 23:18)**

[1]Nathan Yau, a graduate student in statistics at UCLA, has started a self-experiment about procrastination. He is measuring his procrastination by how much he surfs the web. To reduce it, he is doing two things: 1. Make to-do lists. 2. Block favorite sites. More info [2]here. He's starting today or tomorrow.

1. <http://flowingdata.com/about-nathan/>

2. <http://flowingdata.com/2008/03/03/how-to-stop-procrastinating-so-that-i-am-not-a-bum-a-self-experiment/>

nathan (2008-03-03 20:55:23)

she's kind of creepy-looking with those bloodshot eyes...

Timothy Beneke (2008-03-03 21:04:42)

Pretty powerful image; you might warn people to avoid staring at it at night... Maybe I'll try to spend some morning time with it...

seth (2008-03-03 21:23:53)

yes, the bloodshot eyes are puzzling.

gabe (2008-03-04 04:29:13)

Any reason to believe that it's being on screen has any additional effect? Could a large portrait on the wall be just as effective?

seth (2008-03-04 06:19:47)

When I studied this effect, I found that distance mattered. The best distance was roughly the distance you'd be from someone when having a conversation with them. A large portrait on the wall would not be as effective if the face was larger than usual and you stood further away.

Seth's blog » Blog Archive » The American Time Use Survey: Valuable Info? (2008-03-04 06:58:34)

[...] Pretty Life-Size Face [...]

Nansen (2008-03-04 14:48:24)

Simulation might be another route to get more faces. This work at Stanford looks interesting:  
<http://graphics.stanford.edu/~sifakis/>

Jeff Winkler (2008-03-08 19:15:48)

She definitely falls into the uncanny valley..especially on the smile.

## Internet Addiction (2008-03-03 21:37)

... is likely to become a recognized psychiatric disorder via inclusion in the next edition of the DSM (Diagnostic and Statistical Manual) of the American Psychiatric Association. From [1]an editorial about it:

[There are] at least three subtypes: excessive gaming, sexual preoccupations, and e-mail/text messaging. All of the variants share the following four components: 1) excessive use, often associated with a loss of sense of time or a neglect of basic drives, 2) withdrawal, including feelings of anger, tension, and/or depression when the computer is inaccessible, 3) tolerance, including the need for better computer equipment, more software, or more hours of use, and 4) negative repercussions, including arguments, lying, poor achievement, social isolation, and fatigue. . . Some of the most interesting research on Internet addiction has been published in South Korea. After a series of 10 cardiopulmonary-related deaths in Internet caf  s and a game-related murder, South Korea considers Internet addiction one of its most serious public health issues . . . . The average South Korean high school student spends about 23 hours each week gaming.

Stop reading this!

1. <http://ajp.psychiatryonline.org/cgi/content/full/165/3/306?etoc>

thegayrecluse (2008-03-04 09:01:01)

They should totally add "blogging" to the list, but I haven't yet decided if it's a good addiction or a bad one (?)

dgm (2008-03-04 21:55:10)

This might explain behavior we have noticed in our kid when she is pulled away from either her computer or her nintendo DS after more than an hour-she becomes very agitated, rude, and frighteningly moody. After talking to other parents who have experienced the same thing with their children, we have limited our daughter's time to a maximum 45-60 minute increments only a few times/week. This has helped immensely.

Stephen M (Ethesis) (2008-03-04 12:05:15)

"and who had pretended to love her back." – pretty much captures the writer. That was interesting. The real issue with the Mum Effect is the way it poisons future relationships.

Jeff Winkler (2008-03-08 18:47:01)

On expectations and wine... the same thing happens with expensive wine glasses, Riedel's. They are very expensive and sold in home gatherings. The leader tastes first and comments on the flavor..everyone follows and convinces themselves. <http://www.podbean.com/podcast-detail-episode/77540/kitchen-window-episode-2- june-6-2007>

### **Useless Data and Me (2008-03-04 06:50)**

[1]Odd Numbers, an excellent blog by Jubin Zelveh at Portfolio.com, recently listed a few [2]findings from the American Time Use Survey, which is in danger of being ended. They included:

- First-born children receive 20 to 30 minutes more quality time each day from parents than second-born children.
- Married couples have very little influence over each other when it comes to how much time each spends on leisure, child care, and chores.

A comment was:

Valuable information?

You can't be serious. What can possibly be done by anybody about these "observations"?

This seems like a welfare program for economists.

Time use data – from 13 countries, including America – had a huge effect on my research and I suppose my life, since I applied my research to my life. The time use data I'm referring to showed that Americans were awake an hour later than people in the 12 other countries. They also watched TV an hour later. In other words, America was an outlier in two distributions: time of going to sleep, and time of stopping TV watching. I knew about research that showed that exposure to other people controls when we sleep. The time use data suggested that watching TV can substitute for ordinary human contact in the control of when we sleep. I wondered if seeing faces in the morning would improve my sleep; so I tried watching late-night TV early in the morning (via tape). I did that on a Monday morning. On Tuesday morning, I felt exceptionally good. Thus began [3]the self-experimentation behind [4]my pretty-face post. My best work. (The self-experimentation, not the post.)

### **Gary Taubes' Influence on Me (2008-03-05 07:38)**

Yesterday I had my cholesterol levels measured. My HDL was better than usual – I have ten years of records – and the Total Cholesterol/HDL ratio was good, which is unusual for me. Thinking about what might have caused this, I realized that over the past few months, mainly because of Good Calories Bad Calories, I've shifted toward what I think of as a pre-agricultural diet: plenty of meat and greens, no grains, a little fruit. Long ago I stopped eating packaged food. That was the pre-factory diet – a hundred years ago. Now I've moved back in time two more log units (log unit = factor of 10).

[1]My interview with Taubes.

1. [http://docs.google.com/Doc?id=dhm4f3rg\\_36gg4956dm](http://docs.google.com/Doc?id=dhm4f3rg_36gg4956dm)

---

Pearl (2008-03-05 07:59:01)

That's what I did recently too; belly has been coming off slowly but steadily.

Mel (2008-03-05 20:20:09)

It has been amazing. I started eating the same way since reading Taubes' book in October. I've lost 5 pounds a month, my waist is smaller by at least 2 inches and my blood pressure is averaging 115/68 from 140's/90's. I feel so much better. I started with tasteless EVOO but couldn't tolerate it, so I went with crazy spicing, which I still do. But not much changed about my appetite until I dropped nearly all carbs. I'm especially successful the more fat of any kind that I'm able to work into each meal. Mel

Dennis Mangan (2008-03-05 21:07:10)

The recent news of a study which showed that evolution is proceeding at a rate up to 100 times faster than previously thought, and in any case much faster than several thousand years ago, makes theories about a "paleo diet" into so many "just-so" stories. We might be able to speculate on what the diet was like in paleo times, but that doesn't equate to healthy. We've evolved a lot in 10 thousand years.

Dennis Mangan (2008-03-05 21:08:52)

Also Seth, since you're on record as asserting that cholesterol levels don't correlate with heart disease, why do you have them measured?

seth (2008-03-05 22:28:06)

I have them measured because I might learn something. My position is not what you say; a more correct statement of what I think is that Malcolm Kendrick makes good points. My total cholesterol was 215, above the supposed cutoff of 200. You are correct that I think the cutoff is wrong; I think it should be higher and that 215 is perfectly okay. If my cholesterol were 300 or 400, however, I'd be concerned. As for the speed of evolution, there's a world of difference between (a) assuming a paleo diet (or whatever) is best and (b) taking that as a possibility to be tested. I'm doing (b).

Aaron Blaisdell (2008-03-06 08:44:13)

Gary Taubes explains how it is not total cholesterol that should be measured, or even just HDL and LDL, but importantly also VLDL. He gives compelling reasons why VLDL likely plays a key role in coronary heart disease. Gary also writes that the triglyceride profile is more important than overall cholesterol, since the lipoproteins are just cargo holders for triglycerides.

seth (2008-03-06 11:42:07)

Thanks, Aaron. Good point.

Sara R (2008-03-06 17:50:57)

There is also a difference between a paleo diet and just not eating the processed junk-food, processed carbohydrate diet. I stopped eating refined carbs and limited my grain and fruit intake overall in September 2007 (before reading Taubes' book) and I've lost over 17 % body fat during that time. I also stopped being anemic and my LDL:HDL ratio improved, my triglycerides went down to normal ranges and my CRP (cardiac disease risk factor) also went down.

Willy (2008-03-07 06:48:22)

Seth, the problem with fruits is sugar?. Too bad, I like fruits too much.

seth (2008-03-07 07:58:16)

the problem with fruit is too much quickly digested sugar.

Willy (2008-03-07 12:14:00)

Thanks, yes, i should have mentioned GI. unfortunately fruits with low GI are expensive, like berries. If anyone can give tips on how to incorporate more vegetables I'd appreciate it. e.g. vegetables that do not need cooking or are easy to prepare. Recently I tried spinach salad and liked it, before I eat it cooked.

Stephen M (Ethesis) (2008-03-08 15:48:37)

Spinach salad, spring mix, broccoli are all foods you can eat raw. Carrots too.

Thomas M Seay (2008-03-19 13:07:25)

Cruciferous vegetables like broccoli, cabbage, cauliflower, etc. should always be cooked. It's the one vegetable that I know of that is actually healthier when cooked: <http://www.westonaprice.org/basicnutrition/crucifers.html>

cartes (2008-07-02 09:41:09)

According to non-mainstream but plausible French researchers (Zermati/Apfeldorfer), you can only lose weight if you are above your set point. Your set point is the weight you are genetically programmed for. It's the weight at which, if you eat exactly in accordance with your hunger sensations (i.e. your energy output equals your caloric input), you remain stable. From there, it doesn't matter what type of calories you eat: fat, carbs... it's all the same. A weight loss treatment according to this principle means you must rediscover your hunger sensations, and stop eating when no longer hungry. Then your body will automatically go back to its set point. The problems: (1) if you are below your genetically determined set point, you will put on

weight, not lose it. (2) your set point is not necessarily stable during your lifetime and can go up, due in particular to overeating for a certain length of time. (3) you can never maintain your weight below your set point, except at the cost of life-long (and increasing) restrictions. Finally: why does the set point go higher if you overeat for a long time? Because your fat cells, instead of just getting "fatter" with all the lipids they are absorbing, start to multiply. This is symptomised by feeling hungry when you shouldn't be. If you mostly eat without feeling hungry, you are probably above your set point: and therefore can hope to lose weight until you reach your SP by reacquainting with your body sensations. To me, this makes sense.

### Calorie Learning: First Results (2008-03-05 14:23)

I made random flavors by mixing 4 randomly-chosen spice mixtures into butter. I spread the butter on 2 pieces of Wonder Bread. I used each mixture more than once – twice in a row (1st mixture), three times in a row (2nd mixture), four times in a row (3rd mixture). Each trial consisted of a flavor-calorie pairing – flavor from the spices, calories from the bread. Each trial also provided a rating, which measured the learning.

Here are the ratings of how good the bread tasted.

This was good. 1. The ratings started near 50 (neutral) each time. I'd like to have a large supply of flavors so that I can start fresh each time. These results suggest that randomly mixing 4 spice mixes provides this. The 4 spice mixes were randomly chosen from 10 spice mixes – so there are a lot of possible combinations. 2. The learning per trial was

substantial.

More in the category Calorie Learning.

LemmusLemmus (2008-03-05 17:53:17)

Just in case nobody's pointed it out yet, I think that in this experiment there is a very, very big danger of results being marred by the placebo effect. Yes, I know you're a bit of a skeptic in this respect. But you wouldn't dispute it exists, would you? That's not to say the experiment isn't interesting; it certainly is and I'm going to follow it.

seth (2008-03-05 18:49:18)

"very very big danger" – on what do you base this belief?

LemmusLemmus (2008-03-06 13:44:35)

a) on the general knowledge of the placebo effect b) on the knowledge that you know which results you want to find Granted, "danger" may be too strong a word. Nobody's going to get hurt.

LemmusLemmus (2008-03-06 14:10:30)

I forgot: c) on the knowledge that liking a food is subjective - there is no objective measure, so you'll have to rate, and in this respect b) comes into play.

Matt Goff (2008-03-08 13:11:44)

I've noticed what I suspect is the same effect with the flavored Wheat Thins. When I eat Parmesan Basil or the Tomato Basil crackers for the first time after a long break, I don't care for the taste (though I don't find it horrible). Usually I eat a few more anyway because they're convenient, and I find they seem to taste much better. Before long, I have a hard time not eating them because they taste so good. This experience has been consistent every time I've eaten them (which isn't very often), and before reading about Calorie Learning, I didn't have a good theory for why it worked that way. One thing I wonder about is whether it would be possible to use this idea to develop tastes for foods that I feel like it would be worth liking. I'm thinking in particular of locally produced foods that would be good to eat for a variety of reasons, but I'm not so thrilled with the taste. Also, given that the Wheat Thin flavor seems to reset after some period of time, I wonder if it's even possible to make the Calorie Learning-based perception of good flavor permanent (by which I mean the perception that they taste good remains even if there is a significant gap between times of consumption or the fast calories disappear, but the flavored (s)low calorie food remains).

## **Yay, EW Popwatch! (2008-03-05 23:36)**

A recent [1]EW Popwatch post compared several YouTube versions of Leonard Cohen's Hallelujah, much like I did [2]here. It's like Leno and Letterman [3]telling the same joke. We have an Instinct of Connoisseurship, Veblen would say.

### Is LDL Bad Cholesterol? (2008-03-06 11:33)

You've heard a million times that there is "good" cholesterol (HDL) and "bad" cholesterol (LDL). Recently I got my cholesterol measured. My LDL was 151 mg/dl. The test results were written on a form that said your LDL should be "Below 100 mg/dl. Below 70 mg/dl if High Risk." The person who handed the results to me said, "These are not the best results . . . "

How concerned should I be? [1]A 2005 study in the Journal of the American Geriatric Society surveyed several thousand "elderly people [who] were recruited from a general Italian population, and mortality was monitored from 1983 to 1995." The emphasis of the study was on whether LDL was good or bad.

People with more LDL lived longer. You read that correctly. For women, mortality was lowest at the highest level of LDL. For men, mortality was higher at the highest level of LDL (60 deaths/1000 patient years) than at the next highest (50), but still lower than at the lowest level of HDL (90). Going from the lowest to the highest levels of LDL is associated with a one-third decrease in mortality, in other words.

What should I make of my 151 mg/dl? To convert to the units of the paper (mmol/L), I needed [2]to divide by 39.  $151/39 = 3.9$ . Looking at the graph relating mortality to LDL, an LDL concentration of 3.9 mmol/L is where the mortality vs LDL function reaches a minimum – the lowest mortality. According to this study, my LDL is optimal.

Thanks to Joel Kauffman.

Tom (2008-03-06 13:24:13)

Seth, there are many kinds of LDL, and the LDL level handed to you was almost certainly *not* measured (as that's expensive), but rather inferred from other results and then calculated (which is very inaccurate.) So you really have no idea what your LDL is, and you certainly don't know your LDL particle size (which is crucial.) Here are some posts that explain things: [http://heartscanblog.blogspot.com/search/label/LDL %20cholesterol](http://heartscanblog.blogspot.com/search/label/LDL%20cholesterol)

David Marcus (2008-03-06 14:52:34)

It's optimal if you are "elderly." It's well known that "bad" cholesterol is a significant predictor of cardiovascular disease and mortality in middle aged men.

peter (2008-03-06 14:57:30)

also, there's different kinds of LDL, i.e., very lower density, which, as i recall, are the most dangerous. my guess is that if an elderly person survives with hi ldl, it's probably not vldl and probably there is some genetic reason the elderly person can deal with hi ldl, whereas many in middle age cannot. Your seeming conclusion is (with all due respect) unscientific and dangerous.

Aaron Blaisdell (2008-03-06 15:54:47)

These discrepancies and caveats underscore the need to look at LOTS of studies – epidemiological, human experimental, lab animal experimental – and in multiple categories – old, middle, and young aged; various ethnicities and both genders; and with various risk and environmental factors – in order to build a strong framework from which to derive testable hypotheses. This, I thought was one of the strengths of Gary Taubes book "Good calories, bad calories".

Varangy (2008-03-06 17:07:54)

*It's well known that bad cholesterol is a significant predictor of cardiovascular disease and mortality in middle aged men.* @David Marcus It may be 'well known', rather, many believe it as such — but that certainly doesn't prove that 'bad' cholesterol is any sort of predictor. Taubes and many others such as Eades and Kendrick have done some serious damage to the validity of the lipid hypothesis and its attendant correlaries and ostensible implications. LDL levels may be a marker, but we really don't know for what. We don't don't know if there is any optimal level of any sort of cholesterol. Kendrick thinks it may be for stress. See *The Cholesterol Con* and his take on the lipid hypothesis. The low-fat and low-cholesterol myths-sum-informational cascades we have been drenched by prove absolutely nothing. The more and more research I do, the more and more I think those who have promoted the aforementioned have gotten it wrong. What is 'The Unifying Answer' to cholesterol and diet and health? I dunno, but I think we are all better off admitting our ignorance than being swept away by these misinformational cascades.... BTW that is exactly why Taubes' book is such a great one.

Sara R (2008-03-06 17:34:27)

Triglycerides are a more telling marker of heart disease risk. LDL levels on their own don't mean as much as the LDL:HDL ratio. I work in a medical lab. Also the size of the LDL molecule is telling as well. VLDL or very dense molecules are stickier and are more likely to clog artery walls. They are associated with greater consumption of carbohydrates.

Varangy (2008-03-06 23:57:48)

@Seth Here is a pretty good summation of some of the myths of LDL, HDL etc etc <http://www.marksdailyapple.com/cholesterol/> For your next self-experiment, you might want to look at the relationship between inflammation and flax seed oil.

seth (2008-03-07 05:41:30)

Varangy, that's a good idea – about studying inflammation as a function of flaxseed oil. Any suggestions how to measure inflammation? I was thinking of measuring the redness of my gums, but that isn't easy. Hard to quantify.

SusanJ (2008-03-07 12:13:14)

I believe you can get tests that will give a breakdown of your LDL particle size. As others have already written, this is much more useful information than is the total.

Varangy (2008-03-07 12:32:59)

Yep. I was just thinking that. Dunno if you saw this post over at Art de Vany's blog on evolutionary fitness — <http://www.arthurdevany.com/?p=961> but the guy in the pictures, himself, references the inflammation in his face in the 'before' photo. Quite dramatic difference a year makes. Two questions: 1) Is it really 'inflammation' not just excess body, in this case, facial fat? 2) If it is inflammation, what is an objective definition, and moreover, what is an objective measurement? Here Mark Sisson talks about inflammation and reducing it, without really defining it. In the cholesterol post two comments above he had referred to biomarkers for inflammation without naming them. <http://www.marksdailyapple.com/naturally-reduce-inflammation/>

Chris (2008-03-07 16:37:59)

I've been tracking the severity of my psoriasis using a cellphone camera. I take snapshots of left hand, open them in ImageReady (but any reasonable graphics program will do), take a colour sample of an affected area and copy the red-blue-green values into a spreadsheet. The most obvious variation is in the level of redness, which I expect has to do with underlying inflammation. I've posted some October/November results [1]here. The results are false-colour: the red really is reddish; the brown is my

slightly swarthy caucasian skin tone. Displays best in Firefox.

1. [http://www.islandnet.com/~catchword/family/medical/psoriasis\\_2.html](http://www.islandnet.com/~catchword/family/medical/psoriasis_2.html)

Tom (2008-03-07 17:03:41)

Seth, you might see if there is a medical researcher at Berkeley or UCSF who is willing to run regular tests on your C-Reactive Protein...might be a good proxy for systemic inflammation. (Or they might be able to identify a better proxy.) Would make an interesting research paper.

Tom (2008-03-07 17:04:35)

Possibly a rheumatologist?

seth (2008-03-08 06:35:26)

Chris, that's an intriguing idea, using the red-green-blue values of a photo as a way of measuring redness. Your psoriasis data is very impressive. Have you reached any conclusions from it? Tom, there is no medical school at Berkeley; UCSF is an hour away. I want to make daily measurements for months. That would be too much travel.

Chris (2008-03-10 10:56:16)

Yes, my aim is to see how different factors affect my psoriasis. I've come to some provisional conclusions: (1) less redness in the morning, more in the evening; (2) less redness immediately after an acupuncture treatment; (3) strong redness after certain foods - red wine, aged cheeses, shellfish, for example. I'm continuing to experiment.

### **Science in Action: Omega-3 (motor-learning surprise) (2008-03-08 10:30)**

The more I played racquetball, the more accurate my shots became – the more control I had. It was a kind of learning: learning to place the ball. I was fascinated by how little we knew about how that learning took place. I studied associative learning in my own research. The motor learning during racquetball resembled associative learning in the sense that my actions (hitting the ball with the racket) were shaped by what happened next (accuracy of placement). Yet I knew nothing non-obvious about motor learning.

This background of ignorance is why I find my latest flaxseed oil results so interesting. [1]As I've posted, I've started using a new test in which I use the touchpad to "toss" the cursor from one spot to another (that is, move the cursor with a single finger movement), and measure how close it "lands" to the target. The function relating cursor position to finger position on the touchpad isn't simple.

Of course I wanted to see how flaxseed oil affected performance on this task. I doubted that it would. This task is untimed. No time pressure. It is like shooting free throws. Most of the previous tasks I've used that have shown a flaxseed-oil effect have been tasks where you respond as fast as possible. My balance test was go at your own pace, but it involved a huge amount of computation. Balancing my body on one foot for several seconds seemed to involve a lot more computation than moving a finger about an inch.

Usually I take 4 tablespoons of flaxseed oil just before bedtime. One recent day I took it much earlier and did the toss test at 30-minute intervals before and for several hours afterward.

Here are the results plotted as a function of test session number.

Here are the same results plotted versus the time of the test:

Here is a close-up of the crucial data:

About two hours after I drank the flaxseed oil, my accuracy got worse. Then it slowly got much better. The amazing thing about the improvement is that it reached a maximum long after you would think that the effects of the flaxseed oil had worn off. My overall level of omega-3 is high because I take 4 T flaxseed oil per day. The effect of shifting when I drink the 4 T is just to change the timing of a short-lived peak. Usually that peak happens when I'm asleep and my omega-3 levels are reasonably constant while I'm doing the test. In this case the peak happened while I was doing the test.

I'll discuss what this might mean in a later post.

1. <http://www.blog.sethroberts.net/2008/03/01/why-are-games-powerful-part-2/>

---

Phillip J. Eby (2008-03-09 15:04:16)

Have you ever compared what type of omega-3's work best? I mean, the whole ALA vs. DHA vs. EPA thing. I've heard that what people really need is DHA and EPA, and that not everybody can convert ALA to those other forms in their bodies. Personally, my gums have been staying pretty healthy after I switched from taking an ounce of flaxseed oil to taking a few "Fisol" capsules that had about the same amount of DHA and EPA as the ounce of flaxseed oil. And it's a lot easier to take the capsules. I'm curious, though, what findings you might have.

seth (2008-03-09 21:27:04)

I once took some fish oil and got a headache. Flaxseed oil has never given me a headache. In any case, I'm still working out the phenomenology of flaxseed oil. Later I'll try different oils, including fish oil.

Ben Hyde (2008-03-10 06:13:28)

No doubt you've seen this, but if not is hip-slapping-amusing. "... supply of long-chain polyunsaturated fatty acids that are essential for neurodevelopment. Thus, waist-hip ratio (WHR), a useful proxy for the ratio of upper-body fat to lower-body fat, should predict cognitive ability in women and their offspring. Moreover, because teenage mothers and their children compete for these resources, their cognitive development should be compromised, but less so for mothers with lower WHRs. ..." - [http://www.ehbonline.org/article/S1090-5138\(07\)00073-6/abstract](http://www.ehbonline.org/article/S1090-5138(07)00073-6/abstract) soukous

Seth's blog » Blog Archive » Science in Action: Omega-3 (motor-learning surprise, continued) (2008-03-10 06:28:03)

[...] Science in Action: Omega-3 (motor-learning surprise) [...]

Igor Carron (2008-03-11 06:31:53)

Seth: I am not sure I am reading your x-axis right, but isn't there a "correlation" between taking omega-3 + sleep and improvement? It reminds me of this entry in my blog: <http://nuit-blanche.blogspot.com/2005/01/we-sleep-because-we-want-to-assimilate.html> which talks about experiments performed by Daniel Wolpert on sensorimotor learning that seem to parallel bayesian statistics (the last Paragraph). The sleep issue appears in small print in the nature paper (study done over two days) <http://www.hera.ucl.ac.uk/sml/publications/papers/KorWol04.pdf> But I think I read the more complete report which showed that learning after the first day was not optimal but was better when people had slept on it. Btw, It is interesting that some of his experiments (<http://learning.eng.cam.ac.uk/wolpert/projects/index.html>) look like what you are talking about in your blog (about boredom and games...) The Nature paper is: <http://www.hera.ucl.ac.uk/sml/publications/papers/KorWol04.pdf> Igor.

Jim (2008-03-12 04:18:35)

I read somewhere that the carbon chains in the fatty acids from flaxseed oil are too short and while the body does synthesize the longer chains the process is very inefficient, meaning that flaxseed oil must be taken in huge quantities. On the other hand, fish oil provides long chain fatty acids. I'm veggie, so I'm taking algal omega-3 oil from v-pure.

Seth's blog » Blog Archive » Science in Action: Omega-3 (more motor-learning data) (2008-03-16 08:59:59)

[...] Science in Action: Omega-3 (motor-learning surprise) [...]

Howard Wainer (2008-03-31 17:55:33)

Hi Seth, Vastly enjoyed your presentation today and had a million questions. Three of them are: (i) do you know anything about side effects of flaxseed oil? (ii) interactions of flaxseed oil with other supplements? Other drugs? (iii) which other oils offer the same amount of Omega-3? Grapeseed oil? fish oils? (iv) you said that it was cheaper to buy in liquid form. Where (if there is no Whole Foods nearby)? Best, H

seth (2008-04-01 08:51:25)

1. The only important possibly negative side effect of flaxseed oil seems to be a lengthening of clotting times. Fish oil has the same effect. 2. An average doctor would say that flaxseed oil "interacts" with medication designed to reduce clotting times. 3. No other readily-available oils offer the same amount of short-chain omega-3. Fish oil has lots of long-chain omega-3. 4. The Spectrum Organic website has a way to locate stores that sell their stuff. Barlean's is another widely available brand. Trader Joe's has an inferior version (with lignans, which are a useless complication).

Nathansmommy1973 (2008-10-14 20:24:05)

It seems flaxseed oil is becoming more and more popular. I myself have not tried it however I have taken Omega 3 supplements, specifically the one from Neurovi.com, for a while because of the effects I've read about it improving brain function. I also took it when I was pregnant and had no problems at all. One thing I do see in article after article is the importance of the DHA to EPA

ratio when taking these supplements. The one I'm taking now seems to meet those standards ideally so I am happy. Thanks for your very interesting article!!

### Science in Action: Omega-3 (motor-learning surprise, continued) (2008-03-10 06:24)

The results I described in [1]the previous post surprised me because (a) my performance suddenly got better after being stable for many tests and (b) after the improvement, further practice appeared to make my performance worse. I'd never before seen either result in a motor learning situation. If you can think of an explanation of the result that practice makes performance worse, and animal learning isn't your research area, please let me know.

Learning researchers used to think of associative learning as a kind of stamping-in process. The more you experience A and B together, the stronger the association between them. Simple as that. In the 1960s, however, several results called this idea into question. Situations that should have caused learning did not. The feature that united the various results was that in each case, learning didn't happen when the animal already expected the second event. If A and B occur together, and you already expect B, there is no learning. Theories that explained these findings – [2]the Rescorla-Wagner model is the best known, but [3]the Pearce-Hall model is the one that appears to be correct – took the discrepancy between expected and observed – an event's "surprise factor" – rather than simply the event itself, to be what causes learning. We are constantly trying to predict the future; only when we fail do we learn.

In my motor-learning task, imagine that the brain "expects" a certain accuracy. When actual accuracy is less, performance improves. Performance stops improving when actual accuracy equals expected accuracy. The effect of more omega-3 in the blood, and therefore the brain, was to increase expected accuracy. (One of the main things the brain does is learn. If we do something that improves brain performance in other ways, it is plausible that it will also improve learning ability.) Thus the sudden improvement. The decrement in accuracy with further practice came about because, when the omega-3 concentration went down, actual accuracy was better than expected accuracy. Accuracy was "over-predicted," a learning theorist might say. So the observed change in performance was in the opposite-from-usual direction. Accuracy got worse, not better.

[4]Related happiness research. "Christensen's study was called "Why Danes Are Smug," and essentially his answer was it's because they're so glum and get happy when things turn out not quite as badly as they expected."

---

LemmusLemmus (2008-03-10 10:18:37)

"If you can think of an explanation of the result that practice makes performance worse, and animal learning isn't your research area, please let me know." Wild guess: Repetition makes the task more boring, which reduces concentration.

seth (2008-03-10 12:53:55)

Thanks, LemmusLemmus. The repetition rate wasn't unusual when accuracy started getting worse.

LemmusLemmus (2008-03-10 15:55:18)

Seth, yes, but even with a constant repetition rate, couldn't the task get more boring? If I see film XYZ once a week, it's going to get more boring (on average) every time I see it.

LemmusLemmus (2008-03-10 16:09:14)

To add to my first post, it may reduce not only concentration, but also motivation. To add to my second post, I think there may be threshold effects. Both is nothing more than personal experience, but to illustrate, a few years ago, I got into playing a popular computer game (basically, a move-cursor-and-shoot game). Once I was pretty good at it, I lost interest. The same happened with a pinball machine earlier. I broke the record on one and then couldn't be bothered anymore both about that particular machine and others of the same type.

seth (2008-03-11 08:24:04)

I'm sure the accuracy reduction over time wasn't due to boredom. It started just after I'd observed one of the most fascinating-to-me results in all my self-experimentation.

ronburk (2008-03-11 19:56:04)

Performance gets better after period of stability. Isn't that a standard feature of learning, as the learnt stuff gets shuffled into neurons in a more permanent part of the brain (e.g., research on stroke victims who thought they reached limits of improvement possible with therapy, but found more improvements when therapy was kept up for longer periods). Further practice makes performance worse. Well, Tim Gallwey (Inner Tennis) kinda built a career on that, didn't he? Once you've learned the basic task, focus from the wrong part of the brain can interfere with performance, eh? Also, if you haven't already, you probably really need to control for aspirin use with these tests, due to aspirin's ability to combine with docosanoids to form potent, inflammation-terminating resolvins and protectins. But I just learn this stuff from Oprah, so it might be wrong. :-)

## **Eight Ways of Looking at Self-Experimentation (2008-03-10 22:57)**

[1]Scientific American Online has started a eight-part series about self-experimentation. Part 2 is about Morgan Spurlock of Supersize Me.

1. <http://www.sciam.com/article.cfm?id=self-experimenters&sc=rss>

---

Tom (2008-03-11 09:42:41)

I'm surprised that Scientific American is not reporting on the fact that no one has been able to replicate Spurlock's results, and the fact that he refuses to release his food logs or comment on the controversy.

Tom (2008-03-11 10:40:05)

Maybe that was part of Spurlock's experiment. 8-)

Varangy (2008-03-11 12:31:38)

I agree with Tom. There was a comedian, Tom Naughton, who undertook a similar 'Spurlockian' experiment in 'Fat Head', and his health markers, I believe, improved. He repeatedly called Spurlock's representatives for his food diary and was studiously ignored. While very trendy and seductive to the anti-McDonaldists, Spurlock is a really bad example and I don't think it behooves someone like Seth to be compared to him. Forgive my language, but Spurlock is an attention-whore and

tireless self-promoter, not a real or even amateur scientist. See this video for Tom Naughton's analysis of Spurlock's numbers that don't add up. <http://www.youtube.com/watch?v=Ccdfzq2M1Ec> &url=<http://www.fathead-movie.com/> More here: <http://www.fathead-movie.com/>

Varangy (2008-03-11 15:51:39)

@Seth BTW if you or your publisher would implement comment subscriptions for each of your posts – that would be a great way to further encourage the, generally, very stimulating commentary on this great blog. Having to check back every day is a bit tiresome.

LemmusLemmus (2008-03-12 01:19:39)

It's a bit weird the post on Spurlock makes much of his weight gain. In the film (which is very entertaining), two facts are clearly stated: 1) To maintain his weight, he should have consumed about 2500 calories a day. 2) He consumed about 5000 calories a day. Big surprise: He gained weight. I would think the same would have happened if he would have consumed 5000 calories/day in apples.

seth (2008-03-12 06:23:48)

I think the main point of the film was not the weight gain – which as you say seemed very likely – but the other bad health effects. What Spurlock did was a little like feeding rats large amounts of saccharine – larger than anyone would ever ingest – as a way of finding out quickly what the effects of smaller and more realistic amounts would be. He ate a large amount of fast food to find out what the effects of small amounts of fast food are.

LemmusLemmus (2008-03-12 09:39:06)

"He ate a large amount of fast food to find out what the effects of small amounts of fast food are." I'm not sure. In an interview one finds on the German DVD edition of the film, he is asked whether his experiment has any value given that nobody eats like that. He makes a big point of arguing that, no, he doesn't know anyone who eats at McDonald's every day, but he does know people who eat at McDonald's in the morning, KFC at noon and Pizza Hut in the evening.

Observer (2008-03-14 13:09:14)

"the fact that no one has been able to replicate Spurlock's results" That's probably because Fredrik Nystrom has replicated Spurlock's results. His test group, consisting of 12 male and 6 female students, showed a large individual variation, including one male test person that suffered as badly as Spurlock, and had to be removed from the experiment: <http://www.liu.se/en/news-and-events/startpage?newsitem=16242> "Blood tests of the fast food eaters showed sharp increases in the liver enzyme alanine aminotransferase (ALT). ALT levels more than quadrupled during the 4-week study period and 13 of the 18 subjects developed morbidly high status of ALT in their blood serum. One male had such extreme values after three weeks that he was withdrawn from the experiment and put on a normal diet."

### **If Not Noseclips, Dark Sunglasses? (2008-03-11 22:10)**

In [1]this interesting video about losing weight, Paul McKenna, a British hypnotist, recreates a study in which people ate food blindfolded. In the study, they ate one-quarter less when blindfolded than when not blindfolded. This doesn't impress me; nothing is stopping the blindfolded subjects from eating more at later meals. But it makes me wonder how not seeing your food affects flavor-calorie learning. It might make it stronger (you're less distracted) or it might make weaker (the sight of food acts like glue to strengthen flavor-calorie associations – there is actually evidence for something like this).

While wearing noseclips while eating with others is too weird, wearing dark sunglasses might not be. And what about listening to music (for distraction) while you eat? My calorie learning experiments are continuing; eventually I should be able to test these possibilities.

Thanks to Gary Skaleski.

1. <http://www.youtube.com/watch?v=UQv1JBZ197Q>

---

Ali Choudhury (2008-03-12 04:26:07)

I would think distraction would cause you to consume more, since you're not paying attention to how much you eat.

seth (2008-03-12 06:21:52)

I meant: what would be the effect of distraction on the flavor-calorie learning that takes place at every meal?

SusanJ (2008-03-13 10:00:53)

It's funny this shows up with an ad for the book on "Mindless Eating." My recent experiences with SLD and lo-carb coupled with long experience with eating and various shortterm attempts at dieting have completely convinced me that Taubes is right when he says that hunger is physiological, not psychological. Once you've decided the exact amount you are going to eat or drink - a nose-clipped protein shake, say - and treat it as fuel, you aren't going to consume more or less. I can now break a single potato chip into a dozen or more pieces and savor each little piece if I want to. I think I can do this enjoyably because lo-carbing means my body is no longer associating that taste sensation with a forthcoming sugar rush which it can hardly wait for. And I'm sure that SLD has also helped to break a flavor-calorie association although I think perhaps the important thing is breaking the flavor-sugar rush association. I'm not sure how to test this.

Ali Choudhury (2008-03-14 10:01:41)

D'oh. Looks like I better up my flaxseed dosage.

Jeff (2008-03-14 21:22:40)

It sounds like more distraction = more [1]mindless eating: "Where you are, what you're doing, and who you're with all affect how many calories you're likely to consume. When you're in a restaurant with low lighting, you tend to eat more. You also eat incrementally more as the number of people at the dining table increases, and **you'll eat more if you're watching television or reading the newspaper. According to Wansink, eating in front of the TV can increase your consumption as much as 60 percent, depending on how long you sit there watching.**"

1. <http://www.runnersworld.com/article/printer/1,7124,s6-242-304--11628-0,00.html>

danielle (2009-05-22 13:38:21)

The answer is simple. It takes certain amount of time for the body to feel satisfied and full. When you have blindfolds on, then it takes longer for you to eat. Then when the time comes when you actually feel full, you didn't have as much food as usually. - this isn't news to me. It's re-doing work that has been done already! When you eat with other people, many more things are going on. You look at how others eat and you excuse your own behavior "I guess everyone is eating a lot, then it means I can too". If everyone eats just a little, maybe you'll be a little ashamed to eat twice as much as everyone else. Nose-clips - sure if you wear nose-clips all day long, maybe you won't be teased by the smell of food and maybe you won't think of eating as much. In my personal opinion, that's not the way to do this, because we need to breathe through our nose, we need to filter the air with nose hair, etc. Knowing how to breathe properly through the nose may actually lower people's depression, may improve posture, and may cause them to eat a little less. Noises - I don't think there's much of a relationship, because people eat in clubs where there's a lot of music, and in restaurants where there's a lot of noise. The amount of food you eat depends on how fast you eat, which depends on how hungry you are. Or simply, you eat and eat, even when you are full and even when you sweat. If you do the second one, then you have too many problems to handle alone. Don't get me wrong I wouldn't be surprised if there was a relationship between noise and overeating, but I predict there would be a small effect size. I would

call that doing science for the sake of doing science, not for the sake of helping humanity. There wouldn't be much value in this study. If someone really wants to loose weight, they need to change their relationship with food, they need to make a commitment, and they have to do the work. Shortcuts don't work in the long run, just like 99 % of diets! Determination, eating moderately, diet full of nutrients, exercise and therapy are the only things that really help.

Tom in TX (2009-05-23 20:23:18)

I wonder if the kind of noise would matter, e.g., soothing classical music vs. traffic noise.

### **Twisted Skepticism (2008-03-12 18:31)**

Scientists are fond of placing great value on what they call skepticism: Not taking things on faith. Science versus religion, is the point. In practice this means wondering about the evidence behind this or that statement, rather than believing it because an authority figure said it. A better term for this attitude would be: Value data.

A vast number of scientists have managed to convince themselves that skepticism means, or at least includes, the opposite of value data. They tell themselves that they are being "skeptical" – properly, of course – [1]when they ignore data. They ignore it in all sorts of familiar ways. They claim "correlation does not equal causation" – and act as if the correlation is meaningless. They claim that "the plural of anecdote is not data" – apparently believing that observations not collected as part of a study are worthless. Those are the low-rent expressions of this attitude. The high-rent version is when a high-level commission delegated to decide some question ignores data that does not come from a placebo-controlled double-blind study, or something similar.

These methodological beliefs – that data above a certain threshold of rigor are valuable but data below that threshold are worthless – are based on no evidence; and the complexities and diversity of research imply it is highly unlikely that such a binary weighting is optimal. Human nature is hard to avoid, huh? Organized religions exist because they express certain aspects of human nature, including certain things we want (such as certainty); and scientists, being human, have a hard time not expressing the same desires in other ways. The scientists who condemn and ignore this or that bit of data desire a methodological certainty, a black-and-whiteness, a right-and-wrongness, that doesn't exist.

[2]How to be wrong.

1. <http://www.blog.sethroberts.net/2007/11/19/too-skeptical/>

2. <http://www.blog.sethroberts.net/2008/02/06/how-to-be-wrong/>

---

LemmusLemmus (2008-03-12 19:48:09)

"The scientists (...) desire (...) a black-and-whiteness, a right-and-wrongness, that doesn't exist." Relatedly, it is remarkable that statistical associations are either "significant at conventional levels" or not, when the actual statistic is continuous.

Andrew Gelman (2008-03-12 19:54:35)

Seth, Yes, but think about [1]statistical power. Some studies just don't have enough data to be relevant; they're just noise machines.

1. <http://www.stat.columbia.edu/~gelman/research/unpublished/power.pdf>

NE1 (2008-03-12 21:12:08)

Saying there is no evidence for the beliefs that some studies provide more trustworthy directional implications than others, and that anecdotes can be misleading, is just silly. Scientists seek out the most perfect studies so that they can update their Bayesian predictions most efficiently. All of these "methodological beliefs" come from a simple analysis of random sampling and the logic of science, of data. If you want to get down to brass tacks, start wagering. The people whose income depends on predicting the future know exactly how much to weight evidence towards a correlation or cause. And it's not going to be as much as well-structured studies. We may be quick to seize upon a study's failings because it's often so easy to do it right. A simple calculation. A sentence of instruction to the subject. Once you know how much better it is to randomize faces in a lineup, would you ever congratulate a police department for neglecting this? Lemmus: the  $p = .05$  is there as a courtesy to the reader, no? Not because there is a step-function of a conclusion's relevancy.

seth (2008-03-12 22:37:04)

"Some studies just don't have enough data to be relevant." What's an example? I find it hard to believe there is a threshold for relevance: above the threshold, relevant, below the threshold, not relevant. NE1, I'm not saying there is no point being discriminating. Of course some studies are more meaningful than others. It is the black-and-whiteness of the judgments that is the problem. The way studies that don't meet some arbitrary criterion are ignored. They really are ignored, completely discounted; I'm not making this up. Whether the  $p$ -must-be-.05-or-less convention is helpful or harmful is a hard question, at least for me. It gives scientists who know very little something to shoot for; but it ignores the reality that there is no important difference between  $p = .04$  and  $p = .06$ . It distinguishes things that are the same, in other words. Should bikes be built with permanent training wheels?

michael vassar (2008-03-13 21:19:46)

Seth, the problem is that "the scientific method" is not an epistemology but rather an evolved set of hacks optimized for, among other things, improving the quality of naive human epistemology. All of the forms of pseudo-skepticism you complain about involve rules that deviate from optimal epistemology, but by default humans also deviate from optimal epistemology. These are the best known rules that we have, not for reaching truth, but for indoctrinating into a crowd of people so that those people can do a better job of reaching truth than they would by default.

LemmusLemmus (2008-03-14 02:53:18)

"Lemmus: the  $p = .05$  is there as a courtesy to the reader, no? Not because there is a step-function of a conclusion's relevancy." Oh, in the stuff that I read (I'm a sociologist), it's pretty much treated like a "step-function".  $p = .06$  equals "no association".

Seth's blog » Blog Archive » Twisted Skepticism (continued) (2008-03-14 06:09:54)

[...] Twisted Skepticism [...]

seth (2008-03-14 06:14:52)

Michael, yeah, I agree, a binary function is better than a flat function. That's what I meant by "gives scientists who know very little something to shoot for." A little scientific education is a dangerous thing.

michael vassar (2008-03-14 07:39:36)

It's definitely worse to build bikes with permanent training wheels than to teach people to ride bikes without training wheels, but better than to have a population of bikers who are always falling down. The question is, do we (collectively) know any fairly reliable way to teach people to use the "no training wheels" version of rationality instead of just "faking it" with the "scientific method". If so, do we (personally) know how to get there from here, e.g. how to influence the culture in the relevant manner. Honestly, I think 'no' and 'no', but I think I'm closer to the second bit than to the first.

seth (2008-03-14 11:28:49)

Were I to teach the basics of science, I would tell a bunch of stories chosen to show the value of a wide range of evidence,

experimental, non-experimental, case reports, etc. I would say: we need all types, and explain why. A story-driven approach is a lot different than the current approach (e.g., evidence-based medicine) with its emphasis on rules (do this, do that) and value judgments (this is good, that is bad).

Andrew Gelman (2008-03-14 12:28:27)

Seth, You question my claim, "Some studies just don't have enough data to be relevant" and write, "What's an example?" Follow the link that I put in my comment. It gives an example, in excruciating detail.

seth (2008-03-14 13:24:45)

Andrew, thanks for clarifying that. Your paper argues that the Kanazawa study was too small to have a good chance of finding results with  $p < .05$  given the likely size of the effect. Sure. I don't agree that this means its info is useless. You write: "A study of this size is not fruitful for estimating variation on this scale." That is too strong, I believe. I don't think it's true that nothing can be learned from the Kanazawa data. The Kanazawa data make some ideas more plausible, other ideas less plausible.

Tony (2008-03-14 15:02:39)

Susan Haack was once taking questions after a talk, and was asked "What, essentially, do you think the scientific method is?" Her (prescriptive) response was: "Trying really hard to figure out the truth." The problem I have with this is that many scientific advances are made when scientists almost dogmatically hold onto beliefs in the teeth of contrary evidence. Their perseverance leads to the uncovering of evidence that does support their position ...

Andrew Gelman (2008-03-14 17:05:17)

Seth, There are no "Kanazawa data." Kanazawa analyzed existing public data sources. You could give these data to your psych undergrads too, and if they know SPSS, they might come up with some interesting things too. What made Kanazawa's work break the attention barrier (so that people like you and me have heard of him) was that his findings were surprising. He got surprising findings by making statistical errors. If he'd gathered his own data, I'd respect his work more. The point of my paper is not about p

Andrew Gelman (2008-03-15 15:09:44)

Hi, Seth. The rest of my comment got cut off because I used the "less than" sign, which got interpreted as html. But I think I made the basic point above. It's fine to respect unorthodox research, but, at some point, the work is so crappy that it's the equivalent of reading tea leaves, or throwing darts at a newspaper and using the words to write poetry. It might provoke interesting thoughts, but I don't consider it science. It's more like literature, or philosophical speculation, leavened with statistical errors and irrelevant data.

Darius Bacon (2008-04-06 23:33:47)

I just came across a ref to an article by V.S. Ramachandran titled "Creativity versus skepticism within science: more harm has been done in science by those who make a fetish out of skepticism, aborting ideas before they are born, than by those who gullibly accept untested theories." That reminded me of this discussion - perhaps you'll find it of interest. <http://www.amazon.com/Creativity-versus-skepticism-within-science/dp/B000KIXE RI/>

Gustavo Lacerda (2008-04-07 12:28:14)

Darius, This link seems to have the full article: "Creativity versus skepticism within science: more harm has been done in science by those who make a fetish out of skepticism, aborting ideas before they are born, than by those who gullibly accept untested theories." [http://www.encyclopedia.com/doc/1G1-1542\\_38670.html](http://www.encyclopedia.com/doc/1G1-1542_38670.html)

Mike Brown (2008-04-12 08:05:58)

This may be tangential to your discussion, but have you run across <http://www.institutionalreviewblog.com/> The blogger there is a history teacher at Geo. Mason who has been thwarted by IRB rules intended, of course, to protect human subjects, but misapplied (he feels) to the social sciences. I'm currently going through the online IRB training through CITI and, while I totally

agree that psychological and medical experiments need oversight, is it really necessary if I'm testing a user interface for data entry? For whatever reason, I'm seeing parallels between this series of posts and my recent reading of horror stories related to getting IRB approvals. Another article about the blog is at <http://insidehighered.com/news/2007/01/19/irb>

### Twisted Skepticism (continued) (2008-03-14 06:09)

Writing about [1]advances in obstetrics, Atul Gawande, [2]like me, suggests there is a serious downside to being methodologically "correct":

Ask most research physicians how a profession can advance, and they will talk about the model of "evidence-based medicine" the idea that nothing ought to be introduced into practice unless it has been properly tested and proved effective by research centers, preferably through a double-blind, randomized controlled trial. But, in a 1978 ranking of medical specialties according to their use of hard evidence from randomized clinical trials, obstetrics came in last. Obstetricians did few randomized trials, and when they did they ignored the results. . . . Doctors in other fields have always looked down their masked noses on their obstetrical colleagues. Obstetricians used to have trouble attracting the top medical students to their specialty, and there seemed little science or sophistication to what they did. Yet almost nothing else in medicine has saved lives on the scale that obstetrics has. In obstetrics . . . if a strategy seemed worth trying doctors did not wait for research trials to tell them if it was all right. They just went ahead and tried it, then looked to see if results improved. Obstetrics went about improving the same way Toyota and General Electric did: on the fly, but always paying attention to the results and trying to better them. And it worked.

Is there a biological metaphor for this? A perfectly good method (say, randomized trials) is introduced into the population of medical research methods. Unfortunately for those in poor health, the new method becomes the tool of a dogmatic tendency, which uses it to reduce medical progress.

Aaron Blaisdell (2008-03-14 07:17:57)

But wasn't Gary's book, Good calories, bad calories, a critique of the problem with NOT using rigorous scientific methods and practices to promote nutritional policy?

seth (2008-03-14 08:03:25)

Interesting question. When I interviewed Taubes, he spoke of the importance of skepticism. But since his book was full of data I think by skepticism he meant "value data" (e.g., look at data) rather than "ignore data". I'm not sure, though.

Is there an Engineering approach to medicine? « Entertaining Research (2008-03-15 10:48:04)

[...] Atul Gawande, in a must-read piece in New Yorker, titled The score: how childbirth went industrial; via Seth. [...]

Charles (2008-03-15 12:39:11)

There's a fundamental difference between the way individual people learn and the way public policies are determined. People learn only through self-experimentation, in which a healthy skepticism is necessary. But if there is too much rigidity in that skepticism, novelty is discarded as anecdote, rather than clue. I think we can learn much from a scientific approach, but not necessarily by accepting the conclusions of scientific investigations as gospel, but rather seeing those conclusions as more data points. And the conventions of the scientific method do yield data points that have a unique, though not exclusive value. I think nutritional data are particularly affected by the fact that we are much more biochemically unique than Nutritional Science posits and assumes. So generalizing investigations of nutrition to larger critiques of science in general is dicey. I've been involved in this kind of nutritional self-experimentation for decades, so I've thought a lot about this. Coherence still escapes me, however.

Seth's blog » Blog Archive » Stoplights, Experimental Design, Evidence-Based Medicine, and the Downside of Correctness (2008-03-15 16:01:27)

[...] Twisted Skepticism (continued) [...]

Stephen M (Ethesis) (2008-03-16 14:47:33)

I'd add that trials in Europe determined that there were much better positions for childbirth than the standard one in America – more than thirty years ago. OBs, for the most part, stick with what is most convenient for them. /Sigh

## **Stoplights, Experimental Design, Evidence-Based Medicine, and the Downside of Correctness (2008-03-15 16:01)**

[1]The Freakonomics blog posted a letter from reader Jeffrey Mindich about an interesting traffic experiment in Taiwan. Timers were installed alongside red and green traffic lights:

At 187 intersections which had the timers installed, those that counted down the remaining time on green lights saw a doubling in the number of reported accidents . . . while those that counted down until a red light turned green saw a halving in . . . the number of reported accidents.

Great research! Unexpected results. Simple, easy-to-understand design. Large effects – to change something we care about (such as traffic accidents) by a factor of two in a new way is a great accomplishment. This reveals something important – I don't know what – about what causes accidents. I expect it can be used to reduce accidents in other situations.

It's another example (in addition to [2]obstetrics) of what I was talking about in[3] my twisted skepticism post – the downside of "correctness". There's no control group, no randomization (apparently), yet the results are very convincing (that adding the timers caused the changes in accidents). The [4]evidence-based medicine movement says treatment decisions should be guided by results from controlled randomized trials, nothing less. This evidence would fail their test. Following their rules, you would say: "This is low-quality evidence. Controlled experiment needed." The Taiwan evidence is obviously very useful – it could lead a vast worldwide decrease in traffic accidents – so there must be something wrong with their rules, which would delay or prevent taking this evidence as seriously as it deserves.

1. <http://freakonomics.blogs.nytimes.com/2008/03/14/taiwans-solution-to-traffic-jams/>

---

ronburk (2008-03-15 17:58:02)

I had not heard that someone (anyone?) was claiming that "nothing" should be put into practice without RCTs. The traffic light example seems like a straw man. We routinely \*stop\* RCTs when a large effect is seen. We routinely make bad medical decisions when small effects that are unvetted by RCTs are the goal. Use of EPO to treat chemo-induced anemia was approved, in part, because no large enough negative effect on cancer outcome was noticed. Only RCTs could show that there is indeed good reason to suspect that EPO worsens the outcome for some cancer patients that receive it. Likewise, the effect of HRT on heart disease and cancer risk seemed small but compelling (due to the N of the uncontrolled studies done). Only an RCT was able to show that the heart benefit was overestimated and the cancer risk underestimated. That RCT, of course, did not answer all questions about HRT, but it did answer the "first, do no harm" question. It's hard to forget that one of the first applications of statistics to medical treatments was to inspect the efficacy of "bleeding" patients (i.e., cutting, or leaches). When the results showed that "bleeding" was not at all correlated with outcome, what did the study author do? He concluded that the study must be wrong, and that we must bleed patients earlier and more aggressively. Such is the power of subjective experience and expectation over objective, statistical correctness. Like Feynman said, the first order of business is not to fool ourselves. When medical effects or benefits are small or subjective, it's hard to point to any tool more successful at preventing self-fooling than the RCT. Large, non-subjective effects are obviously less likely to be proved false by an RCT. However, it appears that at this point in history, a large percentage of new medical practice is focussed more in the area of the smaller, more subjective effect – hence there is no shortage of places where RCTs continue to be required to avoid fooling ourselves and hurting patients. If you want to see what medical practice looks like without RCTs, look no further than the snake pit that is back surgery to relieve pain today.

scott (2008-03-15 18:27:51)

I'd also argue that the study in Taiwan very well could have elements of a control group and randomization. There are many more than 187 intersections in Taiwan and one could easily consider deciding which intersections to place the countdown timers on randomly and comparing them to a control group of similar intersections. Great research in that it was a roll-out to test something (timers) that were believed to be helpful and the analysis was done to determine that there were unexpected results, but I think the RCT argument in this case is a bit of a stretch.

NE1 (2008-03-15 18:45:16)

No control group? Where did the baseline from the "doubling in the number" come from? Presumably the control is the long period of time for which data exists and there was no countdown. This assumes that the base rate hasn't changed because drivers are confused as to which type of countdown might be at any particular traffic light. I think this is a neat result, and it would be nice to see the total cost of the study. Especially given the unconvincing data cited for red light cameras, it would be a breath of fresh air to hear motions for wider tests, if the accident rate changes are pretty uniform. I really don't know where you're coming from here. To the extent you and I find the study "convincing", I'm sure it can be traced to intuition leached from proper statistical theory (fairly large N, control data, and no stated bias in randomization). To the extent that it is not iron-clad, I'm sure there are traditional objections.

Aaron Blaisdell (2008-03-15 20:56:57)

NE1 writes "No control group? Where did the baseline from the "doubling in the number" come from? Presumably the control is the long period of time for which data exists and there was no countdown." I agree, and furthermore, though I've never been to Taiwan, I bet they have a hell of a lot more than 187 intersections with traffic lights, so the remaining intersections that didn't receive timers also serve as controls (assuming there is a record of the accident rate at those intersections as well).

seth (2008-03-15 21:49:06)

NE1 & Aaron, yes, the baseline came from earlier measurements of the same intersections. "Like Feynman said, the first order of business is not to fool ourselves." I think this gets to the heart of the matter. I would prefer that medical research concentrate on maximizing the benefits of treatment rather than on minimizing the extent to which doctors fool

themselves. I agree that RCTs are often helpful. It's when non-RCT evidence is ignored or dismissed or not taken seriously that the trouble begins. "I had not heard that someone (anyone?) was claiming that "nothing" should be put into practice without RCTs." A high-level panel making nutrition recommendations ignored non-RCT evidence. For details, see <http://www.blog.sethroberts.net/2007/08/08/something-is-better-than-nothing-part-2/>

LemmusLemmus (2008-03-15 23:28:37)

A broader political point is the question whether the NHS/medicare/whatever it's called in one's country should be expected to pay only for those treatments which have been shown to work by the most rigorous scientific standards. I think it's not hard to make the argument that the answer is "yes". Of course, this is distinct from the question whether scientists should disregard evidence that doesn't live up to those standards.

Stephen M (Ethesis) (2008-03-16 14:39:06)

**He concluded that the study must be wrong, and that we must bleed patients earlier and more aggressively.** Hmm, seems like the studies and the low fat/high carb debate ...

Jeff Winkler (2008-03-17 10:04:43)

[1]Taking back science - "Ideas are tested by experiment. That is the core of science. By teaching people to hold their beliefs up to experiment, Mythbusters is doing mere to drag humanity out of the unscientific darkness than a thousand lessons in rigor."  
- Zombie Fenyman

1. <http://imgs.xkcd.com/comics/unscientific.png>

seth (2008-03-17 11:37:43)

I'm not saying don't test ideas. I'm talking about the nature of the test. Different purposes suggest different types of test. If your goal is maximizing patient benefit, you do Test X; if it is "not fooling yourself" you do Test Y.

Markus (2008-03-19 10:23:48)

If traffic in Taiwan is anything like that of mainland China, then these results don't surprise me at all. People drive a lot differently over there with a great deal less observance of "traffic laws" and consideration of safety. I would guess that it's common to treat a red light more like a stop sign when you don't know how long it'll last. With the timer, knowing that it'll turn green in X seconds, you may be more likely to wait. Similarly, I can imagine that drivers would speed up to get through the intersection on seeing that only 2 seconds of green are left - higher speed -> more accidents.

current grad student (2008-04-02 11:19:57)

Ummm.... is there something wrong with not wanting to fool yourself? I mean, the whole point of experimental design is to guard against fooling yourself into believing that your treatment is responsible for the supposed patient benefit observed.

seth (2008-04-02 14:48:21)

If you have "not fooling myself" as your only goal, you will be too conservative.

current grad student (2008-04-03 23:48:12)

I am actually ok with being labelled conservative if that means I am hesitant to update my beliefs based on a poorly designed experiment or an observational study. I do not deny that such studies have the potential to find interesting, and real, results, but the quality of the data, study design, and analysis, should all affect how and to what extent I update my beliefs. In regards to the traffic study, I am particularly concerned with your statement, "There's no control group, no randomization (apparently), yet the results are very convincing (that adding the timers caused the changes in accidents)." Aside from the fact that you made a causal inference about the result seen, I don't know how you can seemingly care so little about the design of the experiment.... you seem to not know anything about the design, and the scary part is that you don't seem to care! I know of a great way to "reduce" the number of traffic accidents. Place the timers at intersections which had the highest accident rates the previous year. You are almost guaranteed to observe lower accident rates the following year. This is a simple example

of regression to the mean.

seth (2008-04-05 07:19:50)

"You don't seem to care". Please see my posts on experimental design and scientific method – e.g., interviews with Brian Wansink and Saul Sternberg. The broad point I am making is following or advocating rules without understanding them, including their weaknesses, causes trouble. Randomization is good but other schemes may be good enough.

### Science in Action: Omega-3 (more motor-learning data) (2008-03-16 07:08)

Background. I took 4 T of flaxseed oil during the day (instead of just before bedtime) and [1]measured its effect with a cursor test. The test was [2]how accurately I move the cursor from one point to another with a single movement. The result was a sharp improvement – some of which lasted, some of which didn't. (Just to be perfectly clear: what's varied is not my daily amount of flaxseed oil. It's the time of day I take it. I'm varying the time between a short-lived peak in omega-3 concentration, which happens shortly after ingestion, and doing the cursor test. Usually they are far apart. The interesting data are what happens when I move them close together.)

New data. I tried the same thing again. Here are the results.

The green line shows when I took 4 tablespoons of flaxseed oil. I took the oil at 8:30 am. The first test after that, at 9:30 am, showed the improvement. (In previous measurements of the short-term effects, it has taken closer to 2

hours to see the maximum effect.)

Here is a longer view, which emphasizes the constancy of the pre-test baseline.

For comparison, here are the earlier results.

Conclusions. When I take 4 T of flaxseed oil, it creates for a few hours a higher-than-usual concentration of flaxseed oil in my blood. I'm pretty sure the active ingredient is omega-3. This has two effects:

Better performance due to temporary effects. It's hard to give these effects a good name. Better coordination, perhaps.

Better performance due to long-lasting effects. This is why performance was constant at a lower (better) level after the test than before. The higher-than-usual concentration caused a change (more "learning" than usual) that outlasted it. The concentration of flaxseed oil dropped back to average levels but the learning persisted.

1. <http://www.blog.sethroberts.net/2008/03/08/science-in-action-omega-3-motor-learning-surprise/>
2. <http://www.blog.sethroberts.net/2008/03/01/why-are-games-powerful-part-2/>

---

MT (2008-03-16 10:27:37)

I'm curious how your general consumption of flax influences these results – I was under the impression you took flax more regularly. I'm also wondering whether the persistence of a good-performance effect reflects learning as opposed to enhanced cognitive functions that are directly related to some more persistent aspect of the flax. Perhaps it is less a learning effect and more an efficient neurological function effect. A graph that showed longer timelines and multiple dosages would be illustrative. Interesting though – thanks.

seth (2008-03-16 11:20:28)

I take 4 T flax daily. Usually late in the evening – 11 pm, for example. (This is not shown on the graphs.) These graphs show what happens when I take it earlier. This is why the persisting effect reflects learning – aftereffects of the combination of Event A (very high flaxseed blood level) and Event B (doing the cursor test) at the same time. Usually the very high flaxseed level happens while I am asleep. In other words, usually Events A and B happen far apart. The treatment is to bring them close together just once. A reasonably high level of omega-3 is nothing new because I take flaxseed oil every evening.

MT (2008-03-16 15:35:28)

Gotcha. It would be interesting to see that tested with a more common athletic skill, such as free throws – you any good at basketball?? Maybe it could help my squash game too. If you want to test other cognitive functions the Nintendo "How Old Is Your Brain" game might be interesting – it tests math and other skills and you might be able to see a performance effect there, though it isn't as quick as your current test. Another simple one (though missing your game criteria of being fun, depending on your idea of fun) might just be speed and accuracy in solving a few tough randomly generated math questions in your head. A performance effect there would be very interesting as well.

Kristen's Raw (2008-03-16 20:32:33)

Interesting :)

### **Ranjit Chandra and Milk Allergies (2008-03-16 21:08)**

The following letter is from a Swedish professor who was president of the European Society of Pediatric Allergy and Clinical Immunology. [1]Background about Ranjit Chandra.

Lerum, March 16<sup>th</sup> 2008 Dear Prof Roberts, The correspondence/letters I have found or remembered are as follows.

1. In 1993, The European Society of Pediatric Allergy and Immunology, ESPACI) intended to publish a position paper on Cow's milk allergy(1). In my position as secretary of ESPACI, I wrote that paper in collaboration with the authors listed. We had intense discussions on whether or not we should cite Prof Chandra, whom we all knew, but did not trust, mainly since we found his inclusion criteria and symptoms curious and not according to scientific knowledge at that time. We also opposed, since he had not performed any blinded oral provocation tests and several authors, e.g. Arne Host(2) have found that less than 50 % of those reporting symptoms at exposure had cow's milk allergy at scheduled blinded oral provocation testing. I wrote a letter to the dean of the university of St John asking whether or not the rumors about Prof Chandra, that his nurse/secretary(?) had produced the results without the involvement of patients, were true. The reply was: "Since the allegations against Prof. Chandra have not been proven or disproven, he is still in office". I do not find that letter in my files.
2. In 1997 Ranjit Chandra published a 5 yrs follow up study on his cow's milk allergic children(3). This paper included DBPCFC. Then some of my colleagues drew the conclusion that everything was in order.
3. In 1998 we published a second position paper together with the European Society on Pediatric Gastroenterology and Nutrition, ESPGAN, on cow's milk allergy(4). At that time we accepted the Chandra paper, according to point 2.
4. In 2003 we were writing up three papers later published in PAI(5-7). These publications were based on papers read during the ESPACI/Section on Pediatrics meeting in Padua, Italy on Dietary prevention of Allergy. Since at that time I was President of ESPACI and Chairman of the Section on Pediatrics within EAACI and organizer of the meeting, I wrote (in collaboration with the speakers) paper I and II and Arne Host and Susanne Halken paper III.

Since I was still skeptical of the data by Chandra, I wrote [2] a letter on Feb 15 2003 to the dean of St John's (enclosed), without any response. The three papers were published in 2004.

5. January 19 2006 [3] I wrote once again to St John since I never got any response from the dean, correspondence enclosed.
6. On February 16 2006 [4] I got a response from St John from Prof Strawbridge and responded. On February 20 2006 I got another response and [5] again responded to Prof Strawbridge, Dean of St John, enclosed.
7. On Feb 24 I got a copy from German Friends and on March 3<sup>rd</sup> another one from Arne Host on the (enclosed) TV series in CBC on January 29<sup>th</sup> 2006 and later

The rest you know much better than I do. Actually, I don't know whether my correspondence has any value on a website. But maybe you can use it for your documentation.

## Bear Stearns and Self-Experimentation (2008-03-17 05:44)

Understanding and investment go together: The more you understand something, the more you should invest in it. On Friday, Bear Stearns owners thought their stock was worth \$30/share; they were [1]utterly wrong, it turned out.

In this sense, self-experimentation – research so cheap it can be done as a hobby – is a statement of complete ignorance. Because it is so cheap, you can test a hundred absurd ideas. If you use more expensive research methods, you cannot afford to test ideas you think are absurd. You must search a smaller solution space. If you are not correct about where the answer to your question will be, the region of possibilities that contains it, your research will fail to find it.

[2]My self-experimentation about why I was waking up too early revealed that I was almost completely ignorant about what I was studying. Two of the causes I found – eating breakfast and not standing enough – were not on my list of possibilities when I started. The Shangri-La Diet is outside the range of weight-loss methods that obesity researchers consider reasonable; without self-experimentation, it would never be tested.

1. <http://www.nytimes.com/2008/03/17/business/17bear.html?hp>

2. <http://repositories.cdlib.org/postprints/117/>

---

Aaron Blaisdell (2008-03-17 07:29:21)

The Bear Stearns deal just proves what I've noticed since I was a teenager. Something is only worth what someone else is willing to pay for it. I was never one to "Ooh" and "aah" over expensive cars, purses, coats, boats, etc., but since that realization I have had a reason why. The question I have never been able to answer is why do most people buy into the "luxury item = status" equation? I guess if something is difficult to buy (i.e., takes a lot of money) then this prevents most people from buying it. Thus, those who CAN buy it are by definition in a special minority. An elite minority. It is a symbol of power. But the success of that symbol requires the masses to buy into this equation even if they can't afford to (puns intended). I unplugged myself from those masses a long time ago and I feel like I'm looking down into an ant jar and watching the ants duke it out whenever I see people caught up in this struggle for symbols of success. I also think they guy who built the ferrari get the credit for building a beautiful machine, and not the guy who buys it. This is especially true of art.

Tony (2008-03-17 11:36:11)

I wish it were so easy to escape the status game. You might disdain the process, but it's real and it affects you, whether you want to close your eyes and wish it away or not. Looking like a bum on the subway? People will instantly judge you, and usually they will be correct. Dress extremely well and you'll get a very different judgment. Status symbols are used because they are usually reliable. When they stop being reliable indicators of status, they will stop being used, I'm guessing. The idea that the masses only should buy into them if they accord status to the masses is illogical, because high status by definition require differentiation from the mass of people.

Aaron Blaisdell (2008-03-17 12:14:56)

Tony, you make some good points. Even when academics (such as myself) dress more casually than our counterparts in the corporate world, its likely because our status as allows us to do so (the standards are different). I guess the status symbols I feel unaffected by are the real luxury items, such as very expensive cars, designer clothing (not just nice clothes, but name brands like Versaci and the like), and a house in Beverly Hills. Sure, some of these things are nice, but others are no different than the

Scion XB that I drive (and LOVE) or my beautiful 1,500 square foot home in Culver City where the sun is bright, the birds are singing, and life slows down to a day dream. I don't have city or ocean views or a truly expensive zip code (though that has changed dramatically these past few years), etc. Once I have achieved a nice standard of living (a wife and kids, a nice home to house us, a great job that I love going to every day, good food to put on the table), then the rest is just fluff. Do I wear a Rolex or a Timex? Doesn't matter to me (actually it's a cheap Indiglo). I've had a couple of suits custom tailored in Hong Kong (from where my wife hails) which aren't name brand, but they fit me like a glove! I'm comfortable, happy, and content. Maybe these are status symbols, but for the most part they aren't out there for most people to see and I don't have a drive to compare my stuff to that of others.

Tony (2008-03-17 14:59:23)

Oh, you absolutely have a good point that being impressed by fancy cars and so on is something to avoid, and that status games in general tend to be superficial. (Although I think that status in some way is a basic need for almost all humans.) Status in the academic world is a little different from most parts of the world, as you pointed out, which I think is why so many academics get so heated when others question or attack their ideas. Distinguished originator of ideas = status in the academic world (often). Attack the pedigree of the ideas, and you attack the basis of that person's distinction. The seemingly irrational counter-attacks and refusal to give credence to different ideas or data has its basis in a very rational desire - to keep or increase one's own status.

## **Procrastination and Self-Experimentation (2008-03-17 16:36)**

Nathan Yau has [1]posted results from the first two weeks of a self-experiment about procrastination. He tried

1. making a to-do list every evening for the next day
2. blocking the sites he wastes the most time at.

The results were not what he expected.

1. <http://flowingdata.com/2008/03/17/a-self-experiment-my-mid-month-report/>

---

gwadzilla (2008-03-18 07:05:56)

wow! alcoholism procrastination and weight management looks like I could gain a great deal by reading these pages right now I am about to try the Shangri La Diet it all seems to make such simple sense! my brother tried it and it worked and he is a Phd that did not poo poo your theories he read about it he tried it it just made sense but that chocolate just tastes so good!

Phillip J. Eby (2008-03-18 10:40:06)

If, per David Allen, one's to-do list only contains "amorphous blobs of undoability", it won't have any effect on the kind of procrastination that's caused by unclear goals. Resistance procrastination, on the other hand, will find ways around browser tricks. In other words, his results are about what I would have expected, i.e. Hawthorne-effect "willpower" improvements only. When his concentration lapsed, so did the improvements. My hypothesis: only if he reduces his anxiety response to either the goals or the tasks will he significantly reduce his procrastination over any period longer than can be accounted for by the active use of willpower/concentration. Otherwise, when energy drops, he will abandon his approach or find new

ways to procrastinate. (In other words, I posit that the real problem here is his conditioned feeling-response to the intention to work, not environmental distraction or lack of focus per se.) The anxiety reduction might be through changes in ideation about the goals or tasks, breaking them into smaller increments, or other methods. (Of these, I think the most effective ones can be classified under "other methods", as it's faster and easier to directly remove the response or association in the mind, rather than applying external workarounds.) Of course, it's also possible that he hasn't adequately defined his tasks, and isn't doing anything because he doesn't know what to do! But I don't consider that the same thing as procrastination. Hm. I just noticed something interesting about his first post... He says he wants to stop procrastination so that "I am not a bum". What's funny about that, is that in my experience chronic procrastination is often strongly associated with identity fears, i.e. fears that "I am/will be (undesirable label) if/because I don't do (project)". Such fears are usually a significant \*cause\* of the procrastination, rather than its effect! If he's genuinely afraid of being "a bum" (i.e., it was not just self-deprecating humor), then it's highly likely that this is THE major cause of his procrastination (as the source of the goal/task anxiety), and eliminating it might slash his perception of procrastination and resistance by 50 % or more. Some more on how anxiety leads to procrastination: <http://dirtsimple.org/2008/02/backpedalling-your-brain.html> In simple terms, we have two broad modes of behavior that might be called "acquisition" and "preservation", and preservation-mode tends to bias behavior strongly towards low-risk, short-term rewards (like web browsing), rather than investing in long-term gains (like a degree). One reason why sufficiently fine-grained to-do lists and techniques like working in short bursts can sometimes help procrastination is because they decrease the time to rewards. Unfortunately, they can also just replace one set of large tasks with another, especially if the person begins to think, "I'd better make that to-do list, \*or else\*," – a clear sign that they're still operating in preservation mode. In my work with myself and my clients, I've found the most reliable way to eliminate procrastination on large, highly-desired projects (writing a book, recording an album, getting a degree, etc.) is to remove the threat focus so that the "acquisition" mode is reinstated. In this mode, people do things because they want the result, rather than because they fear the consequences of \*not\* doing them. And long-term goals are much more easily able to override short-term distractions, when not under the stress of a threat. I'll leave the full evolutionary explanation of why we have different reward biases under perceived threat and non-threat conditions as an exercise for the reader. ;-)

Tony (2008-03-21 13:42:34)

Phillip, That was a very interesting comment. Would this fit under your model? I realized that when thinking about doing various tasks, I thought about it being completed. I typically would then think about how hard it would be to complete (perfectly). I changed to thinking about some task and thinking "I'll just get started" (with no or little concern about it being completed), which is kind of fun, often with a sense of exploration or excitement. Doing this, I've gone from doing what I really want to do 1-2 hours a day to 10-12 hours a day. Basically, it came about by examining the phenomenology of the key moments before starting a task. What was stopping me? It seemed there was some (half-)conscious kind of thought that tended to appear.

## Alcoholism and Self-Experimentation (2008-03-17 21:17)

I'm impressed:

[1]This is the story of Olivier Ameisen, a brilliant physician and cardiologist who developed a profound addiction to alcohol. He broke bones with no memory of falling. He nearly lost his kidneys; he fractured ribs and suffered a hemopneumothorax that left blood and air in the sac around his lungs. He gave up his flourishing practice and, fearing for his life, invested himself in Alcoholics Anonymous and, later, rehab. Nothing worked.

So he did the only thing he could: he took his treatment into his own hands. Searching for a cure for his deadly disease, he discovered baclofen, a muscle relaxant that had proven effective in curing rats addicted to every substance from nicotine and alcohol to cocaine and heroin. Ameisen prescribed himself the drug and, over a two-year period, experimented with the dosage until he reached a level high enough to leave him free of any craving for alcohol. That was four years ago.

[2]More.

1. <http://www.amazon.com/End-My-Addiction-Olivier-Ameisen/dp/0374140979>

2. <http://www.sciam.com/article.cfm?id=alcoholic-cardiologist-prescribed-experimental-drug>

---

Pearl (2008-03-18 08:06:13)

This is so interesting; great article and inspiring. I've been reading a lot about GABA recently in relation to anti-anxiety treatments; it has a decent reputation in Japan where it is primarily known as being a byproduct of sprouted brown rice, is infused into a chocolate candy called Gaba, and readily available in supplement form. I'm taking about 840 mg a day to see what happens. Interesting there would be a drug made that might do the same thing. I suppose that's because it's easy to regulate i.e. reap profits from.

Causalien (2008-03-18 18:17:30)

Seth, I found your site through scientific america's article. I didn't know that there are others like me who are conducting experiments on ourselves. Thanks for making this known to the world and thanks for letting me know that there are other like minded people.

### **Sweet and Ignorant (2008-03-19 09:31)**

[1]Speaking of ignorance, after all this time, [2]we don't understand the effects of artificial sweeteners. Excellent health journalism by Jill Adams. The Shangri-La Diet shows we didn't understand the effects of sugar. (Universally believed to be fattening, even by Gary Taubes, it turns out to be extremely slimming under some conditions.) Which we have been eating even longer.

Thanks to Dave Lull and Andy Pattantyus.

1. <http://www.blog.sethroberts.net/2008/03/17/bear-stearns-and-self-experimentation/>

---

david (2008-03-19 15:25:29)

Based on SLD, I would expect a 0 cal drink to suppress appetite if taken within a two hour window, but to increase appetite if taken with food (though it should be better than a regular soft drink). Or is there a reason that flavor with no calories, wouldn't break the flavor-calorie connection as well as calories with no flavor? But then by the same logic, I would have expected the rats on the glucose sweetened yogurt to gain a little more weight than the other rats because they had the same flavor with a few more calories. Or perhaps the artificial sweet ends up not being "invisible" in the way sugar water sweet is?

Ronald Pottol (2008-04-02 23:22:15)

From what I have heard, the data is all over the map, and why should each sweetener have the same effects? They don't even taste the same, and how the body handles them is not considered.

## What Beleg Means (2008-03-20 12:54)

A friend living in Holland writes:

I found this word [beleg] in my Dutch/English dictionary today.

Definition 1: to declare martial law. Definition 2: sandwich filling.

huh?

---

jan (2008-03-20 15:31:33)

It's really not that difficult at all.... Leggen in Dutch means to put/lay (something). Beleggen means (to put something upon something else beneath it). So "beleg" is all about the something that is put upon/over something else: in Def. 1-Force, in Def. 2 Cheese, ham, marmelade, etc. Helps?

seth (2008-03-20 16:40:54)

thanks, jan

Wouter Lievens (2008-03-31 01:13:56)

"Beleg" is actually a siege when used as a noun. I think the use for martial law is archaic and obscure, at least in Belgium.

Blegging « Shifting Gears (2008-03-31 09:12:42)

[...] A bleg = blog + beg "i.e., using a blog to beg for information. (This is not to be confused with the Dutch beleg "which is either a sandwich filling or the declaration of martial law.)" [...]

## Robin Hanson on Doctors (2008-03-21 08:01)

I am visiting George Mason University. Yesterday, as I was answering email, I heard a class in progress on the other side of the partition by my desk. It was Robin Hanson lecturing about the economics of health care to 20 undergraduates. It was so interesting I ended up listening to about 90 minutes of it. "Do your students know what a great class they're getting?" I asked Robin during a break. "I don't know myself," Robin replied.

I have heard hundreds of professors lecture. I had never heard anything like this. It wasn't the usual stuff. It wasn't the usual stuff made entertaining with cartoons or demonstrations or jokes or war stories. Instead, it was a straight-forward look at how the medical profession operates, and a lot of it was about how it operates to empower doctors, reduce the power of patients, and reduce health care innovation. Robin traced the history of the profession from the 1800s until today. "What separates a trade from a profession?" he asked his class. Professionals have ethics, he said. Doctors devised a code of ethics. At the top was "first, do no harm." What does this mean in practice, he asked his class. If a patient dies, does the doctor feel shame? No. If a patient wants a medical procedure that isn't recommended, does this mean the doctor doesn't do it? Apparently not. In contrast to the remarkable vagueness of "first do no harm" the rest of the doctors' ethics code was quite clear: no practice without a license, no advertising, and so on – each item with clear economic implications.

Robin also discussed how little doctors are supervised. A British doctor managed to kill over 200 people before anyone noticed; he was finally caught only because he forged a will. A nurse at a local hospital was assigned to measure how often doctors wash their hands. They're supposed to always wash their hands but many do not. The nurse did the survey, and, as requested, correlated hand-washing compliance with death rates. It turned out that the doctor who washed his hands the least had the highest death rate. The nurse reported this. The exceptional doctor had her fired.

On and on like this. Several books cover bits of this territory. A Sacred Trust by Richard Harris, very well written, is about how the AMA fought public health legislation. [1]Overtreated by Shannon Brownlee, which Robin assigned, is a recent overview. The nice thing about Robin's critique is that it was very accessible and at the right level of detail – I didn't have to spend 10 hours reading a book to learn what Robin said in 20 minutes – and it was very wide-ranging. During my last visit to GMU, Robin had told me about [2]the RAND study that found groups with different access to health care had the same health. Uh-oh. This was a much broader, more narrative look at same thing – how well is our health care system working? – and was a kind of explanation of the results of the RAND study.

Robin Hanson (2008-03-21 10:26:21)

Wow - I'm very flattered! :)

Brandon W (2008-03-21 10:52:02)

When I first started in the California Workers' Compensation industry in 1993, I thought the shady people were the attorneys. I now know it is the doctors. In my opinion, somewhere over the last 30 years or so making a really good living as a doctor no longer was enough. Now, many doctors attempt to maximize their earning potential. As soon as that bridge was crossed, healthcare costs exploded and patient care suffered.

lasser83 (2008-03-21 11:11:07)

It is interesting how the AMA is winning the public relations battle. The public is quick to blame everyone in the health care industry, with the exception of the doctors.

Heidi 555 (2008-03-21 16:13:44)

I am in the middle of reading Shannon Brownlee's book "Overtreated" and I highly recommend it. More people need to be made aware of how the medical profession operates. And thus be allowed more conscious choice and freedom in their healthcare decision making process. Perhaps Robin could be persuaded to put a lecture or transcript online.

lasser83 (2008-03-21 17:32:26)

I know Seth Roberts disagrees with this, but I strongly believe the health care industry needs to be run more like a business. There needs to be more transparency with costs and doctor performance. And there desperately needs to be more competition. Screw the AMA and their lawyers, Walmart should be able to open clinics.

seth (2008-03-22 07:46:47)

"I know Seth Roberts disagrees with this." ??? I agree with your suggestions. More transparency with costs and doctor performance and more competition are excellent ideas, well worth testing. I'm for more empowerment of everyone else involved, including nurses, hospital administrators, and especially the rest of us, before and after we get sick. My self-experimentation

was a way of taking my health care into my own hands.

Stephen M (Ethesis) (2008-03-22 13:07:15)

I ended up at a Wal-Mart clinic this last vacation, due to an emergency and it was a seamless experience. I was impressed. BTW, Taubes ought to just write a fiction novel. **White Death** and interleave factoids about medicine with a codebreaker on the run from unknown enemies who turn out to be cardiologists in league with flour and sugar manufacturers ... treat the misfeasance in diet as intentional malfeasance. Makes a much easier way to get across the real problem.

Tom (2008-03-22 13:17:14)

I think Taubes is moving the culture – not as dramatically as with "Big Fat Lie", but perhaps more lastingly. "Good Calories, Bad Calories" is beginning to get into the groundwater.

Stephen M (Ethesis) (2008-03-22 15:39:12)

You are right, consider Curtis' recent diet: *To fix it, she dropped 20 pounds by giving up "fattening" foods that most Americans would consider relatively healthy – like crackers, bread and granola, which have white flour and sugar and are surprisingly high in fat. She hopes American women will learn from her example.* <http://www.people.com/people/article/0,,20185529,00.html>

lasser83 (2008-03-22 19:54:53)

I apologize for misrepresenting Seth Roberts. Looking back it, I think Roberts argued in a previous post that the profit motive should be more limited in health care (wall street shouldn't make all of the decisions on health care). That is much different than what I claimed above.

### **Bryan Caplan on Blogging (2008-03-22 09:15)**

I asked [1]Bryan Caplan what effect his blogging had had. It made [2]his first book a success, he said. Or helped make it a success. He had started blogging about two years before it appeared. Other bloggers wrote about his book as if they knew him. They knew him from [3]his blog.

bobvis (2008-03-22 11:03:17)

I would not have known who you are except for Tyler Cowen linking to your paper on Marginal Revolution. That led to my reading your paper on self-experimentation, then your blog, and finally your book. None of that would have happened though if the initial paper hadn't been really good. It may be an obvious point, but I think it is worth saying explicitly: blogging (or any kind of marketing) will help an excellent product sell well; it will always be hard to sell trash.

Tim Lundeen (2008-03-22 11:10:01)

Seems very true – I bought his book because of his blog :-)

LemmusLemmus (2008-03-23 07:42:21)

(completely offtopic, feel free to delete) This might interest you: <http://www.clapclap.org/2007/04/hallelujah.html>

## Empowering Patients (2008-03-23 10:24)

Speaking of empowering patients, [1]this is incredibly important.

He clicked on baclofen, and the Web site informed him that nearly 200 patients registered at [2]Patients-LikeMe were taking the drug. He clicked again, and up popped a bold bar graph, sectoring those 200 across a spectrum of dosages. And there it was. Contrary to what his neurologist told him years ago, 10 milligrams wasn't the maximum dose. In fact, it was at the low end of the scale. "They're taking 30, 60, sometimes 80 milligrams" and they're just fine," Small recalls. "So it hits me: I'm not taking nearly enough of this drug." A few days later, Small asked his neurologist to up his dosage. Now Small takes 40 milligrams of baclofen a day. His foot drop isn't cured "there are no miracles in M.S." but he has found that after 14 years, he can walk to his car without sinking into quicksand.

Long ago diabetics did not have access to blood-glucose meters. Doctors resisted this innovation, now considered the greatest advance in the treatment of diabetes since the discovery of insulin.

Thanks to Tyler Cowen.

2. <http://www.patientslikeme.com/>

---

beagle (2008-03-23 15:39:18)

On the subject of MS, there are no miracles but apparently great advances - see <http://www.lowdosenaltrexone.org/> Both this and DCA ( <http://www.thedcasite.com/> ) are treatments based on drugs that have been long in use, thus with a well known safety profile, except that they are used in smaller doses and for different uses. And they are both cases in which self-experiment is the norm, because people with either MS or cancer are very willing to experiment and not willing to wait 10 years for the standard process.

## Tyler Cowen on Blogging (2008-03-24 07:10)

"I can say what I really think," said Tyler about blogging a few days ago. Not only that, (a) this truth-speaking is on a topic he cares about, (b) what he says is based on considerable knowledge (what an ignorant person "really thinks" about something isn't helpful), and (c) a lot of people listen. This is a potent mix.

The magic of blogging is that when you start you can tell the truth because no one is listening. With zero audience, it makes sense - it feels good - to tell the truth. If you are an expert like Tyler, this sort of thing is irresistible to readers (economics confidential) so your audience grows. Now it is too late to start censoring yourself; people are reading your blog because you tell the truth.

[1]Tyler's blog.

### **What Philip Weiss Really Thinks (2008-03-24 11:44)**

[1]In this case, Weiss says what he really thinks by repeating what someone told him:

She can never bring these ideas up with her Jewish relations, they go haywire. She never talks about these ideas in company.

But Weiss can express them without breaking a sweat. This is amazing.

[2]Tyler Cowen on blogs as truth.

1. <http://www.philipweiss.org/mondoweiss/2008/03/my-dinner-partn.html>

2. <http://www.blog.sethroberts.net/2008/03/24/tyler-cowen-on-blogging/>

---

Stephen M (Ethesis) (2008-05-25 19:48:33)

I wonder if he really does bring them up without breaking a sweat? The issues seem too complex and emotional to be so easily discussed.

### **Bryan Caplan on How to Lose Weight (2008-03-25 07:11)**

[1]My self-experimentation inspired [2]Bryan Caplan to do his own self-experiment: Could he lose weight by eating less without discomfort? He did two things:

1. Stopped eating when he wasn't hungry. During a meal he began to pay close attention to how hungry he was. When he stopped being hungry, he stopped eating, even if it meant leaving food on his plate. Before this he rarely left food on his plate. Now it was common.

2. Cut down on his soda consumption. Previously he was drinking at least two cans/day of Coke or IBC Root Beer (both non-diet). He reduced this to one can/day, which he found was enough to keep his energy up.

Bryan is 5' 10". When this started he weighed about 178 pounds. Over 9 months, his weight went down to 155, where it has remained for 9 months. "Is this something I'm willing to do for the rest of my life?" he asks. "Yes."

I'm sure that non-diet soft drinks – primo ditto food – are very fattening but it isn't easy for me to believe that cutting

back on them could cause so much weight loss. Did the don't-eat-when-not-hungry rule also help Bryan lose weight? I don't know of research that answers this question.

1. <http://repositories.cdlib.org/postprints/117/>

2. <http://economics.gmu.edu/bcaplan/>

---

david (2008-03-25 08:32:17)

I can believe that he went from 178 to 155 over 9 months doing what he described, but I suspect few people have the discipline to pull it off.

Timothy Beneke (2008-03-25 10:34:58)

I'd be curious what else he was eating; eliminating the ditto food probably helped a lot. One thing is clear to me: it is impossible to lose weight if you eat when you are not hungry; so it is necessary to be aware of your hunger levels when you eat and not go beyond them...

jon (2008-03-25 11:15:22)

Well, from an overly simplistic mathematical standpoint, he lost 80,500 Calories worth of weight in say 270 days, or just under 298 a day. Dropping one can of coke (160 Calories) a day (maybe even more, since he says he was drinking "at least" 2 per day) puts us at 138. Assuming that the meals he stopped eating when he wasn't hungry previously were about 1500 Calories (not sure if this is reasonable, I really don't have a good idea of how many Calories cooked food has), he could drop the remainder of the weight by just eating 10 % less, which seems very reasonable.

jayesh (2008-05-27 12:20:54)

to add a wrinkle to jon's calculation: That 80K is what he cut down from his REQUIREMENT, not consumption. If he was stable at 178 Lbs, they are the same. However, if he was gaining weight when he met Seth, he had to cut down on the excess he was consuming, PLUS the 298 calories he had to cut down. Now assuming most people are gaining weight when they seek help, he needed to cut down on much more than the 10 % you calculated.

## **The Amish and Organic Farming (2008-03-26 07:03)**

One modern invention accepted by Pennsylvania Amish farmers is pesticides: They use horses to pull pesticide dispensers. This may play a part in [1]an increase in birth defects in their community, which are usually explained by inbreeding. (However, large increases over short periods of time are almost always due to environmental changes.) A few years ago, Sally Fallon, head of the [2]Weston A. Price Foundation, was part of a group visiting an Amish farm that had recently become organic (i.e., stop using pesticides). Someone asked the farmer why he had decided to change. Show them, he told his son, who had been standing with his arms behind his back. One of his arms had no forearm. We took that as a sign from God, said the farmer.

### **Comparison of Strategies for Sustaining Weight Loss (2008-03-27 07:07)**

A recent issue of JAMA has [1]an article titled "Comparison of Strategies for Sustaining Weight Loss: The Weight Loss Maintenance Randomized Controlled Trial". It reports an experiment that compared three ways to keep from regaining weight you've lost.

If you want to lose weight it paints a discouraging picture. It was an very expensive study, 27 authors, five grants. About 1000 subjects. Four years just to collect the data. The whole thing might have taken seven years. Must have cost millions of dollars. Might have cost tens of millions of dollars.

Given the huge expense, surely the subjects got the best possible establishment-approved weight loss advice. They did lose 19 pounds in six months. Here's how the advice was described in the article:

Intervention goals were for participants to reach 180 minutes per week of moderate physical activity (typically walking); reduce caloric intake; adopt the Dietary Approaches to Stop Hypertension dietary pattern . . . and lose approximately 1 to 2 lb per week. Participants were taught to keep food and physical activity self-monitoring records and to calculate caloric intake.

Shades of Marion Nestle's "move more, eat less"! Aside from the DASH "dietary pattern," which was meant to reduce blood pressure, not weight, this advice could have been given fifty years ago. Apparently, those who did the study and those who funded it – who are representative of the larger research establishment, I assume – believe there has been no theoretical or empirical progress since then.

Many fields haven't progressed in 50 years. Fifty years ago,  $2 + 2$  equaled 4. The basic principles of thermodynamics and inorganic chemistry were the same then as they are now. Lack of progress in weight loss advice would be fine if the advice actually worked but the whole study derived from the fact that the advice is poor – the weight loss it produces cannot be sustained.

To help people sustain their weight loss, the study compared three methods: 1. Monthly contact. Usually a 10-minute phone call ("with an interventionist"), every 4th month a hour face-to-face visit. Although the article claims this treatment was "practical," I suspect it is too expensive for widespread use. 2. Encouragement to visit an interactive website. The website helped you set goals, allowed you to graph your results, and had a bulletin board, plus several other features. This was the focus of the whole huge research project: the effect of this website. It could be offered to everyone practically free, except that if the subject didn't log on after email reminders she got a phone call. 3. "A self-directed comparison condition in which participants got minimal intervention [that is, nothing]."

The personal contact condition was slightly better than nothing. By the end of the study, the website was no better than nothing. And nothing was bad. The subjects regained about two-thirds of the lost weight during the maintenance year and, looking at the weight-versus-time graph, were apparently going to regain the rest of the lost weight during the coming year. Subjects in all three conditions continued to regain the lost weight throughout the year of maintenance.

In other words, this exceedingly expensive study could be summed up like this: We tried something new, it didn't work. The abstract didn't face this truth squarely. It concluded: "The majority of individuals who successfully completed an initial behavioral weight loss program maintained a weight below their initial level."

It's a Catch-22: Without a good theory, it's hard to find experimental effects. You're just guessing. Most of what you will try will fail. Without strong experimental effects, it's hard to build a good theory. I was in this situation with regard to early awakening. I had no idea what the cause was. It took me ten years of trying everything I could think of, dozens of possibilities, before I managed to find something that made a difference. From that I managed to build a little bit of a theory, which helped enormously in finding more experimental effects.

The people who did this study had no good theory about weight control. Nothing wrong with that, we all start off ignorant. The website they tested was just the usual common-sense stuff. What's discouraging for anyone who wants to lose weight is how little progress was made for such a huge amount of time and money. If it takes seven years and ten million dollars and a small army of researchers to test one little point in a vast space of possibilities . . . you are unlikely to find anything useful during the lifetime of anyone now alive (or any of their children). The people behind the study also had a poor grasp of experimental design. With 300 people in the website group, it would have been easy to test many website design variations: weight-loss graph (yes or no), bulletin board (yes or no), etc., using factorial or fractional factorial designs. Their study merely showed that one particular website didn't work. They learned nothing about all other possible websites. They might have been able to say: no likely website will work. They can't because the study was badly designed. The study cost something like \$10 million and that was the statistical advice they got!

The huge expense and the lack of progress in the last 50 years go together. The methodological dogmatism [2]I discussed recently has bad consequences. It leads to studies that are more expensive and take longer. The proponents of the methodological rigidity say they are "better" not taking account of the cost: continued ignorance about health. A better research strategy would be to fund and encourage much cheaper ways of testing new ideas.

1. <http://jama.ama-assn.org/cgi/content/abstract/299/10/1139?ct>
2. <http://www.blog.sethroberts.net/2008/03/12/twisted-skepticism/>

---

Tom (2008-03-27 07:32:42)

The writing of abstracts that diverge from the findings of the paper itself, while common, is criminal. Rather than a worthless study that cost \$10mm, we are left with one that actively spreads disinformation.

michael vassar (2008-03-27 08:20:08)

Agreed with Tom. Seth, maybe you should write a book on experimental methodology and design. I hope you are somewhat familiar with Bayesian Statistics. It would be pretty essential for such a task but you might be able to do it in collaboration with someone else who is familiar.

larry (2008-03-27 10:09:30)

Speaking of dogmatism, the recent flap over tobacco companies funding lung cancer research seems odd to me. In the New York Times, the editor of JAMA says flatly that she would never publish ANY lung cancer study if the author had accepted funding from a tobacco company. This prohibition is obviously irrational and seems more related to politics than to good science. Tobacco companies share with the public an interest in finding more effective treatments for lung cancer, if only to make their products less harmful to customers. No mention was made of any similar bar on authors accepting funding from pharmaceutical companies, despite their potential interest in study outcomes. [http://www.nytimes.com/2008/03/26/health/research/26lung.html?\\_r=1&st=cse&sq=tobacco&scp=1&oref=slogin](http://www.nytimes.com/2008/03/26/health/research/26lung.html?_r=1&st=cse&sq=tobacco&scp=1&oref=slogin)

LemmusLemmus (2008-03-27 10:21:53)

Michael, the stuff Seth complains about is pretty basic; I should think that there are lots of books that could have told the researchers and the funding agencies what the problem with their design was - if those people would have read them. In case I'm wrong, Andrew Gelman would seem to be a natural choice for a co-author who knows lots about Bayesian ideas as well as Seth.

Lancaster (2008-04-02 15:41:37)

The other "Seth" comes up with a good illustration of this from a completely different field of endeavor: [http://sethgodin.typepad.com/seths\\_blog/2008/04/which-comes-fir.html](http://sethgodin.typepad.com/seths_blog/2008/04/which-comes-fir.html)

Vic (2008-07-07 14:53:56)

Considering the magnitude of the problem, only miniscule resources have been devoted to research on weight loss techniques. Fast food companies spend billions every year promoting their products compared to a few million a year from NIH to study obesity. Do you think that long-term weight loss is important? This was the first randomized trial to systematically compare behavioral weight loss maintenance strategies with more than one year of follow-up. The blog writer asserts that only minimal weight loss occurred, but that is not the case. 2/3 of the participants in the first six months of the trial lost 4kg or more. That is enough weight loss to show improvements in blood pressure and glycemic control. Similar amounts of weight loss in the Diabetes Prevention Program (DPP) resulted in significant reduction in the risk of becoming diabetic.

seth (2008-07-07 17:28:22)

"The blog writer asserts that only minimal weight loss occurred." No, I wrote "They did lose 19 pounds in six months." I would like to hear someone defend this study. I think \$10 million should have bought a more sophisticated experimental design. Vic, do you disagree?

Sherylle Grace Francia (2009-12-07 17:08:32)

Have you seen what your site looks like with safari? It looks a bit funky on mine. Is it just me or?

seth (2009-12-07 18:00:05)

no I haven't seen what it looks like with Safari. So I can't answer your question. Thanks for pointing it out.

## **Cramps and Self-Experimentation (2008-03-28 06:12)**

Does too little potassium cause cramps? [1]Quite possibly:

Dr. Stephen Liggett, a professor of medicine and physiology at the University of Maryland, . . . got terrible cramps in his calf during yoga. The culprit, he decided, was the drugs he takes for asthma, which can diminish the body's supply of potassium. He knew that potassium is sold over the counter. But because high levels of potassium can be dangerous, store-bought potassium supplements are not very strong. . . . Before he does yoga, he measures the potassium levels in his blood before and after taking what he describes as a hefty dose of over-the-counter supplement. Then he calculates how much additional potassium he thinks he needs, securing it from concentrated potassium tablets from his research lab – how much he declined to say."I didn't want to drink two gallons of Gatorade," Dr. Liggett explained. He hasn't had cramps since he began "preloading," as he calls it, with potassium. But, he said, "I haven't done a controlled trial."

Thanks to Evelyn Mitchell.

Addendum. Someone commented that the potassium/cramps connection is widely known. And he or she is right. No wonder Dr. Liggett didn't do a "controlled trial".

1. <http://query.nytimes.com/gst/fullpage.html?res=9F00E2D7173BF937A25751C0A96E9C8B63&sec=&spon=&pagewanted=all>

---

Stacey (2008-03-28 12:18:46)

Any pregnant woman will confirm this is true. With both of my pregnancies, I experienced horrible leg cramps/charlie horses once I hit the 3rd trimester. By that point in the pregnancy, the body is pretty much at its limit and potassium is depleted quickly. To remedy this, I ate a banana before bed every night. On the nights I did that, no cramps. The nights I skipped my banana(s), I woke up with horrible charlie horses and cramps. Proof enough for me!

August (2008-03-28 13:26:50)

I thought this was established science. I take potassium supplements whenever I do something I suspect will diminish my blood levels, and I regularly include bananas in my diet for this very reason. Recently, I've added B-12 supplements too after some searching on the internet.

## Human Subjects Research at Drexel University (2008-03-29 02:37)

I am visiting Philadelphia. Yesterday I learned that if you want to do human subjects research at Drexel University you must:

1. Include indemnification language in the consent form. The subject must promise to not sue Drexel no matter what happens. This is a bluff: You cannot sign away your ability to sue. Of course this requirement leaves subjects more vulnerable, not less, the usual purpose of consent forms. Shades of [1]twisted skepticism.
2. Never contact subjects via email.
3. Never advertise your research on the web.
4. Never contact subjects who have been in a previous experiment.

The Drexel IRB (Institutional Review Board) will never approve any study that involves giving any drug to a non-patient. This means the very important [2]studies by David Healy that involved giving Prozac to ordinary (non-depressed) people – some of whom became suicidal – wouldn't be possible.

I suppose it's no surprise that Drexel IRB members, such as literature professors, criticize research designs. In an NPR piece, [3]a former IRB member boasted about the accomplishments of her membership, which included correcting faulty designs. At UC Berkeley a few years ago, I submitted to the animal research IRB a proposal to test with rats a key observation behind the Shangri-La Diet: Drinking sugar water caused me to lose weight. The proposal was turned down: It couldn't possibly be true that sugar water can cause weight loss, said the IRB. Testing this idea was a waste of time.

[4]IRB Watch. [5]Earlier post about IRBs.

1. <http://www.blog.sethroberts.net/2008/03/12/twisted-skepticism/>
2. <http://search.barnesandnoble.com/Let-Them-Eat-Prozac/David-Healy/e/9780814736692>
3. <http://www.npr.org/templates/story/story.php?storyId=5358288>
4. <http://home.earthlink.net/~irbwatch/>
5. <http://www.blog.sethroberts.net/2007/08/13/the-troubles-with-irbs/>

---

LemmusLemmus (2008-03-29 09:35:50)

This is a very extreme example, and I can't even guess the reasoning behind points 2-4. But one hears these kinds of things about American IRBs all of the time. I wonder: Why is it in a University's interest to sabotage its own researchers? It just doesn't make any sense at all. Anyone?

seth (2008-03-29 09:47:02)

Why does this happen? Because lawyers for Drexel want to prevent Drexel from being sued. They exert far more power than the researchers.

LemmusLemmus (2008-03-29 10:18:18)

Seth, that *does* make sense. Reminds me of other stories I hear from the US - doctors performing useless medical tests just

to be on the safe side, companies having their products come with hilarious warning labels ("Remove child before folding stroller!") and the like. It seems that American tort law needs some serious overhaul.

Andrew Gelman (2008-03-29 13:54:19)

I probably shouldn't admit this, but I've forgotten to remove child before folding stroller. Many times, in fact.

LemmusLemmus (2008-03-30 00:17:51)

Andrew, we'll take you to the cleaners!

Stephen M (Ethesis) (2008-03-31 06:19:30)

"indemnification language" In many states you can give up your right to sue. Indemnification language, however, is a contract by you to pay for their cost to defend against your lawsuit and to pay them for any damages they have to pay out as the result of your suit (or someone suing through you – e.g. your health insurance company who would have a right of indemnification). That is much stronger than a mere waiver. Just FYI. Too bad about the rat study being nixed. Wonder what it would cost to have it funded by private donors?

## **Blood Sugar Measurements? (2008-03-29 03:16)**

Speaking of [1]blegs, Howard Wainer, [2]a renowned statistician at the National Board of Medical Examiners, is looking for sets of blood sugar measurements in Excel format. The ideal set would be measurements six or more times per day for several months. He is writing a paper about better ways to analyze such measurements, which are commonly made by diabetics and persons at risk for diabetes. He has collected such measurements himself; he wants to see how well the methods he developed using data from himself work with data from someone else. You can reach him at hwainer at nmbe dot org.

I told Howard: You will be the first statistician (a) to use your professional skills to improve your own life and (b) publish the results. (Which is what I did with [3]my self-experimentation.) Lots of statisticians must have done something similar, said Howard. For example? I asked. He mentioned John Tukey making traffic measurements to help his wife push a change in traffic rules. However, Tukey didn't publish the results and the relevance to Tukey's own life was tiny. If anyone reading this knows of an example, please let me know. Statistics is hundreds of years old; there are thousands of professional statisticians. It seems strange that it has taken this long for such a thing to happen but that seems to be the case.

[...] Blood Sugar Measurements? [...]

## **I'm Speaking at Penn (2008-03-29 07:05)**

This coming Monday (March 31), at noon, I'm giving a talk at the University of Pennsylvania titled "The Value of Self-Experimentation, with Examples from the Study of Omega-3 and Brain Function." The talk will be in the Large Conference Room of the Institute for Research in Cognitive Science, Suite 400A, 3401 Walnut Street.

---

Kevin C (2008-04-01 18:24:57)

'Walnut' street? Coincidence? I don't think so.

## **Praying With Lior and Labors of Love (2008-03-30 04:48)**

Last night I saw [1]Praying with Lior, a documentary about the bar mitzvah of a boy with Down's Syndrome. Easily the best movie I've seen this year, better than There Will Be Blood, Mary Poppins (leaving aside the great song [2]Feed the Birds), Blade Runner, and several documentaries, for example. I asked a friend why she liked the TV show ER. "It makes you feel happy and sad," she said. Praying for Lior made me sad again and again, which is part of why I liked it so much. I also liked seeing someone with a handicap struggle and succeed; Praying with Lior has a lot in common with My Left Foot, one of my favorite movies.

The person responsible for the film is Ilana Tractman, [3]who met Lior at a religious retreat. Her day job is making television documentaries. She got the money to make the film – from a large number of foundations and people – while she was making it. As far as I can tell, she had almost total freedom, in contrast to her TV documentaries. I use the term superhobby to describe activities that combine the skills and resources of a professional with the freedom of a hobbyist. All of the blogs I read regularly are superhobbies. My self-experimentation was (and is) a superhobby. Writing open-source software is a superhobby. Most books are superhobbies. When a superhobby produces art, we call the product a labor of love. As we get richer and richer – thus can afford more freedom – and skills and knowledge improve, these labors of love become better, more possible, and more common.

The Praying with Lior [4]website revealed to me that the film had/has a "mission": "to change the way people with disabilities are perceived and received by faith communities." Perhaps that is another reason why such a good film was made: This purpose helped it get funding and other help (a lot of people worked on it). And maybe it was part of why Ms. Tractman began and continued a difficult and uncertain project.

## 3.4 April

### Buried Treasure (part 1) (2008-04-01 08:38)

Not long ago, Howard Wainer, the statistician I [1]mentioned recently, learned that his blood sugar was too high. His doctor told him to lose weight or risk losing his sight. He quickly lost about 50 pounds, which put him below 200 pounds. He also started making frequent measurements of his blood sugar, on the order of 6 times per day, with the goal of keeping it low.

It was obvious to him that the conventional (meter-supplied) analysis of these measurements could be improved. The conventional analysis emphasized means. You could get the mean of your last  $n$  (20?) readings, for example. That told you how well you were doing, but didn't help you do better.

Howard, who had written [2]a book about graphical discovery, made a graph: blood sugar versus time. It showed that his measurements could be divided into three parts:

measurement = average + usual variation + outlier (= unusual variation)

Of greatest interest to Howard were the outliers. Most were high. They always happened shortly after he ate unusual food. Before a reading of 170, for example, he had eaten a pretzel. He had not realized a pretzel could do this. He stopped eating pretzels.

When Howard told me this, it was like a door had opened a tiny crack. Recently a deep-sea treasure-hunting company found a shipwreck off the coast of Spain. [3]They named it Black Swan, apparently a reference to Nassim Taleb's book. Shipwrecks are black swans on the ocean floor; black-swan weather had sunk the ship. For Howard, outliers were another kind of buried treasure: the key to saving his sight.

It isn't just Howard. Outliers are buried treasure in all science. They are a source of new ideas, especially the new ideas that lead to whole new theories. The Shangri-La Diet derived from an outlier: Unusually low hunger in Paris. My self-experimentation about faces and mood started with an outlier: One morning I felt remarkably good. My discovery that standing improved my sleep started with a series of days when I slept unusually well.

Modern statistics began a hundred years ago with the  $t$  test and the analysis of variance and  $p$  values – very useful tools. Almost all scientists use them or their descendants. Almost all statistics professors devote themselves to improvements along these lines. However, conventional statistical methods, the  $t$  test and so on, deal only with usual variance. (Exploratory data analysis is still unconventional.) As Taleb has emphasized, outliers remain not studied, not understood, and, especially, not exploited.

2. <http://books.google.com/books?id=ux1Yf0FFVx4C&dq=%22howard+wainer%22+graphical+discovery&pg=PP1&ots=oEYpVLtI7&sig=KHlmytmkwbq8Rcr2LqUYluFec&hl=en&prev=http://www.google.com/search?q=%22howard+wainer%22+graphical+discovery&ie=utf-8&oe=utf-8&rls=org.mozilla:en-US:official&client=firefox-a&sa=X&oi=print&ct=title&cad=one-book-with-thumbnail>

3. [http://www.newyorker.com/reporting/2008/04/07/080407fa\\_fact\\_colapinto](http://www.newyorker.com/reporting/2008/04/07/080407fa_fact_colapinto)

Howard Wainer (2008-04-01 10:51:09)

I didn't lose the weight first and spot blood sugar outliers afterwards. They happened at the same time and were related. Losing weight is hard. It is hard because if you weigh yourself in the morning and then eat a double bacon cheesburger, extra fries and a thick shake and weigh yourself again, nothing has changed. Similarly, if you eat very carefully all day and then weigh yourself again at night, nothing has changed. So there is no immediate feedback to reward good behavior or discourage bad. Blood sugar is fast – if you eat something you shouldn't you find out immediately. And the long-term consequences of poor eating habits are dire (you go blind and your legs get amputated before dying prematurely (see Jackie Robinson as one very sad example). By controlling blood sugar I was forced into healthy eating (a Hobbitt diet – eating 5-6 small meals a day) and the weight fell away at a bit over 1/2 lb/day. I went from 240 to 191 in a few months. Unfortunately, despite maintaining a very vigorous exercise regime, I lost muscle as well as fat. Now, a year later I am still between 190 and 195 and blood sugar is well controlled. And although I can do as many push-ups now as I could before, I can't bench press what I used to.

Tony (2008-04-01 11:40:54)

Seth: I love the metaphor of outliers as buried treasure. The problem is to distinguish between junk that you dig up and really valuable stuff. Howard: Immediate feedback is very important in game design (players get frustrated and give up if they can't figure out what the effects of their actions are). I think Seth has actually blogged a bit about the concept before ... Putting these sort of situations in place in everyday "games" is one element that increases motivation. Runners often use a similar sort of approach by measuring their heartbeat rate.

Tim Lundeen (2008-04-01 14:33:09)

Lower blood sugar after eating familiar food is the result of a conditioned compensatory response, the "cephalic-phase insulin release". Your body learns to pre-compensate for familiar food to reduce both insulin and blood glucose exposure. Interesting that the unlearned state would have such significantly higher glucose levels. Maybe this is why my major indulgence, a very small hot-fudge sundae after dinner, doesn't have more of an effect on my blood sugar in the morning :-). Howard, you might want to try eating less-frequent meals with lower carbohydrates. What I've found is that eating less often moves my body's adjustment down into the normal range, because it takes my metabolism a long time to bring my blood sugar down. So now, instead of being adjusted to blood sugar of 90-100, I'm adjusted to 75-85. In this range, you should lose more weight, have more energy, and can skip meals without feeling bad.

Varangy (2008-04-01 16:14:34)

@Howard Wainer You may want to check out two fascinating blogs. They might be able to assist you with your weight loss, retaining your sight (None of my business, but I assume this is diabetes related) and general health. Both are well-written, somewhat out of the mainstream thought, for an educated audience and employ statistics and logical reasoning in their arguments. 1) Art de Vany's Blog on Evolutionary Fitness and Diet - <http://www.arthurdevany.com/> Excerpt from an interview on [1]T-Nation **Charles:** *I don't know if I read in the first chapter of your book on in the blog, you said that when you were in your 40's you started making changes in your lifestyle. I wanted to ask you what was the catalyst for those changes and what did you start doing differently?* **Art:** *That's very interesting, because it was probably when my wife developed type-1 diabetes and we moved to California in '84. She had developed it 2 years prior to that. My son had been an infant onset juvenile diabetic at the age of 2, so I began studying metabolism quite intensively, just trying to keep track of his health and keep him healthy. And then having my wife have the same problem develop, obviously it's in her genetic stock on that side of the family, the autoimmune illness.* **Charles:** *Sure.* **Art:** *I, by that time, accumulated a lot of evidence as to what foods elevated what glucose, and began systematically eliminating those, even with my son. But we became more ruthless at it when my wife also developed type-1 diabetes. So, if you just look at the evidence, somebody who can't control their blood sugar adequately, because they don't respond with an insulin response, as do normal people, then what you find is the kinds of foods that I eliminated from the diet were all of the things apparently so heavily criticized for having high glycemic index or high glycemic load. So, that was the beginning of it. And then, I migrated towards a hunter/gatherer model, simply by looking at the evolutionary history and what kinds of foods our ancestors ate.* 2) The Hyperlipid Blog - <http://high-fat-nutrition.blogspot.com/> Written by a man named Peter who is a physiologist and biochemist training. He follows an 80 % fat diet and is constantly trying to prove himself wrong ala Karl Popper. Two posts on diabetes: <http://high-fat-nutrition.blogspot.com/2008/03/diabetes-and-hunger.html> <http://high-fat-nutrition.blogspot.com/2008/03/diabetes-and-cardiac-apoptosis.html> Best of luck.

[...] Buried Treasure (part 1) [...]

Howard Wainer (2008-09-26 12:16:33)

Seth - two thoughts on outliers. 1. An outlier in statistical jargon is often called a contaminant – as in a contaminated normal distribution. One goal of statistical analysis is to reduce the influence of outliers on the overall estimate. This is typically done by separating outliers from the main body of the data for different treatment. Contaminant is not meant as pejorative. In south Africa good building stone is sometimes contaminated by diamonds. 2. I am reminded of Isaac Asimov's observation that scientific discovery is almost never accompanied by "Eureka." Much more often it is signaled by "that's funny." Hope you are well, H

### **More from Holland (2008-04-02 05:42)**

[1]My friend in Holland wrote again:

Last year, the Dutch Supreme Court ruled that it was OK to have sex with animals, as long as the animals enjoyed it.

She attached a newspaper article in the Hague/Amsterdam Times dated 20 March 2008 that began:

Under a new law being debated by the government, sex with animals will be allowed as long as people don't enjoy it.

It ended:

The Animal Party was mainly disappointed about the fact that the new bill does not refer to the animals' dignity.

1. <http://www.blog.sethroberts.net/2008/03/20/what-beleg-means/>

---

Varangy (2008-04-02 16:55:03)

Call me old-fashioned, Victorian, and ridiculously judgmental, but even as a libertarian, isn't condoning sex with animals, er, wrong, for lack of a better word.

## **Bad is Good (2008-04-02 15:03)**

A health study by Japanese researchers has found that people with low levels of LDL cholesterol – often referred to as "bad cholesterol" – are more likely to die than those with higher levels.

[1]More. Thanks to Pearl Alexander.

1. <http://mdn.mainichi.jp/national/news/20080329p2a00m0na021000c.html>

---

Varangy (2008-04-02 16:46:26)

Great post. While I am suspicious of all studies, even ones that confirm my POV/biases, I think this study ultimately leads to what I got from Taubes' book and others. We simply do not know if the Lipid Hypothesis is valid, nor if cholesterol levels, or accompanying levels of lipoproteins signal/indicate anything. And if they do, how to interpret them as markers. I suggest this to people at cocktail parties and am always roundly laughed at. No one ever takes me up on my (perhaps Aspergian) offer to provide them with reading materials that may enlighten them. My guess is that we have suffered a lot from the mis-information cascades of the low-fat diet and the lipid hypothesis — and as humans, as long as we remain intellectually arrogant, will continue to in nutrition and other fields.

Aaron Blaisdell (2008-04-03 06:39:15)

I thought ALL people were 100 % likely to die. If you strictly interpret the text above ("A health study by... ... with higher levels"), it suggests there are a bunch of immortals walking around Japan.

## **Buried Treasure (part 2) (2008-04-03 06:10)**

Before the invention of statistical tests, such as the t test, science moved forward. People gathered data, computed averages, drew reasonable conclusions. As far as I can tell, modern ways of analyzing data improved the linkage between data and conclusion because they reduced a big source of noise: How the data were analyzed. Procedures became standardized. Hypothesis testing improved. Hypothesis formation, however, did not improve. Knowing how to do a t test and the philosophy behind it will not help you come up with new ideas. Yet data can be used to generate new ideas, not just test the ones you already have.

Our understanding of outliers is in a kind of pre-t-test era. People use them in an unstructured way. As [1]Howard Wainer's analysis of his blood sugar data indicates, better use of them will improve hypothesis formation. A kind of standardized treatment should help generate ideas, just as the t test and related ideas helped test ideas. Here are some questions I think can be answered:

1. Cause. What causes outliers? It's a step forward to realize that outliers are often caused by other outliers. Howard has found that unusually high blood sugar readings are caused by eating unusual (for him) foods.

2. Inference. I'm fond of saying lightning doesn't strike twice in one place for different reasons. The longer version is if two outliers could have the same explanation, they probably do. I think this principle can be improved.

3. Methodology. To test ideas, you want variation to be low. To generate ideas, you want outlier rate to be high. Howard could make progress in understanding what controls his blood sugar by deliberately testing foods that might produce outliers. In genetics, x-rays and chemical mutagens have been used to increase mutation rates; mutations are outliers. ([2]Discovery of a white-eyed mutant fruit fly led to a wealth of new genetic ideas.) In physics, particle accelerators increase the outlier rate in order to discover new subatomic particles. There are no comparable procedures for psychology. Self-experimentation increased my rate of new ideas because it increased my outlier detection rate. It increased that rate for three reasons: 1. I kept numerical records. 2. I analyzed my data using the same methods as Howard. 3. I did experiments. Travel is like experimentation; there too it helps [3]to keep numerical records and analyze them. The question: What are the basic principles for increasing outlier rate?

[4]Part 1.

1. <http://www.blog.sethroberts.net/2008/04/01/buried-treasure-part-1/>

2. [http://www.genomenewsnetwork.org/resources/timeline/1910\\_Morgan.php](http://www.genomenewsnetwork.org/resources/timeline/1910_Morgan.php)

3. <http://www.blog.sethroberts.net/2007/06/30/science-in-action-omega-3-a-surprise/>

4. <http://www.blog.sethroberts.net/2008/04/01/buried-treasure-part-1/>

---

Aaron Blaisdell (2008-04-03 06:43:06)

"There are no comparable procedures for psychology." What about the rorschach test? Granted, I had to stretch all the way to psychoanalytic theory to find an example.

seth (2008-04-03 07:24:55)

Well, Rorschach tests haven't generated any new psychological ideas, as far as I know. But they may be the best possible answer for psychology, as you say.

Varangy (2008-04-03 16:43:15)

*Hypothesis testing improved. Hypothesis formation, however, did not improve. Knowing how to do a t test and the philosophy behind it will not help you come up with new ideas.* Exactly! I have had the misfortune of taking a graduate degree and one of the most irritating aspects of it was the fetishism on hypothesis testing and rather intentional devaluation of hypothesis formation. This resulted in quite a few, extremely intelligent and creative (and subsequently frustrated) people being sidelined and passed over for their (relative) weaknesses in statistical methodology, while their unfairly devalued talents and insights clearly lay in what you call hypothesis formation. I always thought this was a tremendous waste of human capital.

Stephen M (Ethesis) (2008-04-03 18:32:31)

Economists found botulism spores in honey by studying SIDS and diet and data mining. They find a number of things.

## How Things Begin (I Got UGGs!) (2008-04-04 13:44)

Mohamed Ibrahim, the New York schoolteacher who does [1]Behind The Approval Matrix (which I have [2]blogged about) also has a blog called [3]I Got UGGs!. I asked him how the Ugg blog began. Here's what he said:

I have a fetish about Uggs. Whenever I see a girl wearing Uggs, it's the sexiest thing in the world to me. It drives me crazy. You know how they say "do what you love and the money will come later"? I read an article in Time about bloggers and blogging. One of the blogs they profiled was by two ladies who post pictures of kittens and cats and write little blurbs about them. This gave me an idea: I'll do the same thing about girls in Ugg boots. They got \$5-6000/month from ads and all they do is post pics and write blurbs about them. I'll take pics of girls wearing Uggs. Not only will I enjoy it but maybe I can also make some money. I went to Best Buy, got the cheapest digital camera, and hit the streets. The first place I went was Times Square. Initially I would approach people and ask them if I could take their pic for the blog. I discovered later it's better to just take the pic and put it up. That's what I do now. Now I get people sending me pics - they take a picture of their friends or they send me pics of celebrities. We're getting over 500 page views/day. It's only been about 4 months.

The [4]Gawker link Mohamed got by telling them some crazy guy was taking Ugg pics and blogging about it.

## **Interview with Kamran Nazeer (part 1) (2008-04-05 06:54)**

[1]Send in the Idiots: Stories from the Other Side of Autism (2006) by Kamran Nazeer is [2]one of my favorite books. Nazeer works as a policy advisor to the British government. When I found a reason to interview him, I took it.

ROBERTS At a conference of experimental psychologists, I heard about some test results that found that autistic kids did better than non-autistic kids. The researchers were expecting the opposite. They expected the autistic kids to have deficits in processing of faces, how well they can perceive faces. But they found the opposite. That's what prompts this. I spoke to the researcher afterwards, and he said it wasn't the only example. Another researcher has several findings along these lines and parents are fond of the idea that autistic kids have a different set of skills.

NAZEER I'm not convinced that we need to think of these things as polar opposites. I think what's going on is that autistic kids have equal or even higher attention to particular details, or particular kinds of details. There can be two issues; one issue is sometimes that their sense of hierarchy about sense data is different from what we regard as normal. So it may be that autistic kids will regard particular sense data as being more interesting to them

than sense data that might be more socially useful. So they might well pick up just as much, or more, information about people's faces, but it's just not the thing that they focus on. They might focus on something completely different instead. So then, it's a question of how do you change the kid's focus so that the data that all the time they've been taking in is the data that they actually use to form judgments about the world. So I think that that's one thing that happens. I think the other thing that often happens is that, because of language difficulties, even though autistic kids might be picking up equal or higher levels of sense data, they're just not able to articulate to other people, and hence probably not even that well to themselves, what it is that they're perceiving.

ROBERTS You're saying that autistic kids favor some kinds of sense data over other kinds of sense data?

NAZEER Right. To give you an example that I use in the book, which is about Elizabeth, who you might remember is the only girl that I write about. There is this scene in which her parents took her along to a bus stop. It's not that she wouldn't notice that there was a bus coming, and it's not that she wouldn't notice what the number on the bus was; it's that she would also notice who in the queue for the bus had their nails cut, or what color people's sneakers were, or if there was a missing apostrophe in the advertisement on the side of the bus. So, you know, it's not that she was missing out on the crucial piece of sense data, which is "where is this bus going?", but she was not realizing that this was the most important piece of sense data for her at that time, to be paying attention to. So in that sense, she had a different hierarchy.

ROBERTS So you're saying that for other people, where the bus is going would be higher on their hierarchy?

NAZEER Exactly. That's because the non-autistic have a better social sense of what the relevant piece of sense data is at any particular time, whereas an autistic person might have a different hierarchy, or might have no hierarchy at all of sense data. That's what often happens with autistic people when they feel overwhelmed by their surroundings. It's because they're not forming a hierarchy of sense data, it's because they're taking on all the sense data, it's random, and as you can imagine, we're always overwhelmed by sense data. But the reason why we don't feel overwhelmed is because we have a hierarchy for sorting them out. So, when we're sitting and reading the newspaper, we realize that it's the words on the page that are at the top of the hierarchy. When we're standing at a bus stop, we realize that it's whether or not the bus is coming in, what the destination at the front of the bus is that's at the top of the hierarchy. I think that what often happens with autistic people is that they don't hierarchize. Either they don't hierarchize in the same way, or they don't hierarchize at all?

ROBERTS What does it mean, to not hierarchize at all?

NAZEER It means that you just feel overwhelmed by what you see around you, and so you don't know, what if it is useful to you? And so you don't know, what if it is useful to you, so you experience it all as being sort of alien and unsettling. That, I think, is why a lot of autistic people display what I and many other people have called desire for local coherence. So because they're not forming a hierarchy of sense data, which ultimately is the only way in which we can stop ourselves from feeling overwhelmed in the world, what they do instead, instead of forming the hierarchy, they ache for some simple way of bringing order to the chaos around them. So rather than sorting out the sense data, they just pick one thing to focus on, so they pick a pen, or the edge of the table, or they start rocking, or they walk on the soles of their feet. So they take one random thing and put it on the top of the hierarchy, so that

everything else thatâ€™s under it doesnâ€™t overwhelm them any more.

---

a. nonymous (2008-04-05 15:58:16)

I find your habit of identifying yourself only as "Interviewer" in the interviews you post here totally contradictory to the rest of your work. Isn't part of what you're saying/showing that you can't isolate the scientist from the experiment? Shouldn't you be more up front about the fact that it's \*you\* and not some random person doing the interviewing?

seth (2008-04-06 06:43:08)

You might be right. Let me think about it. The interviews are transcribed by someone else – she chose "interviewer". I found it amusing so I left it that way. I like to think that no one could misunderstand who "interviewer" is.

[...] Interview with Kamran Nazeer (part 1) [...]

## **Interview with Kamran Nazeer (part 2) (2008-04-06 07:35)**

ROBERTS I got the sense reading your book that the autistic persons got more pleasure from focusing on small details of things. Those details were comforting. Like a favorite piece of music, or whatever; anything you enjoy is comforting. So when they were uncomfortable, they would go to an unusual place. If somebody likes small details, theyâ€™ll pay more attention to them, simple as that. Because if you donâ€™t youâ€™ll do something else with your attention.

NAZEER We get taught that itâ€™s more socially useful not to focus on the small details. Sometimes we get taught that in explicit ways, or sometimes thatâ€™s just the way things are. So people forget about small details, because theyâ€™re focusing on something thatâ€™s more socially useful.

ROBERTS When you say focus on the small details, you gave an example. The opposite of a small detail is where the bus is going; thatâ€™s sort of a big thing. So whatâ€™s another example thatâ€™s opposite of the small detail?

NAZEER Iâ€™ll give you an example of Craig, whoâ€™s the speechwriter, also in the book. Craig will often find that heâ€™s sitting in a meeting and heâ€™s supposed to be focusing on the political issue or the speech that is the topic of discussion at that meeting. That is the thing that heâ€™s supposed to be focusing on professionally. But heâ€™ll often find difficult is that heâ€™s noticing lots and lots of other small details, as well. He tries very hard to keep his focus where it ought to be, but because he keeps noticing these other small details, they can drag him away from where heâ€™s supposed to be focusing.

ROBERTS Details of the meeting, or details of the argument, or what?

NAZEER It could be that. So he could be seeing a level of nuance that actually isnâ€™t all that useful. Because sometimes when youâ€™re in a meeting, you have to ignore certain nuances to get the bigger points. Or it could just be

sometimes that heâ€™s focusing on the fact that somebodyâ€™s missed a button when they buttoned up their shirt, or that their cufflinks are unusual, or that theyâ€™re flicking their pen. He might notice and focus on things that are completely irrelevant to the conversation heâ€™s supposed to be having.

[...] Interview with Kamran Nazeer (part 2) [...]

### **Tools Not Rules (2008-04-07 05:09)**

I am fascinated by how human nature interferes with science. This [1]article in the Wall Street Journal helped me understand one way this happens.

A civility campaign in Howard County, Maryland, centered on a book called *Choosing Civility: The Twenty-five Rules of Considerate Conduct* (2002) by [2]P. M. Forni, a John Hopkins professor of romance languages. Rule 7, for example, is "don't speak ill." The book bothered Heather Kirk-Davidoff, a pastor. She visited Professor Forni. "Jesus didn't say, 'I am the rule,' right?" she told him. Professor Forni agreed. "Yes, Jesus said, 'I am the way.' If I had met you before, probably I would have used way. The 25 Ways of Being Considerate and Kind," he said.

Hmm. The way versus the rule: similar. The way versus a way: big difference. Neither the professor nor the pastor noted that a better title would omit the: 25 Ways of Being...

The writer of a book about civility – in that very book – fails to grasp a big point about civility. The pastor who points out the problem makes a similar omission. Our tendency to turn tools into rules must be strong.

If you invent a useful tool, you have made the world a better place. If you denigrate non-users, the improvement is less obvious. Randomization, for example, is a tool. Many scientists treat it like a rule. Were I to write a book on scientific method, it would contain a paragraph beginning: "A few years ago, the head librarian of the Howard County, Maryland, county library bought 2300 copies of a book called . . ."

[3]Twisted skepticism.

Andrew Gelman (2008-04-07 08:45:25)

A pluralist is a dogmatist who's been mugged by conformity.

### **The Robot Diet (2008-04-07 06:46)**

The robot works by talking to you about how much you're eating and exercising. It helps people stick to their diets by verbally asking dieters to input data about what they ate on a touch screen. The robot then provides encouragement and advice.

[1]More. [2]Social facilitation effects are powerful. For example, if you are riding a bike with someone else you will be able to go faster and farther than if you ride alone. Next, perhaps: A robot that judges your appearance (praise only!).

Thanks to Dave Lull.

### **My Theory of Human Evolution (frugal materials) (2008-04-08 05:23)**

What's art? The [1]2008 Whitney Biennial at the Whitney Museum of American Art provides an answer – whatever the work of the eighty-odd artists has in common.

The exhibit included some videos, documentaries (Spike Lee), photographs, drawings, and paintings. Most of the work, however, was everyday stuff – what artist [2]Adam Putnam called "frugal materials" – used in unusual ways. Here are some examples:

- [3]bird excrement (Charles Long)
- [4]automotive paint (Daniel Martinez)
- [5]styrofoam and resin (Jedediah Caesar)
- [6]CDs and styrofoam balls (Jason Rhoades)
- [7]drywall (Lisa Sigal)
- [8]rebar and chain-link fence (Ruben Ochoa)
- printed matter (many)

Collages (e.g., [9]Rita Ackermann) are the school-art-project example of this sort of thing. The goals of the artists seemed to be about 20 % beauty, 30 % emotional impact, 50 % novelty. The Biennial also included old technologies used in new ways: [10]Matt Mullican made drawings while hypnotized and then did similar drawings while not hypnotized. An outpost of [11]Neighborhood Public Radio allowed anyone to be on the air for an hour.

[12]As I've said, I believe the tendencies behind art evolved because they generated material-science research. The tendency to make art caused some people to make new things that required control of materials but weren't obviously useful; enjoyment of art meant that others would trade for what they'd made, allowing artists to spend more time making art. A premium for novelty kept artists on their toes; it pushed them to find new ways of making things. Wandering around the Whitney Biennial, these ideas seemed easy to believe.

Mike Kenny (2008-04-08 15:34:02)

I can see beauty as being obviously valuable, and novelty as useful research. What's your take on why emotional impact is a goal of the art? Are the artists trying to show empathy and therefore their value, or learn about the psyche by creating something that stimulates reactions? Part of me wants to say artists might be precursors to psychologists. Maybe market researchers too? :)

nathan (2008-04-09 06:53:44)

i agree, and i happen to procrastinate a lot.

### **In the Google Cafeteria (2008-04-09 07:20)**

I recently had lunch at the Google New York cafeteria with [1]Tom Ritchford, whom I met at a Toronto hostel while helping Sarah Kapoor make [2]a CBC segment about the Shangri-La Diet. No company personifies the Internet more than Google. Eating the wonderful free food at their cafeteria was like reading The New Yorker online. A this-can't-be-happening experience.

Most successful dish: Orange Marmalade Whipped Cream.

Least successful: Thyme Nectarine Water.

Tom works at home three days a week partly to avoid the cafeteria, which caused him to steadily gain weight.

### **Self-Experimentation and Murphy's Law (2008-04-09 10:45)**

While studying Air Force records [in the 1940s], Dr John Stapp realized that simple, everyday car accidents â€” not plane crashes â€” were responsible for a huge proportion of pilots' deaths. Dr Stapp decided to test the limits of humans' ability to withstand an impact to demonstrate the need for proper restraints in airplanes and in cars. One of the tests, in 1954, in which Dr Stapp, "the fastest man on earth," rode a rocket-powered sled from zero to 1,019 km/h in five seconds and then came to complete stop in 1.4 seconds, temporarily blinded him due to retinal hemorrhages, broke both of his wrists and caused other injuries. In an earlier test, an engineer named Edward Murphy managed to install both of the two sensors incorrectly, rendering the data useless. "If there are two or more ways to do something and one of those results in a catastrophe, then someone will do it that way," Captain Murphy declared after seeing Dr Stapp emerge from the sled bloodied and hurt, spawning his famous law.

From [1]a very good article about self-experimentation.

zero to 633.177245 mph in 5 seconds...yikes

### **How Bad is Dairy? (2008-04-10 11:37)**

A most intriguing comment on Tim Ferriss's excellent post about [1]how to sleep better:

To require less sleep and yet still feel awake, energetic and not sleep deprived in general:

The single biggest factor for me has been the elimination of all dairy products from my diet. I have experimented with this over 4 years now and it is clear the most benefit is achieved with the most radical approach to this. In other words, removing dairy products completely from my diet has the biggest benefit. Yes this means no chocolate, no products with whey in them, no milk, yoghurt etc etc. it's also interesting to see how difficult this is to do, but the benefits are so astounding from an energetic lifestyle point of view that I do it for long periods of time at a stretch.

Huh. Cheese makes me sleepy, so much so that I use it to fall asleep on planes. I didn't always understand this. Several years ago, I was in New York and bought expensive tickets to a Broadway show. Before the show I ate some cheese - samples at a store, maybe. During the show I fell asleep.

1. <http://www.fourhourworkweek.com/blog/2008/01/27/relax-like-a-pro-5-steps-to-hacking-your-sleep/>

---

david (2008-04-10 14:15:10)

I never fall asleep after eating dairy...the sharp intestinal pains keep me awake! Oh, another reason to reconsider dairy is all they feed the cows now to keep them alive on the diet of corn that they were never meant to eat. Hmm...might be interesting for someone who can tolerate dairy to do some experiments with dairy from corn fed cows, "organic" non-drugged, but still corn fed cows, and grass-fed, non-drugged cows.

Peter (2008-04-10 14:57:43)

Seems to me that some people are allergic/sensitive to dairy, and some aren't. I can eat cheese without any noticeable effects. Of course the last time I ate cheese (the other night) it was made from milk produced by goats that I've met, and they eat mostly grass or whatever is growing in the pasture supplemented with organically-grown alfalfa.

Mike Kenny (2008-04-10 16:20:16)

Huh, is milk meant to relax and put babies to sleep? Makes some intuitive sense.

seth (2008-04-10 18:27:44)

yeah, great point, Mike.

Caleb (2008-04-10 20:55:10)

casein (milk protein) has opiate-like qualities.

david (2008-04-11 07:51:15)

Got Opium?

Pearl (2008-04-11 10:39:12)

Cheese is and always will be the greatest creation on Earth, for me. It has never made me sleepy, rather it regularly makes me the happiest being imaginable, and I eat it whenever possible. I would only be willing to believe that it affects some negatively and other not, or perhaps that strengths of fermentation could play a role in negative effects; I recently read that strong fermentations can aggravate candida. Perhaps it is opiate-like for me, although elimination from my diet upon moving to Japan did not make me energetic, it only made me incredibly grumpy. Reclaiming cheese made me happy once again. Cheese!

Timothy Beneke (2008-04-11 12:30:52)

Fascinating - raises the whole question of the relationship between diet and sleep quality and need; and then is that a confound that influences all the correlational findings on which nutritional claims are based? We know that quality sleep is tied to good health...

Aaron Blaisdell (2008-04-11 16:44:22)

My experiences mirror those of Pearl. Cheese keeps me awake and happy. Since reading Good Calories, Bad Calories about two months ago, I have dramatically increased my consumption of hard cheese, whole milk (organic, presumably corn-fed), cottage cheese, and yogurt. Likewise, I have dramatically reduced my consumption of most sugars, refined grains (still eat whole wheat bread and pasta), white rice, etc. I used to require a nap in the afternoon (after a meal containing a fair amount of carbs). No more! I feel FULL of energy, more so than ever in my life. I've always been a day dreamer in class, with a poor ability to control my mind wandering or feeling "hazy" or sluggish. I now RARELY experience these feelings of lethargy. Instead, I feel much more alert, awake, high-energy, up-beat, etc. I'm sure many people have adverse reactions to dairy, but not me. There seems to be overwhelming evidence for individual differences in how people react to dietary content. I actually used to think milk was an issue for me (for other reasons) and tried to eliminate it from my diet. At the same time I continued to consume carbs, including from refined sources in large quantity. I didn't feel any better, though. The only change to significantly improve my health and well being has been to drastically reduce carbs, in particular refined carbs. Increasing my consumption of animal protein and fat, including lots of dairy has if anything helped (but it is difficult to say for sure since I made both changes at the same time).

NICOLE (2008-05-02 15:48:13)

dairy products inhibit digestion-this is the major health concern. if you don't want to give up meat or dairy, try organic or kosher products. the animals are killed as humanely as possible. additionally, on a spiritual level, if an animal is tortured prior to death, this can be be very traumatic. if you are consuming the remains of an abused animal, chances are you are also ingesting the trauma and suffering that the animal experienced.

NICOLE (2008-05-02 15:50:19)

check out the book: skinny bitch. just google it. tons of nutrition info and pro-vegan resources

k (2009-09-21 23:10:50)

cheese undoubtedly makes me sleepy, there's a direct connection. i'm trying to figure it out that's how i found this blog entry

Vivek (2010-06-18 11:04:38)

Slept at around 11 pm last night. Woke up at 8 all fresh and chirpy. Ate 2 slices of cheese and a bowl of cereals and there I go!! Slept for 7 hours straight. And I realised something must be wrong- I googled it and I found this blog

Eri Gentry (2011-01-26 22:19:33)

I have used yogurt (plain, fat-free) as a sleep-aid in the past, though its effects were not 1:1. Cheese tends to make me feel strange: not exactly sleepy but similar in that it makes me less able to think clearly (fuzzy mind, sometimes dizzy body - reminds me mostly of the effect from L-Tyrosine when I wasn't used to it). Some cheeses (ones with bolder flavors, perhaps fat or mold) cause this effect more than others. For example, a benign cheese for me is low-fat mozzarella. A friend suggested a Tyramine sensitivity. No idea. Overall, I'm happy to avoid cheese :)

## **Brave New SLD World (2008-04-10 15:19)**

The blogger behind [1]voluntaryXchange ([2]nice name) has been on the Shangri-La Diet for two years.

I gave a positive report after one year. After a second year I'm supposed to give you a second report that I've gained all the weight back. Sorry about that - I've had only the smallest rebound. Maybe I'm wrong, but I attribute that to not having played a racquet sport on Saturdays in the last 9 months. I still have no confirmable side-effects. I had a couple of cavities - that might be something. I think I'm more inclined to doze off when I'm tired, but that could be middle age too.

Compare that to weight loss from conventional methods in the wildly-expensive study I [3]mentioned recently. Two years after starting, subjects in the no-intervention group had regained about half of the weight they'd lost.

1. <http://voluntaryxchange.typepad.com/voluntaryxchange/2008/04/shangri-la-diet.html>
2. <http://www.blog.sethroberts.net/2007/06/27/my-theory-of-human-evolution-directory/>
3. <http://jama.ama-assn.org/cgi/content/abstract/299/10/1139?ct>

---

Stephen M (Ethesis) (2008-04-11 06:12:42)

I was 245 when I started, got down to 167, hurt my shoulders and had to quit Judo, stabilized at 189. When I exercise more, my weight begins to drop, if not, it slowly glides back to 189. I'll be at three years in November, 2008. I find that when I'm low carb (not excessive no carb, just doing without sugar) I don't doze off in the afternoons. Not sure what that is about. I sleep a lot better. But I'm glad to see other people enduring with their weight loss. With significant exercise I lose weight on two tablespoons of oil a day, without exercise in any meaningful amount, I'm stable with three tablespoons. I find it interesting how exercise makes such a difference when I'm on SLD, not as much when I wasn't.

Stephen M (Ethesis) (2008-04-11 06:50:48)

I should note that my "after" picture was taken at 189 - I look the same today as when that was taken.

david (2008-04-11 07:36:38)

I originally did SLD in October 2005 using [whatmakesfoodfattening.pdf](#) posted on the Freakonomics blog. I started at 170, used sugar water SLD for about three (not every day though) weeks and got down 145. Decided that was too much and let myself gradually go up to 150. Stayed there until recently. I noticed I was creeping slowly back up to 155, so I did sugar water a couple of times and am back down. No cavities in the past 2.5 years. I also do nose clipped Flaxseed oil a few times a week for the omega 3s. So after 2.5 years, it still works for me. I too doze off sometimes in the afternoons, but then I also quit all forms

of caffeine about a year ago to self-treat nighttime teeth grinding.

### Interview with Kamran Nazeer (part 3) (2008-04-11 06:31)

ROBERTS This is a big theme of your book, right, sort of a difference in attention. To my way of taking it, you didn't have any lesson you were trying to teach the readers of your book. You were just trying to tell four stories, or five stories. But reading the stories, someone like me says "Oh my God, how can this be?" Not exactly that, but I felt like this wasn't something that was supposed to be. There was a recent piece in the news about how kids who are disruptive in kindergarten grown up fine; they grow up without problems. One of the founding assumptions of our society is that things that we say are bad are harmful. They go together so well, right: harmful and bad? If your child has a problem, then presumably they're going to grow up in some kind of bad way, and something bad is going to happen to them as an adult. But your book didn't support that assumption, because these kids grow up to be unusual adults, but not terribly impaired, or anything. Is that a fair reading of your book?

NAZEER I think that's a fair reading. The gloss that I think I would add to it is what happened to them in childhood was incredibly important. What was important about it was all the people in the book, what they have in common was that they all received the diagnosis very early on and received very early and very good intervention. That was fundamentally important to their success in later life. So autistic kids who don't get the diagnosis early on, and don't get the help that they need — and I'll resist the word deficits, because I don't think they are deficits — to understand the world better and to overcome the kind of differences that they have, then those kids actually do struggle. Whereas I think the kids in the book struggle less because they were lucky enough to get a diagnosis early on and get very good help early on.

ROBERTS I see. So this was unusual, the timing of the diagnosis.

NAZEER It's usual now. It's now thankfully becoming much more common for kids to be diagnosed at the age of three or four. It's now becoming much more common for kids to actually get a decent level of education. It's still not common enough, but it's much more common than it was in the early 80s, when we were all at school.

ROBERTS What would have happened if the level of schooling had been worse, or less appropriate?

NAZEER I think it would have taken them a lot longer to overcome — and I don't use this word in a perjorative way — overcome their disabilities. It would have taken them a lot longer to develop their language abilities, to develop useful hierarchies of sense data, and develop a sense of confidence about themselves, which I think is really fundamentally important as well. I think one of the big benefits of early intervention for autistic children is they begin to get a sense of things that they can do. And getting a sense of things that you can do then in turn builds a sense of confidence in yourself. So it means that even when you're 13 and you've had a really really bad day, you can still remind yourself that you have had moments of progress, and there are things you can do at 13 that you weren't able to do when you were 11.

ROBERTS What is an example of these things that you can do?

NAZEER Sometimes it can be very, very simple things. For Elizabeth, it was things as simple as teaching herself how to ride a bike. For somebody who perhaps was at the higher-functioning end of autism, somebody like Craig, that sense of confidence came from being able to write a good essay. So even though he might have still very profound

social difficulties, because he knew that there was this thing that he was good at doing, that gave him a certain sense of confidence, even when it came to activities that he found much more challenging.

ROBERTS So you're saying the way he was taught helped him to be confident, because somehow, his ability to write an essay was stressed, or something? Is that what you're saying?

NAZEER Right. I think that's what I'm saying. I think, in that sense, autistic young people aren't any different from anybody else. I think, ultimately, nobody ever becomes brilliant at everything; we all become decent at some things, but being decent at some things gives us the confidence to try out things that we're not so good at.

ROBERTS I think you're right. I think that's the incredibly important thing about education: to help people figure out that there are some things that they're good at.

NAZEER People end up being good at different things. That is what I think — your deficit and difference opposition comes into play, which is that autistic people may well be different — may well be good at other things to other people. But as long as they get to the position where they feel comfortable, capable, and confident in doing some things, then that gives them confidence in functioning socially.

ROBERTS So they need schooling in which their abilities are recognized and developed and encouraged.

NAZEER That's right.

ROBERTS That's what you seem to be saying: that if autistic kids have different skills, then they have to have teachers who know how to develop and recognize those skills.

NAZEER That's exactly it.

## **My Theory of Human Evolution (the cellphone effect) (2008-04-11 23:39)**

In poor countries, cellphones have [1]a big anti-poverty effect:

Jan Chipchase and his user-research colleagues at Nokia can rattle off example upon example of the cellphone's ability to increase people's productivity and well-being, mostly because of the simple fact that they can be reached. There's the live-in housekeeper in China who was more or less an indentured servant until she got a cellphone so that new customers could call and book her services. Or the porter who spent his days hanging around outside of department stores and construction sites hoping to be hired to carry other people's loads but now, with a cellphone, can go only where the jobs are. . . . Over several years, his research team has spoken to rickshaw drivers, prostitutes, shopkeepers, day laborers and farmers, and all of them say more or less the same thing: their income gets a big boost when they have access to a cellphone.

This is exactly the effect I propose that the very first words had: They helped two traders find each other. Having a word for knife made it much easier for the person who had a knife to trade to find someone who wanted a knife. I was in Guatemala when I ran out of contact-lens solution. Not knowing the Spanish term for it, it was extremely hard to find. Once I knew the Spanish term, it was very easy to find. In a Guatemalan market, I heard a man shout "toothpaste" (in Spanish) over and over. He was selling toothpaste.

I think the first words were also the first names; You became identified by the name of what you were good at making (and therefore had to trade, since you made many of them). This information spread, like a cellphone signal, from tower to tower: From one person to another. If you were Mr. X, and someone wanted X, and they said so ("X?"), someone would point them to you. All it took were single words.

Later in the article, Chipchase responds to the author, who wonders if more technology is always better. "People once believed that people in other cultures might not benefit from having books either," he says. I would go further: Not having cellphones is like not having language.

1. <http://www.nytimes.com/2008/04/13/magazine/13anthropology-t.html?ei=5087&em=&en=e46d649779a0b9be&ex=1208145600&pagewanted=all>

---

Chris B. (2008-04-14 06:50:54)

"This is exactly the effect I propose that the very first words had: They helped two traders find each other. Having a word for knife made it much easier for the person who had a knife to trade to find someone who wanted a knife. [...] In a Guatemalan market, I heard a man shout "¡toothpaste!" (in Spanish) over and over. He was selling toothpaste." Yet there's evidence that some higher primates have vocalisations associated with particular objects - types of food for example. Yet they don't trade. What they have may not be language, but it would be as much language as your toothpaste man is using.

seth (2008-04-14 11:31:15)

Thanks, Chris, interesting point. The toothpaste man is using a system that has thousands of nouns. (And can easily make room for even more.) The higher primates have just a few object-specific vocalizations. I'm saying that the many-noun system evolved because of trade. If you have a lotta stuff to trade you obviously need a more flexible system - I think the word is "scalable".

Seth's blog » Blog Archive » My Theory of Human Evolution (directory) (2008-04-28 05:27:59)

[...] I Recommend material-science research) the cellphone effect (the first words facilitated trade) micropygms (hunter-gatherers w/ trade different from those w/o trade) [...]

## Ask Your Dentist Some Pointed Questions (2008-04-12 06:59)

[1]This video, about mercury exposure from amalgam fillings, is all too convincing. Ugh.

1. <http://www.youtube.com/v/9ylnQ-T7oiA&hl=en>

---

Chip Morris (2008-04-14 02:58:31)

There are serious doubts about the validity of this video. See "this post":<http://quackfiles.blogspot.com/2005/04/smoking-teeth-truth-gets-smoked-out.html> for a good analysis of the video. Also, "QuackWatch":<http://www.quackwatch.com/0-1QuackeryRelatedTopics/mercury.html> has a general article on mercury amalgam fears/hoaxes.

seth (2008-04-14 05:56:06)

Thanks, Chip, that's helpful. As for the Quackwatch article, it's by Stephen Barrett. My mom told me he criticized a website named Planetree that helps average people get medical research information. I suppose he felt they couldn't be trusted with it; the details of his criticism are no longer on Quackwatch. Given that attitude, I don't take him seriously. I'd guess the criticism of the video is right. But I also think the video probably makes a correct point: mercury probably does leak from your mercury

amalgam fillings into your body.

Alex C. (2008-04-14 08:29:05)

I e-mailed IAOMT to ask them about this question of mercury vapors rising vs. falling. I have quite a few amalgam fillings in my mouth, so I want to get to the bottom of this. I'll post another comment if and when I get a response from them. As for Stephen Barrett, he tends to go after the easy targets. I'd have more respect for him if he exposed the pseudoscience behind more-conventional treatments that have no basis in science.

seth (2008-04-14 17:23:03)

Thanks, Alex. Among Barrett's many dislikes is the Weston Price Foundation.

Tom (2011-06-29 09:33:14)

The **only** reason anyone listens to Stephen Barrett is because he bought a great URL. More really ought to be required.

### **Jane Jacobs and Collapse (2008-04-12 08:57)**

Soon after it was published, I listened to an audiobook (abridged) version of [1]Collapse (2005) by Jared Diamond. It is about how several societies destroyed their ecosystem and died. One example was Easter Island; the islanders cut down all the trees, and disappeared. The whole book was meant as a warning, of course: This can happen to us. At first I liked it – interesting stories. Then I heard that Jane Jacobs didn't like it. I was unable to find out why. I began to wonder what I'd missed.

Now I can guess what she'd say: "Collapse doesn't make clear that overexploitation has been avoided countless times. That is the usual outcome. Even before cities, humans were constantly creating new ways to make a living, which decreased reliance on the old ways."

I could make a video that shows Michael Jordan missing 20 free throws in a row. Every moment would be true but the whole thing would be false. That's not far from what Collapse does – at least the audiobook version.

1. [http://en.wikipedia.org/wiki/Collapse:\\_How\\_Societies\\_Choose\\_to\\_Fail\\_or\\_Succeed](http://en.wikipedia.org/wiki/Collapse:_How_Societies_Choose_to_Fail_or_Succeed)

---

Peter (2008-04-12 14:12:10)

this is a really lame 'criticism'. it's like the "you're not reporting on the \_good \_ news" criticism of media coverage of Iraq. The analogy is too close for comfort, and i'm very surprised - possibly even disappointed - to read it here. I believe that most of the people who criticize Diamond and his work are jealous that he's achieved remarkable success and popularity, and his work stands up, which makes a lot of people who think they are really smart - look bad. Lots of other people, however, \_love \_ Diamond, and for good reason. He's not petty - he just does what he does, and reading what he's written and watching the shows he's been on - it's very clear that he does his work, at least in part, in the service of humanity. Of course, the book is titled 'Collapse: How Societies Choose to Fail Or Succeed". Now, I'm not a very educated person - I don't have a PhD - and I don't know much about anthropology and literary criticism, but the title leads me to think that this particular book might be about the \_collapse \_ of civilizations, as opposed to maybe the \_triumph \_ of civilizations. But that's just me. I wouldn't expect a book on bicycles, or on the nature of clowns, and I wouldn't be so pretentious as to tell someone they wrote their book 'incorrectly' - they should have talked to \_me \_, first. Instead, I would write it myself. And if i couldn't write it myself, I would not lob hand grenades in a ham-handed attempt to try to bolster my own public image. If I just didn't like the book for some

inconsequential reason - like it didn't use the proper font or something - I would just tell the truth. I would say: "You know, this is a good book, but I did not like it because I prefer books that avoid attempting to drive home the seriousness of the situation so as to act as a warning, but instead try to alleviate our fears about our collapsing environment so that we can be lulled back to sleep, if we weren't already. But that's just me." Or... "You know, this is probably a great book for some people, but I hated it. It spent far too much time talking about how the occupation of Iraq was being lost, and not nearly enough time talking about how the occupation of Iraq was being \_won\_. But, you know, that's just my opinion." There are lots of books about the Romans. This book, however, seeks to provide a comprehensive analysis of those factors which lead to the collapse of any civilization. It is \_not\_, obviously, intended to act as a cheerleader for civilizations that have managed to continue to exist either by design or by chance. This book is a warning and reference and analysis that can be used by regular people, citizens, public policy planners, central planners, and politicians to stave off the collapse of one particular country/society - the good old US of A. Now, if Diamond is wrong - say so. If his logic is flawed or his theories nonsensical or his writing just utter crap, then say so, but don't waste my time with some overly-qualitative, essentially-meaningless, personal preference that has nothing to do with the central theme of the book. It's petty, bad style, and it does not help 'the cause'. You'd be better off criticizing the color of the book jacket. Would we take seriously criticism of the Shangri La Diet that suggested that it did not spend enough time talking about how thin people stay thin without the need for dieting? It's absurd. If we want to read everything about everything without diving too deeply, we go to Wikipedia, not the local book store. >8-(

seth (2008-04-12 15:02:01)

Peter, okay, why do you think Jane Jacobs didn't like Collapse? It's quite possible I'm wrong, that she had a different reason. I'm sure it wasn't jealousy, however.

Ben Webster (2008-04-12 21:47:43)

Not only is it lame criticism, it's actually wrong. Maybe Diamond didn't emphasize the point enough for your liking, but he does discuss why Greenland failed and Iceland and the Faeroes didn't, and which differing factors amongst Polynesian Islands led to success or failure which sounds like....exactly what you were saying he should have written about.

seth (2008-04-13 05:45:48)

Ben, thanks for those examples. Yes, I knew Diamond described successes as well as failures. If successes outnumber failures 1000-to-1, and a book describes 5 failures and 5 successes it's not so obvious that book has done a good job. In any case, I was trying to figure out what Jacobs didn't like about it. Do you have a better idea than mine?

Aaron Blaisdell (2008-04-13 09:27:02)

I guess someone could always ask her why she didn't like the book. Many comedies are based on one person wondering why another person did what they did, and drawing the wrong conclusion - which leads to an embarrassing culmination (A man suspects his wife of cheating on him based on a few snippets of odd behavior he exhibits. She hatches a plan to catch him in the act, and her plan unfolds only to discover he was planning a surprise birthday party for her which she ruins due to acting on her suspicions). Many tragedies are based on the same thing but with tragic results (Romeo & Juliet is a great example). Sometimes a direct confrontation can stave off useless or even misleading speculation. But the process of speculation (basically hypothesis generation) can be so much fun I guess we are all often tempted to engage in it! Why did the chicken cross the road. (speculation: there must be a rooster on the other side!)

seth (2008-04-13 14:50:32)

I wish I could ask her! But I don't trust Ouiji boards.

Peter (2008-04-14 00:23:40)

Peter, okay, why do you think Jane Jacobs didn't like Collapse? As a commenter suggested, we should first try to figure out what she actually thought and or said about Collapse - if anything at all. We know something about what she thought about GG & S: From p. 19 of 'Dark Age Ahead', Jane Jacobs writes: "Diamond's analysis of winners and losers, elegantly precise and predictable wherever the forces at work were geography, climate, plants, animals, microorganisms, and demography, turned

mushy and unreliable as soon as human decisions entered the equation. Yet, as he himself was the first to admit, a science of human history that omits the behavior of human beings is an absurdity. His brilliant analysis, as is, explains most outcomes of unequal contests between cultural winners and losers. But I think he limited its explanatory power unnecessarily by the way he posed his initial question: 'What are the advantages that enable cultural conquerors to win conflicts with losers?' The first part of her book basically paints JD as the Second Coming, so I wouldn't expect jealousy would get the better of her. I only know about JJ what I read here, what I read in wiki, and what i've been unable to find via Google - any criticism of Collapse. I only know of critics of JD what I read all over the web a few months ago - dozens/hundreds of his colleagues crucifying him with anonymous comments at annual conferences. The wiki review page talks about the anonymous review in the Economist that is 'generally favorable', but that criticizes the book on a couple of counts, one suggesting that Collapse is not 'optimistic enough'. Does that actually mean anything at all? [http://en.wikipedia.org/wiki/Collapse\\_\(book\)#The\\_Economist](http://en.wikipedia.org/wiki/Collapse_(book)#The_Economist) [http://www.economist.com/books/displaystory.cfm?story\\_id=E1\\_PVVVRJQ](http://www.economist.com/books/displaystory.cfm?story_id=E1_PVVVRJQ) So, given Jacobs' heavy praise of Diamond in her book, Dark Age Ahead, the tone of this review does not seem like it would be her. But who knows? More reviews, here: <http://www.metacritic.com/books/authors/diamondjared/collapse> So, let's forget about whether Jane Jacobs said anything about Collapse or not, and concentrate on Seth's review. Does it make sense to criticize, say, a zombie movie because it has too much killing? A hot fudge sundae because it has too many calories? A book about the collapse of societies because it has too many stories of...collapsing societies? I'm gonna argue 'no'. So, take this particular line: "doesn't make clear that overexploitation has been avoided countless times" Should Diamond have gathered a count of Failed vs. Survived societies throughout the history of mankind, and then finding that more societies survived than failed (true? false?), provided a more reassuring message to the masses - "but don't worry - this \_probably\_ won't happen here"? Should he have added to his book a analysis that would have provided a Pentagon-like statistical likelihood of the collapse of American society? It just doesn't strike me as valid criticism - or particularly meaningful criticism. It's like criticizing your soon-to-be-daughter-in-law because she decided to attend Michigan instead of a true Ivy League school. I could be wrong, no doubt - I often am - but a book is just a book - it can't be all things to all people - and you wouldn't want it to be - else you end up with an intractable tomb of pseudo-scientific babble - something not completely dissimilar from The World is Flat. :-D Had to get that dig in. But seriously - is the book being unfair? Did Katrina not just happen? Did I not just see bodies floating in the streets? Are the polar ice caps not melting, and water levels rising, and islands disappearing, and societies already collapsing? Are we not locked into our horrendous suburban nightmare of asphalt and pollution and oil dependency? Are India and China not industrializing like crazy? Are people not starving? Are large swaths of the lower-48 not drying up? Is ocean pH not acidifying? Did Arnold not just declare a state of emergency because the salmon disappeared? Are many and serious scientists around the world not calling for drastic national policy changes across the board, across the world, to avoid complete ecological collapse? Is not ecological disaster already occurring - the only thing left to decide is whether or not it actually does wipe us out completely? I don't know Diamond's intentions in writing the book, but I kinda doubt it was to suggest we should all tuck our heads between our legs and kiss it all goodbye. I prefer to think he wrote it in the spirit of humanity, which his previous book/articles/shows demonstrated. I have a feeling that Diamond believes that we can, in fact, survive. The "has been avoided countless times" phrase, to me, is really just a repackaged "don't worry about it, nothing to see here, keep consuming, move along". Anybody can write whatever book they want - and anyone can offer any criticism they want - but they should do it with an appreciation for the context of the times. If Collapse doesn't go out of its way to give us all a warm fuzzy about how everything will \_probably\_ be alright, then I'm not gonna be all that upset about it, because I know this is exactly what the people who own this country would want - they want us to go back to sleep, to mind our own business, and stay out of the affairs of learned men.

Nansen (2008-04-14 18:56:45)

Jacobs writes in Dark Age Ahead (p. 24-25): "It may seem surprising that I do not single out such failings as racism, profligate environmental destruction, crime, voters' distrust of politicians and thus low turnouts for elections, and the enlarging gulf between rich and poor along with attrition of the middle class. Why not those five, rather than the five [community and family; higher education; science and technology; taxes and governmental powers; self-policing by the learned professions] that I have selected to concentrate upon? Surely the second five indicate serious cultural dysfunction. Perhaps my judgment is wrong, but I think these second five are symptoms of breakdown in the five I have chosen to discuss." This suggests that Jacobs would not fault "Collapse" so much for its cherry-picking, but rather for misdiagnosing the nature of the problem.

seth (2008-04-14 19:51:35)  
Good point, Nansen.

Peter (2008-04-14 22:37:57)

Here's a review that criticizes 'Collapse' for being too optimistic: <http://www.richardheinberg.com/museletter/154> A second disappointment that readers already familiar with the subject matter may encounter with Collapse is the perception that, while the author is warning us that modern industrial civilization may be headed the way of the Classic Maya or the Easter Islanders, he seems satisfied with this warning. He offers, in essence, a message of the type we have come to expect: Humanity is undermining its ecological viability, but there are things we can do to turn the tide. Indeed, Diamond predictably devotes the last section of his last chapter to "reasons for hope," leaving the reader with evidence for thinking that collapse will not occur in our own instance after all. ... Suggest that it's possible to avert complete disaster, and you're basically making the case that you're OK with things as they are. But talk too much about collapse, and well, you're not being optimistic enough. I guess winning the Pulitzer is a bit like winning the Heisman - something to be avoided. One point to recognize, I think, is that Collapse focuses on collapses that have had at least an environmental component to their failure. It looks like Jacobs' book 'Dark Age Ahead' considers all societal failures. Seems like it might be a chicken/egg problem to a certain extent, too. Is our environment being wrecked because most Americans want it? No, of course not - but it helps that we have a dysfunctional government. Is our government more dysfunctional than any other has ever been? I'll have to read Jacobs' books. Not crazy about those '5 pillars'. To me, for instance, 'family' and 'community' are easily separable and are mostly mutually exclusive in America today. The 'higher education' and 'intellectual subservience' make me think we're attempting to put too much stock in intellectuals to save us or any other society. Haven't intellectuals always been servants of power? Here's Diamond at UCSB: <http://video.google.com/videoplay?docid=3641551737596451012>

thekingofcheap (2009-04-27 08:03:04)

Isn't Jacobs referring to "Guns Germs & Steel" in Dark Age Ahead? Guns Germs & Steel might rightly be criticized for taking the social elements out of an examination of societies. However, Diamond bases his arguments on the assumption that cultures adapt to and become rooted in their specific environments. Collapse is the extension of Guns, Germs & Steel, an attempt to add human culture to the equation. (In Guns, Germs & Steel, he does briefly address this topic, though, when he illustrates Australian aboriginals, who were given the technology for bows and arrows and rejected it.)

## **Interview with Kamran Nazeer (part 4) (2008-04-13 06:09)**

ROBERTS What about your case? Did that happen in your case? Your special skill seems to be language, but — what do I know?

NAZEER Yes, maybe that's it. It's a certain kind of precision of expression. Or not even a precision of expression, but an agility of expression, which for me, in the first place, came about because of learning how to write well. Then, from learning how to write well, it turned into being able to speak well about particular topics. Whereas I'm not so good at being in a meeting with 12 people and trying to get what I want out of that meeting, I'm better at writing a very persuasive email to 12 people.

ROBERTS A less-useful skill. So your teachers recognized your language ability, your early teachers?

NAZEER No, because at that stage I didn't have it.

ROBERTS You didn't have it?

NAZEER What my early teachers helped me to do was to develop it, was to put me on the first steps of the ladder towards having it.

ROBERTS What did they do?

NAZEER Well, to begin with, it was very simple things, like giving, kind of forcing me to say particular words, showing me flash cards again and again until I would use particular words, beginning by kind of letting me be able to point to things when I wanted them and then actually withholding them until I would actually say the name of the thing. So there were techniques of that sort. There were also techniques of encouraging me to talk to other kids in the school who were at a similar position in their language development to me, so that we weren't being over-awed in talking to much more linguistically agile kids, or fully linguistically developed adults, but in fact we were talking to people who were in a similar linguistic position to ourselves. That helps linguistic development.

ROBERTS So you're saying that, by certain measures, you were linguistically behind. Your language development was retarded relative to other kids.

NAZEER It certainly was. I didn't start speaking until I was about 6 years old.

ROBERTS It wasn't because you thought it was boring, or anything.

NAZEER No, not at all, no, no.

ROBERTS So somehow, at some point, you caught up. Is that true?

NAZEER Yes.

ROBERTS So at some point, you caught up. You started off more slowly, and then you caught up, and then you surpassed.

NAZEER I'm not sure I surpassed, but yeah, I'll agree with the 'caught up' bit.

ROBERTS Well, you wrote a book. Very few people write a book, and not only that, your book is very well written, which is much rarer.

NAZEER But I chose to focus on writing as a skill that I wanted to develop and I worked hard at it in the same way that somebody else might focus on becoming an electrician, and work very hard at it, and they'd become much better at wiring than I'd ever be, possibly. But for me, writing is very much that thing; it's a craft. It's something I decided I wanted to be good at, and then I spent a lot of time learning to be good at it.

[...] Interview with Kamran Nazeer (part 4) [...]

### **Interview with Kamran Nazeer (part 5: the end) (2008-04-14 05:21)**

ROBERTS You enjoyed reading, I assume.

NAZEER Yes. That's true.

ROBERTS So your language development was retarded, even though you enjoyed reading. That's unusual, I would think.

NAZEER I certainly didn't enjoy reading at that age. I didn't read much at all when I was a kid. I started reading a lot more when I was older.

ROBERTS Reading was something that you discovered you enjoyed relatively late in life.

NAZEER Yes.

ROBERTS So, while the other second graders are reading their books, you were not.

NAZEER No, I wasn't.

ROBERTS Huh. So, did you have any other abilities? I think it's common enough for people to develop late. There's a word for it: late bloomers. We don't normally hear this word in reference to autism. But you know more about it than I do. Is this a common developmental trajectory in autism? The person starts out slow, but slowly and surely passes everyone else?

NAZEER I'm not sure about the passing everyone else, and I'm not sure that's the case with me, either.

ROBERTS Well, you are an extremely good writer.

NAZEER I chose to focus on a particular skill. What you're seeing is the result of me having chosen to focus on that. So I'm more uncomfortable with the surpassing idea, but on your idea of developing late, I think that probably is true. I think that autistic young people find it very, very difficult to develop certain skills, but with the right support, they can develop them; they just often develop them much later and much more slowly than other kids.

ROBERTS Well, it helps to have many different kinds of people in the world, with many different kinds of brains, because we need many different skills to have a well-functioning economy. So from that point of view, the fact that autistic kids have different skills, or different abilities, letâ€™s put it that way, makes a lot of sense, because then theyâ€™ll grow up to be adults who can do things the result of us canâ€™t. But thatâ€™s really different from the idea that theyâ€™ve got a handicap that theyâ€™ve got to spend the rest of their life trying to overcome. Your story, in your book, suggests there are certain things that autistic kids can do as adults that other people canâ€™t.

NAZEER I donâ€™t think I am suggesting that.

ROBERTS You probably didnâ€™t write the book with that in mind, obviously, but do you think thatâ€™s fair?

NAZEER No, I think, on the whole, itâ€™s not fair because most autistic adults, even as adults, even though they might have developed the confidence to do certain things well, experience often quite profound difficulties. Everybody whoâ€™s in the book still has quite profound difficulties of one sort or another. So I donâ€™t think itâ€™s at all the case that all autistic adults, or even most, completely overcome the difficulties that they have. But that said, I think there is particular aspects of the condition of autism which might mean you have a particularly good focus on detail, which might suit you very well for certain types of jobs. It may mean that you think in a very structured way, which again, may suit you for particular jobs. I think another thing that comes about for autistic people is because they know that they have to work harder at things than other people, that kind of leads to a certain determination and resourcefulness and kind of reliance on being logical, which again, suits you for certain kinds of jobs.

ROBERTS Thanks very much for your time.

NAZEER Thanks, it was an interesting discussion.

## The Secret Non-Shame of the Shangri-La Diet (2008-04-15 11:45)

Before I wrote The Shangri-La Diet I anticipated the diet would reduce hunger and weight and increase peace of mind but [1]this surprised me:

So far, I have told NO ONE what I am doing, not even [my husband]. A couple of my teens (I'm the mother of 3 teenage boys, ages 19,16 and 15) have walked into the kitchen as I was taking my oil and wondered what I was doing. I just told them it was to take care of some pooping problems I've been having.

SLD = more off-limits than poop.

1. <http://boards.sethroberts.net/index.php?topic=6203.msg67056#msg67056>

---

Peter (2008-04-15 13:56:17)  
hilarious!

Ed (2008-04-15 15:56:21)

I have to agree, I casually mentioned SLD to a couple of friends and they all reacted horribly. I decided it was best not to discuss it.

Tom (2008-04-15 16:15:52)

Yep, people freak if you tell them you're drinking oil. But tell them you ate a half gallon of Rocky Road last night before bed, they'd only wonder why you prefer it to the Cookies and Cream they'd had.

LemmusLemmus (2008-04-16 08:47:43)

I think the problem - if it is a problem - is that the method sounds absolutely wacky if you don't know the theory behind the diet. (The book's subtitle, anyone?) I once explained it to a friend and made sure to start out with, "Ever heard of the concept of a weight set-point?" rather than, "It's all about drinking oil!"

seth (2008-04-16 11:41:18)

Perhaps a better subtitle would have been - "now you may be surprised by this..."

## Happy Birthday, LSD! (2008-04-16 10:28)

On this day 65 years ago LSD was discovered via self-experimentation. [1]Here is an in-depth account; the title of this post is [2]here. When I was a grad student, a faculty member had recently retired and his reprints were available. I took one from the 1950s about the effect of LSD on snails.

1. [http://scienceblogs.com/neurophilosophy/2008/04/lsd\\_discovered\\_on\\_this\\_day\\_65.php](http://scienceblogs.com/neurophilosophy/2008/04/lsd_discovered_on_this_day_65.php)

---

Nansen (2008-04-16 17:37:35)

We look forward to your paper, "The Effect of Snails in the SLD".

David Weman (2008-04-17 04:15:09)

Well, what were the effects?

seth (2008-04-17 05:24:06)

Immobilization, if I remember correctly.

## **Interview with Mark Liberman about Blogging (2008-04-16 17:00)**

Mark Liberman, a professor of linguistics at the University of Pennsylvania, blogs at [1]Language Log. Recently I asked him a few questions about blogging.

ROBERTS Why did you start Language Log?

LIBERMAN Several reasons. First, I had started reading blogs and enjoyed them. Second, I was spending quite a bit of time exchanging email with friends. They were like long-distance dinner-table conversations. Each email was a couple of paragraphs. I was spending quite a bit of time on that. It was interesting and fun, a way of keeping up with friends and former colleagues. I realized that many of these emails were close to blog entries that might be interesting to a wider audience. Some of them could have been blog entries. I thought to myself: If there was a weblog, instead of sending this to 1 or 2 people I could put it on the weblog and send a link to those people. Third, I had felt for a long time that linguistics, in our current culture, was in an historically atypical and irrational place. Almost nobody learned about linguistics, got any intellectual information about language. It was undertaught to the general public. It has been valued much more in the past. Now we're in a situation where many English professors have never taken a course that teaches anything about the analysis of language. They don't know how to do it. One small way to improve that situation would be to put stuff out there that people could read.

ROBERTS How has blogging affected you?

LIBERMAN Three things. First and most important, I've met – mostly digitally – a large number of people that I would never otherwise have met. They send me email. If I look over my email logs, there are probably 5 or 10 people that I correspond with frequently whom I've met that way. Most of them are not linguists; I wouldn't have met them otherwise. Some of them are not even academics. Second, it has allowed me to influence the conversation inside linguistics and related fields in a way that I hadn't really expected. It wasn't my motivation. I've always thought of writing for people outside the field. Issues that I've raised within the field, including how the field ought to view itself, people respond to. I was invited to give a plenary talk at the Linguistics Society of America meeting about the status of the field in academia. I had blogged about such things. Third, I get a lot of calls from journalists asking me to comment about this or that. A lot of things they ask me to comment on I don't know about. It made me someone that journalists call.

ROBERTS How have your views about blogging changed since you started Language Log?

LIBERMAN There is a spectrum of blogs; some are just sets of links – minimal comment and a link. When I started I thought that was what I was going to do, along with email-to-friends kind of pieces. Along the way I learned that a blog entry is a good way for me to learn things. If there's something that I'm interested in, I may write a blog-like essay about it. I compose quite a few blog entries that I never publish. When I'm working through some ideas, I often organize my thoughts an awful lot like an blog entry. Like an annotated bibliography but with more structure. I don't publish some of those things because I don't think the general audience of Language Log would be interested in them. They're too difficult. They take the form of an extended blog entry – links plus evaluation and discussion but more informal than a paper. Very helpful in organizing my thoughts. I read some things, put in some links, quotes, weave it all together into some structure. I produce an html document. It's a way of taking notes. Something I do at the very beginning of an intellectual enterprise. A journal article is what you do at the end. For example, I've become interested in auditory texture. I've been composing a few things that are like weblog entries.

Once a month or so I try to do what I call a breakfast experiment. Some issue has come up in the world that I want to comment on. There's an experiment that I wouldn't want to submit to a journal. Better than an anecdote. For example, a few months ago somebody wrote that a journalist who had been living in Japan had been learning girl Japanese. Is it true that there is more gender difference in pitch in Japanese than in other languages? At the Linguistic Data Consortium we had conversations in many languages, including Japanese and English. I could select appropriate conversations, throw values into R, look at quantiles. (There were a few issues you'd want to clean up for a journal article.) I got up early, set up scripts, made coffee, had cereal, plotted quantiles. By 7:30 am I had some pictures. It was true that there was more gender polarization in pitch in Japanese than in English. The analysis involved 18 Japanese conversations and a similar number of English conversations.

I had been abstractly aware for a long time that there's a lot of value in doing experiments on published data. One of the problems in doing empirical linguistics has been that gathering data takes a lot longer than anything else. For English we've now got about 10,000 extemporaneous telephone conversations, with demographic info about the speakers. I thought of experiments on that sort of data where someone had to spend a lot of time gathering the data, but once it's gathered and published, there are a lot of ideas that you can try out very quickly.

Seth's blog » Blog Archive » Before There Was News, There Was Gossip (2008-04-17 08:24:14)  
[...] Interview with Mark Liberman about Blogging [...]

syz (2008-04-19 04:38:26)

Hi Seth, thanks for the insightful co-mingling of themes on amateurism and gossip with these responses from Liberman. His Language Log style of using data to advance a conversation beyond simple opinion is an inspiration to us amateurs in the "gossip" business. It's a style that differentiates good gossip from mere gossip. When you try to emulate it, you find yourself working harder at blog entries, learning more in the process, and also getting more fruitful, thoughtful comments from readers that in turn inspire better blog entries – a virtuous cycle. And it is hopefully a cycle that leads this kind of amateur blogging to "fill a gap" (as you mentioned in the other article) between the true professional and the truly unreflective gossipier.

## Before There Was News, There Was Gossip (2008-04-17 08:24)

Did the professionalization of science – people could make a living doing science – cause harm because although more science was done scientists – the professional ones – were no longer free to pursue the truth in any direction? Because their jobs and status were at stake? It's plausible. Recall that Mendel and Darwin were amateurs. A more recent example is Alister Hardy, the Oxford professor who conceived the aquatic ape theory of evolution. He didn't pursue it because he feared loss of reputation. The more sophisticated conclusion, I suppose, isn't that professionalization was bad but that loss of diversity was bad. We need both amateur and professional scientists because each can do stuff the other can't. Right now we only have professional ones. No one encourages amateur science; there is no way they can publish their work. (Unless, like Elaine Morgan, who wrote several books about the aquatic ape theory, you're a professional writer.)

These thoughts were prompted by [1]this remarkable blog post, which has nothing to do with science. What an amazing piece of writing, I thought. I don't even agree with it, and here I am staring at it. A work of genius? No, lots of blog posts are really good. This one was merely better than most. Would something this brazen and effective appear in any major magazine, newspaper, TV show, radio ad, etc.? No, not even. Do we realize that, all these years, stuff like this has been missing from our media consumption? No, we don't. Before there was news, there was gossip, I realized; news (such as newspapers) was a kind of professionalization of gossip. The blog post I admired was a bit of riveting creative gossip. Blogs are just new-fangled gossip. Bloggers are endlessly scandalized, indignant, judgmental, just as gossips are. Just as gossip is usually "passed on," most blog posts have links and many posts consist almost entirely of "passing on" something. Just as gossip can be anything, bloggers can say what they really think, as [2]Tyler Cowen pointed out. That's why they're so successful, so easy to write and read. Gossip is good for our mental ecology, just as science is. Mark Liberman's [3]Language Log blog is a blend of (good) gossip and science; as you can see from [4]my interview with him, it filled a gap. I hope blogs will provide a kind of support structure on which amateur science can grow.

LemmusLemmus (2008-04-17 09:46:22)

"bloggers can say what they really think" Depends. I could easily create a few blogposts that might end your career if you posted them under your name. That's why I use a pseudonym. As it happens, I've never posted anything that most people would find strongly objectionable (I think), but I like having the freedom to not even have to think about whether a post might be bad for my career. Still, blog authors have a high degree of freedom to write what they want, but I don't think that is the main reason that I read more blogs than professional sites on a typical day; I think the main factor is sheer mass. The main reason you can find blogs you like is the same reason you can find a forum for people that get sexually aroused by bird feathers or whatever: There's just *lots* out there.

Tom (2008-04-17 16:42:42)

Gossip is more primal than news. It is fundamental to our species' ability to grow beyond small bands in which everyone knew each other. Gossip and the prefrontal cortex are inextricably linked – it is where we store our stories about who we are, who we're ideally supposed to be, and who others are. That lobe is where society and politics live, and gossip is the data that fills that lobe. "Does he do his share? Can he be trusted? Who are his allies and his enemies?" If we know these answers about strangers, there is no limit to our society's size. And we know how to behave in a way that keeps us from being destroyed. It's

been said, and subsequently disproven, that tools are what make us human. I would argue that gossip makes us human. Even crows use tools. Humans use gossip.

Blogs as gossip, and gossip as support structure for amateur science « Entertaining Research (2008-04-18 19:08:05)

[...] Blogs as gossip, and gossip as support structure for amateur science Seth on blogs as gossip and what role they can play in increasing the diversity among the practitioners of science: Blogs are just new-fangled gossip. ### 80% Empty or 20% Full? (2008-04-18 14:07)

A study in the latest issue of Journal of Nutrition wondered if following dietary guidelines ("eating healthy") is helpful. From [1]the abstract:

Few studies have found that adherence to dietary guidelines reduces the incidence of chronic disease. In 2001, a National Nutrition and Health Program (Program National Nutrition Santé®) was implemented in France and included 9 quantified priority nutritional goals involving fruit, vegetable, and nutrient intakes, nutritional status, and physical activity. We developed an index score that includes indicators of these public health objectives and examined the association between this score and the incidence of major chronic diseases in the Supplémentation en Vitamines et Minéraux Antioxydants cohort. . . . Men in the top tertile [ = most adherence] compared with those in the lowest one had a 36 % lower risk of major chronic diseases . . . No association was found in women.

No association in women. Suppose the guidelines were half correct – half of the advice was useless, half was helpful. You'd still expect an association because the helpful advice would help and the useless advice would neither hurt nor help.

Did the authors of this highly-informative study [2] face their results squarely? No. The abstract concludes: "Healthy diet and lifestyle were associated with a lower risk of chronic diseases, particularly in men, thereby underlying relevance of the French nutritional recommendations." Particularly in men, huh? The study started with about 2000 men and 3000 women. It lasted eight years.

Perhaps because women has more complex physiology

### **More about Procrastination (2008-04-19 10:04)**

Nathan Yau, who is trying to reduce how much he surfs the Web, has posted [1] a report of what he learned during his first month of self-experimentation. It reads exactly like my experience of research: In the beginning, few things turn out as planned.

1. <http://flowingdata.com/2008/04/14/how-to-stop-procrastinating-one-month-report/>

---

### **What Do Jobs Need to Be Good? (2008-04-19 12:44)**

I've always wondered what makes a job satisfying. Yeah, it varies from person to person. What about features that are true for everyone? What about [1] this, for example?

For a while at Amazon, I was the Manager of Website Performance and Availability. . . . Whenever something went wrong, and some chunk of the site got slow, I tracked down why and got people to fix it. Each week I wrote a report summarizing everything that went wrong in excruciating detail, and presented it to a room of directors and VPs in a weekly metrics meeting. It was as Sisyphean a task as any you can possibly imagine. In a software system as large, complex and constantly changing as amazon.com, something is always going wrong. . . . My job was to make a list of irritating things each week, and I was widely regarded as having done it as well as anyone ever had. . . . I found this job to be the most soul-crushing work I've ever done. I totally burned out in a year, as did the person who held the job before me.

I tell you this story as a cautionary tale. Try to find work that allows you to focus on positive things. Avoid like the plague any work that focuses on negative things.

[2]Related research. [3]The writing cure.

3. <http://www.blog.sethroberts.net/2006/10/11/the-writing-cure/>

---

Peter (2008-04-19 14:57:31)

that job sounds exciting. very similar in what i used to do as a tech support engineer. big challenges - technical and otherwise - helping people - working with people, a sense of urgency, you get to be proactive, eventually working to reduce complexity and up reliability. good stuff. but it sounds like it was stressful and probably required a lot of overnights. i never had that. we were usually able to fix our probs, and if not, it was never mission critical or something we could fix by completely swapping out software/hardware - we didn't have 50,000 computers. a good manager is clutch to having a 'good job'. someone who believes in human dignity. having a say in decision-making is important - a little democracy in the work place instead of the totalitarian top-down approach that most of us are used to right now. so, co-ops are a good model. look for the fascists and corporatists and Republicans to vilify co-ops as they continue to grow in popularity. here's a good example of one: <http://www.blackstar.coop/> and, increasingly, people are starting to realize that having some time to play with their kids, visit and take care of their parents, go to church, volunteer, make love to their spouses, plant some veggies in the community garden, etc. are important - so 'full time' jobs with 30-hr work weeks will increase, as will people's happiness and satisfaction with their jobs. :)

Varangy (2008-04-20 12:34:50)

*having a say in decision-making is important - a little democracy in the work place instead of the totalitarian top-down approach that most of us are used to right now. so, co-ops are a good model. look for the fascists and corporatists and Republicans to vilify co-ops as they continue to grow in popularity.* I guess I am a fascist-'corporatist'-Republican because I have always observed that too many cooks in the kitchen spoil the broth.

TomG (2008-04-23 02:11:55)

Well about that broth, it really all boils down to who calls the shots (doesn't it always) - and I see the traditional top-down management structures as inherently dysfunctional, where authority is fear-based and coercive rather than one fostering an atmosphere of mutual respect - that actually capitalizes on human dignity, and actually benefits a company with greater individual output and much less turnover. Peter only mentioned "a little democracy" - so not sure why that's too much to mention. The reality is that we're supposed to justify our pay to the stockholders/owners or a company - and the quality of management and culture they engender truly do matter. When I hear the usual crappola such as "don't bring problems, only solutions" - then you know the company has slothful types running the show (a disservice to the true owners). You can have the most skilled kitchen staff, and provide the best stove and appliances - but if the head chef ignores the remarks and stressors in making the broth, it'll come out spoiled excepting sheer luck. The typical replacing of one inept chief for another will procude no better results - since a good leader listens to his staff and allows them the freedom to do what they're supposed to for the sake of all, and especially the owners.

## Never Enough by Joe McGinniss (2008-04-20 07:17)

I am reading [1]Never Enough, [2]Joe McGinniss's latest book. I was browsing at the Berkeley Public Library and there it was! It was a little [3]like discovering a painting by Jackson Pollack in a thrift store. The typical book I want to read at BPL has 15 holds on it.

I am trying to read it as slowly as possible so that it will last as long as possible. It is surely the best book I have read this year. It is one of the best books I have read since I read [4]The Miracle of Castel di Sangro (1999) by McGinniss, which was also incredibly good. That was another book hard to stop reading. In both books, the characters are bathed in a golden authorial light. Events are described with a beautiful simplicity, as if in a story for children, except what happens is intricate, meandering, morally complex, and true. In Miracle, McGinniss falls in love with the soccer team of a little town only to have his heart broken when they throw their last game. In Never Enough, a man is murdered – and then his brother, half a world away, is also murdered. (Which happened while McGinniss was writing about the first murder.) Surely the murders are unconnected yet how could they not be connected?

Nansen (2008-04-21 18:02:09)

Your spoiler kind of ... spoils Miracle.

seth (2008-04-21 21:00:30)

as I told someone yesterday who'd seen the movie Atonement...Nabokov said, "Curiously enough you can never read a book you can only reread it." He meant the first time you read a book learning the details of what happens, the plot, etc., gets in the way of appreciating the rest of it.

Seth's blog » Blog Archive » More about Never Enough (2008-04-25 19:35:37)

[...] Never Enough by Joe McGinniss [...]

Joe McGinniss (2008-04-27 15:27:22)

Thank you, Seth, for the generous comments about not one, but two of my books. I hope the SF Chronicle (if it's still in business) hires you as its book editor (if it still has one) before my next book.

## Glimpse of the Future: Dim Sum? (2008-04-21 23:03)

The most surprising finding of [1]my self-experimentation was that we need to see faces in the morning – every morning for most of us – to be in a good mood during the day. Morning faces push an oscillator that controls our mood. During the Stone Age, this need was fulfilled by talking to your neighbors. The function of this oscillator was to synchronize the moods of people who live together. It greased the wheels of cooperation. It's much easier to work with someone in a good mood than someone in a bad mood.

Since I discovered this, I've wondered: What will this mean for everyday life? Will people chat via videophones?

Watch YouTube videos ("This is my response to . . .")? Look in a mirror? Gather in cafes? Or what? You need a community to make this work, since you need to see one or more faces for a half hour or more.

Last night at [2]Teance, at a Slow Food event, I learned of two modern communities where people manage to get the needed face time. One is in [3]Chaozhou, a city in Guangdong Province, China. Every morning retired people get together and drink tea. Where do they meet? I asked. "Anywhere," I was told. They may meet in a park, for example. In Guangdong they drink more tea than anywhere else in China and, I was told, have better health than the rest of China.

The other community are those Cantonese, both in Hong Kong and in Guangdong Province, who eat dim sum every day for breakfast. They gather in restaurants that serve dim sum. You can come whenever you like but the restaurants open around 5 am and the whole thing may last four hours. (My results imply that the face-to-face conversation should happen during the first hours or so after you get up. Wait till 10 am and there won't be any effect.) You might have three business meetings during that time. You can stretch out eating dim sum in a way you can't easily stretch out eating breakfast that appears all on one plate at once. So it lends itself to longer meals. The longer everyone spends at the dim sum restaurant, the easier it becomes to meet there.

Nansen (2008-04-23 19:35:55)

Sometimes I wonder which is the more remarkable: your discovery itself, or the fact that a widespread appreciation of the discovery could take another fifty years.

seth (2008-04-24 03:42:54)

That's an interesting way to put it because countless times I have thought something with a similar logical structure but more positive: The remarkable thing about this discovery is that whatever recognition I get for it won't bring me as much happiness as the discovery itself.

Andrew Gelman (2008-04-25 19:15:50)

Seth, Why is this remarkable? Isn't that the nature of all, or almost all, scientific discoveries? Recognition is a motivation, but my impression is that psychological studies have found that recognition doesn't bring much happiness at all. (I have to say, it's brought me some happiness, but I've just always assumed that I'm more recognition-loving than most. I imagine you're closer to the norm.) P.S. I guess I should correct this slightly, since some scientific discoveries bring negative happiness. For example, I once met the guy who invented napalm.

## **How Things Begin (Reading the OED) (2008-04-22 04:57)**

Maybe this post should be titled How Books Get Written. A curious feature of the book industry is that it gets almost all of its key ingredient – book manuscripts – from amateurs. No other big industry is like this. If our economy is a giant experiment, [1]this point is an outlier. A huge outlier. What does it mean?

To find out, it would help to look at specific cases. I asked [2]Ammon Shea, author of [3]Reading the OED (forthcoming), how he managed to write it. He replied:

The advance was plenty for me to live on for a year, which is approximately how long the book took. However, I live cheap. I moved in with my girlfriend, who owns her own apartment, and so the rent, or maintenance costs, are low. We cook at home, tend to not buy things that we don't need, and our idea of excitement is to go to a new library.

I had wanted to read the OED for quite some time, but knew that I didn't have the leisure to spend ten hours a day doing so. I wrote the book proposal to see if I could convince some publisher to, in effect, subsidize my hobby.

I've worked as either a musician or a furniture mover for most of the past twenty years - both are occupations which allow a certain freedom; freedom from both responsibility and security. Taking off time was not so much of a problem. In terms of circulating the proposal I had my agent send it out. He's the same one that I had when I wrote several other books, some eight or ten years ago.

Ammon's editor is the same as mine (Marian Lizzi), which is why I knew about his book. Reading the OED: One Man, One Year, 21730 Pages (= 60 pages/day) will be published in August.

3. <http://www.ammonshea.com/oed.html>

---

knackeredhack (2008-04-22 07:07:26)

Seth, it looks like an increasing number of web apps are coming from amateurs, the self-funded or students. Perhaps journalism is in effect heading that way too. Tim

LemmusLemmus (2008-04-22 08:52:46)

Given that he got an advance, he wasn't really, really an amateur. Even so, I think you're basically right. I think there are two simple reasons why so many books are superhobbies, as some might call it: 1. Having produced a book is fun. Having produced 100.000 screws probably isn't (for most people). 2. Producing a book costs next to nothing (as opposed to producing a film, an epidemiological study, etc.).

## **Self-Experimentation, Dogged and Useful (2008-04-22 21:50)**

Studying himself, Piotr Wozniak, a Polish computer programmer, [1]learned some useful things:

In 1985, he divided his database into three equal sets and created schedules for studying each of them. One of the sets he studied every five days, another every 18 days, and the third at expanding intervals, increasing the period between study sessions each time he got the answers right. This experiment proved

that Wozniak's first hunch was too simple. On none of the tests did his recall show significant improvement over the naive methods of study he normally used. But he was not discouraged and continued making ever more elaborate investigations of study intervals, changing the second interval to two days, then four days, then six days, and so on. Then he changed the third interval, then the fourth, and continued to test and measure, measure and test, for nearly a decade.

Based on his results he created a popular program called [2]SuperMemo.

Wozniak has ridden SuperMemo into uncharted regions of self-experimentation. In 1999, he started making a detailed record of his hours of sleep, and now he's working to correlate that data with his daily performance on study repetitions. . . . Wozniak has also invented a way to apply his learning system to his intake of unstructured information from books and articles, winnowing written material down to the type of discrete chunks that can be memorized, and then scheduling them for efficient learning.

Thanks to John Kounios, Robert Simmons, and Navanit Arakeri.

Paul Brentano (2008-04-23 09:07:05)

That is an extremely cool and provocative article. So, I can't help but to think about what kind of an effect omega-3 + the "spacing effect" would have together. I'm guessing that maybe omega-3 would "flatten" the forgetting curve a little bit. Maybe I'll experiment on my kids a little.

Phillip J. Eby (2008-04-23 12:53:11)

There's also an open-source version of a similar concept, at <http://www.mnemosyne-proj.org/>. It supports pictures and sounds as well as text, and uses a somewhat older version of the SuperMemo algorithm. Personally, when I saw this, I was really excited at first, and then I realized I don't have much use for jamming my declarative memory full of facts. It would be much more useful to have a way of quickly adding things to your procedural memory: then you could install new eating or exercise habits, or other daily routines. (Let alone the whole, "let's download Tae Kwon Do and how to fly a helicopter" scenario in the Matrix movies.) Know of anybody who's got software for that? ;-)

NE1 (2008-04-23 18:25:29)

That site is one of the biggest black hole of consciousness I've visited on the net since like the 90's. The guy is probably mentally ill. I used Supermemo for a couple months. The program is analogous to the website. So much crazy crap added in, and it still doesn't have basic usability features. Content creation is pretty tough, so I think you need dedicated peers to make it work. If I were to start doing it again, I'd lower my projected retention rate. It was definitely not working for learning new material—the sets just blew up.

### **More about Acne (2008-04-23 22:40)**

The highlight of my recent trip to New York was a talk I gave at Landmark High School, a public high school near Columbus Circle. The students paid close attention. Afterwards, a student named John Cortez told me what he'd figured

out about what causes his acne. His skin was clear so I had to believe he knew what he was talking about.

He has three rules: 1. Eat less greasy food. 2. Work out hard. 3. Wash face extremely well, especially after working out. The last rule is surprising because one of Allen Neuringer's students found that acne got better when she stopped washing her face. John explained his reasoning like this:

When I was little I got something because of the lack of hand washing. Nothing serious – it went away – but it caused me to become sort of a neat freak. When i started to get pimples I thought it was because i didn't wash my face well. When i started to wash my face better, my acne stopped getting worse. One day i got lazy and from there on I stopped washing. Then I noticed that I was almost covered with pimples. When I got in a gym I realized that when i sweat and as soon as possible, washed my face got less pimples and prevented those nasty huge acne.

Amount JC figured out about acne while in high school: A lot. Amount SR figured about acne while in high school: Zero.

Addendum. Another unexpected aftereffect of my talk was that [1]Shangri-La Diet forum traffic went way up. That evening, at one point there were 307 people simultaneously reading the forums, a new record. The average daily maximum during the days just before was about 150. There were about 50 people at my talk. Go figure.

1. <http://boards.sethroberts.net/index.php>

---

a\_guy (2008-04-24 01:18:41)

There are two medical things that I know of that are simple and cures quite serious conditions amazingly well but are not well known. One is the shangri-la diet. The other is eating large quantities of vitamin B5 to cure acne. I have had acne for many many years, and I have tried many things. Until I found B5 the only thing that worked was an antibiotic, but after I had been on it for over a year my doctor didn't want to prescribe it to me any more. I searched for solutions online and tried a bunch of things that people were talking about. Nothing helped. I finally tried B5, and it worked amazingly well. I'm not 100 % cured, but almost. If I skip the B5 for just a couple of days it comes back though. And sometimes it seems like some batches of the stuff I buy are bad and don't work as well. We're talking about large quantities, around 10 grams per day. That's somewhere around a thousand times RDA. From what I've read on different forums it doesn't seem to work for everyone, but it works for many. It worked for the only one I recommended it to, but that was a relative. This knowledge could help a lot of people. Many years of my life were much much worse than they could have been because I had not found B5 yet. Unfortunately, there is no Seth Roberts to promote it. Even worse, the only one who is seriously trying to promote it have done a study that wasn't very well made, and he has a theory about how it works that is most likely completely wrong. Instead of pointing to the fact that people seem to be cured by it, he mostly focuses on his theory, and since it's obviously wrong nobody takes him or B5 seriously. Whenever someone looks into B5, all they see is a flawed study and a bogus theory. The fact that there is tons of anecdotal evidence is not enough to compensate. It doesn't help that the only ones who sell B5 cheaply enough are pretty shady companies, and most of them refer to the flawed study and theory. So, even if I know that it works, I can't really prove it to someone else. I hope the day will come when it becomes more mainstream, it helps more people, and I can start buying it from some more serious and trustworthy sources. It shouldn't have to take more than a well made double-blind study.

seth (2008-04-24 03:36:27)

I did a little self-experiment that found that B vitamins – a B-vitamin pill – reduced my acne by about 50 %. I can't remember what caused me to try it. By then my acne was pretty low, which is perhaps why it wasn't a dramatic effect. What persuaded you to try it initially?

Andrew Sidwell (2008-04-24 06:41:43)

I found that two things significantly helped my skin health (not acne, but they did together reduce the number of spots/pimples to single figures from some amount much larger than that). One was flax-seed oil, the other was dropping dairy from my diet.

Ian (2008-04-24 09:10:52)

I can imagine that after sweating, the bacteria on your face would be kind of turned up, and allowed to spread. It might be the most vulnerable time. By cleaning at that point, maybe it reduces that risk (and presumably a person's immune system is capable of handling at least some of the burden of the bacteria).

a\_guy (2008-04-24 11:02:20)

Seth, People were talking about it in different Internet forums, and many reported success. Much like the way I found SLD. The normal dosage of B5 (or Pantothenic Acid, same thing) is 10 grams per day. That's one kg in three months (and 8 pounds per year). The biggest pills they sell are 1 gram, because it's too hard to swallow anything bigger. You need ten of these every day. Or you can buy powder to keep the cost down. It's not something you happen to eat by mistake. :-). When people are discussing this you often see people who claim they didn't have any effect, and when queried they say that they used B5 found in some multivitamin or whatever, and it says on the bottle it contains 10 mg. mg and g are not the same of course, so they were just eating one thousand of the required dose by mistake. So, your B-vitamin results are not the same as this. It might be related though. I wish I knew what makes it work. Maybe there is a simpler way to trigger the same effect without eating these huge amounts of a vitamin.

Mike (2008-04-24 12:29:11)

I have to throw in my 2 cents about B5. Yes, it definitely worked for me, but I stopped using it after some very painful self-experimentation results. I'm in my 50's and have had moderate acne (1 or 2 spots at any given time) my whole adult life. I've more or less accepted it now, if people have a problem with my skin, it's their problem. But I still would rather not have it. I agree with what's been posted above. Washing makes it worse. Dairy makes it worse (maybe just dairy fat, need more self-experimentation on that). Chocolate has no effect. Trans fat makes it much, much worse - I'm thinking of renting out my face as a trans fat detector. When I inadvertently eat trans (eating "home-cooked" baked stuff, usually), I find out a couple days later, big time. As to supplements, B5 megadosing worked great for me. I got to the point where I couldn't even remember my last pimple. But I came down with kidney stones for the first time in my life. Read somewhere online that might be related to B5 megadosing, something about leaching calcium. So I stopped taking B5. Pimples came back, kidney stones went away. 6 months later I tried the B5 megadose again after some bad breakouts. 2 weeks later, kidney stones again! Not a controlled study, but proof enough for me.

Kirsten (2008-04-24 14:47:44)

For me, the key was coffee. I never had a problem with acne growing up, but after a stressful summer when I was 27, I spent six or seven years really suffering from it. Nothing helped except Retin-A, and the side effects were too harsh for long term use. I finally removed caffeine from my diet, then one year later removed even decaf coffee (which I drank every morning.) This was the single most important factor in clearing up my skin. I also found a couple other contributing factors, which I'll mention below. Stopping coffee was a hunch based on an Adele Davis book and also some mass media news article on Yahoo!, both of which said that coffee washes vitamin A out of the body. I finally solved 99 % of my skin problems last October when I made a list of everything I knew contributed to acne and everything I knew cleared it, and did as little of the first and as much of the second as possible. Still, more than anything, the clearness of my skin remains directly proportional to the amount of coffee-decaf or otherwise-I drink. Other contributing factors: Causes acne: Eating chocolate, falling asleep without washing my face (even if it's for a half hour on the couch), not washing my hair every day. Also, I suspect a link to sugar, but I'm not sure

about that one. Helps clear acne: Sulfur pills ("Acne Relief"), washing my face twice every night, using only non-comedogenic makeup, swimming in salt water, spending time in the sun, fish oil pills, a multivitamin, mud face masks (Queen Helene's and also bentonite powder mixed with apple cider vinegar). Also, coconut oil applied topically may help, but that's too new to say.

Ali Choudhury (2008-04-25 04:07:34)

My acne decreased a lot by cutting out sugary junk and baked confectionary.

## **How Things Begin (conference-call classes about Indian philosophy) (2008-04-24 23:16)**

Waiting for a BART train I met Krishna Kashyap, a [1]San Diego businessman, who teaches classes on Indian philosophy by conference call. He was born in India and studied philosophy there before he came to America.

There are many such classes. About 15 years ago, a Berkeley student named Mani Varadarajan started a listserv called bhaktilist, which allowed people who were interested in Vaishnava Vedanta to contact each other and exchange ideas. This is how the conference-call classes began. Bhaktilist no longer exists, but many lists came from it, including srirangasri@yahoogroups.com and oppiliappan@yahoogroups.com. There are several thousand people on these lists.

Kashyap himself recently stopped teaching classes so that he would have more time to learn. He is now taking classes with a teacher named K. S. Varadachar. He dials his number in India at a particular time. Other people can dial in as well. They listen and ask questions. "I got isolated from my community when I came to this country 20 years ago," Kashya said. "Reading books is not enough. There wasn't any other way to communicate [besides the conference calls]. When I wanted to learn I had to get teachers from India."

Now there are 4 or 5 classes simultaneously; they meet by phone once/week, using freeconferencecall.com. The Indian lecturers don't get paid or at least such is the convention. They are given an end-of-term "gift," called sambhavana, that is \$200- \$1000.

A vast amount about Indian philosophies is [2]here.

How different from American higher education! People learn easily, without coercion, without threats, without punishments, without external rewards, if they see their teacher as a guru. The American term for guru, of course, is motivational speaker.

1. <http://www.sentacbiz.com/?page=aboutus>

2. <http://www.ibiblio.org/sripedia/>

Motivational speaker as the American equivalent of Indian guru! « Entertaining Research (2008-04-25 09:22:25)

[...] Motivational speaker as the American equivalent of Indian guru! Seth on conference calls on Indian philosophy: Kashyap himself recently stopped teaching classes so that he would have more time to learn. He is now taking classes with a teacher named K. S. Varadachar. He dials his number in India at a particular time. Other people can dial in as well. They listen and ask questions. "I got isolated from my community when I came to this country 20 years ago," Kashya said. "Reading books is not enough. There wasn't any other way to communicate [besides the conference calls]. When I wanted to learn I had to get teachers from India." [...]

## Brain-Enhancing Drugs (2008-04-25 12:02)

A [1]helpful collection of stories about the use of drugs that help you get things done. This amused me:

Individuals who experiment with these substances are on their own, testing drugs on themselves in a wild, crowdsourced, ad hoc brain-enhancement experiment. They join a [2]scientific tradition of self-experimentation that stretches back to [3]Santorio Santorio, a 16th-century physiologist.

If you experiment with mood-altering drugs, you join an older tradition.

## More about Never Enough (2008-04-25 19:35)

From Never Enough by Joe McGinniss, which I [1]blogged about:

One day she noticed that Michael wasn't wearing the [ \$7000] watch [she'd given him]. He was embarrassed to tell her why. Finally, he said he'd told his brother Lance about the affair but Lance had been born again and told Michael he was immoral. More to the point, he told Michael he was fired. They argued. Finally, Lance said that Michael could keep his job in return for the watch.

Shades of the indulgences that upset Martin Luther! You don't find this sort of detail in other books.

1. <http://www.blog.sethroberts.net/2008/04/20/never-enough-by-joe-mcginniss/>

---

Andrew Gelman (2008-04-26 08:51:42)

Seth, Did you read Absurdistan or Then We Came to the End? These had this sort of detail. I respect that you like this particular book—I'm a McGinniss fan too—but no need to praise it by putting down all other books!

seth (2008-04-26 09:05:37)

It's not quite the same. Absurdistan and Then We Came to the End are novels. Never Enough is not. But you're right that I might like Then We Came to the End, I've heard good things about it.

## More about Acne (continued) (2008-04-26 12:42)

When I was a teenager, my dermatologist gave me a long list of foods that might cause acne. It wasn't any help at the time but later, when my acne was better, it helped me realize that drinking Diet Pepsi caused me to get acne 2 or 3 days later because "cola drinks" was on the list.

Now I learn from [1]Tucker Max that it was probably the caffeine that did it:

I had bad acne in high school. I cut all caffeine out of my diet—cola, chocolate, etc—and about 90 % of the acne went away. I got the rest with Accutane.

Very useful information. The list my dermatologist gave me was too long and too homogenous. "The acne caffeine link is well-known to dermatologists," Tucker added. Except those [2]who claim acne has nothing to do with diet.

1. <http://tuckermx.com/>

2. <http://www.blog.sethroberts.net/2007/12/20/diet-and-acne/>

---

Aaron (2008-04-28 21:33:27)

I've found this to be the case too - but with a twist. It isn't caffeine per se that makes me break out, it's coffee. Weird though it seems, I can drink two or three cups of caffeinated tea a day and have no flareups at all. But a day or two spent drinking even decaf coffee, and I've got three or four pimples on me. Someone explained to me once that coffee has extra compounds in it that promote a kind of sweaty aggressiveness, while tea has compounds that promote ease and relaxation. I certainly find this to be the case. When I drink coffee, I'm much more dynamic, determined, and combative. I'm also prone to set out on all kinds of ambitious new initiatives, and for my energies to scatter. On tea, I'm calmer, don't sweat so much, am wary of new initiatives, and can behave in a more organized fashion. Anyway, for me: coffee equals acne, tea doesn't.

Raffaella Ducoli (2008-05-11 09:54:53)

Although some research claim that food is not a cause of acne, some other researches show that certain food increases the inflammation in the body. I used to have a cup of coffee a day and my skin had breakout and it was drier. Now I replace coffee with tea and I have no more breakout.

Serge (2008-10-15 21:54:26)

The issue in my experience is not diet. The causes of acne are specific and relate to the release of sebum (oil) that clog the sebaceous glands and cause acne. The release of these oils actually have more to do with hormones and gender than they do with diet. There's actually emerging discussion about how gender effects acne. These discussions often contain facts about the differences in the genders and how that creates a need for a gender-specific acne treatment. I researched the topic myself and came across this site which provided some useful info that helped me understand: [http://campusacnetruth.org/html/acne\\_gender.html](http://campusacnetruth.org/html/acne_gender.html)

browneye (2008-10-26 18:40:51)

The skin is your body's largest detox organ, after the liver and kidneys. As a general rule, caffeinated coffee, red meat, cheese and all manner of drugs and environmental toxins that we absorb each day can overwhelm these organs and then it shows up in the skin. All makeup clogs the pores and the chemicals in skincare products can also make things worse. After years of trying to practically peel off and dry up the skin on my face with marginal improvement, I found that pure olive oil soap, lots of

distilled water, and rarely wearing makeup (and with the olive oil to moisturize, no other products are needed) has cleared the adult acne that has grossed me out for years.

### **Better in Google Books (2008-04-27 16:32)**

I've heard that Samuel Beckett's plays, written in French, are better in English. I have no idea if that's true but I am sure that *Television Without Pity: 752 Things We Hate to Love (and Love to Hate) About TV* by Tara Ariano and Sarah Bunting is better in its more accessible, abridged [1]Google Books version. I remember Sarah from when she was an especially visible fan of *My So-Called Life*. I got a much-enjoyed soundtrack cassette from her. Then she and Ariano started [2]*Television Without Pity*, a brilliant entrepreneurial idea, which has helped me understand so many erudite HBO dramas.

1. <http://books.google.com/books?hl=en&id=cm28udLiQlkC&dq=%22sarah+bunting%22+&printsec=frontcover&source=web&ots=16SxVHaW7S&sig=9p7KDY6DkcrAmLMoB4k7yj4r5E#PPA3,M1>

Visit my SLD blog if you get a chance.

### **My Theory of Human Evolution (micropygmies) (2008-04-27 18:20)**

In 2004, anthropologists discovered fossils of tiny human ancestors on an Indonesian island. Called micropygmies, they were about three feet tall. Their brains were smaller than chimpanzee brains. They appeared to be descended from *Homo erectus* rather than *Homo sapiens*.

They survived until about 20,000 years ago – which was impressive, since *Homo sapiens* reached nearby islands about 50,000 years ago. Why didn't the *Homo sapiens* kill off the micropygmies? [1]Jared Diamond was puzzled by this:

The discoverers of the Flores micropygmies conclude that they survived on Flores until at least 18,000 years ago ([2]1, [3]2). To me, that is the most astonishing finding, even more astonishing than the micropygmies' existence. We know that full-sized *H. sapiens* reached Australia and New Guinea through Indonesia by 46,000 years ago, that most of the large mammals of Australia then promptly went extinct (probably in part exterminated by *H. sapiens*), and that the first arrival of behaviorally modern *H. sapiens* on all other islands and continents in the world was accompanied by similar waves of extinction/extermination. We also know that humans have exterminated competing humans even more assiduously than they have exterminated large nonhuman mammals. How could the micropygmies have survived the onslaught of *H. sapiens*?

One could perhaps seek a parallel in the peaceful modern coexistence of full-sized sapiens and pygmy sapiens in the Congo and Philippines, based on complementary economies, with pygmy hunter-gatherers trading forest products to full-sized sapiens farmers. But full-sized sapiens hunter-gatherers 18,000 years

ago would have been much too similar economically to micropygmy hunter-gatherers to permit coexistence based on complementary economies and trade. One could also invoke the continued coexistence of chimpanzees and humans in Africa, based on chimps being economically too different from us to compete (very doubtful for micropygmy), and on chimps being too dangerous to be worth hunting (probably true for micropygmy). Then, one could point to the reported survival of the pygmy stegodont elephants on Flores until 12,000 years ago ([4]1, [5]2): If stegodonts survived so long in the presence of *H. sapiens*, why not micropygmy as well? Finally, one might suggest that all of the recent dates for stegodonts and micropygmy on Flores are in error [despite the evidence presented in ([6]1) and ([7]2)], and that both stegodonts and micropygmy became extinct 46,000 years ago within a century of *H. sapiens*' arrival on Flores. All of these analogies and suggestions strike me as implausible: I just can't conceive of a long temporal overlap of *sapiens* and *erectus*, and I am reluctant to believe that all of the dates in ([8]1) and ([9]2) are wrong. Hence I don't know what to make of the reported coexistence.

Yes, I know, when you have a hammer everything looks like a nail. But I think Diamond is quite wrong about the nature of *Homo sapiens* economies 50,000 years ago. To Diamond, the big change was the invention of agriculture. Before that, hunter-gatherer; after that, farmer and occupational specialization. I believe there were vast economic changes long before agriculture – it took a long time to evolve language, and that didn't start until there was already plenty of trading. By 50,000 years ago, I'm sure there was lots of specialization (Person A makes/knows X, Person B makes/knows Y), giving the *Homo sapiens* all sorts of tools and other useful expertise that the micropygmy didn't have. They both hunted and gathered but much larger brains and a vast amount of expertise would have been for naught if they didn't hunt and gather different foods. [10]*Homo erectus* did not have anything like human language, as far as I can tell; therefore they didn't have lots of trading or expertise. The two groups could co-exist because their foods were different. I suspect the *H. sapiens*, able to hunt really large animals, thought small animals, which supported the micropygmy, a waste of time.

---

Kevin C (2008-04-27 21:26:33)

A small point, but the micropygmy would not be human ancestors. They would have belonged to another branch of hominids as you point out. They would be our evolutionary cousins, but not our ancestors.

seth (2008-04-27 22:22:51)

Yeah, I was simple and somewhat wrong rather than complicated and correct. I wondered how to describe them and followed Diamond, who called them "a primitive human micropygmy population".

Kevin C (2008-04-28 06:53:43)

I can sound like such a nitpicker. I think that is part of my evolutionary niche: to find tiny problems with things I otherwise like or agree with.

seth (2008-04-28 07:16:06)

Thanks, Kevin. It was helpful to be corrected.

Seth's blog » Blog Archive » My Theory of Human Evolution (directory) (2008-05-05 06:13:00)

[...] I Recommend material-science research) the cellphone effect (the first words facilitated trade) micropygmyies (hunter-gatherers w/ trade different from those w/o trade) autism (autistic "obsessions" reveal a universal tendency toward expertise) [...]

### **The McCarrison Society (2008-04-28 17:13)**

The [1]McCarrison Society is named for Robert McCarrison, a British doctor who studied nutrition in India. Its website is full of important nutritional info, including [2]this:

When I worked in East Africa from 1960 - 1965, there was not a single case of breast, colon or prostate cancer, no cardiovascular heart disease and any diabetes seemed relatively mild. Nor was this absence of such diseases due to poor diagnostic facilities.

It's like a British version of the [3]Weston Price Foundation.

[4]Interesting lecture by Michael Crawford, its president.

More. It was founded in 1966 and has about 300 members.

### **How Much Play Will This Get? (2008-04-28 17:51)**

How will Al Gore respond to [1]this, I wonder?

Disconcerting as it may be to true believers in global warming, the average temperature on Earth has remained steady or slowly declined during the past decade . . . All four agencies that track Earth's

temperature (the Hadley Climate Research Unit in Britain, the NASA Goddard Institute for Space Studies in New York, the Christy group at the University of Alabama, and Remote Sensing Systems Inc in California) report that it cooled by about 0.7C in 2007. This is the fastest temperature change in the instrumental record and it puts us back where we were in 1930.

Thanks to [2]Geoffrey Kidd.

More. A [3]response to this article. Thanks to Kathy Wollard.

## **The Scientific Method, Half-Finished but Wholly-Accepted (2008-04-29 12:23)**

In a science classroom at a middle school I saw a poster about "the scientific method." There were seven steps; one was "analyze your data." According to the poster, you use the data you've collected to say if your hypothesis was right or wrong. Nothing was said about using data to generate new hypotheses. Yet coming up with ideas worth testing is just as important as testing them.

It's like teaching the alphabet and omitting half of the letters. Or teaching French and omitting half the common words. While no one actually teaches only half the alphabet or only half of common French words, this is how science is actually taught. Not just in middle school, everywhere. The poster correctly reflects the usual understanding. I have seen dozens of books about scientific method. They usually say almost nothing about how to come up with a new idea worth testing. An example is *Statistics For Experimenters*, a well-respected book by Box, Hunter, and Hunter. One of the authors (George Box) is a famous statistician.

The curious part of this omission is how unnecessary it is. Every scientific idea we now take for granted started somewhere. It would be no great effort to find where a bunch of them came from.

---

LemmusLemmus (2008-04-30 06:23:17)

I think the problem is that you can't teach how to come up with new ideas. You can tell a pretty standardized story about how to test ideas, but not about how to develop them. I remember reading in a book about the methods of empirical social research something along the lines of: "Hypotheses can come from reading the previous literature, the researcher's intuition... pretty much anything goes." Which sounds about right to me.

Marc (2008-04-30 07:10:00)

For me one of the valuable ideas which I've taken away from G. Box and his writing is his stress that experimentation is a dialog between theory and practice. One generates theories and then one tests them using sound methods. The results from the tests generate new perspectives which get fed back to the original theory and the cycle repeats. Another idea which I remember getting stressed quite a bit in the DOE literature was not to put all ones resources into the first experiment. The first experiment is most likely to reveal that ones thinking about the problem is way off track. The ideas are there, in the background, that the experiments themselves generate the ideas/theories which step by step bring one closer to understanding.

Aaron Blaisdell (2008-04-30 07:41:40)

Allen Neuringer and other experimental psychologists would disagree with the statement that "you can't teach how to come up with new ideas." Allen's research paradigm directly addresses this question and finds that variation—the foundation of creativity—can be selected for through operant reinforcement. I remember reading similar studies in human children being selected for creative (i.e., novel) output in art media (painting if my memory is correct). That said, it is very neglected in the science classroom and literature, but I think it is alive and kicking in the mentor-apprentice model that takes place in most ph.d. labs. Also, see Platt's famous 1964 Science paper "Strong Inference" for a well-stated explanation of the scientific method.

seth (2008-04-30 09:11:34)

"You can't teach how to come up with new ideas." I think you can. One way to come up with new ideas – that is, increase the chances of this happening – is to do a better job of analyzing your data. To examine it more thoroughly. This will sometimes reveal hard-to-explain anomalies. These anomalies will often inspire new ideas. Note that this particular method was not one of the ones listed in that methodological book LemmusLemmus read.

LemmusLemmus (2008-04-30 09:35:40)

Seth, the "you can't teach..." wording was much too strong, even wrong. It would be more accurate to say that it is harder: My main point was that there is a fairly standardized method to test ideas - formulate the hypothesis, collect data, etc. - and there is no such standardized method for coming up with ideas. I'm definitely not against telling students to come up with ideas by looking closely at the data, introspection, self-experimentation, and so forth. In fact, it would be useful to have an as-exhaustive-as-possible-list in a textbook. The list is going to vary depending on the subject. (It's been a long time since I read that book; that was not a verbatim quote.) As an aside, I once read an article in a German sociology journal that included a long and winding paragraph in which the authors justified not deriving their hypothesis from the previous literature, but simply from everyday observations. I have a funny feeling that one was included in response to a reviewer's comment.

seth (2008-04-30 13:43:23)

"The list is going to vary depending on the subject." Interesting idea – why do you think this?

LemmusLemmus (2008-04-30 15:35:07)

Seth, for example, if you're an astrophysicist, self-experimentation will not help much.

Nathan Myers (2008-05-02 22:37:37)

Astrophysicists have much bigger problems these days than not being able to apply self-experimentation. Most of what they theorize about (black holes, neutron stars, dark matter, dark energy) very likely doesn't exist at all. Everything they see (planets excepted) and everything in between is made out of stuff whose behavior is governed by completely intractable mathematics they prefer not to think about at all. The scientific method was invented in its entirety by one ibn al-Haytham, a bit more than a thousand years ago. (He is known in mathematics as Alhazen and Alhacen, in different contexts.) He was under house arrest in Egypt, and spent his time in confinement founding the study of optics. He invented science in order to obviate the need to appeal to authority. His book on optics was the standard reference for centuries after, and well known to Francis Bacon. Hypotheses fall from the sky like rain. Science provides a way to cull the wrong ones. It fails completely if you don't want to cull the wrong ones.

seth (2008-05-03 02:50:54)

thanks for the explanation, LemmusLemmus. I think self-experimentation isn't a basic principle of science, it just is one way to follow a basic principle, which I would state as: "to find new ideas worth testing, gather data quickly and cheaply." Nathan, what does "hypotheses fall from the sky like rain" mean? It sounds too passive. It is hard to increase the rate of rainfall; it is much easier, I'm sure, for a scientist to increase the rate at which they generate new ideas worth testing.

Nathan Myers (2008-05-03 11:01:33)

My point was that any competent scientist can come up with more hypotheses than he can afford to test carefully, and way more than his or her colleagues can afford to pay attention to, in aggregate. With science, we can offer reasons why somebody else should pay attention to our ravings. This was the problem that al-Haytham first addressed. Ravings were perhaps more prevalent then.

seth (2008-05-03 19:24:13)

"Any competent scientist can come up with more hypotheses that he can afford to test carefully." More *plausible* hypotheses? That is the opposite of my experience. In my field, experimental psychology, it is extraordinarily hard to come up with new treatments that will plausibly have a big effect on the main things we study. What are you basing this statement on?

Nathan Myers (2008-05-05 08:28:11)

I'm not an experimental psychologist. Doesn't it take a long time to test a hypothesis thoroughly? Aren't there many, many phenomena still lacking definitive explanation? For many years the only plausible hypotheses were behaviorist. Inventing plausible behaviorist hypotheses is really hard. More generally, the hardest part about inventing hypotheses is to stop pretending to know what you don't really. Limiting yourself to what grant committee members and journal referees would welcome makes hypothesizing artificially difficult.

John Hunter (2008-05-31 13:35:09)

One of the other authors of [1]Statistics for Experimenters was my father :- ) [2]William Hunter. It is great to keep hearing from people that like the book.

## Happy Birthday, SLD! (2008-04-30 10:40)

The Shangri-La Diet (the book) is two years old. What's happened during the last year?

The nerd in me is enormously concerned with numerical measures of popularity. Is the diet spreading? If so, how fast? This can be measured dozens of ways; the number I trust most is number of visitors to the [1]SLD forums. This

number has been steadily increasing. Plotted on a log scale, the visitors-vs-time function is roughly linear (= same percentage increase each month). The number has doubled in a year. It was about 7,000 a year ago; it is about 14,000 now. The increase has happened/is happening without much effort from me. During the first year, I posted on the forums several times per day; now I post less than once/day.

Which brings up Topic 2: Improvements by users – which the populist in me cares about. I like to think that allowing anyone to contribute ideas and experience, which they can do via the SLD forums, will be a good thing. (Not only here: the Weston Price Foundation website should have forums.) I also like to think the ideas behind SLD have a life of their own. More than other weight-loss methods, the Shangri-La Diet is based on a theory. Most weight-loss methods are based on good/bad classifications: Food A is good, Food B is bad. Not much room for improvement. A theory, on the other hand, can be used in many ways. Mixing a new theory with lots of user experimentation should be really powerful – especially when the user-experimenters can trade ideas and experience. It should produce a different kind of growth: growth of efficacy. Over the last year I was especially impressed with comments on the SLD forums about nose-clipping. [2]This thread in particular. Heidi555 wrote:

I think it's much easier to nose clip a higher percentage of food. The AS is noticeable and you don't have to exert any will power. I don't worry about a two hour window. . . . The weirdest thing is that I always feel like I'm eating a lot. Maybe eating as much as you want, of whatever you want, always feels like a lot.

By "much easier" she meant much easier than other ways of applying the theory ("taking oil, sugar water, or a smaller amount of nose clipped food). Wearing nose-clips in public isn't easy, but that could change. Isn't wearing nose-clips a lot like wearing glasses?

Another part of me likes a good story – e.g., American Idol. If I wanted to tell a story about SLD during the last year, I would stress the omega-3 storyline, especially 1. [3]Tyler Cowen no longer needs gum surgery after he starts taking flaxseed oil (FSO). 2. Anonymous finds himself [4]healing more quickly after martial arts practice when he starts taking FSO.[5] Stops taking FSO, returns to baseline, restarts FSO, improves again. I like the unexpectedness of it: Why would a new diet lead to this? Speaking of fights, in New York, I met a woman who works on reality TV shows. "That's what my job is about," she said. "Getting people to fight." Yes, fight = good TV. Over the last year, the SLD forums [6]remained bad TV: exceptionally well-behaved and conflict-free. I'm not sure what this means, but I really like it.

[7]Stephen Marsh's 2.5 yrs on SLD.

Craig (2008-04-30 15:37:14)

Purslane high in omega 3, in India traditionally used as a remedy for dry coughs, swollen gums.

Andrew Gelman (2008-04-30 20:42:52)

I don't think being interested in "numerical measures of popularity" has anything to do with being a nerd. Lots of non-nerds are interested in numerical measures such as how much money they have, how fast their car can go, etc. And I'm sure that just about every book author, nerd or not, wants to know sales figures.

seth (2008-04-30 22:43:08)

True. Perhaps nerds are more interested in such measures?

Sam (2008-05-03 03:45:01)

About Omega-3, I just read that Omega-6 and Omega-3 are taking up each others spaces in our body, so taking in much more Omega-3 than Omega-6 would deplete our body of Omega-6. I wonder what this will do to your body, on long term (if anyone would know, it should be you I'd think). I'm just starting a mercury/amalgam detox using Chlorella, wild garlic, protein, sunflower oil and flaxseed oil, and they recommend 1 part flaxseed oil (omega-3) for 4 parts sunflower oil (Omega-6) to rebuild cell damage from mercury/amalgam - so far I only used flaxseed oil, but I'll get started with sunflower oil, too (btw. reading about amalgam and conventional wisdom being wrong is very interesting - amalgam was accepted for teeth for all the wrong reasons against knowing mercury for being toxic).

### **Idol-Wise (2008-04-30 16:04)**

The most popular TV show is American Idol. On Survivor, one of the most popular TV shows, an "immunity idol" has a big role. Next: a restaurant chain called [1]Potlatch.

### 3.5 May

#### The Aquatic Ape Hypothesis (2008-05-01 22:37)

Recently I visited some friends whom I hadn't seen for a while. You're more talkative, they said. I attribute this to flaxseed oil.

I became interested in the effects of flaxseed oil partly because of the aquatic ape hypothesis, the idea that living near water had a big effect on human evolution. During a long period of human prehistory, the theory says, we swam a lot, presumably to catch fish. If we ate lots of fish (high in omega-3) at the same time our brains grew large, it was quite possible that our brains need large amounts of omega-3 to function properly. Flaxseed oil is high in omega-3.

Elaine Morgan, the theory's main proponent, has written several books about it, "each more po-faced [= academically correct] than the last," she has said. I have finally read two of them and was pleased to find more scrutiny made the theory more plausible.

Background to the idea that humans were once aquatic is that several mammals have obviously become aquatic – starting on land they shifted to water. Sea lions, whales, and so on. Birds have become aquatic – for example, ducks. Insects have become aquatic. Elephants appear to have become aquatic and then terrestrial again – note how well they can swim. There is ample precedent, in other words.

Humans differ in all sorts of anatomical and physiological ways from other primates and the aquatic ape theory has straightforward explanations for many of them:

1. Humans have subcutaneous fat, other primates don't. Other aquatic mammals do. Explanation: The fat serves as insulation.
2. Humans have almost no fur, other primates do. Other aquatic mammals don't. Explanation: Fur creates drag in the water. In the air, fur insulates.
3. Humans are bipedal. Explanation: Walking upright keeps the head out of the water, allowing breathing.

---

Hamish (2008-05-02 01:15:49)  
Regarding point 2. What about fur seals?

Varangy (2008-05-04 15:37:27)

Don't get me wrong, I am open to the idea of the aquatic ape theory, but I don't find theory compelling. *During a long period of human prehistory, the theory says, we swam a lot, presumably to catch fish.* This holds no water, no pun intended. Ever try spearfishing? Even with a high-powered modern speargun, powerboat and modern wetsuit, it is on a calorie expended basis, by far, the least efficient way to obtain calories. Probably negative, if you count all the times one goes spearfishing and comes back with nothing. Also, humans have to be taught how to swim and most of us, are instinctually, afraid of the water. *Humans have subcutaneous fat, other primates don't. Other aquatic mammals do. Explanation: The fat serves as insulation.* Again, I am very skeptical about how much insulation subcutaneous actually provides. After all, we where clothes and air is much less of a conductor of heat than water is. 2. *Humans have almost no fur, other primates do. Other aquatic mammals don't. Explanation: Fur creates drag in the water. In the air, fur insulates.* Again, other marine mammals DO have fur. Seals and sea lions certainly do, river otters do. Beavers. Not to mention the animal with the most dense fur of all animals, the sea otter. Also, marine birds certainly have feathers. Penguins, ducks, cormorants etc etc. 3. *Humans are bipedal. Explanation: Walking upright keeps the head out of the water, allowing breathing.* Back to marine mammals, no marine mammals is bipedal. And the other animals that are bipedal, namely birds, such as herons, use their bipedalism essentially as terrestrial animals to stalk small game in very shallow waters. By the AA theory, based on bipedalism and tallness, a crane would be ideal for getting INTO the water and stalking game that way. I think the theory is fun, but ultimately sort of romantic and not serious.

Varangy (2008-05-04 15:39:04)

One more thing, I just don't see aquatic apes spearing fish with crude spears, no flippers and no goggle like device.

seth (2008-05-04 16:06:17)

Efficacy of fishing. To use your own experience as a guide here is to underestimate the effects of learning, tradition, and practice. Not to mention over-fishing. "Humans have to be taught how to swim." You haven't seen pictures of swimming babies. They swim very easily. What's your explanation of why humans have subcutaneous fat and other primates don't? Human subcutaneous fat increases when humans are exposed to cold. And what's your explanation for why humans became bipedal? Thanks for the correction about aquatic mammals and fur. I should look at that more carefully.

Kevin C (2008-05-04 17:06:56)

Isn't bipedalism conventionally explained by our shift from forests to open plains? The open plains of Africa gave an advantage to apes that could stand up and see above the grasses and across the plains.

seth (2008-05-04 19:05:08)

Re the open-plains explanation of bipedalism. It would be nice to have one coherent explanation of the dozens of ways early humans differed from chimps rather than separate explanations for each difference. The forest-to-plains explanation doesn't offer a good explanation for subcutaneous fat – surely the plains were hotter than the forests. And the "see over the grass" explanation is pretty arbitrary. What about looking up into the leaves? Why didn't other primates develop bipedalism so that they can more easily look up into the trees?

anthrosciguy (2008-05-05 10:40:23)

As has been pointed out, not just fur seals but *all* seals have hair, and for that matter all aquatic and semi-aquatic mammals except whales, serenia, and hippos. All these can be explained by two factors which are well-supported: large size and thermodynamics, and in the case of the smaller whales, swimming speed. Although it's also likely that the hairlessness of whales only evolved once and then spread to all descendants, all species we have now, rather than for each individual species. The "swimming babies" business is an old zombie. There is an "infant swimming reflex" (just as there is an infant crawling reflex and a host of other interesting reflexes in infants). The infant swimming reflex is not unique to humans but is found in all mammals tested, including opossum, rat, kitten, rabbit, guinea pig, and rhesus monkey. They all lose this reflex within a few months after birth, and it's likely present because the infant has just spent its life immersed in fluid up until birth. The subcutaneous fat in humans is just like primates which are allowed to get fat. In the wild primates, like most other animals, don't get very fat because even though fat is great for lean times, it limits mobility and makes one more vulnerable to predators.

In animals which have relatively little danger from predators, they get fatter than their close relatives. Humans have had, due to fire and "advanced" weapons like spears, had relatively little predator problems for hundreds of thousands of years compared to our close relatives. It's also clear that fat has not evolved for insulation, as we can see, for instance, by the fat deposits of whales and seals. The fat there is for shaping, to make the animal more hydrodynamic; the fat across the belly is very thinly deposited which wouldn't make sense if it was for insulation, also in winter and cold water and poorer food supply the fat nearest the skin gets used up first which also wouldn't make sense if it was for insulation. This according to Caroline Pond, who is certainly the foremost expert on the evolutionary significance of fat. On the subject of hydrodynamics, fur is not a drag in the water, it aids in hydrodynamics due to breaking up the boundary layer (this has been confirmed through testing). And dolphins, for instance, have no fur but instead have evolved dermal ridges which do the same thing that a layer of fur would do. In fact, the one thing we find that's bad for swimming speed is exactly what we have: some hair (sometimes a lot of body hair) which is often curly and decidedly non-hydrodynamic. On bipedalism, the normal paleoanthropological explanations involve looking at how and when non-human primates use bipedalism (they all do sometimes). A very tiny fraction of that is walking in deep water (usually when they do wade, they're quadrupedal), most is during food getting and carrying, also for observation, for displays, etc. And of course some apes (orangs and gibbons) use bipedalism virtually exclusively on the ground, because they use it a lot in trees (as do other apes and monkeys of course). In short, there are no real good reasons to think the AAT/H holds water, and plenty of really good reasons to think it doesn't. As you can see just from these few bits of data, the only way an argument can be made for it is to ignore the real evidence and twist data into an unrecognisable pretzel. And the idea of one cause for everything, one stop shopping (or an "umbrella hypothesis" as it's called) is appealing to people who don't know much about the subject but falls apart when you look at it and start learning. Even Seth's interest in flax seed oil shows one way the theory doesn't make sense; one of the common claims for it is that the oil he prizes (quite rightly) in flax seed and other plant and terrestrial sources is only found at the seashore – obviously that's nonsense, yet the proponents still make the claim. If you want to know more about the problems with the idea, you can check out my web site (the link is above). I've been doing this for quite a few years now and my site is used by college courses as well as by magazines and online sources, and I recently wrote the entry on the theory for the *Sage Encyclopedia of Anthropology*. Apologies for the long comment.

Varangy (2008-05-05 10:59:59)

I think antrosciguy has it about covered. But to respond to Seth's comments: *Efficacy of fishing. To use your own experience as a guide here is to underestimate the effects of learning, tradition, and practice. Not to mention over-fishing.* I couldn't, respectfully, disagree more. My experience is based on fish behavior when being hunted. In modern spearfishing we observe all the effects of learning, tradition and practice that you mention — and yet, with all of its the very, very modern accouterments such as specialized freediving goggles, specialized freediving wetsuits, specialized freediving flippers, specialized freediving gloves, specialized freediving knives, and unbelievably powerful spearguns, spearfishing is hard. Very hard. It takes a considerable amount of courage practice, time, and skill to kill large fish regularly. And yet, there is no way one could harvest enough fish over an extended period of time to actually subsist on or even support a family. Unless aquatic apes looked like dolphins with arms, in-water/swimming around with a crude spear is impossible. *Humans have to be taught how to swim.* You haven't seen pictures of swimming babies. They swim very easily. I have. And that is quasi-myth. They don't actually 'swim'. They can naturally hold their breath, but unless you bring the child to the surface, rest assured it will drown. *What's your explanation of why humans have subcutaneous fat and other primates don't?* Human subcutaneous fat increases when humans are exposed to cold. I suspect that other primates do — these certainly do. *And what's your explanation for why humans became bipedal?* There are various theories on this, I don't want to go into the pros and cons of each – however, logically, I do not have provide a competing explanation to reasonably cast doubt on AA theory. *Thanks for the correction about aquatic mammals and fur. I should look at that more carefully.* More to antrosciguy's point — take a look at the Fastskin by Speedo: <http://www.sciam.com/article.cfm?id=the-olympians-new-clothes> *One fabric, the Fastskin, works like spandex to compress the body and limit muscle oscillation. Fastskin is designed to reduce friction drag by creating ridges and valleys similar to those on a shark's skin—the water skims over the ridges and skips the drag-inducing valleys in between them. At points where bodies curve, another spandexlike material called Flexskin—joined to the other fabric by low-profile seams—enables greater mobility. Speedo suits also feature titanium-silicon scales on the inner forearm that grip the water better on down strokes. Lastly, rubber bumps across the chest help reduce another type of resistance called pressure drag. The overall effect, Speedo asserts, is a 4 percent reduction in passive drag for men and a 3 percent reduction for women.*

Varangy (2008-05-05 11:04:30)

We cannot forget the prevalence of large marine predators as well, both in freshwater as well as salt i.e. crocodiles, alligators, hippos (while they do not technically prey on humans, they often kill them, both in the water and out), of course, various sharks, — there also no reason that a marine mammal like a killer whale wouldn't snack on a human, even though that, for some unknown reason, is thought to be impossible.

seth (2008-05-05 20:58:30)

Anthrosciguy, do you have a reference for your apparent claim that humans and other primates do not differ in amount of subcutaneous fat? I couldn't find one at your website. Since people gain subcutaneous fat when exposed to cold, I cannot believe that fat has nothing to do with insulation, no matter what Caroline Pond says. You are plainly wrong when it comes to omega-3, the part of your comment that I know the most about. Some seafood, such as salmon, has a lot of omega-3. The aquatic ape theory doesn't suppose it is "only" found in seafood. Of course not. Omega-3 is in every plant. It supposes that seafood is an unusually good source.

anthrosciguy (2008-05-10 10:54:36)

It's not amount of fat. What the situation is is that humans can and do get fat, just as all animals do when they can get away with it. The controlling factor for most animals, including primates, is predation. Extra fat is very useful because it's stored food, and when your food supply is off and on having that extra food is very handy; it can be the difference between life and death, or between healthy pregnancies and nursing or weak, sick young. But it limits mobility, so it makes the animal more vulnerable to predators. In situations where predation is limited, an animal will become fatter than its relatives in situations where predation is not so limited. For humans, this relatively limited predation has been the case for hundreds of thousands of years, since we were able to use fire and "advanced" weapons like spears. Now all these fat deposits are anchored to internal depots, and those of humans are just like those of other primates. When the fat of either humans or other primates gets more plentiful it spreads out and eventually is found under the skin in larger amounts, just as it is elsewhere in larger amounts. But humans can get fatter, although it's not clear that "wild" humans actually are fatter than wild non-human primates. For instance, most primates in the wild are similar to most other terrestrial mammals at around 5 % fat (it goes up at certain times of the year and down at others, particularly for animals which don't live in the tropics, although even there rainy and dry seasons cause quite a change). For modern humans, who don't live in anything like a "wild" situation anywhere – not even gatherer-hunters – the average fat is higher, and of course it's getting crazy in North America. But we also find, for instance, that Eskimos have lower body fat than adults in Canadian cities (people *do not* gain subcutaneous fat when exposed to cold, AFAIK, would you please send me a reference for that if you have one), and some gatherer-hunter tribes were measured at around 5 % body fat, so it's not unlikely that normal, everyday humans tens of thousands of years ago were not much fatter, if at all, than non-human primates even though they *could be*, and sometimes were. In short, when any primate gets fat, the fat which is anchored in internal depots spreads out and under the skin. Due to predation, non-human primates tend not to get that fat, and in zoos they are fed a diet which tries (not always successfully) to keep them trim. BTW, a common thing you'll see in AAT/H proponents' claims is the "ten times fatter" claim; this is a serious misreading (originally by Morgan and endlessly repeated by others) of Caroline Pond's work in which she found that humans, *just like other primates*, have numerous and small fat cells compared to rodents, that *compared to rodents* we have "ten times the expected number of fat cells". She was describing why rodents aren't a very good model for fat in humans, since they can expand and decrease the size of their fat cells as they get fatter while we, *just like other primates*, add fat cells instead, and this makes it harder to lose fat since losing fat cells is much harder than reducing their size, yet the small size of our fat cells makes it very hard for them to be reduced in size. As far as insulation goes, any benefit of fat is secondary rather than a reason it was selected for. And I've given an outline of the basic reasons why, and Caroline Pond is one heck of a source, having devoted her career to studying this; your dismissing her work in favor of your wishes is not very good science, to say the least. :) Many AAT/H proponents claim that seashore sources are far better than inland sources for DHA (an example is from the BBC Radio 4 program, where it was incorrectly claimed "And the only place to find that accessible and abundant supply of brain selected nutrients was at the shoreline, in the marine food chain."). This is one of those "true but false" things: One the one hand, DHA itself is found more in some marine sources, but especially in cold water marine fish, which is fairly easy for us to get but let's face it, impossible for our early ancestors to obtain. But DHA and LNA are found in many inland terrestrial sources, and these are not that hard to find. Wild game, especially brains,

various plant fats from various plants (just as you're promoting flax, and it's far from the only one) are some sources. And other needed nutrients are, according to studies, far more abundant in terrestrial sources than at the shore.

Ilana (2008-05-12 16:54:02)

I was under the impression that the main purpose of fat in the Aquatic Ape theory was not for insulation but in order to help with bouyancy. That in turn would help the ape/human to swim. And it would help with insulation in the water - that's why women can compete with men in swimming - they have more fat than men do which makes them more bouyant, and they can stay in cold water for longer periods of time than men can for the same reason. Of course, this would not help if they were to stay in water for long periods of time, but the AAT never said that the apes/ humans would live in the water, just that they would live by water sources and spend a frequent amount of time in the water. Also, clearly other primates can get fat, but can they get as fat as humans can? And about the fishing - you're all ignoring another method of gaining marine food that would have been very possible for the apes/humans - diving. There's not just fish in the sea, there's also seaweed and crustaceans. It's very possible that the apes/humans started picking seaweed and crustaceans up in shallow water, and gradually moved deeper, learning to dive for their food. They would have then had a ready supply of food much easier to attain than fishing. You can see examples of this in modern times in the Amo and Haenyo diving communities. The women dive in the ocean for food and occasionally pearls. While it takes great skill and training to do this, it wouldn't be improbable for apes/humans to learn how to do this if they gradually moved out into deeper and deeper water. There would also be a far greater food supply if they lived off seaweed and crustaceans than if they lived off game and brains, competing with the big cats and other hunters of the area. And if they got bigger brains from eating the same food that terrestrial hunters ate, then why are modern humans brains so much bigger than any brain of a terrestrial animal of the same size? Wouldn't the terrestrial animals' brains be the same size in proportion to their bodies as humans? Also, I'm sure those nutrients are found in plants, but would those plants have been found in abundance in that particular part of africa? I don't know the specific nutrients in plants, but I know that many vegetarians have to be careful about their diet to be sure they get the right amount of vitamins to keep their bodies healthy. That would seem to point that the apes/humans did not get much of the nutrients needed entirely from plants, because then our bodies would be designed for vegetarianism, which they are not. However, I do not know the specifics on that one, so I could be completely off on the plant point. If someone knows more detail about it, please let me know. Also, the predator argument against the theory doesn't hold water, because there would be a similar amount of predators on land. They wouldn't not go in the water once they had found it to be a good food source because of marine predators, and stayed on land, where there were other predators. It doesn't make sense. Also, the various aquatic predators would differ from area to area, so they wouldn't have hippos, crocodiles, alligators sharks and killer whales diving at them all at once. At most they would have one or two, and they would have learned to cope with them, the same way that they would have learned to cope with the predators on land if they lived in a land based environment. And they probably would not have had to deal with sharks and killer whales unless they lived in the sea, which is unlikely. According to the AAT, they would have lived along the coast, where shark attacks, though they do occur, are minimal. and, yes, clearly hairlessness would not be as effective in reducing speed as ridges on dolphin skin, but as simply shaving off body hair increased swimmers speed according to a 1989 study, losing thick, curly hair from all over the body would have had quite an effect on increasing both speed and efficiency in the water. If you think about it, it is more likely for an ape to have lost hair in order to be more efficient in the water than it is to have changed its existing hair into the water efficient hair of a seal or an otter. Remember, the ape/human would only be semi aquatic, rather than fully aquatic, so it would have had no reason to grow ridges on the skin like dolphins or other fully aquatic animals. And to assume that in order for it to be aquatic it would have had to change its pelt into one similar to an otter or a seal is just silly. And yes, humans are instinctively afraid of the water. However, we spend quite a lot of time in the water for creatures who are afraid of it. Yes, we have to learn to swim, but we also have to learn to walk, and to speak. What of it? Is language not a part of our brains or our evolution simply because we have to learn it? OK, I'm done now. I think. Sorry that took so long. You were all giving such intelligent arguments that I had to jump in.

seth (2008-05-12 20:03:43)

thanks Ilana. If fat provides buoyancy the more fat the harder to dive - which makes it harder to get food that you have to dive for. Insulation is an unequivocal blessing since the water will be cold. you remind me that collegiate swimmers shave themselves before big meets - to go faster, of course. So even the hair we have left slows us down in the water. This makes

the idea that more primate-type hair would be better in the water (fur "aids in hydrodynamics" according to anthro guy) very hard to believe.

Varangy (2008-05-13 11:43:09)

That in turn would help the ape/human to swim. And it would help with insulation in the water - that's why women can compete with men in swimming - they have more fat than men do which makes them more buoyant,

Women don't compete with men in swimming. And as they generally have more fat as percentage of body fat to muscle, I would say that is a hindrance rather than advantage. Lastly buoyancy is almost irrelevant to swimming speed. Check out the backstroke next time, why is so much of the race **underwater** off the wall using dolphin-kick? (This is legal BTW)

And about the fishing - you're all ignoring another method of gaining marine food that would have been very possible for the apes/humans - diving. There's not just fish in the sea, there's also seaweed and crustaceans. It's very possible that the apes/humans started picking seaweed and crustaceans up in shallow water, and gradually moved deeper, learning to dive for their food. They would have then had a ready supply of food much easier to attain than fishing.

That is incorrect. Crustaceans and shellfish are extremely hard to find and dislodge from their crevices. On a per calorie expended basis, diving, even with modern spearfishing equipment is a negative proposition. Sustaining oneself or a family is impossible.

You can see examples of this in modern times in the Amo and Haenyo diving communities. The women dive in the ocean for food and occasionally pearls. While it takes great skill and training to do this, it wouldn't be improbable for apes/humans to learn how to do this if they gradually moved out into deeper and deeper water.

These women use all the modern free-diving accouterments (mask, fins, wetsuit, boats, nets, abalone bars to pry abalone off rocks etc etc) (My guess scuba is too expensive and limits mobility) Some pics here: <http://quebecjeju.blogspot.com/2007/09/d-ominatrix-women.html> They do NO subsist nutritionally from diving.

There would also be a far greater food supply if they lived off seaweed and crustaceans than if they lived off game and brains, competing with the big cats and other hunters of the area. And if they got bigger brains from eating the same food that terrestrial hunters ate, then why are modern humans brains so much bigger than any brain of a terrestrial animal of the same size? Wouldn't the terrestrial animals' brains be the same size in proportion to their bodies as humans? Also, I'm sure those nutrients are found in plants, but would those plants have been found in abundance in that particular part of Africa? I don't know the specific nutrients in plants, but I know that many vegetarians have to be careful about their diet to be sure they get the right amount of vitamins to keep their bodies healthy. That would seem to point that the apes/humans did not get much of the nutrients needed entirely from plants, because then our bodies would be designed for vegetarianism, which they are not. However, I do not know the specifics on that one, so I could be completely off on the plant point. If someone knows more detail about it, please let me know.

This is a complete non-sequitur.

Also, the predator argument against the theory doesn't hold water, because there would be a similar amount of predators on land. They wouldn't go in the water once they had found it to be a good food source because of marine predators, and stayed on land, where there were other predators. It doesn't make sense. Also, the various aquatic predators would differ from area to area, so they wouldn't have hippos, crocodiles, alligators, sharks and killer whales diving at them all at once. At most they would have one or two, and they would have learned to cope with them, the same way that they would have learned to cope with the predators on land if they lived in a land based environment. And they probably would not have had to deal with sharks and killer whales unless they lived in the sea, which is unlikely. According to the AAT, they would have lived along the coast, where shark attacks, though they do occur, are minimal.

Being in the water and having to face predators negates many of the advantages that humans have. Relatively keen color eyesight in air/land, being able to aim and throw a spear/rock/club (we know chimps defend themselves with clubs), height to see

over obstructions, being able to climb a tree/cliff for evasion and reconnaissance. BTW there are also fresh-water sharks like the Zambezi and Bull Shark that do attack Africans in rivers. I and maybe a few experienced men with spears have a far better chance against several lions (aren't lions afraid of the Masai?) than we do against one shark/killer whale/croc/snake/hippo whathaveyou in the water. In short, they couldn't have coped.

If you think about it, it is more likely for an ape to have lost hair in order to be more efficient in the water than it is to have changed its existing hair into the water efficient hair of a seal or an otter. Remember, the ape/human would only be semi aquatic, rather than fully aquatic, so it would have had no reason to grow ridges on the skin like dolphins or other fully aquatic animals. And to assume that in order for it to be aquatic it would have had to change its pelt into one similar to an otter or a seal is just silly.

So it went from a chimp pelt, to hairless, to current status? How and why exactly?

Yes, we have to learn to swim, but we also have to learn to walk, and to speak. What of it? Is language not a part of our brains or our evolution simply because we have to learn it?

Completely different and irrelevant. All healthy humans learn to, innately/built-in, speak and walk. As birds learn to fly. It is part of the definition of being a human, genetically wired and part of growing. Swimming is a skill learned, much like driving a car or baking a cake. The baby swimming myth is just that, a myth.

you remind me that collegiate swimmers shave themselves before big meets "to go faster, of course. So even the hair we have left slows us down in the water. This makes the idea that more primate-type hair would be better in the water (fur "aids in hydrodynamics" according to anthro guy) very hard to believe.

@Seth So how do you explain the marine mammals I have brought up? Not to mention, the platypus! Also, feathers on penguins? You have to stop thinking linearly on this. The function probably dips and rises like this: -No hair "okay/good. -Some curly hair (especially in very un-hydrodynamic places, head, genitals, armpits) "very bad -Hydrodynamic thick coat (that may insulate as well "ala sea otters) "very good. -Ridges ala dolphins/sharks "best.

Ilana (2008-05-13 15:19:57)

actually, what you said about the divers is untrue. The ama have been diving for 1,500, before modern technology was created. And traditionally, they do not use modern diving equipment - that has only been introduced recently, in the past hundred years. Traditionally, they would dive mostly nude. In diving communities untouched by tourism, they still dive nude. As for the tools they use to prise the abalone shells from the rocks, those would not be too difficult for a human/ape to come by. They could have used thick sticks. And saying that they would have not been able to live off it is illogical. Humans have been eating shellfish for thousands of years, long before modern technology came along and made it easier for us to collect. Shellfish mounds have also been found in many ancient cultures. They probably obtained their shellfish through diving, and then switched to more efficient methods as they became more experienced. But the fact that humans have been eating shellfish for thousands and thousands of years points to the fact that not only could it have sustained a family, but that it couldn't have been as difficult to obtain as you portray. Also, the fact that humans learn to talk and walk as well as swim is not irrelevant. In our modern culture, children still have to learn to talk and walk. Therefore, in a culture that lived at the edges of lakes and rivers and on the sea shore, they would have had to learn to swim as well as walk, talk etc... In those cultures, swimming would be "part of the definition of being a human, genetically wired and part of growing," just like walking and talking is for modern humans. Bouyancy may be irrelevant to swimming speed, but it is not irrelevant to swimming. And the whole AAT argument centers around the hominids being efficient in the water. Being able to float would make it easier for them to swim. It also would help them to swim faster, because they could focus more of their energies on moving forward rather than staying afloat. Seth - you make a good point. However, one of the whole reasons that the Ama and Haenyo cultures use women is because they can withstand the cold for far longer than men because of their fat. This would mean that fat is good for insulation, like you said. But as fat is also bouyant, this bouyancy would not prevent them from diving deep. Again, it is the women, with the most fat, who dive in these cultures. So humans are able to use their brains to cope with land predators, but the moment that they step in the water, those brains are gone? If early humans can learn to cope with lions, there's no reason that they couldn't have learned to cope with water predators as well. At that very least they could

have gotten out of the water and climbed a tree (after all, they're more aquatic than other apes, rather than fully aquatic) Perhaps learning to deal with water predators helped humans/apes gain intelligence? Also, there are many sea based cultures in modern times such as the sea gypsies of southeast asia that must have found methods of coping with sharks and other predators simply because they live so close to the sea. Besides, sharks would not be the biggest threat, crocodiles would. And not all crocodiles are deadly. In fact, in the area where Lucy was found, the crocodiles are considerably smaller than Nile crocodiles and are not a threat to humans. Either the humans/apes would have found a way to deal with man eating crocodiles, and in doing so gained in intelligence and experience, or the water predators where the humans/apes lived were not as threatening as we might assume. When talking about hairlessness I was referring to our current status. That was what stimulated so much speculation on human evolution, the fact that compared to other mammals, humans are remarkably hairless. (and we stand on two feet). As to why we have armpit, head, and pubic hair, I really don't know. We probably have armpit hair and pubic hair because they grow in sheltered spots of the body and would not majorly detract from speed and efficiency in the water, or were simply one of the last areas of hair left as the body hair grew thinner and thinner. Also, when looking at the aquaticness of humans, you have to remember to compare them with apes, rather than fully aquatic animal, or even semi aquatic animals such as otters. After all, Hardy's original thesis proposed that the aquatic ape would be more aquatic than an ape, and less aquatic than an otter. So is a human's skin and hair as efficient in the water as a dolphin's, or a seal's? Obviously not. But is it more aquatic than an ape's? Clearly it is. If, according to you, Varangy, a human's skin and hair is not efficient in the water, than an ape's would be even less so. Apes do not have hydrodynamic thick coats, so their fur would be even less efficient in the water than our state of relative hairlessness. This only proves the point of AAT - humans are clearly more aquatic than apes, and the only theory providing an explanation for that is AAT. Sorry, that was long again.

Ilana (2008-05-13 17:49:14)

I forgot to mention edible seaweed again in my last post. Sorry about that. Edible seaweed as well as shellfish and fish as well as sponges would provide a lot of food to an ape/human, and edible seaweed certainly would not be difficult to obtain. Oh, and the Haenyo cultures used to live off what they gathered through diving, and it was only when Japan and Korea's relations improved that the Haenyo divers began exporting their gatherings for cash. So clearly it is possible to live off, and support families, from what could be gathered by diving into the sea. And if it's possible for Haenyo divers, it was certainly possible for apes/humans as well.

anthrosciguy (2008-05-14 11:44:00)

Several points: The proponents of the AAT/H have tended to go for moving the goalposts when it comes to what features are supposedly for, initially fat was said to be for insulation, then when (valid) objections were made to that claim, they shifted it to buoyancy. They always assume a modern western human degree of fatness, which is problematic, but more importantly they dismiss the sensible idea that features often have side benefits. As far as predators go, I have a section on my site that deals with predators and there are several big problems with the AAT/H view of aquatic vs. terrestrial predators. One is that we can see how even our most primitive ancestors could deal with terrestrial predators, by looking at how chimps do. Contrary to common AAT/H thought, this isn't simply by running away and climbing (although those options were available to our ancestors too); mostly they do it by harassing them, and in fact we see that leopards, for instance, will actually actively avoid chimp groups. Some predation occurs, of course, but we also see that there's not enough to cause the species to have a significant problem, because they have continued to exist for millions of years in the face of these predators. This shows that a species with similar reproduction to us - medium sized mammals with relatively slow reproduction rates - can survive in a terrestrial environment in the face of terrestrial predators. OTOH, we see no such species in a semi-aquatic or aquatic environment anywhere in the world. This is likely because the situation with aquatic predators is quite different from terrestrial. For one thing, the primary predators - crocs and sharks - are unresponsive to intimidation and counter-attack, very unlike terrestrial predators. And they are numerous. Rather than go over all this here, let me suggest reading that section of my site for the info. As for hair, it's quite true that shaving off body hair improves swimming times, and it's partly due to hydrodynamics (part seems to be due to changes in lactic acid build-up caused by removing the hair), but that only shows the extent of the problem. For swimming speed, we can either shave off our hair or don suits that mimic having lots of hair - the one thing competitive swimmers *don't want* is exactly *what we have*, and what we have is, according to the AAT/H claim, due to swimming speeds and efficiency. If it were, we wouldn't expect it to be *exactly what we don't want* for that purpose. There are a few other problems

I've seen pointed out that I haven't gotten into on my site, such as the littlest, and most deadly, predators: microorganisms, which we find we suffer from in water. We also have a number of ailments due to swimming and diving – the field of sports medicine goes into detail about them – that we would expect to have been weeded out of a species that spent a great deal of time swimming and diving, as those ailments have been weeded out of actual aquatic and semi-aquatic animals. For one example out of many, actual diving species have lost the instinct to breath in when they run out of air underwater; we have the opposite instinct, which is of course rather bad news for us when we're underwater and know full well we shouldn't gasp for air but can't help but do so.

anthrosciguy (2008-05-14 12:16:30)

There are a couple other points I realised I should've put in my last comment. First is on the subject of aquatic vs terrestrial predators: one of the bigger problems with the AAT/H claim that predators aren't a problem for the idea is that unless you're suggesting an exclusively aquatic species (which no one even halfway sensible is suggesting) they would have to face both types. All their arguments, bogus though they are, about terrestrial predators would apply to their scenario as well, plus the aquatic predators added in. The usual claim there is that the little beasties just run in and out of the water depending on what predator they are avoiding, but this founders for two reasons. One is that terrestrial predators will, and often do, chase their prey into water where their bounding abilities give them an even greater advantage compared to their prey; the other is that aquatic predators are generally not even seen or detected before the attack, while terrestrial predators often are. The other point is on fat. We see that fat is generally adapted for two things, extra food and – often – body shaping. This body shaping can be sexually selected, as our life history shows it is in humans, or for a functional purpose like streamlining, as it is in whales and seals (the animals the AAT/H says we resemble in this feature, although they don't like to name them because then it's obviously ridiculous and the feature is not at all similar in life history). For whales and seals, their fat is adult-like at an early age (at birth for whales), as soon as they hit the water. For humans, we start off fat as babies, go through an extremely lean period as children (except for modern overfed kids), then get remarkably fatter right at puberty. If this was due to water use, whether for insulation or bouyancy, this would mean that babies were aquatic, children weren't, then we become aquatic again exactly at puberty... and females would be more aquatic than males at puberty. The alternative explanations – unique-among-mammals fatness for our babies as part of our unique-among-mammals extended post-partum development, fat at puberty and variation between the sexes due to sexual selection – don't have this tortured path to follow.

Ilana (2008-05-14 16:03:56)

That's not true. The big cats stalk their prey - therefore, they, like aquatic predators, rely on not being seen. That is the method by which most predators work, on land or in water. Also, the predator argument against AAH often relies on finding each and every vicious aquatic predator and having them all prey on the apes at once, while they founder in the water. But most aquatic predators that people list would not even apply to the AAH, and it is highly unlikely that even if they did, all the most vicious of these species would happen to exist in the same place that early humans were developing. SHarks, for instance, would not be a serious threat. The amount of shark attacks in shallow waters is very low, even in modern times when we have far more people than existed then. It is still highly unlikely to be attacked by sharks in the water. Even in diving communities, the chances of being attacked by sharks is very slim. When it does occur, however, the sharks can usually be deterred by punching or kicking them, which would imply that sharks do indeed respond to threats. There also are documentations of dolphin groups intimidating sharks, which would render your claim, that marine predators do not respond to threats or intimidation or counter attacks, entirely false. The primary predator would be the crocodile. However, there is evidence that it would not be as terrible as it is played up to be. There are many species of crocodiles throughout the world, and in only a few areas are they serious man eaters, mainly in the Nile and the marine crocodiles of Australia. However, evidence shows that early humans lived by the Afar sea. The crocodiles in that region are not the man eaters of the Nile or Australia. They probably could be dealt with by humans/apes. Also, crocodiles and alligators jaws can easily be held closed. It is ludicrous to assume that these early humans/apes would not have known about this, yet would have known how to deal with lions. AND yes, terrestrial predators will often chase their prey into the water. However, an animal that can swim and dive will have the advantage in that situation, and would probably be able to get away, because they would be more efficient in the water than the terrestrial predator. I don't understand your point about shifting goal posts. All theories revise when new evidence is presented. Therefore, what's wrong about shifting the purpose of fat within the theory to suit new evidence? That's what's done in every other theory

of evolution, yet when the AAH/T does it, people imply that they are twisting facts, etc... You can't have it both ways. Such double standards should not exist in science. The same goes for the theory itself. The AAT/H has been subject to extreme scrutiny, and not one all encompassing flaw has been found, and it still hasn't been accepted by mainstream science. Yet other evolutionary theories have far more holes in them and are not subject to the same scrutiny. The theory that apes stood up to better reach fruit is ludicrous, because apes climb trees. Yet apparently that theory is more scientific than AAH/T. The theory that apes stood up to see over grass is also implausible, because they would simply return to all fours when they were done looking, if that were the case. I don't feel like listing all of them right now, but in all of them the disadvantages about becoming bipedal outweigh the advantages, and they are still more accepted by mainstream scientists than AAH/T. Why does this double standard exist? And it's not because AAH/T is not scientific, because it has far more evidence behind it than many of the other theories. It even has fossil evidence - many of the early fossils have been found by lakes or in wooded areas that would imply the existence of a close water source, which directly ties in with the AAT/H.

Ilana (2008-05-14 16:09:34)

Oh, and about the hair and skin. What we have may be inefficient when compared to true aquatics, such as dolphins or seals, but compared to apes? Our relative hairlessness would be far more efficient in the water than their pelts. Besides, you're missing the point. If even a little hair shaved off makes us more efficient in the water, then how much difference must hair loss have made to an ape?

Varangy (2008-05-14 17:20:16)

@Ilana I will respond to your comments later, but with all due respect (this is not a slur), you are not really engaging in logic-based debate and argumentation, rather you appear to be overtly exploring unbound conjecture and trying to fit the data to the hypothesis, when clearly, it should be the other way around.

Ilana (2008-05-15 15:45:01)

no, that's not true, it seems to be that your arguments are in fact illogical. You exploit every scrap of data that would refute the theory, without looking at the theory as a whole. Much of what you have been saying - that all possible extreme water predators would be there to prey upon the apes, that because human skin and hair does not match that of true aquatics - which the theory never claimed - then they couldn't have possibly spent more time near water than other apes and the theory must be false, seems much more like trying to fit data to refute the hypothesis, rather than looking at all the information out there objectively. However, this is not a slur, and should not be taken as such. no, I'm not trying to be petty, but the moment you start criticizing me as a person (and yes, you were doing so) goes far beyond having a fun and interesting debate. If you think I am wrong, then say why I am wrong, with facts and reasons, do not start attacking me and calling me illogical. By the way, I was not 'exploring unbound conjecture'. Much of what I was saying has facts and reasons behind it. However, since this was merely an interesting debate on the internet, I didn't bother to site any sources. And of course neither did you. However, if you want me to trace everything I was saying back to a source, then I will. I am going to make myself very clear. Debates, whether online or in person, are only fun when both sides respect one another. Now, I do disagree with the points you make, and have said why I do so, but I also respect your opinion and can understand why you think the way that you do. Clearly that same respect is not afforded to me, if you have to belittle me and write at me in a condescending manner. (although I did the same to you in this post, thought it was a reaction) Please, if you feel that I am being illogical, list every point and say in black and white why you think it is illogical. I do the same when I find something to be illogical. But saying in general that my arguments are illogical, that AAT/H proponents arguments are bogus is not really respectful, nor does it make you come across in a positive light, if that's what you have to resort to merely because you dislike a theory.

anthrosciguy (2008-05-21 19:11:59)

*That's not true. The big cats stalk their prey - therefore, they, like aquatic predators, rely on not being seen. That is the method by which most predators work, on land or in water.* We find that chimps just don't have the huge problem with predators that we might think they would, and they don't handle predators simply by running away or climbing. Predators mostly avoid them, and the predation they suffer is too little to have kept them from prospering for millions of years. There is no reason to assume that our ancestors couldn't do what chimps do vis a vis predators. However, your assumption that

terrestrial predators are not seen by chimps doesn't seem to be how the real world operates. Sometimes sure, but mostly no. The claim that Afar crocodiles are special friendly non-hominid eating crocs is something started by Morgan, and it founders on several points. First, there is no reason to try to posit that there was an aquatic period centered on Afar; even Morgan has dropped that apparently, and for good reason: we find earlier and earlier fossils in other places. Also, we're not talking about which crocs now live there, but which crocs lived there in the past. We are also not talking about preying on modern humans (with modern weapons, even "modern" weapons like spears), but preying on our ancestors which is not the same thing (even so, crocodile attacks are numerous and dangerous for reasons I go over in detail on my site). Shark attacks would not, IMO, be as bad a problem, but would be in some areas. The biggest problem for both sharks and crocs, though, is that the attacking animal is generally not seen *at all* until it has bitten the victim, and then it's too late. I'm afraid I don't find the notion of crocodile-wrestling hominids to be anything other than ludicrous. Ditto for your argument that humans are pretty much like dolphins – really, come on... Also note that today (besides shark fences on many swimming beaches) only a small part of our population is in the water, whereas the AAT/H insists that the entire population used water every day for massive amounts of time – otherwise there's no selection pressure for these massive changes. *Oh, and about the hair and skin. What we have may be inefficient when compared to true aquatics, such as dolphins or seals, but compared to apes? Our relative hairlessness would be far more efficient in the water than their pelts. Besides, you're missing the point. If even a little hair shaved off makes us more efficient in the water, then how much difference must hair loss have made to an ape?* The point is that we have *just exactly what swimmers don't want*. We could have no hair and that's better; we could have lots of hair (like most aquatic mammals) and that would be better. Both those possibilities fit the evidence from sports science. But instead the AAT/H proponent is forced to argue that millions of years of evolution devoted to swimming and diving has left its mark on our hair patterns, and done so by leaving us with *exactly what we don't want*. That doesn't make sense. And our hair patterns are rather obviously the result of sexual selection, which is of course another mark against the notion that it's due to environmental determinism. I'm afraid the notion that the AAT/H doesn't have any major flaws is just silly. It has many major, and very bad, flaws. *Therefore, what's wrong about shifting the purpose of fat within the theory to suit new evidence?* Well, to start with, the fact that the "new" purpose doesn't fit the facts either. *The theory that apes stood up to better reach fruit is ludicrous, because apes climb trees. Yet apparently that theory is more scientific than AAH/T. The theory that apes stood up to see over grass is also implausible, because they would simply return to all fours when they were done looking, if that were the case. I don't feel like listing all of them right now, but in all of them the disadvantages about becoming bipedal outweigh the advantages, and they are still more accepted by mainstream scientists than AAH/T.* These ideas do make sense, although you've worded them inaccurately. They not only make sense because that's when we see other primates using bipedality, but they've been tested. Actually, the most common, and long-lasting, use of bipedality is food-getting and carrying. But displays and observation are also very common uses of bipedality. The idea that wading is a major time when bipedality was used is interesting but doesn't hold up; other than unusual times when wading in very deep water without swimming, what we see mostly is wading while doing food-getting and carrying... so is the wading really the reason, since it's what they do on land so often too? And the majority of wading time for non-human primates is quadrupedal.

Ilana (2008-05-22 18:36:10)

anthrosciguy - thank you very much for pointing out the arguments that you found illogical, rather than just insistently accusing them of being bogus. However, you do still seem to have some problems with respect, as in almost every piece of writing you have, you consistently drop in slurs against AAT/H proponents. A word of advice - this lessens the credibility of your arguments, and your standing as an authority on the subject. Now, in response to what you've written: First off, you completely misunderstood the point I was trying to make about the crocodiles. I most certainly did not imply humans wrestling crocodiles. However, if a culture lives by crocodile-infested waters, and have to use those waters as a food source, they are going to have to find ways to deal with those crocodiles. When I wrote about holding crocodiles' jaws shut I was trying to illustrate a known way in which humans could deal with crocodiles, not to suggest that they valiantly went about daily wrestling crocodiles. Also, I was not trying to say that they definitively developed in Afar and that the Afar crocodiles were "special friendly non-hominid eating crocs", but to suggest that not all crocodiles need be huge man eaters, and that there are crocodiles who are currently not extremely dangerous in the North east of Africa where it is likely that early humans developed. I thought I made myself very clear on that point, but obviously I did not. I apologize if you misunderstood me. I also never suggested that humans were like dolphins. I actually have absolutely no idea where that came from. What I actually

said what that since dolphins can intimidate sharks, it would imply that sharks actually could be intimidated. Humans are like dolphins never even entered in to that. I did say that the Amo and Haenyo diving cultures dealt with shark attacks by punching them and by intimidation. However, that has nothing to do with humans being like dolphins. Also, the Amo and Haenyo cultures often will see the shark coming - which is why they can deal with them. AAH does not demand that "the entire population used water every day for massive amounts of time", and it does not have to be so in order to work. Even for a population that only used water as a food source, and did not enter it for massive amounts of time, selection would still be made to prevent drowning and to increase food getting efficiency - by swimming, etc...After all, completely terrestrial mammals also have methods to prevent drowning, such as the diving reflex. Why would these selections not have increased in a population that was mostly terrestrial, but which used the water frequently as a food source? AAH does not depend on them practically living in the water, not by the slightest stretch of the imagination. Hair loss - you're stressing the point that what we have is exactly what we don't want entirely too much, especially since it's not strictly true. That would imply that out of the thousands of different types of hair and fur variations in the animal kingdom, humans have absolutely, categorically the least efficient form ever. Of course this is not true. That is not to say that our skin is as efficient in the water as a dolphins, because it isn't, not by any stretch of the imagination. You also make the rather simplistic point that hair is good, no hair is good, and what we have is terrible. This fails to distinguish between the different types of hair. Of course an otter's hair or a seal's will be extremely efficient in the water. But a housecat's will not be nearly as efficient. What you should be doing is comparing the efficiency of chimpanzee and bonobo hair - and maybe gorillas and other monkeys for good measure- to humans in the water to see what is more efficient. The question is not whether humans rank as aquatic in relation to aquatic mammals in the rest of the animal kingdom, but whether they rank as relatively aquatic in relation to apes. That question would easily apply to an ape's fur. If a reliable experiment is done that says that what humans have is less efficient in the water than even a chimpanzee's hair, then I will rest my case. However, your answer on hair is sidestepping the issue, and is not fully answering it in the context of the theory (or theories.) I also have a problem with the notion that our hairloss - practically unique among the animal kingdom - was done by sexual selection. Why would hairloss be sexually selected for humans and not for any other ape? There would have to be a pretty strong reason. I have heard another somewhat similar theory that hairloss would be sexually selected because it would decrease parasites. But why would that be so for humans and not any other ape? All apes suffer from parasites. It would only make sense if humans lived in an environment where parasites were much worse - such as by rivers - for that to work. There has to be a reason for something to be sexually selected. Even in modern human history, there are reasons for what is considered beautiful. Pale skin used to be extremely desired in many cultures up until recently because it showed off a woman's status, and the fact that she had the luxury of not getting tan through working in the fields. There are reasons for things to be sexually selected. It seems to me that many scientist - amateur and professional - rely on the blanket term 'it must be a sexually selected feature' for something they really can't see the purpose of. Of course, things like peacock's tails really are sexually selected. But I don't think hairlessness would fall into this category, unless there were other strong reasons accompanying it, because then why don't apes also have a tendency to sexually select less fur? I don't think AAT/H has any gaping holes - minor ones, yes, such as the idea that there was a distinct aquatic phase, etc..., but gaping ones, no. I also find that many of the arguments against it are extremely flimsy, or they take the idea to the extreme, or they 'disprove' a point by falling back on the same analogies that they hate so much or by providing analogies that don't really apply yet make them seem as if they do apply. I also think that all the other theories are at least as flawed, or even more so, than the AAH. However, as you clearly disagree with me, and have stated by you do so, let's let this one drop and not get into a spitting match over it. No, I did not necessarily word the theories inaccurately, although I didn't describe them the same way that textbooks etc.. that favor them do. Regardless of whether apes reliably stand up for food getting, it still does not explain why that would provide enough pressure for human ancestors to become bipedal. And the majority of wading time for non human primates is not quadrupedal, it's bipedal. Where on earth did you get that idea from? That was long again. Sorry about that.

CJ Alexander (2008-06-01 17:38:47)

I thought the Aquatic Ape hypothesis was delightful and intriguing when I first read about it here on Seth's blog, several months ago. The subsequent comment thread (after that post) thoroughly convinced me otherwise, and left me confused about Seth's obstinacy in the face of obvious and overwhelming arguments against it. THIS thread has so thoroughly curbstomped the idea, largely due to anthrosciguy's contributions, that Seth's stubborn adherence to it is frankly making me question his judgment about everything, to the point where I'm considering an unsubscribe from his RSS feed. This just isn't good scientific thinking

on display...

Varangy (2008-06-02 13:29:03)

@CJ Alexander *THIS thread has so thoroughly curbstomped the idea, largely due to anthrosciguy's contributions, that Seth's stubborn adherence to it is frankly making me question his judgment about everything, to the point where I'm considering an unsubscribe from his RSS feed. This just isn't good scientific thinking on display!* I think this blog is great and I like Seth's POV on quite a lot. But I know exactly how you feel. I too, as someone who knows a bit about anthropology and has spent more than little time in the water, am surprised, perhaps even a bit appalled as to Seth's clinging to the very romantic, but highly improbably, theory of AA. But hey, we're all human.

anthrosciguy (2008-06-09 17:05:41)

Sorry to leave a comment so long after the rest, but I just had a couple of points to make for Ilana: *AAH does not demand that the entire population used water every day for massive amounts of time, and it does not have to be so in order to work.* That's what most AAT/H proponents will now say, but then you look at what features they claim are due to this "hardly in the water" lifestyle and you see that those features, like hair, fat, and several others, are found only in a very few fully aquatic mammals which have been fully aquatic for several times longer than hominids have existed. This means they are either actually claiming we spent an enormous amount of time in the water, or that somehow just being near water gave us characteristics found only in whales and serenia. At least Hardy was honest about the amount of time he thought our ancestors would have to have spent in water, but then he was a scientist, even though he did make many elementary errors of fact in his "aquatic ape" idea, just as he did in his telepathy and psychic phenomena ideas. The fact is that they also describe those characteristics inaccurately, and they really aren't like those of aquatic or semi-aquatic mammals, and that's just an additional nail. *Hair loss - you're stressing the point that what we have is exactly what we don't want entirely too much, especially since it's not strictly true.* Look at aquatic and semi-aquatic mammals; they have either lots (most of the them, the vast majority of them in fact) or none (a very few fully aquatic mammals which have been fully aquatic for several times longer than hominids have existed). *I also have a problem with the notion that our hairloss - practically unique among the animal kingdom - was done by sexual selection. Why would hairloss be sexually selected for humans and not for any other ape?* That's typically what you see in cases of sexual selection; for instance, why do lions have manes but other big cats don't? (There is also a tendency toward less body hair in apes, compared to other primates.) But the most critical part is that when you see characteristics like fat or hair being due to environment, an aquatic environment specifically in this case, those characteristics are set by the time the creature hits the water. Naturally. And they don't vary between the sexes. Naturally. In humans, however, you find those characteristics change right at puberty and vary between the sexes, which are hallmarks of sexual selection. This also leads to the odd internal inconsistency in the AAT/H: babies need to be aquatic to explain their fat, and non-aquatic to explain their larynxes; later, as children, they need to be non-aquatic again to explain their lack of fat and sebaceous glands, and aquatic to explain their larynxes. Women need to be far more aquatic than men to explain their fat and hair differences, but men need to be far more aquatic than women to explain their sebaceous glands. This contradictory jumble just doesn't make sense, while all those things can be explained simply with non-AAT/H ideas: fat, hair, and sebaceous glands are sexually selected (they near all the hallmarks), the baby fat is unique to humans and no doubt due to our also unique to humans post birth development, especially brain development. And the larynx is now pretty conclusively shown to be due to selection for a deeper voice and is now known to not be unique to humans among primates, not to mention other mammals (others known, so far, include chimps, red deer and elk, koalas, "lions, tigers, and other members of the genus Panthera", dogs, pigs, goats and monkeys, and even at least some birds, like roosters and cardinals. (It was thought otherwise until recently - 15-20 years ago - because most research on this was done by dissection, but newer research with imaging on living animals shows that the descended larynx is a common feature. And of course until relatively recently we concentrated most research on ourselves, or things of medical benefit to ourselves, which limited our knowledge about a range of non-human animals.) *And the majority of wading time for non human primates is not quadrupedal, it's bipedal. Where on earth did you get that idea from?* From actual primate researchers' actual reports on actual primate behavior. That's what they find. A couple of AAT/H proponents have claimed otherwise, but Morgan did so on the basis of no research whatsoever and counter to the actual research (guess which position I accept?) and another fellow does so on the basis of 5 hours of observation at a zoo where bonobos reached very quickly into water (no more than a few seconds at a time for a total of 37 seconds) where he got radically different results

from all other researchers who did hundreds of hours of observations in the wild. He doesn't wonder at all (as any researcher should) why his results were so far different from everyone else's – other observation of bonobo populations show ranges of 0-24 % of wading time done bipedally; and other apes, as well as monkeys, do so even less often. Again, guess which research I find most compelling, the many studies done by many dispassionate observers or the guy who thinks his numbers from 37 seconds of wading should be used in place of all other studies?

William Bond (2008-11-04 12:28:25)

Hi Everyone If people want to find out more about the Aquatic Ape theory there is a 7 part Documentary (Discovery Channel/BBC 1998) of it on Youtube at - <http://uk.youtube.com/watch?v=VFsgtLxALac> Or you can look at Elaine Morgan's web-site. <http://www.elainemorgan.me.uk/> William Bond

Uill (2008-11-04 13:21:10)

AAT is not about having aquatic ancestors as such, but ancestors who lived on the shore, as opposed to the savanna. It is about the role water, waterside living played in human evolution. See: AAT - Shore Adaptations in the Genus Homo <http://tech.groups.yahoo.com/group/AAT/> AAT is based on human behavior/anatomy/physiology/DNA compared to chimps & living animals: Waterside food collection (fruits/(coco)nuts, turtle/bird eggs, shell/crayfish, water(side)plants, drowned bovids, stranded whales...) explains unique Homo traits (not in apes/australopithecids) better than forest or plains dwelling: brain size, slow-diving skills, breath control, small mouth & biting muscles, tongue bone descent, projecting nose, poor sense of smell, handiness/tools, late puberty aligned-spine-legs, flat feet, fur loss, fatness, sweating, reduced climbing, high needs of water/sodium/iodine/poly-unsatur.FAs(DHA)... features present in different combinations in (semi)aquatic animals but absent in savanna mammals.

Marc Verhaegen (2008-11-04 13:58:09)

Somebody wants to defend AAT on the basis of: 1. Humans have subcutaneous fat, other primates don't. Other aquatic mammals do. The fat serves as insulation. 2. Humans have almost no fur, other primates do. Other aquatic mammals don't. Fur creates drag in the water. 3. Humans are bipedal. Walking upright keeps the head out of the water, allowing breathing. These 3 arguments can easily be dismissed: 1. Sea otters have no SC fat. 2. They have an extremely dense fur. 3. They're not bipedal. And these arguments can be repeated for a lot of other (semi)aquatic mammals. The point is: most features that discern humans from chimps are \*in different combinations\* typically seen in waterside mammals that spend a lot of their time in the water: large brain, high sodium, iodine, DHA & water needs, head & spine & legs on 1 line, dexterity & stone use, external nose etc. Another point is: all H.erectus fossils apparently lay next to shellfish. It's obvious that H.erectus did not disperse on "Savannahstan" to other continents as some PA postulate, but along the coasts & from there inland along rivers & lakes. The Mojokerto skull 1.8 Ma lay in marine sediments in a river delta, the Dmanisi population 1.8 Ma lived next to abundant lacustrine resources etc. Why would a dextrous intelligent tool-using thick-enameled omnivorous ape not have collected part of his foods from the water, esp.cray- & shellfish?? Many people discussing AAT still think AAT is about australopithecines or human ancestors millions or years ago, but this only shows how uninformed they are. I suggest that people trying to discuss AAT should first inform properly, eg, P.Tobias <http://allserv.rug.ac.be/~mvaneech/outthere.htm> <http://allserv.rug.ac.be/~mvaneech/Symposium.html> [http://users.ugent.be/~%7Emvaneech/Verhaegen et al. 2007. Econiche of Homo.pdf](http://users.ugent.be/~%7Emvaneech/Verhaegen%20et%20al.%202007.%20Econiche%20of%20Homo.pdf) [http://users.ugent.be/~%7Emvaneech/Verhaegen & Munro. New directions in palaeoanthropology.pdf](http://users.ugent.be/~%7Emvaneech/Verhaegen%20&%20Munro.%20New%20directions%20in%20palaeoanthropology.pdf) or google "aquariboreal"

Marc Verhaegen (2008-11-05 12:54:28)

Sorry, there seems to be something wrong with the spaces in the links. It's not but and In any case, it's likely IMO that our semi-aquatic phase was once rather profound (otherwise we wouldn't be able to dive 50 metres deep & more than 5 minutes), but also that it didn't last very long (otherwise we hadn't returned so completely to the land) & that it didn't happen millions of years ago (otherwise we hadn't preserved so many (semi)aquatic features). I guess it happened at some time during the Pleistocene when our ancestral Homo population spread along the coasts (so-called "Out of Africa 1"?), possibly somewhere around the Indian Ocean & not unlikely on offshore islands (SE.Asia? Flores? Danakil? Andamans? ...). During the Ice Ages, sea levels were lower, there must have been large areas on the continental shelves where cray- & shellfish were abundant. These

foods have lots of poly-unsaturated fatty acids (DHA etc.) that are essential to brain growth, and that were easily procurable by tool-using & thick-enamel omnivore. No wonder this phase (100 m below sea level now?) didn't leave many traces in the fossil & archaeol.record. And no wonder their descendant trekked into the continents along the rivers where their diet included cattails (traces on neandertal tools) & where they caught small & large prey in shallow waters & butchered stranded whales & other sea mammals, eg, - M.Gutierrez cs 2001 "Exploitation d'un grand cétacé au Paléolithique ancien: le site de Dungo V À Baia Farta (Benguela, Angola)" Comptes Rendues CRAS 332:357-362, - CB Stringer cs 2008 "Neanderthal exploitation of marine mammals in Gibraltar" PNAS 22.9.08. :-) -Marc

Marc Verhaegen (2008-11-06 08:11:02)

Sorry. Apparently something went wrong again. I hope the correct links are <http://users.ugent.be/~7Emvaneech/Verhaegen%20et%20al.%202007.%20Econiche%20of%20Homo.pdf> <http://users.ugent.be/~mvaneech/Verhaegen%20&%20Munro.%20New%20directions%20in%20palaeoanthropology.pdf> -Marc

Beard (2009-03-13 18:26:51)

I think too many posters are looking at this the wrong way. If I was to create a simulation on a computer and place two apes on the savanna and two apes on the shores. Which one do you think would survive in each climate. What features would evolution select out as an advantage in the different environments. The ape who could hold it's breath, whose nose pointed downward, who had little hair enabling it to dry quickly and not become chilled would have an advantage. Extra fat deposits help as well. On a savanna, the hairless ape would easily get sunburned, would excrete too much salt (no one has mentioned this tremendous sweating of salt humans do) and water to survive. To make this post short, I won't go on, but readers should stop trying to defend theories and start thinking intelligently about what would offer a survival advantage or disadvantage of one ape over another in different environments. Then you will find the right answers.

marc Verhaegen (2009-10-09 03:31:09)

Well-said, Beard. 'Aquatic ape' is an unfortunate misnomer IMO: it's not about 'aquatic', but about 'littoral', finding foods at the beach & in shallow water, and it's not about apes or australopithecines, but about Pleistocene Homo dispersing to other continents along sea coasts & inland along rivers, collecting shell/crayfish, bird & turtle eggs, (coco)nuts, whatever at the waterside. IMO (speculation) this happened (partly?mostly) when during the glacials sea levels were 100 m or so below today's sea level, when vast continental shelves were available to dextrous tool-using omnivorous human ancestors for beachcombing, wading & diving for sea & other foods. From there different offshoots of these littoral populations ventured inland along rivers & lakes, in savannas & elsewhere.

marc verhaegen (2012-05-01 11:44:44)

Still no answer after more than 2 years? Most people agree? :-) Recent work on the littoral theory can be found in M Vaneechoutte, A Kuliukas & M Verhaegen eds 2011 ebook Bentham Sci Publ "Was Man More Aquatic in the Past? Fifty Years after Alister Hardy: Waterside Hypotheses of Human Evolution" with contributions of professor Phillip Tobias, Elaine Morgan & all important proponents of this theory. Or you can contact me for our recent paper (with Stephen Munro) in HOMO - J compar hum Biol 62:237-247, 2011 "Pachyosteosclerosis suggests archaic Homo frequently collected sessile littoral foods"

## **Middle School Visit (2008-05-03 02:34)**

On Monday I visited a cooking/gardening class at Willard Middle School in Berkeley. One student told me it was his favorite class. "Why?" I asked. "Because you can talk," he said. He and two friends were standing by a stove. They were making grits and waiting for the water to boil. Out in the vegetable garden - the students are divided into three groups, and one group spends the class period in the garden - another student told me it was his favorite class, too. "Why?" I asked. "Because you can move around," he said. I was very impressed. Two different students say the class is their favorite - for two different simple non-obvious reasons. The cooking and gardening program at Willard is run by Matt Tsang, who has been at Willard ten years.

Later that day I saw a slide show of architecture theses. One slide showed a page of a thesis that said: "Work with nature, not against it."

Maybe middle school students have strong desires to talk and move around. Maybe "work with nature" means, in that context, teaching in such a way that students can talk and move around. Maybe classes can be set up so that the existence of those desires makes learning easier rather than more difficult. Like swimming with the current rather than against it. In the typical Willard class students can't talk and move around. And teaching at Willard is hard; the average teacher lasts only five years.

The existence of the slide in the slide show showed that work with nature, not against it needs to be learned; it wasn't obvious. Nothing like that is taught in schools of education, I'm pretty sure.

---

beowulf (2008-05-03 21:13:25)

Seth, I noticed that that both students quoted were "he". One of the arguments for single-sex schools is that boys and girls have different learning styles. Boys do best in classes where they can move around and don't have to be quiet. Girls do better in the traditional format- sit at your desk and listen quietly to the teacher. *"In its all-boysâ€™ classes, students are not required to sit still and be quiet. They are welcome to stand or sit or curl up under their desks, or jump up and down if they like. Just about anything is allowed, short of punching a classmate. When I first entered the classroom, it didn't look like any classroom I had seen before. It looked more like a can of worms or a beehive, with boys gyrating, bouncing, and buzzing like bees. But the boys' dynamic teacher, Jeff Ferguson, assured me that his students were paying attention and, in fact, they were thriving with the more relaxed format."* <http://www.schoollibraryjournal.com/article/CA6472910.html>

seth (2008-05-05 21:44:44)

Thanks, beowulf, that's a great comment.

Zenzoa · Feminist Woman versus Aqua Apes (2008-05-07 05:02:28)

[...] On the other hand, one of his commenters suggests that boys do better than girls in interactive classrooms: "Boys do best in classes where they can move around and don't have to be quiet. Girls do better in the traditional formatâ€ sit at your desk and listen quietly to the teacher." I feel like I need to find a phone booth and a Feminist Superhero costume... all I need is research to back up my visceral objections. There's just no way boys are genetically predisposed to have more fun! [...]

## **The Twilight of Expertise (fugu liver removal) (2008-05-03 20:28)**

Fugu is a puffer fish prized by Japanese fish connoisseurs. Its liver is poisonous, thus only specially-trained chefs can serve it. A episode of The Simpsons featured Homer poisoned by fugu.

Recently, however, [1]researchers determined that fugu liver is poisonous because fugu eat poisonous food. When fugu is farmed, and given non-poisonous food, its liver is harmless, and the fish tastes almost as good. No more need for special processing. Unsurprisingly, the National Fugu Association wants to preserve the status quo. But you can now buy fugu liver in the town of Useki.

Masataka Kinashi, the head of the tourism association in Usuki and a fugu dealer himself, suddenly stared down at his desk when asked about the widespread sale of fugu liver.

“Officially, you can never eat it here,” Mr. Kinashi said. “Well, it’s not that you can’t eat it, but, no, you can’t eat it. That’s the only answer I can give you.”

1. <http://www.nytimes.com/2008/05/04/world/asia/04fugu.html?hp>

---

Aaron Blaisdell (2008-05-04 20:25:38)

I had Fugu in Tokyo in February. My tongue didn’t tingle even a little bit—contrary to what I’d been led to expect. I wonder if they used a farm-raised fugu with a non-poisonous liver. They didn’t serve the liver, but even other parts of the fish are supposed to impart a little bit of a tingling due to trace amounts of the toxin.

## **My Theory of Human Evolution (autism ) (2008-05-05 00:27)**

In the journal [1]In Character, Simon Baron-Cohen, the autism expert, [2]writes:

Clinicians describe the deep, narrow interests in autism as “obsessions,” but a more positive description might be “areas of expertise.” Sometimes the area of expertise a person with autism focuses on appears not to be very useful (e.g., geometric shapes, or the texture of different woods). Sometimes the area of expertise is slightly more useful, though of limited interest to others (e.g., train timetables, or flags of the world). But sometimes the area of expertise can make a real social contribution (such as fixing machines, or solving mathematical problems, or debugging computer software).

My guess is that in autism, something is turned off that should be turned on. This allows the rest – in particular, the rest of what motivates us – to be seen more clearly. Everyone has a tendency toward expertise, says my theory of human evolution. Why everyone? Because everyone suffers from procrastination and the tendency toward expertise is the tendency that causes procrastination: It’s harder to do something new than to do what you did yesterday. Back in the Stone Age, this tendency toward expertise caused different people to do different hobbies, and become good at them. This was the beginning of occupational specialization.

1. <http://www.incharacter.org/index.php>

2. <http://www.incharacter.org/article.php?article=101>

---

Phillip J. Eby (2008-05-05 08:33:21)

Er, it’s not THE tendency that causes procrastination. A lot of things cause procrastination, so much so that it’s probably useless to have only one name for it. There should probably be some specialized words, the way we have terms for different types of cancer. Meanwhile, I don’t think I’ve seen any literature in either psychology or economics about procrastination treats it as being related to being harder to do new things. It seems to me much more likely that specialization is the simple result of it

being \*easier\* and \*more attractive\* to do more of something you already know a little about. Occam's razor suggests that dragging procrastination into the equation is unnecessary, since procrastination is a deferment of something you \*want\* to do, or believe you \*should\* do. And how is that even relevant to wanting more of something you've previously found rewarding?

LemmusLemmus (2008-05-05 09:56:37)

I'll second Phillip on this one: The reason I'm not doing the dishes is not that it's a new task; it isn't, it's just unpleasant, full stop. Doing it another 100 times will not make me like it more. Although being new can make a task more unpleasant by making it harder, it can also make it more pleasurable (e.g., reading an unknown book vs. one you already know).

Ryan Holiday (2008-05-05 14:26:08)

The Essential Difference is a GREAT book.

seth (2008-05-05 16:38:41)

Philip, what's the evidence that "a lot of things cause procrastination"? If you look at the other posts in this series, you'll see evidence for my explanation – which is new.

Tyler Cowen (2008-05-05 17:14:07)

Great post...

Phillip J. Eby (2008-05-06 07:41:02)

Procrastination is just doing something other than what you believe you \*should\* be doing. And there are almost as many reasons people have for doing something else, as there are people. Not to mention quite a few specific processes by which people arrive at a decision to do something else. I've worked with people who put things off because: \* They thought of all the \*other\* things they should be doing, too, then felt bad about doing the desired task \* They made mental predictions about how things would turn out, then felt bad about the prediction \* They had generalized feelings of despair or ineffectiveness \* They felt bad because of how the task or their skill at it would reflect on their self-image And I can show that these factors were, if not "the" cause, were at least a requirement for the procrastination to exist, since correcting the above issues resulted in an end to the procrastination. Now, I should note that in most of the cases I'm describing above, the task did not involve \*doing anything new\*. These were people putting off things they knew how to do, and were in fact IN the people's area of expertise. (E.g. a musician putting off work on his next album, and a writer putting off work on her next book.) And that part alone seems to falsify a hypothesis that links procrastination to expertise-development. If it's merely that these people hadn't worked on the right thing for a while, then why did changing the specific thoughts or feelings make a difference? Shall we hypothesize that these were created by not working on their projects for a few days? Then the issue should return if the artist takes a vacation... but I know at least the musician and writer I'm referring to are still working despite having taken breaks. Meanwhile, skimming back through your previous articles on procrastination, I get the distinct impression that you're using a significantly different definition of procrastination... like comparing acne to skin cancer. Mere difficulty getting started isn't even remotely close to being real procrastination. Let's call your brand of procrastination, "difficulty getting started", or perhaps "task inertia". Task inertia is easily explained by the lack of a clear representation of the task to be performed, and/or a clear representation of the goal state. Why? Because in my experience it's immediately correctable by doing one or both of these things: 1. forming a clear representation of the task in the client's mind 2. forming a clear representation of the end-state in the client's mind I usually try the second one first, though. For example, if you want to get started cleaning your desk, the best way to do it is to visualize the clean desk, overlaying it on the real desk with your eyes open. Simply holding that visualization and thinking about how nice the clean desk would look – without trying to take any deliberate action – will generally produce a noticeable feeling of motivation to pick something up within oh, 15-30 seconds. And, if you simply continue to consciously focus on the image of the clean desk, you'll find yourself doing the whole thing, without needing to direct any of the action intentionally. (This is all assuming, of course, that you don't have other linked thoughts or feelings that intrude – i.e., \*real\* procrastination, by my definition – and that the feeling associated with the visualized end-state is at least mildly pleasant.) However, if the task is something more complex, you may also need to work out a plan, even if that plan is, "do something and see what happens", or to choose a subgoal state to focus on in the same way as above. Anyway... it's reasonable to assume that task inertia will be greater for something you haven't done in a while, because the normal mechanism of memory would mean that

less-frequently-used representations would take longer to retrieve and be less consciously accessible. And it's certainly much easier to treat task inertia – and even procrastination in general – as spandrels or side-effects of other evolved systems, rather than as selected-for characteristics. Adding a brain mechanism to specifically induce procrastination is a big stretch, since all the pieces you'd need to create task inertia and procrastination already need to exist for other things. Also, there's a deeper reason why I believe the idea of a procrastination-specific brain mechanism is a misleading idea. When we don't do what our conscious mind wants, we call that procrastination. But, from an evolutionary standpoint, why should our body do what our conscious mind wants, *\*ever\**, unless it happens to correspond to an already-defined goal, evolutionarily speaking? It's only consciousness-centrism that leads us to think that we ought to do what we "decide" to do, ignoring the fact that most of our "decisions" aren't conscious anyway. We really only notice it when our "conscious" intent conflicts with our actual actions – and then call it procrastination or lack of willpower. But the error here lies in assuming that we should have been able to control our behavior in the first place! Procrastination doesn't require a special mechanism – it's merely a label we attach to noticing that we're not really in control, and never were to begin with. If consciousness is a recent addition to our brains, it stands to reason that our brains were already capable of making decisions before consciousness arrived... and without consciousness, there's *\*nobody there\** to be in *\*conflict\** with the decision, and call it "procrastination". This seems a vastly simpler – and far more likely – explanation. Procrastination has many causes simply because *\*it's not a real thing\**, just a label we attach. And the actual behaviors we attach it to, are just *\*normal decision-making\** – there is nothing special about a decision, just because it happens to conflict with a conscious intent! After all, having intentions and free will is probably not what consciousness is "for". Why evolve something that might freely choose to do something not in your genes' interest? Thus, I consider it to be simply a happy accident that we sometimes seem to be able to influence the mechanism enough to get it to do what we want at all! :)

seth (2008-05-06 19:06:00)

Phillip, can you point me to evidence that supports your views about procrastination?

Phillip J. Eby (2008-05-07 08:54:45)

Er, you mean like all my client session tapes? Or did you mean evidence that people put off doing things that are *\*in\** their areas of expertise? I mean, are you asking me for evidence that *\*writer's block\** exists? I'll tell you what, though, if you'll line up somebody who is *\*chronically\** procrastinating on some project – to the point of being emotionally distraught about it – I'll do a conference call with you and them and fix it for them. Better yet, get more than one person so you'll have a better chance of seeing that there are multiple mechanisms that can cause the effect. (e.g. belief interference vs. personal judgment vs. conditioned association vs. erroneous thought patterns, etc.) If you're looking for more "official" research, though, it seems to me that there's plenty of books, papers, etc. on procrastination out there with evidence that one thing or another can cause procrastination. My take is that (nearly) all of them are correct, because I've seen (nearly) all of them in action in myself or in clients. (The reason I say "nearly" is that there are a few quasi-correct theories that introduce ideas like "fear of success" or "self-handicapping", which are in fact just sweeping labels for a handful of more specific phenomena – much like the idea of "procrastination" itself!) Anyway, I'd be happy to participate in an experiment designed to falsify either my theory or yours. Every so often I learn some new distinction that refines my view, so this would be no different. For example, when I first started, I focused on removing blocks to action, but now I work on removing the person's so-called "motivation" to do the task in the first place. Paradoxically, this is a *\*lot\** faster than removing a person's blocks to action! I tried it because my pain vs. gain theory predicted that the key to getting a person positively motivated is to remove whatever "unacceptable risks" are in play. And, in most cases of chronic procrastination I've encountered, the "unacceptable risk" lies not in difficulties with the task itself, or fears related to its performance, but rather the fear of what it will *\*mean\** about the person if they do not complete the task, or do not complete it to some standard of excellence. Thus, targeting this issue first gets them back into "gain" mode (positive motivation) much more quickly than the way I was doing things before. Now, if I were sloppy in my thinking, or if I'd stumbled on this method first, I could perhaps be forgiven for jumping to the conclusion that all procrastination – or at least all *\*chronic\** procrastination – is a matter of ego fears about successful completion of the task. However, I'm a bit more cautious than that, which is why I would certainly welcome a well-designed experiment.

Andrew Lehman (2008-07-27 15:42:54)

Please consider visiting <http://www.neoteny.org/?cat=7> to review a unique and unorthodox theory for the cause of autism based on an evolutionary interpretation of the condition. Thank you, Andrew Lehman

### More Acne Self-Experimentation (2008-05-05 20:29)

[1]This post from the [2]self-experimentation forums deserves to be reprinted in full:

After being plagued with acne for years, I took a job which caused me to work in remote bush camps for short periods in the far north. My acne would invariably disappear within a few days of exposure to this. When I returned to the city, the acne would return with a vengeance. Did not know why.

My theory: Soap residue left after washing my face with hardwater was the true acne culprit. Washing my face with ultrasoft lake water in bush camps leaves little or no soap residue, so no acne. Soap residue stimulates excessive skin oil secretions which leads to increased acne. A rich diet aggravates the problem by feeding the oil secretions.

My self-experiment: I experimented with different types of soap and different concentrations of soap in hard and soft water.

Conclusion: Soft and slightly soapy water only (a very mild soap) produced the least amount of acne. Never apply soap lather directly to your face! If you have only hard water to work with, then no soap at all is the best choice by far. Compensate for the lack of soap with hotter water.

Added benefit: Washing your face with no soap causes acne lesions to heal much faster - a couple of days compared to a week or more with soap.

Great work!

The same technique [3]applied to cold sores.

2. <http://boards.sethroberts.net/index.php#2>
3. <http://boards.sethroberts.net/index.php?topic=6244.msg67427#msg67427>

---

spacenookie (2008-05-05 22:09:53)

Soap seems to be a holdover from the days when people used to bathe in cold or lukewarm water and share bathtub water (several people might bathe in the same tub of dirty water). In addition to once a week or once a month baths - Nasty. My experience is that you do not need to use soap or shampoo at all in a modern hot water shower unless you are unusually dirty.

Stephen M (Ethesis) (2008-05-06 05:49:48)

If you have soft water, soap can be marvelous. It also helps reduce the amount of bacteria that remains on the skin. But the heat of the water makes a huge difference.

LemmusLemmus (2008-05-06 06:23:58)

I'm surprised about this post because I learned from my parents never to use soap on my face when I was about three years old. (I still never do; water only.) I had always assumed this was something that all children learned, like putting your trash in the trashcan. This may be a cultural difference. (I live in Germany)

Raffaella Ducoli (2008-05-08 10:43:47)

I think soap is both the cause and the cure of skin problems. Chemical soaps cause problems and natural soaps cure. Soap should be simple and free of chemicals or any complicated words in the ingredient list. The base of soap should be Lard as this is the most similar to human skin. Simplicity is generally the best solution and with something placed on your skin daily, you need to trust that your soap is naturally pure and clean and will therefore make your skin clean and natural as well. If your soap cleans up your skin and doesn't leave any chemicals on it, then it can finally get clean and be clear of acne.

Fernando Almaguer (2008-11-13 14:41:39)

I have sensitive skin and wash my face with a clearasil for sensitive skin formula. I believe it also contains Aloe. To wash it off i always use bottled spring, or bottled purified water. Try it!

The Acne Relief (2008-12-05 23:43:28)

I learned something today. This is very interesting. I'm done with soap.

Sarah (2009-01-24 12:50:00)

Hmmm. I will have to try some different soaps. Maybe it can help. It can't hurt to try.

### **Jane Jacobs and Chinese Restaurants (2008-05-05 21:41)**

Why did Chinese immigrants to America start so many restaurants? Because Chinese cuisine is glorious, right? Well, no. Chinese immigrants started a lot of laundries, too, and there is nothing wonderful about Chinese ways of washing clothes. As Jennifer Lee explains in [1]this excellent talk, the first Chinese immigrants were laborers. They were taking jobs away from American men, and this caused problems. Restaurants and laundries were much safer immigrant jobs because cooking and cleaning were women's work.

A character in Jane Jacobs's [2]The Nature of Economies says this:

This is why societies that are oppressive to women and contemptuous of their work are so backward economically. Half of their population, doing economically important kinds of work, such cooking and food processing, cleaning and laundering, making garments, and concocting home remedies, are excluded from taking initiatives to develop all that work [that is, start businesses] – and nobody else does it, either.

My grandparents, Jewish immigrants, were in the garment industry. Now I can guess why.

Ben Hyde (2008-05-06 08:06:17)

Tilly's marvelous book *Durable Inequality* has more subtle things to say about this. For example why in Boston we know that Brazilians make good housekeepers, while in Chicago they know that's the Polish. Why Italians are good at lawncare, or stone. Why most the motels in the country are run by one Indian caste. Why the Koreans dominate the small grocery stores in NYC. While I'd not take issue with the model you outline above, Tilly lays the majority of the blame at what these days one might label preferential attachment. I.e. that one a community puts down roots in a given trade it's common for that community to specialize. Jacobs talks about that as well, why certain cities end up specialized. The just so stories aren't, to my mind, as important as the preferential attachment - or if you like the positive feed back loops. Sociologists are particularly good at teasing out which of these feedback loops is or isn't responsible, but it is certainly tough in the face of peoples desire for simple stories.

Bloix (2008-05-07 10:53:48)

This sounds like one of those, "I think it therefore it's true" moments. What's the evidence? And what about other ethnic groups? Irishmen became cops. Was that women's work? Bohunks became coal miners. Women's work? Italians became haulers. Women's work? If you look at the history of the laundries, you find that they were owned by Chinese owners, who hired and exploited the hell out of Chinese workers. You could open a laundry with a small amount of capital, gained not from a bank (which wouldn't lend to you) but from an informal community association. You could hire workers of your own ethnicity, who couldn't work elsewhere because of discrimination and the language barrier. This pattern is repeated over and over again in American history: Jews: the needle trades. Greeks: diners. Koreans: greengrocers and dry cleaners. Indians: motels. Irish: bars and pubs. Germans: butchers and bakers. Italians: fruit and vegetable wholesalers. It's the fact that these small businesses can be started by members of the ethnic community without the support of the majority business community that leads to their existence. Whether the work is women's work or men's work is irrelevant. The Chinese found themselves the target of discrimination even in the supposed "women's work" of laundry - see, e.g., *Yick Wo v. Hopkins* 118 U.S. 356 (1886), in which the US Supreme Court struck down a San Francisco ordinance designed to drive the Chinese out of the laundry business. In New York, they organized to oppose municipal efforts to destroy the Chinese laundries by forming the Chinese Hand Laundry Association. See the book, *To Save China, to Save Ourselves: The Chinese Hand Laundry Alliance of New York*. [http://www.textbookx.com/product\\_detail.php?upc=9780877229964&type=book&affiliate=froogle](http://www.textbookx.com/product_detail.php?upc=9780877229964&type=book&affiliate=froogle) PS -about your grandparents- At the time your grandparents were garment workers in New York, Italian immigrants were working down at the docks and Irish immigrants were filling the ranks of the police force. Now, unless you think that there was some two-tiered prejudice going on so that non-immigrant men didn't mind losing their jobs to Italians and Irishmen but didn't like losing them to Jews, I don't see the explanatory power of this analysis. PPS- I love Jane Jacobs. The quote doesn't support Lee's argument.

seth (2008-05-07 13:30:26)

For the basis of Lee's analysis, see her book *The Fortune Cookie Chronicles*.

Sheila Buff (2008-05-07 18:03:20)

Hi Seth- I think one reason many immigrant groups open inexpensive restaurants is that the barriers to entry are low-and were even lower a century or more ago when there was far less regulation. The initial capital investment is relatively low, family members can be employed, there's a built-in market among fellow ethnics looking for familiar and inexpensive food, good command of English and high educational attainment aren't necessary, etc. The Chinese restaurant story has parallels among every ethnic group throughout American history: Italian pizzerias and restaurants, Jewish delis and dairy restaurants, Polish pierogi restaurants, German beer gardens, barbeque joints in the South, Greek diners. And I wouldn't suggest to a French chef that he was doing a feminine job-cooking for the public is men's work in many societies-as in fact it tends to be in America today, where most of the chefs and most of the kitchen staff are men. And in China, being a chef was not only a man's job but also one that was fairly prestigious, attained only after a long and arduous apprenticeship.

Varangy (2008-05-08 08:14:33)

While I like JJ, I too am skeptic. I think she overreaches and projects herself on many topics she does not know much about. My guess is that so many Chinese restaurants sprouted up was: a) low barriers to entry b) cheap, novel and unique cuisine (which is part of their staying power) Looking at European immigrants that came to the States such as the Poles, Hungarians etc etc — you see that many started restaurants but, I think, weren't sufficiently unique to the States and ended up serving mostly the very same immigrant community. Nowadays, one is hard-pressed to find a Hungarian restaurant outside of NY/NJ, Cleveland or Toronto. Chinese food, by definition, is not of European extraction – and therefore sufficiently novel. I remember the very first time I tasted it — it blew me away. Also, most importantly perhaps, cooking, especially fine cuisine, has long been a !man's! occupation in Europe, and yet Chinese restaurants have sprouted up all over Europe such as in (very recently) Hungary, where I am from.

ã,çãf;ãf<sup>a</sup>ã,«ç™ã! (2008-05-26 03:30:29)

Hi! I am a Japanese. Though I looked for English study in various ways, I commented because contents were interesting. I was able to enjoy it very much. In addition, I come to look. Please keep it for us. Thank you!

Best Chinese Restaurant? (2008-10-13 07:33:33)

Every other guy I know wants to open a cafe...

Karl Merdises (2009-08-19 21:26:36)

You cannot take the iss<sup>Ä</sup>¼ much better.

LemmusLemmus (2008-05-07 03:15:38)

The "proofreading fiasco" link doesn't work for me.

Jaap (2008-05-07 06:02:07)

You linked to Chapter 8 of "LSD, My Problem Child," rather than the table of contents. The link you probably intended to have is <http://www.psychedelibrary.org/child.htm>

seth (2008-05-07 06:30:22)

Jaap, thanks for the correction. LemmusLemmus, the link repeatedly works for me. I don't know what could be wrong.

LemmusLemmus (2008-05-07 07:38:13)

Now works. Hm.

## **Scaled-Up Self-Experimentation Proposed (2008-05-07 14:56)**

From an [1]article in Nature Medicine:

A British biotech entrepreneur named William Bains is proposing that self-experimenters should form collectives, pooling resources to make their findings more acceptable to the mainstream scientific community. Bains, who also lectures on the business of biotechnology at the University of Cambridge, UK, believes that the high costs and red tape associated with clinical trials have forced pharmaceutical companies to become increasingly conservative in the treatments they will test—leaving radical but potentially effective therapies out in the cold. . . . A radical alternative to conventional clinical trials, which he proposed in a paper published in April, is to have people who are willing to experiment on themselves band together and form what he calls 'biomedical mutual organizations' (BMOs) ( Med. Hypotheses

70 , 719–723; 2008). These collectives would pool resources to provide their members with more test subjects (each other), greater analytic capacity and access to more novel therapies, Bains claims.

---

Nansen (2008-05-08 13:12:10)

What has become of your [1]web trials idea?

1. <http://www.blog.sethroberts.net/2007/02/04/web-trials-update/>

seth (2008-05-08 21:08:52)

Nothing has become of it. The first thing I'd like to do is get a few more people to do self-experimentation they tell other people about.

Aaron Blaisdell (2008-05-09 14:25:56)

Reminds me of something I learned from a friend of mine when I was an undergraduate at SUNY Stony Brook. He was taking a course on parasitology and apparently, most of the significant early work (pre 1900) in the field of parasitology came from a small but dedicated group of parasitologists who studied their parasite of choice by infecting themselves with it and logging the results. They then wrote their self-experimental results up in scientific publications that the other members of this group read. So there is a precedence (probably many if we looked harder at the history of science and medicine) for Bains' proposal.

## The Greatness of Mondoweiss (2008-05-08 10:32)

Day after day I read [1]Mondoweiss, Philip Weiss's blog, even though his main subject – Israeli treatment of Palestinians, how this is enabled by Jewish Americans, what a mistake that is – is not something I read about elsewhere or think about when I'm not reading Mondoweiss. It would be too self-congratulatory to say now I care more about it but it is undeniable that now I know a lot more about it. Without any effort at all.

It's like a really great column in a newspaper or magazine except it's much better than that: Weiss can write anything he wants at any length at any time, unlike any columnist. The whole thing has a raw and impassioned and narrow and personal aspect unlike any column I've ever read. And it's so easy to read, even though it's unfamiliar and complicated. Here's [2]an example why:

I heard a crushing story about Aaron David Miller. He's from Cleveland and a big Jewish family. He went to a synagogue there recently and spoke from the pulpit and said, The problem's simple, two peoples fighting for a disputed piece of land, there will have to be a compromise. There was dead silence in the synagogue and the rabbi came up and said, "[3]In Numbers 34, God promised the land of Israel to Moses, from the Dead Sea to the Mediterranean...."

What a chilling story.

2. <http://www.philipweiss.org/mondoweiss/2008/05/from-the-financ.html>
3. <http://www.biblegateway.com/passage/?search=Numbers%2034:1-15;&version=31;>

---

Stephen M (Ethesis) (2008-05-09 18:06:17)

I'm amazed this hasn't drawn comments, one way or the other.

Stephen M (Ethesis) (2008-05-11 20:21:42)

I'm going to make a comment about the situation Modoweiss blogs about. Most Americans would be well served if every time a map of Israel was displayed it was superimposed over a major metropolitan area in the U.S. People would understand a lot of things a good deal better if Californians realized that Israel and the West Bank are, together, smaller than Los Angeles County. Texans would be surprised that Israel is not as large as the complete Dallas-Fort Worth metroplex. Etc. The entire scope and perspective of the conflict need to be better understood, I think, and a good start would be helping people to get just how small of an area we are talking about.

## Magazine Article of the Year (2008-05-08 21:34)

The year isn't half over, but [1]this brilliant profile – by Lauren Collins in The New Yorker, about a photo-retoucher you've never heard of – gets my vote.

I mentioned the Dove ad campaign that proudly featured lumpier-than-usual "real women" in their undergarments. It turned out that it was a Dangin job. "Do you know how much retouching was on

that?â€ he [Dangin] asked. â€œBut it was great to do, a challenge, to keep everyoneâ€™s skin and faces showing the mileage but not looking unattractive.â€

1. [http://www.newyorker.com/reporting/2008/05/12/080512fa\\_fact\\_collins](http://www.newyorker.com/reporting/2008/05/12/080512fa_fact_collins)

---

Profiles in Self-Education: Pascal Dangin (2008-05-09 07:31:49)

[...] (Hat tip to Seth Roberts for bringing my attention to the profile.) [...]

Observer (2008-05-13 15:23:12)

I assume you've noticed by now that the quotation you included in your post turned out to be inaccurate – Dangin didn't work on Dove's "Real Women" campaign featuring "lumpier-than-usual women in their undergarments" that the journalist appears to mention, and wasn't talking about that one either. Instead, he worked on the "Pro-Age" photos by Anne Leibovitz, which featured older (50+), mostly thin, and \*naked\* women. And according to both Dangin and Leibovitz, he did dust removal and color correction, not heavy retouching. (Not sure if they ever used those photos in the US; too much skin, I guess...) (And yes, the New Yorker has confirmed this, even if their arrogance forbids them to actually admit that they didn't bother to fact-check their own article, and instead claims that one inaccurate word ("undergarments") in a 6,308 word article isn't that bad.)

seth (2008-05-13 17:22:43)

Observer, no I hadn't noticed this. Thanks for pointing it out. My take is that Collins accurately reported what Dangin unwisely (but accurately) said. I'll believe Dove, Dangin, and Leibowitz when they release the originals . . . which they haven't. Rather than say the quotation "turned out to be inaccurate" I'd say it turned out to be embarrassing.

Observer (2008-07-17 12:47:37)

But now you're doing the same thing as the journalist: mixing up two campaigns, and using Dangin's comments about one of them to attack the people behind the other. Again, Leibowitz/Dangin didn't do the "Real Women" campaign with lumpy women in underwear that you're both referring to; that was a different photographer (Ian Rankin). Leibowitz/Dangin worked on a \*different\* campaign (and a campaign that probably wasn't used much in the US, since it featured \*nude\* women. Have you seen that one? You would remember it if you had...) I mean, if a journalist were to ask McCain what he meant by something that Obama said, and then accuse McCain of hiding something when he denied saying that, surely everyone would think that the journalist was a complete tool (especially if the defense was "yeah, whatever, I say so many words, surely you cannot expect me to get them all right?"). So why does the journalist get a free pass in this case? Because it's a well-written article and everyone knows that companies lie all the time, so who cares about the details? I'm not sure I get this.

seth (2008-07-17 22:32:34)

The New Yorker shouldn't have said "undergarments" because that was a different campaign, yes. I fail to see how that makes the quotation less interesting – it is merely about a slightly different campaign – although I do see that the mistake makes it easier for Leibovitz and others to be indignant. Here is Leibovitz: "He is primarily a printer – and only does retouching when asked to." Right. "When asked to." Please. Here is Dangin correcting the record: "I only worked on the Dove ProAge campaign taken by Annie Leibovitz and was directed only to remove dust and do colour correction – both the integrity of the photographs and the women's natural beauty were maintained." Of course. Whatever "integrity" and "natural beauty" mean. Not exactly a statement that he was misquoted. Quotes from <http://www.brandrepublic.com/News/808249/Dove-Dangin-dispute-real-beauty-ad-r-etouching-claim/>

## Should Those Who Are Part of the Problem Be Part of the Solution? (2008-05-09 06:49)

At a press conference about endangered salmon, I met Heather Hardcastle, who works at [1]Taku River Reds, a fishing company in Juneau, Alaska. She went to graduate school at Duke in 2002 where she studied marine conservation biology. "Everyone thought fishermen were bad," she told me. "I'd grown up in a fishing family, so to them I was a bad person. Most of the students thought of themselves as environmentalists – as if I wasn't."

What a failure of education. Surely people who make their living fishing would suffer the most if fish runs out; and surely people who have spent a lifetime fishing might know something useful to fish preservationists. Somehow this escaped the majority of the Duke students and, apparently, their professors. At the end of *The Shangri-La Diet*, I mention this problem: the idea that business is the enemy. In the case of obesity, of course, lots of people think that big food companies are the enemy. Well, yes, it's pretty clear that big food companies are responsible for the obesity epidemic – but maybe that means they should be more involved in the solution, not less?

Stephen Dubner interviewed me in my office to write about me in the [2]Freakonomics column. I mentioned a discussion I'd had with a friend about the Enola Gay controversy at the Smithsonian; my friend and I thought it was unfortunate, I told Dubner, that neither of us knew someone on the other side of the argument. Dubner said that a lot of reporters at the New York Times wrote about military stuff, but hardly anyone at the Times that he knew had even visited West Point, which was less than 60 miles away.

Varangy (2008-05-09 09:04:04)

Great, great post. On many different levels. Almost heresy in academia. *At the end of The Shangri-La Diet, I mention this problem: the idea that business is the enemy. In the case of obesity, of course, lots of people think that big food companies are the enemy. Well, yes, it's pretty clear that big food companies are responsible for the obesity epidemic – but maybe that means they should be more involved in the solution, not less?* I like your openness, but I take a different view. If anyone is responsible for the obesity 'epidemic' (other than us being responsible for our own health, first and foremost) it is government! Not business. Government should not be in the business of telling us what government scientists think is good/healthy/natural etc etc and then spending taxpayer's monies on promoting their nonsense, and even worse, setting public policy to their tune — when they have no idea what they are talking about. Be it on nutrition or 'global warming'. I think Taubes made that point, at least implicitly, and more eloquently, with review of the low-fat diet recommendations promoted by government funded scientists in the 80s. The most recent government mandated nutrition debacle that comes to mind is the trans-fat ban in NYC under the current Health-Nazis. Because *\_we \_know \_that \_trans-fats \_are \_bad \_for \_us.* Hhhhhhhhhmmm, why did restaurants start using trans-fats in the 80s? This may have already slipped down the memory hole forever, but if I remember correctly, (and I may be mistaken), ironically, NYC's government banned the use of animal fats sometime previously. This forced restaurateurs to switch to trans-fat type products. I leave you with this:

After gaining national media attention for spearheading an almost total ban on trans fats in city restaurants starting last July, **Bloomberg was photographed in this month's issue of *Wired* magazine munching on those very same dangerous fats.** The photo, which accompanies a short Q & A about technology and politics, features Bloomberg at his City Hall desk, looking thoughtful and serious. Meanwhile, his right hand is seen almost absent-mindedly pulling a Cheez-It out of a single-serving bag of the crackers. The mayor's food choice directly counters the guidance of his own Department of Health, which specifies on its Web site that **"there is no safe level of artificial trans fat consumption."**

<http://texasholdemblogger.wordpress.com/2008/01/11/trans-fat-bans-for-thee-but-not-for-me/> Do as I say, not as I do.

Andrew Gelman (2008-05-12 07:42:49)

Seth, You write, "Surely people who make their living fishing would suffer the most if fish runs out...." This makes sense, but remember that fishing is a classic example of the tragedy of the commons: it makes sense for each person to grab as much as he or she can while the resources run out. The issue isn't whether Heather Hardcastle is "a bad person," it's more a question of the economic and social incentives in play here.

seth (2008-05-12 13:19:24)

Andrew, the relevance of the grad students thinking that Heather was "a bad person" is that when you demonize someone it becomes harder to learn from them. Not to mention work with them. This is why it matters that the grad students saw her that way. It is truly weird that the Duke professors, not to mention a thousand other teachers, didn't teach that.

## **Calorie Learning: Better Design (2008-05-12 19:06)**

I finished a better-designed calorie-learning experiment. I mixed 5 randomly-chosen spice mixes into one chunk of butter (Mix A) and another 5 spice mixes into another chunk of butter (Mix B). Then I alternated two types of trials:

1. 2 saltines spread with Mix A followed by a piece of bread eaten nose-clipped.
2. 2 saltines spread with Mix B followed by nothing.

On each trial I rated how good the saltines tasted on scale where 50 = neutral, 60 = slightly good, and 70 = somewhat good. Here are the results:

When a new flavor was followed by a piece of bread, it tasted better than a similar flavor not followed by a piece of bread. After several flavor-bread pairings, the difference became large.

---

SusanJ (2008-05-13 08:42:10)

Interesting and plausible. I'm wondering if it's not just the calories from the bread but the "sugar spike" from the carbs in the bread? Could you try a similar experiment using an isocaloric NC follow-up item for both A and B but one follow-up being carbs and the other being protein or some other item that doesn't quickly raise your blood sugar?

seth (2008-05-13 10:37:28)

SusanJ, as far as anyone can tell, other calorie sources, such as protein and fat, also produce this learning, which surely predates foods that are quickly digestible, such as bread. Because rats and other mammals show this learning, it must have evolved long ago.

Varangy (2008-05-13 13:46:25)

I suspect the sugar spike has something to do with how you interpret how good something tasted. /"I'd like to buy the world a Coke and keep it company."/ :)

## John Tukey and the Shangri-La Diet (2008-05-13 15:40)

About ten years ago, John Tukey, the great statistician, gave a talk at Berkeley. After his talk, I went up to him.

"The tools you've invented have been really helpful to me," I said.

"If they work just some of the time, we should be pleased," he replied.

A curious answer, I thought. But I found myself thinking the same thing when [1]a woman named Darkhorse on the SLD forums said something similar to what I said to Tukey:

As of today, I am one pound below my original arbitrarily chosen "goal weight", and some 40 lbs. lighter than I was one year ago. No one is more surprised than I am . . . SLD is exquisite in its very simplicity, and I saw no need to complicate it. Best of all, it works!

If SLD works just some of the time . . . Thanks, Darkhorse.

## For Whom Do Law Schools Exist? (2008-05-13 23:29)

In the [1]Freakonomics blog, Ian Ayres, a Yale law professor, described a Law Revue skit at his school:

A group of students [were] sitting at desks, facing the audience, listening to a professor drone on. All of the students were looking at laptops except for one, who had a deck of cards and was playing solitaire. The professor was outraged and demanded that the student explain why she was playing cards. . . . She answered, "My laptop is broken."

Not bad. The professors in the audience were stunned.

The skit was "several years ago." I wondered how Ayres would manage to connect revelation of a timeless truth about higher education (see [2]For Whom Do Colleges Exist?) with something new. Here's how:

Saul Levmore, the dean at the University of Chicago Law School, has recently announced an end to classroom surfing.

The big truth behind the little joke was . . . hard to see. Or at least hard for professors to see. The big truth is that law schools, like most institutions of higher education, are run in dozens of ways that benefit professors at the expense of students. Boring lectures are one example. In response to a small revelation of this big truth, Dean Levmore – presumably after consultation with many other law school professors – created another example of how law schools are run for professors rather than students.

Difficulty with basic concepts at [3]Duke and [4]UC Berkeley.

More. I suppose solitaire is still okay at the University of Chicago since it doesn't involve surfing.

Stephen M (Ethesis) (2008-05-14 19:35:42)

Seth, you hit one what used to be an interest of mine. <http://adrr.com/law0/> is material I wrote in the early to mid 90s (around the time period of the events in <http://adrr.com/living/>) in response to a request from a friend who was doing a project. I've not done much to edit or update it since I started being able to think again, but you've hit a very sharp point indeed.

Andrew Gelman (2008-05-16 19:26:31)

Seth, I think this is a more general issue, not specific to universities. People in a system who have some control over their working environment will seek to make themselves more comfortable. Getting to the specifics-yeah, I don't want my students emailing or surfing the web during my classes. It distracts them from thinking about the course materials, distracts other students too, also I think it sets a mood in which students don't take the course seriously. That's one reason I do classroom activities in pairs, to keep the students involved.

seth (2008-05-16 19:40:52)

Universities are a peculiar "working environment". In certain ways they resemble jails - that professors have trouble seeing this is interesting, especially because they were once students. Given that law is about equity, it is especially interesting that law professors have trouble seeing this.

Andrew Gelman (2008-05-17 12:19:58)

Seth, I've never been to jail but this comparison seems like a stretch to me! I'm not saying that I enjoyed college, but . . . jail?? Ya gotta be kidding.

seth (2008-05-17 13:03:59)

Yes, jail. Many students would not be in college if they had any choice in the matter. They feel forced to be there. Before Dean Levmore decided to ban surfing in classrooms, I'm pretty sure he didn't consult any students, which is an indication of how little power they have - like prisoners. John Taylor Gatto has often compared school to prison.

Andrew Gelman (2008-05-17 17:48:08)

Hmmm . . . I don't know that anyone is being forced to go to law school! Elementary school, sure, but law school?? Nobody's stopping these kids from cutting classes and flunking out. Heck, if they really want, they could commit some crimes and go to jail, saving themselves all that tuition in the process!

seth (2008-05-18 06:08:21)

If there is a way to become a lawyer without going to law school, I'm unaware of it. Of course, law school is unlike jail in dozens of ways; I thought that was obvious. The similarities - and the way professors have trouble seeing them - are what's interesting. It will cost you dearly if you flunk out of Yale Law School. A friend of mine got into Yale but for irrelevant reasons

went to a much less prestigious law school. Huge mistake, she now says. She didn't realize that where she went to law school would affect how she was treated for her entire professional life.

### If Weston Price Had Been a Dermatologist (2008-05-15 23:02)

[1]This review article – comparing several commonly-prescribed treatments for acne – ends up close to what I figured out [2]as a graduate student via self-experimentation: that benzoyl peroxide works much better than antibiotics.

I like to think that in 100 years people will look back on current treatments for acne (and a hundred other things) as medieval, like leeches. If [3]Weston Price had been a dermatologist, we would now have evidence, I'm sure, that certain traditional lifestyles produce very low rates of acne. Examination of those lifestyles would provide good clues about what aspects of our way of life cause acne. That would be a good starting point for experiments to zero in on what matters. Once we knew the environmental causes of acne, such as [4]caffeine or [5]soap, they could simply be avoided; no need for powerful dangerous expensive medicines. At the moment, however, determination of what aspects of modern life cause acne isn't even close to being studied. You might think it is better to study safe cheap cures than dangerous expensive ones but you'd be wrong. At least now.

---

david (2008-05-16 05:17:13)

I've often wondered about that. I used to study classics (Latin and Greek). To my knowledge, in the ancient authors there was never a mention of acne being a common phenomenon. I would think that if it had been a problem, it would be mentioned somewhere (whether to joke about it or whatever). Ask your colleagues from other departments who study traditional cultures (living or dead) if there is any mention of acne in the texts or representations of it in visual arts. If it was problem associated with adolescence in those cultures, it would surely show up in the texts. The only character from literature I can think of is Bardolph in Shakespeare's Henry IV part I. Not sure if that was acne, but he had some kind of boils on his face.

Andrew Gelman (2008-05-16 18:44:29)

Perhaps they had more important things to worry about!

Nathan Myers (2008-05-17 01:42:48)

Safe cheap cures are generally not patentable. Ginger, incidentally, has worked twice as well as dramamine against motion sickness, in double-blind trials. Such trials are conceivable (but not inevitable, or immediate) only since the patent on dramamine expired.

Gittit Shwartz (2008-05-17 14:55:50)

Actually, Loren Cordain (author of The Paleo Diet) showed that a paleolithic diet/lifestyle eliminate acne.

bjk (2008-05-18 03:48:28)

I read a book by a dermatologist about 15 years ago who experimented on his patients. He found that partially hydrogenated sat fats were the worst, although all sat fats were bad. His theory was that any fat that was a liquid at room temperature (like butter) is bad for you and would clog up the pores, and that liquid fats like olive oil are good for skin. Many Asians believe this, and attribute acne to things like chocolate. The dermatologist found that a diet that totally eliminated saturated fats and caffeine would eliminate acne. Very high doses of niacin were also effective, the theory being that niacin affected skin temperature. I don't remember the title of the book. I bounced his ideas off a dermatologist. He was dismissive and offended that I would question his authority.

David (2008-07-11 23:17:36)

sigh\* I absolutely hate prescription acne treatments. In my opinion its all just a psychological issue, with prescription placebos to advance your thinking.. try a natural acne cure for once. at least the detox diets actually work. check out this link to see what im talking about: <http://noacnenow.com/top-five-acne-treatments/>

Zeke (2009-05-26 02:44:54)

I got acne at a very early age (fourth grade) and had it bad until high school, when it started going away. I was on everything from oral and topical antibiotics to Retin-A to Accutane. The Accutane was horrible. It gave me chapped lips so bad the middle of my bottom lip would occasionally split open and bleed. The only thing I found that worked was products with salicylic acid. I still occasionally crush up an aspirin and put it on the rare zit.

## **Read-Off (2008-05-17 11:21)**

Or should that be Write-Off? Last night I compared, as in a cook-off, the first few pages of four books I want to read. (I also want to read Cookoff by Amy Sutherland.) Here are my notes:

1. [1]The Geography of Bliss: One Grump's Search for the Happiest Places in the World by Eric Weiner. Slow start. Weiner goes to Rotterdam to visit happiness researcher Ruut Veerhoven. I am unamused that a Dutch waiter asks "Maybe now you would like some intercourse?"

2. [2]Natural Capitalism: Creating the Next Industrial Revolution by Paul Hawken, Amory Lovins, L. Hunter Lovins. Disappointing, although possibly a great book. The beginning is abstract and preachy – although the central idea – we are beginning an industrial transformation that will transform our lives as much as the Industrial Revolution did – is incredibly important.

3. The Man Who Loved China: The Fantastic Story of the Eccentric Scientist who Unlocked the Mysteries of the Middle Kingdom by Simon Winchester. About Joseph Needham. Another slow start. Begins with his arrival in China. No amount of well-written detail will make someone getting off a boat or plane interesting, although I expect the rest of the book will be excellent. Here's how the [3]USA Today review of the book begins:

Simon Winchester's The Man Who Loved China proves the adage that if you really want to learn a foreign language, fall in love with a native speaker.

Winchester's new non-fiction book is the tale of what happened after brilliant British scientist Joseph Needham lost his heart to Lu Gwei-djen, a 33-year-old Chinese biochemist. She had come to Cambridge University from China in 1937 to meet with Needham, 37, and his wife Dorothy, also a prominent biochemist.

Much better.

4. [4]The Fortune Cookie Chronicles: Adventures in the World of Chinese Food by Jennifer 8. Lee. (I have no idea why Lee spells her name with a period after the 8.) This was the book I kept reading. After a poor prologue (a cluster of Powerball winners due to a fortune-cookie fortune – unsurprising), the book moves to a well-written mix of stuff I didn't know about an interesting topic (Chinese take-out) and personal story.

Winner: The Fortune Cookie Chronicles.

1. <http://www.ericweinerbooks.com/content/index.asp>

2. <http://www.natcap.org/>

3. [http://www.usatoday.com/life/books/reviews/2008-05-07-china\\_N.htm](http://www.usatoday.com/life/books/reviews/2008-05-07-china_N.htm)

thehova (2008-05-17 12:42:44)

"The Geography of Bliss: One Grump's Search for the Happiest Places in the World" is a wonderful book. I highly recommend reading the entire book.

**Ditto Soda: Compliment or Coincidence?** (2008-05-17 23:45)

Which of the following doesn't belong?

- Fanta
- Dr. Pepper
- Coke
- Pepsi
- Skipper
- Parker
- 7Up
- Sprite
- Mountain Dew
- Mr. Pibb
- Ditto

All are names of soft drinks. Ditto is the name of a new lemon-lime drink that is the Safeway house brand. It strikes me as so different than the other names on the list that I flatter myself to think that there is some connection with my invention of the term ditto food in The Shangri-La Diet. Soft drinks are prototypical ditto foods.

A few years before Nabokov's novel *Lolita* was published, [1] a short story by Dorothy Parker titled "Lolita" appeared in *The New Yorker*. Nabokov had published often in *The New Yorker*, and he wrote an angry letter to Katherine White, the fiction editor, complaining that the manuscript of *Lolita* that he had shown them in confidence had somehow leaked. White wrote back that it was a coincidence.

## What Do Iceland and Sierra Leone Have in Common? (2008-05-18 07:58)

[1] Something important. After reading this, my question is: What else has John Carlin written?

1. <http://www.guardian.co.uk/world/2008/may/18/iceland>

---

Mel (2008-05-18 18:53:15)

Well, I took the hook and read the article. Ah, it sounds like a feminist fantasy land. The part about being pagan as the foundation of all this happiness forced me to read the Wikipedia entry about Greenland and it has had a history of Christianity, but I think that's all behind them now. I'm glad all 316,00 of them have created government heaven on earth and I wish them success. Don't think I'd care for the weather.

pd3 (2008-05-19 10:39:32)

that's fine as far as it goes, but the next time I find someone who went through a break up and found it emotionally easy, will be the first. He quotes Oddny who relates the positive experience of another woman for the proposition that there was no crisis as far as the children. That is highly unreliable evidence, at least as far as how that woman took it. And, there really is no way to measure that sort of thing anyway. Oddny said the divorce rate is not something to be proud of, which can be read as a tacit admission that the success of the country may be in spite of the divorce rate. The next witness to mention marriage credits the economic boon of World War II and seems to have stayed married and keeps care of his invalid wife. The remainder of the article credits the picking and choosing of the best policy structures that other countries have to offer and the power of the extended family. Seems pretty traditional to me. So, Iceland seems like a pretty nice place to live—at least since 1939—but the article has not necessarily proven that the success is because of they got over any "hang ups" which I am not sure what that even means.

LemmusLemmus (2008-05-19 12:21:38)

pd3, I don't think the article proves anything either - it's just a journalist's article, after all, not a scientific paper. I agree that we have no hard social scientific evidence of the effects of divorce on children. Neither does it follow that divorce is good for children nor that it is bad. In which case you have to use anecdotal evidence, which is better than nothing. My anecdotal evidence says that I was relieved when my parents got a divorce. A friend of mine said the same. It's just not much fun living in a household where you have to be constantly afraid that a fight is going to break out between your parents for no reason whatsoever any minute - even if it's just a verbal fight.

Varangy (2008-05-19 14:05:21)

This article is a cute puff piece but really makes some completely irrelevant and obfuscatory points. *it's the only country in Nato with no armed forces (they were banned 700 years ago)*; This is because, like the rest of Europe (with weak armies), their defense is completely subsidized by the USA.

Andrew Gelman (2008-05-20 19:03:51)

John Carlin is the second author of Bayesian Data Analysis, so I'd say he's made some major contributions already!

Chris B. (2008-05-23 09:31:41)

LemmusLemmus wrote: "I agree that we have no hard social scientific evidence of the effects of divorce on children. Neither does it follow that divorce is good for children nor that it is bad. In which case you have to use anecdotal evidence, which is better than nothing. My anecdotal evidence says that I was relieved when my parents got a divorce." I think you're understating the amount of research done in this area. It's difficult, of course, to get "hard scientific evidence" in the sense of controlled experiments, but the effects of family structure on life outcomes for children has been studied extensively. One of the stronger conclusions seems to be that children's experience tends to vary depending on the kind of marriage the parents had before their divorce. If their marriage was highly conflictual, the children tend to do better after divorce than their peers whose parents stay together. If the marriage was low-conflict, the children tend to do significantly worse than their peers. However, most divorces (something like 70 percent) occur in what sociologists rate as low-conflict marriages, so the net impact of divorce on children appears to be distinctly negative. There are the usual caveats about correlation and causality, but, as I've said, this topic has been studied extensively, so I doubt the researchers aren't falling into any of usual traps for the naive or inexperienced. Here's a paper on the general issue - not the best I've seen, but the best I could Google up in a couple of minutes: [http://papers.ssrn.com/sol3/papers.cfm?abstract\\_id=984487](http://papers.ssrn.com/sol3/papers.cfm?abstract_id=984487) #PaperDownload

## Self-Experimentation and the Nicotine Patch (2008-05-18 10:09)

Murray Jarvik, inventor of the nicotine patch, died recently. I [1]learned:

When the researchers could not get approval to run experiments on any subjects, they tested their idea

on themselves. "We put the tobacco on our skin and waited to see what would happen," Jarvik recalls. "Our heart rates increased, adrenaline began pumping, all the things that happen to smokers."

Why, I wonder, didn't they start with self-experimentation?

### **The China/Tourist Interface (2008-05-20 21:45)**

When I gave a draft of my [1]Robert Gallo article to my editor at Spy, Susan Morrison, she called it "well-reported." I hadn't heard the term before, but I understood what it meant. (And, yes, I do remember every compliment I have ever been given.)

I thought of well-reported when I read this in [2]The Fortune-Cookie Chronicles by Jennifer Lee:

This eighty-one-year old Chinese woman was a professional Jew.

She lives in Kaifung, China, where long ago there had been a community of Jews large enough to build a synagogue. She is one of the few Jews left; pilgrims visit her. She makes a living selling them paper cutouts that combine Jewish and Chinese themes. You could read a hundred books about China and not come across anything like this, but it reminds me of my experience. When I was in China – I taught psychology at Beijing University – some friends and I visited the Great Wall. To avoid tourists, we went to a remote and less popular section. As predicted, it was nearly deserted. But along the path to the wall, just before it got steep, sat an old man in a chair. "2 yuan" said a sign. He wanted 2 yuan (about 25 cents) to allow us to pass. We paid.

Nathan Myers (2008-05-21 16:22:52)

Curiously, there's no such physical object as a Great Wall in China. There are lots of walls, to be sure, some of them very photogenic, but "The Great Wall" as such is purely a marketing construct. One might as well speak of Europe's "Great Castle Chain"; there are lots of castles, but each was an independent project. Some walls attach end-on to previous projects, some run parallel, some are just out there by themselves. People who are convinced nobody ever walked on the moon are nonetheless happy to believe that you can see "it" from there.

## Calorie Learning: Somewhat Better Design (2008-05-23 05:49)

I've done several experiments where I add a bunch of randomly-chosen spices to butter, spread the butter on saltines, eat the saltines, and then follow (or not follow) them with a piece of Wonder Bread eaten with my nose clipped shut.

In the previous experiment in this series, I made two spice mixes, A and B. After eating saltines spread with A, I ate a piece of bread. After eating saltines spread with B, I ate nothing. I did one trial per day, going back and forth between a trial with A and a trial with B. For example, Monday (A Trial), Tuesday (B Trial), Wednesday (A Trial), etc. Here are the results:

In an experiment just finished, I improved this design a bit: 1. I had trials with both A and B on the same day. (I made two new random spice mixes for this experiment.) 2. The first saltines of the day I rated "blind" – that is, without knowing what mix it was. Here are the new results superimposed on the previous results.

So far so good. The new results agree with the earlier results.

### How Amazon Computes Book Ranks (2008-05-23 17:27)

Given how interested authors are in the Amazon rank of their books, it's curious how little I can find about how those ranks are computed. [1]Amazon won't say. Let me try to figure it out.

Is it based on the number of copies sold in some unit of time – say, one day? Surely not. If the unit is too small, then most books will have zero copies sold. That's too many ties. If the unit is too large – say, one week – it won't change very quickly. That's boring.

That leaves average time between orders – what an animal psychologist would call interorder interval (IOI). If one copy is sold at 10:00 am on Monday and the next copy is sold at 12 noon on Tuesday, the IOI is 26 hours. This is easy to track for each book and can discriminate between books that don't sell many copies.

How many IOIs does Amazon use to compute the rank? One, five, twenty? Surely more than one. Using just one would be too noisy and would do a terrible job of discriminating best-sellers. This morning my editor asked me if [2]Stephen Dubner's Freakonomics blog post about SLD yesterday helped its Amazon rank. I checked: the rank was about 5600 (better than usual). This afternoon, I checked again: the rank was about 1700. I am sure there is no delayed effect of a mention on the NY Times website; Dubner's post must have had its biggest effect on sales yesterday. So why is the rank improving today? Because Amazon uses a fixed number of IOIs (or at least a maximum number) to compute the rank and today the longer ones are still being replaced by shorter ones. In other words, the rate of sales, although lower today than yesterday, is still higher than usual.

According to [3]this article, a book ranked about 2000 sells about 10 copies per day (on Amazon, I assume). SLD's current rank (about 2000) reflects an average of long IOIs (before yesterday) and short ones (yesterday and today). Yesterday, therefore, it must have sold more than 10 copies – but this wasn't enough to get rid of all the long IOIs. So the rank is based on more than 10 IOIs.

Further than that I cannot go.

[4]Using Amazon rank to compute sales. The Bookscan/Amazon-rank correlation I show in that post indicates that a book with an Amazon rank of about 2000 sells about 40 Bookscan copies per day, which is why I assume that the 10 copies per day mentioned above refers just to Amazon sales.

Andrew Gelman (2008-05-23 18:35:26)

Hi, Seth. I don't know if this helps, but our recent book sold about 4000 copies in 9 months—that would be about 15/day in total, not just Amazon, and it's typically ranked around 5000 on Amazon. My point is that technical books such as mine sell proportionally more on Amazon, while Stephen King etc sell more in stores. I'm not sure where your book falls in this spectrum.

John Hunter (2008-05-31 13:42:42)

I also wonder about several things: is the rank based on book count volume, or \$ volume? I am guessing \$ volume. I also wonder if it is some kind of decaying rank (sales today count more than yesterday which counts more than 2 weeks ago).

### **Blogging: Megaphone and Microscope (2008-05-24 09:49)**

If I had said to someone twenty years ago, "In twenty years there will be a way for you to say what you really think about everything related to your job, with a big audience" they would have looked at me as if I were crazy. Now, as [1]Tyler Cowen pointed out, that's actually the case, thanks to blogs. It's a kind of psychological miracle. It's due to technology, sure, but the achievement is essentially psychological.

It's not the only psychological miracle that blogging provides. Consider [2]this account of being in a mental hospital:

K, so since the night I got there, I would get a whiff of this nasty smell. It 's hard to describe, it was just nasty and I couldn't figure out where it was coming from.

One day, I'm in my room with two roommates and I smell it.

"There it is again!" I yelled.

"It always smells like this." The older lady said.

"OmG, you've been here so long, you're used to it," I said, repulsed. However, I still couldn't figure out where it came from. Some times I would smell it, then go back to that same place and it would be gone.

It was making me (excuse the pun) feel like I was going crazy.

After using the bathroom, I went to wash my hands. Maybe it was the soap? No.

Later, I took a shower and sniffed the shampoo that came out of the pump on the wall.

It was the friggin shampoo! No wonder I got a whiff here and a whiff there. Everyone in the building (32 people) had that crap in their hair!

Vivid, easy to read, even enjoyable to read. Now you know a little - very little, but more than zero - about what it's like to be in such a place. I read *Girl, Interrupted*. Lots of movies include scenes in mental hospitals - as stylized as a Dove ad. I didn't see [3] *Titicut Follies*. Maybe Sylvia Plath wrote about it, I don't know. It's been nearly impossible - or actually impossible - to get an accurate idea of what it's like to be in a mental hospital without actually visiting one. But now it is.

Stephanie (2008-05-24 17:23:06)

Thanks for reading my blog and stuff.

### **Anchorage = State of Being Anchored (2008-05-24 23:15)**

[EMBED]

Anchorage by Michelle Shocked is one of my favorite songs. This twenty-year-old video was put on YouTube two weeks ago. It's as fresh and alive as the deer in my backyard.

---

Fedoemami (2009-01-06 21:25:41)

There are 5 houses in five different colors In each house lives a different nationality. These 5 owners drink a certain beverage, smoke a certain brand of cigar and keep a certain pet. No owners have the same pet, smoke the same brand of cigar, or drink the same beverage. The CLUES: The Brit lives in the Red house. The Swede keeps dogs as pets. The Dane Drinks tea. The Green House is on the left of the White House. The Green House's owner drinks coffee. The person who smokes Pall Mall rears birds. The owner of the yellow house smokes Dunhill. The man in the center house drinks milk. The Norwegian lives in the first house. The man who smokes Blends lives next to the one who keeps cats The man who keeps horses lives next to the man who smokes Dunhill. The man who smokes Blue Master drinks beer. The German smokes Prince. The Norwegian lives next to the Blue House. The man who smokes Blends has a neighbor who drinks water. The QUESTION: Who owns the fish?

Fuzu (2009-10-28 21:21:05)

Ooh gosh i just typed a long comment and as soon as i hit post it came up blank! Please please tell me it worked right? I dont want to sumit it again if i do not have to! Either the blog bugged out or i am just stuipd, the latter doesnt surprise me lol.

jeffery adamczyk (2009-10-30 18:41:02)

Hi just thought i would let you know i also had a problem with this blog appearing frozen also. Might be gremlins in the system.

## **How Things Begin (The Approval Matrix, part 1) (2008-05-25 04:59)**

New York magazine's [1]Approval Matrix is my favorite magazine feature. I asked Emily Nussbaum, an editor at New York, how it came to be.

ROBERTS When did you come up with this? What happened in the beginning?

NUSSBAUM I'd been hired soon after Adam Moss came on board as Editor-in-Chief and my job was essentially to oversee the redesign of the culture section. It was a collaborative process with editors like Chris Bonanos and writers including Boris Kachka and Logan Hill. I wanted to open with something more substantive – an essay on a cultural matter or a profile – follow with reviews and fun devices. and then close with something really visual, ideally that combined different genres. We rejected a variety of things before we managed to come up with something. Actually, the idea [for The Approval Matrix] came off a piece I saw in Wired magazine. Which was a kind of Matrix-y sort of chart, a one-off thing. The two directions, one of them went geek to cool, the other went nerd to wonk. It didn't have any visuals and it didn't have any jokes. It was all of these different people. It had Joss Whedon and Joss Whedon was nerd/cool. Names of different technology people, a little bit of pop culture. It was funny, it was hard to understand in its own way, which I think is true of The Approval Matrix as well – but that was part of the appeal. So I brought it in and showed it to Adam. We were talking about it and I suggested we use it as a back-page round-up, a visual catch-all for stuff from theatre to television to books . . . Commentary on little news items in culture, events, people, a whole range of things. That was the basic concept. Then I had suggested that it go highbrow/lowbrow and something like good/bad or great/terrible. Adam said we should make the extent of the continuum longer than that. So I said "brilliant" and he said "despicable" – which in the long run was one of the more controversial aspects of The Matrix! Every once in a while, I'll come across someone who says, "How can you call something despicable?" The larger philosophy of the section was to combine access – talking to creators – with judgment and authority. So the Matrix was about making judgments but also being playful and random, by comparing totally different things to each other. The extremeness of brilliant/despicable was supposed to be part of that. And then there's the highbrow/lowbrow thing, which can also be controversial. It's both something that we're literally doing and something we're being satirical about. For me personally, one of things that I thought was appealing about it – not to be, as I'm already being, incredibly overanalytical – but one of the things that I wanted for the section as a whole, was to say the obvious but true thing that you can have something that's lowbrow that's absolutely fantastic or something that people think of as mass-y, like comics books or whatever, that's incredible, and some opera that's actually incredibly dull; it's just that they operate on different parts of the spectrum. So the idea was that putting those things together was essentially saying what really matters is the quality of them, not whether people consider them an elite taste or whether people consider them a mass taste. But obviously it's also supposed to be something fun, geeky and mathematical. There was an initial concern that it might be hard to understand. Just because it's a graph, and people found it a little confusing. So, anyway, we drew up a prototype of the Matrix. The designers did a great job. Then there was a gradual move toward launching the Culture section. And we launched The Matrix. It didn't change that much from the time that we put it out. What changed was the developmental process of figuring out which jokes work and what works best in terms of combining visuals and text.

[...] How Things Begin (The Approval Matrix, part 1) [...]

### **How Things Begin (The Approval Matrix, part 2) (2008-05-25 23:30)**

NUSSBAUM I remember during the first Matrix, there was this Uggs fever in New York. I put them on the slightly highbrow and slightly despicable side. [1]A picture of an Ugg. It just said Ugg. A one-word thing.

ROBERTS Ugg spelled U-G-H?

NUSSBAUM It just said U-G-G-S. On the other side was some "brilliant" fashion thing. So we started pairing things. Initially, the illustrations were way too literal. They would just illustrate the thing we were talking about it. But I think The Matrix works better when there are some big and some small things, some visuals that are jokes themselves.

ROBERTS You said there were big things and small things. What do you mean by big and small?

NUSSBAUM Just visually. Sometimes there would be one big blown-up thing to add visual interest to it. We were constantly sending notes to the photo department saying, "if there's a thing about something being slow, just show a snail." Silly dopey things like that. Finding a visual that made its own joke, as opposed to simply being straightforward: We think this book is good, we think this TV show is bad. We wanted something that would kinda make it work together. And then of course there were debates about what constituted highbrow and lowbrow. The way we actually created the Matrix was, it was mostly the people who worked in culture – it was myself, Chris Bonanos, and, once we hired Adam Sternbergh, he was very involved, and he really helped sharpen the voice. Because he used to be a comedian and he was incredibly funny at coming up with these compressed one-liner ways of saying things. At the time, I was top-editing it, and then later, he took that on, and now there are other people doing it: Emma and Ben. I would send out a big mass email, trying to get stuff from all of the different people who did different areas, classical music, art, etc. But the truth is, it was just a few people contributing initially. People would send in their jokes or their elements. They would send us something that was highbrow/despicable. And sometimes, more specifically, it would say "highbrow/despicable but very close to the brilliant/despicable line", describing where it should go on the Matrix. Then I would top-edit the jokes. And often at the end of the day, when we were closing the thing, the three of us would gather in Bonanos' office and we all just would hash it out and try to sharpen or improve some of the jokes in the way that you do. We would do it collaboratively and try to get it to work. Then I would send it by Adam Moss and he would add or sharpen things further. It was often an incredible crunch because it was such a visually-complicated thing to lay out. And very last-minute. Because they would be trying to get a photo of something odd or difficult.

### **Andrew Solomon on Autism (2008-05-26 21:01)**

After reading an [1]excellent article about Craig Newmark by Philip Weiss in New York magazine, I turned to a New York article about [2]controversy over how to deal with autism. (New York, you see, is more humble and thus more interesting than The New Yorker.) Its author, Andrew Solomon, who wrote *The Noonday Demon*, once [3]wrote about the deaf rights movement. The neurodiversity movement is similar. What I found most revealing about Solomon's article is the level of animosity he uncovered.

Researching this article, I spent a lot of time being talked at by people on both sides, one more doctrinaire than the next. Not since my early days reporting from the Soviet Union had I found myself so bullied about what I should and shouldn't be mentioning.

It's a kind of debate that didn't happen until recently: on one side are parents who want to help their kids; on the other side are people who want more acceptance for autistic behavior. On the face of it they should be allies but in reality they are enemies. It reminds me of my complaint about how graduate students are trained (or rather not trained): they never learn to praise, to see what's good about this or that study, so their natural inclination to be negative does a lot of damage.

1. <http://nymag.com/nymetro/news/media/internet/15500/>

2. <http://nymag.com/news/features/47225/index3.html>

3. <http://query.nytimes.com/gst/fullpage.html?res=9A00E2D91639F93BA1575BC0A962958260&scp=2&sq=deaf+&st=nyt>

---

Mary (MPJ) (2008-05-27 00:50:20)

I read the article too and thought it was a good overview. I'm the mother of an autistic son and fall in with the neurodiversity movement. Not all parents believe that vaccines cause autism (I don't) or believe that the same things will help their children. I agree most with Phil Schwarz, who commented on the article, that we're looking at a false dichotomy when we talk about cure/no cure. Of course, as with autism itself, there is a spectrum of opinion, even if in what appears to be two clear warring factions.

Kristen's Raw (2008-05-27 02:08:42)

Interesting about autism and the "sides." On a separate note, I love Brian Wansink's book.

Aaron Blaisdell (2008-05-27 16:20:59)

Seth, you wrote "It reminds me of my complaint about how graduate students are trained (or rather not trained): they never learn to praise, to see what's good about this or that study, so their natural inclination to be negative does a lot of damage." We all have our own experiences as graduate students (those of us who are or were) and some of this set later on become mentors. I must say that my experiences differ markedly from yours. My own graduate and postdoctoral mentors (Ralph Miller and Bob Cook, respectively) both taught me how to praise as well as criticize. I have attempted to emulate both sides of critical analysis when mentoring my own postdocs, graduate, and undergraduate students.

seth (2008-05-27 17:44:42)

Aaron, it's good to hear about that. About a dozen people have told me they were trained "to think critically" – that is, to find flaws. You're the first person to say they were trained to find strengths.

Jay Verkuilen (2008-06-05 15:29:06)

I'm now a psychometrics prof at but spent a long, long time as a grad student—in two fields—at University of Illinois. I had different mentors over time. My first (who shall remain nameless) was incredibly critical, far more than is good for anyone. I had to unlearn that because it literally poisoned my thinking as I got way too good at turning the guns on myself. My later mentors were much better about being even handed and modest. Look for what's good, what you yourself can learn from, and what can be improved. Don't automatically reach for the 12 gauge and start blasting away. In fact, in the unlikely event that they're reading I'll thank, in alphabetical order, Carolyn Anderson, David Budescu, Larry Hubert, Jack Knott, Jim Kuklinski, Gerry Munck and Michael Smithson, various senior faculty members with whom I worked, was supervised by or just got a lot of advice from when a grad student, all of whom taught me how to do it right. The remaining faults are, of course my own. :)

### **How Things Begin (The Approval Matrix, part 3) (2008-05-27 18:44)**

ROBERTS To me one of the fascinating things about The Approval Matrix is not only that it works so well but also that it has this despicable/brilliant dimension. This is fascinating because they're not opposites, obviously. But also because despicable is an unusual word to see in highbrow American journalism.

NUSSBAUM All credit to Adam Moss for people who like and dislike the word despicable. Who find it both brilliant and despicable.

ROBERTS I'm saying that people usually don't pass moral judgment. Are you saying that despicable is just a synonym for idiotic or awful?

NUSSBAUM To me, what despicable does is it says there is something outrageous about this and not entirely serious about the judgment. Because, the truth is, to me the voice of The Matrix, much more than the rest of the Culture section, sounds like people mouthing off in a bar. When you get in one of those crazy High-Fidelity-like debates about something. Where you say, "Don't you think that this is a tiny bit better than the other thing?" These two characters on a TV show, one of them is two notches better than the other one.Â Somebody says: I just can't abide anything from that genre, it's completely despicable. It has the voice to me of people being, hopefully, witty blowhards. To me, despicable kind of refers to them.

ROBERTS An underreported category.

NUSSBAUM Yes, the witty blowhard! The thing signalsâ€"because you can't judge things so literally, on a mathe-

matical chartâ€”it both displays our judgment about things and to me slightly undercuts it. Because part of the point of The Matrix is for people to argue about the placement of things. Or object to them. Because that's what happens. If you hand it to somebody, nobody's going to agree with everything. Often what they disagree with is not the literal placement of things but the placement of things in relationship to one another. For instance, wait a second, a Sondheim musical is more highbrow than this particular HBO drama. And then there's this weird discussion: Why is that? What constitutes more highbrow? Or, often, my favorite thing: Early in The Matrix, one of the fun things to do was to create a something like a constellation. . . .

ROBERTS You mean, if you connect the dots, it makes a shape? Is that what you mean by constellation?

NUSSBAUM No, not a literal constellation like that. I mean a bunch of things that all cluster together and are all being judged in relation to one another. This was several years ago and we had a tiny cluster that was essentially Paris Hilton, Nicole Richie, Lindsey Lohan, these starlet types who had been caught in various scandals. They were all in lowbrow/despicable but they were in slightly different sections next to each other. Lindsay Lohan was slightly more highbrow than Nicole Richie and a little bit more brilliant. They were funny in relationship to one another. This was at the point when Sternbergh, a couple months into it, he started being the top editor. And his sensibility has been really important to it. He was overseeing it when there was an end-of-the-year matrix thing. There were a lot of Jude Law movies out that year. So it was Jude Law's face right in the middle of The Matrix and then four of his movies were right around him, each of them in one of the quadrants. The bizarre thing is – they were weirdly accurate. I'm trying to remember what they were. The Closer was highbrow/despicable. God, what did he make that year? He had literally done four movies that you could kind of justify as being very close to one another but each crossing into a different category. I always enjoyed when we did things like that.

Jim N (2008-05-28 07:27:22)

Seth, on the previous post, I was going to respond to your tangential comparison of the New Yorker and New York Magazine, and then I realized that what I was about to do was almost exactly the topic of this post - debating "a bunch of things that all cluster together and are all being judged in relation to one another". This blog is causing me to observe my own behavior objectively, even as I read this blog.

[...] How Things Begin (The Approval Matrix, part 3) [...]

### **How Things Begin (The Approval Matrix, part 4) (2008-05-30 00:11)**

NUSSBAUM Occasionally we'd throw something in that had nothing to do with culture. At one point this year the weather was really miserable. I just suggested putting overflowing sewers on one side and then hot soup on the other – or something like that. The main thing we got flack for was the highbrow/lowbrow aspect of it.

ROBERTS Why? What was the flack?

NUSSBAUM We got this objection from people who have a strong feeling about these cultural categories. About the

art of the charticle. The strongest objection was essentially, to be super-academic about it, that we were reifying the categories of highbrow and lowbrow.

ROBERTS What does reify mean?

NUSSBAUM Instead of critiquing, or being playful with, or using but in a knowledgeable way, those categories, that we were solidifying them, and acting as if they were real and making them into solid objects.

ROBERTS I'm not grasping the criticism. Oh, ok, you're doing that, so what?

NUSSBAUM Basically, that we were taking them at face value, or, even more cynically, that we were presenting them at face value even though we knew better. By setting up a chart like this, we were basically saying opera is highbrow and comics are lowbrow. When to me, part of the point of it was making visual those illusory categories. Effectively setting up a kind of stimulus for people to react to the way that we place things. You do end up saying to yourself, at least if you're in-house and you're debating these things – you do end having this weird conversation about: are the Oscars more highbrow or lowbrow than the Grammys and the Tonys? This kind of crazy way of determining things. Sternbergh once wrote something to the guy [Mohamed Ibrahim] who was doing [1]Behind the Approval Matrix – we were so excited that someone was doing a blog about it – he wrote a note to him at one point describing our thinking on several of the items in it. Also, occasionally people would just come up to us and say, I don't understand why is this in this category, it should be here! And then we would have an absurdly overanalytical conversation about our thinking. For good or bad there was actually a lot of conversation and real analysis about where to place things.

[...] How Things Begin (The Approval Matrix, part 4) [...]

## **High School Graduation Confidential: Lack of Stories Speaks Volumes (2008-05-30 11:45)**

In the 1920s a young woman moved to an isolated North Carolina town in part to oversee construction of a church. When she suggested that it be built out of stones from a nearby river, the locals laughed. It wasn't possible to build buildings out of stone, they said. Their ancestors had done so (in Europe); they had forgotten. Jane Jacobs tells this story in *Cities and the Wealth of Nations*.

Unsophisticated villagers, huh? Yesterday I went to a high school graduation. A private high school in Los Angeles. There were six speakers: two adults, the school's headmaster and a history teacher, and four students. Here's what was so strange: No one told any stories. (One of the students told the beginning of a story.) The headmaster speaks at every graduation. The history teacher has given hundreds of lectures. Neither of them, apparently, knew to tell a few stories in that situation. No wonder the students didn't know. Long ago, before cheap books, I'm sure everyone knew this basic point about public speaking. Now it's as if no one knows it. What a vast forgetting!

I was surprised, but maybe I shouldn't have been. [1]Made to Stick sort of says the same thing. One of the authors, a Stanford professor, asked his students to rate a bunch of short talks. Their ratings had no correlation with how memorable the talks were. In other words, the students had no idea what made a talk memorable. They thought a good talk meant you told a joke. What actually made talks memorable were stories, the research showed.

Even Edward Tufte, a presentation expert, seems to not understand this. In his [2]complaints about PowerPoint, he doesn't tell any stories, doesn't say anything about PowerPoint's lack of encouragement of stories, and doesn't say that students should be taught to tell stories (preferably by example).

I'm giving a talk next week. It's going to be one story after another, which is not what I would have said before that graduation.

2. <http://www.wired.com/wired/archive/11.09/ppt2.html>

---

Tim Lundeen (2008-05-30 16:17:45)

Made to Stick is a great book, yes. Thanks for the reminder!

Tom (2008-05-30 17:53:56)

The school wasn't Buckley, was it?

seth (2008-05-31 03:13:46)

It wasn't Buckley.

Jake (2008-05-31 16:44:24)

Not everyone has forgotten: Joel Spolsky of Joel on Software addresses exactly this point in his [1]Introduction to the Best Software Writing. It's not in the context of graduations, obviously, but in it he makes a similar point. Incidentally, I bought the book and keep meaning to write about it on [2]The Story's Story, as the essays are a) interesting, b) tell stories and c) offer a rich load of metaphors for other fields of endeavor. And if he manages to produce another volume, I'll be sure to read that too – not because I'm particularly interested in software, but because the pieces are so compelling. And why are they compelling? Most tell stories, as you say.

Why public speakers are usually so bad? « BC in OC (2008-06-01 13:43:26)

[...] Why public speakers are usually so bad? Posted on June 1, 2008 by bryan They don't know how how to tell stories. [...]

Varangy (2008-06-02 13:34:50)

I have come to the conclusion that we are evolutionarily hard-wired for understanding the world through stories. I think NNT wrote about this in The Black Swan as well.

Nansen (2008-06-03 14:46:43)

Steve Jobs gave a highly non-traditional commencement speech at Stanford—the entire speech consists of just three stories ([1]YouTube , [2]text ) . Edward Tufte's background is in statistics, which is not usually associated with effective storytelling. You might be interested in John Allen Paulos's thoughts on this in Chapter 1, "Between Stories and Statistics" of his book Once Upon a Number (1998). @ Varangy: But in The Black Swan, Taleb says we may have to [3]denarrate in order to rise above the "animal form of life".

1. <http://www.youtube.com/watch?v=UF8uR6Z6KLc>

2. <http://news-service.stanford.edu/news/2005/june15/jobs-061505.html>

3. <http://www.humblemoney.com/?p=251>

Brice (2008-06-03 23:15:01)

Regarding PowerPoint, Cliff Atkinson has written a book about using PowerPoint. [http://www.amazon.com/Beyond-Bullet-Points-PowerPoint®-Presentations/dp/0735\\_623872/ref=pd\\_bbs\\_sr\\_1?ie=UTF8&s=books&qid=1212559939&sr=8-1](http://www.amazon.com/Beyond-Bullet-Points-PowerPoint-Presentations/dp/0735_623872/ref=pd_bbs_sr_1?ie=UTF8&s=books&qid=1212559939&sr=8-1) "He guides you, step by step, as you discover how to combine the tenets of classic storytelling with the power of projected media to create a rich, engaging experience."

Varangy (2008-06-04 09:21:51)

@Nansen Exactly. The point that Taleb is making is that we are hard-wired for storytelling or rather, interpreting the world through stories. And to employ as unbiased reason in order to make truly rational decisions, one has to separate our innate desire for the narrative explanation i.e. don't get fooled by randomness.

Seth's blog » Blog Archive » The Story of Hyundai: A Lesson in Public Speaking (2009-06-26 07:24:21)

[...] Krafcik repeated an old Jay Leno joke: "How do you double the value of a Hyundai? Half-fill the gas tank." So he had a great story to tell, the return from ignominy, but curiously he barely told it. Probably this was because he was working at Ford at the time. I have no great interest in cars, I'm not particularly interested in why one company does better than another, yet I was entranced. I came away thinking that most of what I'd heard about public speaking was wrong — most of the stuff in *Made to Stick*, for example. Sure, the advice to tell a story — and most speakers don't even understand that — is right. Krafcik did tell a story. But that's the easy part. I think everyone understands what a story is. The harder part is convey emotion. Carl Willat has said to me that in movies, that's all that matters. Absolutely, and I think what's he saying applies to talks as well. Of course an academic talk must have content. But the practical lesson for me is that when planning a talk I should pick something I care a lot about and in the talk do my best to convey how I feel. That's all. Don't worry about telling a joke, don't worry about slick visuals, don't try to impress them. I plan to show Krafcik's talk to graduate students (in psychology) because it makes a point I doubt they've heard: It's fine if it's other people's work that you feel strongly about. Krafcik isn't the head of Hyundai. He had nothing to do with their long comeback. But he's proud of his company — and he conveyed that in spades, and that was enough. Suppose you do research on X. You're giving a talk about it — perhaps a job talk. Maybe your research is mediocre. But you think research on X is incredibly important. Fine — just make that clear. Everyone in the audience will like you for being able to appreciate the work of others, that's so rare. When you point them to other work that is great, you're helping them. Suppose you're teaching a class. Find the parts of the subject that you feel strongly about. Do your best to convey how strongly you feel. Better positive than negative but negative works. (Ask Nassim Taleb.) Avoid the parts you don't feel strongly about. [...]

## How Things Begin (The Approval Matrix, part 5) (2008-05-31 23:31)

NUSSBAUM For good or bad there was actually a lot of conversation and real analysis about where to place things. In the very beginning one thing I did try was to make it a policy, if we could avoid it, to not snark on things that we hadn't actually experienced or really knew nothing about, just make jokes at the expense of the names of books that we hadn't read. I wanted to make the jokes about things that were very specific. Instead of saying we don't like the movie *Godzilla*, saying "the ridiculous scene in . . ." — a specific scene, a specific performance, or a specific song in a musical, or something like that. Because to me it makes it more useful and more authoritative, and less just striking out at the general world of culture and saying good, bad, good, bad, good, bad, which is always a danger with something like that. Because we were under a time crunch.

ROBERTS Yeah, a little less *Entertainment Weekly* with its A+, B+. . . . I happen to like that.

NUSSBAUM I don't actually have a problem with that. What *Entertainment Weekly* does with that is very basic, and a lot of places do that, is using a school metaphor thing to judge things. They've read the book. They're actually writing a review of it. The Matrix isn't writing reviews. but because it's putting things on this chart, I do think we have to have some sense of responsibility about not just throwing something on just because that doesn't sound good.

ROBERTS You're real critics. You actually know about what you're talking about.

NUSSBAUM The whole thing works better if we know what we're talking about, if it actually seems like...it operates

as though it has its own consciousness and it's this weird hive mind of a lot of different opinionated people who've experienced a lot of different culture.

ROBERTS If a book is on The Approval Matrix, someone at New York has read the book.

NUSSBAUM Ideally, yes. I'm talking to you because I began the thing. But I've switched jobs now, I'm not the head of Culture now. Sternbergh isn't editing it, either, it's been passed on. But even if it was a very silly book, you should at least take a look through it. That was essentially the premise. Some things are about news items. Those don't have the same necessity in terms of . . . I feel like I'm being so crazily over-analytical! Of course it is a charticle.

ROBERTS A charticle? There've been many charticles in the history of journalism.

NUSSBAUM Of course it is a visual device. It's supposed to be entertaining.

ROBERTS I think it's wonderful. Not because it's entertaining, although it is, but because it's enlightening. It's opening up a world. It does it so well. Let's take Entertainment Weekly. If they give something an A, I'm going to look into it. If they give a book an A I'm going to check out that book. But they take two pages to give one book an A. The Approval Matrix can give something an A or A+ five times in one page.

NUSSBAUM This is the transcendent beauty of the reductive. We can chart something in this pseudo-scientific way. It does have some kind of ...

ROBERTS Pseudo-scientific? I don't know about that. I think it's scientific.

NUSSBAUM Just in the sense that it's so absurdly hyper-specific that it's unreal.

## 3.6 June

### BB = Before Blogs (2008-06-01 05:24)

BC, AD, and BB. Before blogs, exactly how often could you read something like [1]this – Philip Weiss (a Jewish journalist) criticizing pro-Israel bias among powerful (Jewish) journalists? Exactly never. Illustrating [2]Tyler Cowen's point that blogging allows him to say what he really thinks.

[3]The Greatness of MondoWeiss.

1. <http://www.philipweiss.org/mondoweiss/2008/05/this-piece-in-the-forward.html>

2. <http://www.blog.sethroberts.net/2008/03/24/tyler-cowen-on-blogging/>

3. <http://www.blog.sethroberts.net/2008/05/08/the-greatness-of-mondoweiss/>

Andrew Gelman (2008-06-02 14:12:22)

You gotta be kidding. Before blogs, Jewish journalists never criticized each other on the topic of Israel???? C'mon.

seth (2008-06-02 17:59:30)

What's an example, Andrew?

Andrew Gelman (2008-06-03 04:05:25)

Just so many it's hard to know where to begin . . . Jews are notorious for disagreeing with each other and journalists are no exception . . . look at some back issues of the Village Voice, or to go further back, all the writings of the so-called New York Intellectuals . . . Norman Podhoretz . . . Hannah Arendt . . . I'm sure you can find lots of lesser names too. Journalists criticize other journalists all the time.

seth (2008-06-03 04:45:42)

What Philip Weiss wrote was not merely an example of "[Jewish] journalists criticizing other [Jewish] journalists". It was very specific criticism: criticism of pro-Israel bias. It is this specific criticism that I claim is very rare or non-existent. If I'm wrong I'm happy to learn that – but you haven't provided an example. It is too vague to say "back issues of the Village Voice" or "Norman Podhoretz" or "Hannah Arendt" (who wasn't a journalist).

Andrew Gelman (2008-06-04 15:28:04)

Hey, you're the one who made the "exactly never" claim. I think if you go to back issues of the Village Voice you'd find about 3 zillion examples of Jewish journalists criticizing other Jewish journalists of pro-Israel bias. Since neither of us is being paid to do this, I doubt either of our assertions will ever be checked, but that's my impression.

seth (2008-06-04 18:19:08)

"3 zillion examples" exist and you can't give one?

## **How Things Begin (The Approval Matrix, part 6) (2008-06-02 07:41)**

NUSSBAUM We do want it [The Approval Matrix] to be useful. Somebody told me that they were sitting on a subway and they saw somebody circling things on it. That was really cool, I suppose it was things they wanted to see.

ROBERTS Exactly!

NUSSBAUM I thought that was really great. There are the two reactions that I like the most: people finding it really useful and also people arguing with it. It was always interesting to trigger an argument where people just have a conversation about how good or bad something was in relation to something else. We actually made a little bit of a specialty in the Culture section in general of doing quasi-mathematical charts. We did a crazy guilt/pleasure index for reality television as a way of covering reality television. The other big one was when Sternbergh and I collaborated on this thing called The Undulating Curve of Shifting Expectations. I don't know that you've seen that. That's the flowing time chart that shows how things move from buzz to saturation point, how good people think things are going to be, to backlash to backlash to the backlash. We've done a few mathematical things. But they're kind of tricky. We tried to come up with others but sometimes they just didn't work. Or were too complicated. It's hard to come up with anything original just because magazines, this is their stock in trade. The thing I do really love about The Matrix and I did feel really proud about, was the fact that... I felt like it managed to combine a bunch of things in a good way.

ROBERTS Like what? What did it combine?

NUSSBAUM It's fun to respond to, so it's an entertaining thing. It allows us to have a final say on the culture for the week. In a magazine sense, it closes the section nicely. And it's kind of a destination place, people open the magazine and go to it.

ROBERTS That's very true.

NUSSBAUM Give a quick shot of wit and humor.

ROBERTS It's easy, pretty easy.

NUSSBAUM On the one hand it's easy and reductive. On the other hand, I'm telling you, I guess people who are just not mathematically-minded at looking at charts: I don't get it. I don't get it.

NUSSBAUM They don't understand how charts work. I had somebody say: I don't like it, it makes me feel dumb, it makes me angry. I mean, I think it's clever but it's not THAT smart.

ROBERTS They didn't understand what the placement of the points meant? Is that what you're saying?

NUSSBAUM Exactly. This wasn't an uncommon reaction. There was a moment when it first came out where people felt like they had to work to understand it. I don't think that was a bad thing. There was also a question of the tone of it. We had a meeting early on, when we first put out the section, where there was a discussion about whether it was too kind of snarky, bloggy, online, maybe juvenile in its sensibility, whether that was in some way problematic, or didn't match what the rest of the section was supposed to be. I never agreed with that. But it's always a discussion because when you have something that's funny and punchy in that way, there's the question of: Is it going to be sour and kind of rim-shot-ish, like it'll just be a roast? To me it doesn't feel like that at all. And obviously we celebrate things. A whole half of it is about things we think are brilliant! So those were the main points of debate. One of them was tonal, one of them was the idea of acting as if there really was a distinction between highbrow and lowbrow. And then, that's it.

Seth's blog » Blog Archive » Emily Nussbaum Interview Directory (2008-06-04 07:31:49)

[...] How Things Begin (The Approval Matrix, part 6) [...]

## **How Things Begin (The Approval Matrix, part 7) (2008-06-03 04:06)**

NUSSBAUM The other thing is it [The Approval Matrix]Â got picked up all over the place. Which was exciting for me. We would start noticing people started refering to things as highbrow/despicable.

ROBERTS By "picked up" you mean by other magazines? People on the street?

NUSSBAUM A lot of people did imitations of it. Some of them mentioning it, other ones ripping it off. I've seen 10 or 12 other magazines doing things that were like The Politics Matrix or whatever. A bunch of European magazines did things. At one point Stuff magazine did something and we put their matrix on our matrix. I wasn't involved in the placement at that point. We put their matrix on our matrix, and then they put our matrix on their matrix. It was this strange little down-the-rabbit-hole issue. I would occasionally read different articles or online things where people would start refering to something as lowbrow/brilliant. And at one point we talked about making stickers to put around town so that people could tag things as lowbrow/brilliant or highbrow/despicable like that. It never happened. There was a New York magazine event where they made t-shirts. I think the t-shirts are going to be a problem because I don't think people are going to get a t-shirt that says highbrow/brilliant.Â Everybody will want a t-shirt that says lowbrow/brilliant or maybe lowbrow/despicable. It was an interesting question: What labels are people willing to put on themselves? Which t-shirts would be more popular than others?

Later they created a online interactive Matrix on the website, but I don't think it was that successful even though it

was incredibly beautifully done. To me that was because people don't want to place things on the matrix, they want to argue about the matrix.

ROBERTS I did it once and everything landed in the middle. It was no fun.

NUSSBAUM It was an interesting idea in theory because it was a Wiki-matrix. But to me it missed the point of what people liked about it. First, people like the authority of it being set and then responding to it. They don't necessarily want to create their own. The other thing was that the jokes out of context of their actual placement are not that interesting. If you just see a factoid about a particular fashion show that week – it's not that meaningful unless you see where it's placed on The Matrix. To me, it wasn't supersuccessful. Did you find it that, technologically, it was lovely? I wasn't surprised that it didn't take off.

ROBERTS I did it once and the average answers were so boring I stopped. I don't care what I think, I'm more interested in what other people think.

NUSSBAUM Exactly. I think that that's the case. I launched it, and oversaw the editing for – I don't even remember how long, I was working so hard at the time, the whole thing is such a blur to me. After a couple of months, like I said, we hired Sternbergh and he came on and he was the overseeing editor of it for quite a long time. If you want to talk to him, he's another good person to talk to.

ROBERTS Well, I'm just writing a blog entry about this, not a book. This is wonderful. This is so interesting to me, you can't understand how interesting this is to me.

NUSSBAUM So why are you interested in it? How did this become a thing for you? I'm just so excited when someone likes it. It's nice. What interests you about it?

ROBERTS Partly it's that I worked at Spy . . . No, the first thing that happened was that I read Spy. I loved Spy. The interesting thing is not that I was so into dissing powerful people, it was that Spy made me interested in New York City in a way that I'd never been before. Spy did all sorts of things that made New York come to life and made it seem like a wonderful place. This was the city that has The New Yorker, remember? Spy did better, way better. Then I worked at Spy and I talked to the editors, I know they were very interested in coming up with new ways of telling things. I could see that it was very successful at this. And then Spy goes away, and a long time later The Approval Matrix comes up which has the same quality as Spy of making me interested in stuff. In a big way. It really succeeds in ways that other magazines don't do so well.

NUSSBAUM I was very into Spy as well.

[1]Interview directory. [2]Behind The Approval Matrix.

Seth's blog » Blog Archive » Emily Nussbaum Interview Directory (2008-06-04 19:01:30)

[...] How Things Begin (The Approval Matrix, part 7) [...]

## How Things Begin (The Approval Matrix, part 8) (2008-06-04 07:30)

ROBERTS Were there really some people that didn't think that opera is highbrow and comics are lowbrow? Was that a hard thing?

NUSSBAUM The complicated thing is: why is opera considered highbrow and why is comics considered lowbrow?

ROBERTS That's a different question.

NUSSBAUM We were trying to articulate this. Part of it is a mass versus elite thing. Part of it is a notion of the complexity of ambition of the thing. But that doesn't really work.

ROBERTS That's not quite fair.

NUSSBAUM You can have an opera that's incredibly dumb and not very well thought through. And you can have a comic book that is the most ambitious thing ever in terms of its narrative or in terms of its artistry. The tricky thing is: what pulls something up or down? Also, I just couldn't over the fact that people didn't understand that lowbrow is not a bad thing. It's not a bad thing for something to be mass and enjoyable. That's why there are two different things. The visual is meant to literally suggest that highbrow and lowbrow are not same thing as brilliant and despicable.

ROBERTS I liked The Approval Matrix for that. I took it for granted.

NUSSBAUM I'm kinda chatterboxy today for lack of sleep.

ROBERTS That's fine. You've helped a lot. The wonderful thing about The Approval Matrix is that in a small space it makes me aware of many new things I would like to find out about. It improves my world. It opens me up to lots of stuff. It opens me up to lots of art. It helps me find lots of great art.

NUSSBAUM That's great!

ROBERTS Other magazines don't do that as well. I think every magazine does that a little bit.

NUSSBAUM Not only is that very exciting to hear, it was one of the things when I was redesigning the section that was really difficult. When you read a section on culture it is generally divided into genres. So if you're interested in visual arts, that's what you end up reading about. If you're interested in visual arts, you flip to the visual arts section. You're likely to perhaps never read the book section or the TV section or something you're not interested in. The thing about The Matrix is, because it's a destination that sort of forces everyone to go to this place where it's like a big bus station where everyone interested in everything is forced to hang out, I hope it has that service quality you're talking about. Which is it opens your eyes to things you'd normally not have heard of, you're forced to mingle with all art forms, to be very high-faluting about it.

ROBERTS That's a good way to put it.

NUSSBAUM Are there other questions?

ROBERTS There's aren't any other pressing questions, no. You've done a wonderful job answering my questions. Thanks a lot, Emily.

## **Murakami, Baseball, and Inspiration (2008-06-05 18:31)**

About ten years ago Haruki Murakami, the author, gave a talk at UC Berkeley. in which he said he had decided to try to become a writer during a baseball game – specifically, when someone hit a single to left field. I told this story as often as possible. My listeners were always puzzled. It made no sense. Was he kidding?

Now Murakami has told the story [1]in print. Turns out it was a double, not a single. And I missed another crucial detail. Murakami was a "fairly devoted Yakult Swallows fan." It was the Swallows lead-off batter who hit the double. Now the story makes sense. Something wonderful had just happened on the field. Surprising, too. Wonderful unpredictable things happen, Murakami realized. They could happen to him. "Something flew down from the sky at that instant," he wrote, "and, whatever it was, I accepted it."

### **FDA Acknowledges Risk of Teeth Fillings With Mercury (2008-06-06 07:22)**

The Food and Drug Administration has [1]settled a lawsuit related toÂ mercury in dental fillings. As part of the settlement, it will acknowledge that these fillings may harmÂ some people. This is from an email by someone behind the lawsuit:

To change FDA policy, we tried petitions, Congressional hearings, state fact sheet laws, Scientific Advisory Committee hearings, and letters galore – to no avail. So in the great American tradition, we sued. The case came to a head this spring. On April 22, working with Johann Wehrle and Gwen Smith, I filed a motion for an injunction before Judge Ellen Huvelle. Three sets of briefs later, the government and I presented our oral arguments on May 16. In a crucial ruling, Judge Huvelle ruled that our 11 plaintiffs – the diverse group listed below – have standing. She said FDA should classify, and invited the two sides to mediate. On May 30, before Magistrate Judge John Facciola, Bob Reeves (who flew in from Lexington KY) and I hammered

out an agreement with FDA's officials and lawyers.

The impact of the re-writing of its position on amalgam can hardly be understated. [A curious mistake: the writer means overstated.] FDA's website will no longer be cited by the American Dental Association in public hearings. FDA shows awareness of the key issues involved. As it prepares to classify amalgam, FDA has moved to a position of neutrality. Indeed, having repeatedly raised the question of amalgams risk to children, young women, and the immuno-sensitive persons in its website, I find it inconceivable that FDA will not in some way protect them in its upcoming rule.

Mercury fillings were once very common and are still common. Unfortunately that it took a lawsuit to get the FDA to change. Judges have little or no relevant experience understanding scientific papers. Scientific advisory panels have much more relevant experience. However, they suffer from [2] a "purity" bias – they are evidence snobs.

### **While They Slept (2008-06-06 23:10)**

From a [1] review of Kathryn Harrison's new book *While They Slept*, about a boy who murders his parents:

When Billy Gilley is 13, stealing cigarettes leads him to the Children's Services Division, where the boy trustingly told a social worker about his family: the drinking, fighting, extreme verbal abuse in a family where customarily, after sentencing by his mother, his father would tie him to a tractor tire in order to immobilize him for beating with a rubber hose. He described for the social worker how his parents were, in Billy's terms, "crazy and unfit."

The child told his story, and the social worker's response was to repeat it to those abusive parents. Furious, they demanded to speak with him in private, so that he recanted and said he had been lying. The parents threatened to sue the agency, which fired the social worker and destroyed the record of her conversation with Billy, leaving only the annotation that the child was a liar. . . . Having acquired literacy skills in prison, he writes and illustrates children's books. In these books, large-eyed animals play an important role: children are in trouble or distress, and human adults cannot understand or help. The animals understand the children, and bring them to safety.

This reminds me of two things. Many years ago, such as in the 1920s, cancer was a terrible thing and a total mystery. People didn't like to talk about it. Likewise the social worker's actions are a terrible thing and a total mystery. What should be done about such behavior? Nobody wants to talk about it. The other thing this reminds me of is the Ten Commandments. Here is something else no one talks about: There is no commandment against child abuse. No stealing: yes. No murder: yes. No adultery: yes. No child abuse: no. Stealing is worse than child abuse? Huh?

Well, at least the review is titled "Speaking the Unspeakable."

1. <http://www.nytimes.com/2008/06/08/books/review/Pinsky-t.html?ref=books>

---

LemmusLemmus (2008-06-07 07:32:53)

"No child abuse: no." What's more, there's even a commandment on honouring your parents. Unconditionally, that is. That was a popular favourite in religious education: "Why should I honour my parents if they hit me?" "What if my dad's a murderer?" I've never heard a decent answer.

Mike Kenny (2008-06-07 11:23:27)

Sad story. In defense of the social worker, maybe he or she had heard made-up stories by kids a lot in his or her line of work. When I was in pre-k (so very young) I told my mom that my teacher hand-cuffed me to a chair. I'm pretty sure I believed this to be true at the time, though it seems highly doubtful now! My mom asked the teacher about it, probably to get a sense of what really happened.

seth (2008-06-07 12:37:48)

I asked someone who works in the child protective system about this. She said the whole system is broken, in many ways. Caseworker overload, caseworker burnout, corruption, etc. She thought *The Wire* was accurate. I said, "Why do we bother to have a system that fails so completely? To make politicians look good?" She said, "Yes, there is that. Politicians are in office for 2 or 4 years. They won't fund something that would produce results when they're out of office."

Janet R (2008-06-12 11:02:04)

1. The commandment is against kidnapping, not stealing. It's a mistranslation. 2. The ten commandments are not more important than the other commandments. A better translation is "the 10 utterances" — the ones "spoken" by G-d at Sinai.

### **Jane Brody Misses Many Opportunities (2008-06-08 08:37)**

Jane Brody has written about health for the New York Times for a long time. Recently, a blood test indicated that [1]her total cholesterol was 222 and her LDL was 134, which she believed was too high.

Missed Opportunity #1: She had no idea of the error in these numbers. It would have been better to get a second measurement to get some idea of the error. What if the second measurement of total cholesterol was 180?

She made various non-drug changes. She stopped eating cheese and lost a few pounds. She believed this would lower her cholesterol. It didn't. A new test found total cholesterol was 236 and LDL was 159.

Missed Opportunity #2: She still had no idea of the error in these numbers.

Missed Opportunity #3: If the change from 134 to 159 was not random error, it was possible that cheese was lowering her cholesterol – the opposite of what she believed. She failed to consider this possibility – at least, she doesn't mention it.

She made more extreme changes:

Now it was time to further limit red meat (though I never ate it often and always lean), stick to low-fat ice cream, eat even more fish, increase my fiber intake and add fish oils to my growing list of supplements.

Her cholesterol numbers got even worse – total cholesterol was 248 and LDL 171.

Missed Opportunity #4: She still had no idea of the error in these numbers.

Missed Opportunity #5: She again failed to consider the possibility that what she was told was wrong – that things she did to lower her cholesterol actually raised it.

Her doctor tells her: "Your body is spewing out cholesterol and nothing you do to your diet is likely to stop it."

Missed Opportunity #6: She failed to consider what this says about her doctor. If her doctor believes this, why didn't he or she say so earlier?

Missed Opportunity #7: She failed to ask her doctor the basis for such an extraordinarily broad claim ("nothing you do").

Missed Opportunity #8: She failed to realize her own data called this statement into question. Her own data suggests that diet made a difference (if the random error is small enough). She changed her diet, her cholesterol changed.

My own self-experimentation started with the discovery that some of what my dermatologist told me was wrong. A certain antibiotic was supposed to reduce my acne; if anything it increased my acne.

The classic case of a self-experimenter failing to learn something he could have learned is Barry Marshall, the Australian doctor who won a Nobel Prize for showing that bacteria cause ulcers. He drank a flask full of the bacteria – this was the self-experiment. Results: 1. He didn't get an ulcer. 2. He became infected and the infection went away after treatment with a drug later found to have no effect against the bacteria. Warren might have concluded that some people can successfully fight off infection from the bacteria and that the people who get ulcers are not those who are exposed to the bacteria (which is probably almost everyone) but those who can't fight it off. Warren's self-experimental results, like Brody's, supported a conclusion quite different from the conclusion he started with, and he failed to notice – or at least mention – this.

Aaron Blaisdell (2008-06-09 10:32:00)

Hi Seth, This anecdote reminds me of something Ralph Miller said in one of our lab meetings. "Data never overthrew a theory, only another theory overthrows a theory." So long as the medical community and its customers (i.e., us) continue to spout the AMA party line, there not only will be a refusal to accept the new theories like that discussed in Taubes' GCBC (I say this with a laugh since the new theories are really the old ones!), but a blindness to one's own self-based data. Aaron

Tom (2008-06-11 11:19:01)

I think it's because most people, like Brody, are incapable of understanding data. We (I have to include myself) only understand *stories*. Mere data simply cannot gain purchase in 99 % of human minds. It's why Seth's paper is such astounding reading.

Varangy (2008-06-12 12:25:48)

@Seth I read a different story about Marshall – do you have an online source that takes the POV you describe? I would love to check it out.

seth (2008-08-08 10:45:24)

Varangy, the POV I described I figured out for myself. I have never read it anywhere else.

### **Evidence Snobs (2008-06-08 17:30)**

At a reunion of Reed College graduates who majored in psychology, I gave a talk about self-experimentation. One question was what I thought of [1]Evidence-Based Medicine. I said the idea you could improve on anecdotes had merit, but that proponents of Evidence-Based Medicine have been [2]evidence snobs (which derives from Alex Tabarrok's [3]credit snobs). I meant they've dismissed useful evidence because it didn't reach some level of purity. Because health is important, I said, ignoring useful information, such as when [4]coming up with nutritional recommendations, is really unfortunate.

Afterwards, four people mentioned "evidence snobs" to me. (Making it the most-mentioned thing I said.) They all liked it. Thanks, Alex.

### **Lutein (2008-06-08 18:44)**

Â

Ever heard of [1]lutein? If you have consider yourself well-informed.Â There is no Recommended Daily Allowance. But a study of monkeys fed a laboratory diet, presumably containing all necessary nutrients, found that they got macular degeneration eight years earlier than monkeys fed ordinary foods. The missing nutrient appears to be lutein, which is found in green leafy vegetables such as spinach. More info [2]here.

One more indication that our knowledge of nutrition is incomplete even at the simplest (single nutrient) level.

Thanks to Martha Neuringer, who was one of the first researchers to study the brain effects of omega-3s.

1. <http://en.wikipedia.org/wiki/Lutein>

2. <http://www.luteininfol.com/home>

---

Aaron Blaisdell (2008-06-09 12:09:58)

I checked the Wikipedia link to Lutein (which I had heard of) in your post. I was struck by the statement in the first paragraph describing the sources of lutein: green leafy vegetables, flowers, egg yolk, and animal fat. This struck me as so glaringly obvious when I connected this with a prior sentence in the same paragraph explaining that lutein binds to fatty acids. Well, then of course lutein should be found in animal fat-grazing animals (cows, sheep, goats, etc.) eat grass and leafy greens, they consume the lutein which after entering their system binds to fatty acids, which then get deposited in animal fat! This logical sequence was something I probably would never have made if I just read the paragraph without thinking about it. But my training in science, and more recently, my reading of Taubes' GCBC which discussed how animal fat is loaded with vitamins and minerals AND with a lot of mono-unsaturated fat (fatty acids) prepared my mind for this logical inference. I had salad and steak for dinner last night. I feel great this morning. I can't wait to get my next physical and see what my blood lipid profile looks like.

Aaron

### **Less Carbs -> Better Sleep? (2008-06-09 20:37)**

I haven't heard [1]this before:

My insomnia seems to have gone. This may be something to do with my bold adherence to [2]Nassim Nicholas Taleb's low carb diet. I have not drunk and barely eaten a single gram of carbs for the last two and a half weeks. I am ten pounds lighter and I sleep like a baby. . . . I am attaining a steady seven and a half hours of unconsciousness nightly. This hasn't happened in at least ten years, possibly more. I have also become optimistic, amiable and energetic.

Perhaps drinking less alcohol improved his sleep. This has nostalgic interest for me. A turning point in [3]my self-experimentation came when I analyzed my data and saw that I started sleeping less exactly when I lost weight (by eating less processed food).Â In a complicated way this helped me discover that eating breakfast caused me to wake up too early.

Thanks to Dave Lull.

1. <http://www.bryanappleyard.com/blog/2008/06/insomnia-lack-of.php>
2. <http://www.bryanappleyard.com/blog/2008/05/psychotropic-peach.php>
3. <http://repositories.cdlib.org/postprints/117/>

---

thehova (2008-06-10 20:32:56)

I do seem to wake up too early often. So it's tempting to try not to eat breakfast. But couldn't that be a bad trade off. Nutritionally, isn't breakfast crucial to focus and energy throughout the day? I found this article interesting: <http://nymag.com/restaurants/features/breakfast/47396/>

seth (2008-06-11 02:27:23)

Thanks for the link. When I stopped eating breakfast, I didn't notice any problems with energy throughout the day.

Varangy (2008-06-11 08:31:55)

I think the "You need breakfast for energy" meme is ultimately a canard. Also, ever since starting a hyperlipid diet, I too, have experienced better sleep.

thehova (2008-06-11 19:43:53)

I recently started eating breakfast regularly and I've noticed positive results (strikingly less hunger throughout the day and evening, plus an overall more positive mood). The nice thing about breakfast is that it's an easy meal to eat right. Because I eat alone for this meal, I can eat disgustingly healthy, organic food. Lunch and Dinner are different. I often eat out or invite people over for the two meals. Eating healthy food in a social setting is much more difficult. So I know that at least one meal I eat daily will be healthy.

MT (2008-06-16 15:20:36)

Hey Seth, the link you post in this post leads to an article by Brian Appleyard's mood being effected by breaking his low-carb diet – very interesting, but it doesn't seem related to the link title (Nassim Nicolas Taleb's Low-Carb Diet) or to the relationship between sleep and carbs. What's the connection? Also, the article's description of his sudden mood change when he took in carbs is interesting, but wondering if it is suggesting something – that low-carb diets are bad for mood for instance. I have heard that it takes a couple weeks to adjust to low-carb, during which time you can feel tired and even sick, but that afterward you end up with more energy, a better metabolism that reduces body fat etc. So could Appleyard have been experiencing a temporary adjustment? I would definitely be interested in more discussion on this one as I'm reading more about, and increasingly convinced by, low-carb diets including so-called paleo-diets. Again, it may be a matter of personal physiology though, whose success is exposed through self-experimentation. Cheers.

MT (2008-06-16 15:22:10)

D'oh!! Missed that first link :) Would still be interested in hearing more thoughts though!!

## **The Ketogenic Diet (2008-06-10 06:19)**

Speaking of [1]evidence snobs, this is from the TV movie [2]... First Do No Harm (1997) about a family's discovery of [3]the ketogenic diet (a high-fat low-carb diet) for their severely-epileptic son:

DOCTOR The diet is not an approved treatment.

MOTHER But there have been a lot of studies.

DOCTOR Those studies are anecdotal, not the kind of studies we base sound medical judgment on. Not double-blind studies.

Later:

DOCTOR I assume you know all the evidence in favor of the ketogenic diet is anecdotal. There's absolutely no scientific evidence this diet works.

The doctor prefers brain surgery. When the diet is tried, it works beautifully (as it often does in real life). "What could have gone so horribly wrong with this whole medical system?" the mother writes the father.

1. <http://www.blog.sethroberts.net/2008/06/08/evidence-snobs/>
2. [http://en.wikipedia.org/wiki/...First\\_Do\\_No\\_Harm](http://en.wikipedia.org/wiki/...First_Do_No_Harm)
3. [http://en.wikipedia.org/wiki/Ketogenic\\_diet](http://en.wikipedia.org/wiki/Ketogenic_diet)

---

Patri Friedman (2008-06-12 23:20:45)

But...but...there is tons of evidence for the ketogenic diet, including plenty of controlled studies. It's hard to blind the diet, but it's not like this hasn't been studied. When I started eating low-carb 6 or 7 years ago, and I looked into research on the safety of being in ketosis, most of what I found was studies of ketogenic diets to reduce epilepsy in children. So I'd say the problem here is that this doctor is ignorant, not that the whole system is wrong.

seth (2008-06-13 03:21:10)

Patri, thanks for your comment. I don't think the film was saying that the doctor was ignorant. The doctor knew about the studies, she just didn't like them. She didn't find them convincing. In the film, the doctor showed the mother a comprehensive book about the treatment of epilepsy, the "bible", and told her that the ketogenic diet wasn't in the book or according to the book wasn't an approved treatment. It wasn't just one doctor who thought the diet was not worth trying. It was also the authors of that book. If the film didn't present an accurate picture of how the ketogenic diet was viewed by the vast majority of doctors, please let me know.

[...] The Ketogenic Diet [...]

konja (2011-05-03 05:58:10)

I found your blog in google. I want to print this but i could not find any print button :(

### **"My Advantage Was Ignorance" (2008-06-11 02:42)**

While both of us were waiting for a bus at the Oakland Airport, Andrew Sutherland asked me where I was going. He was from New Zealand, on a two-week visit to America. I asked him what he did. "I'm working on retirement," he said. He's in his mid-forties.

When he was 18 years old, he bought his first house for \$1000. It was in terrible shape but he was good at making things so he was able to fix it up. Later he owned a bunch of houses in Denedin, where the University of Otago is located, and rented them to students.

"What advantage did you have over your competitors?" I asked.

"The main advantage I had was ignorance," he said. He didn't know all the things that could go wrong. "I wasn't afraid." Someone who knew more would have been. Geoffrey Bateson said something similar: If I'd known how hard everything was going to be, I would never have done anything. This is the upside of the ignorance that Nassim Taleb talks about.

---

Ben Hyde (2008-06-11 06:24:36)

Sometimes it bothers me that we give so much respect to the opportunistic fools that survive. The exuberance and confidence of creatures in r-selected contexts belies the hundred of their kind that tried and died. But then, if you hang for a while in a K-selected community it's stoggy residents come to drive you bonkers too. Not to hot, not to cold I guess. But is it a strategy?

### **Compound in Red Wine Has Effects Like Calorie Restriction (2008-06-12 03:07)**

Here's part of the abstract from [1] a recent paper titled "A Low Dose of Dietary Resveratrol Partially Mimics Caloric Restriction and Retards Aging Parameters in Mice":

We fed mice from middle age (14-months) to old age (30-months) either a control diet, a low dose of resveratrol . . . or a calorie restricted (CR) diet and examined genome-wide transcriptional profiles. We report a striking transcriptional overlap of [the effects of] CR and resveratrol in heart, skeletal muscle and brain. Both dietary interventions inhibit gene expression profiles associated with cardiac and skeletal muscle aging, and prevent age-related cardiac dysfunction. Dietary resveratrol also mimics the effects of CR in insulin mediated glucose uptake in muscle.

This is from the introduction:

Resveratrol, a natural compound found in grapes and red wine has previously been shown to extend lifespan in *S. cerevisiae*, *C. elegans* and *Drosophila* through a SIRT1 dependent mechanism. However, recent studies have failed to reproduce these life extension results and other studies have demonstrated that the ability of resveratrol to activate yeast Sir2 or human SIRT1 is substrate-specific in vitro and resveratrol has no effect on Sir2 activity in vivo . . . . Recently, mice fed a high fat diet supplemented with high levels of resveratrol . . . were shown to have extended lifespan as compared to controls, and several metabolic alterations similar to what is observed with CR.

I first heard of the wonders of resveratrol from James Johnston and Donald Laub, authors of The Alternate Day Diet. [2] Here is a review article about it. The interest of the new study is that a low (i.e., practical) dose is effective.

Thanks to Bob Levinson.

talisman (2008-06-15 20:05:15)

Do you take resveratrol? Is there a reliable provider? Etc.

seth (2008-06-15 20:16:08)  
No I don't.

### **Why Entertainment Weekly Rules the World (2008-06-12 16:15)**

Recently Tyler Cowen and I wrote the following dialogue about Entertainment Weekly, of which we are both big fans. We failed to get it published – perhaps because we broke an important freelancing rule: Never submit a finished piece, as [1] Jack Hitt told Berkeley journalism students. Our loss is your gain.

SETH When my friends look puzzled that I subscribe to EW I say "entertainment" means art. It's about art. They could have called it Art Weekly but they didn't want to scare people.

TYLER The age of the review has been replaced by the age of the cue. There's too much wonderful stuff out there to read pages of reviews. I want a letter grade and a few sentences on what it is and whether I might like it. If I love the product I can go read lengthier reviews on the web afterwards, when I understand the context and don't have to worry about spoilers. Most critics don't realize just how much they are dead in the water, and replaced by trusted intermediaries – like EW or favorite bloggers – who offer just a few guiding sentences. I often disagree with EW but I always know where they are coming from. I can usually gauge my own best guess, relative to the evaluation in their review.

SETH After a reading I overheard a famous author and his friend discuss the B that EW had given his book. "It helped settle debates around the house about who's the better writer," he said – his wife's book had gotten a B+. They agreed that assigning grades to books was shallow. Listening to them, Tyler, I thought what you say: Hey, the rest of us need the time. Sure, there's something superficial about treating complex artistic productions, such as books and movies and albums, like homework assignments – but why exactly is that bad? I call it the Chez Panisse model. The distinctive style and concerns of Chez Panisse came from mixing haute cuisine with French bistro food – bistro food treated as seriously as haute cuisine. Your blog, Marginal Revolution, is another example. Blogging is just a variation of diary entries, the lowest form of literature – but people such as you are lavishing great care on it and creating new effects. Likewise, EW lavishes great care on the assignment of lowly, shallow grades – the accompanying review, for example. The rest of the magazine also treats "low" culture with great respect. All that praise of Buffy the Vampire Slayer. All that space devoted to American Idol. What I want from magazines is to take me where I wouldn't have gone. To expand my world. Long ago, The New Yorker managed to often do that. Now, not so often. Now it is EW more than any other magazine that manages to get me to read or watch or listen to stuff I otherwise wouldn't have encountered. It's not just reviews; it's reviews of beach books ("which no poet would deign to touch" as one of Nabokov's characters put it).

TYLER I find the grades for books are the least reliable section of EW. Which for me means they are the most reliable section. If they like a book, I know to stay away. How could a critic be better or more trustworthy than that? Too many readers are too concerned about affiliating themselves with prestigious magazines, rather than learning something. EW takes us to new places because the magazine covers only what is new, or newly reissued. Other cultural contributions (dare I call them "products"?) simply don't exist for the magazine. That's what is truly startling about the pages, not what is there but what's not there. We need to take that seriously, as our culture already operates on that basis.

SETH I once wrote EW to say they should cover radio. I want to know what's as good as [2] This American Life. What do you think they should cover but don't?

TYLER I'd like to see more coverage of satellite radio in particular, plus Internet radio, both of which are na-

tional. Most of all, I'd like their take on new technologies for consuming culture.Â What's the best way to connect a computer and a television?Â Is there anyone you would trust to give a better answer about a simple and cheap method?

SETH I can rent a DVD for \$1/day at a local store. At my public library, they're free for a week. With so much "entertainment" so available, the value of filters goes up. Whether the founders of EW foresaw this or were lucky, I don't know. I do know that the grades ( e.g., B-) attached to every review are filters of filters. Smart. At EW they are clear on the concept. Entertainment in the EW sense might be America's biggest export in terms of dollars. It could easily be America's most influential export, since it enters the brain. So economists should pay more attention to EW, the only magazine that gives a sense of what all this stuff is about and might answer the question of why American entertainment has achieved such world dominance. Does sheer wealth mean a country can make more easily exportable movies and TV shows? Or is it the universality of English that is the secret? I don't think there is a magazine like EW in any other country. Nor earlier in history. While TV Guide seems to be fading away even as TV is booming, EW, with its much greater emphasis on reviews and broader coverage, is thriving. I think stories teach values – we imitate the hero, don't do what the bad guy does – and EW is the first magazine to devote itself to this market: What stories are we telling? The values of EW staffers, therefore, get huge leverage. Maybe the magazine is written by about 50 people. Each of them may have more power over what stories people are exposed to– keeping exports in mind – than the President of the U.S. Than anyone else in the entire world! Than the editor of The New Yorker. All 50 of them. Where is EW, with its vast power over our values, taking us – meaning the world? They are probably more pro-gay than the average person. They certainly like The L Word, for example, and think that Ugly Betty is a great show. They have never published a "courageous" (muck-raking) article, such as Silent Spring, but neither do they publish fawning profiles. I think the Must List demonstrates tolerance and acceptance of differences; relatively small and quirky projects make the list. They have embraced reality shows and cable TV, both of which thrive on quirkiness.

TYLER This is getting complicated. Let me try some familiar territory. Here's what I think of Entertainment Weekly:

TV coverage: A

Movie and DVD coverage: A-

Music coverage: B-

Radio coverage: D

Book coverage: A+

Advertisements: B

The Must List: A

Columnists: A-

Awesome! A+!

## **Harvard Psychiatrists Don't Disclose Millions of \$\$ From Drug Companies (2008-06-12 19:22)**

From [1]the latest BMJ:

Findings that a leading Harvard professor of psychiatry failed to report substantial payments that he received from drug companies has caused Harvard Medical School, one of its affiliated hospitals, and the US National Institutes of Health (NIH) to come under fire.

An investigation by the US senator Charles Grassley showed that the psychiatrist, Joseph Biederman, and two of his colleagues, Thomas Spencer and Timothy Wilens, had altogether received more than \$4.2m (£2.1m; €2.7m) from drug companies since 2000.

The financial disclosure forms filed by the three doctors, according to Mr Grassley, "were a mess" and made it seem that they had received only "a couple of hundred thousand dollars" in the past seven years. . Professor Biederman, at the centre of the scandal, has been widely recognised as one of the most influential psychiatrists in the world. He is a leading proponent of the diagnosis of paediatric bipolar disorder and he is currently conducting a study of the antipsychotic, quetiapine (Seroquel) in children aged 4 to 6 years with bipolar disorder.

Nansen (2008-06-13 14:14:04)

Absolutely sickening.

seth (2008-06-13 15:56:43)

I agree. Especially since these professors are promoting giving powerful dangerous poorly-tested drugs to young children.

Monet (2009-05-09 12:38:53)

I am absolutely astounded, not surprised, but it just makes me sick since I am a BP patient who weaned myself from drugs over 4 years ago! The fact that they are doing a "study" and promoting these drugs for children is extremely dangerous and UNETHICAL. As an adult who took them, I can tell you that they can KILL YOU. Once I weaned myself I did not have the suicidal thoughts that were prevalent while on them! I can also tell you that fish oil and flax oil have helped stabilize my moods!!! Monet

I'm glad to have written something so exciting. You can buy it [1]here.

Thanks to Pearl Alexander.

More: A Japanese government program that should help sales: [2]Mandatory waist measurements, with sanctions for being overweight.

## **"I Can Has Skinny Pants" (2008-06-14 12:46)**

I like [1]this set of posts about the Shangri-La Diet, especially this:

I had to borrow a black vest for the prom I worked last night. Twenty pounds ago, that vest would have NEVER fit this monkey.

I give credit to my kettleball, and the Shangri-La Diet. When I mentioned the vest situation to the crew during set-up the new guy chimed in, Oh yeah, I lost 40 pounds on Shangri-La. Got a few more to go. I don't even bring it up to people any more. I'm tired of being told I'm crazy and that it sounds like it wouldn't work.

Why do I laugh?

1. <http://spiritualmonkey.livejournal.com/tag/shangri-la-diet>

---

Darkhorse (2008-06-14 17:16:17)

Seth, yours will be the last laugh. I secretly laugh too when I see so many of the people who sneered at Shangri-La who are still overweight, still dieting, still hungry, while I have gone from 160 lbs. to 116 lbs. in one year and loved every minute of it. After I read a NYT article on his research and findings. It just dang ol' made sense...in a twisted way. You add flavorless calories to your diet twice a day. Don't have anything with flavor (not even brushing your teeth or chewing gum) for an hour on either side. And that's it. Also, two words: shot glass. That's exactly all I did, with some nose-clipping, and without trying to improve something that was already excellent. I also now have skinny pants. Who wouldn't laugh? It's so simple, it's hilarious.

seth (2008-06-14 23:00:14)

Thanks, Darkhorse. That's nice to hear. At a party today I learned that vaccination was once controversial. Which supports your point.

## **Why Do We Touch Our Mouths So Much? (2008-06-15 10:46)**

This photo documents something anyone can notice: While we're sitting, we touch our mouths a lot.

The photo shows the full faces of 22 men; 7 of them are touching their mouths. I have noticed something similar at many faculty meetings. I started to notice this after I read about its observation in a study designed to measure something else.

I've known about this for many years but have never read an explanation. Do we enjoy touching our mouths – or is the absence of touch for a long time unpleasant? If so, why?

---

Mike Kenny (2008-06-16 15:04:50)

Maybe to hide emotions? I notice sometimes people hide their smiles, or hide a yawn. Perhaps hiding our emotions in some cases helped us pass on our genes and so the behavior has been encouraged via evolutionary pressures.

Ryan Holiday (2008-06-17 10:55:18)

THAT is the odd thing you noticed about this photograph? Who is that woman and what could she possibly be doing in that room?

MarkH (2008-06-18 22:08:59)

Men in that photo? Oh, over on the right.

James (2008-06-19 04:04:49)

What about a means to sample the local microbial environment? A safer route to building immunity to bugs common in your environment by constant, low-dose intake (whether swallowed or inhaled)?

Dave (2008-06-19 08:50:54)

"Who is that woman and what could she possibly be doing in that room? " I count 6 guys who are eying her up. Maybe the reason they're all covering their mouths is because they're all saying ":cough: dude, check out the hottie :cough:"

## **The Ketogenic Diet and Evidence Snobs (2008-06-15 22:26)**

If we can believe a movie based on a true story, the doctors consulted by the family with an epileptic son in ...First Do No Harm knew about the ketogenic diet but (a) didn't tell the parents about it, (b) didn't take it seriously, and (c) thought that irreversible brain surgery should be done before trying the diet, which was of course much safer. Moreover, these doctors had an authoritative book to back up these remarkably harmful and unfortunate attitudes. The doctors in ...First, as far as I can tell, reflected (and still reflect) mainstream medical practice.

Certainly the doctors were evidence snobs – treating evidence not from a double-blind study as worthless. Why were they evidence snobs? I suppose the universal tendency toward snobbery (we love feeling superior) is one reason but that may be only part of the explanation.Â In the 1990s, Phillip Price, a researcher at Lawrence Berkeley Labs, and one of his colleagues were awarded a grant from the Environmental Protection Agency (EPA) to study home radon levels nationwide. They planned to look at the distribution of radon levels and make recommendations for better guidelines. After their proposal was approved, some higher-ups at EPA took a look at it and realized that the proposed research would almost surely imply that the current EPA radon guidelines could be improved. To prevent such criticism, the grant was canceled. Price wasÂ told by an EPA administrator that this was the reason for the cancellation.

This has nothing to do with evidence snobbery. But I'm afraid it may have a lot to do with how the doctors in ...First Do No Harm viewed the ketogenic diet. If the ketogenic diet worked, it called into question their past, present, and future practices – namely, (a) prescribing powerful drugs with terrible side effects and (b) performing damaging and irreversible brain surgery of uncertain benefit. If something as benign as the ketogenic diet worked some of the time, you'd want to try it before doing anything else. This hadn't happened: The diet hadn't been tried first, it had been ignored. Rather than allow evidence of the diet's value to be gathered, which would open them up to considerable criticism, the doctors did their best to keep the parents from trying it. Much like canceling the radon grant.

[1]The ketogenic diet.

1. <http://www.blog.sethroberts.net/2008/06/10/the-ketogenic-diet/>

---

Stephen M (Ethesis) (2008-06-17 11:05:07)

The entire history of how the ketogenic diet was discovered and then swept away is an amazing one, as is its return. BTW, just for amusement, <http://drdeborahserani.blogspot.com/2008/05/10-illusions-in-2-minutes.html>

Julia Schopick (2008-06-30 20:39:20)

Seth: As one who has long been wary of a medical establishment that only respects the results of studies – and, even sadder, the results of studies that they believe have been conducted in the “right way,” by the “right researchers,” at the “right institutions” (or by the “right pharmaceutical companies”), and written about in the “right journals” – I find your ideas wonderfully refreshing. (Of course, many of us know that a majority of these so-called “studies” that doctors trust so much are carried out by pharmaceutical companies with pre-ordained agendas, and that these studies therefore come to conclusions that will benefit the companies themselves. Scary.) Concerning “First Do No Harm”: Although it was made in the 1990s, the action of this wonderful movie takes place in the 1970s. And you are very right that, at that time, most doctors believed that drug therapy and surgery were the only “proven” treatments for childhood epilepsy. Many still do. But, their belief, even then, was misguided, and – I can only conclude – shaped by financial interests. For one thing, as the movie pointed out, the diet has been used very successfully for decades at Johns Hopkins, under the direction of John Freeman, MD, and registered dietician Millicent Kelly. But, even more puzzling, since 1925, there has been a huge amount of published literature extolling the efficacy of the diet. For instance, on April 4, 1925, one of the “rightest” of journals, the AMA’s own JAMA, published an article, “The Ketogenic Diet in Epilepsy,” in which M. G. Peterman, MD, reported on the results of a study at the Mayo Clinic, in which 37 children with “essential epilepsy,” between 2-1/4 and 14-1/2 years of age, were treated with the ketogenic diet. The results were stunning, with a majority of the children experiencing improvement. In fact, quoting from the article, nineteen, or just over 50 % “have been free from attacks since the institution of this treatment.” JAMA published the results of another study in 1927, the conclusion of which was that “twenty-nine of ninety-one patients suffering from idiopathic epilepsy have been freed from attacks by means of the ketogenic diet. Twenty others are definitely improved, so that 54 per cent have been definitely benefited by the dietary treatment.” Similar studies were published in every decade thereafter. And to my knowledge, the results reported in all these studies are much better than those achieved by any anti-epileptic drug. So, why did the doctors in “First Do No Harm” react the way they did? Frank Lefevre, MD and Naomi Aronson, PhD, in an article (“Ketogenic Diet for the Treatment of Refractory Epilepsy in Children: A Systematic Review of Efficacy”), published in 2000 in “Pediatrics,” the official journal of the American Academy of Pediatrics, offer a possible rationale: (See <http://pediatrics.aappublications.org/cgi/content/full/105/4/e46>) Quoting from their article: “This diet was used as a treatment for epilepsy fairly commonly in the 1920s and 1930s. In the late 1930s and 1940s, as effective antiepileptic drugs, such as phenytoin and phenobarbital, were introduced into clinical practice, the ketogenic diet was largely replaced by drug therapy.” I received my education about the ketogenic diet from Hollywood producer/director/writer, Jim Abrahams, the man who deserves a huge amount of credit for spreading the word about the diet. Jim is the man responsible for “First Do No Harm.” His own experience with the diet, which worked so well for his son Charlie (when nothing else, including surgery, would), has led him to labor tirelessly since the 1990s to promote the use of the diet. Through his Charlie Foundation, Jim has produced and disseminated informational videos, and regularly sponsors training seminars for professionals so they can become qualified to implement their own ketogenic diet programs. Thanks to Jim’s efforts, the ketogenic diet is now available in many hospitals in both the US and abroad. (Estimates range from 65 to 200 programs worldwide!) You may read Jim’s and Charlie’s inspiring story at <http://charliefoundation.org/>, where you’ll find lots of other resources, as well. In addition, I have written an article, “Four Lifesaving Medical Treatments: Not So ‘Anecdotal,’ After All.” My article features the ketogenic diet – as well as three other equally impressive “anecdotal” treatments. It is posted on my website, at <http://www.honestmedicine.com/2008/05/four-lifesaving.html> Thanks much for the work you are doing. Hopefully, together we can (finally!) get the word out there. Julia Schopick [www.HonestMedicine.com](http://www.HonestMedicine.com)

Damon (2008-08-05 10:57:01)

I can’t believe how silly this post is. “Evidence snobs?” So basically what you’re saying is: If you want evidence that something works, you’re a snob. Seriously? Double blind studies are important because they remove human bias. Yes, you can argue that if something works without a double blind there is “evidence” for it, yes, you can say that in this particular case there was some very bad personal interference. But To say this somehow makes double blind studies a snobbery is pretty irresponsible, and frankly, stupid. A good double blind study -will- tell you if a drug is “sometimes” effective. You should know that. What it will also tell you is how statistically relevant that outcome is. I find all of this boogey-manning of the “medical establishment” to be a little weak. It’s basically a thinly veiled conspiracy theory. Maybe you already know these things, Seth, but look at the people

commenting in your threads. Many are basically clueless about the scientific method and a lot of them are conspiracy theory types who's intellectual laziness should warn you that they are not the kinds of supporters you want. If you spend a minute thinking about it, you can either attribute their comments to zaniness, or perhaps conclude that your posts on occasion aren't diligent enough to clearly explain to these people what you are getting at. "Evidence Snobbery." Come on.

seth (2008-08-05 17:54:47)

An evidence snob is not someone who "want[s] evidence that something works." An evidence snob is someone who disregards evidence – evidence that doesn't reach a sufficient level of quality. As far as "bogey-manning" the medical establishment, the stuff in ...First Do No Harm actually happened. It's not speculation, as conspiracy theories are.

Tom in TX (2008-08-10 20:24:29)

The diet is worthless because it has not been proven by a double-blind placebo-controlled study. So why not do the study? That would be a waste of time, since the diet is worthless. 8-b The logic is irrefutable.

### **Crazy Spicing Works (At Least Once) (2008-06-16 21:44)**

The [1]theory behind the Shangri-La Diet says that the more variable the flavors of your food, the less fattening it will be. The problem with junk food is not just the quickly-digested calories (from bread and sugar), it is also the remarkably constant flavor. Coke tastes exactly the same each time.

A [2]new study has just come out that supports these ideas. Sprinkling essentially random flavors on food (which an SLD forum member called crazy spicing) caused a lot of weight loss:

Alan Hirsch, MD, founder and neurologic director of the Smell & Taste Treatment and Research Foundation in Chicago, studied "tastants," substances that can stimulate the sense of taste. He asked 2,436 overweight or obese individuals to sprinkle a variety of savory or sweet crystals on their food before eating their meals during the 6-month study period. Subjects put liberal applications of the salt-free savory flavors on salty foods and applied the sugar-free sweet crystals on sweet or neutral-tasting foods. They did not know what the flavors were other than salty or sweet. The hidden flavors of the savory tastants were cheddar cheese, onion, horseradish, ranch dressing, taco, or parmesan. Sweet flavors were cocoa, spearmint, banana, strawberry, raspberry, and malt.

A control group of 100 volunteers did not use tastants. Both groups were allowed to diet and exercise if they were already doing so. For both subjects and controls, Hirsch measured weight and body mass index (BMI) – a measure of height and weight – before and after the study.

At the start of the study, the treatment group had an average weight of 208 pounds and average BMI of 34, which is considered obese. After 6 months of using the crystals, the 1,436 subjects who completed the study lost an average of 30.5 pounds, compared with just 2 pounds for the untreated controls. Their BMI dropped by an average of 5, moving them from obesity to the overweight range. Controls had an average BMI decrease of 0.3.

Hirsch theorized that subjects lost more weight than controls did because the tastants made them feel full faster and therefore eat less. However, he did not track the amount of food the subjects ate. Another possibility, he said, is that the crystals improved the taste of bland but healthy foods, such as tofu and some vegetables, causing a change toward healthier eating habits. He said he believes this approach works because, unlike most diets, it is not based on food restriction.

Subjects lost an average of nearly 15 percent of their body weight, results showed. It is not clear whether the apparent weight loss benefits of the tastants would extend past 6 months or to people who weigh less than the obese subjects in this study.

"It could be that the percent of weight reduction would be lower in people who are less obese," Hirsch said. "In theory, tastants won't work for people who eat even when they're full and for people who have lost their sense of smell."

Hirsch said the tastants worked so well that they contributed to the dropout rate. Some of the subjects stopped the study before 6 months because they already had reached their ideal body weight—an unexpected result, he said.

Hirsch has done similar experiments, with similar results, in the past.

Thanks to Sheila Buff.

Phillip J. Eby (2008-06-17 11:24:12)

Awesome. You gonna point him to your alternative explanation? And don't forget... you can now put out an updated edition of your book, "NEW: Now with Crazy Spicing and Scientific Proof!" ;-)

Kevin C (2008-06-17 22:20:32)

Wow, Seth! This is really great. I think this has re-inspired me to try crazy spicing again to help me lose those last 10 pounds. I'm a little confused though about the study, were they given randomized flavors, or was each participant given a specific flavor?

seth (2008-06-18 09:06:28)

I think each participant was given all the flavors. Each person was given – if I'm right – two sets of about six flavors each – one set for sweet foods, one for non-sweet foods.

SusanJ (2008-06-18 10:43:24)

This is way too good to be true. I've NEVER seen a weight loss study where the participants have ever come close to an average loss of more than a pound a week for six months.

seth (2008-06-18 17:08:39)

Hmm. Isn't there a first time for everything?

VeganKitten (2008-06-18 21:32:10)

1,436 subjects lost an AVERAGE of 15 % of their body weight. That's colossal.

Kristin (2008-06-20 21:44:46)

Hi Seth - I read on your blog that you would love to experiment with the product. Give me a shout and I'll send some off to you! I would also be happy to send you a copy of the clinical study that was published in Prague. The one just presented at the Endocrinology Conference is awaiting publication.

### **SLD in Indonesian (2008-06-17 07:14)**

There is a long discussion of the Shangri-La Diet [1]here on an Indonesian forum. I like the locations some posters give: "the hottest city in Java," "space," "a quiet little house," "above the earth," "nowhere to be found."

Thanks to Mark Schrimsher of [2]CalorieLab. The 2005 [3]CalorieLab post on SLD – now an historical artifact. [4]Why Japanese People in Japan Don't Get that Fat.

Andrew Gelman (2008-06-17 18:58:44)

Isn't every record from the past a "historical artifact"?

Mark (2008-06-18 00:12:19)

Igor, if you send us your IP address ( <http://checkip.dyndns.org/> ) via e-mail to [inquiry@calorielab.com](mailto:inquiry@calorielab.com) we can look into your problem. We've blocked a few IP ranges due to abusive access by automated robots.

seth (2008-06-18 23:49:29)

Andrew, good point, I will tag this post as "self-congratulation".

### **Dinner in an Amsterdam Banlieue (2008-06-17 23:24)**

A friend in Amsterdam writes:Â

I went to my [Moroccan] friend's family's apartment in Slotervaart and we watched Turkish soap operas dubbed in Arabic.Â At one point, the characters showed a map of Europe and the Middle East, with

various arrows pointing back and forth. I asked her what they were, and she said they were maps of drug trafficking routes from Holland to Istanbul. Then my friend and her sister laid out a plate of sheep's stomach while I was in the bathroom and waited to see whether I would eat it. I explained that although it had smelled good before I knew what it was, the thought of eating it made me feel sick, but I felt obligated to eat a tiny bite of it anyway.

Slotervaart is not technically a banlieue (outskirt) of Amsterdam but it is functionally the same as the Paris banlieues. It is where Muslim immigrants live.

---

### **Bloggers Can Say the Truth (2008-06-18 09:42)**

As I blogged [1]earlier, Tyler Cowen said that on [2]his blog he can say what he really thinks, unlike other economists, who are often unable to say what they really think. Here is [3]another example of the same thing from a blogger who writes about stuttering:

At least four [researchers] have told me that they try not to provoke or openly criticize work by a big name [researcher], because they are scared of having a paper rejected or getting no funding. Actually, they like me because I say what they do not [dare] to say [for] political reasons ! So view my blog also as the voices of some in the research community!

This blogger isn't a researcher so his situation isn't the same as Tyler's. But my point is the same: Blogs allow uncomfortable truths to be said that otherwise would not be said.

In the past this was much harder. To say some uncomfortable truth about this or that field of expertise (such as stuttering research or economics), the truth-speaker had to be (a) close enough to the field to understand it (which usually omitted journalists, with a few exceptions, such as Gary Taubes and John Crewdson) and yet (b) outside the field, so as to not suffer professional damage. There was also the problem of publicizing the uncomfortable truth. These requirements were hard to meet. [4]Richard Feynman's O-ring demonstration was a rare example where they were. Feynman knew what he was talking about yet was outside the industry, so he could say what insiders could not. (His criticism came from insiders.) [5]Saul Sternberg's and my criticism of Ranjit Chandra is another example. We knew enough about the sort of data Chandra had collected to criticize the work but were outside nutrition so we could say what we wanted to without risking professional harm.

[6]A Philip Weiss example.

## Why Do We Touch Our Mouths So Much? (continued) (2008-06-19 09:46)

I asked this question in a [1]recent post. If you look at people sitting in an audience, about one-third of them will be touching their mouth.

I had wondered about this for years. Somehow blogging about it helped. A few days ago I was on the subway. Of the persons sitting, the usual fraction were touching their mouth. Nobody standing was touching their mouth with their hands but now and then I noticed them purse or lick their lips.

Which suggested an answer to my question: We get a small amount of pleasure from touching our mouths. The pleasure declines after it is "harvested" and takes several minutes to become available again. This mechanism evolved because it kept our lips moist. At the time it evolved, people spent little time sitting. The pleasure was obtained by pursing or licking your lips, which moistened them. Predictions: 1. if you watch people whose hands are busy, they will purse or lick their lips roughly as often as people in an audience touch their mouths. 2. The more you lick or purse your lips, the less you will touch them with your hands. 3. The more you touch your lips with your hands, the less you will purse or lick them.

Pagophagia (compulsive ice eating) is similar. It is [2]caused by anemia (too little iron). In the Stone Age, there was no ice. An intense desire to crunch something in your mouth would have led you to crunch bones. Bone marrow is high in iron. It's another mechanism that worked well in the Stone Age but now malfunctions (not that there's anything wrong with touching your mouth with your hand). [3]My self-experimentation is all about this sort of thing. It's easy to sit, so we don't sleep well. It's easy to be inside in the morning, so we don't sleep well. It's easy to eat breakfast, so we don't sleep well. it's easy to avoid faces in the morning, so we get depressed. And so on.

More. [4]Andrew Sullivan's readers have other ideas: [5]here and [6]here. Thanks to Tyler Cowen.

---

James (2008-06-20 06:46:47)

"This mechanism evolved because it kept our lips moist." How does touching our lips w/ our hands keep them moist? More importantly, why is keeping them moist important? I agree with your suggestion of periodicity and with licking taking over when we're mobile. Both of these attributes, however, to me suggest a larger purpose - and I'd posit that moist lips are a great surface for capture of local microflora whether by contact with air (while mobile) or by direct sampling (with hands, while seated). Swallowing would then allow for a measured immune response and a constant re-adjustment of immune capability to the local microflora environment. Same goes for swallowing mucus from the nasal passages.

seth (2008-06-20 12:01:33)

"How does touching our lips w/ our hands keep [our lips] moist?" It doesn't – just as chewing ice doesn't cure an iron deficiency. Back in the Stone Age, with a different environment, the mechanism kept our lips moist because it caused us to touch our lips with our moist tongue.

James (2008-06-20 16:12:39)

"the mechanism kept our lips moist because it caused us to touch our lips with our moist tongue" I'm still not sure I understand the connection between touching one's mouth and maintenance of moist lips; wouldn't touching a dry hand to your lips dry them further? Accepting your reasoning, this still doesn't explain \*why\* it's so important for us to maintain moist lips.

kevin (2008-06-20 16:33:09)

I have found that licking my chapped lips dries them out further, causing more harm than if I left them alone, just as washing dry skin doesn't restore moisture, it makes it worse. What the lips need is probably not water, its skin oil, right?

Cliff (2008-06-20 21:23:19)

Kevin is exactly right- licking your lips will not keep them moist, it will dry them out. I am skeptical that touching your lips gets skin-oils on them and keeps them moist, but that is more probable than your opposite-world conclusion.

seth (2008-06-20 22:50:42)

I have no idea what chapped lips need. Perhaps more oil. Perhaps something else. I'm talking about normal lips.

Cliff (2008-06-21 13:53:53)

Yes. you are talking about normal lips and you are wrong about normal lips. There are no lips that licking makes moist, that is the bottom line. If you don't believe me, do a little research, then revise your theory because it does not fit reality. Think about it. Would washing your hands really often keep your hands moist? No. It dries them out. Try washing your hands 100 times a day and see what happens to your hands, they will be destroyed. If you bothered to google, you would find stuff like this: <http://www.wikihow.com/Make-Your-Lips-Smooth> [http://www.ehow.com/how\\_2115815\\_cure-chapped-lips.html](http://www.ehow.com/how_2115815_cure-chapped-lips.html) [http://www.carefair.com/Skincare/Tips\\_to\\_Stop\\_Biting\\_Your\\_Lip\\_1427.html](http://www.carefair.com/Skincare/Tips_to_Stop_Biting_Your_Lip_1427.html) Looks like unanimous agreement- don't lick your lips. Btw, I have been watching people who are busy, and have not seen any lick their lips.

seth (2008-06-21 16:37:09)

If you can find data – not just assertions – that support your idea, please post again.

moruno28 (2008-06-21 21:34:30)

i think that when i touch my own lips i often rub the ends, moving the moist buildup towards the middle of my lips. thus, my lips become more moist, even though moistening my lips in this fashion is not my intention, maybe it's instinctive.

Rob (2008-06-22 04:53:25)

Hey Seth, Cliff is right. I have a nervous habit of licking my lips sometimes and all it does it dry them out during the day by removing the natural oils on the surface. After hours of licking my lips I have to start using lip balm! Maybe there's a benefit to licking lips - but it ain't keeping them lubricated!

seth (2008-06-22 06:01:06)

Rob, maybe doing something 20 times is helpful but doing it 100 times is harmful. Maybe you're licking your lips too much.

Bob (2008-06-23 11:13:49)

Touching one's mouth may have a social meaning as well; in acting they say that touching your mouth or your head with your hands lowers your social status relative to other people in the room. I've never seen any data or experiments to test this though.

Greg (2008-06-24 04:37:14)

Seth, I think you're now taking your conclusion and searching for somewhat tortured justifications for it - e.g., maybe 20 times is helpful but 100 times is harmful. As far as I know, it's commonly held that licking your lips dries them out, and it's consistent with my experience. If you disagree, why not try licking your lips various numbers of times per day and see if it keeps them moist?

Jas (2008-11-22 09:40:22)

It's a nice theory you have, but I have to disagree a little. I think the lip licking and lip touching has more to do with nervousness or interest in a person. We lick our lips and when we do so, they are for a little while moist and glistening, which is the same effect you get from lip gloss. It's a way to draw attention to your mouth. I won't go in to detail, but it is also a sort of reference to something else. Also, by licking our lips, we show our tongue, or part of it, for a split second, which could be seen as another way of showing interest and wanting that someone to notice you. The lip touching has the same use, to draw attention to our lips. It's a simple way of intentionally, but mostly unintentionally, show that you are interested in someone. It doesn't have to be someone you're in love with, just someone you just saw and found attractive/cute/sexy whatever.

drbganimalpharm.blogspot.com (2009-01-02 01:44:32)

Silent celiacs have an incurable addiction to iceberg lettuce when they exhibit when iron deficient. They may also chew on things - like clothes, anything close to their mouth. Autistic children are reported to exhibit the same thing. In celiac (wheat-intolerance), the gut becomes fenestrated ('leaky') and blood leaks out into the stools. Perhaps our bodies respond to ancient signals that defy our current understanding?? In the nutrition world this is known as 'pica'. Thanks for this post! This explains a lot that we observe. :)

## **Morning Light and Better Sleep (2008-06-20 06:35)**

Song Cato, a friend of mine in Taiwan, writes:

I was very surprised that the quality of my sleep greatly improved after I switched to waking up at 5:30 am and walking in the park soon after that. I started it about a month ago. The park is packed with people doing everything from tai chi to ballroom dancing. I used to go to bed at 1 or 2 am. and wake up between 7 and 8:30 am with a foggy head. Now sometimes I feel tired and go to sleep at 10 pm which has never happened in my life since I went to middle school.

She got the idea from me. I go outside around 7 am every morning and fall asleep between 11 pm and midnight.

More. She gets up at about 5:15 am and gets outside about 5:30. She stays outside for at least 2.5 hours, mostly in the park, where she walks, talks to vendors, shops a little, and does simple stretching exercises. Talking to vendors

= very good!

---

hp (2010-03-25 04:52:00)

Hi seth, question on morning sunlight. I have to be to work before sunrise, but i can, if i choose work with the sun shining directly on me through a glass window in the morning. Do you think this would this give me the same benefit as direct sunlight outside, (it's a standard house window, no special properties to it) Thanks

Shawn (2011-08-24 05:19:15)

They key is to get up around sunrise while maintaining an adequate amount of sleep (I checked the charts and sunrise in Taipei in June is around 5 am). It has helped me immeasurably. I get a sense of overall well-being, and lack the foggy-headed tiredness that has dogged me like a black cloud over my head.

## Can You Change Something If You Don't Love It? (2008-06-21 12:01)

At a bookstore reading, I learned that Elizabeth Pisani wrote [1]The Wisdom of Whores – about doing HIV epidemiology among sex workers – because she wanted to have more of an effect on HIV prevention programs. Scientific papers didn't have much effect unless a journalist wrote about them. Journalists, she found, tended to focus on the exceptions rather than the rules. The exceptions – e.g., sex trafficking – were a poor basis for policy, of course. So she did what drug dealers call "jump the connection": She wrote a book about the rules, illustrating them with good stories. Speaking directly to the public. It seems to be working, she said.

Jane Jacobs (whom Pisani hadn't heard of) said something enormously relevant to her enterprise. I think it was in an interview. "It's a funny thing," Jacobs told the interviewer. "You can't change something unless you love it." What a broad statement, huh? Could it be true? HIV prevention programs, in Pisani's experience, have mostly failed. She was hopeful that private foundations could do what governments could not. The Gates Foundation, for example – could they crush HIV the way Microsoft crushed Netscape? Jacobs would have been skeptical: Is the usual attitude at the Gates Foundation to love, or at least respect, sex workers? Well, probably not. Indeed, the closer Pisani got to private foundations, the more skeptical she became. They were getting advice from former CDC bureaucrats and the like, full of the same ideas that had already failed.

Pisani held up one country as an example of how to do it right: Brazil. Why Brazil? I asked. Funny thing: In Brazil, they respect sex workers. Unlike everywhere else. In this case, at least, Jacobs was right.

More: [2]Here's one version of Jacobs saying this: "I think people [who] give prescriptions, who have ideas for improving things, ought to concentrate on the things that they love and that they want to nurture."

2. <http://www.gse.buffalo.edu/fas/bromley/ccs/part5.htm>

---

MT (2008-06-22 00:48:27)

I think it is likely that there are people at the Gates Foundation who are motivated by a love of and compassion for women – who are mothers, daughters, and sisters – and who happen to also be in the sex trade. Although there are a variety of motivations for working in philanthropy, and the Gates Foundation pays better than other non-profits, those who work there are still on average driven by different motivations than most people. There is more money for people of comparable talent in other sectors, so those working in non-profits are likely doing so out of empathy and compassion for others and would be aware of the economic and social conditions that conspire to put women into the sex trade.

seth (2008-06-22 06:18:19)

MT, I edited the post make it clear I was talking about the usual attitude of people who work at the Gates Foundation. The average attitude. You're right, there may be exceptions.

Tom (2008-06-23 22:01:21)

"The Gates Foundation, for example – could they crush HIV the way Microsoft crushed Netscape?" Yes, they could crush HIV exactly the same way they crushed Netscape – by flooding the market with thousands of HIV-free prostitutes who would give their services away at no charge. 8-)

[...] Can You Change Something If You Don't Love It? [...]

Patri Friedman (2008-06-24 14:51:34)

This seems like a good argument for social freedom and harm reduction rather than criminalization, for things like prostitution, gambling, and drugs. If they are illegal, we tend to demonize them, and the people who do them are people willing to do illegal things, who tend to be sleazier. You get a feedback cycle of sleaziness. And then when there are problems (drugs that are bad for you, STDS among sex workers), they are hard to fix. If instead you acknowledge that these things are going to happen anyway, make them legal and regulated, when problems come up it will be much easier to find smart, competent people who respect drug users, prostitutes, and Johns, and can provide good suggestions for fixing the problems.

seth (2008-06-24 15:00:23)

that's a great point, Patri. I'm going to write a post based on it.

## **100 Pounds Lost on the Shangri-La Diet (2008-06-22 06:06)**

WheatenDad, a 70-year-old man who lives in San Carlos, California, started the Shangri-La Diet two years ago and began [1]posting his weight on the [2]Shangri-La Diet forums. At the time, he weighed 300 pounds (BMI = 38). Now he weighs about 200 pounds (BMI = 26). He lost about 1 pound/week for 2 years:

He did SLD by taking 3 tablespoons/day of extra-light olive oil. In February 2008 he increased it to 4 tablespoons/day. In May 2007 he started walking 1-2 miles/day, eventually increasing this to 3-4 miles/day.

1. <http://boards.sethroberts.net/index.php?topic=1258.0>
2. <http://boards.sethroberts.net/index.php?action=collapse;c=1;sa=expand#1>

---

Douglas Clegg (2008-06-23 11:27:51)

This is great. A little over a year ago, I read the book, and started the diet using sugar water. For whatever reason – maybe my body chemistry – it was the wrong thing for me. Truthfully, sugar itself – despite my love for the stuff – has never tasted good to me, neither has sugar substitutes. So it may be that when something doesn't actually taste good to you, it means your particular body says, "I really don't want this in me, you idiot." I went off it within a few days (and suddenly had an attack of vertigo, which really made me nuts until a doctor diagnosed it. I doubt it had anything to do with sugar water, but it happened at the same time, so I went off any kind of diet or program at that point – and even gave up martinis, because I'd had one the night before the vertigo jumped me and threw me on the floor.) So, I decided sometime after that to go low-sodium with food to mainly lower my blood pressure, and voila, lost about 30 pounds this way over about 7 months – without doing anything other than keeping my sodium intake to 2,000 mg per day (or thereabouts). This meant I had to cut out all fast food, fried food, and most frozen and overly processed foods. I also made sure I walked or got on a bicycle about 4 days a week for 40

minutes or so. But I had been doing that long before, and I hadn't lost any weight from it. So the 30 pounds definitely moved by watching sodium and keeping it well-within the reasonable 2,000 mg level (which is still a lot of sodium every day.) I ended up cutting out all kinds of food I had been eating prior to this – just by watching sodium on the labels. Still I ate everything I wanted, whenever I wanted it, within my sodium range. Then, I hit a plateau, and even though I've exercised about five hours a week over the past year, I couldn't make the scale move lower...given my work, which is very sedentary, those five hours a week really aren't that much... So, in semi-desperation, I decided to re-try The Shangri-La Diet with flavorless oil. For reasons of health, I went with walnut oil, as well as some fish oil. The fish oil comes in a bottle, so I use a tablespoon with that. I don't believe that Extra-Light Olive Oil has much health benefit, and I needed some Omega-3s and also to reduce my triglyceride level (there is some evidence that fish oil can help with this.) I cover my nose when I take the fish oil, but the cold pressed walnut oil has zero flavor. 1 tbsp fish oil and 3 walnut oil each day (I do mornings when I rise and night just before I get into bed.) Then, still keeping my nose shut, basically, I drink a glass of water and swoosh some of it around in my mouth to remove any linger fish oil taste. Now, this is only my first week but...four pounds down. Four pounds down in one week – without my even watching what I'm eating – after no movement on that scale for several months. I'll keep it up and see how it goes from there, but I am impressed. As I said, I hit a plateau for about five months after losing the initial 30 pounds via going to a sane sodium-intake level (and realistically, I don't always – sometimes when I eat out, who knows how much sodium is in that food? And I eat out in restaurants about 4 times a week.) I don't count calories at all – I've never believed that works for people, or the idea of deprivation. When I'm hungry, I really want a good meal. I didn't feel as if any eating habit of mine changed while taking this oil, so it makes me wonder if there aren't several mechanisms at work here besides set point and satiety. Could it be that oil has another action in the body that helps this? Still, it could be satiety – it could be that I'm actually eating less than I usually do, but am not noticing what "less" is because the set point is lowering. Who knows? So, just wanted to post this, particularly after having read of this amazing success story here. Thank you, Seth.

Ascription is an Anathema to any Enthusiasm » Blog Archive » Shangri-La Diet (2008-06-24 06:59:28)

[...] This data is tainted by the how it is self reported, but none the less it is amazing.Â The other day Seth reported some fun data for one dieter, who lost about a pound a week for two years!Â He wrote a nice posting a while back about the fun he is having with his little community of users.Â And this is a nice research result that makes complete sense given the diet's punitive explanation, i.e. that standardization make food more fattening. [...]

Nick (2011-05-04 00:32:34)

That's kind of incredible - but more down to determination than the diet he chose. If he could have stuck with calorie counting, for a whole year, i'm sure his results would have been pretty good. Congrats to him!

Seth Roberts (2011-05-04 02:35:40)

Nick, I don't know anyone who has lost 100 pounds by calorie counting. Perhaps calorie counting is too hard and SLD is much easier?

## **Trailer » Movie (2008-06-22 23:35)**

The trailer for Robin Hood: Prince of Thieves contained a shot in which the camera was mounted on an arrow. The shot, done especially for the trailer, was far more memorable than anything else in the movie. I'm afraid this line from [1]an abstract of a New Yorker article by Andrea Lee about growing up in Pennsylvania–

Writer briefly describes a lunch with an Italian movie director who tells her about an affair he once had with a woman from Bucks County, Pennsylvania.

–is going to be more memorable than anything in the article.

You can see the arrow shot [2]here.

### **Scott Adams, Magnesium, and Knee Pain (2008-06-23 06:44)**

The creator of Dilbert [1]blogs:

About two years ago I started taking magnesium supplements because I saw something on the Internet that indicated it might help my knees problems. (My knees always hurt after exercise.) The magnesium either worked, or it was a remarkable coincidence, that after 15 years of knee pain it suddenly went away and has stayed away.

Recently I realized I haven't had any allergy or asthma symptoms for well over a year. For the first time in my life I went through the entire allergy season without so much as a sniffle or a wheeze. And I didn't even use my allergy or asthma meds. On a hunch, I googled "magnesium allergy" and discovered that doctors sometimes use magnesium to treat asthma attacks. And a magnesium deficiency apparently does promote allergies.

One of the comments is curious: "There's nothing wrong sharing what happens to you, Scott."

Thanks to cp.

1. [http://dilbert.com/blog/entry/magnesium\\_and\\_vacatios/](http://dilbert.com/blog/entry/magnesium_and_vacatios/)

---

Varangy (2008-06-23 08:53:28)

On a random, yet related note: I suffered a sports career ending knee injury as a younger man. A few years ago, against my doctor's and others' advice, I began doing barbell squats, in a matter of months my knee felt an order of magnitude better and I no longer experienced pain upon strong twisting/lateral type movements. I later learned from some olympic lifters, that squats (done properly) are excellent for rehabbing knees suffering from damage to the ligaments/tendons.

Ben T. (2008-06-23 10:46:38)

That's fascinating. My knees also hurt after exercise and I have mild allergies. I also often have "restless legs" when trying to sleep, which a commenter at Scott's blog reports are ameliorated by taking magnesium supplements. (All these conditions are mild and I haven't been actively looking to fix them.) I'll try magnesium supplements starting tomorrow and report back in a few weeks. It may be just confirmation bias etc. But here's the really fascinating thing. I just checked which foods are high in magnesium and this list has a surprisingly large overlap with my list of favourite foods. Did my tastes adjust in order for my body to get more magnesium? This suggests the following conjecture: To identify which nutrients you might be chronically deficient in, look at which nutrients are present in higher-than-normal amounts in your favourite foods. Does anyone have evidence to support/reject this?

SusanJ (2008-06-25 09:02:15)

Thanks so much for this! Most of my (very longstanding) knee pain has gone away and my knees are much more flexible since I started supplementing with magnesium 5 or 6 months ago. It never occurred to me that it was due to the magnesium since I had started taking it when I made a lot of changes switching from SLD to SLD plus low-carb. Mineral supplements are advised when on low-carb because of the diuretic effect of low-carb. I had assumed the reduction in my knee pain was the result of weight loss together with some positive effect of not consuming grains. It's funny if it's just the magnesium. Maybe someday I'll know for sure.

Aaron Blaisdell (2008-06-25 10:27:31)

When my wife experienced pre-term contractions during her 29th week of pregnancy, the doctor put her on a magnesium sulfate IV drip to stop them.

Stephen M (Ethesis) (2008-06-25 19:02:05)

That is interesting. I'll note that doing squats has helped my knees too.

Mark (2009-01-18 21:54:31)

I have had pain in my medial part of my knee for seven years. Knew exercise would help so I decided to use the elliptical machine since it hurt the least doing that exercise. Every day for four and a half weeks I was on that machine for 30 minutes to an hour everyday. Somewhere along the line the pain went away. I now do swats again with no pain. I can also play basketball without the pain I had before. I did not do any special pills or vitamins just the elliptical machine everyday. No longer do I get out of bed and feel that pain in the knee that I did for so many years especially after exercise. I also did leg stretches before and after which you should be doing anyway.

p. canter (2009-07-04 21:53:54)

Thank you for all the information on how magnesium has helped each of you. I also have alot of pain in my knees one I've had surgery on recently. So my question is how much magnesium does one need? All your information has been so helpful. Looking forward to trying it myself. Especially something natural.

Brenda Nicholson (2009-12-29 13:40:00)

I have torn miniscus, torn tissue behind my right and left knees. The right is the worst. Surgery is scheduled for late January 2010. I want to know how much magnesium do I need to take. What is an elliptical exercise machine? I certainly can not do any squats at this time; I am a person that walked, rides a bike, exercise and roller skates. I can do barely nothing now. Can someone steer me in the right direction? Thank you.

## **The Paradox of Advice (2008-06-23 10:44)**

[1]A long post by Ben Casnocha tells how to give advice. The subject fascinates me because I've noticed what a strong tendency I have to give advice when told of this or that problem – yet I also realize that advice giving is usually obnox-

ious. I think this is why Ben's post is long: It's a difficult problem, like an addiction: The bad consequences are hard to avoid. Why do I have this tendency? No obvious reason. It certainly isn't learned or copied or sustained by reward. Why is it obnoxious? Again, there's no obvious reason. Giving advice has good and bad aspects: trying to be helpful (good) and acting superior and ignorant (bad). Why the bad seems to predominate I have no idea.

This is one reason I think Jane Jacobs's [2]you can only change what you love is usually true: because in your communication with someone you love (or at least respect) there will be enough positive in the whole message to overcome the negative of the advice itself – so that the advice doesn't push the person away. (Another reason I think she's right is that to give good advice you usually need to know a lot about the person you are advising.)

1. <http://feeds.feedburner.com/~r/ItsLikeBensBlog/~3/315907281/if-i-were-youth.html>

2. <http://www.blog.sethroberts.net/2008/06/21/can-you-change-something-if-you-dont-love-it/>

---

Tim Lundeen (2008-06-23 12:40:48)

Giving advice confers higher status on the advice giver, and reduces status for the advice taker. This is what makes it so hard to take :- (And pleasant to give.) This is a large part of the job satisfaction of being a doctor/minister – you are acknowledged to be an advice-giver, and earn much status in that role. I think one thing that helps both sides is a strong foundation of mutual respect, so that the acceptance of advice doesn't materially change the status balance; another way to do this is to trade advice, accept advice that you don't (think you) need in order to give advice that (you think) will materially help someone. A knotty problem :-)

seth (2008-06-23 13:01:49)

Yes, giving advice has a lot in common with putting a bumper sticker on your car, as Robin Hanson pointed out: <http://www.overcomingbias.com/2008/06/lo ud-bumpers.html>

Mike Kenny (2008-06-23 19:19:36)

i've heard from a psychologist that you can't really change people, which is interesting, though i'm not sure exactly how to take it. i've also heard it said you can't really change people's minds with an argument which is similar to advice-giving. that seems true to me, since i can't think of a time i really changed anyone's mind with an argument. on the other hand, maybe i am not noticing, since i can think of arguments that have changed my mind, and perhaps it's not obvious my mind was changed by the people who persuaded me, since i don't like to linger on my own errors :)

Tim Lundeen (2008-06-23 22:00:58)

I liked the "strut" update to Robin's post. My dog struts after she has an encounter with a submissive dog, it is really funny to see. All of her 15 pounds of white fluff, strutting down the street.

Darkhorse (2008-06-24 04:21:11)

A lot of people are giving advice. Peter Kollock (Univ. of California, L.A.) has researched motivations for contributing to online communities. <http://narrowmindboat.blogspot.com/2007/07/peter-kollock-economies-of-online.html> He lists as egoistic motivators: "anticipated reciprocity" reputation (bragging rights) sense of efficacy And as altruistic motivators: help someone who has a need attachment to a community Seth, I see your own motivators for the advice you give in the SLD forums as purely altruistic, and I don't sense any "strutting", either. This wikipedia piece on motivators is also interesting [http://en.wikipedia.org/wiki/Virtual\\_community](http://en.wikipedia.org/wiki/Virtual_community)

Ben Hyde (2008-06-24 06:33:52)

"Give a stone before advice." My dad was a fan of this poem on advise "A GARLAND OF PRECEPTS" by Phyllis McGinley But, I'd advise fixing the Jane Jacobs link. There is an ironic tension in the Jacobs quote. In particular, she had little love for urban planners. They didn't love cities, but she yearned to change them.

Varangy (2008-06-24 07:36:18)

Not to intentionally go off-topic, but this article - [http://www.wired.com/science/discoveries/magazine/16-07/pb\\_theory](http://www.wired.com/science/discoveries/magazine/16-07/pb_theory) - touches a lot of the themes that this blog regularly comments on. Would love Seth's take on it.

Aaron Blaisdell (2008-06-24 11:57:09)

In response to Mike Kenny's response, when I do take someone else's advice, it is usually after their argument is over and they are long gone. This way I save face (i.e., status) by appearing not to take their advice, but get the benefits of their potential wisdom. I guess this happens a lot, otherwise advice would never do any good.

Ben Casnocha (2008-06-24 14:39:59)

Thanks for the link, Seth! And I agree that bad advice predominates.

peter (2008-06-25 07:49:39)

my take on giving advice is that our bodies probably reward us in some hormonal/chemical way. For example, chimps in the wild who dominate have higher levels of testosterone. giving advice is, in a manner of speaking, dominating or being in a superior position and probably leads to enhanced and perhaps pleasurable hormonal/chemical releases. dominating results in greater likelihood of survival and it makes sense that we are reward in a many ways, including hormonally/chemically. I recall that a neighbor knocked on my door to give me my key, which i left hanging from my mail box. rather than simply hand them to me and say something like "here you left these in the mail box" he looked excited and exhilarated and recounted the experience in detail (i.e., "i walked up to the mail box a notice" etc...) as if it were a thrilling adventure. relative to his life this was domination and he obviously got a thrill out of pointing out a mistake.

Aaron Blaisdell (2008-06-25 08:21:45)

Here's another piece of evidence that fits with the idea that giving-taking advice raises-lowers the status of the giver-taker, respectively. When my wife and I were first dating, and she knew I was a college professor trained in the behavioral and neural sciences, she would listen to my advice about certain topics. But we are married and with a 2 year old girl. I'm still an expert in the behavioral sciences, but she won't take my advice about how to help train our daughter (as all little kids need lots of constant training!). I that since my wife obviously doesn't want to feel inferior to me, she often won't listen to my advice, no matter how helpful and kindly it is given. I could tell my wife something that I know from the medical community that will help her (e.g., take omega 3 supplements every day, especially while pregnant) but she won't listen to me. But if her prenatal doctor tells her that that is a great idea, she WILL listen to her. No worries about loosing status to the doctor, the doctor is supposed to have more status than the patient. But the wife is not supposed to have more status than the husband (at least not in our relationship). Maybe I should switch tactics and tell her stories instead of giving advice or offering helpful tips (the latter sounds more benign, doesn't it). Something like "I saw a prenatal doctor give a talk on campus and she had a whole discussion about how most pregnant women don't get enough omega 3 fatty acids. This can lead to all kinds of problems for the developing fetus, such as ..." Sure, it's a fictional tale, but maybe she will listen to the ideas in the story to heart. After all, I wasn't offering advice, I was telling a story!

The Paradox of Advice: as good a place as any to begin « Enjoymentland (2008-09-17 23:16:52)

[...] Turns out Seth Roberts has thought about this paradox as well.Â A good quote from Jane Jacobs, writer of "The Death and Life of Great American Cities" that he quotes is: "You can't change something unless you love it." [...]

## Lessons Learned about Book Writing (2008-06-24 14:24)

1. At [1]Writers With Drinks I met a woman who is writing a memoir. Since I had actually published a book, she wondered if I had any advice about finding a publisher. I said don't get your hopes up. Practically no one makes anything resembling a living from writing books. (I meant books like memoirs – what a friend calls real books.) It's a hobby. I asked her if she'd heard this before. No, she said. She said she's around people who are "positive" whereas I was "realistic."

2. My friend Phil Price is a researcher at Lawrence Berkeley Laboratory. A few years ago he wrote a chapter ("Assessing uncertainties in the relationship between inhaled particle concentrations, internal deposition, and health effects") for a handbook-like compendium. It was a big mistake, he said. There were three problems: 1. It was much harder to write than he expected. 2. The quality of the final product was lower than he expected. 3. The audience was tiny. Maybe 11 people would end up reading what he'd written.

1. <http://www.writerswithdrinks.com/>

---

Andrew Gelman (2008-06-24 15:57:08)

I don't make a living from writing my books, but I wouldn't call it a hobby. I don't think that, just because something isn't one's main source of income, that it necessarily falls into the "hobby" category.

seth (2008-06-24 21:24:01)

What would you call it? Writing your books I would call a superhobby because they are based on what you do for a living yet writing them is optional and different from what you do for a living. But *superhobby* is a term I invented.

Nathan Myers (2008-06-30 17:00:42)

Many people writing books would bill the time to their marketing budget.

Alex C. (2008-07-05 09:45:19)

This is a very good (and funny) essay about publishing books: <http://philip.greenspun.com/wtr/dead-trees/story> It's a bit long, but I think it's worth reading.

## The Cost of Demonization and How to Avoid It (2008-06-24 15:22)

In response to my post [1]Can You Change Something if You Don't Love It? Patri Friedman wrote:

This seems like a good argument for social freedom and harm reduction rather than criminalization, for things like prostitution, gambling, and drugs. If they are illegal, we tend to demonize them, and the people who do them are people willing to do illegal things, who tend to be sleazier. You get a feedback cycle of sleaziness. And then when there are problems (drugs that are bad for you, STDS among sex workers), they are hard to fix.

If instead you acknowledge that these things are going to happen anyway, make them legal and regulated, when problems come up it will be much easier to find smart, competent people who respect drug users, prostitutes, and Johns, and can provide good suggestions for fixing the problems.

Besides being a great point all by itself, it is eerily similar to something [2]Eduoard Servan-Schrieber told me at lunch when he was a grad student at Berkeley. He'd been a sailor in the French navy when he was about 21. Every day, everyone on the ship had lunch together, the officers at the same table as the privates. This was great, said Eduaord, because when a problem came up it was easy to speak with the officers about it. You weren't scared of them, they weren't mistrustful of you.

I've repeated this story many times. I think there is something basic and biological that makes us trust and work well with people we see regularly and makes us mistrust and work poorly with those we don't see regularly. When you are in the same company or organization with people you don't see regularly, great problems can arise, especially if you have power over them or they have power over you.

More. Elisabeth Pisani – the source of the post to which Friedman responded – wrote me, "I agree 100 % with Patri, not just on principle but with the weight of the evidence of 15 years experience."

### **to other (2008-06-24 21:19)**

I learned a new verb today: to other, meaning to treat someone else as "other," as different. The person I learned it from had used it once before. She had learned it from a graduate student. Sample usage: "They were othering him and I didn't like it." I like to other because there's room for a milder term than demonize.

[1]Definition of othering, which isn't in Merriam-Webster's Online.

1. <http://www.cwrl.utexas.edu/~ulrich/rww03/othering.htm>

---

### **Science versus Engineering (2008-06-25 23:09)**

Varangy wonders what I think about [1]this editorial by Chris Anderson, the editor of Wired. Anderson says "faced with massive data, this approach to science – hypothesize, model, test – is becoming obsolete." Anderson confuses statistical models (which are summaries of the data) with scientific ones (which are descriptions of the mechanism that produced the data). As far as the content goes, I'm completely unconvinced. Anderson gives no examples of this approach to science being replaced by something else.

For me, the larger lesson of the editorial is how different science is from engineering. Wired is mainly about engineering. I'm pretty sure Anderson has some grasp of the subject. Yet this editorial, which reads like something a humanities professor would write, shows that his understanding doesn't extend to science. It reminds me why I

didn't want to be a doctor. (Which is like being an engineer.) It seemed to me that a doctor's world is too constrained: You deal with similar problems over and over. I wanted more uncertainty, a bigger canvas. That larger canvas came along when I tried to figure out why I was waking up too early. Rather than being like engineering (applying what we already know), this was true science: I had no idea what the answer was. There was a very wide range of possibilities. Science and engineering are two ends of a dimension of problem-solving. The more you have an idea what the answer will be, the more it is like engineering. The wider the range of possible answers, the more it is like science. Making a living requires a steady income: much more compatible with engineering than science. I like to think my self-experimentation has a kind of wild flavor which is the flavor of "raw" science, whereas the science most people are familiar with is "pasteurized" science – science tamed, made more certain, more ritualistic, so as to make it more compatible with making a living. Sequencing genes, for example, is pasteurized science. Taking an MRI of the brain while subjects do this or that task is pasteurized science. Pasteurized science is full of rituals and overstatements (e.g., "correlation does not equal causation", "the plural of anecdote is not data") that reduce unpleasant uncertainty, just as pasteurization does. Pasteurized science is more confusable with engineering.

There's one way in which Anderson is right about the effects of more data. It has nothing to do with the difference between petabytes and gigabytes (which is what Anderson emphasizes), but it is something that having a lot more data enables: Making pictures. When you can make a picture with your data, it becomes a lot easier to see interesting patterns in it.

[2]Andrew Gelman's take.

More. [3]Derek James, a graduate student at the University of Louisiana at Lafayette, agrees with me.

Araglin (2008-06-26 07:55:40)

Seth, You said: "That larger canvas came along when I tried to figure out why I was waking up too early." I know this a bit off topic, but, in dealing with this question, did you discover any possible means by which a person who chronically sleeps late could be made to spontaneously wake *earlier*? Thanks, Araglin

seth (2008-06-26 12:03:14)

to spontaneously wake up earlier get a lot of sunlight early in the morning. Go outside soon after you get up. The shade is fine. Try 2 hours outside.

Araglin (2008-06-26 12:54:42)

I'll definitely try that, although, the fact that I have to work (office job) Monday through Friday would require that I start out only getting the morning light on weekends... Oh: Could it be that staring at a computer monitor at night makes me want to go to sleep later and wake later? Thanks, Araglin

Scot (2008-06-26 14:02:10)

Hmm...I'm thinking that there's uncertainty in engineering or other applied sciences too. Not sure that the uncertainty disappears just because it's an applied science. Just a thought. When I think of engineering I think of a skunk works.

Science and engineering approaches « Entertaining Research (2008-06-27 00:42:23)

[...] Science and engineering approaches Here is another take on the Wired piece of Chris Anderson — this time around, by Seth Roberts: Varangy wonders what I think about this editorial by Chris Anderson, the editor of Wired. Anderson says “faced with massive data, this approach to science — hypothesize, model, test — is becoming obsolete.” Anderson confuses statistical models with scientific ones. As far as the content goes, I’m completely unconvinced. Anderson gives no examples of this approach to science being replaced by something else. [...]

## Shangri-La By Another Name? (2008-06-27 15:57)

There’s a new diet called something like Fat Loss For Idiots or The Idiot-Proof Diet in which you lose weight by constantly changing what you eat. [1]Here’s how the creators put it:

To lose weight your diet menu needs to be SHIFTED every few days –and this is something you’ve never tried before, and that’s why you’ve never been able to change your body when dieting.

Never tried before? When I go to a foreign country that’s close to what happens. And I do lose weight. According to the theory behind the Shangri-La Diet, this should work – because you are constantly eating flavors you haven’t yet associated with calories. Thanks to Tim Lundeen.

1. <http://fatloss4idiots.com/1280index3.html>

---

VeganKitten (2008-06-27 16:48:51)

\$55.95 to get the info, from what I can see. Someone’s going to make a lot of money, but they won’t get mine. ”9 pounds every 11 days” indeed!

Andrew Gelman (2008-06-27 17:45:47)

Seth, If you’re going to mock these people, you should also consider mocking the ”2008 Diet of the Year” that you have a Google ad for on your page. I clicked on it just for laffs and it started popping up windows all over my computer! It looks much worse than ”Fat Loss For Idiots.”

## How Art School Reveals Human Nature (2008-06-27 22:43)

Sure, we can learn about human nature by looking at art. [1]I’ve done that. What’s less obvious, at least to me, is how muchÂ can be learned about human nature by observing art students. I got a glimpse of this from talking to a student at [2]California College of the Arts. Three things I learned:

1. Every department looks down on every other department. Or, at least, there is a vast amount of ”looking down on”. One example is that students in the illustration department look down on students in the fashion department. This is puzzling because the two subjects are unrelated (unlike, say, graphic design and illustration, which are closely related). Why does it happen? My informant thought it was because so many people looked down on illustrators that

they were desperate to find a group they themselves could look down on; they chose fashion even though it made no sense.

2. Students in each major have distinct personalities. Photography majors tend to be self-centered and outspoken. In class, they talk more than they need to. Illustration majors are relatively childlike; they are wacky and playful and fun and less serious. In the illustration department, unlike other departments, critiques are always sugar-coated: "This is great, what a nice job you did, you might think about ..." Graphic design majors are "urban" – more sophisticated, more interested in being cutting edge, more concerned about the job market. Fashion majors tend to be flighty.

3. Almost all students at CCA enter with their major already decided. They are intensely focused on their subject – think about it all the time. They have little interest in what can be learned from other disciplines. Somehow focus seems to get in the way of curiosity. You might think that art is about being creative and creativity is helped by curiosity. Somehow this doesn't occur to them and isn't taught.

Shown the above, my informant, wanting to give a more complete picture, added:

I also think that a lot of those students who help to create these perceptions are probably also the ones that feel the need to be labeled. The photography students who create the image of self-assuredness, the ones who talk about themselves and their work all the time, probably feel they need to do it because it's the image of themselves and of photographers that they need to create. Same goes for fashion and illustration and all others. There are probably other students who feel the way that I do and just choose not to get into it and would rather leave those "personas" for someone else to convey.

I think it's specific to art students, and [part of a] desire to be seen as artistic, since most artists i know outside of school don't seem to perpetuate this. i don't want to make it seem as if art students are superficial and uninspired. i've met my share of really great people.

More. Russ Roberts, [3]interviewing Diane Coyle: "The culture among the graduate students [in economics at the University of Chicago in the late 1970s], and probably among the faculty, was to really look down on the other social sciences and to see them as a total waste of time."

1. <http://www.blog.sethroberts.net/2007/06/27/my-theory-of-human-evolution-directory/>

2. <http://www.cca.edu/>

3. [http://www.econtalk.org/archives/2008/04/coyle\\_on\\_the\\_so.html](http://www.econtalk.org/archives/2008/04/coyle_on_the_so.html)

---

Chris (2008-06-28 00:09:43)

Funny, the description of the different majors reminded me of your post of differentiating scientists from engineers. I bet all the artists look at that rift as similarly comical. We all want our cognitive shortcuts. From the time of being a baby, people become successful by copying the successful. If a photo major has idols to emulate with all the profiles/interviews of famous photographers happening these days they may think that being articulate and opinionated is a big part of being a successful photog. Similarly, illustrators in industry can be recluses, more child-like, etc. But above all, everyone in western society wants to be an individual but doesn't want to fall so far from the tree that they're alone. It's better to be a \_\_ \_ major than to be that weird guy.

Mike Kenny (2008-06-28 09:42:07)

hm, do you have thoughts on personality tendencies among students of various degrees at a university along the lines of this post? i'd be very interested in your observations.

seth (2008-06-28 12:47:22)

good question, Mike, but I'm not close enough to a wide range of students to answer it. Most of my contact has been with students from just one major (psychology).

Aaron Blaisdell (2008-06-30 05:52:24)

...and the physical anthropology students look down on the cultural anthropology students (poor archeology students are caught in the middle of that cold war), and the experimental psychologists look down on the clinical psychologists (who think this is ironic), and the UCLA middle campus (biological and social sciences) looks down on the UCLA north campus (humanities and arts), and the south campus (medical school) look down on both middle and north campus. It all reminds me of a funny scene in *Stranger in a Strange Land* where the Martian protagonist (forgot his name) is trying to figure out why humans laugh (an alien concept and emotion to the Martian—pun intended) until he visits the zoo. He is at the monkey (or was it ape?) enclosure and observes the biggest male walk up do and hit the second biggest male, who then proceeds to go on and hit the third biggest male, and so on down the line. All of a sudden the Martian laughs with a sudden insight into human nature and a major source of all of its comedy. I guess this is why the ancient Greeks linked comedy to tragedy so well. By the way, REAL artists – those that ply their craft for a living – tend not to be like the art students described (at least not in my limited interaction with them). I used to hang out on a regular basis with New York fashion designer Byron Lars and many of his friends and colleagues who designed, illustrated, photographed, etc. Each artist I met, no matter what their niche, not only respected the practitioners of the other niches, but actually utilized them in plying their own craft. Whoever things illustration and fashion are different spheres of art has never met a real fashion designer. Illustration is probably what they do most, more than cutting fabric, I can assure you of that! I've observed that many successful artists and scientists do not wear blinders to their own field, but have much broader interests and had more unconventional and highly varied educations and past experiences.

Brian Sherwin (2008-07-17 13:11:55)

Interesting post.

## **The Difference Between Being Fat and Not Fat (2008-06-28 12:28)**

I have never read a better description of the difference between being fat and not fat:

I had a gastric bypass and ate 750-1000 calories of liquid meal replacement a day. I had complications and couldn't swallow food. I lost over a hundred pounds. I regained it over a number of years. Once I lost weight and was normal, my life did change for the better. It's the only reason I had my child. For the first and only time in my life it was easy to have people in my life. People wanted to be around me. I had boyfriends who treated me well for the first and only time in my life. I got married. All this happened very quickly and easily with no effort on my part. Being fat is completely different. I think the way people treat a fat person is similar to being disfigured or in a wheelchair with your legs cut off. In many instances it is better to be dead than to be this fat.

[1]From an anonymous blogger who weighs about 280 pounds. She isn't trying to sell anything, make a journalistic or academic point, appear to be this or that. The post goes on:

My daughter had a fat friend over for a sleep over the other day. It's the second fat friend she's ever had over. The difference between these girls and the thinner girls is striking. The fat girls are obsessed with

food. They are more driven to eat, more interested in food, more hungry than the thinner girls. The thin girls are interested in food far less. It's not that they are better than the fat girls, they are simply less hungry. My daughter first fat friend got up all through the night to raid our refrigerator. This child acted as if she were starving. She ate until she was literally ill and threw up on the sleeping bags. Then later she peed on my daughter. My daughter is fastidious and she was completely revolted. That was the end of the friendship.

I came across this because she is trying the Shangri-La Diet.

---

Dennis Mangan (2008-06-28 18:07:06)

Sad story. The fact remains, however, that the incidence of obesity has risen dramatically over the past generation, which means that in the past people must have had more self-control. Or at least, that's what it means based on this blogger's statements about being "obsessed" with food; she's put on all that weight despite the fact that it makes her feel "disfigured". Why wasn't the previous generation "obsessed"? Put this way it makes it seem that obesity is a moral failing - which it might be.

seth (2008-06-28 18:34:16)

"People must have had more self-control." Must is too strong. That is one possibility. Others are plausible. I believe their set points were lower. It doesn't take any self-control to lose weight if your set point goes down.

spacenookie (2008-06-28 21:35:54)

studies have shown that fat people eat no more and expend no less energy on average than lean people. Taubes' Good Calories, Bad Calories suggests that fat people are effectively starving because nutritional energy is disproportionately consumed by the fat cells (because excess insulin signals fat to store more energy, not release it). Starving people are obviously prone to become obsessed with food. Note that the poster doesn't say the lean girls "had more self control", they just were not interested in more food. Taubes effectively blames the obesity "epidemic" on the low fat, insulinogenic diet recommended by the govt and most doctors since about 1980.

Tom (2008-06-28 23:20:56)

Hard to see how one could get 'poor self-control' from that story; it's exactly what the writer is taking pains to refute. And yes, Taubes takes apart the "poor self control" theory quite convincingly.

Kevin C (2008-06-29 15:19:28)

I agree Seth. This idea that people are fat because they have no will power is very unhelpful. None of us have much will power when our body is telling us to do something. It doesn't matter if your body is screaming out for coffee or alcohol or potato chips or pad thai. If your body wants it, you are going to eat it. What's nice about SLD is that it circumvents this. I got a friend of mine to try SLD and the change amazed her. Even on the first day, her desire to eat her normal sweet treats was almost completely gone. It was easy for her to resist, because her body had little interest in it.

Dennis Mangan (2008-06-29 17:27:34)

You guys are pretty funny, you know? The two girls can't stay away from the frig, and you see no lack of self-control? But wait, the bible of Taubes, 3:23 explains all: it's low-fat diets that are to blame! "Studies" have shown that the fat eat no more and exercise no less than the slender? Who am I to believe, "studies" or my lying eyes? All around me, I see people eating

constantly, between meals, between snacks even, raiding vending machines, turning themselves into blubber. And guess what, they're not eating low-fat diets either, which is heresy against that Taubes bible. They're cramming themselves full of every french fry, Oreo, and cheese curl in sight. As for the self-control issue, everyone has a hunger drive, just as they do a sex drive. I suppose y'all want to excuse rapists and adulterers; "I just couldn't help myself! My drive is too strong!" Reminds me of the criminals described by Theodore Dalrymple, who say things like "The knife just went in", absolving themselves of all responsibility. That's how it is everywhere these days.

Mel (2008-06-29 18:35:18)

Dennis, I'm guessing that you have no problem with your own body weight but that you have family or friends that do. There is something bad that happens to some people when they eat foods full of carbohydrates (as recommended by "everybody") for too long. That feeding style causes lots of insulin to be excreted into the blood stream and as the Taubes' bible says, it makes the stored fat invisible to the body's food supply system. In fact it makes every cell in your body scream to be fed. It is impossible to resist eating constantly when all your cells are starving. I think the Shangri-La diet works wonders in two ways. It supplies lots of quality fat to feed the starving cells and it 'tricks' the weight regulation center to let go of excess fat. I've been there, I've wondered for years how I could be hungry not long after eating. When I quit eating carbs (mostly), and upped my fat intake, and crazy spiced my meals, the feeling of satiety after and between meals has been heaven. Even if I didn't lose weight, I'd never go back to being fat+starving. I'm glad you're metabolism is not broke. Please give others a break, it's not will power! It's the wrong information!

Tom (2008-06-29 20:16:24)

These comments might as well be in response to Seth's post "Can You Change Something If You Don't Love It?" Love the victim and anything's possible. (And in my mind, the anonymous blog writer seems to love the overweight girl who can't stop eating, even if it forces her into exile after she can't help but urinate on the writer's own daughter.) But conflate the obese with rapists and adulterers and the conversation's over. One is just shouting in one's private echo chamber.

Dennis Mangan (2008-06-29 20:20:15)

Yes, clearly the hunger and sex drives have absolutely nothing in common. Thanks for straightening me out.

spacenookie (2008-06-29 21:57:34)

Dennis, oreos, cheese curls, and french fries are 60-70 % calories from carbs. These are not low-carb items. Sodas, gatorade etc are usually 100 % calories from carbs. If lack of self-control causes people to become fat, and lack of self-control causes people to become rapists (because they don't control their hunger/sex drives), then lack of self control would cause people to become fat rapists. I don't think so.

Anonymous (2008-06-30 08:54:46)

I wonder how many people who aren't overweight or obese refrain from eating when they're hungry? How many mind their diets carefully, such as severely limiting carbohydrates or sugar, when they've never been heavy? Or do people who have never been overweight or obese eat when they're hungry, eat to satisfaction, then stop? Do they eat basically what they like and want? I have never been not overweight or not obese without severely restricting my food with constant discomfort, vigilance and considerable effort. I don't think I lack self control more than average size people. I exercise considerable willpower in other areas of my life. For example, I stopped smoking over twenty years ago. I remember the effort was negligible in comparison to what it took to diet or even to maintain a low weight. I complete (write) entire books and I've noticed average size acquaintances have been unable to exercise the discipline to complete a book even when they strongly desire to do so. Do normal weight people really exercise constant self-control? I wonder.

Stephen M (Ethesis) (2008-06-30 10:55:28)

Seth, this was a great post. The link wouldn't work for me, I wanted to read more, and I hope SLD works for her. But you couldn't have asked for more, down to the comments by people who exhibit classic blindness to reality. Thanks again for your efforts to share SLD.

seth (2008-06-30 12:25:27)

Thanks, Stephen. The whole blog has become unavailable, I don't know why. There are plenty of other good posts. It turns out the blogger is a well-known novelist. (I have no idea who.) Her books are so popular that she hears other people talking about them while she's at the beauty parlor. Anonymous, I agree completely.

seth (2008-06-30 17:08:58)

The link is now working again.

Aldarris (2008-06-30 17:46:38)

It is indeed true that low weight people rarely exercise more self control than fat people, but this is beside the point. We all have passions of varying degrees, and if a passion controls a person, if it makes one eat until one is bloated or go violent on a regular basis, one shouldn't look for excuses "hey, they do not have will power, they are just lucky", but exercise self-control to do something that comes natural to other people – to control the passion. Life is not fair, is it?

Tom (2008-06-30 22:48:33)

Aldarris, I'm sure you think you're making a point, but you have not succeeded. I can't for the life of me figure out what you're trying to say.

Kevin C (2008-07-01 05:47:21)

No one is making excuses. We want explanations, and methods of weight loss that actually work. Telling people to simply control their impulses when their impulses are that out of control doesn't work. The key is to find ways to turn off the impulses to overeat, not to scold people because they are obsessed with food. When one changes the types of foods one eats (i.e. a low carb, ketogenic diet), or one uses a method like SLD which lowers your set point, the impulses to overeat subside. It makes it much easier to lose weight. When someone is so obsessed with food that they are waking up in the middle of the night to gorge themselves and eating until they are ill, it's only rational to look for other explanations besides "will power". There is something else going on here.

Dennis Mangan (2008-07-01 07:27:27)

Aldarris's point is perfectly clear: psychological impulses and drives vary tremendously between persons, and we don't excuse those who let their impulses get away from them by saying that they couldn't help themselves. Or rather, we do excuse them now, which was partly my original point. In the old days, the obese were much rarer and more stigmatized socially, and I submit that there's a connection, just like there's a connection between the increase in illegitimate births and lack of stigma. As for people "gorging themselves until they are ill", it's not hard to imagine that that little girl's parents are exercising any discipline at all over what she eats. So aside from a bad diet or even a psychological disorder, lack of standards and discipline is part of the problem. At my workplace, lots of people eat all day at their desks, and then wonder why they're overweight. That's a lack of discipline. You're not supposed to eat all day long.

seth (2008-07-01 09:53:38)

Dennis, I guess you mean "are **not** exercising any discipline." I read it the opposite: The little girl's parents are exercising so much discipline that when freed from that discipline she goes too far. In terms of her setpoint, she really is starving.

Kristin (2008-07-05 23:00:52)

Dennis and Seth- This has been an enlightening experience, reading these opinions. I am obese, but not ashamed, as if I have some horrible disfigurement, simply because I will not allow it. To some degree, I was that little girl in the blog. I grew up thin, and I believe my natural set point is lower. I am losing weight now by not eating meat and limiting my portion sizes. My mother kept a close eye on my food intake, and commented on anything I ate that she thought was inappropriate. We weren't allowed sugared anything. When I went to other children's homes, I tended to over-eat, because it was available. I didn't do it to a large degree, like the little girl did, because I was afraid my mom would find out. Seth, I agree with your assessment. The little girl probably ate like that because it was some of the only freedom she ever got. Dennis, I know you feel attacked. What you see in

your environment is the truth to you...people over eat and then wonder why they are fat. Well duh!! I would feel the same way you do! What you are not looking at however, is WHY they do it...it is too easy to say that it is because they don't have will power. (Kind of a B.F. Skinner approach- the behaviorist approach to psychology) The reasons why people over eat, and are overweight are as complicated and varied as the people themselves. Trying to find a simple answer is understandable, and to some degree, true. But it's not ALL of the truth. Lack of willpower is not all of why someone eats too much, just the outer behavior that you see. For example, after having such a restricted eating environment at home, when I left for college, I didn't binge drink or binge sleep around (I was thin and very pretty, I could have) I ate. It was like all at once there wasn't a nag at my shoulder all the time, so I could eat what I wanted. My decision making had been returned to me! It was my own form of rebellion. Since then, I have realized that my reactions to my emotional state, or stimuli for outside myself are things that can provoke the need to eat. YES, I fight it. YES I am aware of what I eat and am constantly trying to control it and make the right decisions. But until you have been in an obese person's shoes, regardless of what you see everyday, please don't judge us. Obviously, you are not struggling with your weight, and never have. Otherwise, you would have more understanding and compassion. Thank you though, for being brave and saying what you think. It helps others to be able to voice their opinions and sort out how they feel. You helped me!

accorn (2009-01-16 06:51:33)

I think there is partial truth to what Dennis was saying, but it's not the whole picture. I went to China for two weeks, and eat a vegetarian diet. As such I didn't touch the "westernized" meat foods offered over there and eat much like the average Chinese person does. (plain rice with cabbage and other fairly plain vegetables and light sauces.) What was really interesting to me only a few days into this diet, was that my body was not hungry at all for large amounts of time until right up to the moment I was about to eat (going to restaurant etc). Once I arrived at the place we would have lunch, I would be famished and eat - and then be good again for hours. Whereas in the USA I always feel hungry, and always driven to snack. It made me aware of how powerful our culture is on our health in general. I think it is largely that in our need to keep a fast lifestyle going, we've given power to corporations to make our foods, and they have produced foods that are chemically designed to make cravings. In our culture everyone is eating this food - and everyone is wondering "why am I so fat" when everyone else is eating this - but it's only when you go to a completely different culture will you see that in fact everyone doesn't eat like we eat. Anyways I'm not saying that we are not responsible for choosing what we eat like Dennis asserts - but at the same time you can't deny the forces that have encouraged our problems.

## **The Ketogenic Diet (continued) (2008-06-30 22:22)**

Thanks to [1]Honest Medicine, I found some interesting videos about the ketogenic diet. The first two are from Date-line NBC: [2]Part 1 and [3]Part 2. In Part 1, Dr. Donald Shields, head of pediatric neurology at the UCLA Medical Center, says, in answer to a question about why he didn't recommend the ketogenic diet to the Abramsons, who discovered it for themselves:

Because I don't think we had exhausted all the medical approaches [to treating their son's epilepsy] yet. There were actually still other medications that we hadn't tried yet.

The last is [4]a great talk (9 minutes) by Dr. Deborah Snyder. "To say the ketogenic diet has touched my heart would be a great understatement," said Dr. Snyder.

Tom (2008-06-30 23:08:12)

Carbs are disastrous. Unfortunately for us, they are also incredibly addictive: <http://drbganimalpharm.blogspot.com/2008-05/wheat-would-you-give-your-kids-crack.html>

Dennis Mangan (2008-07-01 18:38:01)

"Carbs are disastrous." Yeah, broccoli and apples and brown rice are just killing us. Watch out for figs and beans too.

Varangy (2008-07-01 21:23:20)

@Dennis Mangan They may well be. <http://www.plantpoisonsandrottenstuff.info/content/toxins.aspx>

... Though there are many toxins and pharmacological chemicals in nature, the following chemicals are found in foods we eat and can cause adverse effects in the wrong individual: Lectins (beans, pulses, grains, nuts, nightshades) Cyanogens, cyanogenic glycosides, and amygdalin (seeds of many fruits and nuts, rose family, particularly amygdaloideae - cherry, almond, peach) Coumarins (tonka bean, woodruff, bison grass, clover) Goiterogens (soya, cabbage family) Alkaloids and glycoalkaloids (diverse sources, caffeine, theobromine, solanine, chaconine, nicotine) Oxalates and oxalic acids (vegetables particularly leafy green, sorrel, spinach, rhubarb) Protease inhibitors (beans)

Aaron Blaisdell (2008-07-02 07:50:15)

So how did our hunter-gatherer ancestors survive? Humans are one of many generalist forager species on the planet (pigs and rats are also generalist foragers). Generalist foragers must learn what to eat from the availability in their environment. Such species typically live in much broader ranges, both in terms of geography and in terms of habitat type. I doubt our HG ancestors sat around the camp fire at night discussing which categories of food were associated with thyroid problems later in life. The statistical associations presented in studies that keep appearing in this and related blogs are weak at best and contentious at worst. Maybe the answer is that, while certain natural foods (plant parts in particular) may have chemicals associated with epidemiologically detectable adverse effects, these effects are too weak to select for a natural mechanism to avoid such foods (e.g., taste detectors). While I take much of what I read in Taube's GCBC to heart, I am not going to give up soy milk (I don't drink that much anyway), dairy (great source of protein, fat, calcium, and Vitamin D), fruits, nuts, or vegetables. I WILL avoid overly processed foods and refined carbohydrates because these things have been so altered that they don't even resemble the thing plucked off of the tree or sheared off the stock. And the scientific and epidemiological evidence for their dietary malfeasance is much stronger. I'm not saying certain people shouldn't avoid certain foods that they know they have allergies to. That makes obvious sense. But to worry about each fruit, vegetable, whole grain, and nut or seed that goes into my mouth just goes too far.

Varangy (2008-07-02 10:53:28)

*Maybe the answer is that, while certain natural foods (plant parts in particular) may have chemicals associated with epidemiologically detectable adverse effects, these effects are too weak to select for a natural mechanism to avoid such foods (e.g., taste detectors).* You are missing one piece of the puzzle. What we know today as fruit and vegetables did not exist in our ancestors' world. Today's fruits and vegetables are distant domesticated cousins — that is, we ate fewer plants than today — of wild plants for which we most certainly developed natural mechanisms such as morning sickness (see Margie Profet) which might be an evolutionary response acting to protect the growing fetus from 'natural' teratogens (toxins that cause birth defects) and abortifacients (toxins that induce miscarriage) found in edible plants. Also, ever try to eat a very unripe apple — you will get sick to your stomach as the apple tree doesn't want its apples to be eaten before its seeds are ready for dispersal — and your body is

clearly reacting to the plant toxins found therein. I don't think we can reject the hypothesis that plant foods may not be harmful.

seth (2008-07-02 10:59:28)

You mean, "plant foods may be harmful"?

Aaron Blaisdell (2008-07-03 06:19:15)

Thanks for your comment Varangy. What you say suggests the hypothesis that there should be a strong correlation between the degree to which modern fruits and vegetables (and tubers, legumes, grains, etc.) have been altered through domestication and with how toxic to the human body they may be. Primates (including Chimps) living in natural conditions eat a lot of plant materials that we also still eat, such as figs. It would be a very interesting analysis (hint, hint, somebody reading this blog).

Dennis Mangan (2008-07-03 07:46:46)

Some plant foods are obviously toxic enough to be considered inedible. As for the ones we do eat, they are indeed loaded with toxins, most of which are identical to the "phytochemicals" and antioxidants that make fruits and vegetables health-promoting, and which is why five or more daily servings are recommended. If anything, I would suspect that domesticated plants would have fewer of these toxins than their wild cousins, precisely because we can care for the former, but the latter are on their own.

Dennis Mangan (2008-07-03 10:15:14)

"New study shows how broccoli helps reduce cancer risk" The study shows that those who ate cruciferous vegetables regularly had changes in gene expression that lower cancer risk. If one wants to consider them toxic, go ahead. Also, I believe that broccoli has been greatly modified by man. <http://www.physorg.com/news134232276.html>

Howard (2008-07-04 08:36:25)

Take eggplant. It used to be white and about the size and shape of an egg. Now it is large, black and squash shaped. Or lima beans. They have 1 % of the cyanide they used to have and produce four times as many beans. Lots of modification going on. Much of it causing health problems. Corn drove out the prior food which had a lot more protein in it (and also did not taste as good).

Tom (2008-07-04 23:26:24)

"New study shows how broccoli helps reduce cancer risk" Rather bizarre study, and certainly a headline that isn't supported by the data. The correct headline would be something closer to, "Certain genetic markers were more likely to change when subjects ate a pound of broccoli a week, relative to eating a pound of peas a week."

Miley-Cyrus-Fan (2008-08-01 10:22:01)

hmm.. thank you very much. usefull information

Marians (2008-08-03 10:37:43)

Yay! Interesting...

## 3.7 July

### Is Childhood Obesity Due to Not Enough Exercise? (2008-07-01 21:54)

As any reader of The Shangri-La Diet knows, I attribute the obesity epidemic to ditto foods – foods that taste exactly the same each time, such as factory food and fast food. We eat a lot more of these foods today than 50 years ago or even 20 years ago.

An alternative explanation of the obesity epidemic that many people believe is too little exercise. People who deal with childhood obesity, in particular, often say the problem is too much TV, too little playground.

If kids are fat due to lack of exercise, more exercise should be a good solution. [1]A new study shows it isn't. It turns out that giving kids more P.E. doesn't cause weight loss:

In studies involving nearly 10,000 children, primarily in elementary schools, none demonstrated a reduction in BMI with those who were assigned to the most phys-ed time, compared to those who didn't have as much.

Via [2]Calorie Lab.

1. <http://www.canada.com/montrealgazette/news/story.html?id=8c57f212-0450-4ba5-bc6a-0505800603fa>

2. <http://calorielab.com/news/2008/06/26/nibbles-more-gym-classes-dont-help-kids-acomplia-okd-in-uk-and-unlocking-the-chocolate-genome/>

---

Nathan Myers (2008-07-01 23:57:03)

I find this result entirely unpersuasive. My recollection of P.E. classes is that they mostly amounted to standing around waiting, with a total of less than ten minutes of movement in any given class period. Such a signal is completely swamped by how far a kid has to walk to the bus stop, never mind whether they ride their bike after school.

Kevin C (2008-07-02 08:50:59)

Well, it seems obvious that the students did get more activity since the ones who had more physical activity had "improvements to bone mineral density, aerobic capacity, reduced blood pressure and increased flexibility." It would probably be best to look at the details of the actual study to see just how much more activity the students got before dismissing it based on your memory of phys ed classes.

Dr. Patrick Havey (2008-07-02 14:18:45)

The obesity pandemic is certainly out of hand and children today are being brought into a world of processed foods with little nutrition. With the digital age in full force, and less 'labor' being performed, the calorie expenditure has declined tremendously. It's easy to get more calories into the diet, and easier to expend few calories, and that adds up to trouble for the health of our country now and for the next generation. We may start seeing heart disease and heart attacks in teenagers very soon. It's not unthinkable that we may be making ourselves extinct considering the course the world is on. It takes moving back to nature - fruits, vegetables, hard work. Science may never be able to duplicate what nature perfected long ago.

Tom (2008-07-03 06:15:33)

The Medifast bars you're pushing - what trees do they grow on?

Mark (2008-07-03 11:27:24)

I think that there are many factors that contribute to it, and changing just one or two at a time is not enough to reach a tipping point to reverse it.

SusanJ (2008-07-04 14:39:05)

I believe there is good epidemiological evidence to show that the rather sudden rise of childhood obesity in the US coincided with the recommendations to lower fat consumption and eat more carbs. IIRC this is documented in Taubes' "Good Calories; Bad Calories." The reason, as Taubes explains in much more detail, is that the body can only store fat in the presence of insulin and carbs cause a rise in insulin. This evidence doesn't negate the possibility that the "ditto foods" setpoint theory could also account for at least part of the rise. High-calorie, high carb foods are especially addictive as well as fattening since the "sugar rush" from the carbs coupled with the high calories increases their addictive power.

Cure of Ars (2008-07-07 09:46:44)

BMI is a very poor measure. It does not take into account muscle gained through exercise. It lists bodybuilders with 6 % body fat as obese and fat people with little muscle as normal. Heavy kids running around in P.E. are going to gain muscle just due to the weight that they are not used to moving around. I know for me that when I exercise that it makes me eat more. This study does not show that exercise does not work; it just shows that it is not sufficient, at least at the intensity level of a P.E. class. Diet is probably the more important factor.

beowulf (2008-07-13 10:17:50)

A daily PE requirement (as Florida recently adopted) is a good idea if only for the benefits to mental health (see John Ratey's new book "Spark"). This study reminds me of two from the 90's that Gina Kolata mentioned in Rethinking Thin- and in a 2006 NY Times article she wrote (quoted below). Kolata makes the point that since the current worldview (fad, frame, paradigm, whatever you want to call it) is that modifying children's diet and exercise schedule is the best way to reduce childhood obesity, no one wants to hear about evidence that it doesn't make a difference in terms of weight loss. A fine example of cognitive dissonance for your Psych students, Seth. :o) "In the 1990's, the National Institutes of Health sponsored two large, rigorous studies asking whether weight gain in children could be prevented by doing everything that obesity fighters say should be done in schools - greatly expand physical education, make cafeteria meals more nutritious and less fattening, teach students about proper nutrition and the need to exercise, and involve the parents. One study, an eight-year, \$20 million project sponsored by the National Heart, Lung and Blood Institute, followed 1,704 third graders in 41 elementary schools in the Southwest, where students were mostly Native Americans, a group that is at high risk for obesity. The schools were randomly divided into two groups, one subject to intensive intervention, the other left alone. Researchers determined, beginning at grade five, if the children in the intervention schools were thinner than those in the schools that served as a control group. They were not. The students could, however, recite chapter and verse on the importance of activity and proper nutrition. They also ate less fat, going from 34 percent to 27 percent fat in their total diet. Alas, said the study's principal investigator, Benjamin Caballero, director of the Center for Human Nutrition at the Johns Hopkins Bloomberg School of Public Health, "it was not enough to change body weight"... The paper appeared in The American Journal of Clinical Nutrition in 2003 to no acclaim, Dr. Caballero said. No press release, no media coverage, no invitations to speak about the results at scientific meetings. On the journal's

Web page, a search of articles that refer to the study comes up empty. It has not been cited anywhere. The second study, of 5,106 children in 96 schools in California, Louisiana, Minnesota and Texas, had a similar design and the same results: all that help made no difference in the children's weights." [http://www.nytimes.com/2006/02/12/weekinreview/12kolata.html?\\_r=1&oref=slogin](http://www.nytimes.com/2006/02/12/weekinreview/12kolata.html?_r=1&oref=slogin)

seth (2008-07-13 11:05:50)  
great comment, thanks!

VesnaVK (2008-08-03 08:53:26)

That's the sort of valuable information in Rethinking Thin that makes me so very disappointed in Kolata's shallow, misguided take on Taubes in her NY Times book review, and her response to Taubes's response to it.

### **SLD on TV (2008-07-03 16:58)**

This coming Wednesday (July 9), [1]Stephen Marsh and I will be on [2]The Morning Show with Mike and Juliet to talk about the Shangri-La Diet. (In the Bay Area, this show starts at 9 am on the FOX affiliate. It lasts one hour.) When Stephen asked his boss for time off,Â she said, "But you've always been thin." Music to my ears.

1. <http://www.blog.sethroberts.net/2006/12/12/stephen-marsh-on-the-shangri-la-diet/>
2. <http://www.mandjshow.com/>

---

buxi (2008-07-04 11:46:42)

Hi! I would like to see that, but i live in Ireland.Is there any chance to put the video on the internet so i could possible watch it latter.

seth (2008-07-04 15:00:43)  
Depends how embarrassed I am!

buxi (2008-07-05 13:03:27)  
lol, you are going to be ok!

## My Theory of Human Evolution (Fourth of July) (2008-07-04 10:21)

Why do holidays exist? For the same reason as festivals, ceremonies, and souvenirs: To increase demand for hard-to-make stuff. This helps artisans at the cutting edge make a living. They are the innovators. Helping them advances technology. Our celebration of Independence Day, for example, creates demand for fireworks, firecrackers, and American flags.

[1]The case of Christmas.

1. <http://www.blog.sethroberts.net/2006/12/24/christmas-an-evolutionary-explanation/>

---

Seth's blog » Blog Archive » My Theory of Human Evolution (directory) (2008-07-04 10:23:40)

[...] Fourth of July (holidays increase demand for finely-made stuff) [...]

mike kenny (2008-07-04 12:27:24)

hm, costume manufacturers would certainly be up a creek if they didn't have halloween, and people talk about hallmark holidays created to sell cards, so that makes intuitive sense. i guess another idea that leaps to mind is that holidays are a time when people are more likely to be focusing on a certain seemingly culturally valuable narratives or sets of ideas. i'm reminded of how muslims have to pray five times a day and have ramadan once a lunar year presumably effectively reminding them of their muslim values. with the fourth of july there's a nice overlap of the commercial ends of holiday's and the end of reminding

people of american values, given american free-market friendliness. :)

Andrew Gelman (2008-07-05 18:12:28)

I love the American flag but I wouldn't call it "hard-to-make stuff" or a product of "artisans at the cutting edge"! I mean, maybe in the Betsy Ross's time, but now???

seth (2008-07-05 18:47:06)

True, not hard to make any more.

### **SLD: "A Lazy Person's Diet" (2008-07-04 23:37)**

I wish I could embed YouTube videos here but it messes up the layout. Especially I would like to embed [1]this charming video from Kevin Mullaney, whom you may remember from [2]an earlier video about the Shangri-La Diet. In the newer video, he calls SLD "a lazy person's diet". I like that!

[3]Kevin's ticker indicates he has lost about 60 pounds. The last 10 were from SLD plus a low-carb diet.

Thanks to [4]Buxi.

1. <http://www.youtube.com/watch?v=BpUL9Io97u8>

2. <http://www.youtube.com/watch?v=CjLU97F0DfE>

3. <http://boards.sethroberts.net/index.php?topic=6427.msg70574#msg70574>

4. <http://sldbuxi.blogspot.com/>

---

Graham English (2008-07-05 07:21:29)

You can change the height and width of youtube videos so they fit your layout. It's pretty easy to find in the embed code. If it's 425x344, change it to 375x303 and it's sure to fit. SLD rules! :)

seth (2008-07-05 07:47:00)

Thanks, Graham. I tried your suggestion but unfortunately it didn't work. Curiously it used to be possible to embed YouTube videos.

buxi (2008-07-05 13:20:33)

yes i remember that sentence too,i identify completely with that,lol. I left a tutorial on my blog to shrink youtube videos if you like.

buxi (2008-07-05 13:24:20)

And thanks for mentioning me :)

### **Short Story of the Year (2008-07-06 15:07)**

"[1]The Headstrong Historian" by [2]Chimamanda Adiche is the best short story I have read in The New Yorker in years, and in the book I am writing now – on self-experimentation – I will quote from it:

How she had puzzled over words like “wallpaper” and “dandelions” in her textbooks, unable to picture them.

No wonder the author won the Orange Prize last year for her novel [3]Half of a Yellow Sun.

[4]An essay by Adichie about being called “sister” contains the following:

The word “racist” should be banned. It is like a sweater wrung completely out of shape; it has lost its usefulness. It makes honest debate impossible, whether about small realities such as little boys who won’t say hello to black babysitters or large realities such as who is more likely to get the death penalty.

In college I wrote an essay saying essentially the same thing about the word scientific – that it was too vague and pompous to be helpful.

[5]A Chimamanda Adiche website.

---

Andrew S. (2008-07-08 00:02:28)

I don't know why they switched away from this logo: <http://www.flickr.com/photos/maoman/34279163/>

**Chocolate is Good For You** (2008-07-09 13:21)

I put cocoa powder in my black tea. I like the complexity it adds and believe it's good for you. More evidence of its health benefits has [1]just been published:

Design: Randomized, placebo-controlled, single-blind crossover trial of 45 healthy adults [mean age: 53 y; mean body mass index (in kg/m<sup>2</sup>): 30]. In phase 1, subjects were randomly assigned to consume a solid dark chocolate bar (containing 22 g cocoa powder) or a cocoa-free placebo bar (containing 0 g cocoa powder). In phase 2, subjects were randomly assigned to consume sugar-free cocoa (containing 22 g cocoa powder), sugared cocoa (containing 22 g cocoa powder), or a placebo (containing 0 g cocoa powder).

Results: Solid dark chocolate and liquid cocoa ingestion improved endothelial function (measured as flow-mediated dilatation) compared with placebo (dark chocolate:  $4.3 \pm 3.4\%$  compared with  $-1.8 \pm 3.3\%$ ;  $p < 0.001$ ; sugar-free and sugared cocoa:  $5.7 \pm 2.6\%$  and  $2.0 \pm 1.8\%$  compared with  $-1.5 \pm 2.8\%$ ;  $p < 0.001$ ). Blood pressure decreased after the ingestion of dark chocolate and sugar-free cocoa compared with placebo (dark chocolate: systolic,  $-3.2 \pm 5.8$  mm Hg compared with  $2.7 \pm 6.6$  mm Hg;  $p < 0.001$ ; and diastolic,  $-1.4 \pm 3.9$  mm Hg compared with  $2.7 \pm 6.4$  mm Hg;  $p = 0.01$ ; sugar-free cocoa: systolic,  $-2.1 \pm 7.0$  mm Hg compared with  $3.2 \pm 5.6$  mm Hg;  $p < 0.001$ ; and diastolic:  $-1.2 \pm 8.7$  mm Hg compared with  $2.8 \pm 5.6$  mm Hg;  $p = 0.014$ ). Endothelial function improved significantly more with sugar-free than with regular cocoa ( $5.7 \pm 2.6\%$  compared with  $2.0 \pm 1.8\%$ ;  $p < 0.001$ ).

Conclusions: The acute ingestion of both solid dark chocolate and liquid cocoa improved endothelial function and lowered blood pressure in overweight adults.

22 g cocoa powder = 2.5 tablespoons. If you live near Berkeley, you might want to attend the [2]Charles Chocolates annual open house, which is this Saturday (July 12) at 2 pm. They are located in Emeryville at 6259 Hollis.

David Marcus (2008-07-10 00:47:06)

studies suggest that cocoa increases insulin response to a meal and that it is bad for the kidneys

Nansen (2008-07-10 12:55:59)

@David Marcus that's interesting. do you have any references to these studies?

Varangy (2008-07-10 15:54:39)

@David Marcus Presumably sweetened cocoa prompts a sig. insulin response – I would assume that unalderated cocoa does not. <http://www.nutritiondata.com/facts/sweets/5471/2> Thoughts?

G. Coker (2008-07-10 18:31:42)

Cocoa powder is healthy. It lowers the blood pressure. Black tea is also health. I am going to try this combination.

Stephen M (Ethesis) (2008-07-10 19:06:13)

Too bad I've an allergy to chocolate.

Stephen M (Ethesis) (2008-08-21 17:28:15)

BTW, you might find this interesting: [http://www.diet-blog.com/archives/2008/08/19/diet\\_and\\_exercise\\_what\\_the\\_research\\_says.php](http://www.diet-blog.com/archives/2008/08/19/diet_and_exercise_what_the_research_says.php)

## GrownChildCam: New Treatment For Depression? (2008-07-11 10:50)

Jacob Nelik, the friend of a friend, is a businessman/engineer in Los Angeles whose business, [1]ISS Corporation, makes high-tech solutions from off-the-shelf components. Their projects include video camera systems for luxury yachts and retail stores, and technical and marketing support to Israel Aerospace Industries for their wiring design software. His mom, who is 85, lives in Israel in an old-age home. She has short-term memory problems. Jacob wrote me:

I try to visit her 3-4 times a year but at this age the feeling of loneliness and emptiness, compounded with the feeling (and fact) that because of distance, I can't come and visit her whenever she (or I) would like to, brought her to a stage where she felt she didn't have a reason to live ("living for what?" as she said). I felt that with my knowledge, experience and the internet, I can make it easier for her. So I utilized a TV set she already owned to create a live picture of me in my office. Whenever I am in the office, she can see me (live). It is on 24 hours a day just like a picture but with live image. I felt that this would bring her closer to me and she would feel (on a daily basis) that I am there with her.

I utilized video parts that my company uses. I took an old home camcorder and connected it to one of the parts we use for our video projects, called a video server or video encoder. It takes the Analog video/picture that the camcorder provides, digitizes it, compresses it, and converts it to IP (Internet Protocol). There are many like this in the market; the one I used allows me to control many parameters including picture compression algorithm, so I can maintain a large physical picture (to fill up the TV screen on my mom's end without being grainy or fuzzy) with high quality, high frame rate, very short delay (under 2 seconds) and very low bandwidth so I can use the cheapest internet service available. On my mom's end, I used the same type of circuit to perform the reverse function (Taking the IP video stream, decompress it and convert it back to an Analog video to be fed into the TV set to the same connector where a VCR is connected). I am skipping some technical details but the net result is high quality video from end to end (when each end can be located at different place in the world).

What happened?

From the moment the system started operating (about a year ago) I could see tremendous positive effects on my mom. She no longer says "why do I need to live, what for?" I can detect a smile in her face just by listening to her. Just yesterday she told me that she saw me eating ice cream at my desk. She mentioned a new shirt I was wearing. It gives her many new conversational topics. She tells me that she enters the room and starts talking to me as if I am there with her. She became much more relaxed and as a result, even her blood pressure is better controlled. It fills a void in her life. It affected me positively as well, because I see how much better she is.

1. <http://www.issc.net/index.htm>

---

Ed (2008-07-11 13:37:07)

Thank you for this great story! This sounds like exactly what I need to deal with the same problem. Where can a mere mortal turn to do the same thing?

s (2008-07-11 16:39:00)  
seeing is believing..

VeganKitten (2008-07-11 18:58:03)  
what a fantastic idea! I wonder if that would help pets too. Highly social, intelligent birds like parrots (left home alone all day) would probably really dig it, and maybe dogs with separation anxiety, too. Cats wouldn't care – as a cat owner I'm pretty sure of this ;) Although I have thought of setting up a cam so I can see what THEY do all day.

seth (2008-07-12 08:55:31)  
"Where can a mere mortal turn to do the same thing?" I suggest you contact Nelik via his business.

peter a blacksberg (2008-07-13 11:10:46)  
I was introduced to picture phones at RIT in 1972. The idea was for deaf students and teachers to use the system. However, it became apparent that seeing each other talk opened a channel of human relationship. I hope this becomes packaged so I can use it with my aging parents. Peter

MT (2008-07-14 10:27:29)  
Great story – this will be a commercial product within the next ten years, to the chagrin of many kids and delight of many parents.

Scott (2008-11-05 21:26:42)  
It's nice that it makes the author's mother and author happy, but is anyone else immediately reminded of Fahrenheit 451?

Laura (2009-07-28 09:45:08)  
Would Jacob be willing to do a step-by-step on this so that some of us with limited resources could consider a DIY project?

seth (2009-07-28 15:00:22)  
Laura, I suggest you ask Jacob that question.

## **Fannie Mae and The Black Swan (2008-07-12 08:14)**

In response to the trouble at Fannie Mae – its stock plunged – we have [1]this:

“There is a sort of a panic going on and that’s not what ought to be,” said Senator Christopher J. Dodd, the Connecticut Democrat who heads the Senate banking committee. “The facts don’t warrant that reaction, in my view.”

Mr. Dodd said that he was persuaded by conversations with Mr. Paulson and Mr. Bernanke that the two companies “are fundamentally sound and strong.”

Nassim Taleb begs to differ – a year ago:

The government-sponsored institution Fanny Mae, when I look at their risks, seems to be sitting on a barrel of dynamite, vulnerable to the slightest hiccup. But not to worry: their large staff of scientists deemed these events “unlikely.”

A footnote on p. 226 of The Black Swan, published April 2007. Asked to comment on the Fannie Mae situation, Taleb replied, “I discuss events before, not after. I despise postdicters.”

1. [http://www.nytimes.com/2008/07/12/business/12fannie.html?\\_r=1&hp&oref=slogin](http://www.nytimes.com/2008/07/12/business/12fannie.html?_r=1&hp&oref=slogin)

---

Dennis Mangan (2008-07-12 11:10:34)

Taleb "despises" most everyone and in his opinion most everyone is stupid, except for himself of course. That's one thing that makes him so insufferable and his books so unreadable. In his first book, "Fooled by Randomness", he bragged that he resisted his editor's efforts at correcting his English, which is his third language. It showed on every page.

seth (2008-07-12 11:54:12)

Dennis, if The Black Swan is "so unreadable" why has it been so popular?

Varangy (2008-07-12 13:48:18)

@Dennis Mangan NNT is certainly arrogant — but why take personal offense? (Personally, I enjoy opinionated arrogant persons as what else is there to talk about politics and religion?) As far as his dismissal of the prediction pundits, he certainly includes himself in that lot – that is what The Black Swan is all about. That WE fool ourselves all the time by fitting a narrative to a certain set of data and ultimately being fooled by randomness. I though his book quite readable and enjoyable. In fact, I have re-read multiple times for sheer enjoyment. IMHO he demonstrated a command of the English language better than 95 % of native speakers. BTW how many languages do you speak, and moreover, can you write in? :) @seth Unfortunately, your argumentum ad populum has to be rejected — why is unbearably unreadable PoMo so popular among the college crowd? :)

Dennis Mangan (2008-07-12 14:09:38)

I haven't read "Swan", simply because, even absent the self-congratulation, "Randomness" was low in substantive content. Taleb constantly boasts about his investment prowess, but to my knowledge has never released any performance data, nor has he given any details of his trades, other than that they are deep OTM puts and calls. I could stand the arrogance if he was actually saying something beyond what would fit into a short article. My own fluency or lack thereof in a 2nd language is irrelevant to criticism of Taleb's writing. That's the fallacy in criticism Johnson addressed 250 years ago. ("Sir, I may not know how to make a table. It is not my business to make a table.") That being said, if I ever wrote for publication in Spanish I'd be more than happy to have an editor go over it.

Ali (2008-07-13 13:24:14)

Dennis - Taleb is arrogant and insufferable at times. And you can argue that this is off-putting. Or that if he had used an editor or made an attempt to be more approachable (in language and tone), then he would have had a larger reading audience. But that's hardly an argument against the content of his books, especially with regard to the specific that Seth pointed out. I admit I suffer from this when the content is politics. I find I have to issue a mental override when an insufferable politician or partisan/ideological think-tanker says something smart or reasonable. It's difficult though and I don't always succeed. Seth - It's not clear to me that everyone who bought his books actually read them. Not unlike the Stephen Hawking fare back whenever. Popularity has a way of snowballing especially when the book is declared smart, innovative or some such. It makes for a good coffee table or bookshelf item. It works for fiction too. One of these days I'll finish my copy of Pynchon's Rainbow.

John S. (2008-07-14 03:42:00)

I agree wholeheartedly with Dennis. The substantive content in "Fooled by Randomness" would fit on a matchbook cover, with room left over. Having been fooled once, I decided to skip "The Black Swan". Is it anything more than a rehash of his first book?

seth (2008-07-14 06:00:15)

"Matchbook cover"? Here's something that fits on half a matchbook cover: Faces in the morning push an oscillator that controls mood. Little things can have big implications.

Nansen (2008-07-14 11:09:16)

William James, in Lecture I of Pragmatism (1907) wrote: Whatever universe a professor believes in must at any rate be a universe that lends itself to lengthy discourse. A universe definable in two sentences is something for which the professorial intellect has no use. No faith in anything of that cheap kind!

c. (2008-07-14 14:07:56)

Generally agree with Dennis, here. Don't know that I would call Fooled or Black Swan "unreadable" – they read relatively easily and the writing style (if not the tone) is compelling. They're "unreadable" in the same way that cheez whiz in "inedible." It's technically edible, but lacks nutritional value, tastes bad, and hurts your stomach later. While I agree w/ Seth's point that little things have big implications, I see a real difference between Seth's example, which suggests a concrete relationship or effect, and suggests actions to test or exploit it. Taleb's thesis in Fooled and Black Swan, are, as near as I can tell: "Shit happens. If you can manage to bet on it (or insure against it), you might make money." And while Taleb had two books to spell out the concrete implications of his thesis and test them, he didn't. Instead he spent a lot of words railing against perceived lesser intelligences and making up loopy new buzzwords.

seth (2008-07-15 05:31:02)

Very nice quote, Nansen.

Ian Marion (2008-07-16 23:11:54)

I read both books and enjoyed them. NNT's message is I think, simple. Do not take the "experts" at face value; the best laid plans often fail due to unpredictable outside circumstances. As you pointed out Seth NNT is right when it comes to Fannie Mae, full stop!

Jeff (2008-07-23 18:03:42)

I was just witnessing congressional spending at its finest when it bailed out Fannie Mae and Freddie Mac as well as all those folks who were dumb enough to get in over their heads on mortgages when I realized what was happening. We are now losing our ability to hold ourselves individually accountable for our actions. Collateral damage is the ability to hold others accountable as well. Individual bankruptcy, stomach staples, misbehaved children at restaurants, public profanity, credit card debt and other excesses that are largely caused by the lack of individual self control are entry points for collective controls over everyone's lives. Those of use who are responsible are left exposed to unnecessary controls, laws, and limits on our freedom. Now on to the collateral damage – we can no longer hold companies (unless you are an oil company), government, or groups accountable for their terrible lack of control either. When are we going to hold the US Congress and members of either party responsible for ANYTHING? Last I checked they made the laws that allowed the current banking and real estate crisis possible (besides the dumb individuals). They are also the same group who thinks that those of us who have behaved responsibly should be taxed on some of our hard earned 401K savings – no kidding. How about the companies who thought sourcing everything to China was a great idea for costs, now we have lost numerous jobs – where is the outcry about China's human rights violations. Lastly, where is the press? Where is the in depth analysis of the cost of oil and the real reason for the supply side issues, or the pollution caused by third world countries. I see so much written negative about the United States it amazes me how we gloss over far more significant violators on this planet and give them a free pass. Did you know that China is shutting down factories up wind of Beijing prior to the Olympics so it does not appear too polluted? When are we as Americans going to say enough and hold individuals and the groups to which they belong accountable?

J. Joseph (2009-09-11 04:55:26)

With regard to Fannie Mae, I would say NNT turned out to be a prophet. Whether he is a polite prophet, I am not sure. I found the first hundred pages of Black Swan rather uninspiring, but liked it as I gained momentum. The digressions in his book are heavier than the main story. And he deliberately used polemics, which I don't believe is his true nature, but more of a

marketing ploy. That he was rather concerned about sales is evident from the many references to book sales in *Black Swan*. But in the end we must appreciate him for the counter-intuitive insights presented in his book.

J. Joseph (2009-09-15 03:25:45)

Gaussian distribution talks only about the probability of occurrence of events. Nicholas Nassim Taleb talks about the impact of the occurrence of improbable events. Probability of occurrence and impact of occurrence are different. It seems Taleb inadvertently or deliberately wrote his book as if they are the same.

Fannie Mae (2009-12-31 17:53:08)

Seth's blog » Blog Archive » Fannie Mae and The Black Swan was very interesting while I was researching fannie mae for our next generation game. We wanted to created an up to the minute version of Bailout! The Game.

### **David Lawrence: Down 100 Pounds! (2008-07-13 07:22)**

I met David Lawrence when I appeared on [1]his radio show [2]a year ago. Since then, he has lost more than 100 pounds. He started at 355 (BMI 50); now he's at 246 (BMI 34). Very impressive. How did he do it?

I'm not really doing anything special other than portion control (very easy, just eat a little not everything), and being more active. Occasionally I'll remember to drink a Mexican Coke [he lives in Los Angeles] an hour or so before a big meal, and that cuts it down to size, but I can't really claim that I'm following the SLD regimen. More like, I park in the first spot I come to in the parking lot, and walk to the buildings. Feels great.

There seem to be three changes here: 1. Eating less. 2. More walking. 3. Mexican Coke before some meals. I am skeptical that trying to eat less can have massive long-term effects, so I discount that factor completely. More walking can certainly be potent if pre-walking you are very sedentary, as perhaps David was. I've never heard of anyone losing 100 pounds by walking more, however. And the additional walking doesn't sound like much.

So perhaps the Mexican Coke before big meals is actually doing something. This is fascinating because in general soft drinks are fattening. (They are the perfect ditto food: strong constant flavor, quickly-digested calories.) Yet it is possible that with this particular timing the calories in the Coke don't get associated with the flavor of either the Coke or the following meal. If so they would function as SLD calories and that could indeed cause substantial weight loss (or at least make it much easier to do portion control).

There isn't any precedent in the study of learning for "associative strength" (generated by the calories) to get lost, as it were, but then no one would ever look for such a thing. Normally the flavor of the Coke would hang around in the brain waiting for the calorie signal generated by the sugar but when the meal comes along the flavor signal gets muddled. Perhaps combining the Coke flavor memory with a wide range of other flavor memories creates a jumbled mess that is so inconsistent that the Coke goes from ditto food to the opposite, completely-new-flavor food.

David will appear in two episodes of [3]Heroes in October.

1. <http://www.thedavidlawrenceshow.com/index.html>

2. <http://www.blog.sethroberts.net/2007/07/08/an-sld-marketing-puzzle/>

3. <http://www.nbc.com/Heroes/nexton/>

---

buxi (2008-07-13 14:31:53)

Thats really intriguing. I noticed that here in Ireland that the coke tastes really diferent from the coke in Portugal, i really dont like it. Maybe there is a remote possibility that the coke as some kind of unusual flavor? Before i used oil in SLD i used candies with some "flat" flavor, exactly before lunch and it really toke my appetite away. Maybe there are some particular flavors that are "null" besides salt and sugar.

Stephen M (Ethesis) (2008-07-13 20:24:23)

Interesting. My mother got started, lost a fair amount of weight, but didn't need to keep taking the SLD calories once she had lost 20-30 lbs. I think the way he talks about the Mexican coke cutting meals down to size is interesting. You've hit an interesting facet, many people do experience spoilers for meals. Some people can spoil their appetite (I never could, it just ramped it up so I could eat more).

seth (2008-07-13 22:09:23)

Salt and sugar are null because when dissolved in water they have no smell. They are detected only by the tongue, not the nose.

ame (2008-07-13 22:55:10)

Dear Seth, I'm now following this diet since 1 week ago and I've lost 3 kgs, thanks for the inspiration, first I've trie ELOO but it turns unuseful for me, then I tried sugar,...then here I am losing 3 kgs, well, still got 12 kgs to lose, wish me best luck on my program

Douglas Clegg (2008-07-14 15:50:42)

Doesn't Mexican Coke use real cane sugar as opposed to corn syrup that's in U.S. Coke? Are we all going to be terrified if that's the secret to a lot of weight problems: the overabundance of corn syrup in our diets since the 1980s or thereabouts?

Stephen M (Ethesis) (2008-07-14 16:42:45)

About fructose, here is an essay by a group of self- and small-group experimenters. [http://www.figureathlete.com/article/diet\\_and\\_nutrition/the\\_low\\_fructose\\_diet](http://www.figureathlete.com/article/diet_and_nutrition/the_low_fructose_diet)

Douglas Clegg (2008-07-16 14:55:03)

Stephen - Thanks for that link. I will herewith go fairly low fructose (particularly of the corn variety.)

Janet (2008-08-01 22:54:10)

Yes, Mexican Coke does use real cane sugar. There is another brand of soda called Jarritos. It also uses sugar and has interesting flavors, such as tamarind.

## **SLD on TV (postmortem) (2008-07-14 06:08)**

On Wednesday Stephen Marsh and I appeared on The Morning Show with Mike and Juliet to talk about the Shangri-La Diet. The clip, alas, is no longer available. There were two critics: a doctor and a dietician. A friend of mine was amused by the doctor's belief that because someone from Berkeley had criticized the diet it couldn't be any good. [1]Discussion in the SLD forums. Before the segment, the producer said to me, "What happens determines the length. If it's interesting, it will be longer. If it's boring, it will be short. That's just the reality." It was really short. If she hadn't told me that . . . I felt bad for a while but other people convinced me it was okay. I'm pleased by the publicity, of course. Overall, I like the show; I like its focus on everyday issues and problems.

Two other diets were covered in [2]the previous segment: [3]The Flat Tummy Diet and [4]The Warrior Diet. The author of the latter [5]wasn't pleased.

[6]Stephen Marsh answers the critics.

david (2008-07-14 08:37:14)

> "What happens determines the length. If it's interesting, it will be longer. If it's boring, it will be short. That's just the reality." That was your cue to hit someone with a chair during the segment. You see, these shows aren't scripted at all, but if you want your segment to be long, you do need to find some spontaneous, honest, authentic way to make it interesting. Hitting someone with a chair for example. That's just "reality."

buxi (2008-07-14 08:38:38)

I think you have to have some brain to understand this diet.

Aaron Blaisdell (2008-07-14 08:40:02)

Seth, This is the second time I've seen you criticized by a nutritionist for the fact that you are a psychologist. Both times, they suggested that psychologists have no business giving nutritional advice. You really should remind these people that nutrition is a sub-discipline of physiology (or should be!), and that the scientist that discovered the type of learning that underlies the SLD was Ivan Pavlov, a famous Russian physiologist. Physiologists (including learning psychologists) are probably more qualified to discuss diet and nutrition than are most nutritionists which don't have a strong background in physiology.

Aaron Blaisdell (2008-07-14 08:47:27)

Oh.. and you should beat them in the head with a chair while telling them this.

Varangy (2008-07-14 09:52:53)

I think Taubes compellingly demonstrated that historical nutrition science is anything but...

Stephen M (Ethesis) (2008-07-14 10:00:55)

Liked the chair suggestion. They already had the next clip up, so I suspect that it didn't matter how interesting anyone was. Still, it was great to meet Seth face to face.

david (2008-07-14 11:32:36)

I just watched the clip. Pretty amazing when they say "He didn't lose weight because he drank oil. He lost it because he ate less food." They did deserve to be hit with a chair, but I can see where that wouldn't have advanced your cause any. Anyway, things like this remind me why I don't own a TV.

Darkhorse (2008-07-14 14:44:28)

"Still, it was great to meet Seth face to face." I'm so jealous of you, Stephen.

Nile (2008-07-14 17:15:01)

The link seems to have been taken down or broken. I get a 404 error when I click on the link. Is it just me or do others have that problem.

Stephen M (Ethesis) (2008-07-14 19:11:59)

Darkhorse, well, maybe on his next book's tour. BTW, just checked Amazon. Amazon.com Sales Rank: #9,378 in Books (See Bestsellers in Books) Popular in this category: (What's this?) #47 in Books > Bargain Books > Health, Mind & Body Good move from over 100,000

Tom (2008-07-14 19:56:42)

I was able to find the first segment at <http://www.mandjshow.com/videos/âœm j-investigatesâœ-new-dieting-trends/> but the 2nd segment (with SLD) is missing. Can anybody find it?

Valerie (2008-07-14 19:57:49)

Losing weight is all about controlling the 2 hormones - insulin and glucagon. Insulin stores energy (fat), glucagon releases energy. This is easily manipulated by the foods you eat. Get this right, and the weight will just fall off. I went from over 150 pounds to 119 in a very short time.

Tom (2008-07-14 20:43:02)

"Valerie," or should I say Jason LeGris, you have built the phoniest affiliate squeeze page I have ever seen. (And it takes a bit of gall to promote a diet that rips Seth's work off on his blog!)

Tom (2008-07-14 21:09:41)

And it's even more impressive that "Valerie" managed to write ten weeks of blog entries...considering the blog was created yesterday. [http://who.godaddy.com/Whols.aspx?domain=myfatloss4idiotsjournal.info &prog\\_id=godaddy](http://who.godaddy.com/Whols.aspx?domain=myfatloss4idiotsjournal.info &prog_id=godaddy)

Laura (2008-07-15 07:47:16)

David wrote: I just watched the clip. Pretty amazing when they say "He didn't lose weight because he drank oil. He lost it because he ate less food." Was that not the stupidest thing you've ever heard? Did that woman think Seth was claiming some sort of magical fat-burning properties for the oil? Ugh. I agree...chair throwing was in order. And re: "Valerie"...hilarious!

seth (2008-07-15 09:05:49)

Yeah, saying he lost weight "because he ate less food" is some sort of low point. Aaron, that's a good point about Pavlov. Yeah, I should do that.

Aaron Blaisdell (2008-07-16 09:34:18)

Wait a minute. I thought the whole point of the SLD was that it allows the body's set point to move to a lower value, which then leaves you less hungry, so that you eat less. Wasn't this the logic presented in the book? So in a sense the critic was right, Steve lost weight because he ate less. But what allowed him to eat less was that drinking the flavorless oil caused his set point to lower which thereby reduced his hunger and cravings, thus leading to a reduction in caloric intake (smaller, less frequent meals, loss of appetite for ditto foods, etc.). So the critic was right, but failed to see the significance of the oil in kick-starting and maintaining the weight loss.

Chaim Rubin (2008-07-20 13:45:27)

I found the second (SLD) segment Googling this site:<http://www.mandjshow.com investigates trends> The page is gone or broken but click 'Cached' below the link with -continued in the URL and you will find enlightenment (actual

link:<http://209.85.141.104/search?q=cache:0bnSNMkYoZYJ:www.mandjshow.com/video/%E2%80%9Cmj-investigates%E2%80%9D-new-dieting-trends-%E2%80%93continued/+site:http://www.mandjshow.com+investigates+trends&hl=en&ct=clnk&cd=2&gl=us> Get it while it's hot. I may try this. I have not watched TV for years, and found the panel including the accredited ones to be buffoons, but maybe they were instructed to be confrontational. There is a big trade off trying to discuss anything intelligently in that kind of forum. All three diets look fine, I guess the quest for Shangri-La is to work smarter and not harder

VesnaVK (2008-08-03 08:39:11)

"S/he just ate less food, that's all" is also a common criticism of low-carb approaches to weight loss. I've never understood how it's supposed to translate to a negative comment, but somehow people mean it that way, and take it that way. If eating less leads to weight loss (I don't agree with the positive/negative energy balance theory of fat accumulation and loss, so I say "if"), then wouldn't anything that helps you eat less without suffering be a good thing?

Stephen M (Ethesis) (2008-09-09 10:50:16)

**But what allowed him to eat less was that drinking the flavorless oil caused his set point to lower which thereby reduced his hunger and cravings, thus leading to a reduction in caloric intake (smaller, less frequent meals, loss of appetite for ditto foods, etc.). So the critic was right, but failed to see the significance of the oil in kick-starting and maintaining the weight loss. Exactly.**

## Who I'd Like to Meet (2008-07-15 05:56)

At dinner I asked my friend who he'd like to meet. "Good question," he said. Let me try to answer it:

1. [1]John Horton Conway. A Princeton math professor who's combined math and human interest better than anyone since John Von Neumann. I especially like his work on numbers and games and [2]The Book of Numbers, which he wrote with Richard Guy.
2. Lauren Collins. She and Mark Singer are the best writers at The New Yorker. As I [3]recently blogged, I loved [4]her profile of Pascal Dangin.
3. [5]Chimamanda Adichie. I [6]blogged about [7]a recent short story of hers. Reading her reminds me how I used to read lots of fiction and how much I liked it.

The person I don't know who I most wish would write another book is Renata Adler. If a book can be stillborn, [8]Private Capacity, supposed to be published in 2002, was that. From [9]Wikipedia: "Renata Adler's investigation of the Bilderberg group reveals the true history of the organization, its membership and its nebulous function. With an astonishing cache of Bilderberg archives and secret files, Adler charts the history of the organization and the extent of its power." Sounds like it exists, doesn't it? It ranks 5 million on Amazon, maybe because I ordered a copy. Second most: Ben Cheever. I loved [10]Selling Ben Cheever.

1. [http://en.wikipedia.org/wiki/John\\_Horton\\_Conway](http://en.wikipedia.org/wiki/John_Horton_Conway)

## Should Those Who Are Part of the Problem Be Part of the Solution? (continued) (2008-07-15 23:24)

In the last chapter of The Shangri-La Diet and [1]this post, I said it was foolish for those who want to improve the world to denigrate those in industry. ("[Food] companies will put anything in their food if they think the extra marketing hype will help them sell more of it," said [2]Marian Nestle.) [3]A recent article in the NY Times described in detail how a wash-your-hands campaign became more effective by studying industry tactics. The head of the campaign said pretty much what I've been saying:

"For a long time, the public health community was distrustful [not to mention scornful] of industry, because many felt these companies were trying to sell products that made people's lives less healthy, by encouraging them to smoke, or to eat unhealthy foods, or by selling expensive products people didn't really need," Dr. Curtis said. "But those tactics also allow us to save lives. If we want to really help the world, we need every tool we can get."

And every person.

Thanks to Marian Lizzi.

2. <http://www.nytimes.com/2007/01/14/business/yourmoney/14omega.html?ex=1186632000&en=b311b8942efb47dd&ei=5070>

3. <http://www.nytimes.com/2008/07/13/business/13habit.html?ei=5087&em=&en=32fb055cb7b06b25&ex=1216267200&pagewanted=all>

---

Dr. Patrick Havey (2008-07-16 10:44:22)

There's no doubt that those who sell fast foods that are unhealthy try to position themselves as having a solution to the obesity epidemic by marketing 'healthy salads' or other healthy items, when in fact 90 % of what they're serving is unhealthy. We purchased hamburgers from a fast food restaurant and have kept them, with no preserving techniques, and have seen NO deterioration or breakdown of them. They look the same. (You can view them here - <http://www.GuessTheAge.com>) Companies can't have it both ways - they're either a part of the problem or part of the solution!

## Blog Power (three parts) (2008-07-16 06:42)

Part 1

[1]Irena Briganti is a widely-feared Fox VP of media relations:

Though one of Briganti's favorite pastimes is [2]leaking to blogs, she'll come to find that her detractors can do the same thing just as easily. Blogs are far less likely to cower in the face of a threat of "denied access."

## Â Part 2

Before I became a blogger, I spent my entire 20's trying to become an academic (English and critical theory was my focus). While I struggled to produce a handful of conference papers or publishable articles during that decade, in my four years as a blogger I have published about 4,400 articles that have received about 50,000,000 direct page views, 46,000 incoming links, and over 100 Lexis Nexus mentions. Had I stayed in academic, none of this would have been possible, and I would have continued to receive an endless series of rejections from the gatekeepers. The "experts" that Appell describes did not see the same value in my writing huge numbers of other people clearly have.

From [3]Chris Bowers.

## Part 3

Yoely made some compromises. He miscalculated, however, when he wired his home with Internet access. "He thought, If I give her this, then she'll shut up and be satisfied," Gitty says.

"Once I read blogs from people who had gotten out of places like KJ, there was no turning back. Yoely begged me to stay. It is humiliating for a Satmar man to have his wife leave him. But it was too late," says Gitty, who would start her own blog, 1 Beautiful Stranger, where she wrote about her misplaced life in Kiryas Joel.

From [4]New York.

## Cheap vs. Expensive Wine (2008-07-16 10:20)

The Harvard Society of Fellows, I learned from this [1]great post by Steve Levitt, drink expensive wine – like \$60/bottle. Steve, who was a Fellow for 3 years, did a simple experiment that showed the other members couldn't tell expensive wine from cheap wine. Although the other members had liked the idea of doing the experiment, they didn't like the results:

There was a lot of anger when I revealed the results, especially the fact that I had included the same wine twice. One eminent scholar stormed out of the room stating that he had a cold "otherwise he would have detected my sleight of hand with certainty.

Stormed out of the room! Why were they so angry? I think they were embarrassed. And not just that. Steve doesn't say it, but I think there had been lots of dinner table conversation about how great the wine was. Now all that conversation was revealed to be delusional. Noting the greatness of the wine was – to be crude about it – a way of noting the greatness of those assembled at the table. "We appreciate the finer things in life," they were saying. "We deserve to be here." Snobbery is reassuring. In a tiny voice, the results said, yes, you are here, congratulations, but the reason you are here is more complicated than "you deserved it".

1. <http://freakonomics.blogs.nytimes.com/2008/07/16/cheap-wine/>

---

Stephen M (Ethesis) (2008-07-16 10:25:46)  
That is an interesting observation.

Brent Pottenger (2008-07-16 10:44:20)

At the world-renowned Viticulture and Enology program at UC Davis, the message is two-fold: Primo, "Average \$10 per bottle of wine in your consumption schedule," and Segundo, "If you buy a bottle of wine that costs more than \$25, especially if it is over \$50, make sure that everyone drinking the wine knows exactly how much you paid for that bottle."

Darkhorse (2008-07-16 11:11:34)

At a Christmas party last year, we conducted a similar experiment, with a similar result, on our (now former) wine-snob friends. We thought it would be a hoot. Interesting how snobs are totally without humor. Also, thanks for quoting from my other favorite blog.

Chris B. (2008-07-16 12:27:07)

Next time you have a dinner party, blindfold your guests and see if they can tell the difference between white wine and red wine. I failed! Still, there is an obvious difference between home-made wine and \$15-a-bottle stuff, and between \$15 wine and \$30 wine (I'm less sure of this, because I don't drink much \$30 wine). Above \$30? I doubt it matters.

Aaron Blaisdell (2008-07-16 15:12:28)

The quality of a wine is only weakly positively correlated with its price. It is also true that there are more poor quality wines at lower prices (e.g., less than \$10 a bottle) than at higher prices. This is simply because consumers will not pay high prices for low quality wine, and the critics will out them pretty quickly anyway. But at lower prices, there are many gems to be found! I've been really enjoying delicious wines at great values (less than \$12 a bottle) currently being exported from Spain, Italy, Chile, and Argentina.

cyates (2008-07-16 17:34:12)

Seth, in one of your previous posts I remember you noting that developing your palette and allowing you to distinguish between low and high quality actually increased the pleasure you got out of consuming the high quality goods. This would suggest you disagree with Levitt's idea that 'ignorance is bliss' when it comes to wine.

seth (2008-07-16 17:49:40)

that's true, cyates, I do disagree with Levitt that ignorance is bliss in this case. Lately I've been buying two bottles of wine from the same grape – e.g., two bottles of sauvignon blanc – and doing blind comparisons. Eventually I can tell them apart. And it does make me enjoy that type of wine more.

Matthew (2008-07-17 00:08:58)

The comments from cyates are just what I was thinking when I read this post. Actually, when I read Levitt's original piece, my first thought was that you would be rolling your eyes at this. Part of that was my knee-jerk reaction to what I perceive as other economists getting a little too enamored with their own cleverness and "discovering" something that experts in the fields they're colonizing have known all along. Wow, so experts know good wine and non-experts do not-this is surprising? The implication is that non-experts have nothing to gain by developing a palette for good wine? It wasn't long ago that I would have picked a soda over a beer. It's cheaper too! The authors of this paper would have suggested that I had nothing to gain by developing a taste for the more complex but more expensive beverage (actually, it seems like their assumption is that taste doesn't develop at all). But now, even though I'm poorer for it, I enjoy the drinking experience more. Also, trotting out the "finding" that price does not equal quality, which is nothing more than a misconception by people who don't know anything about wine, hardly makes this experiment a worthwhile enterprise. Their interpretation of their finding is that non-experts shouldn't rely on the opinion of experts or price in making wine choices. But among non-experts, casual white zinfandel drinkers won't be reading those opinions anyway, and eager learners may be developing an appreciation for those wines that they wouldn't have picked in a taste test. According to these authors though, they should have stuck with soda! Investing in enjoyment that may come in the future as well as enjoying the hobby of learning more about wine doesn't figure in to their interpretation (in the conclusion or abstract, anyway).

Stephen M (Ethesis) (2008-07-17 05:19:19)

A great related post is: <http://ozarque.livejournal.com/536010.html> The real story about wine and beer is the same as random flavors mixed in with butter and served on toast – you can learn from the calorie and alcohol associations a good amount that makes you appreciate rotted fruit and grain better. Note that without alcohol, the market in premium near beers just hasn't done well, in spite of numerous efforts.

seth (2008-07-17 07:59:36)

I seem to have mistitled this post. To me the fascinating thing about Steve's story is how angry the Fellows got. Do you think I'm right that they were embarrassed? If so, why? They're not wine experts.

Lose 10 Pounds In 7 Days (2008-07-17 12:41:07)

I think that it was embarrassment. Since they talk about something so much and act like they know what their talking about, only to be exposed as "phonies" can be quite humiliating. Very interesting experiment but I'd like to know the psychology of their angry reaction more in depth.

Tim Lundeen (2008-07-19 14:01:21)

Great links, thanks! I particularly liked the talk by Sam Gosling, and ordered his book. Some interesting insights. He says that you can't get much information about someone from one observation, that you need to put together a number of data points. This reminds me of gene analysis, where knowing one allele for an individual doesn't give you much information, but from 100 alleles you can make a number of predictions with high probability of being right. I don't agree with Gosling's conclusion that some people are inherently messy, even though they want to be neat and organized. My experience is that a lot of being organized comes from training and learning good techniques: I know my life was changed by two books, Marla Cilley's Sink Reflections and David Allen's Getting Things Done. Allen's rule is to do things that take less than 2 minutes right now, instead of putting them off. Just following this one rule makes a dramatic difference, and it isn't hard to do.

seth (2008-07-19 14:06:50)

Thanks for the comments, Tim. I've known Gosling a long time; he was a grad student at Berkeley.

### **Interview with Bruce Gray, Web-Savvy Sculptor (part 1) (2008-07-19 06:07)**

Wandering around the [1]Brewery Art Colony in Los Angeles with [2]Len Mlodinow, we met [3]Bruce Gray, a sculptor who works there. I was amazed how much the Web helps him sell his work. Later I interviewed him about it.

ROBERTS What were you doing before you were a sculptor?

GRAY I was living in Boston and I was working in advertising as a graphic designer and I also worked as a photographer.

ROBERTS When did you make the transition?

GRAY January 1989. I moved out to Los Angeles and I pretty much jumped right in with both feet. I got a studio and just started making stuff. It just took off from there.

ROBERTS What gave you the confidence to do that?

GRAY Probably lack of planning and thinking things out. I don't know if it was actually the smartest move to try to do something like that. It's certainly been a bit of a struggle. But it's the kind of thing that when you have a dream of something that you want to do bad enough, you just have to make it happen. I think that's kind of half

the battle and there was nothing that I wanted more than to try to be able to make my own art creations and make a living off that.

ROBERTS Had you gone to art school?

GRAY I went to school for design and photography and of course I took all kinds of art classes as well—design and illustration and sculpture, photography.

ROBERTS Where did you go to art school?

GRAY University of Massachusetts.

ROBERTS When you were doing the photography and graphic design, you took other people's ideas and executed them.

GRAY Right. And that's what I kind of got tired of, actually. I really do like doing graphic design—things like logos and stuff. The interesting jobs were few and far between and I wanted to do something that I had more control over, and also something a bit more permanent. I just wanted to make my own legacy, I guess.

ROBERTS How did you manage to sell your first sculptures?

GRAY Well, it wasn't easy. I really didn't even know L.A. hardly at all, so I went around to galleries; I went around to a lot of the high end furniture stores were really my first big clients, near the Pacific Design Center. There's a lot of high end furniture stores down there and a lot of those guys became clients pretty quickly and it got to the point within, oh, just a year or so, they were ordering quite a few of my early pieces at a time and that's been keeping me quite busy.

ROBERTS So they would place your pieces next to their high end furniture and their customers would buy some of them. Is that how it worked?

GRAY Right. Also, a lot of what I was making at that time was more furniture—a line of unique art furniture, like my red, angry dog table and my s-shaped aluminum form table. Things like that were very popular. I think I sold probably fifty of those form tables, mostly all back in that time. But people have a very different view about furniture than they do about sculpture. It's way easier to get money for sculpture, comparatively to furniture, and a good example of that is: I had one furniture store, and I had a very interesting table that I had made, all these intersecting shapes and aluminum and it was kind of expensive and they were having a hard time selling it. They decided that it just looked so cool that they would put it up on the wall and see how people reacted and it sold within just a few days of doing that.

ROBERTS You mean they took it off the floor and they put it on the wall and it sold quickly?

GRAY Exactly. And that's just the difference in perception. People think, "oh well, for that many thousands of dollars, how much can I get at IKEA," or whatever. I don't know how they think about it, but they certainly

have a much harder time spending the comparable money for furniture over sculpture.

ROBERTS Wow! I would have thought that it was the opposite. You can use the furniture.

GRAY Right.

ROBERTS When did you learn that lesson?

GRAY It was quite a long time ago.

ROBERTS Within the first year of selling the stuff?

GRAY Within the first three years, probably. But then I've gotten more into doing the sculpture stuff instead. I still like to do the furniture pieces, but I'm also not going to kill myself to make pieces that I have to sell for less than I think they're worth just because that's the way the market works.

ROBERTS So you're saying that with sculpture it's easier to get the price you think it's worth.

GRAY Exactly.

ROBERTS So you shifted from the furniture-like stuff to the sculpture-like stuff. Is that a fair description of what you've been doing since then?

GRAY Yes, but I still do some of the furniture stuff, just not that much and mostly by commission. If someone sees something that I've done that they like or they like my work and they want something custom done, then I'll do that, but they're going to be paying my sculpture prices for that stuff.

ROBERTS When did you get interested in the internet?

GRAY Pretty early on. For someone like me that can end up needing to do some research on a fairly regular basis . . . there's a lot of times I may just need an image of a certain kind of insect or something like that, and the internet is just a ridiculous amount of searchable information. You can spend the rest of your life just looking up insect pictures.

ROBERTS So true.

GRAY As many images as I want, the videos; it's like the encyclopedia on steroids. Anything is there that I need for research. Initially I had wimpy websites, through AOL or Earthlink, those things are really kind of half-assed; they don't really do much of anything. But I quickly realized that the internet is worldwide and it's open 24 hours a day, seven days a week. No one else is pushing my work like that. And I get contacts with people from other states and other countries—there's just no way I would have had these kind of distant contacts without the internet.

ROBERTS Before the internet, how did you usually sell your stuff?

GRAY Mostly through the local high-end furniture stores, the art galleries, direct mail—I do a lot of postcards that I mail out. That’s actually worked out to be a pretty good thing too.

ROBERTS You mailed out postcards?

GRAY Yes. The first postcards I ever mailed out, I ended up getting one of my long-term collectors off of that mailing—they ended up buying three or four pieces for their company, and then they bought another eight pieces or more over the years for their home, and that’s all from one postcard.

ROBERTS Where did you get the mailing list for that mailing?

GRAY I just looked around and came up with it myself, basically looking through interesting businesses that can relate to modern art, the film industry people, things of that nature, the Academy of Motion Pictures was actually the one that ended up buying a bunch of stuff.

ROBERTS Oh my god, you didn’t buy someone else’s mailing list? You made the mailing list yourself?

GRAY Right.

ROBERTS Wow! When did you do that?

GRAY When I first started, pretty much.

ROBERTS 1990?

GRAY Right.

ROBERTS Okay, so you were selling stuff that way, and then the internet comes along, and you have a wimpy home page, and then what happened next?

GRAY Then I decided that having a web page is the only way to fly. I just knew that this was the thing to do and I’ve always felt that I was pretty savvy with computer programs, at least things like Photoshop, but putting the web stuff together, I really didn’t know how to do it, so initially I had a friend of a friend doing some of the stuff for me. He never had time, it was expensive, it would take me weeks to get any update done and I’m thinking to myself, well this is ridiculous. I’m going to be using this website for the rest of my life, so I might as well just bite the bullet here and buy the program and take a class or whatever I have to do. So I bought Dreamweaver and ended up paying a guy to give me private lessons for about eight to ten hours or so, and a few weeks later that guy’s calling me up to ask questions.

I picked it up pretty quickly and it’s been the greatest thing I ever did. Like today alone, I just took a picture of my latest wall sculpture and boom, it’s already up there. I photographed it digitally and put it right up. There’s no middleman, there’s no problems, no delays. It’s a very workable system not only for the artist but basically for any entrepreneur or sole proprietor who’s running their own business.

ROBERTS When did you figure out that this was the way to go? Why did you think, in the very early stages, that this was going to be so great?

GRAY Because it just seemed that was nothing else really like it in the world, where you could connect with people, distant people. One of my best friends has always told me that if you really want to succeed in the art world, the biggest mistake you can make is trying to rely on your home market alone. Even a city like L.A. If you try to just sell your work here, youâ€™ll probably never have your bills caught up, so you have to get your work in front of people from other cities and other countries and the web is the way to do it for free, you know?

ROBERTS Yes. Well, youâ€™re in a building with 30 or 40 other artists, right?

GRAY Well, Iâ€™m in a complex with somewhere over 300-something studios and well over four hundred artists. Itâ€™s supposed to be the biggest art complex in the world, they say.

ROBERTS Do they all agree with you? Do they all have their own web site?

GRAY I would say that just about everybody does at this point. A lot of them have taken my word for it and I had to talk them into it.

ROBERTS You were the first person.

GRAY I was definitely one of the first. To be honest, though, a lot of my artist friends who have done websites have told me that theyâ€™ve never sold anything from it. Even a very well-known successful artist whoâ€™s a good friend of mine—heâ€™s told me that heâ€™s never sold a single piece. A lot of it is what you put into it—you canâ€™t just throw some images up on a website and expect that to be changing your world for you. I spend several hours every week, minimum, adding new stuff and trying to get additional links and things into the site. Right now, the parameters for what ranks you highly keep changing on quite a regular basis, but the thing that is very important right now is good qualified links into your site, especially from things like publications, universities, museums, things like that. A link in from your sisterâ€™s cat website is not going to rank that highly, but valid press links weigh very heavily.

ROBERTS How do you go about getting those links?

GRAY Most of them come naturally from people whoâ€™ve done articles on me and stuff like that, and other times I go around to all the websites that are art-related and see whatâ€™s going on with those. I tend to try to stick with the ones that are free to list with.

ROBERTS You list yourself where you can.

GRAY Right, and then people who have done articles, if they donâ€™t have a link, I ask them for one, and that sort of thing.

ROBERTS Do you think that thereâ€™s something about your work that is especially web-friendly?

GRAY I think, partially, my success is due to the fact that I am quite diverse. I have a lot of different types of work that I do, so I have a little bit of an advantage as far as that goes.

ROBERTS When we visited you, you said you made about 90 % of your money from the web?

GRAY Yes, definitely. It's probably going to get even higher than that. It's been slow. We have an open house here twice a year and several thousand people come through that, and I've been doing that for sixteen years, but the past five years, I don't think I've sold a piece during that art walk. I think that people have a hard time spending several thousand dollars on the fly like that. It's something that they need to consider a bit more. The one thing I'm amazed at with the web is that people will see an image of one of my sculptures and then just, without even calling me up, or any letter, they'll send me an email, ask if it's available, and next thing I know I get a check in the mail. No phone call or no discussion about it or no question about how is this going to look in person, or that kind of thing. It's always kind of surprising to me that people will make these large purchases- \$10,000 or so-over the net with just seeing one small image.

ROBERTS What fraction of the people who buy from you live in the United States?

GRAY Most of them do.

ROBERTS What fraction of them speak English?

GRAY Just about everybody. I get emails sometimes that take a bit of translation; I get some overseas calls once in a while. It gets a little tricky to deal with that kind of situation sometimes if there's a bit of a communication problem. I do recall one time that I kind of thought I was being scammed because it really didn't sound like it was a legitimate thing and it turned out to be very legitimate.

ROBERTS Where was it from?

GRAY Korea. It was actually a museum there. They ended up commissioning two large sculptures for their permanent collection.

ROBERTS Wow! How had they heard of you? What led them to you?

GRAY Through the web. They just Googled "rolling ball machine," or something and my work popped up and they sent me a few emails and just made it happen.

ROBERTS When was that?

GRAY It was last year.

ROBERTS After you started having a nice website, or a conscientious website, how long did it take before you realized that it was going to be a big success?

GRAY I knew fairly close to the beginning that it was working. I don't get sales from it every week, or even every month. You just never know in my world. I can get five major sales in a week, and then literally nothing at all for five months; it's very, very hard to predict and plan, but I will say that the sales that are coming in are definitely from the web. The last four pieces I'm working on or that I have just finished up right now-those are all through the

web. I'm trying to remember the last time I got something that wasn't.

ROBERTS These are commissions, you mean?

GRAY Yes, all through the web. This one I'm just finishing right now is going to New Jersey. Even if I had a ton of stuff in galleries over in Santa Monica, I wouldn't be doing these sales to the East Coast or to Korea.

ROBERTS I hear there's a lot of tourism involved in art galleries.

GRAY There is. But it's still hard to make that sale if they just see it temporarily, especially if it's over a couple of thousand dollars.

ROBERTS Do you still have shows? Do you still have your stuff in galleries now?

GRAY I do shows from time to time, when I get asked to, but I don't really push it as much as I used to, partially because it's just so much of a better deal to not split the money with anybody. That's another huge benefit of the internet. There's no one taking a cut.

[...] Interview with Bruce Gray, Web-Savvy Sculptor (part 1) [...]

## **Nutrition and Physical Degeneration (2008-07-20 07:31)**

Weston Price's masterpiece, *Nutrition and Physical Degeneration: A Comparison of Primitive and Modern Diets and Their Effects* (1939), is online [1]here. The chapters I like are the ones where he visits eleven groups of people around the world and compares those eating traditional diets with those eating modern ones. Those eating traditional diets had very few cavities, even though they didn't brush their teeth. They also had very little "dental malocclusion" – crooked teeth caused by a too-small jaw. This was presumably because they got enough of certain growth factors in childhood. (The [2]NIH health encyclopedia says dental malocclusion "is most often hereditary" – a mistake that speaks volumes.) The main thing I learned from this book was the importance of fat (to supply fat-soluble micronutrients) including animal fat. (There's an evolutionary reason we like the taste of fat.) Swiss in isolated areas had to grow

almost all of their food in spite of living in the mountains. They ate lots of dairy products, especially butter; apparently they were in good health because their dairy animals ate lots of fresh green grass, high in all sorts of necessary micronutrients including ones that may not yet have been identified. The isolated Swiss also ate lots of whole grain bread. To walk around any supermarket and see all these labels saying "low-fat" as if it were a good thing makes me think of the Middle Ages when people had all sorts of strange ideas about what caused disease – such as too much excitement.

This book seems to be emerging from obscurity due to mentions by Michael Pollan in *In Defense of Food* (2008) and Gary Taubes in *Good Calories, Bad Calories* (2007).

John (2008-07-20 08:33:28)

Where in *Good Calories, Bad Calories* does Taubes mention Weston A. Price? I couldn't find it and don't remember it being in there. It certainly fits the theme of the book. I'm glad to see you mentioning it regardless.

Charles (2008-07-20 11:58:05)

Based on Taubes's recommendation, I picked up the book from Amazon, and read it cover-to-cover. It's worth doing so to get the full message, and Price's support for his arguments. While there seems to be some disagreement as to the influence of nutrition on facial structure, it's awfully hard to argue with the pictures of generations and see the changes over time as their nutrition changes from a traditional diet to a westernized (Processed carbohydrates-based) diet. In particular the repeated pattern of no tooth decay on traditional diets vs. increasing tooth decay on western diets was a revelation. We have accepted tooth decay as normal and natural, but it appears it isn't at all. Disgusting as it may sound, I almost never brushed my teeth growing up. Maybe 2-3 times a year. But I never had bad breath, and I never had a cavity until I was in my 20s. Not one. And I ate lots of sugar and was overweight. The rest of the family had plenty of cavities. The only difference is that in my early 20s, I stopped drinking milk. Up until that time I was drinking upwards of a half gallon a day. When I stopped, I started to get cavities. Not many, but it went from zero to a few within a few years. Price would have understood this immediately. This kind of study is probably impossible at this point in history. When Price and his wife were traveling in the early 30s, transportation and the degree of modernization was such that there were still genetically-identical populations that could be separated by only a short distance, and where one of the group might be eating a traditional diet and the other a westernized diet, so you could reasonably and easily compare the two. That isn't the case anymore I don't think.

David Brown (2008-07-20 13:59:10)

Charles, The Kitava Study is an interesting example of recent research similar to Dr. Price's. You can Google "Kitava Study" or paste <http://paleodiet.com/lindeberg/> into your browser. David Brown Nutrition Education Project

Charles (2008-07-20 20:39:25)

I think Price was mentioned in Seth's interview with him. At least that's where I remember seeing it.

Stephen M (Ethesis) (2008-07-20 20:45:29)

Thanks for that link, a good reminder.

Varangy (2008-07-21 09:12:32)

*To walk around any supermarket and see all these labels saying "low-fat" as if it were a good thing makes me think of the*

*Middle Ages when people had all sorts of strange ideas about what caused disease – such as too much excitement. One day, low-fat diets will be seen for what they are – the contemporary version of bloodletting.*

seth (2008-07-21 10:03:44)

John, Taubes mentions Price in the acknowledgements section of *Good Calories, Bad Calories*. Page 575. He says *Nutrition and Physical Degeneration* is the book that most affected his thinking but wasn't mentioned.

Seth's blog » Blog Archive » Errors in The Queen of Fats (2008-07-21 23:24:55)

[...] *Nutrition and Physical Degeneration* [...]

John (2008-07-22 06:28:40)

Aha! Thanks!

Stephan (2008-08-11 21:23:43)

Just wanted to mention, in case some of you haven't heard, Price's "X-factor" has been identified as the menaquinone-4 form of vitamin K2. Chris Masterjohn wrote an article about it for the WAP foundation; I highly recommend it. Get this... K2 levels during development affect facial structure. Price truly was a genius.

Lauren (2009-04-01 07:42:22)

re dental malocclusion: straight teeth in less industrial society probably results from lengthy breastfeeding as a child. I had an orthodontist who insisted that prolonged sucking on the roof of the mouth pulls the structure down a bit (with the nose as well) and that the lowering of this arched structure would push the sides of the arch outwards. So the jaws would become wider. He also contended that over time the arch narrows, the roof of the mouth moves up, the nose protrudes more, nasal cavity space is decreased and tmj problems may result. Certainly I have noticed that protruding noses and narrow faces go together. Perhaps sucking hard on marrow bones (or other difficult to extract foods ) would counter this effect of aging and/or the industrial world diet. I would love to know what you think! best, Lauren

## Errors in The Queen of Fats (2008-07-21 23:24)

Susan Allport's [1]The Queen of Fats is the best introduction to omega-3 fatty acids and their importance that I know of. I learned a lot from it (and [2]interviewed the author). This is why its errors are interesting; they shed light on the big nutritional misconceptions of our time (as Weston Price, the subject of [3]yesterday's post, did in a different way). Joel Kauffman, a chemist, made a list:

1. On p1 low-carb bread and beer are ridiculed despite evidence (see Nielsen JV, Joensson EA, Low-carbohydrate diet in type 2 diabetes. Stable improvement of body weight and glycaemic control during 22 months follow-up, *Nutrition & Metabolism* 2006;3(22) doi:10.1186/1743-7075-3-22) to the contrary. There are at least 10 studies supporting Nielsen. Low-carb means low insulin demand. Insulin converts carb to fat. Allport's claim that the world's leanest peoples mostly eat carbs neglects to mention that they are malnourished.
3. On p2 and later Allport calls saturated fatty acid chains "straight", then still later by the correct term "zigzag", but never by the chemist's term "unbranched". She is not aware that a saturated fatty acid chain of 22 carbons has many more conformations than the 22-carbon DHA with 6 carbon-carbon double bonds, or that double bonds keep 4-carbon groups rigid. If DHA is constantly on the move there must be some other reason.

5. On p10 canola oil, which is not rapeseed oil, is not usually promoted for its linolenic acid content, but for its low saturated content, lower than olive oil. This is not a real advantage, according to all the books (except Sears's™) I have listed above.
6. The conundrum of eating fish for its omega-3s despite the mercury content was not resolved on p11 or elsewhere. There are two long-term studies showing that there is not a big problem: The Chicago Western Electric Study followed the effects of fish consumption in 2,107 men aged 40-55, and followed for 30 years. Those who ate an average of \*35 g daily (about 1 big fish dinner every 5 days) had only 9/10 of the all-cause mortality rate of men who ate no fish. The Nurses's™ Health Study on 84,688 women aged 34-59 years and followed for 16 years for outcomes vs. fish and omega-3 fatty acid intake, had the following findings: women consuming fish five times weekly had only 7/10 the all-cause mortality rate of those eating fish once a month. Pregnant women have been cautioned to restrict their intake of fish ([4][http://www.cbc.ca/storyview/CBC/2002/10/21/Consumers/mercuryfish\\_021021](http://www.cbc.ca/storyview/CBC/2002/10/21/Consumers/mercuryfish_021021)) despite evidence that children receive most of their mercury from vaccines. Hepatitis b vaccine carries 12.5 micrograms per dose; influenza and other common vaccines carry 25 micrograms per shot, over 830 times the amount in a can of tuna. It has been reported that vaccines said not to contain the mercury compound, thimerosal, still might have it. The long duration of the diet studies makes it very clear that the mercury content of fish, in general, is not shortening life.
7. On p14 eating fat in general was used as a straw man and implied to be the major cause of heart disease. Not so; see below (section titled More at bottom of post).
8. On p15 the Framingham Study was claimed to have shown a positive link between serum cholesterol and risk of heart disease. This was disproven by 1937 by experiments on cadavers. See The Cholesterol Myths and either Great Cholesterol Con [there are two books with this title]. See above for evidence that the Seven Countries Study was a fraud. A more recent study on free-living elderly in Manhattan showed the opposite – those with the highest cholesterol and LDL-C levels lived the longest. See Schupf N, Costa R, Luchsinger J, et al. (2005). Relationship Between Plasma Lipids and All-Cause Mortality in Nondemented Elderly. *Journal of the American Geriatrics Society* 53:219-226.
10. On p20 the excessive bleeding in Eskimos is said to be unimportant vs. lower heart attack rates than those of Danes, but external bleeding, as with aspirin, probably indicates internal bleeding.
11. On p21 it was written that polyunsaturated fats held down cholesterol levels. Actually HDL levels were held down and there was no drop in mortality: Rose GA, Thomson WB, Williams RT (1965). Corn Oil in Treatment of Ischaemic Heart Disease. *British Medical Journal* 12 Jun:1531-1533.
12. On p22 gas-liquid chromatography was said to have been developed in the 1950s by oil companies. A Google search showed its invention in the 1940s to separate fatty acids: see James A T & Martin A J P. Gas-liquid partition chromatography: the separation and microestimation of volatile fatty acids from formic acid to dodecanoic acid. *Biochem. J.* 50:679-90, 1952. [National Institute for Medical Research, Mill Hill, London, England]
13. On p22-3, 25 it is implied that the increase in heart disease in Eskimos who adopted aspects of a Western diet is solely due to differences in omega-x fat intake. No attention was paid to the effect of carbs on a very carb-sensitive population.
14. On p25 Allport insults Spam for being "highly saturated". This is nonsense, since lard is only 40 % saturated. See *Know Your Fats* by Mary G. Enig, 2000.

17. On p49 the “pure cholesterol” fed to rabbits has been shown to be oxysterol, which is not healthful.

18. On p51 Ancel Keys, MD, was said to link serum cholesterol to heart disease, but this link had already been shown to be false in 1937 by work on cadavers.

19. On p54 Allport wrote that EPA was responsible for low cholesterol in Eskimo blood on traditional diets, but linoleic acid based fats do this also, and human fat is 10 % linoleic (lard 6 %).

20. On p57 was written that pork and dairy fats are very saturated. Actually, the former is about 40 % saturated and the latter 62 %. See Know Your Fats.

31. On p66 a crack was made about an unbalanced diet. Since some populations have survived for centuries on all animal diets, a balanced diet turns out to be a fantasy designed to raise carb consumption despite a lack of evidence that there is any requirement for carb at all in the human diet. See the Ottoboni’s book. Also, there is vitamin C in fresh meat, so worrying about scurvy was not justified.

32. On p68 the claim that fats and carbs make up over 80 % of the calories in every diet consumed by humankind is absurd, based on traditional Eskimo and Masai diets, among others.

33. On p 69: “so fat gives foods their distinctive aromas and tastes.” What about the odor of fresh bread, hot marshmallow, citral and neral in fruit, licorice, mint, wine, beer, etc.? These are not fats.

34. On p71 the statement that the increased energy in fats compared with carbs or proteins comes from their dense packing. The no-nonsense explanation is that carbs and proteins are partially oxidized because they contain oxygen and nitrogen, so oxidizing them the rest of the way to CO<sub>2</sub> and water gives less energy than the all-hydrocarbon parts of fats.

35. Also on p71 is the fantasy that unsaturated fats contain less energy than saturated because a double bond contains 10 % less energy than a single bond. My old physical organic chemistry text has 80 kcal/mole for the C—C single bond, and 142 kcal for the C=C double bond, a far cry from Allport’s fantasy. And the energy available on digestion is given above “much less from mostly saturated fatty acids.

36. On p74 the slow melting of butter is not due to the melting points of the fatty acids in its triglycerides (fats), but the different melting points of the fats themselves.

37. On p78 and elsewhere Allport wrote of the high concentration of arachidonic acid and DHA in brain and nerve tissue. Her conflicted position on cholesterol is shown by her refusal to mention that the highest concentration of cholesterol in the body is in the brain. But on p148 she writes that cholesterol is a necessary component of brain function

39. On p88 the fantasy begun by Ancel Keys that overconsumption of fats was the major health problem in the West was reiterated without any of the evidence from the books cited above that this was false.

40. On p89 domestic cow fat is said to be only 2 % unsaturated. Know Your Fats says it is 42 % unsaturated, and the CRC Handbook of 1983-4 says 52 % unsaturated.

43. On p100: “In men, it [aspirin] cuts mortality from heart disease by more than half.” This is one of the most flagrant misquotations of the aspirin findings I have yet seen. Actually Bufferin cuts the

number of non-fatal heart attacks by half with no change in mortality, and plain aspirin maybe by 1/3, also with no change in mortality.

44. On p104 a common omission characteristic of drug ads is found: “...mortality from heart disease goes up linearly with the increase in omega-6s...” does not include the crucial all-cause mortality, without which no amount of lowered mortality from some single cause has any meaning for action.

46. On p107 Allport implies that the incidence of heart disease in the US has not changed from 1909-1985. In Heart Frauds by Charles T. McGee (2001), p59, heart disease death rate was shown to have changed from 15/100,000 in 1910 to a peak of 331/100,000 in 1968, then falling to 194/100,000 by 1990. McGee shows that this drop corresponded well with an increase in vitamin C intake.

47. On p109 there is a disconnect between Allport’s generalization that seeds contain mostly omega-6s and leaves mostly omega-3s. Both canola and linseed oils are high in omega-3s which are in their seeds.

49. On p114 it was written that certain Nigerians with high omega-3 levels, presumably in blood, ate “a lot of greens” and most fat was palm oil, high in saturated fats, meaning that sat fats (and the other half of palm oil, the monounsaturated oleic acid 18:1\*9) do not interfere with the transformation of linolenic acid from those greens into DHA and EPA. OK, then, why did she not relent on her anti-sat fat position?

50. On p118, Allport actually said that “...small amounts of saturated fats are better than large amounts of omega-6s.” This shows her conflict: such small amounts would require much less total fat consumption, and the value of this move has no positive evidence.

51. Also on p118 and 142, Allport minimized the dangers of trans fats, being totally unaware that controlled tests in human subjects showed serious adverse effects. Risérus U, Abner P, Brismar K, Vessby B (2002a). “Treatment with Dietary trans-10cis-12 Conjugated Linoleic Acid Causes Isomer-Specific Insulin Resistance in Obese Men with the Metabolic Syndrome.” Diabetes Care 25(9):1516-1521; Risérus U, Basu S, Jovinge S, Fredrikson GN, Arnlov J, Vessby B (2002b). “Supplementation with Conjugated Linoleic Acid Causes Isomer-Dependent Oxidative Stress and Elevated C-Reactive Protein. A Potential Link to Fatty Acid-Induced Insulin Resistance.” Circulation 106:1825-1929.

52. On p126 in an otherwise good discussion of bad aspects of leaky membranes, a bad simile was used: “...we all know what happens to engines when they run constantly...” Do we? It was found by the 1960s that most car engine wear occurred immediately after startup from cold, while there was no measurable wear during constant running at moderate rpms.

54. On p129 Allport notes that there was not a single known case of diabetes (no type given) in Eskimos of the Umanak district in 1971 on their traditional diet. The implication is that omega-3s did the job, but no airtime was ever given to the zero-carb diets.

55. On p134, again, diabetes (type not given) and obesity were equated to caloric intake, not, as so often demonstrated, carb intake.

56. On p135 one of the classic objections to the Atkins low-carb diet is given “that it causes kidney and liver failure due to higher protein consumption. This was twice false, since no such damage was seen by Atkins in his patients who did raise protein intake; but more important, the missing carbs

are ideally to be replaced by fat, which has no glycemic index, unlike protein with a GI of 20 or so.

58. On p139 the blanket recommendations to eat “lots (and lots) of fruits...” is very destructive to diabetics (both types) and pre-diabetics. Many kinds of fruit are high in sugars. Barry Groves, PhD, Nutrition, Richard K. Bernstein, MD, and William Cambell Douglass, Jr., MD, have avoided fruit for decades and are all in their seventies in good health.

59. Also on p139 the advice to avoid any high omega-6 oil is OK, but the advice to minimize butter is not. Not only is there no danger in butter, but its medium-chain fatty acids have antimicrobial properties. See Know Your Fats, above.

60. On p140 and 142 the advice to eat a wide variety of fish does not account for differences in EPA and DHA content, or differences in mercury content. Benefits of supplements of EPA and DHA have been shown in controlled trials.

61. On p143 saturated fats come in for another absurd hit, this time with the epithet “solid”. Phew! Of course lard and tallow are not solid at body temperature! And they do not cause heart disease: Ravnskov U (1998). The Questionable Role of Saturated and Polyunsaturated Fatty Acids in Cardiovascular Disease. Journal of Clinical Epidemiology 51:443-60.

62. On p144 Allport reverses herself from her position on p138 and gives amounts of EPA and DHA supplements to take daily. She wisely cautions against supplements containing omega-6s since we get too much of them anyway. But she says that strict vegetarians need more linolenic acid as though they are not getting it from eating massive amounts of leafy vegetables.

65. On p149 a study within the Physicians’ Health Study (the one with the misquoted and misinterpreted info on aspirin) there was a finding that 94 of 15,000 of them who experienced sudden cardiac death were 90 % less likely to do so if they had the highest omega-3 levels in their blood. First, in the absence of all-cause mortality, you cannot tell whether high omega-3 levels did any overall good. Next only 0.6 % of the total or 1 in 170 had this cause of death, so the benefit is pretty small. Dietary intake of omega-3s was not even given.

66. On p151 it is not clear whether all omega-3s in blood are measured by the commercially available tests, or whether the individual ones are assayed and reported. If EPA and DHA levels are not reported, there will be little if any value in the tests.

67. On p192 Allport wrote that rapeseed oil “has a high alpha linolenic acid content.” My CRC Handbook of 1983-4 lists 1 %! Such is the result of confusing rapeseed and canola.

You can see from the numbering I’ve omitted some of them; for the full list, contact Dr. Kauffman at kauffman at bee dot net . For more on health misconceptions, read his book [5]Malignant Medical Myths, Infinity Publ., West Conshohocken, PA, 2006. ISBN 0-7414-2909-8 326 pp. \$24.95.

Science, especially health science, is so important yet it is remarkably hard to learn about. Part of the problem seems to be that those who can write well (such as journalists) don’t understand the science and those who understand the science (such as scientists) can’t write well. (Another part of the problem, as Veblen pointed out, is that among academics to write clearly is low status, to write “mumbo-jumbo” is high status.) This is why I like [6]Leonard Mlodinow’s work so much; he writes well and understands the science.

But don’t misunderstand this post. The Queen of Fats is an excellent book. The most impressive and hopeful thing

about it is that it was written by a non-scientist – in other words, that a non-scientist was able to figure out that the common neglect of omega-3 fats was seriously wrong. (Omega-3 fats receive almost no attention in *Eat Drink and Be Healthy* by Walter Willett et al. for example. There is no RDA for them.) I like to think it's some sort of turning point that non-scientists have become able to grasp how wrong the health establishment can be; another example is Taubes's *Good Calories, Bad Calories*.

More. The list of errors unfortunately omitted some general comments:

The Seven-Country Study by Ancel Keys that was so influential (cholesterol and saturated fat being "bad") was not presented as the fraud it was. For a great description, see *The Great Cholesterol Con* (GCC), by Anthony Colpo (2007). For an honest Fourteen Country Study see another GCC of 2007, this one by Malcolm Kendrick, in which Kendrick showed that the 7 countries with the lowest saturated fat consumption had the highest mortality from heart disease (450/100,000 per year), while the 7 countries with the highest saturated fat intake had the lowest mortality from heart disease (170/100,000). See also *The Cholesterol Myths* by Uffe Ravnskov, 2000. Low-carb high-fat diets were ridiculed from start to finish as destructive and a fad, despite overwhelming evidence that they are not. See Nielsen JV, Joensson EA, Low-carbohydrate diet in type 2 diabetes. Stable improvement of bodyweight and glycaemic control during 22 months follow-up, *Nutrition & Metabolism* 2006;3(22) doi:10.1186/1743-7075-3-22. While Allport may be correct in claiming that omega-3s will prevent or reverse diabetes (and she is not always clear on which type), the evidence is clear that type-1 is much more easily controlled with a low-carb high-fat diet, and type-2 may be controlled so well on a low-carb diet that no medication is needed. See *Dr. Bernstein's Diabetes Solution*, rev. ed. by Richard K. Bernstein, MD, Boston, MA: Little, Brown, 2003. So Allport's recommendation to eat large amounts of fruit (p139) could be a disaster for diabetics. Eskimos are often obese albeit healthy, so omega-3s for weight loss seems too much to claim. And she seems unaware of the prevalence of grain allergies. See *Natural Health & Weight Loss*, Barry Groves, 2007; *Know Your Fats* by Mary G. Enig, 2000. Also Allport seems to equate eating linolenic acid as the equivalent of eating EPA and DHA in fish, and does not recommend supplements of the latter two. Neither idea had any supporting evidence presented. Nor was the ideal range of omega-3 intake given. A study of the conversion of radioisotopically-labeled linolenic acid to EPA in humans showed poor conversion, and even poorer conversion to DHA. Adequate intakes of pre-formed DHA are needed for good health. See Burdge G, alpha-Linolenic acid metabolism in men and women: nutritional and biological implications, *Curr Opin Clin Nutr Metab Care* 2004;7:137-144.

Varangy (2008-07-22 09:05:44)

*(Omega-3 fats receive almost no attention in Eat Drink and Be Healthy by Walter Willett et al. for example. There is no RDA for them.)* Seth, I think we can agree that RDAs are complete and meaningless fiction produced of political machinations. The more the government stays out of nutrition 'science'/public policy, the better off we are. Witness the low-fat mis-information cascade (RDAs being directly tied to) promoted relentlessly by the government. Just like cholesterol markers are largely meaningless (again, subject to political and biased processes i.e. statin suppliers), RDAs are insidious because of their strong

fooling effect — they are printed onto every product and determined by government 'science' ergo they MUST be right. Yeah right...

seth (2008-07-22 09:18:15)

"Complete and meaningless fiction"? That goes much too far. The reports issued to support each set of RDAs have convinced me that they are valuable. But there certainly is lots of lobbying as well.

Mike Kenny (2008-07-22 09:56:27)

It seems the more scientific progress affects our everyday lives, we'll need good writers to explain to us what is going on in terms we can understand. At some point will that be possible I wonder? I think of the health debate, but also the global warming debates and public policy generally.

Tom (2008-07-22 10:03:53)

Seth, you'll be interested in the following review of Taubes, and in Taubes' rebuttal. <http://www.proteinpower.com/drmike/weight-loss/gary-taubes-responds-to-george-bray/> Rebuttal (pdf file): <http://www.proteinpower.com/drmike/wp-content/uploads/2008/07/taubes-response-to-bray.pdf>

Varangy (2008-07-22 10:09:17)

@seth I don't think so – RDAs have completely and entirely vilified fats for one small example — we may not be getting enough saturated fats in our diets — whatever value they may have is undermined by the false confidence they promote.

Varangy (2008-07-22 10:18:50)

*Part of the problem seems to be that those who can write well (such as journalists) don't understand the science and those who understand the science (such as scientists) can't write well* I think you overlook scientists who don't understand scientific methodology or are not scientific, either intentionally or unintentionally — and that is what makes NNT's book valuable BTW. Ostensible unbiased scientists have become High Priests in our society today — the masses and the media have all fallen for the argumentum ad populum and argumentum ad verecundiam. Believe me b/c other scientists ("experts") agree with me! You hear over and over and over again. As Crichton has pointed out many a time — consensus is not an argument for AGW. Semmelweis is the exemplar. Back to AGW — skeptics are reviled! Skepticism is the basis of the scientific method. Irony, irony and more irony.

Cyan (2008-07-22 11:14:05)

Point 35 is wrong – unsaturation does reduce the available energy in a hydrocarbon. Kauffman's mistake is that unsaturation replaces H-C-C-H with C=C; he's neglected the energy of the C-H bonds. But Allport is wrong too about the "10 % less energy" statement – I can generate neither a true nor an erroneous calculation that would give that result.

chris (2008-07-23 13:42:45)

Elevated mercury levels are of great concern, however safe seafood is available. For the first time there is a company that doesn't rely on only the age or location of the fish caught to claim that it is lower in mercury than FDA action levels. Safe Harbor guarantees that the fish it certifies is lower than FDA action levels because it tests every large fin fish released under the Safe Harbor brand. For the first time I am 100 % confident about the safety of the seafood I eat and buy for my family. All their mercury certification levels are available online, along with details about their testing process and where their product is available at <http://www.safeharborfoods.com> Check them out and enjoy the health benefits of seafood without worry!

maximumgravity1 (2008-10-22 19:00:46)

I appreciate Chris' comments about high levels of Mercury and other heavy metals in seafood. Having seen countless fishing places disappear on the Eastern Shore of Maryland over a span of about 20 years due to "contamination", it is disheartening to know that some of our best sources of Omega-3's are being corrupted by environmental factors. It gets even more depressing knowing that if we at least catch our own, we know something about the streams, oceans or rivers we pull the fish from.

Although it is a bit naive to think that one location on the shore is contaminated, and that 5 miles up the road it is "clean" enough to eat the same fish that swim through the same waters. Without trying to sound like a sponsored plug or shameless self promoting, I am glad to finally find a supplement that is highest in concentration of any omega-3's on the market, and due to their process of extracting the oils almost eliminates all traces of mercury (almost - not quite). The extract comes from the Green-Lip Mussel in New Zealand, which is just recently finding its way on the scene as a very powerful source of concentrated Omega-3 (<http://www.mymoxor.com/ProductScience.aspx?ID=maximumgravity1>). This company combines the Green-Lip Mussel with grape seed extract for high levels of antioxidants as well. Here is a purity test of the Hoki Stick oil (the carrier in the gel)<http://www.naturalnews.com/moxor/HokiOilCertificate.jpg> Anyway, the point without seeming like I am stepping on your thread with plugs for products is to mention that it is encouraging to see science finally starting to advance in areas that give us the ability to eat healthy foods without fear of becoming victims of our environment. Some great articles on GreenLip Mussel oil <http://www.mymoxor.com/ProductArticlesandResearch.aspx?ID=maximumgravity1> Good info on your blog - keep it coming.

DonH (2008-12-15 08:51:08)

Joel's list of "errors" indicates that he didn't actually read the book for what it is, a history of the investigation into fats as well as how we came to be at the point we are at now. It is not meant to be a scientifically critical review of the research. The errors of early assumptions become obvious as the book progresses. The book would be unapproachable by her intended audience had she relentlessly cited all of the studies that Joel offered as proof of errors. Further, I don't understand his assessment that Alcott is "conflicted". She doesn't set out to prove anything. If she is conflicted, it is a reflection that much of the nutritional advice has been conflicted over the years. The thing that I liked most about her book was that it didn't relentlessly try to push a point of view. She told the story of how we arrived at our current knowledge of dietary fat. The history has been, and continues to be, full of conflicting views and advice.

Ronald Pottol (2009-02-02 22:27:51)

Infant formula does have requirements for omega 3s, so that is a start.

So, what about writing cases that promote inquiry and collaboration? · MyPlant IT Blog (2010-07-15 07:04:57)

### **City of Berkeley Economics: The Value of Snobbery (2008-07-23 06:38)**

The City of Berkeley, which Jane Jacobs called a "pretentious suburb," isn't doing well economically. There was a Barnes & Noble downtown, a kind of anchor store. It closed. There was a Ross downtown. It closed. Chain stores don't do well in Berkeley. One downtown corner has gone through several renters, including Gateway Computers, Cody's Books, and L.L. Bean, in just a few years. The main reason I go to downtown Berkeley is to take BART to San Francisco.

My neighborhood, North Berkeley, is doing much better, although there are two empty storefronts and the Starbucks will close. Elephant Pharmacy, a New-Agey kind of pharmacy ("the drugstore that prescribes yoga"), has been successful and has started opening branches in nearby cities. (It's a good place to shop, too. Yesterday I bought some whole nutmeg there.) The Cheese Board, a worker's cooperative, with a great selection of cheese, has done a good job adding pizza sales to cheese sales.

The overall economic record of the neighborhood is staggering, since it includes the original Peet's, the inspiration for Starbucks, and Chez Panisse, the most influential restaurant in the world. It also includes the first Papyrus store. I don't drink coffee, and didn't start drinking tea until the Shangri-La Diet, so I never shopped at Peet's until recently. A friend, however, has been going there almost its entire history. He says that when Mr. Peet died, the workers became

a lot friendlier. Before that they had a snobbish attitude. Some workers from Peet's started a similar business in Seattle, which they called Starbucks. It was very successful and they sold out to Howard Schulz, who greatly expanded it.

Was Mr. Peet's snobbery "bad"? Well, it – plus the corresponding attitudes of Berkeley residents – allowed him to develop a unique business. After that business was developed, that attitude could be shed and the whole thing could be moved to a place (Seattle) where its business potential could be revealed. The shift of ownership allowed the idea to become separated from the "big business is bad" notion (which was helpful at first) and launch a thousand Starbucks. (An excellent company, by the way, that not only provides me a place to work but also produced *How Starbucks Saved My Life*, a very good and persuasive book.) This is yet another tiny illustration of my theory of human evolution, how it all started with hobbies which eventually became businesses. Peet's wasn't a hobby, but it was hobby-like in its expression of the owner's attitudes. It was far more a labor of love than most businesses. There are other examples. Survivor is to The Real World as Starbucks is to Peet's. The Omnivore's Dilemma is to Slow Food as Starbucks is to Peet's.

---

david (2008-07-23 07:30:09)

"The Omnivore's Dilemma is to Slow Food as Starbucks is to Peet's" I must be dense. I don't get it.

seth (2008-07-23 07:43:00)

The Omnivore's Dilemma was a big commercial success built on what you might call the intellectual capital of Slow Food. Just as Starbucks was a big commercial success built on what you might call the intellectual capital of Peet's.

Brandon W (2008-07-23 10:14:57)

I may have written of this in a prior comment. One reason Berkeley business may be struggling is the fact the City gives out tickets for not having a front license plate ( \$25 fine). I received one in front of the Newman Center a few months ago while attending a funeral. I understand if the meter person is already writing a me a parking ticket but my meter still had time on it when I got back to the car. Basically, the meter person was looking for cars with no license plates as a revenue stream for the city. When I sent my payment in for the fine, I sent a letter and copied Peet's coincidentally enough as we were planning on getting coffee after the funeral. The letter stated instead of shopping in Berkeley waiting for the reception, we got out of there. I love Berkeley but I will never go into the city again if I do not have to (or to attend a football game). Brandon

Aaron Brown (2008-07-23 10:42:52)

"How Starbucks Changed My Life" -> "How Starbucks Saved My Life"

Tom (2008-07-23 13:18:31)

How Starbucks Saved My Life was really good. Tom Hanks bought the rights and may star.

seth (2008-07-23 13:51:53)

thanks for the correction, Aaron

Bonnie (2008-07-23 15:20:17)

I work at Elephant Pharm, and stumbled across your blog b/c I get a daily Google Alert for all things "elephant pharm". Thanks for the shout out! I love Elephant Pharm, and not just because I work there... I work there because I love it! :)

mike kenny (2008-07-23 17:28:13)

this post reminds me of a post at overcoming bias regarding how people enjoy unpopular or unrewarding (i guess in a monetary sense) hobbies: <http://www.overcomingbias.com/2008/04/sincerity-i-lik.html> i guess the point of the overcoming bias post is money can complicate a certain authentic communitarian experience which is valuable to people.

### **Slow Weed (2008-07-24 09:54)**

Guthrie said that the quasi-legal status of smaller growing arrangements, combined with consumers'™ preference for potent, high-maintenance weed, has shifted the balance of the pot business away from large-scale farms. "There's a lot more people doing little scenes," he said. The welter of laws pertaining to medical marijuana in California has offered careful operators like Guthrie the best of both worlds: prosecution for growing and selling has become much less likely, while federal busts and seizures keep prices high.

Too bad David Samuels, the author of [1]this well-reported article, doesn't use the term artisanal marijuana. Artisanal cheesemakers, etc., might learn something helpful from this. For example, maybe it helps that raw milk is slightly illegal. After he wrote Fast Food Nation, Eric Schlosser wrote about underground economies. Maybe he'll eventually write Slow Food Nation.

A friend of mine spent a year growing pot in her California basement in response to the economic trends described in Samuel's article. She stopped when her business partner became too unreliable.

1. [http://www.newyorker.com/reporting/2008/07/28/080728fa\\_fact\\_samuels?currentPage=all](http://www.newyorker.com/reporting/2008/07/28/080728fa_fact_samuels?currentPage=all)

---

mike kenny (2008-07-24 18:03:28)

Hm, it seems like there's a trend of expansion and contraction. People start off developing marketable ideas as autotelic hobbies, then they or someone else popularizes their product, and then the market evolves such that new hobbies can be supported, refining what exists. Someone who's interested in plants discovered the drug-element of marijuana (or coffee to reference your previous post), a subculture develops of enthusiastic hobbyists, then the drug gets popularized and mass-produced, and then a demand for a more refined form of the product develops and new hobbyists breed newer forms of the drug. Are we, through this process, becoming more and more refined aesthetes?

### **Interview with Bruce Gray, Web-Savvy Sculptor (part 2) (2008-07-25 09:14)**

Bruce Gray is a Los Angeles sculptor with [1]an impressive website.

ROBERTS Do you know how art galleries have been affected by the web?

GRAY They definitely don't like it.

ROBERTS How can you tell?

GRAY I've heard them complain about it. They have complained about it a lot. Some galleries won't even represent you if you have a website. They also don't like you to list your prices, because they will usually be asking for twice the money.

ROBERTS Yeah.

GRAY But that's up to the individual gallery, and it depends how bad they want you. The ones that have the very tight rules on that are usually the galleries that are really hard to get into anyway. But let's face it, if it's Gagosian or someone who could triple my prices and turn me into an overnight sensation, then hey, I'll take the freaking website down, but until that happens, I need something to keep the bills paid and the web is definitely doing it. Like I've told all my artist friends, every single artist in the world should have a website.

ROBERTS Yeah, and what will the world be like?

GRAY Another great thing is that it's a portfolio that you have with you wherever you go. It's very easy to show people my work at their homes, or even through my iPhone. I keep 300 dpi images up there too on a hidden page. So say I'm out of town, and I get a call that someone needs a large image for a magazine article, I can just give them that link and I don't even have to send them anything.

ROBERTS Does this mean that people will be able to buy art at lower prices because the middle man is cut out?

GRAY It does, absolutely.

ROBERTS Are there any signs of this actually happening? You're bringing people in to the art market because the prices are lower.

GRAY Of the artists I know, that's basically what people have been telling me. Obviously when you're going directly to an artist's studio, it's kind of the same thing as buying through the internet. You're cutting out any gallery or dealers in most cases, unless people have signed on for one of those deals where you're supposed to give your dealer a percentage even if you make your own direct sales, which I just don't understand why anybody would sign on for that, but I do know people who have that, and they generally get some kind of stipend or something, but I don't know. It doesn't look like a good deal to me.

ROBERTS It sounds like there should be new customers in the art world, and I wonder if there are any signs of that.

GRAY The thing about galleries that you can't escape is they are going to promote you, at least locally, better than you can yourself. And they give you a certain credibility factor. Obviously someone who's been around as long as I have, I have enough credits on my biography where people know that I'm legitimate, so I don't really need to go out there and beg to get in a bunch of shows just to beef up on the lines on my biography. To get in a cool or interesting show, that's still a good thing to do for anybody and I still do that when I get asked, but I just don't have to do it as much.

ROBERTS How is the traffic to your website changed over the years?

GRAY It's pretty damned good. It varies a bit, but it gets a lot of traffic—thousands and thousands of people looking at it every day.

ROBERTS Thousands of distinct visitors per day?

GRAY Yeah. It has been for a long time. Not everybody buys stuff, but a lot of times people, when they purchase art, it's a decision that can take years to make. They may see something and like it, but it actually takes them several years to commit to buying it. I've had that happen a whole bunch of times. People say, "I really want that, and I'm getting that some day," and you're like, "Oh yeah, yeah, I've heard that," and five years later they come back and say, "Hey, I'm getting that!" It does happen.

ROBERTS Have you measured a visitors per dollar or hits per dollar—have you ever computed that index? If you make \$10,000 and it requires a million hits?

GRAY I've never really figured that out.

ROBERTS I wonder how that ratio would change over the years.

GRAY Well, I take all the web statistics with a grain of salt because I don't think any of them are super accurate. If you go to the several different groups that watch that kind of stuff, they're all going to give you a different statistic—whether it's how many sites link into your site, or anything else. If I look online for that kind of information, how many people link to my site, every different page that will give you any of that kind of reference will have a completely different number. You have to just use it like a scale, you just kind of go, "Okay well it's going up at least."

ROBERTS And it might be going up because of robots.

GRAY Robots just basically spider your information and go and update new stuff; that doesn't really represent hits the way that an individual coming in will.

ROBERTS How does the number of visitors to your site compare now to a year ago?

GRAY I figured it's just gradually getting better and better. Every year I have a lot more information on there, which attracts new people in, say, maybe a TV show that I had something on—that might attract in a little bit, or like I had some stuff on this Gene Simmons show a couple of years ago and I just noticed recently that they're using one of my photos from the stills from that on this Gene Simmons site, so all of a sudden I'm getting a bunch of hits in now from that. Each little thing that you add, each little accomplishment, or book appearance or gallery show—all that stuff adds in another layer of keywords and things that people may be searching for. That's all kind of a weird world how that works, too, because for example—Gene Simmons again—he's obviously a very famous rock star guy and if you look up his name, I'm not going to get a gazillion hits because I have Gene Simmons's name on my website, because when you're talking about someone who is super-famous, if their name is on your site—as a collector for whatever reason—there's so much other material about them already, that you are so way down in the bottom of the relevancy that if you get one or two hits a week because of their name, that would be about average. Trying to

kind of beef up your website by putting in a lot of names like that wouldn't really do anything.

[2]Part 1.

1. <http://www.brucegray.com/>

2. <http://www.blog.sethroberts.net/2008/07/19/interview-with-bruce-gray-sculptor-part-1/>

VNM (2008-07-26 08:41:45)

GOgosian should be GAgosian.

seth (2008-07-26 11:05:37)

Thanks for the correction. I thought I had made sure that was correct.

### **Benfotiamine and Self-Experimentation: Surprising Results (2008-07-26 23:03)**

Tim Lundeen, whose [1]fish oil/arithmetic results impressed me, recently tried [2]taking benfotiamine (a fat-soluble version of thiamine) to reduce damage caused by high blood sugar. Things did not go as he expected:

I bought 100mg capsules from Life Extension Foundation, and starting taking 1 per day in the morning with breakfast. Over the course of 3-4 weeks, the two small dead spots on the bottoms of my big toes started to feel normal, and I didn't notice them anymore when I went walking. My energy and general mood were good, and my fasting blood sugar readings were basically unchanged, staying in the 85-95 range. Scores on my daily math speed test were good, possibly slightly better than before.

Unfortunately, I started to gain weight, gaining about 10 pounds over the 10 weeks I took benfotiamine, without any other major changes to my regimen.

Weight gain was not a known side effect. For example, [3]a 2005 study in which 20 patients received the drug for three weeks reported: "No side effects attributable to benfotiamine were observed." This is on a web page that is trying to sell benfotiamine but there's nothing unusual about the situation. Studies of drug efficacy are almost always done by drug companies that want to sell the tested drug. What is the term for such a side-effects reporting system? The fox guarding the hen house, perhaps?

It isn't easy to measure side effects in conventional studies of treatment vs placebo. If you measure the rates of 100 possible side effects, and use a 5 % level of significance, one or two true positives will go unnoticed against a background of five or so false positives. So a drug company can paradoxically assure that they will find nothing by casting a very wide net. And there is a larger and more subtle problem that statistics such as the mean do not work well for detecting a large change among a small fraction of the sample. If soft drinks cause 2 % of children to become hyperactive and leave the other 98 % unchanged, looking at mean hyperactivity scores is a poor way to detect this. A good way to detect such changes is to make many measurements per child. Many did-a-drug-harm-my-child? cases come down to parents versus experts. The experts are armed with a study showing no damage. But this study will inevitably have the weaknesses I've just mentioned – especially, use of means and few measurements per subject. The parents, on the other hand, will have used, informally, the more sensitive measurement method.

For these reasons, I suspect drug side effects are woefully underreported. [4]Here is the story of a child with a neurodegenerative disease that might have been caused by "the Gardasil vaccine (or perhaps some other vaccine with key similarities, such as an aluminum adjuvant)." Her parents are trying to find other children with similar symptoms.

peter (2008-07-27 10:04:14)

Mr. Lundeen appears to have a mild case of diabetic neuropathy. This would seem to call into question the validity of his prior findings relative to consuming DHA. (What would work in a diabetic might not work or work as well in an individual w/o that condition). He also might consider checking out Sangamo BioSciences, Inc. treatment for this condition, currently in phase II; perhaps he could enroll in the phase III, which is scheduled to commence next year (although his condition may not be severe enough).

seth (2008-07-27 10:45:54)

Peter, I don't follow your reasoning here. "What would work in a diabetic might not work or work as well in an individual w/o that condition." Why do you think diabetics might metabolize DHA in the brain differently than non-diabetics? DHA plays a large structural role in the brain, glucose does not.

peter (2008-07-27 11:38:46)

i don't know how a diabetic metabolizes DHA, but i know that it's a serious condition that could skew the results. my sense is that this feature of a study would be criticized by reviewers. (altho i recognize that your experience tends to be consistent with his).

seth (2008-07-27 19:28:05)

Thanks for explaining that. My flaxseed oil results, and Tim's, have a very simple explanation: We don't eat nearly enough omega-3. There's no reason to think diabetics need less omega-3 than non-diabetics.

MT (2008-07-28 02:58:12)

What is the normal variance in his weight? Would it be worth another trial to see if the weight gain was related to another variable changing? Would the weight go away after a month off, and return after a month back on?

seth (2008-07-28 04:37:48)

I'd guess that if you looked at Tim's weight at 10-week intervals you'd see it vary by a pound or so on average and that a 10 pound change would be very rare.

elsa961 (2008-07-28 09:14:33)

don't use drugs only natural products and food!

Stephen M (Ethesis) (2008-07-29 18:59:20)

That was very interesting. I had no idea they were manipulating data like that. How did his weight go when he went off the drug? What about the dead spots?

cynthia (2011-10-06 00:09:57)

The b vitamins supposedly work together. It would probably be a good idea to also take a b complex with the benfotiamine. I probably have a deficiency, but I am taking benfotiamine a b complex several times a day, and my energy is up and my pants size is down. Also go by your belt size, not the scales. It could be that the benfotiamine is making you more muscular.

### **Interview with Bruce Gray, Web-Savvy Sculptor (part 3) (2008-07-28 21:13)**

ROBERTS What mistakes have you made with regard to the web?

GRAY I remember years ago I went to a company that was one of those web search enhancement companies and you were supposed to pay them a monthly fee and they would beef up your meta tags and stuff like this, and give you some advice on how to do the stuff, just tweaking out your website to make it more optimized. I was looking at some of the stuff they do, and one of the things was putting in these pages, your background pages, all kinds of meta tags, like keywords in white on a white background—that was kind of technique—a lot of people still use that, but it's very highly frowned upon in the search engine world and if they catch people doing that kind of thing, they can definitely drop you down on your rankings status there and when I read that, I was like, "Wow, this is the company I'm paying to do this for me and they're doing something that the search engines don't like you to do," so I dropped them. I want to be legitimate. I don't want anybody to have any reason to take away any of my rankings status there.

ROBERTS Are there other artists who have gone into the web more than you? You're by far the farthest in of anyone I've met.

GRAY I don't know anybody else who has remotely the kind of website detail and depth that I do. I just try to put up, literally, almost every piece I've made that I can at least get a photo of. My website is way more in-depth and detailed than any other artist I know, by far.

ROBERTS Yes, that was my impression.

GRAY That helps, obviously.

ROBERTS Yes. Has anyone from the art world come and interviewed you about your web strategy?

GRAY I've definitely been asked about it quite a few times, actually. There was a book that came out years ago about selling art without galleries—I got interviewed about that kind of thing. Actually, almost anytime that I get asked about my sales, I start talking about the web and everybody gets very interested in how I'm doing it.

ROBERTS Has there been articles focused on that particular topic—you and the web?

GRAY No.

ROBERTS What else have you learned besides donâ€™t go with that optimization company?

GRAY That you basically just have to keep up with it, keep it fresh, donâ€™t make it too complex. I canâ€™t tell you how many times, you know, Iâ€™m pretty web savvy, and I go to websites all the time that you get on to them and theyâ€™re so slow loading and when they do finally load, itâ€™s like playing that game Myst to even try to find the buttons to go to anything. Itâ€™s almost more of a showcase for the web designer more than it is for the company that theyâ€™re trying to represent and I think thatâ€™s a huge mistake, because people just get too lost in that, and I think thatâ€™s a mistake thatâ€™s extremely commonplace.

ROBERTS You mean to have some kind of Flash animation, or something?

GRAY Yes, they have just too much crap. Itâ€™s too complex—you canâ€™t even find the buttons, the navigationâ€™s almost impossible. To even find how to make contact, or even get to the next page, you have to mouse all over the images and try to find what is the button, and these are gigantic companies and stuff. Iâ€™m just always amazed that they do things like that. And the other reality is that youâ€™ve got to think who is looking at your website and whoâ€™s your market. In my world—in the art market world—my clientele tend to be older and very wealthy, 50s to 80s, mostly retired or with very hefty bank accounts, and the one thing that they donâ€™t know is computers. Most of these people are not that computer savvy and if they get to your webpage and they canâ€™t navigate around, or if they get to your webpage and it says, â€œYouâ€™re going to have to download the latest version of Flash,â€ and this, that, and the other thing, theyâ€™re going to be like, â€œOh, well the hell with that. What the hell is a download? Whatâ€™s Flash?â€ Seriously, I mean I have very smart people that just donâ€™t have any reason to be that web or even computer savvy. They completed most of their career before everybody really got into computers that heavily, so they just donâ€™t know them that well. So you have to make it—at least make the navigation—pretty simple, and no major drama to at least get to the home page. The fancy Flash opening thing in my opinion is just only a showcase for the Flash or the web designer.

ROBERTS I would imagine artists like yourself donâ€™t have a lot of Flash on their pages.

GRAY Well, a lot of them do.

ROBERTS Really?

GRAY Iâ€™m all for doing that kind of thing, too, but if I wanted to do that, I would have it as the secondary page. Have the home page where you can have the two buttons, because thatâ€™s what a lot of people do. Go to the HTML version or go to the Flash version. At least if you separate it off on your home page, then people at least have the option before they get stuck in this window of a ten minute download.

ROBERTS What are your hopes—do you have other things youâ€™re hoping for out of your webpage, your web presence, that you havenâ€™t gotten yet? Or is it working pretty well?

GRAY Well, itâ€™s been working pretty well. I just basically want it to continue to grow and get better. And it gradually is. Every year I do some new things and it adds a little bit more—new museums and things linking in—the more of that kind of stuff, the better.

ROBERTS When you say you do new things, you mean you add links or you add whole concepts or categories?

GRAY I mean I add the links any time that I'm on television or any books, magazines, weblogs or anything—all of that stuff. I link to them and they link to me, and it's just another notch in the credibility factor.

ROBERTS I see, so it's an ongoing process of trying to increase linkage and so forth.

GRAY Right. But that is the most important credibility factor in the web search engine world these days—good qualified links coming in to your site. Links that go out don't mean anything; you can have six million of them and they don't care.

ROBERTS Yes, I see what you mean. Is there anything about you and the web we haven't asked about?

GRAY The one other thing that I think I should mention is that there is other ways of enhancing your web experience aside from just your own webpage and that's things that are free, like My Space or LinkedIn for instance, are classic examples. They are very searchable in Google and they rank the information on these sites quite highly, so it's good to have supplemental ways of people seeing your work other than just your own website. One of the reasons for that, and one of the reasons I kind of got into trying to go around and hook up with these other art websites is because of things like: Years ago, Yahoo! decided that they weren't going to even list my home page anymore unless I paid them, so when they start doing things like that, you know, my website wouldn't even be listed but all the other websites that mention me or link to me, those are all listed. I still get the listing on Yahoo! but not directly. I think that my website is listed now, but it's down on the third page or so of listings for "Bruce Gray sculptor."

ROBERTS So if I search Yahoo! for "Bruce Gray sculptor," I get your home page on the third page of listings—is that what you're saying?

GRAY Something like that, yes. You'll see a whole bunch of other stuff first, let's put it that way. And that's not that way on Google. That's why everybody uses Google now. If the other search engine's going to make a lot of the cool stuff have to pay to be on there, then obviously they're not going to have anywhere near the level of listings that Google does, so what's the point of even bothering with it?

ROBERTS Yes, I see what you mean.

GRAY That's why they're not doing so well.

ROBERTS Yes, the act of desperation. I think that covers it well. Thank you very much for your time.

[1]The whole interview.

1. [http://docs.google.com/Doc?id=dgb53zjg\\_1dpwpkdfx](http://docs.google.com/Doc?id=dgb53zjg_1dpwpkdfx)

Nadav (2008-07-29 05:06:03)

Awesome interview. Can anyone confirm what Bruce said re "That's why everybody uses Google now." Is it really mostly because Yahoo! makes the most logical top search results pay for the privilege of occupying the top spot? I'm an investment analyst, and in my experience it's almost unheard of for a company that does no advertising and enjoys no obvious barriers to entry to have such a dominant market share.

## More about Unreported Side Effects of Powerful Drugs (2008-07-29 22:57)

[1]A few days ago I blogged about how Tim Lundeen, via careful and repeated measurement – let's call it self-experimentation – uncovered a serious and previously-unreported side effect of a drug he was taking. Tim's example illustrates an important use of self-experimentation: discovering unreported side effects, which I believe are common.

By coincidence today I came across a talk about the very subject of unmentioned side effects: Alison Bass speaking about her new book, [2]Side Effects: A Prosecutor, a Whistleblower, and a Bestselling Antidepressant on Trial. Near the end, Bass said,

It's not the just the antidepressants, it's not just the antipsychotics. This is happening with a lot of other drugs. With Vioxx, with Vytorin, an anti-cholesterol drug, with Propriety [?] and Marimex [?], anti-anemia drugs. Where again and again the drug companies know that there are more severe side effects and they're not letting the public know about that. It just keeps happening, unfortunately.

Just as it would be foolish to think the problem is limited to mental-health drugs, it would be foolish to think the problem is limited to side effects, that drug company researchers do everything right except fail to report side effects. Tim's example shows how hard it is to learn about unreported side effects – so it is only realistic to think that there are other big problems with drug company research we don't know about. Bass mentioned one I didn't know about. A company did a clinical trial of Paxil. The goal was to see if the drug helped with Measures of Depression A and B. Turns out it didn't: no effect. So the company changed the measures! They shifted to reporting different measures that the drug did seem to improve. Creating the hypothesis to be tested after the data supposedly supporting that hypothesis had already been collected. Without making this clear. (Which I presciently mentioned [3]here, in response to an interesting comment by Andrew Gelman.) And if you think that drug companies do research like this – in ways that seriously damage people's lives – but everyone else, such as academia, is really good, that is as realistic as thinking the problem with drug company research is restricted to side effects. Self-experimentation has all sorts of limitations, yes, but (a) you know what they are and (b) it is cheap enough so that you can gather more data to deal with the problems. Drug company research and lots of other research is too expensive to fail – or even be honest about shortcomings.

This is an aspect of scientific method that scientists rarely discuss: the effect of cost on honesty. Is there an economic term (a Veblen good, perhaps?) for things whose quality goes down as their cost goes up?

1. <http://www.blog.sethroberts.net/2008/07/26/benfotiamine-and-self-experimentation-surprising-results/>

2. <http://www.alison-bass.com/books.html>

3. [http://www.stat.columbia.edu/~cook/movabletype/archives/2008/07/an\\_ounce\\_of\\_rep.html](http://www.stat.columbia.edu/~cook/movabletype/archives/2008/07/an_ounce_of_rep.html)

mike kenny (2008-07-30 15:09:31)

hm, are there database of self experimentation available to and created by the public regarding drugs (and i suppose anything self experimentation could help on)? would such a thing be useful if it existed, as a supplement or check on more expensive studies with problematic biases? i guess this database might be a kind of wikipedia of self experimentation.

Nathan Myers (2008-07-30 17:18:26)

Is this the place to repeat my mother's report that 1000 IU Vitamin D supplements caused all-over itching in herself and (later) in my father, mitigated by reducing dosage? Or the place to complain that the huge study skewering vitamin E as increasing cancer risk used a synthetic alpha- acetate formulation, despite that nowhere in nature do you find only alpha-, and that the acetate compound interferes with some people's (e.g., my) digestion? Where is the study using mixed alpha, beta, gamma free-form natural extracts as they appear in, you know, *food*? OK, never mind.

seth (2008-07-30 22:38:11)

Mike, that's an excellent idea. Nathan, I didn't know that about the Vitamin E study. Thanks.

Andrew Gelman (2008-07-31 21:02:49)

Seth, Why do you say "let's call it self-experimentation"? If he's doing an experiment on himself, that's self-experimentation, right? What do you mean by "let's call it"?

BBrolely (2008-08-01 05:47:45)

I can't speak for all pharma's, but several have a transparency policy. [http://www.lillytrials.com/results/results\\_by\\_ta.html](http://www.lillytrials.com/results/results_by_ta.html) Ms. Bass can search to her hearts content through the adverse events reports: rule of thumb- the bigger the number the more there are, help her look for those "severe" adverse events that are "woefully underreported". In regards to vaccines, you're not part of the "Green Vaccine Team" are you now? <http://thestatsblog.wordpress.com/2008/07/17/hurrah-for-amanda-peat-and-salon/> Finally, not that long ago, big pharma was looked upon as a good business model, now they are vilified, why the sudden change? Perhaps it's the same phenomena that Tierney speak about with information cascades: <http://tierneylab.blogs.nytimes.com/2007/10/09/how-the-low-fat-low-fact-cascade-just-keeps-rolling-along/>

seth (2008-08-01 21:05:49)

BBrolely, if you think I'm wrong that serious side effects are "woefully underreported", could you explain why? Ms. Bass said that it was the way drug companies would shift the endpoints after the trial was over that led to the current requirement that clinical trials be registered. Andrew, he didn't take the drug to see how it would affect his weight. He took it because he thought it might help something else. Which it did. He didn't measure his weight because he thought the drug might affect it. He measured his weight for other reasons. So he was doing two ordinary things. To say anytime anyone takes a drug it's self-experimentation is going a bit far. To say anytime anyone keeps track of their weight it's self-experimentation is probably going too far. That's why it's a borderline case.

VesnaVK (2008-08-03 11:52:33)

Speaking of side effects of powerful drugs, here's an excellent post about statins on the blog of Dr. Michael Eades, co-author of Protein Power: <http://www.proteinpower.com/drmike/statins/statin-disaster/> It tells the story of a man with no health problems other than a set of numbers – triglycerides and cholesterol – that his doctor didn't like. His subsequent slide into medicalization and suffering is chilling, and revealing. Lots of great comments, also.

### Research Assistant Needed in Cognitive Science Lab (2008-08-01 09:20)

[1]Saul Sternberg, whom I interviewed about [2]research design and [3]research strategy, is looking for a research assistant:

A full-time research assistantship is available in Saul Sternberg's laboratory at the University of Pennsylvania in Philadelphia. Applicants should be college graduates with computer programming skills and an interest in the study of human behavior. Current research topics include (1) interaction of brain and biomechanics in the control of timed actions (as in music performance), and (2) how visual information is encoded, transformed, and retrieved within the first two or three seconds after it is displayed. [4]Details.

Saul is a member of the National Academy of Sciences and has won the American Psychological Association's award for Distinguished Scientific Contribution.

He and I have written four papers together, three about [5]Ranjit Chandra's research and one about [6]reaction time and mental models. In the Acknowledgments section of *The Shangri-La Diet*, I wrote, "I have learned more experimental psychology from Saul Sternberg, a research scientist at Bell Labs and a professor at the University of Pennsylvania, than from anyone else."

### The Bechdel Test and Denise Richards (2008-08-01 22:41)

I loved Alison Bechdel's [1]*Fun Home*. It was one of the best books I read in 2007. So I was pleased to learn of [2]the Bechdel Test, which can be applied to TV and movies:

To pass it your movie [or TV show] must have the following:

- 1) there are at least two named female characters, who
- 2) talk to each other about
- 3) something other than a man.

Few movies or TV shows pass it, said Jennifer Kesler.

I came across this test after spending a pleasant morning analyzing data while listening to the first six episodes of Denise Richards: It's Complicated which I found on YouTube. (Such as [3]part 1 of Episode 1.) The show consisted mainly of two named female characters – Denise and sister, Denise and friend, Denise and daughter – talking to each other about something other than a man.

I was surprised how much I liked it. When Denise and her dad (who lives with her) interview people to be her assistant, it was amusing (Denise has about 20 pets; one applicant said she didn't like pets); when she gets mad at an entertainment journalist, it was forgivable; when she enters her nephew's room to find him and his friends looking at a Playboy with her on the cover, it was unforgettable. The entertainment journalist wants to know why she is doing the reality show. "My [recently dead] mom wanted me to do it," Denise says. The journalist can barely keep from laughing. "A deathbed wish?" she says. Denise got upset, so let me answer: The better you know almost anyone, the more you like them.

[4]How to avoid demonization.

More. Gillian Flynn, one of Entertainment Weekly's TV reviewers, [5]hated the show – gave it a D. Could reviewers be overly negative because they are forced to watch?

1. <http://www.amazon.com/gp/product/0618477942/sethrobertand-20>

mike kenny (2008-08-02 08:32:46)

oh that's interesting. i do the same thing when i'm editing (which i don't like doing)-i listen to shows or podcasts. i was doing some editing while basically listening to episodes of dexter yesterday and it makes the editing so much easier. i've wondered if politicians could benefit from having their own reality shows. john mccain seems to get a lot of his likability from making himself very available to journalists. what if he had a reality show while on campaign that ran regularly on his website. would that increase public liking of him? i suspect so, but i'd imagine it would have to be kind of a 'warts and all' kind of show, rather than some idealizing-the-person show. this i suspect would apply to lots of politicians, though perhaps some people are so unlikable that getting to know them makes you like them less-i imagine they are a minority though.

Response to the Bechdel post | the Hathor Legacy (2008-08-16 12:29:17)

[...] Seth Roberts, a professor emeritus of psychology at the University of California at Berkeley, suggested a new show you might want to check out in response: I came across this test after spending a pleasant morning analyzing data while listening to the first six episodes of Denise Richards: It's Complicated which I found on YouTube. (Such as part 1 of Episode 1.) The show consisted mainly of two named female characters – Denise and sister, Denise and friend, Denise and daughter – talking to each other about something other than a man. [...]

## My Humor Research (2008-08-02 21:30)

[Rosie Shuster] did have one quality she could privately lord over her classmates: her father was a comedian. . . A life in comedy meant that Frank Shuster nodded, rather than laughed, at jokes that worked.

From [1]American Nerd: The Story of My People by Benjamin Nugent, pp. 62-3. When I was in college I came up with a theory: Laughter is caused by sudden pleasure. Obviously we enjoy jokes, and jokes have punchlines. People laugh in lots of situations not involving humor and as far as I can tell they always involve sudden pleasure – unexpectedly seeing an old friend, for example.

Which is only to say, as this passage implies, there should be a limited number of joke categories and they should be far from mysterious. I once wrote a bunch of jokes from the TV show Cheers on cards and sorted them into categories. Later I classified [2]six months of New Yorker cartoons and Spy accepted it. It was my first submission and I was thrilled.

More. Mike Kenny put it better than me. That I was able to get my research published in a magazine I adored was "[3]a fusing of the intellectual with the practical." I was going to say it was a practical application of pure research.

1. <http://www.americannerdbook.com/>

2. <http://sethroberts.net/spy/ifthereisonething.pdf>

3. <http://michaelkenny.blogspot.com/2008/07/organic-whole-and-pragmatic-souls.html>

---

Toni (2008-08-03 02:56:45)

Yeah, laughter is a way for the autonomic nervous system to quickly move control from the sympathetic to the parasympathetic system. I.e. you get suddenly really excited (kind of fight or flight) and your body realizes it's not dangerous so it tries to relax you back to normal as soon as possible.

non (2008-08-03 13:09:04)

Hi, this question isn't related to this post. I saw this recently: <http://www.trysensa.com/how-sensa-works.htm> this diet is supposed to work by sprinkling flavors (different sets of flavors each month) on food. Average weight loss is claimed to be 30 pounds per six months, or 5 pounds a month. Is this related to your work/diet? Do you think it should work? Do you know anything about it? Thanks.

mike kenny (2008-08-03 19:08:56)

oh, i'm glad you felt that was a good way of putting what you do! i really like your blog for fusing the intellectual with the practical! do you find that some people have difficulty fusing the intellectual and the practical, seth? or that some people are hostile to fusing the two? to me you seem unusually (in a good way) focused on fusing the two.

seth (2008-08-04 05:58:47)

non, yes it is related to my research. I discuss the connection here: <http://www.blog.sethroberts.net/2008/06/16/crazy-spicing-works/> Mike, I think it is rare to find college professors highly interested in practical stuff because they see practical stuff as lower status. Applied research is lower status than pure research. Veblen wrote about this in The Theory of the Leisure Class.

mike kenny (2008-08-04 15:19:54)

i'll have to check out veblen. i wonder if there are any obvious evolutionary psychological explanations for this phenomenon, too. i'm sort of at a loss on that count! i can imagine alpha males not doing drudge work, and having others do it for them, and i can imagine nobles taking on this alpha-male-like role. i tend to not think of academics as a sort of power-elite, like nobles or alpha males, but perhaps this is a mistake. there is some reverence towards the well-educated. i wouldn't be surprised if alpha males tended to have high iqs, given cleverness seems an asset in gaining and maintaining power.

Phillip J. Eby (2008-08-04 17:24:01)

Speaking of status, don't forget to account for social status in laughter: people are much more likely to laugh at jokes made by their superiors than their inferiors, and in the presence of a person of high status, members of the same group will check whether the superior is laughing before laughing themselves. People are also more likely to laugh aloud if other people are present, and less likely to do so when no-one can hear. All of these things seem to point to laughter having a social signaling function that goes beyond the simple expression of pleasure.

seth (2008-08-04 19:26:53)

Yes, laughter is a curious signal – signalling both submission and dominance depending on the situation.

Igor Carron (2008-08-06 13:11:30)

Seth, I am sure you have seen this: <http://www.sciam.com/article.cfm?id=magnifying-taste&sc=rss> Igor.

non (2008-08-07 09:07:44)

thanks for your answer and sorry to be so slow to respond. He claims to have tested which flavors work best. Unfortunately in response to my query, they informed me their product is not kosher. Do you know anything more about his research or which flavors are supposed to work? IIUC according to your theory, any unfamiliar flavor would work.

non (2008-08-07 09:10:17)

also the subjects used these flavors for a whole month, and only switched sets of flavors at the end of each month. Isn't a month a long time dont you theorize a flavor connection is made more quickly than that?

seth (2008-08-07 09:38:09)

I don't know how Hirsch selected the flavors he used in his research. Good question, I will try to remember to ask him. Yes, according to my theory any unfamiliar flavor will work. Nor do I know why they switch after a month. That might have been the most often they could switch. The effectiveness of many diets seems to wear off after 6 months or so. I think they stop being effective – the lost weight starts being regained – because the diet caused the dieter to eat food less strongly associated with calories and new associations were learned over months. if I'm right, apparently it takes months to learn them enough so they make a difference. That sort of data supports Hirsch's choice.

non (2008-08-07 15:47:25)

that's interesting. Do you have results with unfamiliar spices alone? or have you seen an additional weight loss effect with unfamiliar spices. What would constitute an unfamiliar spice? Must it be totally unfamiliar or just not associated with that food? (I guess the latter, since you suggest sprinkling cinammon on pizza?) I did try cinammon on pizza once and didn't notice anything except a weird taste! Dr hirsch claims that "The Tastants slightly enhance the flavor of your food without changing the flavor. In fact, you probably won't even notice they are there!" How do you reconcile that with your flavor - if one doesn't notice it, how can new flavor connections be made?

seth (2008-08-07 18:16:54)

non, this isn't the place for an extended back and forth. Feel free to give me a call and I would be happy to answer your questions. Or you can post them on the SLD forums.

Pattern Recognition (2008-08-08 03:09:06)

The humorous response (including the release of neurotransmitters and endorphins, instant responses in the autonomic nervous system and a reduction in stress hormones) is also, of course, broadcast as laughter, signalling that one has recognized the pattern in question. This humorous response has both voluntary and involuntary neural networks and, consequently, the response can be attenuated or extenuated in certain circumstances. However, laughter is only a minor part of the major cognitive process known as humour, which is fundamental to perceptual proficiency and has played a vital role in the evolution of humankind's unique intellectual capacities.

Basil Hall (2011-03-05 18:28:42)

Everything mention in the above messages is true to some extent but all these ideas must be place into a coherent hypothesis. I believe my essay (see below) does this. It may not be correct but it answers most of the questions that still puzzel researchers. Basil Hall <http://sites.google.com/site/basilhughhall/anewtheoryoflaughterandhumor>

## How Should We Fight Infections? (2008-08-06 18:06)

In the latest New Yorker, [1]an article by Jerome Groopman is about the emergence of even-more-antibiotic-resistant bacteria.

I asked him what we should do to combat these new superbugs. "Nobody has the answer right now," he said. "The fact of the matter is that we have found all the easy targets" for drug development. He went on, "So the only other thing we can do is continue to work on antibiotic stewardship."

All the easy targets, huh? Here's an easy target that hasn't been exploited: Why are colds more common in the winter? Many diseases are more common in the winter. I believe it's because sleep is worse in the winter. While you are asleep is when your body does its best job of fighting off infection. When [2]I vastly improved my sleep – by standing much more, and by getting more morning light – I vastly reduced the number of easy-to-notice colds that I got. I still got cold infections, I think, but they merely caused me to sleep more than usual for a few days.

Several years ago I noticed an introductory epidemiology course in the UC Berkeley School of Public Health was taught by someone I knew. I called him. "Is your course going to cover what makes our ability to fight off infection go up or down?" I asked. No, he said. That is the usual answer. The question of why colds are more common in the winter is not part of the traditional study of epidemiology.

The connections between sleep and fighting off infection are so strong I'm pretty sure I'm right about this (that colds are more common in the winter because sleep is worse). Why, then, haven't sleep researchers looked into this? Strangely enough, they may not have thought of it; I haven't come across this idea in any book about sleep I've read. (If you've seen it somewhere, please let me know!) Justifications of sleep research tend to revolve around car accidents, which are often caused by too little sleep.

More. My point is not that poorer sleep causes more colds in the winter; it's that it's an easy target. Suppose you think the colds/winter connection is caused by less Vitamin D in the winter. An experiment in which one group gets Vitamin D supplements in the winter and another group doesn't is easy to do, given the great health implications.

---

Dennis Mangan (2008-08-06 18:21:15)

I can't think of any reason why sleep should be worse in winter; as far as I can tell, it ought to be better due to longer hours of darkness. As for the relative increase in colds during winter, several other factors come to mind: less sunlight means less vitamin D production and thus weaker immune systems; less sunlight also means lower microbicidal ultraviolet radiation; cold weather means people are indoors more and can more easily communicate pathogenic microbes to each other.

mike kenny (2008-08-06 19:36:08)

dennis, i thought it was odd too that sleep could be worse in the winter. i had an odd thought: if you sleep poorly in winter, you might be groggy and therefore not able to do much during the day, limiting your energy expenditure when you might need to conserve it. in the summer, if you sleep well, you have energy to make use of the long days. winter tends to be associated with depression, which manifests sometimes as low energy and poor sleep.

Ben Hyde (2008-08-06 20:06:53)

Demmet's big book on sleep is full of interesting stuff.

Aaron Blaisdell (2008-08-06 20:13:32)

For a long time now, I've noticed that I sleep much better in the winter when the ambient indoor temperature is cool (and I can snuggle up warm and toasty under the covers) than in the summer, especially when it's hot. In warm weather especially it takes me longer to fall asleep, I feel less comfortable in bed, I wake up more frequently, have more bouts of insomnia, and wake up earlier than when the weather is cooler. I love summer but I always dread the uncomfortably warm sleepless nights.

John (2008-08-06 21:05:30)

I don't buy the bad sleep in winter thing. Not true for me. Besides, I thought it was the lack of vitamin D which caused colds and influenza in winter (unless you lived someplace sunny that is).

seth (2008-08-06 22:06:06)

Dennis & John, I have seen at least one study showing that sleep is worse in the winter. There is a reference to it in that self-experimentation article. I believe sleep is worse in the winter because there is less morning light – that light increases the amplitude of a circadian oscillator that controls sleep is not exactly a revolutionary idea. But even if I'm wrong, something that has a big effect on rate of infection changes a lot from summer to winter. If it turns out to be Vitamin D, for example, that would be very helpful to know.

Mark (2008-08-07 01:24:47)

People cluster closer together, indoors, in the winter, so transmission is increased. Just a small difference in the number of people in proximate location to each other translates into huge exponential growth in infection.

david (2008-08-07 06:05:51)

I agree that inadequate sleep can be a contributing factor to getting a cold. That's definitely been true in my case. Given time to catch up on sleep and some Zicam zinc lozenges I can fight off any cold. As for why colds are more common in the winter, I read "somewhere on the internet" that this is due the fact that the in colder, less humid weather the mucus in your nasal passages dries up making it easier for the germs to get in. My guess would be some combination of factors. I'd be interested to see data about when cold season starts in the northern areas versus southern areas.

Dennis Mangan (2008-08-07 06:54:41)

This may be of interest: "Epidemic influenza and vitamin D" <http://journals.cambridge.org/action/displayAbstract?fromPage=online &aid=469543>

Aaron Blaisdell (2008-08-07 06:55:56)

Just to raise more potential contributing factors, there is the stress from the holiday season to consider, plus all of the extra travel from Thanksgiving to Christmass/Hanuka (sp?), then New Years. This raises the question as to whether infectious illnesses like the common cold are more common in winter in ALL cultures or largely in western society?

Nathan Myers (2008-08-07 13:40:22)

Aaron: they are. Furthermore, they're more common then in completely isolated communities (i.e. not brought in by outsiders). They're more common where it's always hot. They're more common where it's always cold. The only important variable is that in the southern hemisphere, the phase is reversed.

Nathan Myers (2008-08-07 16:43:45)

Evidently I wasn't clear: colds are more common in winter everywhere, even in places that are always cold, and places that never really get cold, and places that get no visitors. You're left trying to explain it by reference to light and to temperature changes vs. the summer baseline.

Nathan Myers (2008-08-07 18:28:58)

Evidently I wasn't clear: colds are more common in winter everywhere, even in the Yukon, and in the tropics, and in places that get no visitors. You're left trying to explain it by reference to light and to temperature changes vs. the summer baseline.

Chris B. (2008-08-13 11:34:38)

I suppose another possibility is that the body's cold-fighting ability has an annual rhythm. Perhaps the systems that fight off infection need a respite after a period of intense activity. If the organism's most important activities (reproduction, food-gathering) take place in summer, it may sense to schedule the down time for winter. The obvious alternative - maintaining a lower but constant level of robustness year round - might be suboptimal.

Chris B. (2008-08-13 11:42:16)

To complete my thought: In that case, looking for environmental cause of wintertime liability to infections would be a dead end. On the other hand, it could be Vitamin D! (BTW, in light of the new studies on Vitamin D, doesn't it strike you as scandalous that this reasearch wasn't done decades ago? You'd think that correlations between all well-known nutrients and population health would be considered basic statistics, the public-health equivalent of the national census.)

### **If You Read Portuguese... (2008-08-07 07:44)**

...you might want to read [1]this webpage by a Brazilian woman about the Shangri-La Diet. And feel free to tell me what it says.

More. The Portuguese edition of The Shangri-La Diet is titled A Dieta Shangri-la. Its ISBN number is 978-85-7684-168-5.

1. <http://www.dietashangrila.blogspot.com/>

Dennis Mangan (2008-08-07 09:59:10)  
Keeping it short, what she says is good.

seth (2008-08-07 13:01:04)  
thanks, Dennis

Tom (2008-08-07 13:34:25)

Here's Google's machine translation: \_\_\_\_\_ Interview with author of the diet - Seth Roberts The author of the diet Seth Roberts agreed to answer questions that all we have on the diet, or any other questions, in an interview. I will organize the questions to which he responds, then publicarei here on the blog! The deadline is until 14/08 to send their questions and doubts! I hope the collaboration of you! Send your questions! It may be by mail, in the commentary here in my blog or orkut profile: <http://www.orkut.com/Profile.aspx?uid=17-96069216891997996> Sobre Dietas... About Diet ... Today I found a very interesting article on diets and weight loss based on searches and would like to post a summary here since the article is longã€| For those who take an interest in original article in English: <http://www.amptoons.com/blog/archives/2006/04/03/the-case-against-weight-loss-dieting> The case against the Diet "Probably no medical advice is given as often and with so little rational basis on the pressure for obese people lose weight" 1) Para a maioria das pessoas obesas, as Dietas nãŁo funcionam 1) For most obese people, the Diet will not work This means two things: that the amount of weight that is lost is not the person ceases to be obese and that this loss is generally not maintained. There is no clinical study demonstrating a long-term success in losing weight (5 years). Large companies earn billions of dollars with promises of weight loss every year, but if a company could certainly make obese people in thin would make more money than any other company on the planet. One possibility that would impede the loss of weight permanently would be for our bodies fit for the reduction of calories ingested by decreasing the metabolic rate and increasing the proportion of food stored as fat. This means that the more you make diets, vai be more difficult to lose weight in the long term. 2) Weight loss does increase the probability of dying before you Often people gain back the weight they lost, but that does not mean that they returned to where they were at the point of view of health. This means that there are studies indicating that the weight loss reduces mortality and others that indicate that even increases. Sometimes people who have diets are more likely to die of cardiovascular problems that obese people who keep their weight stable. Especially people who lose weight and come back to win it (the effect sanfona) further increase the risks to the health effects such as high blood pressure, high cholesterol, cancer ... Moderate physical exercises is the only thing proven that it increases its longevity and quality of life ... 3) The idea of "normalizing" the dietary habits is a myth Normally if you believe that people are obese because they eat more and thus are less exercise and that people are thin. Which is as thin eat fatty would also be obese, and that if the obese eat normally as they lean iram slimmer. Many studies have tried to show that obese people eat more calories, but have had no success. It is true that many people above the weight have diets rich in calories, fats, fast food, etc., but there are many thin people who eat well. Our body is much more complicated than a simple matter of eating more or less and spend as of calories. 4) Para Resumir: 4) To summarise: - "Nunca foi comprovado cientificamente que uma dieta produza substancial perda de peso em longo prazo, a nãŁo ser em uma minãŁscula quantidade de indivãŁduosã€?. - "It has never been scientifically proven that a diet produce substantial weight loss, in the long term, unless in a tiny quantity of individuals." - "If the diet work or not, people who make them is most likely to die sooner than those who keep their weight stable or who gain weight slowly." - "For obese people (or anyone) concerned about their health, the best option is probably moderate exercise and eating fruit, vegetables without worrying about standards of beauty and weight." - "The model that anyone looking for losing weight is based on that obese people eat more and must learn to eat as thin, is probably a myth." Responding to the criticismã€| I found a blog by Stephen M (<http://www.ethesis.blogspot.com/>) very interesting diet on the Shangri-la. He began the diet on November 13, 2005 with almost 110 kilos and in April 15, 2006 already weighed 87 kg or less 23 pounds in 5 months ... It continues with the diet until today to maintain and says be very happy and keep its 81kg today. A great example of perseverance and strength in the mirror and we must follow. The blog it is very interesting and I advise those who want to read a story of success (in English). Well, but let's answers to some of Stephen's criticisms of the diet and some other found on the Internet: Todo esse ãŁleo nãŁo pode ser saudãŁvel!! All this oil can not be healthy! - The amount of oil that is taken in the diet is less than if one eats a large portion of fries. - Some proven benefits of olive oil: It is a versatile food and essential to health as it benefits the gallbladder and liver, stimulates the secretion of bile and tonicity of tissues, also serving as nerve tonic, stimulates muscle contraction. The intake of olive oil is good for people suffering from cholesterol because it helps to dissolve the deposits of cholesterol. You were just

lucky – The calorie intake in the diet shangri-there are differences. With 3 tablespoons of soup Stephen maintained its 85 kg for almost 2 years. If it reduces the quantity, weight gain and when increases start to lose weight. – With 50 years is hard to change the metabolism to lose weight as other diets speak ... Only restriction of calories / starvation diets and exercises to work – For 2 / 3 of 2.8 % of people who can make a diet with much conviction is successful. – With the diet shangri it if you have to lose 18kg or more, 75 % of people seem to have success and maintain the weight reached. Mas vocÃª deveria apreciar a comida! But you should enjoy the food! – You'll still enjoying the food. Just eat less and eat more if their metabolism fits. – Many people try doing this diet try new flavors – Much better not be slave to food. I could never follow this diet – Why not? – It is cheap and uses ingredients you have in your home ... – You can even take the oil in the middle of the night when most convenient to you ... ! It makes no sense! .. – There is the theory of Seth behind the diet ... Why do not you try too?

### Unreported Side Effects of Powerful Drugs (part 3) (2008-08-07 20:06)

A [1]comment on the [2]previous post in this series – thanks, Vesna! – led me to [3]a horrifying story about what happened to someone whose doctor prescribed statins (an expensive and nearly worthless class of drugs) because his cholesterol numbers were bad. (My friend and collaborator [4]Norman Temple has [5]written about the true value of statins.) The doctor did not warn him of the dangers, which were great. When his troubles began, he should have simply stopped the drug. What actually happened was that his doctor prescribed another dangerous drug. And his troubles got worse. Shades of [6]Jane Brody!

I know a similar story. The elderly mother of a friend of mine was taken to the emergency room of a hospital because she had some sort of attack. It was the third such attack in a year. Her children were concerned. She was not of sound mind. Heroic measures to help her? Or a peaceful death? They chose a peaceful death. She was moved to a hospice. By mistake, her six prescriptions failed to be transferred. A clerical error. So she wasn't able to take her usual drugs. She soon got better! Within a week or two she returned home. The drugs her doctor had prescribed had been killing her. Nobody had noticed.

First do no harm is a scary motto because it shows that those who take it seriously – supposedly the entire medical profession – aren't thinking clearly, as I've heard [7]Robin Hanson point out. It's like English teachers having a motto with a word spelled wrong. And the consequences of doctors not thinking clearly – not doing something as obvious as stopping dangerous drugs when the patient gets worse – can be terrible. My suggested replacement motto: Learn something from everyone who comes to you for help.

This is closely related to self-experimentation, of course, which is all about figuring out for oneself what effect something has. I got a lot more interested in self-experimentation when it showed me that an acne drug I'd been prescribed was worthless.

[8]Part 1.

Nathan Myers (2008-08-07 22:17:49)

My wife's grandmother was driven to the brink of suicide by what felt like powerful electric shocks at her left cheekbone, and by the high doses of tegretol her doctor prescribed for it that left her too dizzy to walk. After many months I finally persuaded her to visit a specialist in another city, who in a simple outpatient procedure inserted a spacer between two crossed nerves, completely eliminating the problem. Her husband went from a vigorous, active life to a passive little old man in only a few months from radiation treatments to his prostate. It made him dizzy and he fell from a loading dock, and his broken hip was not detected for six months. When my own father had his pelvis crushed, recently, under a backhoe, the hospital staff decided on their own say-so to stop giving him his bipolar meds, cold turkey, and great risk to him. My sister-in-law presented, some years back, with extreme abdominal pain, and was sent home without being tested for ectopic pregnancy, and nearly died. I could go on. We learned only recently that in treatment of myriad drowning victims in recent decades, their brains deprived of oxygen were undamaged until attending physicians applied oxygen, provoking massive cell death. Medical malpractice has been blamed for 75,000 deaths/year in the U.S., but I suspect that number is a lower bound.

david (2008-08-08 12:46:40)

Good thing we have "tort reform" to protect the medical profession from lawsuits!

Tom (2008-08-08 22:21:18)

Giving pure oxygen is also what blinded tons of premature infants until recently. It was simply assumed, without testing, that more oxygen was better, and it was many years before it occurred to someone that the oxygen might be CAUSING the blindness. Similarly, people assume that eating fat makes you fat. It just makes SENSE, doesn't it? Incredibly, the testing HAS been done and most people still don't believe it.

question (2008-08-11 08:34:48)

Where's part 2?

seth (2008-08-11 09:37:33)

Part 2 = previous post in this series

Methuselah (2008-08-12 22:32:54)

I think that between 'Self Experimentation' and 'self-reported experience' lies a continuum of rigour but that both are valuable. As well as exposing side-effects the pharmas would rather gloss over, I believe these case studies, driven by the aggregation medium of the internet, are starting to reveal the extent to which diet can obviate the need for some drugs, but that the evidence is being undervalued by the research community - I argue this in more detail here: [1]Are we Underrating the Anecdotal - would love to get your views. Methuselah [2]Pay Now Live Later

## **The Best Food Writing I've Read (2008-08-08 12:30)**

I subscribed to Saveur for several years but never finished any of the long articles - which weren't that long. This should have puzzled me, but it didn't. A month ago, however, I got the audiobook of Secret Ingredients, the New Yorker anthology about food. I was surprised how many of the articles I didn't want to listen to. 90 %? Usually I like New Yorker anthologies and read most of the articles. I'm a more tolerant listener than reader which made the comparison even worse.

Here's my explanation. Food writing is like downtown Edinburgh. Its main street has shops on one side, on the other side a park. What should have been the economically most lively street in the city is rendered half as effective as it might be by the fact that half of it isn't businesses. As something to write about, food is similar. Just as a park is economically inert, food is psychologically inert. Like a park, food can be pleasant (to read about) but it doesn't act. It isn't alive. This is why those Saveur feature articles were hard to read, I realized. They resembled flat lists: We cooked and ate X, Y, and Z. It's incredibly hard to make that sort of thing fun to read. The best article in Secret Ingredients was John McPhee's profile of Euell Gibbons. It's a mini-adventure story, with an interesting guy at the center. The food is . . . a condiment.

This is why I'm so impressed by the chapter "Waizhou, USA" in *The Fortune Cookie Chronicles* by Jennifer 8. Lee. Waizhou means "out of state" – in this case, away from New York City. It's the story of a family who left New York to run a Chinese restaurant in a small Georgia town. It took a shocking turn that Lee didn't expect. Police took the children away. The father was arrested. "The offices pointed to the burn scars from cooking oil on the parents' arms and said that was evidence that the couple had a history of fighting." This had horrible and ramifying effects. "Oh, I can't eat there anymore," said a lawyer, "that's the DV [domestic violence] case." The teenage daughter starts using the court system to punish her mother. The parents are arrested again. "They had violated court rules by driving near their children's foster home. Because they had sold their restaurant they were considered a flight risk." Eventually they get their children back, and go back to New York. It's a whole slice of life I'd never read about before. Enormously emotional and unpredictable. The father enjoyed jail. "When I was in jail for two days, it was really relaxing," he told Lee.

---

mike kenny (2008-08-08 17:52:32)

that's a good point about food being psychologically inert. it seems like shifting from list-making to a sort of problem-solving process aimed at obtaining some strongly desired aesthetic experience might be more engaging, along with the dramatic tale you recounted. chef as struggling artist, or mad scientist. 'how can i make this good? how can i make this good and affordable? how can i make this not boring anymore?' i have a good friend who likes to talk about food. i'm inclined to think he and his foodie acquaintances, when they are talking about food, are in part, demonstrating they care, sort of like the stereotypical jewish or italian mothers. 'i hope you like this salad. it had x, y and z in it. i care about what you ingest, and here is what it is. it's only the best for you!' maybe that form of communication is being carried over to food writing?

John S. (2008-08-10 05:20:55)

I found a website for her book. There are some excerpts, including a link to her original Times article about the family who moved to Georgia: <http://www.fortunecookiechronicles.com/excerpts/> Remember the Seinfeld episode where George gets mad when he finds out Susan's cousin named her baby "Seven"? I always wondered if they were poking fun at Ms. Lee, the only person I've seen with a number in her name (besides The Prisoner).

mike kenny (2008-08-10 12:37:34)

that was sort of an interesting read, the secret test. i like the idea of testing what seems like obvious nonsense—astrology for example, as a simple means of disproving the idea, or, because it's possible that there's some value to astrology or the secret. for example, the secret sounds like it could help some people become clear about what they want, which could be half the battle in getting what you want. isn't there some kind of psychological concept of essentially 'faking it till you make it'? you imagine you have a million dollars and so you emulate millionaires and some of that emulation actually has practical value in getting a million bucks. no need for a metaphysical explanation. of course...acting like a millionaire by incurring debts like one...well, that could be a problem! and the magical thinking would maybe obfuscate that possibility. anyway, either way, cheap, low risk testing of claims seems a valuable tool, which i think is in line with your thinking!

david (2008-08-10 15:28:51)

Ok, first let me admit that I haven't read or seen the movie The Secret...but it sounds like the sort of thing that's ripe for exhibiting the Forer effect. You visualize yourself a new car and at some point you receive a toy car or a picture of a car or end up being loaned someone's new car...your mind finds some way to say it worked. It's like a horoscope in reverse. Anyway, it sounds like bullshit to me (or would that be smells?). On the other hand, it would be really ironic if the writer of that blog post about testing the secret ends up with some book deal resulting from someone in the publishing industry reading her blog post.

### **Everyday Humor (2008-08-10 22:08)**

In the checkout line at Monterey Market:

ME Are those mangosteens?

MAN They're baby artichokes.

You eat them raw, he said. Peel off the outer leaves and slice them thin.

MAN With some Pecorino sliced thin, pinenuts, a little olive oil . . .

ME Sounds Italian.

MAN Yes, it is.

Everyone laughed.

Nathan Myers (2008-08-11 10:26:22)

I don't get it. Were they really mangosteens?

seth (2008-08-11 12:15:52)

No, they were baby artichokes. You're right: it isn't a conventional joke. But it was funny enough so that even a bystander laughed.

## **What Do Organizers Do? (2008-08-11 04:21)**

At a cooking class, I met Ami DeAvilla, a professional organizer. It's a profession so new – 15 years old? – that I was curious what sort of problems she works with. She told me some examples:

Example 1. A woman who was 4 years behind filing her taxes. She was collecting the letters from Franchise Tax Board and the IRS. There wasn't that much money involved – she might even have had some money owed to her. Became overwhelming and daunting. As the years went on, doing her taxes became overwhelming. She had a "fear basket": those letters went in it. I was able to come in & open the most recent of the letters. She did have all of the info. There was a lot of fear involved. Also she had gotten divorced. Emotion of having to handle financial stuff on her own. She contacted me because she knew she needed to file but couldn't do it on her own. Her sister found me through the website of the National Association of Professional Organizers. We met twice/week for a few hours. We did 3 years together; she did the last one on her own. Total 15 hours [Ami's current rate is \$100/hour]. One 3-hour session was about her current relationship to money, which was as important as the taxes. Just as having a heart attack can lead you to improve your health habits because it indicates a greater problem.

Example 2. A woman who for 37 years had been in the same home. She needed to decide whether to stay there because her husband's health was getting worse. It was a two-story house. Two sets of steps to climb because it was on a hill. Not possible for him to be mobile in and out of the house. He had severe back pain and had trouble getting up the stairs. It was her home. She didn't want to leave. She was feeling overwhelmed with the decisions to be made. After she decided to move, there were decisions about their stuff. They were moving to a much smaller place. Moving from four-bedroom house to three-room apartment. Sorting through their entire life. Dividing belongings among all their children and grandchildren.

Example 3. A small business owner who had been in practice for over 20 years. His home-based office was a mess. People not billed. Papers all over the office. He works on site. He came to me because it was daunting to take care of tasks that needed to happen. He would hire someone to help in the office but they wouldn't work there until it was cleaned up. They didn't want to feel overwhelmed by the clutter. He wasn't able to clean up his office. He was working a lot of hours, trying to balance personal life with business life. Now that he was taking some personal time, and not working all night, business things weren't being taken care of.

Example 4. Published author, several books out. She was juggling four pressing projects and trying to start a website. Continuing on a book she was halfway into. Couldn't make the writing work. I worked with her for 2 hrs to help her prioritize her time. Previously she was able to manage some of this better. When the website came along it became another project that kept the writing from happening. She'd been working on the book for a year or less; she was more than halfway through, and now falling behind the publisher's deadline. She wanted a plan, plus physical organization of her workspace. We shifted the space a little bit to help her focus on writing. She was getting distracted too much.

Example 5. A woman called me because her house was not the way she wanted it. Three people had died and she had inherited their belongings. She felt overwhelmed in her own home. She'd lived there over 20 years. It was

overwhelming to go through things and make decisions about what she wanted to keep. Stuff had gotten packed in quite a bit. We went through her house room by room and cleared stuff out. Started in the kitchen. Less emotional. Not much room left on the counters. We did 4 or 5 rooms, including office space. She had been a graphic designer.

mike kenny (2008-08-11 20:24:27)

that's a neat idea. your own personal 'fixer' so to speak. to me this person seems to help people who have overdrawn on their finite willpower and don't have anymore to deal with stress, so they pay someone else for his or her willpower, so to speak. your willpower is like your car, and when you run out of gas, the car stops, and you hail a taxi. this idea comes from, i think, a paper tyler cowen linked to at marginal revolution, on willpower as a finite resource, and the paper suggested that when we ran out of willpower, we engaged in behaviors normally restrained by willpower (drinking, binging on food i suppose), or i suppose we failed to do things that willpower would have forced us to do (like taxes, or cleaning up room). this made so much sense to me. does this idea of finite willpower connect with your theory of procrastination at all, i wonder?

seth (2008-08-12 06:12:01)

yeah, I agree with the idea of willpower as finite. Research suggests it is like a muscle: gets stronger with use. To answer your question: No, the notion of finite willpower has little to do with my thinking about procrastination. Although maybe it's why procrastination is a problem worth thinking about.

## **The Undone Work: Electric Cars (2008-08-12 06:08)**

During Bill McKibben's book tour for *Maybe One* (1998), an argument for having no more than one child, he gave a reading in Berkeley. I attended, and asked a question: Jane Jacobs says the problem isn't too many people, the problem is the undone work. (Which I also said at the end of *The Shangri-La Diet*.) For example, air pollution. The solution won't be fewer people, it will be cars that pollute less. I asked McKibben what he thought of this. He said he thought highly of Jacobs, but the EV1 was a failure. Terrible answer, I thought.

Yesterday I spoke to the owner of an electric car. It is entirely powered by electricity from solar panels on the roof of her house. It can't go on the highway but is perfectly good for taking her and her two children around town. She's had it about a year; she bought it after seeing someone else drive one. Leaving aside the cost of the solar panels, driving costs her almost nothing, is very quiet, and produces no pollution. The car was made in Vancouver. In America, it's small; it wouldn't be small in Japan. Looks like the future, I thought.

[1]Green Motors, a Berkeley store specializing in electric cars, started by the man she bought it from. Lovely website, his enthusiasm shines through. [2]Car-maker difficulties.

---

Stephen M (Ethesis) (2008-08-14 15:29:26)

What is really fun is seeing compressed air used as the storage device for energy rather than batteries or gas tanks. Works very well with the minicars, and has little disposal problems ;)

### **Weston Price and the Olympics (2008-08-12 09:39)**

I was surprised how much I liked the Olympics opening ceremonies on Friday. I hadn't been so transfixed by an Olympic event since Joan Benoit won the first woman's marathon, leading the whole way. At one point during the opening ceremonies a young girl in a red dress sang a Chinese song. Or [1]so it seemed:

The girl in the red dress with the pigtails, called Lin Miaoke, 9, and from a Beijing primary school, has become a national sensation since Friday night, giving interviews to all the most popular newspapers.

But the show's musical designer felt forced to set the record straight. He gave an interview to Beijing radio saying the real singer was a seven-year-old girl who had won a gruelling competition to perform the anthem, a patriotic song called "Hymn to the Motherland".

At the last moment a member of the Chinese politburo who was watching a rehearsal pronounced that the winner, a girl called Yang Peiyi, might have a perfect voice but was unsuited to the lead role because of her buck teeth.

Weston Price's research, described in Nutrition and Physical Degeneration, implies that buck teeth are caused by too little of a dietary growth factor, which a commenter described as "the menaquinone-4 form of vitamin K2."

1. <http://www.telegraph.co.uk/sport/othersports/olympics/2545387/Beijing-Olympics-Faking-scandal-over-girl-who-sang-in-opening-ceremony.html>

---

mike kenny (2008-08-12 17:34:50)

the ceremony was pretty amazing, what i saw of it. it's interesting that what visually might have been uninteresting if it were CGI or machinery doing the work (the many people moving up and down in those boxes comes to mind) suddenly becomes amazing because it's a bunch of actual people doing the work. at the same time, i found something creepy about the mass-coordination of individuals during the ceremony. i don't feel that way about dance troupe performances or orchestration, or marching bands. so i'm a little perplexed by my reaction.

### **Science in Action: Why Did I Sleep So Well? (2008-08-13 20:56)**

Last night I slept extremely well. I slept about eight hours and woke up feeling really good. In the past I've slept this well only after being on my feet nine or ten hours. Yesterday I was on my feet maybe four hours. I usually sleep well but this was a distinct improvement.

What caused it? Yesterday had many unusual features (like most days), but I did deliberately vary one thing:

1. I looked at faces (actually, my face in a mirror) earlier than usual. Usually I start around 7:40 am; yesterday I started about 7:10 am. (Background: I discovered that seeing faces in the morning improves my mood the next day. For example, seeing faces Monday morning improves my mood on Tuesday. And makes my mood worse Monday night. Details [1]here.) I've done this before – watched the faces earlier than usual – and hadn't noticed anything unusual. Yesterday may have been different, however, because three days ago I changed something. I always listen to something (audiobook, a Google Talk, This American Life episode, etc.) while I look at my face in the mirror. Three days ago I moved the sound source directly behind the mirror.

This is my best guess why my sleep was better than usual. But yesterday was unusual in several other ways as well:

2. I went outside (in the shade) 30 minutes earlier than usual.
3. Usually wear contact lenses while sleeping but didn't.
4. Usually wear a tooth guard while sleeping but didn't.
5. Salmon for dinner, which isn't unusual, but I had more than usual.
6. No aerobic exercise.
7. Did a lot of chores I'd put off. (Peace of mind?)
8. On the preceding days, the sound source was behind the mirror. In other words, it was the cumulative effect that produced better sleep.
9. The end of a cold.

Now I'll do all sorts of things to test these possibilities.

There's a saying No one believes a theory but the theorist; everyone believes an experiment but the experimenter. This illustrates why. The experimenter can see all sorts of confoundings and special circumstances that others cannot.

---

Igor Carron (2008-08-14 05:23:53)

You also leave out of the equation the actual eight hours of sleep! Do you know for a fact that no specific sound/noise (however small) occurred during your sleep? If one were to follow the "prehistoric" man story you like to come back to, shouldn't an uneventful sleeping state be correlated with a sign of no surrounding predators and therefore be correlated to a good sleep? Just wondering... Igor.

Mike Kenny (2008-08-14 05:25:08)

interesting. maybe hearing voices behind you tends to cause you to feel secure, as if you're with friends who you can trust ("they have my back") and provides a sense of security?

Igor Carron (2008-08-14 06:05:04)

Mike, I was not thinking in that direction (more in the direction that that night, Seth has not heard any noise/sound) but this is interesting. However, how would one explain that snoring is a major impediment for others to sleep in groups ? I am also of the opinion that snoring is also detrimental to the snorer as their noise is bound to make their sleep light. Igor.

Mike Kenny (2008-08-14 06:23:03)

hi igor, i was referring to having the radio behind oneself while looking at oneself in the mirror. i hadn't thought of effects of noise on sleep. i can't recall being bothered by snoring myself (though maybe i don't remember). having people talking around you seems an anti-depressant to me. i used to work in a closed office by myself and being a retiring person, i got a bit isolated, but then i had office mates and the door to my office remained open to the hustle and bustle of people outside it, and i believe my mood got better overall. obviously there could be other causes to my better mood, but it does seem true there's some apparent correlation between hearing people talk and feeling good. placement of the voices seems to speak to trust-if you don't trust people you seem likely to keep them in front of you, and if you trust them, behind you, so if you have voices behind you, it might trigger a feeling of security and friendship, which seems a plausible cause in elevating mood, as seth's experiment might suggests.

peter (2008-08-14 07:04:46)

OT, but related to sleep. there was segment on sleep apnea on pbs' news-hour that talked about an elaborate diagnostic procedure (sleeping in lab hooked up with wires etc.) and treatment that consisted of sleeping with equipment attached to one's face; both of which would be fairly expensive. it turns out that i have had sleep apnea for several years and that merely using a breath right strip across my nose resolved the problem. (i didn't have a scientific diagnosis, but the before and after difference in my sleep was clear). the point is that i did self-experimentation rather than be drag into the medical establishment to spend thousands of \$ \$ \$. (one of the great things about reading your blog is that it leads one to consider and try self-experimentation). It may be that this simple inexpensive "treatment" may not work for everyone, but it ought to be tried before sufferers/society incur the expense of a cumbersome and often ineffective "medical" treatment. There are other simple treatments as well, such as a applying wrap to one's head (from the chin to to the top of the head) to force one to breath thru the nose. I don't see these simple treatments discussed on-line and they weren't discussed in the pbs piece.

seth (2008-08-14 10:21:54)

Igor, I don't think there were any unusual sounds while I was sleeping. It wasn't unusually quiet, as far as I know. Mike, the voices were behind the mirror, not behind me. The effect was that looking at my face while listening to voices was a lot more realistic since the voices appeared to come from the face, rather than somewhere else. Peter, I completely agree. I hadn't heard that before about the breath right strip resolving apnea, that's really helpful to know. Those sleep labs tend to conclude you have disordered breathing whether you do or don't, according to Insomnia by Gayle Greene.

Mike Kenny (2008-08-14 11:59:14)

oh, i see. my mistake! i misread.

MT (2008-08-15 05:39:22)

## The Professor Has No Clothes (2008-08-14 11:32)

In 1953 Harvard appointed an architect named Josep Sert to a powerful position. Sert had some amazing ideas. From a [1]review of a new book about him:

With the help of Walter Gropius, [Sert] was appointed dean [of the architecture school] at Harvard in 1953, where he set up the world's first course on urban design, a perfect platform from which to propagate the modernist Ciam agenda for shaping cities using new science, principles and forms. . . .

As propagandist for a type of urban thinking which would have disastrous consequences, Sert had a programmatic mind-set which could see the beauty of historic cities, but his totalitarian attitude insisted on extrapolating abstract systems out of their features. In 1953, for instance, he proposed that if repeated endlessly, the traditional patio house could make a whole city. . . . Sert continued to insist that since the unplanned energy of cities is "chaotic" and "disorderly", the planner must normalise and "overcome" it. He expressed these convictions in abstract terminologies about neighborhoods, scalar zones, urban functions, categories and so on, and in complacent assertions "every city is composed of cells, and the role of planning is to put these cells into some kind of system or relationship."

His 1952 plan for Havana is one shocking example. Commissioned by a group of speculators intent on carving up the city, Sert's Pilot Plan "addressed the entire metropolitan area of Havana, applying Le Corbusier's rules on classification of roads", a totally abstract theory. Having destroyed the city's historic streets and obliterated all memory of Old Havana, he proposed "clusters" of what he supposed would be "charming streets recalling the city's origins", but with dimensions that would use the completely abstract principles of Le Corbusier's Modulor. This awful scenario was to be dominated by "tall towers for a new financial district" which would have wrecked Havana once and for all.

Thankfully, the 1959 Cuban revolution thwarted this insane plan.

I wonder what real-world events led Hans Christian Andersen to write "[2]The Emperor's New Clothes."

### Science in Action: Why Did I Sleep So Well? (part 2) (2008-08-15 09:14)

A few days ago (Tuesday night) I slept unusually well, presumably because Tuesday day had been unusual in some way. I [1]made a list of nine possible reasons.

Today I realized I'd forgotten something: 10. Stood on one foot more than usual. To pass the time while looking at my face in the mirror I had stood on one foot while stretching the other leg, pulling my foot up behind me. I was curious how long I could do this so I did a few trials with each leg where I did it until it became too painful. I lasted about 2 minutes on one leg and 2.5 minutes on the other.

This might seem trivial – and I forgot about it. But standing on one foot continuously for a relatively long time surely stressed my leg muscles much more than usual. [2]Previous research convinced me that standing many hours improves sleep. Maybe this "extreme standing" produces the same hormonal effects in a few minutes as normal standing does in ten hours. That would be wonderful!

andrew smith (2008-08-15 09:56:29)

I was always very interested by your theory that standing more than 10 hours improves sleep. After you performed all that self-experimentation, did you ever take the next step and check to see if others who routinely stand more than 10 hours a day (waiters, retail workers, etc.) sleep unusually well? Of all your hypotheses, it seems the stand/sleep one would be the easiest to prove because plenty of people naturally engage in the behavior.

david (2008-08-15 10:20:42)

Better us retail workers. Waiters and bartenders tend to abuse other substances that might interfere with their sleep.

Kirk (2008-08-15 14:44:23)

At least one branch of Tai Chi (Cheng Man-Ch'ing as taught by Ben Lo) emphasizes holding postures. Several postures require all weight to be on one leg, such as White Crane Spreads Wings, and Play the Lute. You could wander over to Lenzie Williams classes in Berkeley and ask him and his senior students if anybody has noticed a difference for the days they hold postures.

seth (2008-08-15 15:03:24)

Andrew, I have done such a study. Two students and I compared the sleep of retail workers with people with desk jobs. There was an interaction of job and age. Older workers showed the predicted effect (those who stood a lot had better sleep than those who stood little); with younger workers, their sleep was usually good in both cases (so the lack of difference was probably a ceiling effect).

mike kenny (2008-08-15 17:03:17)

i'll have to try standing on one foot for a couple minutes and then the other to see if my sleep gets better. i sleep pretty well anyway, but why not?

Thomas See (2008-08-15 20:23:09)

I find your site is very interesting and infomative. I personally practise some "Chi Kong" before my bed time, it does help me to sleep better at night. Good Job!

Heidi 555 (2008-08-16 04:45:15)

Seth, I see why you are so successful with self-experimentation. You are willing to entertain some unusual hypotheses in terms of cause and effect. And then you have the patience to test them out. I think that your ability to remain open to unusual correlation is key. It appears that one must initially learn to suspend the mind's (left brain) critical judgement. My brain immediately discredits certain hypotheses as implausible. Also, I tend to assume that there are multiple causes for an effect that work together synergistically, so combinations of variables that play a part can seem overwhelming. (I've been reading the book: My Stroke of Insight by Jill Bolte Taylor so I've been thinking about brain pathways involved with things. She is a neuroscientist who had a severe stroke and was able to articulate what occurred from that perspective. It's a fascinating and inspiring read.) I feel inspired to test your standing on one leg hypothesis. I enjoy yoga one-legged postures even though I rarely do them. Also, I've wanted to improve my balance by standing on one leg on a balance disc. When I did T-Tapp I most enjoyed the exercises that entailed standing on one leg. I did those one legged exercises for quite an extended period of time. I don't recall if my sleep was better, but it might have been. I am curious about other health benefits of one-legged standing.

seth (2008-08-16 10:48:38)

Thanks, Heidi. The hypothesis in this post – that standing on one leg will improve sleep – isn't implausible given my earlier observations that standing for many hours improved sleep. In the earlier work I found that until the standing became stressful (= many hours) it had no effect. I should have realized back then that it might be the stress, not the hours, and that other ways of producing stress might have the same effect. But you're right, I did entertain a strange hypothesis. It happened when I considered the possibility that mere standing (not exercise) would cause weight loss. That's why I started standing a lot many years ago. That hypothesis turned out to be completely wrong – I didn't lose any weight – but I did start to sleep much better.

Heidi 555 (2008-08-16 16:23:12)

That's great how a wrong weight loss hypothesis led to improved sleep. Actually, I was thinking that the standing on one leg was less unusual than many of the other things on your list (in the previous post of why you slept so well). It was helpful for me to read your list and have a glimpse of how you generate self-experimentation ideas. I hope that you'll continue to write about the things that you'll do to test these possibilities. I admire your ability to come up with obscure and unusual ideas. I wrote a list of things that help me to sleep better, but they are more obvious commonly accepted kinds of things. I'm pondering how to look for more unusual correlation. Today I stood on one leg on a balance board while washing dishes. I like the challenge of it – it was fun. I actually was sorry that I didn't have more dishes to wash!

Nadav (2008-08-16 19:30:05)

Consider that humans evolved to stand–actually to walk–for long periods in search of food, and also to undergo short periods of extreme exertion when killing prey or fleeing from danger. Maybe some combination of both produces optimal sleep.

[...] Science in Action: Why Did I Sleep So Well? (part 2) [...]

evconvert (2008-08-18 13:58:58)

Could you elaborate on what "too painful" means exactly? I think I can stand on one leg for a long long time in various states of discomfort to pain.

seth (2008-08-18 16:06:24)

Evconvert, my threshold for stopping is low. "Too painful" means "more than slightly uncomfortable". Or even "slightly uncomfortable." You could say I stop when it becomes difficult to continue.

Kroatien (2008-12-03 00:16:46)

Hello webmaster I like your post "Science in Action: Why Did I Sleep So Well? (part 2)" so well that I like to ask you whether I should translate into German and linking back. Answer welcome. Greetings Kroatien

### **Science in Action: Why Did I Sleep So Well? (part 3) (2008-08-16 22:44)**

Yesterday I did two of the 10 or so possible things that might have caused me to [1]sleep really well recently: (a) looked at my face in a mirror earlier than usual with voices behind the mirror (Factor A) and (b) [2]stood on one foot until exhaustion (twice) (Factor B). And last night I slept better than usual – not quite as great as the first time but still really well. This seems to narrow down the possibilities to:

- Factor A only
- Factor B only
- Factor A and Factor B

I have doubts about Factor A. After I figured out that seeing faces in the morning improved my mood, I tried for months to find the right "dose" (right time, right length) to improve my sleep. I didn't find it. Whereas Factor B is merely a new version of something that has improved my sleep countless times, so much that I've noticed its effects when not looking for them. The effect might have been less clear last night than the first time because I only stood on one foot to exhaustion twice. The first time – I wasn't paying attention, of course – I think I did it three or four times.

So today I did it six times. It was curiously exhausting. After I felt recovered (about an hour later), the rest of the day I felt really good, cheerful and energetic – better than after yoga. That doesn't make a lot of sense. If I do something that makes me sleep better, shouldn't it make me more tired?

Methuselah (2008-08-17 05:46:05)

I guess the problem with experimenting like this on consecutive days is that there's no way to know whether the first day's activity has impacted the second...do you think it's necessary to decide, for each experiment, how much time must elapse between tests to be sure this effect does not apply? Methuselah [1]Pay Now Live Later

mike kenny (2008-08-17 09:56:47)

maybe being on your feet triggers energy during the day. being on your feet a lot could mean there's some benefit to being on ones feet, and so more energy is provided by your body to keep up the beneficial behavior (might explain why runners get addicted to running and feel nervous when not running). but since one is expending more energy on one's feet, one sleeps better. there is a greater need for recuperation. it's a bit like your dieting theory. the body economizes on behaviors, doing them when they are most beneficial and cutting back on them when they aren't terribly worthwhile. maybe in the stone age we benefited from days of long exploration on our feet sometimes, but at other times it was best to relax and not wander around too much.

## Science in Action: Why Did I Sleep So Well? (part 4) (2008-08-17 05:45)

I repeated the two things that [1]remained on my list as possibilities for why [2]I slept so well a few nights ago: 1. Looked at my face in a mirror a half-hour earlier than usual with a better sound source. 2. Stood on one foot until exhaustion (6 times). Lo and behold, I slept great. Now I'm pretty sure one of these two, or their combination, is responsible.

An unexpected twist is that I only slept 5 hours. Usually I'd still feel tired after that little sleep. But I feel like I slept 7 or 8.

I suspect the standing, not the faces, is the cause. Which would be ironic. Of the treatments I've studied by self-experimentation and found helpful, standing 9 or 10 hours, which [3]greatly improved my sleep, was the most difficult. I loved what it did to my sleep. I still remember how wonderful it felt to be so well-rested the next morning. Even so I stopped doing it. As an experimental treatment, it was hard to measure how long I stood. As a lifestyle change, it was really hard to arrange so much standing. Whereas standing on one foot to exhaustion six times might be the easiest effective treatment I've studied (if it's effective). Easy to measure, nothing to buy, no logistical problems.

I may try to repeat the earlier observation a few more times – as a kind of gift to myself – but now the main thing I want to do is separate the effects of the two factors, i.e., test one without the other.

peter (2008-08-17 06:52:16)

there's more to standing on one leg than meets the eye. this article notes that bird do it all the time (and not just flamingos) <http://richarddawkins.net/forum/viewtopic.php?f=5 &t=52446 &start=0 &st=0 &sk=t &sd=a> There doesn't seem to be much literature on it, altho i did not do an exhaustive search. Also, one of the postures of Nei Kung involves more or less standing on one leg (Playing P'i P'a) Kei Kung is a precursor to Tia chi. These practices are generally designed to open up one's meridians; and to generate and disperse chi throughout the body. My understanding of "Chi" is that it is the undifferentiated energy of the universe. A person that practices Nei Kung for several years forms a thick fascia throughout the body (Fascia is strong connective tissue which performs a number of functions, including enveloping and isolating the muscles of the body, providing structural support and protection.<http://www.wisageek.com/what-is-fascia.htm>) my instructor told me that Playing P'i P'a results in fascia being formed along the side of the leg. These Chinese forms evolved over many centuries and are often the result of observing animals (including birds, i would think). If Playing P'i P'a "make the cut" then it's has to do with more than just sleep. I don't know what that is, but it would be interesting to find out.

mike kenny (2008-08-17 09:37:30)

does the time of day you stand on one foot matter, do you think?

seth (2008-08-17 09:55:44)

Mike, I don't know. If standing on one foot does matter, presumably it puts one or more stress hormones in the blood that later (at night) control depth of sleep and during sleep are gotten rid of. If that's correct, then the time of day shouldn't matter because the stress hormones are likely to be stable. It's a question that I will try to answer if standing on one foot turns out to matter.

mike kenny (2008-08-17 11:28:22)

excellent. i tried standing on one foot (right, then left) for about 2.5 minutes a piece on friday fairly close to bed and didn't notice effects (though there are numerous confounding elements in the mix—it's been a high stress time for me). it sounds like you spent more time standing on one foot though, and did it in the morning. i'll play around with the idea.

seth (2008-08-17 12:11:36)

If you want to see if you get the same effects, I'd try six times – three on each foot.

Stephen M (Ethesis) (2008-08-17 12:56:57)

Now you've got me wanting to change my computer desk so I stand while I read my e-mail.

mike kenny (2008-08-17 14:09:17)

will do

seth (2008-08-17 22:15:44)

From Nancy Lebovitz: It'll be interesting to see whether it's the stress or the one-footed standing. If it's the former, you'll get less improvement in your sleep as you get better at one-footedness from practice. Answer: I don't do the one-footed standing for a fixed time. I do it as long as possible. So it is more or less equally stressful each time.

Heidi 555 (2008-08-18 05:36:46)

There's also the element of balance, which is related to the stress and would improve over time. I've been doing a one-legged standing on a balance board or disc about 3 times daily. I've noticed that I feel good after doing it. My balance is improving. Last 2 nights my sleep has been excellent but I sleep well maybe 60-70 % of the time.

Caleb (2008-08-18 08:26:27)

fascinating results, but man this isn't working so easily for me. I decided i'd try it out while doing my 30 minutes with the mirror. The problem is I'm probably on the tail end when it comes to balance and leg endurance. I use a bike as my primary transportation, and I don't use my hands when I ride, so my leg strength and balance are pretty ridiculous. I made it through the whole 30 minutes and I was still standing on the first foot. It was definitely feeling quite tired and sore in places, but I could have gone longer. Still, I might be able to make this work, as I suspect the benefits come from the hormones you produce when your legs endurance gets pushed past it's limits. Maybe if I pre-exhaust my legs with some weight lifting before hand it won't take nearly as long for them to give out. I'll have to look up what are the most important leg muscles for balance.

Nadav (2008-08-18 10:30:54)

Caleb, the important factor may be the stress itself, not the fact that it's induced via the legs. Maybe you could try something you're not already good at, like maintaining yourself in the half-pushup position as long as you can. This will stress your arms, chest, and abdominal core (make sure you're ramrod straight).

Kirk (2008-08-18 16:12:30)

Caleb, sink into the supporting leg. Soften the muscles in the hip. Always keep the knee over the foot, don't let it move inside or outside. I just tested multiple positions and it seems that the easiest to illustrate is: turn the foot of what will be the supporting leg out 45 degrees (if the left foot, then it points to 10:30) extend the other leg in front, sliding on the floor sink, sink, sink into the hip the stopping point is when you can't lift the other foot without lurching Then lift your non-weight-bearing foot from the floor a quarter inch or so. Hold.

mike kenny (2008-08-18 18:58:42)

i tried standing on each foot for about 2 minutes, 3 times last night-i was more or less exhausted by this. i woke up about 2 hours earlier than usual this morning, and couldn't get back to sleep, which was kind of weird. i tried standing on each foot till i was pretty much exhausted three times today, too, and i'll see how i sleep and how i feel tomorrow.

[...] Science in Action: Why Did I Sleep So Well? (part 4) [...]

### **Steep Learning Curve (2008-08-18 19:14)**

The phrase everyone gets wrong. Outside experimental psychology, where the term originated, I have never seen a correct usage. Learning curves show performance (e.g., percent correct) as a function of amount of training (e.g., number of trials). A steep learning curve means the organization, person, or animal quickly went from low to high performance – in other words, learning was fast.

The phrase is always used to mean the opposite (slow learning). An example from [1]Economic Principals:

But experience has shown that high fixed costs, steep learning curves, access to delivery systems and expensively-maintained reputations are powerful deterrents to ambitious start-ups.

1. <http://www.economicprincipals.com/issues/2008.08.17/331.html>

---

Nathan Myers (2008-08-18 20:39:17)

It's routinely used correctly in industrial manufacturing, where it refers to cost reductions that result from manufacturing experience and competition. There, cost starts at a normalized 1 and declines exponentially toward an asymptotic horizontal somewhere (presumably) above zero.

David (2008-08-19 00:13:16)

The normal usage of the phrase is very closely related to the actual meaning, though. When someone says "product X has a steep learning curve", they mean "product X requires that you go from low to high performance very quickly to use it" – it's a product that isn't worth using if you're not going to learn quickly.

whisht (2008-08-19 03:45:33)

ah, thanks for this. I always used it wrongly for a different reason. I use it to mean "difficult" (which would be an axis of Effort and Time). Good to learn where I'm wrong (again) :Â~)

Family Nutritionist (2008-08-20 05:40:25)

Achieving a steep learning curve can feel difficult, because there can be much to learn in a short time. I think you are correct to note that the term is hardly ever used to describe situations where it was easy to go from low to high performance. Intuitively, a steep hill is one that is hard to climb, so the phrase is naturally associated with situations where learning feels like quickly climbing a steep hill.

### **Science in Action: Why Did I Sleep So Well? (part 5) (2008-08-19 06:42)**

I have been sleeping much better than usual. Sharp easy-to-notice improvement. After the first time this happened I made [1]a list of 9 possible reasons (lifestyle changes that might have been responsible). I [2]later added one I'd overlooked: standing on one foot to exhaustion a few times.

Yesterday I stood on one foot to exhaustion four times, twice in the morning and twice in the evening. It took about three minutes each time (12 minutes total). Didn't make any of the nine other candidate changes. And I slept much better than usual. So it is beginning to look like just that one factor is responsible. The one I almost forgot but also the one that seemed most plausible after i remembered it.

---

Igor Carron (2008-08-19 07:02:13)

Seth, Are you talking about just standing on one foot or tiptoeing on one foot ? 3 minutes seems to be a small number to get

exhausted, or am I missing something ? Cheers, Igor.

Nathan (2008-08-19 07:35:35)

I usually spend most of my day sitting in front of a computer and don't sleep as well as I'd like (though not terribly). Yesterday, inspired by this series of posts, I raised my computer 18 inches and worked for several hours standing in front of my desk. I slept very well last night and plan to stand for several hours today as well. I also found that standing helps fight drowsiness, so I plan to stand while doing some of my more boring research work.

Phillip J. Eby (2008-08-19 08:12:55)

Yeah, and what do you mean by "exhausted"? Just that your leg feels tired, that you can't stay standing on it, you lose your balance, or...?

Curious one-footer (2008-08-19 08:24:24)

And what are you doing with the other foot? Holding it slightly off the ground? Bent up behind you? Pressed against the other leg (as in yoga's tree pose)? Extended in front of you?

seth (2008-08-19 08:46:11)

Igor, I just stand on one foot. No moving around. Maybe 3 minutes isn't long, I don't know. I do know that in any yoga class I am the worst student. Philip, by "exhausted" I mean my leg starts to hurt and to continue would be more than slightly uncomfortable. Nothing to do with balance. Curious, while I'm doing this I'm holding my other foot bent up behind me. Because I found that many hours of standing produced similar effects, I discount the stretching aspect of my pose. My previous research (standing many hours) involved no stretching.

Chris (2008-08-19 20:59:50)

I think this works! I've got a Wii fit that I hadn't been using much lately and decided to do 30 minutes of the 'stand on one leg' exercises they had ( 3 yoga poses, 3 'strength' exercises) and I ended up waking up about 1.5 hours earlier and feeling pretty good (although the day's not over yet). Obviously it'll need more trials/comparisons with other exercises, etc. but it's a promising find. Seth, you mentioned during your omega-3 posts that you used balancing on one leg as a test--were there any sleep differences while you were running those tests? Anyway, be curious to here if others get the same result. The wii fit does seem like a decent platform for self experimentation since you get a score and logs of how long you did each exercise for.

seth (2008-08-20 06:38:39)

When I did my balancing tests (standing on one leg) my sleep did not noticeably improve. I don't make anything of this because I would typically balance for 5 seconds or so perhaps 30 times with substantial rest between bouts. Whereas now I am standing 3 minutes or so at one time, that is, with no rest (and doing this 4 times/day = 12 minutes total/day). Old way: not stressful at all. New way: very stressful. I'm sure you need stress to get the effect (if there is one) because I got no sleep benefit from standing until I got up to 8 hours or more per day.

Collective Wisdom for a Good Night's Sleep (2010-07-28 10:01:26)

[...] Still, sleep deprivation is not fun. I'm always looking for new ideas to help me get a better night's sleep. I drink chamomile tea and avoid caffeine. I try to get lots of fresh air and daily walks. I read fiction before bed. I study the science of sleep. I've even tried Seth Roberts' theory that standing on one leg to exhaustion can help you sleep better (I think it works). [...]

## Musical Question (2008-08-19 08:34)

Browsing through the many cell-phone-music videos on YouTube I came across [1]this demonstration of an iPhone piano program. The demonstrator first shows the range of the instrument, then plays Chopsticks, then plays . . .

what? A piece I've heard many times but can't place.

What impresses me so much about the mystery piece is how urgent it sounds. Somehow the composer has figured out what makes something sound urgent. It reminds me of a note Robert Caro, the biographer, has posted above the desk where he writes: "Is there desperation on the page?"

More. It's [2]Clocks by Coldplay. Thanks so much, Sam and Jeff! Only now do I manage to see that the song is identified in the comment section of the video.

1. [http://www.youtube.com/watch?v=j-CFD\\_1tP9w](http://www.youtube.com/watch?v=j-CFD_1tP9w)

2. [http://www.youtube.com/watch?v=c9j\\_RZDqYc4](http://www.youtube.com/watch?v=c9j_RZDqYc4)

---

Sam (2008-08-19 09:00:32)

The song is Clocks, by Coldplay. [www.youtube.com/watch?v=c9j\\_RZDqYc4](http://www.youtube.com/watch?v=c9j_RZDqYc4)

jeff (2008-08-19 09:03:58)

it's "clocks" by coldplay.

Stephen M (Ethesis) (2008-08-19 16:41:38)

That is neat, thanks for the reference.

### **The Quantified Self Meetup Group (2008-08-19 11:55)**

Gary Wolf, a writer for Wired, and Kevin Kelly, one of the founders of Wired, have formed a San Francisco Bay Area [1]Meetup group called The Quantified Self.

This is a monthly show and tell for people taking advantage of various kinds of personal tracking - geo-tracking, life-logging, DNA sequencing, etc. - to gain more knowledge about themselves. Come where what you are doing, and learn from others. Topics include, but are not limited to:

- Chemical Body
- Load Counts
- Personal Genome Sequencing
- Lifelogging
- Self Experimentation
- Risks/Legal Rights/DutiesBehavior monitoring
- Location tracking
- Non-invasive Probes
- Digitizing Body Info
- Sharing Health Records

- Psychological Self-Assesments
- Medical Self-Diagnostics

The first meeting, which I will eagerly attend, will be on September 10 (Wed) evening in Pacifica. Sign up for details.

1. <http://www.meetup.com/>

### **HDL and Vitamin D (2008-08-19 22:09)**

Vitamin D supplementation raises HDL enormously, says [1]William Davis:

Add vitamin D to achieve our target serum level . . . HDL jumps to 50, 60, 70, even 90 mg/dl.

The first few times this occurred, I thought it was an error or fluke. But now that I've witnessed this effect many dozens of time, I am convinced that it is real. Just today, I saw a 40-year old man whose starting HDL was 25 mg/dl increase to 87 mg/dl.

Responses like this are supposed to be impossible. Before vitamin D, I had never witnessed increases of this magnitude.

Thanks to Dave Lull.

Nathan Myers (2008-08-19 22:44:12)

Of course cholesterol levels below 100 are associated with higher mortality. The association is still unexplained, so doctors still exhort patients to get their cholesterol levels as low as possible... by using statins, of course.

Aaron Blaisdell (2008-08-20 08:20:55)

Another reason to drink milk as an adult...if you are lactose tolerant.

### **Science in Action: Why Did I Sleep So Well? (part 6) (2008-08-20 08:58)**

On the SLD forums Heidi 555 [1]posted this:

I've been standing on one foot on an inexpensive balance board or inflatable balance disc. . . . I've been using the balance board while doing dishes and brushing my teeth. . . .

I feel good immediately afterwards. I feel slightly better physically and emotionally. . . . I'm use to feeling better after I exercise, but typically it takes more intensive sustained exercise to get this effect.

I sleep well 60-70 % of the time. . . . For the past 3 days that I've done the one-footed standing I've had excellent sleep. Last night it was especially surprising because I went to bed emotionally distraught and stayed up slightly later than I intended.

Timothy Beneke (2008-08-20 14:26:15)

Fascinating. I've found in the past that helping friends move always led to the best, most relaxing sleep in which I felt my body "letting go" of tension in a deep way. It seemed to be caused by picking up and carrying moderately heavy boxes significant distances and put them down. I was using muscles I don't use, at least not that much. I just did about 6 minutes of standing on each foot, alternating until it became very difficult; I used it as a chance to meditate which I do a lot of anyway lately. I had my head slightly down hands in together on my chest as is done in walking meditation, and I kept my eyes fixed and followed my breath as I do when I normally meditate; as I get lost in my thoughts I gently pull myself back to attending to my breath... I did notice some soreness in my hips and knees, so I changed feet when it got unpleasant... I'll do it again tonight and see what happened.

Timothy Beneke (2008-08-20 20:25:24)

One more comment; I just tried standing on one foot with both arms out - more bang, or muscle usage, for your buck. My arms had to come down before my leg did. Then I switched legs and put my arms out again. I feel stronger relaxation then when just doing it on one leg. This is interesting!

seth (2008-08-20 21:28:45)

That's a good idea, Tim. When I stand on one leg I'm pulling up the other leg behind me so I am using the muscles of one arm.

Darkhorse (2008-08-21 06:24:10)

Seth, this is so great! I have been doing this most days for about a week. I can do it longer when wearing shoes than when barefoot. It also forces people like me, who usually hit the floor running, to find a few minutes for much needed centering and contemplation. I'm assuming that it is best done in the morning to affect sleep that night? Can't you just see all of us in other time zones standing on one leg while you are sleeping deeply? Now, if I could just tuck my head under my armpit!

seth (2008-08-21 06:59:22)

Thanks, Darkhorse. I don't think the time of day matters much (but I'm just guessing, I haven't studied this). I've been doing two bouts in the morning and 2 later in the day. As you say it's something to actually look forward to, there's something pleasant about it.

Mike Kenny (2008-08-21 07:58:29)

I've tried standing on one foot, for about two days, and it seems I was markedly more anxious the next day. I'll try this more to see if the effects seem connected or if it's accidental. I didn't stand on one foot yesterday and I think also the day before IIRC, and didn't feel as anxious the following days as on the days following standing on one foot. So maybe I'm experiencing energy that causes some anxious feeling.

Nibbles: Pollution can make babies fat, plus shrinking supermarkets and standing for more sleep | MProtein.com (2008-09-15 11:36:51)

[...] Finally, there have been all sorts of studies through the years linking lack of sleep and obesity. If you're trying to catch more Zs, try what- Shangri-La Diet mastermind Seth Roberts (who will soon be sharing his wisdom- at Tsinghua University in Beijing) has been experimenting with: standing more on one foot. He's been chronicling things that might be playing a role in sleeping better or worse and says standing up for long periods of the day, particularly when some of that time is spent on just one foot, seems to help him sleep better. We don't know if it works, but would love to hear about it if you try. [...]

Western gal (2009-05-22 14:09:18)

Standing on one foot, and on both feet are well known practices in oriental exercise. For your reference: Stalking Yang Lu-Chan By Robin Johnson <http://books.google.com/books?id=36FkmdsrV8AC> have fun in China!

## Chocolate is Good For You (continued) (2008-08-21 00:04)

[1]A just-published study compared the effects of dark chocolate (flavonol-rich) and white chocolate (no flavonols) on 19 persons with high blood pressure and impaired glucose tolerance. The dark chocolate reduced blood pressure by 4 points (both systolic and diastolic) and improved insulin sensitivity.

I really should test this myself. There is plenty of similar evidence.

[2]Earlier post.

1. <http://jn.nutrition.org/cgi/content/abstract/138/9/1671?etoc>
2. <http://www.blog.sethroberts.net/2008/07/09/chocolate-is-good-for-you/>

---

Sam (2008-08-21 01:03:28)

On the other hand, chocolate is said to put stress on your liver, just like alcohol does - I wonder how one would measure the liver function? Maybe by observing how tired one is?

### **Citizen Science: What's Your Sushi? (2008-08-22 17:28)**

Self-experimentation is an example of the more general idea that non-experts can do valuable research. Another example is that two New York teenagers have shown that fish sold in New York City is often mislabeled. They gathered samples from 4 sushi restaurants and 10 grocery stores and sent them to a lab to be identified using a methodology and database called [1]Barcode of Life. They found that "one-fourth of the fish samples with identifiable DNA were mislabeled" . . . [and concluded] that 2 of the 4 restaurants and 6 of the 10 grocery stores had sold mislabeled fish."

[2]The article, by John Schwartz, appeared in the Science section, which makes the following sentence highly unfortunate:

The sample size is too small to serve as an indictment of all New York fishmongers and restaurateurs, but the results are unlikely to be a mere statistical fluke.

This is a [3]Samantha-Powers-sized blunder. It could hardly be more wrong. How much you can generalize from a sample to a population depends on how the samples were chosen. Sample size has very little to do with it. (John Tukey had the same complaint about the Kinsey Report: Stop boasting about your sample size, he said to Kinsey. Your sampling methods were terrible.) To know to what population we can reasonably generalize these results we'd need to know how the two teenagers decided what grocery stores and restaurants to sample from. (Which the article does not say.) If the 14 fish sellers were randomly sampled from the entire New York City population of grocery stores and restaurants, it would be perfectly reasonable to draw broad conclusions.

I have no idea what it could mean that the results are "a mere statistical fluke".

The effect of these errors is that Mr. Schwartz places too low a value on this research. It's impressive not only for its basic conclusion that there's lots of mislabeling but also for showing what non-experts can do.

The end of the article did see the big picture:

In a way, Dr. Ausubel said, their experiment is a return to an earlier era of scientific inquiry. "Three hundred years ago, science was less professionalized," he said, and contributions were made by interested amateurs. "Perhaps the wheel is turning again where more people can participate."

Stephen M (Ethesis) (2008-08-22 19:50:20)

Good point. BTW, on the warrior diet, I learned some more: [http://www.t-nation.com/free\\_online\\_article/sex\\_news\\_sports\\_funny/the\\_warrior\\_diet\\_an\\_interview\\_with\\_penthouse\\_editor\\_ori\\_hofmekler](http://www.t-nation.com/free_online_article/sex_news_sports_funny/the_warrior_diet_an_interview_with_penthouse_editor_ori_hofmekler)

Methuselah (2008-08-24 02:34:16)

Hi Seth, As someone who works in the market research industry I like the Samantha Powers story and think the article makes a good point. I am more torn on the questions you raise in your post. As you know from [1]my post about the under-use of anecdotal evidence I am a big believer in not letting valuable evidence leak away. I was slightly confused by your statement *I have no idea what it could mean that the results are "mere statistical fluke"* since it seemed from the article that the author was saying it was **unlikely** to be a fluke. So in that respect he seems to be on the same page as us. It is just the sample size issue where there is divergence, and in this respect what I am wondering is this: he has obviously applied some formula to determine whether the sample size can be taken as significant, whereas we perhaps prefer to apply a commonsense interpretation of the results and sampling methodology - but there must be a point at which sample size does matter even for that approach - for example, could we have viewed a sample of 3 as having the potential to be regarded as a statistical fluke? Methuselah [2]Pay Now Live Later

1. <http://paynowlivelater.blogspot.com/2008/07/are-we-underrating-anecdotal.html>

2. <http://paynowlivelater.blogspot.com/>

seth (2008-08-24 04:47:36)

The term "statistical fluke" is usually applied to differences between groups. Group A and Group B differ by some amount - does this mean the populations from which they were sampled actually differ on that dimension or could the results be due to sampling variability? If they are due to sampling variability, that means the observed difference is a "statistical fluke." In the fish case, there are not two groups. So I have no idea what he's talking about. You can't have sample sizes be "[statistically] significant" or not; it is differences between groups or differences from zero that are statistically significant or not.

Methuselah (2008-08-24 14:28:16)

Got it - thanks for the explanation.

Seth's blog » Blog Archive » Suppose You Write the Times to Fix an Error (part 1) (2008-08-28 07:42:20)

[...] Citizen Science: What's Your Sushi? [...]

Seth's blog » Blog Archive » More Schoolgirl Science (2009-09-11 20:43:39)

[...] The students used iodine titration to determine Vitamin C levels. Why had the students managed to see something important that the food giant overlooked? My guess is that an unusual processing step (e.g., high storage temperature) destroyed the Vitamin C and those who knew about the anomaly didn't want to consider the possibility that it had done damage. The possibility that someone outside the company might notice didn't occur to them. Just as those who mislabel fish in New York restaurants and markets never realized that two students could uncover their deception. I found that the omega-3 in a Chinese brand of flaxseed oil was probably destroyed before it got to me. [...]

Sui Fai John Mak (2009-09-11 23:24:31)

Thanks for the post. This revealed the importance of checking the source and accuracy of information before making an judgment. The risk of stereotyping is often overlooked, just as in this case. We could perform lots of scientific experiments and conclude results based on "facts". However, it is imperative to reveal the procedures and ensure that all "facts" presented have been critically examined. When I was at school doing chemistry experiments, I often found the results differing from the

theory quite a lot. Why? There are a lot of factors which could affect the accuracy of the experiments.... Again, it is too unfair to all parties by just looking at the results, without understanding what's behind. This applies not only to scientific "experiments", but also to social observations. If you were the teacher of the students, what would you have advised the students? John

### Science in Action: Why Did I Sleep So Well? (part 7) (2008-08-23 05:56)

I've continued to sleep extremely well. I'm sure there's something to this. I'm almost sure it's because of the one-legged standing.

Here are some technical details. I usually do four bouts of one-legged standing, two in the morning and two later. During each bout I stand on one leg, pulling my other leg up behind me. Sometimes I touch something to balance myself. Usually I watch or read something at the same time. Each bout lasts until it's hard to continue – until it becomes slightly painful. At first the bouts lasted about two minutes, now they last about four minutes. I enjoy it more when I time it with a stopwatch.

I haven't yet systematically varied the number of bouts but I suspect one is too few to get the full effect and four is plenty. I'm still trying different ways of arranging them throughout the day. Doing all four at once is too tiring – it takes too long to recover. Maybe it's best to do two whenever's convenient during the day and then do two more in the evening when it's okay to be tired.

[1]Directory.

---

MT (2008-08-25 01:07:41)

Super interesting. I look forward to hearing more! How many days do you think you would take to compare various protocols (when is best to stand, how long is best to stand, etc). It is also interesting because it helps develop balance, which is a neglected aspect of many people's fitness. A great article about balance in the NYTimes notes that 1/3 Americans over 65 are injured every year from a fall: <http://www.nytimes.com/2008/01/08/health/08brod.html?ex=1357448400&en=d2e8cfe20029acbe&ei=5124&partner=permalink&expprod=permalink> (I'm also curious about whether that statistic is meaningful! I know lots of over-65s who aren't injured from falls, and can only think of one one I have even known who was injured from a fall. Nonetheless!)

Nansen (2008-08-25 13:23:23)

It's not clear that you have in fact separate the effects of the two factors, i.e., test one without the other (see [1]part 4 of the directory).

1. <http://www.blog.sethroberts.net/2008/08/17/science-in-action-why-did-i-sleep-so-well-part-4/>

seth (2008-08-26 20:23:06)

Nansen, yes, that's correct. I have found that the standing alone – without the other factor – produces the effect. But I've only observed this a few times. I'll go from "almost sure" to "sure" when I observe it a few more times.

## The Emperor's New Clothes: Meta-Analysis (2008-08-23 09:19)

In [1]an editorial about the effect of vitamin-mineral supplements in the prestigious American Journal of Clinical Nutrition, the author, Donald McCormick, a professor of nutrition at Emory University, writes:

This study is a meta-analysis of randomized controlled trials that were previously reported. Of 2311 trials identified, only 16 met the inclusion criteria.

That's throwing away a lot of data! Maybe, just maybe, something could be learned from other 2295 randomized controlled trials?

[2]Evidence snobs.

1. <http://www.ajcn.org/cgi/content/full/84/4/680?etoc>
2. <http://www.blog.sethroberts.net/2007/08/08/something-is-better-than-nothing-part-2/>

---

MT (2008-08-25 02:28:36)

It would be interesting to do a second meta-analysis that is more or totally inclusive, and compare results.

Nathan Myers (2008-08-26 12:08:56)

I take the meta-analysis to mean that if you want to discount the benefits of antioxidants, you must discard 2295 out of 2311 controlled trials, or 99.3 % of them. What other proposed therapy is robust enough to stand up to such treatment? Probably not even aspirin.

seth (2008-08-26 20:21:05)

Nathan, the discarding of the "bad" studies was done, I'm sure, according to widely-accepted rules. It wasn't tailored to this particular situation. But it is truly bizarre that this sort of thing is considered reasonable.

NE1 (2008-08-28 16:40:05)

"The a priori defined exclusion criteria were as follows: 1) no data in humans, 2) no original data, 3) observational epidemiologic study, 4) no random allocation, 5) no vitamin-mineral supplement as intervention, and 6) no subclinical marker of atherosclerosis as outcome" Seeing as how supplementation is a subject so prone to bias, I'm not sure it's such a bad thing. Do we need 100 new minerals claiming to be the cure to heart disease? A thousand new snake-oil salesman to hock them, because they're unregulated and so easily obtained? What makes you think a simple dose of vitamins deserves to cure one of the biggest killers out there? Maybe it wouldn't have hurt to list the major culling criterion, but they started out with one huge filter: looking for effects on heart-disease.

seth (2008-08-28 18:26:59)

"I'm not sure it's such a bad thing." Is there any other branch of science in which 99 % of expensive hard-to-collect data is thrown out?

## Everything I Know I Learned from Japanese Curry Instructions (2008-08-24 06:06)

I got this in a Japanese supermarket:

Translation:

How to make soup curry:

Ingredients-

- 1 packet of soup mix
- 1 packet of flavorful oil
- 1 packet of spicy flavoring
- 80g (3 oz.) of chicken thigh meat cut into bite sized pieces
- 1/4 medium sized carrot

1/2 medium sized potato (cut in half)  
400ml water

1. Boil water in a small pan. Add chicken, potato, and carrot, cook until vegetables become soft, about 20 minutes on med-low heat.
2. Turn off the heat, add the soup mix and mix thoroughly, turn the heat back on and cook a little longer until the flavor penetrates the meat and vegetables.
3. Pour the flavorful oil onto a plate and pour the finished curry on top.
4. Add a desired amount of the spice flavoring.

-the spice flavoring is fairly spicy, so please use caution when adding  
-please cook the chicken thoroughly before adding the soup mix  
-to make a double portion, double the meat and vegetables, and increase water to 700ml.  
-the black things in the soup are basil

To make a dish like the picture on the box: Add sauteed japanese eggplant, shimeji mushrooms, green peppers, and hard boiled egg to the dish. Use boned chicken meat.

How to eat: Using a spoon, scoop rice and add a small amount of curry to the spoon. Please keep the curry and rice in separate dishes to prevent the rice from getting soggy.

Caution: Please use the entire contents of the packets after opening. Cannot be preserved for later use.

I have bolded the interesting parts: 1. The use of please. 2. The explanation ("the spice flavoring is fairly spicy"). You won't find them in the instructions on most American products. I became aware of this aspect of Japanese life when I read T. R. Reid's wonderful book [1]Confucius Lives Next Door: What Living in the East Teaches Us about Living in the West, which was based on six years Reid spent in Japan as a correspondent for the Washington Post. At one point Reid quoted from a sign in a park. The sign had a list of prohibitions: No littering, no music, and so on. But instead of saying, as an American sign would, "no littering", the sign said something like: "So that others can enjoy the beauty of the park, please put your litter in the proper receptacle."

A few years ago I taught a class called Psychology and the Real World in which students did some sort of off-campus work of their choosing. (An example of [2]my teaching philosophy.) One student volunteered in a hospital. One day he told a story about being treated rudely by a nurse. I said, yeah, we live in a pretty rude culture. Japan is different, I said, and told the class about Reid's Japanese park signs.

My student was impressed. He had a part-time job monitoring parking in front of a San Francisco hotel. People would often try to park in an area that needed to be kept clear and it was his job to get them to move. His method - pre-Reid - had been to go over to the offending car and say "sorry, you can't park here." Post-Reid, he was elaborately polite: "Please forgive me for disturbing you, but we need to keep this area clear so that taxis can pick up and drop off passengers. I'm sorry for inconveniencing you, but would you be kind enough to move your car?" Something like that. Pre-Reid, about half the time the driver would argue or cause some sort of difficulty. Post-Reid, there were no problems.

Thanks to [3]Pearl Alexander.

---

Aaron Blaisdell (2008-08-24 08:49:51)

Interesting. I noticed the polite nature of public signs in use in Hong Kong. Since the signs are all written in both Chinese and English, I wasn't sure whether it was Chinese politeness or British politeness (or both). The British also seem to be more polite in these matters, too. Perhaps its the tea (as opposed to coffee drinking Americans who are more direct and gruff).

david (2008-08-24 10:25:52)

Some of those things might be so formulaic as to have lost their politeness in the original language. I stayed with a French family as an exchange student. Their daughter had missed a few days of elementary school to go to the doctor. They received a letter from the school that started "I have the honor to inform you that your daughter, Sophie, has missed three days of school..." They said "I have the honor to inform you..." is just how the school starts all letters. I'm a technical writer now. We routinely edit out any words like "please"...the goal is to make the prose as squeaky clean as possible. People read documentation as a last resort anyway. We figure extra words waste their time.

The importance of politeness « BC in OC (2008-08-24 16:01:48)

[...] The importance of politeness Posted on August 24, 2008 by bryan A lesson in the art of persuasion. [...]

mike kenny (2008-08-24 17:50:08)

Maybe we should slap emoticons on street signs. No Parking :) On a related note, some phrases in English strike me as formally polite, but are often aggressively used. "Excuse me?" "Do you mind?" "Thanks a lot."

Chris (2008-08-24 22:00:22)

Japanese grammar has a lot of do with it...There are basically 4 different levels of formality (1-you absolutely better not park here, 2-don't park here, 3-please don't park here, 4-you are higher on the social scale than me, and I beg you, please don't park here and you can even go higher than 4 in some cases). Level 3 the default. Level 1 is reserved for when you intend to scold someone. It's often heard when you have cranky mother punishing a kid. Otherwise, it's usually the stuff of movies and comic books. The rest are pretty polite and going from 2-3 is really simple (1 word tacked on the end) so most people do it out of instinct. In English we usually stick please on the front end as if we're explicitly trying to be nice about it. For Japanese, everyone just tacks it on the end. Anyway, I'd be curious to see how this compares with the stuff in Robert Cialdini's books on influence. He cites research that if you can give a reason (even an illogical one) for anything it's much more effective than having no reason. So "No parking" fares much worse than "No parking because it's not allowed."

### **Suppose Your Book Gets a Great Review in the Times (2008-08-26 00:12)**

Few books, including [1]Lolita ("highbrow pornography"), get great reviews in the New York Times. One that did is Ammon Shea's [2]Reading the OED: One Man, One Year, 21,730 Pages. According to Nicholson Baker, the reviewer, "Shea has walked the wildwood of our gnarled, ancient speech and returned singing incomprehensible sounds in a language that turns out to be our own." Someday – 20 years from now? – every review in the Times archives will be retrospectively assigned an Entertainment-Weekly-style grade by computer analysis and [3]Baker's review will be determined to have given an A to Shea's book. I interviewed Shea about the experience.

Few of us will ever get such a positive review in the NY Times, so we must live vicariously. What were the effects on you of Baker's review?

I have a sneaking suspicion that he liked the book more than I did, which is fine by me.Â I'm an enormous fan of both his writing and his perspective on things, and there is no one who I would rather have had read it.Â It did not change my feeling on who I am or what might lie in store for me in the future, but it did make me feel deeply and improbably happy.

What were the effects on your editor and publisher?

My editor [Marion Lizzi, who also edited *The Shangri-La Diet*] says she is quite happy with it as well, and I see no reason to disbelieve her.

What was the effect on sales?

I don't know what the exact figures were, although I understand that they were significantly higher after the review came out.Â I understand that the publisher is preparing another printing, which I suppose is to be credited at least somewhat to the effects of the review.

Did any friends/family contact you about the review?

Some of them did call or write - butÂ both my family and my circle of friends are fairly small, so there was not so much hullabaloo.

How long did it take for the effect of the review to wear off?

It hasn't worn off in some ways - I'm still delighted that Baker enjoyed reading the book.Â However, in some other ways I'd say as soon as I began to seriously think about writing the next book that the incipient terror of that process nudged the residual celebratory feelings of the review somewhat to the side.

[4]Earlier interview with Shea.

## Science in Action: Why Did I Sleep So Well? (part 8) (2008-08-27 06:11)

[1]My recent experience suggests that if I stand on one foot until it becomes slightly difficult about four times/day I will sleep much better. Two days ago I measured how long those four bouts of one-foot standing actually were: 6.2 (left foot), 4.3 (right), 4.8 (left), and 5.2 (right) minutes. The median is 5.0 minutes. When I started doing this, about two weeks ago, each bout was about 2 minutes.

It doesn't seem to matter when I do them. Now I do two in the morning and two in the evening. Fits perfectly with a subway commute. You'll want to be forced to stand.

In the evening I have a pleasant sense of anticipation: I will fall asleep and wake up feeling really good. I have never before felt this way. I have slept this well before, when I stood 9 or 10 hours/day. The sheer difficulty and all-consumingness of doing that, I now realize, got in the way of anticipating the benefits.

Something else curious is that one-foot standing leaves no mark – I can't tell at 3 pm how many bouts I've done so far just by noticing how I feel. Unlike water or calorie consumption: If I don't drink anything I'll get thirsty. If I don't eat anything I'll get hungry. But if I don't get enough of this particular byproduct of exercise I'll never notice.

1. <http://www.blog.sethroberts.net/2008/08/20/why-did-i-sleep-so-well-directory/>

---

MT (2008-08-27 15:03:12)

Great post! It would be really interesting if you were able to do an optimization curve by alternating shorter and longer periods of standing and seeing where your returns-for-effort peaked. That curve might shift as it is possible that the trigger for the sleep mechanism is from the musculature and requires a certain level of challenge to be set off. The time necessary to induce the deeper-sleep response may increase as you become better at it or develop stronger legs from the process. Very interesting experiment and results.

seth (2008-08-27 16:07:34)

Thanks, MT. yes, that is what I plan to do soon, vary the "dose" (number of bouts, length of bouts) and see how my sleep changes.

Mike Kenny (2008-08-28 06:33:30)

this ultramarathon runner cut his sleep down to four hours to make time for running. i wonder if he can do this because of all the time he spends on his feet: [http://www.wired.com/wired/archive/15.01/ultraman.html?pg=1 &topic=ultraman &topic\\_set=](http://www.wired.com/wired/archive/15.01/ultraman.html?pg=1&topic=ultraman&topic_set=)

Kjitten (2008-08-28 19:21:31)

That's it, I'm trying it. I so rarely wake up feeling Good and Well-Rested.

Toni H (2008-09-01 06:46:10)

It would be really helpful if in a future blog post you could explain what you mean by standing on one foot? ie. are you holding support with your hand from a bar in the subway, are you holding the other foot with your hand behind you, are you balancing on just one foot, etc. I guess this is what's usually called isotonic exercise?

seth (2008-09-01 07:57:03)

Toni H, I've done it two ways: 1. A quadriceps yoga-like stretch. Pulling my other leg back behind me. 2. No stretch at all. The two feet remain close together except one is bearing all the weight.

Seth's blog » Blog Archive » Why Did I Sleep So Well? directory (2008-09-03 19:53:48)

[...] Science in Action: Why Did I Sleep So Well? (part 8) [...]

## **Suppose You Write the Times to Fix an Error (part 1) (2008-08-28 07:38)**

Recently the New York Times published [1] a fascinating article by John Schwartz in the science section about how two teenagers discovered that a lot of raw fish sold in New York is mislabeled. Unfortunately, the article contained two

big mistakes: 1. The teenagers' results were dismissed as unconvincing because the sample size (10 stores and 4 sushi restaurants) was, according to Schwartz, too small. For many purposes the sample was large enough, if their sampling method was good. 2. The sampling method wasn't described. Without knowing how the stores and restaurants were chosen, it's impossible to know to what population the results apply. This was like reviewing a car and not saying the price.

In an email to the Times I pointed out the first mistake:

Your article titled "Fish Tale Has DNA Hook" by John Schwartz, which appeared in your August 22, 2008 issue, has two serious errors:

1. The article states: "The sample size is too small to serve as an indictment of all New York fishmongers and restaurateurs." To whom the results apply – whom they "indict" – depends on the sampling method used – how the teenagers decided what businesses to check. Sample size has almost nothing to do with it. This was the statistician John Tukey's complaint about the Kinsey Report. The samples were large but the sampling method was terrible – so it didn't matter that the samples were large.
2. The article states: "the results are unlikely to be a mere statistical fluke." It's unclear what this means. In particular, I have no idea what it would mean that the results are "a mere statistical fluke." The error rate of the lab where the teenagers sent the fish to be identified is probably very low.

In retrospect the second error is "serious" only if incomprehensibility is serious. Maybe not. I should have pointed out the failure to describe the sampling protocol) but didn't.

I got the following reply from Schwartz:

Thank you for your note about my article, "Fish Tale Has DNA Hook," which appeared in the newspaper on Friday. You state that the story misstated the importance of sampling size as "an indictment of all New York fishmongers and restaurateurs." Although you are certainly correct in stating that poor methodology can undercut work performed using even the largest samples, it is also ill advised to try to establish broad conclusions from a very small sample. The fact that mislabeling occurred one in four pieces of seafood from 14 restaurants and shops in no way allows us to conclude that 25 percent of fish sold in New York or in the United States is mislabeled. And that is all I was trying to say with the reference to sample size was that while the girls' experiment shows that some mislabeling has occurred, their work cannot say how much of it goes on or whether any given restaurant or shop is mislabeling its products. Similarly, when I wrote that it is unlikely the findings are a "statistical fluke," I merely meant that while it is possible that Kate and Louisa found the only 8 restaurants and shops in New York City that mislabel their products, that is not likely, and so the possibility that the practice is widespread should not be discounted. And, of course, I hope you can forgive the pun.

Thanks again for taking the time read the article and respond to it, and I hope that you will find more to like in other stories that I write.

Uh-oh. The email was as mistaken as the article, although it did clear up what "statistical fluke" meant. I wrote again:

Thanks for your reply. I'm sorry to say that you still have things more or less completely wrong.

"Their work cannot say how much of it goes on or whether any given restaurant or shop is mislabeling its products." Wrong. [Except for the obvious point that the survey does not supply info about particular places.] I don't know what sampling protocol they used – how they chose the restaurants and fish sellers. (This is another big problem with your article, that you didn't state how they sampled.) Maybe they used a really good sampling protocol, one that gave each restaurant and fish seller an equal chance of being in the sample. If so, then their work can indeed "say how much [mislabeling] goes on." They can give an estimate and put confidence intervals around that estimate. Just like the Gallup poll does.

Somewhere you got the idea that big samples are a lot better than small ones. Sometimes you do need a big sample – if you want to predict the outcome of a close election, for example. But for many things you don't need a big sample to answer the big questions. And this is one of those cases. There is no need to know with any precision how much mislabeling goes on. If it's above 50 %, it's a major scandal, if it's 10-50 % it's a minor scandal, if it's less than 10 %, it's not a scandal at all. And the study you described in your article probably puts the estimate firmly in the minor scandal category. In contrast to your "it's cute but doesn't really tell us anything" conclusion quite the opposite is probably true (if their sampling procedure was good): It probably tells us most of what we want to know. You're making the same mistake Alfred Kinsey made: He thought a big sample was wonderful. As John Tukey told him, he was completely wrong. Tukey said he'd rather have a sample of 3, well-chosen.

Thanks for explaining what you meant by "statistical fluke." You may not realize you are breaking new ground here. Scientists wonder all the time if their results are "a statistical fluke." What they mean by this is that they've done an experiment and have two groups, A (treated) and B (untreated) and wonder if the measured difference between them – there is always some difference – could be due to chance, that is, is a statistical fluke. In your example of the mislabeled fish there are not two groups – this is why your usage is mysterious. I have never seen the phrase used the way you used it. And I think that the readers of the Times already realized, without your saying so, that it is exceptionally unlikely that these were the only fish sellers in New York that mislabeled fish.

Schwartz replied:

I understand your points, and certainly see the difference between a small-but-helpful sample and a large-but-useless sample. but four restaurants simply cannot represent the variety of dining establishments in New York City. Four restaurants, ten markets.

I also realize that you must think I am thickheaded to keep at this, but I will certainly keep in mind your points in the future and will try not make facile references to small and large samples when the principles are, as you state, more complicated than that.

To be continued. [2]My original post about this article.

1. <http://www.nytimes.com/2008/08/22/science/22fish.html?em>

2. <http://www.blog.sethroberts.net/2008/08/22/citizen-science-whats-your-sushi/>

Vince (2008-08-28 18:45:35)

If the 14 establishments were randomly selected from the population of all NYC fish sellers, then we could use the fact that 8 of 14 had mislabeled fish to estimate what percent of fish sellers have mislabeled fish using standard statistics, the same way that polls calculate the margin of error. Using the exact binomial distribution, I'm getting that we could be 95 % confident that between 29 % and 81 % of fish sellers have mislabeled fish (again, assuming a representative sample).

seth (2008-08-28 20:42:19)

Thanks for doing the calculation, Vince.

Andrew Gelman (2008-08-28 21:11:29)

I'm impressed that he responded to your email at all. But you have to remember that this reporter talks to lots of people. My guess is that he's an expert in hearing people out and in presenting different points of view, not an expert in evaluating expert judgments. The reporter is showing good judgment in taking your comments seriously, even if he's not going so far as to fully address them.

Seth's blog » Blog Archive » Suppose You Write the Times to Fix an Error (part 2) (2008-08-29 10:47:15)

[...] Suppose You Write the Times to Fix an Error (part 1) [...]

### **Suppose You Write the Times to Fix an Error (part 2) (2008-08-29 06:53)**

The [1]Roberts-Schwartz correspondence continued. I replied to Schwartz:

"Dining establishments"? [His previous email stated: "Four restaurants simply cannot represent the variety of dining establishments in New York City"] I thought the survey was about sushi restaurants. Places where raw fish is available.

Quite apart from that, I am sorry to see such a fundamental error perpetuated in a science section. If you don't believe me that the teenagers' survey was far better than you said, you might consult a friend of mine, Andrew Gelman, a professor of statistics at Columbia.

John Tukey – the most influential statistician of the last half of the 20th century – really did say that a well-chosen sample of 3 was worthwhile when it came to learning about sexual behavior. Which varies even more widely than sushi restaurants. A sample of 4 is better than a sample of 3.

Schwartz replied:

The survey included 4 restaurants and 10 stores.

The girls would not disclose the names of any of the restaurants, and only gave me the name of one store whose samples were not mislabeled. Their restaurants and stores might have been chosen with exquisite care and scientific validity, but without proof of that I could not say it in the article.

I wrote:

I realize the NY Times has an "answer every letter" policy and I am a little sorry to subject you to it. Except that this was a huge goof and you caused your subjects damage by vastly undervaluing their work. Yes, I knew the survey included 4 restaurants and 10 stores. That was clear.

As a reader I had no need to know the names of the places; I realized the girls were trying to reach broad conclusions. They were right not to give you the names because to do so might have obscured the larger point. It was on your side that the big failing occurred, as far as I can tell. Did you ask the girls about their sampling method? That was crucial info. Apparently The Times doesn't correct errors of omission but that was a major error in your article: That info (how they sampled) wasn't included.

He replied:

I could have been more clear on the subject of sample size, but I did not commit an error. Neither do my editors. That is why they asked me to write a letter to you instead of writing up a correction.

I don't feel I have been "subjected to" anything, or that this is some kind of punishment. This is an interesting collision between the precise standards of someone with deep grounding in social science and statistical proof and someone who tries to write intelligible stories about science for a daily newspaper and a general interest audience. But I am not sorry that you wrote to me, even a little sorry.

i wrote:

"I did not commit an error." Huh? What am I missing? Your article had two big errors:

1. An error of commission. You stated the study should be not taken seriously because the sample size was too small. For most purposes, especially those of NY Times readers, the sample size was large enough.
2. An error of omission. You failed to describe the sampling protocol – how those 10 stores and 4 restaurants were chosen. This was crucial info for knowing to what population the results should be generalized.

If you could explain why these aren't errors, that would be a learning experience.

Did you ask the girls how they sampled?

His full reply:

We're not getting anywhere here.

Not so. After complaining he didn't have "proof" that the teenagers used a good sampling method, he won't say if he asked them about their sampling method. That's revealing.

Something similar happened with a surgeon I was referred to, Dr. Eileen Consorti, in Berkeley. I have a tiny hernia that I cannot detect but one day my primary-care doctor did. He referred me to Dr. Consorti, a general surgeon. She said I should have surgery for it. Why? I asked. Because it could get worse, she said. Eventually I asked: Why do you think it's better to have surgery than not? Surgery is dangerous. (Not to mention expensive and time-consuming.) She said there were clinical trials that showed this. Just use google, you'll find them, she said. I tried to find them. I looked and looked but failed to find any relevant evidence. My mom, who does medical searching for a living, was

unable to find any completed clinical trials. One was in progress (which implied the answer to my question wasn't known). I spoke to Dr. Consorti again. I can't find any studies, I said, nor can my mom. Okay, we'll find some and copy them for you, she said, you can come by the office and pick them up. She sounded completely sure the studies existed. I waited. Nothing from Dr. Consorti's office. After a few weeks, I phoned her office and left a message. No reply. I waited a month, phoned again, and left another message. No reply.

More. In spite of Dr. Consorti's statement in the comments (see below) that "I will call you once I clear my desk and do my own literature search," one year later (August 2009) I haven't heard from her.

1. <http://www.blog.sethroberts.net/2008/08/28/suppose-you-write-the-times-to-fix-an-error-part-1/>

---

Hap (2008-08-29 07:33:12)

I also recently consulted a Berkeley surgeon about an inguinal hernia. He confessed to me that he has TWO of them, both untreated for the last two years! I said, "Wow, with what you know I'd think you'd leap on the table." He replied, "Well, I'm not sure I trust anyone else with my body." Interesting. Back East for a physical with a friend who is a Western MD running an integrative (wholistic) medicine practice, I learned that he has an untreated hernia, as well. He told me there's no need to treat it. Both doctors agreed that if it gets in the way of things you want to do, or especially if it becomes painful (a very dangerous situation), then surgery would be an option. (Even then, it can be done endoscopically with a small incision and the insertion of a piece of mesh over the weak area of the abdominal wall.) As it is, I'm sticking with Chinese medicine which does not immediately force one to pick up a knife.

Aaron Blaisdell (2008-08-29 07:55:30)

Thanks for this telling story. I really think that a doctor should be obliged to provide the patient with the actual literature reporting relevant research if asked by the patient. Of course, the medical establishment would be against this because it removes their power as the priests of the information and, perhaps more importantly from their point of view, it removes their protection from being vetted by patients who question their authority and expertise.

seth (2008-08-29 08:32:24)

Aaron, yes, I completely agree. I think that's the moral of this story. Of course a surgeon will recommend surgery - I don't think that's a big surprise. But claiming there is nonexistent evidence for that recommendation - that's going too far. I could check her claim very thoroughly but most people to whom she makes such claims would have to take it on faith.

Magicmike (2008-08-29 12:11:16)

Seth, you are completely right. But... But I'm surprised he took the time to answer - your communications seemed confrontational to me. We should embrace guys like Roberts-Schwartz - yeah, he ain't got it all right, and yeah, it would be cool if he did, since it's a science section. But he seems to value research and have a genuine scientific bent. Thanks for publishing the correspondence.

Kirk (2008-08-29 15:15:14)

As for the hernia issue, when I asked my surgeon about how to avoid hernias, he said there is no way to avoid them. 'They show up, we repair them.' Why should they be repaired? Because they may become strangulated. What is the probability of your hernia becoming strangulated? That's the tough question. It's the risk management decision that those of us with hernias are being forced to make, with no information. As for the columnist, he may be a bit out of his depth having to do with appropriate sampling sizes. (Sort of like I am in this particular area.) You might want to rephrase the issue as a set of Action Items for him. Give him specific tasks. For example, if it's important to know the geographical spread of

the sushi restaurants, then write the exact questions that should be posed to the original authors. If it's important to know the number of sushi restaurants in a particular area, ask if a Gayot search for 'sushi' (which shows 62 listings) is sufficient. If it's important to know that the restaurants have different owners and not all part of the same chain, state that as a question. What would be best is if he can use this follow-up investigation to construct another article. Then he has motivation.

Methuselah - Pay Now Live Later (2008-08-30 05:53:36)

Seth - great to see people with responsibility for public health or the perception of it being held to account via the public medium of a blog. I am trying the same approach on my blog with a campaign to bring health food stores to account for the volumes of sugar in some of their products: [1]The Worst Sugar Pushers of all - Health Food Stores So far one of them has responded and made an equally poor job as Schwartz of defending their position (also published.) Suddenly the power shifts to the letter writer and it is no longer good enough for the recipients to fob them off with inadequate and ill-judged responses....

1. <http://paynowlivelater.blogspot.com/2008/08/worst-sugar-pushers-of-all-health-food.html>

Kirk (2008-08-30 07:26:04)

I looked around and found what looks like a relevant hernia study: <http://www.ncbi.nlm.nih.gov/pubmed/16418-463?dopt=Abstract>

sean (2008-08-30 08:13:51)

The dirty little secret is that some doctors are not as driven by evidence as we might hope. That is why the evidence-driven medicine movement is gaining momentum. Remember how medical journals initially refused to published evidence that *helicobacter pylori* was a cause of ulcers and not stress? A number of doctors pretend to be driven by evidence, but they are much more driven by a god complex that says, I'm the expert listen to me. The sampling question is another example of enumerative versus analytic thinking in the world of statistics. Most people think that all statistics is enumerative. Refer the journalist to any of the key articles by Deming.

Gordon (2008-09-03 16:18:24)

Sean, I'd like a reference to the key articles by Deming if you have them. Regarding the question of whether or not one can trust a doctor's recommendation, what about dentists? In the early 20th there were some in the profession who made claims that dentistry had reached the point in history where it was about to start doing more good than harm. Were they right? Have we ever reached that point? How can we know?

eileen consorti (2008-09-12 15:33:59)

Seth, While I am in the process of finding papers in the literature to satisfy your scientific curiosity on why this hernia should or should not be fixed I am additionally trying to care for around 30 new patients referred to me for their new cancer diagnosis in the last 3 months. This may or may not explain why I have not been motivated to answer your call regarding your ambivalence about fixing your hernia. Yes, it is small and runs the risk of incarceration at some time. I will call you once I clear my desk and do my own literature search. Thanks for the update. Eileen Consorti

seth (2008-09-12 18:48:51)

Dr. Consorti, to call my question "scientific" curiosity is highly unfair. I'm sure everyone, not just scientists, cares whether a proposed surgery will do more good than harm. My question is not "why" my hernia should be fixed - it's whether it should be fixed. My calls that have gone unanswered were not about my "ambivalence" - they were trying to determine what happened to the studies you said, several months ago, you would find and copy for me. But thank you for finally responding.

Heather (2009-01-18 23:51:10)

While I did not have a hernia, I just wanted to say I had a horrible experience w/ Dr. Eileen Consorti. I had extra breast tissue removed from my armpit, and she did a horrible job. First off, I would like to say how insulted I was that she did not have a paper gown in her office to adequately fit my breasts. She showed up late for my surgery, did it in half the time she said it would take, and stitched me up like a one-armed blind person who'd never been to med school. I used to be self-conscious about my

underarm breast, but it's nothing compared to the hideous clown smile under my arm now. Oh yeah, and the puckers at both ends of the incision look like the nipples of a girl just entering puberty. DR. CONSORTI SUCKS!

Seth's blog » Blog Archive » The Price of an Unnecessary Operation (2009-10-16 04:21:12)

[...] A few years ago, a Berkeley surgeon named Eileen Consorti, to whom I was referred by my primary-care doctor, recommended that I have an operation to repair a hernia so small I couldn't detect it. I have already written about how she kept saying there was evidence such operations were beneficial but as far as I can tell no such evidence exists. (Dr. Consorti has yet to provide the evidence she still seems to think exists.) Okay, she overstated benefits. What about costs? [...]

Dennis (2009-10-18 15:34:04)

Seth: Here is a good PhD thesis topic: "I. What proportion of medical treatment or procedures have a basis in evidence? II. Looking at the universe of ailments, what proportion of treatments in [1950] are recognized to be (a) harmful; or (b) useless today? III. Given II., what should we infer about accepted treatments today that are not evidence-based?"

seth (2009-10-18 23:15:57)

IV. Is the current emphasis on "evidence-based medicine" helpful or harmful? I don't mind that a doctor recommends a treatment for which there is no study showing it works. That is okay. It was that my doctor claimed the existence of non-existent studies that bothered me.

Seth's blog » Blog Archive » Gatekeeper Syndrome (2009-11-17 13:49:50)

[...] Shades of my surgeon claiming the existence of studies that didn't exist. But that's not the point. The point is this: After reading Atul Gawande's article about mirror therapy for phantom limb pain, she and her husband tried it. "Within 2-3 days, his pain was down to zero." It stayed there so long as they continued the mirror therapy. Soon after this they were able to eliminate his pain medication. [...]

Johann (2010-02-07 16:20:14)

About the hernia problem, you are in good company. Clinical Evidence, the database of evidence-based medicine run by (I think) the British Medical Journal, has a monograph on "expectant management" (doing nothing) compared to repairing an inguinal hernia: "We found no systematic review, RCTs, or cohort studies of sufficient quality" to say which strategy is better for improving symptoms. Also from Clinical Evidence: "Compared with expectant management (in people with minimally symptomatic hernia) Open mesh repair may be no more effective at reducing mortality (very low-quality evidence)." But the bigger problem is that most people have no idea how much of our clinical practice is not guided by solid evidence, and never will be because there are just too many questions and good studies are so hard to do. As a physician I often tell people "nobody really knows what the right thing to do is," but I think it tends to make many patients uncomfortable so I find myself trying to gauge whether someone just wants my advice or is really interested in hearing my evaluation of the evidence as it may apply to them. I certainly try to be as complete as possible if people ask, and I have often been prompted by patients' questions to do literature searches, but I don't print out studies for people even if they ask because I don't have the time. If they are that motivated they can do it themselves.

jessedziedzic (2011-10-20 11:41:20)

I do not disagree with this writing...

Seth Roberts (2011-11-14 14:17:03)

Johann, you write, "I don't print out studies for people even if they ask because I don't have the time. If they are that motivated they can do it themselves." That makes sense. But consider this: Dr. Consorti was going to make a lot of money if I followed her recommendation. That may be why she didn't tell me she was busy.

## Science in Action: Why Did I Sleep So Well? (part 9) (2008-08-29 19:43)

From [1]Nassim Taleb's web notebook:

I was going to have dinner with Seth Roberts in San Francisco. So, out of curiosity, I tried his diet [ clipping my nose and consuming two large tablespoons of flaxseed oil ] . . . When someone who observed me with a noseclip asked: "what are you doing?" , I gave my answer "trying to be healthier". It elicited a smile: "Why don't you dance outside on one leg for ten minutes? That too may work very well".

Strange strange coincidence.

---

Dan (2008-08-30 07:31:43)

Just given the sheer weirdness of your theories, I've repeatedly thought that you're actually doing large-scale research on the placebo effect, and that we're all going to end up as examples in a paper or book down the road. But the flaxseed oil did have a positive effect on my sleep – very vivid dreams. Any weight loss has been minimal, but I did think that I have been less hungry, so I'll keep it up for another couple weeks and see if there is an effect.

seth (2008-08-30 10:01:49)

"The sheer weirdness of your theories." Yeah, I find them weird too. Not the flaxseed oil, which many others before me have praised. (Although the idea that an everyday foodstuff could substantially improve brain performance is weird.) But the standing, the faces, the sugar water, the oil, the nose-clipping, the anti-breakfast – those are weird. I'm not sure what to make of it.

[...] Science in Action: Why Did I Sleep So Well? (part 9) [...]

## The Best Blogs Are Very Good (2008-08-30 07:34)

From [1]It's Raining Noodles:

Before the next batch of snapshots and corresponding captions [on a screen at a fast food restaurant in Singapore] were revealed, a simple message against a plain background read, "To all the great and wonderful mothers out there..." as a sort of enigmatic prelude to the marvels to come, and because I am a cynical bitch with a very gloomy worldview, I asked out loud, "What about the other mothers?" To which Maria put on an affected frown as if she'd been hurt that her loved one was being left out by the onscreen message, and gleefully responded, "What about MY mom?"

More. Not to mention [2]this:

The past three hours can only be adequately described by the word SIGH. Thinking that I was taking a step towards improving my relationship with God, no this is not a long preachy thing so please stay with me, I agreed to sit through a session thingy with a very Christian Mrs. In-Law and a very reluctant Neptune. . . . The sharing session was led by a heterosexual couple (why I am highlighting the heterosexual part will become evident later), and it was interesting because they had a different take on the religion from most that I've heard. In many ways it felt like a lecture in literature class, and for the most part I enjoyed it because of the different perspectives on the same ol' concepts. . . . The only revelation for me, though, arrived when the female half of the heterosexual couple went on to preach that God gives up on people who insist on pursuing sin, such as idolatry and YES YOU GUESSED IT, homosexuality. She was all, "YES, HOMOSEXUALITY IS WRONG! God has given up on people like that."

And I realised in that moment that God had probably just punished me by making me sit through three hours of this thingy thinking that MAYBE I had a shot at heaven when actually? ACTUALLY? NO CHANCE AT ALL. God has abandoned me to begin with right from the start. I'm damned forever. So I looked at Neptune and said, "God has given up on us!" and I was very sad. I find it very difficult to wrap my head around exactly why I deserve to go straight to hell when all I've done is fall in love with another person.

Really enjoyed the mood experiment article. Amazing to see people discovering such little interventions, and even better that the internet and blogging is helping them propagate. I think I will give this one a try – a minute a day is a pretty small commitment! Great find, thanks.

## 3.9 September

### Science in Action: Why Did I Sleep So Well? (part 10) (2008-09-01 07:19)

Long ago, talking about scientific discovery, Pasteur said "chance favors the prepared mind." In my case, I now realize, this generalization can be improved on. The underlying pattern can be described more precisely.

I've made several discoveries because two things came together, as Pasteur said, with one element a kind of chance and the other a kind of knowledge. The two elements were:

1. I did something unusual.
2. I knew something unusual.

Here are the discoveries and how they fit this pattern:

1. Breakfast. Discovery: Eating breakfast caused me to wake up too early more often. Did something unusual: I copied one of my students, who told me about his experiences during office hour. This eventually led me to vary my breakfast. Knew something unusual: I had detailed records of my sleep. The combination made it clear that breakfast was affecting my sleep.
2. Morning faces. Discovery: Seeing faces in the morning improves my mood the next day. Did something unusual: I watched a tape of Jay Leno soon after getting up. Knew something unusual: From teaching intro psych, I knew there was a strong connection between depression and bad sleep.
3. Standing and sleep. Discovery: Standing a lot reduces early awakening. Did something unusual: I arranged my life so that I stood a lot more than usual. Knew something unusual: I had detailed sleep records. They made the reduction in early awakening easy to see.
4. Sleep and health. Discovery: At the same time my sleep greatly improved, I stopped getting colds. Did something unusual: To improve my sleep I was standing a lot and getting a lot of morning light from a bank of lights on my treadmill. Knew something unusual: I had records of my colds going back ten years.
5. The Shangri-La Diet. Discovery: Drinking sugar water causes weight loss. Did something unusual: I went to Paris. Knew something unusual: I had developed a new theory of weight control.

6. Flaxseed oil and the brain. Discovery: Flaxseed oil improves my mental function. Did something unusual: One evening I took 6-8 flaxseed oil capsules. Knew something unusual: I had been putting on my shoes standing up for more than a year and knew how difficult it usually was. The morning after I took the flaxseed oil capsules it was a lot easier.

7. Standing on one foot and sleep. Discovery: Standing on one foot improves my sleep. Did something unusual: In order to stretch my quadriceps, I stood on one foot several times one day. Knew something unusual: I knew that if I stood a lot my sleep improved (Discovery 3).

The unusual actions ranged from things as common as foreign travel (Paris) and stretching to the extremely rare (watch a tape of Jay Leno soon after waking up). The unusual knowledge ranged from quirky and casual (knowing how hard it is to put on shoes standing up) to sets of numbers (sleep records) to generalizations based on numbers (what scientific papers are about) to the sort of stuff taught in science classes (a theory of weight control) to the sort of knowledge derived from teaching science classes (connecting depression and bad sleep). To call this stuff unusual knowledge is actually too broad because in every case it's knowledge related to causality.

Only after Discovery 7 (more precisely, this morning) did I notice this pattern. Read the discussion section of [1]this paper (which is about Discoveries 1-5) to see how badly I missed it earlier.

More on [2]Discovery 6. [3]Discovery 7.

Heidi 555 (2008-09-01 13:31:58)

Seth, I think that keeping detailed records of your sleep and colds (and perhaps other things) is extremely helpful to the self experimentation process. Could you say a bit more about what kinds of records you keep, which details you track, and how you notate them? I am thinking about starting to keep sleep records and am looking for ideas on how to set up a journal, log, or computer data sheet. For years I have kept careful records of 3 different things. I keep a journal in which I record every mushroom and wild food that I've found. (This journal also has photos I've taken and looks beautiful as well as being a tremendous resource.) I keep careful track of my hormonal/menstrual cycle and many things related to it. I record a certain kind of dream that I regularly have. My records are a source of tremendous knowledge/self-knowledge and I consider them my most valuable possessions.

seth (2008-09-01 19:56:53)

Outcome measures: At the moment I record details of my sleep, weight, fasting blood glucose level, and blood pressure. My sleep records consist of when I went to bed, when I got up, how rested I felt when I got up, and if I took a nap, how long. Treatment measures, all related to sleep: when I was outside in the morning, when I looked my face (in a mirror), how often & how long I stood on one foot. What's crucial, I believe, is to make it easy to do and look at. I write the sleep & weight info in a standard college-note-taking-type lined-paper notebook, one line per day. The blood pressure and blood glucose data I enter into my computer using R.

Heidi 555 (2008-09-02 09:18:51)

Thanks Seth. That was helpful. I'm going to start keeping sleep records.

david (2008-09-02 10:30:22)

Seth, Regarding standing on one foot improving sleep: I think you've just independently discovered yoga :-). In fact, a friend of mine who does yoga informs me that standing on one foot is a form of "The Tree Pose". I'd be interested to see if replacing the one-footed balancing with a more traditional yoga improves your sleep and if it does so any more than your few minutes of tree-posing a day. The connection between better sleep and better overall health and well being seems obvious and I'm sure has been empirically demonstrated (I'm too lazy to google for that right now). So it looks like you're demonstrating the connection between yoga and sleep, which in turn validates the connection between yoga and overall health and well-being that's often claimed for it. My guess is that yogic traditions that have been developed over thousands of years are more finely tuned to produce various benefits than the one-footed-balancing you've stumbled upon (no pun intended). For example, if you combined your tree-pose with the mind-clearing, meditative aspects of yoga, your sleep may improve even more. Likewise, there may be other benefits apart from better sleep that result from practices like yoga and meditation. David

seth (2008-09-02 18:37:06)

David, you may have something there. Maybe some of the benefits of yoga derive from better sleep. On the other hand, I recently did a month of yoga classes, and never noticed that my sleep was better. The poses, including the one-legged poses, lasted about a minute, whereas I stood on one foot for a few minutes each time. And it is a million times easier to stand on one foot for several minutes a few times than take a yoga class.

david (2008-09-03 08:42:53)

Ok, perhaps it's the other way around then. You've discovered that yoga, as it's sometimes practiced, is suboptimal because the poses aren't held long enough. I've done very little yoga and know nothing about what's considered the right way to do it and what specific goals it has. My guess is that there are many types of yoga, some more rigorous than others and some with more specific goals. I know that people who do meditation are often studied by psychologists and they usually pick people who've done a lot of meditation (in these examples, one is people who've just done a three-month silent retreat and the other is people who've meditated daily for three years): [http://www.scientificblogging.com/news/meditation\\_may\\_fine\\_tune\\_attention\\_span](http://www.scientificblogging.com/news/meditation_may_fine_tune_attention_span) [http://www.scientificblogging.com/news\\_releases/this\\_is\\_your\\_brain\\_on\\_zen\\_experienced\\_meditators\\_recover\\_more\\_quickly](http://www.scientificblogging.com/news_releases/this_is_your_brain_on_zen_experienced_meditators_recover_more_quickly) So you might want to look for a more rigorous form of yoga. It may also be worth looking to see if yoga and sleep have been studied already by sleep researchers. I also wonder if there's not a 'lowest common denominator' effect in yoga classes, so that the poses are only held as long as the weakest members of the class can hold them. You mentioned that you hold your pose until you can't anymore. I wonder if in the yoga class, the poses are only held until the bottom third of the group starts to fade. Finally, I don't know what the stated purpose of yoga classes is. Is it just to teach you the poses so you can do them on your own? Do instructors tell you to hold the poses as long as you can when you do yoga on your own? Or is the expectation that you only do the poses in class and not on your own at home? David

Adam (2008-09-03 10:51:54)

Hi Seth, I've had problems with sleeping for a few years now, so I've been trying out your possible solution for the last week. I'm curious about something. You mentioned you stand on one foot until you become exhausted, usually 2-6 minutes. Unfortunately for me, I seem to be able to stand on one foot indefinitely, or at least I haven't reached a point where I feel exhausted enough to stop. This is really surprising, since I have an office job and standing isn't exactly something my body is accustomed to. I usually have to stop after 10-20 minutes simply because I have other things to do. I do get a slight pain in the arches of my feet. I wear sandals while doing this, on a hard wood floor. Do you feel "exhausted" in general, or is there some specific kind of physiological sign you use to tell yourself to stop? Initial observation is that if I do this standing routine right before bed, my sleep is extremely shallow, causing sleep interruptions and early waking, but there could be other factors to that. Today I'm trying it throughout the day instead. Thanks for your thoughts.

seth (2008-09-03 16:22:57)

Adam, I found that if I stand on one foot with the other foot just barely off the ground I can stand that way much longer (10-15 minutes) than if I stand on one foot with the other foot pulled back such that its muscles are stretched (5-8 minutes). I've been doing it the second way. This probably explains the difference between your times and mine. Doing it doesn't make me feel

exhausted. What happens is my legs and foot start to hurt after a while, then I stop. I suggest you try the second (stretching) way of doing it. David, the yoga I took (Bikram) was done in a heated room that would be hard to duplicate at home. And there is a kind of motivation supplied by doing it in a room with an instructor and many other students. The poses incorporate all sorts of difficult elements that make them harder to do – I usually stopped not because my muscles were tired but because I wasn't flexible enough. I don't know why poses were held for a minute rather than a shorter or longer time. Thanks for the links about meditation. The yoga I did was a constant struggle, not meditative at all. I liked it, I should add, but it was very time-consuming, not to mention tiring and expensive.

[...] Science in Action: Why Did I Sleep So Well? (part 10) [...]

## **Two Books about Memory Research (2008-09-02 07:05)**

My mom said this:

Finished reading [1]Can't Remember What I Forgot: The Good News From the Front Lines of Memory Research [by Sue Halpern]. As far as I'm concerned, [2]Carved in Sand [by Cathryn Ramin] is much the better book. Less science but better, more careful and detailed, description of remedies tried.Â Halpern personalizes each scientist she talked to in an irritating way, and then describes their theories in great detail, only to report their failures later. As a matter of fact, most of the news she reports, especially about Alzheimer's, is bad news. The good news is that daily exercise appears to be beneficial to memory, as are a host of other things supposedly good for it. Earthshaking.

2. <http://www.carvedinsand.com/>

---

Dave Lull (2008-09-03 17:35:05)

"Exercise 'tackles flawed memory'": <http://news.bbc.co.uk/2/hi/health/7593324.stm> 'Dr Susanne Sorensen, head of research at the Alzheimer's Society, said: "Regular exercise is one of the best ways to reduce your risk of dementia and can help slow progression of the condition. "'This study demonstrates that exercise improves cognition in people with mild cognitive impairment, and that there is a lasting effect even after the exercise intervention stops. "'We need more research to investigate whether exercise not only improves cognition, but also stops people with mild cognitive impairment developing dementia.'"

## **Science in Action: Why Did I Sleep So Well? (part 11) (2008-09-03 17:22)**

I'm now sure it's the one-legged standing that's improving my sleep. The new way of seeing faces in the morning doesn't seem to matter. In case you want to try this, I've found that if I just raise one foot slightly I can stand one-legged much longer (about twice as long) than if I stand one-legged and pull the other foot behind me (stretching my leg muscles). I think this means the stretching pose is twice as effective per minute as the non-stretching pose; it produces the same effect in half the time.

It's only been a few weeks, but my legs are already much stronger. Walking long distances (such as 4 miles) is easier

and so is standing for long periods of time. My notions about exercise are changing, too. Before this, I thought of exercise having three types:

1. Strength. Exercise a muscle, it gets stronger. Benefits: stronger muscles can do more, look better.
2. Flexibility. Improved by stretching, e.g., yoga. Benefit: less chance of injury.
3. Aerobic. The Cooper idea. Improved by running, swimming, etc. Benefit: apparently reduces risk of heart attacks, perhaps reduces risk of other diseases. (Some people do it to lose weight, of course.) To measure aerobic fitness, The Cooper Institute stress-tested executives and found that [1]those with better stress-test scores had lower mortality in the following years. Stress-test fitness was a better predictor of mortality than obesity – some people were "fit but fat".

The one-legged standing seems to be a whole new category:

4. Soporific. When you stress a leg muscle a lot, presumably one or more chemicals are released that both (a) cause the muscle to grow (the well-known effect of exercise) and (b) cause you to sleep more deeply at night (the effect that interests me). In contrast to Types 1-3, there's no need for the concept of fitness here because you don't slowly go up and down in a measure of effectiveness (i.e., become more or less fit). Rather each day you are high or low on this measure, and the next day you start fresh. In contrast to Types 1-3, where the benefits accrue slowly (over weeks and months), the benefits are obvious the next morning (you feel better-rested) and the next day (you're less tired). In contrast to Types 1-3, there is no connection with athletics (such as Olympic events). Conventional exercise is integral-like: It's the sum over days that matters. Whereas this exercise is derivative-like: The benefits derive from doing a little more today than you did on previous days. The psychology is different, too. The benefits are so large relative to the cost that there's no motivation problem. Deciding to do it is about as hard as deciding to pick up a \$!0 bill. Deciding to do conventional exercise is a lot harder.

---

Tom (2008-09-03 17:30:31)

"Soporific" – interesting. I was about to suggest that it's really an offshoot of isometric exercise (as it seems to me that you're really tensing opposing muscles against each other.) And this caused me to wonder if there isn't something in the nature of isometric exercise, rather than standing, that helps sleep. ie, does it have to be standing? Could it just be isometrically exercising, say, your chest muscles by pressing your palms together hard and holding it for a while? Or holding a mid-pushup position (keeping your core solid) as long as you could?

Ryan (2008-09-03 17:48:20)

I've started doing the leg lift thing like you described. For the past few days I've awoken very well-rested and energized, for what it's worth. I wonder what may cause this effect, but in the meantime I'm going to keep doing it. I really like the "Science in Action" series and hope you apply it to other topics.

Charles (2008-09-03 18:01:43)

I wonder if there is a connection with the similar and proven benefits of Tai Chi Chuan? When you are doing Tai Chi correctly, you are slowly transferring your weight from one leg to the other, as if you were standing on each leg alternately.

seth (2008-09-03 20:07:11)

Tom, yeah, I don't think the leg muscles are constructed differently than other muscles; they're just larger. So that you get a larger dose of the crucial chemical per minute of exercise. I like your alternative suggestions because pretty soon my legs are going to be stronger than they need to be for any conceivable task and it might help to strengthen other parts of my body. It might take too long using other parts of the body but it's worth a try.

Sam (2008-09-03 23:11:41)

I wonder if you have to stand on one leg until you are tired - since I couldn't make it. Being a dancer I could stand on one leg for hours, so maybe the effect does not work as well on me? On the other hand, I usually sleep very well and wake up early. I started a dancers workout every morning, which contains a lot of standing on one leg, but so far I noticed not much difference in my sleep.

MT (2008-09-04 04:49:40)

Great posts about your sleep and one-legged standing - I will definitely give this a try in a while. In the interim, here is a post I got today from another blog I like about fitness: <http://conditioningresearch.blogspot.com/2008/09/one-arm-pushup.html> It talks about one-armed push-ups, and one legged squats, which I mention because I have been looking into trying to improve my vertical leap to try and slam dunk a basketball - some research demonstrated that doing one-legged squats helps improve power more than two-legged squats, and they theorise that it is because of incorporating balance. Maybe a series of one-legged squats while balancing would trigger your better-sleep-oscillator still more quickly? Perhaps it is load-dependent? As with your wondering if you'll get strong too quickly, you can ALWAYS challenge yourself with squats! Technique is important, you can often find good form on YouTube. if you are interested in more fitness ideas, there is an interesting group called CrossFit, who believe in functional fitness, and they have an interesting paper on their website about their definition of fitness which incorporates balance and other elements. It is well thought out. I found these leads through my research into so-called evolutionary health, intermittent fasting, etc. Great posting!

seth (2008-09-04 05:11:44)

MT, yes, one-legged squats, or just bending the standing leg, might be an improvement, in the sense of producing the same effect more quickly. I'll try it sometime.

Igor Carron (2008-09-04 12:13:07)

Seth, In a similar vein, I don't know if you remember this study <http://www.msnbc.msn.com/id/6795822/> [http://www.medscape.com/viewarticle/4933\\_23](http://www.medscape.com/viewarticle/4933_23) <http://nuit-blanche.blogspot.com/2005/01/its-all-downhill-from-here.html> that seemed to show that walking downhill did not yield the same results as walking uphill. Is there a mechanism that is specific to the soporific mode as opposed to the others ? Igor.

James (2008-09-04 17:45:18)

I had stuff I needed to do yesterday when I thought about standing on one leg, so I hopped around. In total I only stood on each leg for a few minutes, but the hopping shortened the time it took to become hard to continue.

seth (2008-09-04 21:05:40)

thanks, James, that's a good idea: hopping on one leg.

JohnN (2008-09-05 11:56:40)

On why one-leg standing works, here's one hypothesis to consider: Standing on one leg creates asymmetrical loading forcing our body to engage more of the fine-control muscles and more neurons (firing) to maintain balance. Of course, these fine

muscles tire out very easily - you can tell by the lactic acid burn which incidentally also signals the body to produce growth hormone. This acute but brief stress will force your brain to enter deep sleep to absorb the lesson. I think Tai Chi works for me (like Charles suggest) - probably because of the very slow and deliberate movements with absolute body control ( & concentration). Can we test this hypothesis by standing on one leg with our eyes closed to intensify the experience? My limit on a good day is 20-40 seconds after some refinements to fine-tune the body posture.

Willy (2008-09-05 12:49:09)

> I've found that if I just raise one foot slightly I can stand one-legged much longer (about twice as long) than if I stand one-legged and pull the other foot behind me (stretching my leg muscles). Do you mean keeping both foot on the floor but raising one a bit so the load is put on the other one?. Thanks.

Kirk (2008-09-05 16:01:48)

A brief comment for Sam . . . the teachers in my Tai Chi group say that if the stances are getting easy, you need to sink lower. They tell a story about one of the best students working on Descending Single Whip (also known as Snake Creeps Down) with our master teacher. They were both at the lowest position and the teacher said, 'OK, like all one-legged stances, you should be able to pick your other foot off the floor.' Which he proceeded to demonstrate, while the student struggled. Perhaps one of your fellow dancers has studied Tai Chi and can show you this stance. It can also be found at 4:45 at <http://www.youtube.com/watch?v=USJPmCZ6Efc>. And, by the way, while you're in stance, stay relaxed. (One of our teachers taught a professional dance company; he said they were able to learn the stances and flow immediately, but could never relax.)

Dave Lull (2008-09-06 12:06:46)

Kirk's URL has a period at the end that "corrupts" the link. Here it is without the period: <http://www.youtube.com/watch?v=USJPmCZ6Efc>

seth (2008-09-09 21:25:46)

Willy, no. One foot is an inch or two off the floor.

[...] Science in Action: Why Did I Sleep So Well? (part 11) [...]

## Too Much Flaxseed Oil (2008-09-04 21:24)

I recently got the following email:

I'd like to advise caution about the use of excessive omega-3s, such as flax and fish oil. I discovered that too much of these oils can induce an omega-6 deficiency, since both n3 and n6 oils compete for the same enzymes in the biosynthesis pathways of prostaglandin precursors. In susceptible people, of which I am one, this leads to insomnia, psoriatic lesions, and when combined with food avoidance (e.g. Atkins-like diets, etc.), can lead to loss of immunological tolerance to food antigens. It turns out that n6 arachidonic acid is critical for the development and maintenance of oral tolerance (Newberry, 1999).

I asked her for details. She replied:

I started taking 2 tablespoons of flax oil daily with meals, and this was my exclusive added fat source for several months; I also got fat from meat and dairy. This was back in 2001. The insomnia happened

almost immediately, and the psoriasis and “cellophane-like” skin developed over several weeks. I quit the flax oil after 3 months, but this was around the same time that I learned of Atkins and the Weston Price foundation- so, I cut back on carbohydrates and added fish oil and “whole foods” to my diet. It’s not clear what exactly happened around that time, but I started to descend into chronic illness: chronic flu-like symptoms, blood-sugar fluctuations, disordered sleep schedule, arthritis in my wrists and toes, rapid weight gain, etc. (And I should mention that before that I was an invincible young woman grad student, an outdoorsy athlete, was proud to never get a cold, and only mildly overweight.) I dealt with it as best as I could, since I was also trying to do my PhD thesis in engineering. I also quit taking any dietary supplements, because nothing seemed to help and I would often get weird side-effects from simple things like calcium supplements. On the advice of a physician in 2004, I added more carbohydrate back to the diet (re-introduced wheat carbs) and got hit with some frightening digestive complaints (cramps, vomiting, IBS symptoms.) It looked a lot like celiac disease, but all of the tests were negative. I didn’t have the proper genetic markers for celiac disease, either, but a strict gluten-free and dairy free diet helped nonetheless.

The GI symptoms were much better by 2005 after going gluten and dairy free, but I was still not well. What gave me the “aha moment” was taking a random dose of fish oil during that time, and having an immediate relapse in symptoms. Then I started researching arachidonic acid (the “bad”  $\omega 6$ ), with the question of “well, what is it good for, then?” That’s when I found the Newberry paper, and it dawned on me that I had inadvertently created an  $\omega 6$  deficiency by overdoing it on flax/fish oil. I also became quite an expert on essential fatty acid metabolism. What I had likely done was impair my ability to tolerate the introduction of new foods. I knew that my problem wasn’t gluten per se, because I would develop symptoms soon after adding exotic foods (coconut milk, pork, tapioca flour, etc.) to replace the eliminated things like milk and wheat flour.

Here are the three things I did to get well:

- 1) After discovering the Newberry paper, I decided to focus on acquiring pre-made sources of arachidonic acid in the diet. I found that the best source of pre-formed arachidonic acid is egg yolks and poultry, and I looked to worldwide intakes of AA to gauge my dose. It turns out that the French get a good daily dose of AA (190mg for women), and I settled on 2 egg yolks per day (65mg each) plus incidental sources. This is where I really turned the corner on feeling well.
- 2) I avoided known problem foods temporarily. I consulted with Jonathan Brostoff on food intolerances, and he said that the immune system requires about 6 months to “forget” its hypersensitivity to a food antigen before it can be re-introduced. I did the gluten and dairy free diet for 3 years in total, and added back foods on an experimental basis once I had been on the egg-yolk regime for a year.
- 3.) Finally, a gastroenterologist called my problem IBS, which is a catch-all trash diagnosis. However, I had been thinking in terms of celiac disease for a long time, and after doing searches on IBS I came across some new information about a probiotic that was supposed to help with IBS. I tried Bifidobacterium infantis (Align) for 2 months last winter, and it put me over the top. This was around the same time that I tried gluten and dairy for the first time in 3 years, and I was able to introduce it with no problems.

Today, I feel that I’m back to 100 % and cured, except for the weight that I acquired during the illness. (I stopped gaining after going gluten free, but could never lose anything.) My propensity to experiment on myself led to some serious consequences, but I discovered something that relatively few people know about the importance of omega-6s.

Keep in mind that deficiency of omega-6 is very rare and overconsumption very common (e.g., the [1]Israeli Paradox). In 2002, the Japan Society for Lipid Nutrition recommended reducing linoleic acid (LA) intake; LA is the short-chain omega-6 fatty acid, found in high concentrations in many vegetable oils, such as soybean oil. LA is converted to AA in the body.

1. <http://www.blog.sethroberts.net/2007/02/02/the-israeli-paradox/>

---

MT (2008-09-05 02:25:05)

Great research by the emailer. I have not seemed to realise benefits from flax either, and on my most recent round of experimentation with it felt quite nauseous from it and actually feel an aversion toward it. I am thinking about trying fish oil instead, as there may be a subtlety in how I process the ALA into DHA/EPA or something else (lignans?) causing the nausea – alternatively it may be my body telling me not to consume it. Maybe there is an O6 relationship? I have found that intermittent fasting (limiting eating to a short window during the day, typically 4-6 hours for me, meaning 'fasting' for 18-20 hours a day) has allowed me to become much more aware of the effects of different foods on me. For instance, I get really sleepy within an hour of eating bread – something I've never noticed previously, and it became obvious because the fasting period makes creates more contrast between periods with a food, and periods without. So observations are easier. Incidentally, my energy levels are normal for me, or slightly better – I can exercise vigorously with nothing in my stomach and recover as quickly as I ever have. It does help many people with weight loss and/or muscle gain, if the O6-emailer wishes to keep experimenting :)

SusanJ (2008-09-05 11:23:52)

This is very interesting. About a dozen years ago I luckily discovered by doing something random and unusual (consuming a large egg-salad sandwich for lunch) that an intolerance for eating eggs was the source of a long-standing, mysterious, seeming randomly occurring, disabling lethargy. When this lethargy hit me, simply walking to the end of the driveway was almost too much. I now can eat items, such as baked goods, which include a small amount of egg without a problem. I haven't (yet) tried eating a plain cooked egg since the possibility of the lethargy's recurring seems just too unpleasant. I don't have any other food intolerances, don't have asthma or other chronic problems, and don't have any allergies (with the exception of mild allergies to juniper).

Kirk (2008-09-05 14:49:27)

Agreed, great information by the emailer. I hadn't heard that '6 months' hypersensitivity issue. Maybe this means I can eat chocolate again? (There's nothing like having your throat close down to put you off chocolate.) My readings about Omega-6s and Omega-3s indicate that it is best to aim for a balance, because the two fats compete. The International Society for the Study of Fatty Acids and Lipids recommends a Omega-6:Omega-3 ratio of 1:1 to 2:1. And it is important to keep the overall Omega-6s down to the 4400 - 6670 milligram range; it's not just a matter of increasing Omega-3s. Another thing to consider is that the Omega-3s that improve the body are EPA and DHA: flaxseed oil contains ALA. One author says that 'only a miniscule amount of ALA is converted into EPA and DHA in the body–(the conversion rate is less than half of one-percent, 0.03 %)' As for fish oil capsules, physicians in one book that I'm currently reading say, 'Researchers had pulled bottles of fish-oil capsules off the shelves of health food stores and checked them for rancidity. They found that in almost 50 percent of the cases some of the capsules in a given bottle were rancid. When fish oil becomes rancid it doesn't go from being a good fat to being a neutral fat, it becomes a harmful fat . . . substances called lipid peroxides that cause all kinds of problems once they get inside us.' Thank goodness for canned sardines and grilled salmon.

Stephen M (Ethesis) (2008-09-07 06:39:29)

Kirk, That is interesting (about the chocolate). I'd love to be able to eat chocolate again. I continue in my quest for the perfect oil – easy to swallow, high in O-3, easy to find. ;)

Mary Marvin (2008-09-10 04:49:19)

Thank you for your article on flaxseed oil, fish oil and soybean oil. I have to search for my own answers because doctors do not know how to help with severe RA except methotrexate and Orencia which only suppress some symptoms. You still have your RA and when you stop the meds your RA is worse than it was before starting the medications. The avoidance of soybean oil in America will be extremely hard because it is in just about every product in the grocery from bread and baked items to salad dressings.

reeko (2008-09-17 19:59:34)

I've quit taking fish oil. Been off it now for two weeks - and feel fantastic. The background (and breakthrough) is this: I was diagnosed with hypertriglyceremia 20 months ago. At the same time, I mysteriously began having "panic attacks" that mimicked the exact symptoms of a heart attack: cold sweating, sharp pains in chest, hard to breathe, pains running down left arm and shoulder, tightness in throat etc. I've been admitted through emergency rooms three times in the past year and half. All tests were done and all usual suspects ruled out: no heart enzyme problems etc. NO heart attacks at all. These episodes have been ruled "panic" or "anxiety" attacks and they do seem to come whenever I was stressed... Yet not one of the many doctors suggested a link between my "off the chart" triglycerides (above 400) and these "panic" attacks. Since my cholesterol levels are that of a teenager (I am in my 50s) and I don't smoke or drink excessively, weight lift and workout regularly, I am still about 20 or 25 lbs overweight. Being overweight is a factor in high triglycerides, but no association with the panic or mock heart attacks. The only drug I've been given is Xanax, and that is what I've been taking when I feel those symptoms. Until now. I have religiously taken a daily dose of 1000 mg of fish oil for almost 30 years. For about one year several years ago, I alternated between flax oil and fish oil every other day. That is probably a good reason my cholesterol is that of a teenagers. BUT nobody has made the connection between high triglycerides and fish oil. I've looked all over the internet - nothing. I also can't find anything connecting high triglycerides and panic attacks... On my own (and against my doctor's opinion) I decided to stop taking the fish oil. Since high triglycerides are basically a high amount of soluble fats in the bloodstream, I figured it couldn't hurt. I am glad I did. If anybody knows of any info about "too much" fish oil or toxicity from it, and I don't mean allergic reactions, please let me know ok?

reeko (2008-10-06 22:53:21)

UPDATE: had my quarterly labs done at the VA, and my triglycerides have gone down to 309 from 330 last time. Even though that's still WAY too high and dangerous (100-150 is normal) it is a lot better than the 400 it was. Here's yet another happy side effect of NOT taking fish oil: I no longer have dispepsia/acid reflux. For about a decade, I've been taking Pepcid AC, then Zantac, then Prilosec. All good, but I still took them whenever I needed them - which was every day. Only a few days after stopping the fish oil, I no longer had heartburn/reflux! I'm feeling better all the time... FYI: read somewhere that up to 50 percent of all fish oil sold is rancid or contaminated. Can't google that story right now, but maybe that has something to do with it. I'm sticking with just eating a lot of seafood and to hell with those supplements! - reeko

Jr (2008-12-31 10:40:42)

One of the things that I didn't notice in browsing over this page was whether you or anyone is consuming the flax oil in combination with Whey Protein. It is extremely important for one to mix flax with Whey Protein as Whey has sufficient sulfur proteins that allow the flax to combine with it to make it water soluble and gives the body the ability to easily assimilate it. This is all based on the work of the 6 time Nobel prize nominee Joanna Budwig. She actually doesn't recommend taking flax oil on its own without this combination.... do a search on Joanna Budwig, and you can buy her books translated to English online....

Gary (2009-01-10 23:04:46)

interesting discussion. Some fairly good insight is also provided by Dr. Donald O Rudin so you can look it up. It seems we all have some pretty varied responses to mega doses of omega 3. the only reason to use high doses is to "do an oil change". but we have to listen to our bodies carefully and after a while titrate back to something sane with a good ratio of 6/3. It seems since this is genetic food adaptaion we are talking about here and we are a very diverse genetic world population with out genes all mixed up we are all going to be having different reactions to levels of these fats in our diet in both the long and short run. I have to admit as well that when i try to read the work of Joanna Budwig her reasoning seems to be kind of faulty. The general idea is that we have a regulatory system based on lipids. you could call it a prostaglandin system that needs to be in ballance. remember you cant use fish oil alone for 3 because of no ALA. also might want to include evening primrose oil for GLA. remember that the conversion of molecules in the body is very complex almost like a chemical based computer with many redundant systems and pathways all built up as a response to our environment. we do our best based on current research but actually understand very little about how it all works so diet variety is the key.

reeko (2009-03-04 21:11:24)

SUCCESS! The no-fish-oil regimen worked. I had my lipids checked again today, and after only six months of going off fish oil, my triglycerides are now normal: 145. Just two years ago, they were "off the charts" - over 400. And back in October after only a month of going off fish oil it had dropped to 309. I also began taking a low dose niacin in the mornings as well. I feel fantastic, no more dyspepsia/heartburn, much more energy, no more panic attacks (that mimic heart attacks) and my lipids are all within normal ranges. No matter what anybody says, I took fish oil (or flax) for almost 30 yrs, and here is proof, as far as I'm concerned that it is NOT the greatest thing to do for everybody. To each his own and good luck, but the best "prevention" may sometimes just be living naturally - and save your money on the supplements. ;) reeko

Johan (2009-11-21 07:05:28)

Just entered here via Google. @ Reeko I agree with you on the opinion that the best thing is living naturally and have varying diet. I have been using supplements for quit some time. I stopped because I think fish oil is also a supplement that is very stimulating. I think it can help you being active, but I don't always like that.

Emma (2010-02-14 05:07:59)

SEth, What are psoriatic lesions

## **Rudy Guiliani, Sarah Palin and Self-Experimentation (2008-09-06 09:57)**

Sometimes I'm surprised how much there is to blog about. At the Republican National Convention, [1]Rudy Guiliani bashed community organizers:

[Obama] worked as a community organizer. [Said with a disparaging emphasis on "community organizer"]  
. . . Barack Obama has never led anything, nothing, nada.

So did Palin:

In this world of threats and dangers, it's not just a community and it doesn't just need an organizer.

The interesting thing about community organizing is that (a) anybody can do it (no need to be elected) and (b) you can organize about anything. This wide net, this all-inclusiveness, makes it a way that new ideas can become powerful. Self-experimentation is very similar: (a) anyone can do it and (b) you can study anything. You don't need anyone's approval, the research can be very cheap, the ideas you test can be conventional or wacky. Only if you believe that

the already-powerful know everything should you disparage activities that help new knowledge come to light.

1. <http://robin-loves.blogspot.com/2008/09/dont-knock-community-organizers.html>

---

Ryan Holiday (2008-09-06 12:50:10)

Seth, Have you read any of Saul Alinsky's books on community organizing? Reveille for Radicals is one of my favorite books of all time - and strangely, very relevant to the internet. If I remember correctly, Obama styles himself as being from the Alinsky school of community organizing and Hillary actually wrote her college thesis on him. Ryan

seth (2008-09-06 13:12:00)

No I haven't read anything by Saul Alinsky. Thanks for the suggestion.

Methuselah - Pay Now Live Later (2008-09-06 15:25:38)

Seth - I think blogging could be looked at in the same way. Anyone can do it and the power derives from the empowerment to place correspondence (such as your exchanges with the Times journalist) into public view and thus organisations or those representing them to give more considered responses. I am currently pursuing a few retailers in this way, posting my questions about the foods they sell as 'open' emails to them and publishing their responses. It will be interesting to see how this pans out.

seth (2008-09-06 21:04:33)

I agree, blogging is similar. Anyone can blog and you can blog about anything.

Dennis Mangan (2008-09-07 13:16:51)

"Only if you believe that the already-powerful know everything should you disparage activities that help new knowledge come to light." The type of "communtiy organizing" that Obama and his like do has nothing to do with discovery; it has to do with milking the government and corporations for more money. So I'd say it bears little similarity to self-experimentation.

thehova (2008-09-07 23:18:22)

Come on now. The whole Obama narrative, about walking away from Wall Street to do real work that's helpful, isn't fair either. Of course, Seth criticizes only the Palin attack on Community Organizers. But lets be fair. Wall street workers play a fundamental role in up keeping our society.

mike kenny (2008-09-08 17:42:11)

Entrepreneurs as well seem a like self-experimenters. You have an idea, don't need permission from authorities, can go out and give it a try, and see where it goes.

## **A Hidden Benefit of Self-Experimentation (2008-09-08 22:24)**

Today I met a Unix consultant named Jerry Lugert who has done a lot of self-experimentation. He made a point I hadn't heard before: When you start to measure something carefully, you become a lot more motivated to improve it. In practice, this means when you start to measure something at home every day or often in contrast to having it measured every six months when you see a doctor. One of his examples was blood pressure. He became a lot more

motivated to lower his blood pressure when he measured it himself. Another example involved using chemstrips to measure his urine. He used them to measure both his hydration and the amount of protein in his blood.

The usual idea is that knowledge is power. Sure, if you measure your blood pressure every day you can better control it than if you measure it once per six months. That's obvious. This is different: knowledge is motivation. If you measure your blood pressure every day you'll want to control it more than if you measure it every six months. That's not obvious at all and way more important.

This idea is so close to my idea about connoisseurship (which Jerry of course hadn't heard of) I wonder if the mechanism is the same. I believe connoisseurship arises from side-by-side comparisons of very similar items: close-in-time comparisons of two orange marmalades, for example. Or two vanilla ice creams. Or two cheddar cheeses. Or two merlots. Etc. It's obvious that if you make these close comparisons you'll become better at discrimination – e.g., better at discriminating varieties of vanilla ice cream. What interests me is the hedonic change: making these comparisons causes you to care more about the dimension. You get more pleasure from the good stuff and less pleasure from the bad stuff. Connoisseurs are basically people who will pay more for this or that than the rest of us. (When income or wealth is equated.) Not because they're snobs or showing off – because they derive more pleasure from it. This is part of [1]a theory of human evolution.

1. <http://www.blog.sethroberts.net/category/human-evolution/my-theory-of-human-evolution-directory/>

---

david (2008-09-09 06:37:09)

I think there's also a similarity between hacking (in the computer subculture sense of that word) and self-experimentation...that occurred to me when you mentioned your friend is a Unix geek. Unix admins are also used to monitoring complex systems that log lots of data which then needs to be analyzed to see if anything is about to go wrong.

Jeff Winkler (2008-09-09 13:08:54)

An example of a much tighter feedback loop is the Prius MPG meter: <http://www.washingtonpost.com/wp-dyn/content/article/2008/05/25/AR2008052502764.html?hpid=sec-business>

Maestro (2008-09-09 20:04:16)

"It's obvious that if you make these close comparisons you'll become better at discrimination" Or maybe you'll just start to believe this about yourself. E.g., wine connoisseurs.

## **Science in Action: Why Did I Sleep So Well? (part 12) (2008-09-09 21:36)**

Over the last week I've found that standing on one foot till it becomes difficult just twice during the day is enough to produce much better sleep that night. Maybe the effect is larger with three times but not enough to make much difference.

It now takes 8-10 minutes of one-leg standing (with the other leg stretched back behind me) before it gets difficult. When I started, it took 2-3 minutes.

[1]Directory.

1. <http://www.blog.sethroberts.net/2008/08/20/why-did-i-sleep-so-well-directory/>

---

Mike Yeomans (2008-09-09 22:05:52)

Hey Seth, so do you think this effect is chemically driven? It seems to me there's gotta be some molecules bouncing around between your legs and your sleep neurons that is important. Might this relate to other, pharmaceutical sleep aids? I know that's not a focus of your own experimentation, but while I will still hit google scholar tomorrow, maybe you've already done some research?

Mark (2008-09-10 00:03:18)

I think this hypothesis alone is proof that you are seriously sleep deprived.

Stephen M (Ethesis) (2008-09-10 06:03:19)

Mark, that made me laugh. We need more humor here and there, thanks.

MT (2008-09-10 07:32:17)

On the humourless/pedantic side - are you referring to your legs "singly," as in if you stand on your right leg until tired in the morning, and later in the day again stand on your right leg until tired, you get the effect? When you stand on your leg, is your knee locked, or slightly bent? The former takes less energy - I'm trying to imagine how to tell when I'm 'tired'....

Darkhorse (2008-09-10 07:53:52)

Also, do you always balance on the one leg, or just stand on it while touching something for balance? For me, the former is more difficult, so I suppose more effective? As in yoga, focusing on some point while balancing is the only way: close my eyes, and I fall.

Caleb (2008-09-10 08:16:48)

I just made a connection with something I often see as a massage therapist. When releasing a 'knot' the client often gets very relaxed, goes into a trance, and then starts snoring as they fall asleep. One of the important things the body does during sleep is to try and relax and unwind restrictions in the muscles and fascia. It makes sense that the more residual myofascial tension, the deeper the body will relax overnight as it works to release that tension, which is what may be happening by standing on one foot. This suggests to me that the primary cause may be in the nervous system instead of chemical; in the interaction between the nerves that monitor how much tension is stored in a muscle (proprioceptors?) and the sympathetic nervous system that controls autonomic relaxation. The onset of patients deep relaxation and falling asleep seems like it's too quick to be initiated by chemicals.

seth (2008-09-10 08:58:02)

Mike, yes, I think it's chemical: the stressed muscle puts something into the blood that tells the brain to sleep more. Darkhorse, I usually touch something for balance at the same time. I don't know if it makes a difference whether you touch something or not. Caleb, the time between cause (standing on one leg) and effect (better sleep) can be 16 hours or more. If I stand on one leg at 8 am and sleep better starting at midnight, for example. That's easy for chemicals (hormones) to bridge. Not so easy for change in neural activity to bridge. MT, I always do both legs. One-legged on the left leg (in the morning, say); one-legged on the right leg (in the evening, say). During this the leg is both straight and a little bent - I go back and forth. I do it until it's hard to continue.

Caleb (2008-09-10 10:44:14)

Yeah, the effect only can occur during deep relaxation/sleep. What I'm saying is that during sleep the body runs a program for loosening the muscles. The greater the stimulus (myofascial tension) on the proprioceptors, the greater the activation of the

sympathetic nervous system, and thus the deeper the sleep. It doesn't matter when the muscle tension occurs because the body has to wait until sleep for the brain waves to drop to delta where it can run the program to clear the muscle tension out. I guess that's the key; the program doesn't run until the CNS drop into the theta/delta range.

Jeff (2008-09-10 13:31:51)

Seth - Last year you were studying the link between sunlight exposure and sleep. A large number of hours of sunlight exposure seemed to lead to better sleep. I didn't see this item in your recent list of self-experimentation discoveries. Where did your research on this link ultimately lead?

seth (2008-09-11 08:09:54)

Jeff, I ultimately found it worked, as far as I could tell. But I haven't yet done especially conclusive experiments. It isn't much of a discovery - lots of people already say light is important for the control of circadian rhythms, such as sleep. The value of self-experimentation in this case is the ability to get better evidence and measure the dose-response function.

Nansen (2008-09-11 17:31:33)

Some people might benefit from reading your earlier post on [1]Cramps and Self-Experimentation before trying out your new standing idea. It might also help to stretch the [2]outer calf muscle and the [3]inner calf muscle.

1. <http://www.blog.sethroberts.net/2008/03/28/cramps-and-self-experimentation/>

## **First Meeting of The Quantified Self Meetup Group (2008-09-11 12:41)**

Last night the first meeting of The Quantified Self Meetup Group took place at Kevin Kelly's house in Pacifica. Here are my notes:

### Five-Word Introductions

Kevin Kelly (KK) Magazine junkie science groupie host

Melanie Swan

Lisa Betts-LaCroix home schooling

Joe Betts-LaCroix now future earth people children

Nathan Myers software wind minerals

Lee Corbin software hobbies math chess history

David Kirby machine learning applications

Tim Ferriss athletic performance language acquisition cognition

Hor machine learning life extension

Graham Bullock product health effects

Dan Brown sleep monitoring for better rest

Paul Lindow film binaural language

Jerry Legert ontology unix physics

Peter Mortensen design irrationality

David Duncan writer radio experimental man

Alex Bangs personal health

Alexandra Carmichael open-source health research

Daniel Reda open-source health research

Gary Wolf (GW) reporter utopian  
Vivian Dissler new conceptions of health  
Moor unwilling rebel leader  
Rajiv Mehta tools for living  
Seth Roberts sleep mood self-experimentation flaxseed  
Ka-Ping Yee visualization democracy lambda graphics usability  
Stephanie life-streaming ubiquitous ambient  
Chris social constitution of self online  
Steve complex systems accumulating evidence reflexively  
Neal futurism python family jazz piano  
Emil Gilliam

Kevin Kelly introduction

Like to keep broadening it, before we get to the idea of saying we're not interested in this. Using data & measurement for self-knowledge. Revolving around numbers and measurement. And measuring ourselves. Here we're interested in science upon yourself.

Stuff people are interested in

Actionable measurements

Mood

Self-measurements of health

Gadgets

Service providers

Using geocoding for self-analysis

How have you incorporated measurements into your life?

Where do you do your research? Where do you get your ideas?

When you have a lot of data, how do you extract something you can see from it?

What data people would be willing to share with others? What private?

Measuring the effects of measuring

Resources, other groups

Spheres beyond health - such as time use, learning, how quickly you acquire new items

How to measure learning

Aesthetics of self-documentation

What do to with the data that we gather

Can you learn too much about yourself?

Environmental data, brain scans

How quantified health can be used to collaborate w/ traditional medicine

The greater good of all this - what potential for doing good?

Stuff people are willing to talk about

I've tracked my time for 3 years - how to analyze

Things I've measured

What professional athletes do in this domain

Learning, how quickly you learn

Design principles for measuring oneself

Genes, brains, & body - the Experimental Man

Geocoding

Ka-Ping Yee: Time Tracking

Tracked use of his time. Felt like problem not making good use of time. By collecting data, would help. How much

sleep. Where is my time disappearing? Wrote script that keeps little window open in screen. Types in whatever he's doing. E.g., "at QS meeting". Logged with time. [Question from audience: what have you learned?] not a lot. Hope to learn. Can measure how much sleep I've been getting. Turns out to be getting more sleep than I thought.

Roberts: this data useful if you change something. You can notice unexpected changes.

Ferriss: MeTimer: tracks web browser use

RescueTime: indicates active focus, & local applications. Fascinating. Making me more effective. Doing the right things.

Xobni: identifying email hotspots. Top 10 contacts.

???: made pie graph of where we're spending our time & is it compatible with what we say we're about? Do we spend our time on our kids, business, health?

Clickable menu to help track time.

Yahoo widget stopwatch. Tracking work hours.

Surprises: so much unstructured time, more time spent with kid bigger than expected. Agast to realize one project was taking so much time. I'm really doing a lot of things. Decided to focus my life more. Ultimately the most satisfying thing to me. Now I'm working on that company. Me figuring out where I'm putting my creative energy.

The challenge of assigning tags to things. Too much or too little detail. Just write in your own words.

David Kirby: time tracking mood, sent message at random times to cell phone, got a lot more honesty about activity. Extremely difficult to do in social environment. What are you doing, do you feel productive? What is the sampling period? And what is the associated honesty of the data? I became very afraid of wasting time when each message would come it.

Tracking leads to optimization. As soon as she gets people to track their diet, it massively improves. Helps with eating disorders. Nigerian lawmakers tracked by journalist. Just the fact of publishing it greatly improved voting records.

Tim Ferriss: Athletes

Recorded every resistance training workout since age 15. Now 31. Diet & so forth. Go back to notebooks to see how I looked in this or that photo. Related to performance enhancement. Athletes are v. interested in relative vs absolute measurements.Â Body fat percentage - many different methods. All have problems. Real benefit is in measuring progress - difference up or down. I measure VO2 max. BMI is waste of time. VO2max tends not to change much. Only tested twice. Very similar in spite of different regimens. Cyclists measure to see performance maximum - can I become professional? Lots of blood testing. Every 2 or 3 tests, plus saliva-basted testing. \$500-\$1000 per time. Complete metabolic panel. Cortisol, estradial. Done 1st thing in morning. [Someone else: 120 things I track.] Most athletes use a laundry list of drugs. They cycle off to compete. They look at ratios. E.g., free testosterone to epitestosterone. Steriods are like antibiotics. Many of them. Betablockers: used by Chinese archer, concert pianists, entire orchestras. Subject in expts related to body heat. When does your body shut down? How to best dissipate heat? Wanted the data, would have cost \$100K. Found that my ability to dissipate heat is severey reduced. Surface areas of lungs compared to surface area of skin. Brain shut down at unusually low temperature. Heat stroke susceptible. Recovery time measure of fitness. Sets, Reps, rest periods. Within rest periods you can track several things. Return to basal body temperature, heart rate, muscle tonus (galvanic skin response). Don't believe in general intelligence or general fitness. I measure sex hormones, metabolic panels, IGF-1, indirect measures of growth hormone, free testosterone, T3 T4 TSH insulin (wide diurnal variance). How much insulin is produced, how much remains after meal. Athletes only measure something if they can act on the data they gather.Â I don't want 24/7 measurement - too much data. I take a lot of experimental supplements. I like watch the response of my autonomous nervous system. Ephedrine hydrochloride. Widely studied.Â Yohimbine HCL: proposed as safer alternative to ephedrine. Not a selective agonist. I wanted to measure my blood pressure very closely.

You can order blood tests online & go to local places that will draw your blood & send you the results. Don't need doctor's prescription. Look up symptoms for whatever would require that type of testing.

Any statistical tools that will help you calibrate measurements against each other?

Templates for analyzing small data sets: couldn't find.

Statistics packages, such as R. Google Website Optimizer. Set up experiments for website visitors. Test different pictures on your page. Ramsey 2-color theory. The known Ramsey numbers. If you know there has to be a mutual group of 5 people that all know each other, you have to have at least 43 people in the room.

Suggests data tutorial for the self-experimenter. At future meeting.

If there were a easy to use tool set, if you wanted to run experiments, finding things that were harder to find or predictions. Good tool honeypot for data. Norbert Weiner talks about that.

RescueTime can take aggregate data of 30000 people, reducing data entry from 100 items to 2 items. Hope there will be communities that will follow protocol.

Gary Wolf: Learning/Knowing

Did long story for Wired about managing 5000-item dataset. Keeps track of what you've learned & haven't learned. Makes prediction about what you need to practice something to remember forever. How deeply rooted it is. Street you've lived on when little kid. I'm measuring 2700 index cards. Spanish vocabulary. Modal sentences for grammar learning. Maintaining at 90 % remembering. What 1000 words do you need to know? Super Memo. Pieter Wozniak, Polish computer scientist. When you do your tests every day, you get 85 %-90 % on every test. It shows you a set of cards. If you want to learn the most, maximum efficiency is 40 % efficiency. Unpleasant. A 5-point rating system. Implemented physically in the 1950s. A Liter System. Pimsler implements spaced repetition in background way. Index cards a metaphor - all online. You want to learn constantly for short periods of time over long time spans. What's the lifetime limit on what you can learn? Cabbies in London: larger hippocampus. There are some glitches: learning some things can interfere with knowing other things. Cards in Super Memo that often come up. You can figure out why you're not learning them. A Everyone knows that poor sleep impairs learning. How much will your performance decrease? You need a lot of sleep data & lot of learning data. We're on edge of being able to do that.

David Duncan: One of brain scan tests for my book has to do with memory. As we age, we don't forget things, we have inability to filter out. Series of faces & landscapes. Then forget faces or landscapes. Can you filter out what you're not supposed to remember? Compare young and old. Older people can remember as well as young people but can't filter as well. I came out right in the middle.

I've been doing tai-chi for a number of years. Doing for 5 min/day better than 1 weekend/month.

How do you measure learning? Not just via standardized tests. Cognitive & batteries of tests that people take. Tell you what your brain age is. Column for Portfolio. Cognitive drug research. Did better than I expected, didn't want to take again. On website. On wine, my timing was way off. Check comment stream, people who got younger thought it was a great test. Issues with speed of server.

Rajiv Mehta: Ways This Helps

Helping people take care of their health. Individual perspective. You have some regimen in mind: chicken soup or whatever. What gets in the way of people taking care of their health? We forget a lot, life gets busy. Keeping detailed records impossible for vast majority. Made prototype device. Gives reminders for things that are scheduled. Makes easy to record symptoms moods, etc. anything you think is important health. User tracking exercise. ZumeLife.com.

Tracking her carbs, glucose, medications, symptoms, shortness of breath. Speak into it. Transcription service. Things that don't lend themselves to charts get put into notebooks. USB connected to your PC. Every day or so. NY Time article about 42-year-old person w/ diabetes. Complicated case. Lots of drugs. [can you use any category?] Right now. 5 categories: meds, biometrics, exercise (name, duration), food (carbs, points), health-status questions (how much coughing, how did you feel). Most been using: 7 months. One person had sclera derma. Intense pain, cold hands. She started measuring her pain levels, realized she was having 3 or 4 intense episodes per week. With her printout, she & her doctor said: you have a problem. Over 6 week period she went from 3 or 4 intense to 1 mild episode/week. About \$40-50/month. Can't ask people to buy a special phone. I'm not waiting for United Health Care to say it's interesting. Institutions don't want to deal with smart phones, they want a special device. We've found everyone experiments. If anybody is going to figure out what works for her, it's her. Doctors benefit from charts. The experimenter is her. Our doctors are at best good advisors. We cannot abdicate responsibility.

#### Peter Mortensen: Motivating Running

If you want to help people who are not enthusiasts. Need proud & constant presence. Nike Plus Sports Band. Wear all the time I'm awake. Not just a string around my finger. I can see how much running I've done in last 3 months. Also have my last run. More successful than Nike iPod. You should hide the change you want to make. Also USB key, syncs/ with NikePlus website. Graphs, etc. Even cooler it charges battery when plugged in. I only hear I'm interested I'm wearing a nice watch, never that I'm self-tracking. Chip on shoe, Bluetooth. Impact accelerometer. It's an attractive watch, I'm proud to wear it. Aesthetic thing. An ugly watch would not have the same effect.

Raj: If you're sick it means something bad. If there's going to be a device they have to be proud of it. Before Ms. L got our device she was trying to use her Treo. It got in the way. It's rude to answer your phone if you're having a conversation. People would get upset. This device: It's Ms. L taking care of herself.

Nice scales for tracking weight. Cable going off somewhere. Body composition Bluetooth scale. Tonita.

#### Seth Roberts: Sleep

Early self-experimentation about acne. Found out stuff doctor didn't know: really useful. Maybe would help with sleep problem: Waking up too early in the morning. Tried many things for 10 years, everything failed. All ideas were wrong. Finally got a new idea due to analyzing data, noticing less sleep when lost weight, told class, student told him about another way to eat less, required changing breakfast. Change in breakfast caused early awakening to get worse. This was the first thing that had made a difference. Led to discovery that any breakfast hurts; supported by rat research. Later found that standing a lot improved sleep. Had to stand at least 8 hr to get effect; no effect of 6 hr of standing. Great sleep when stood 10 hr but really hard to do. More recently discovered that standing on one leg to exhaustion helps. Do twice in one day. Same effect, roughly, as many hours of standing but only takes a few minutes. Now working out the dose/response function.

KK: looking for people who want to blog on the blog itself. If you'd rather just share a comment or idea just mail it to us (GW & KK).

GW: lot of dry timber waiting for a spark here. Value of this meeting, can something bigger grow out of it?

Bodymedia.com making their gadget available to retail. Measures body temperature, galvanic skin response. \$399 plus \$20/month. 2. Body computing conference at UCSF Oct 25. internal 3. 23 & me has dropped their price. Version 2. 1/3rd price.

Send stuff to KK & GW to post on blog.

More [1] Gary Wolf's account.

1. <http://www.kk.org/quantifiedself/2008/09/but-why.php>

---

Trey (2008-09-11 13:22:28)  
Thanks for posting this.

Jeff Winkler (2008-09-11 16:20:28)  
I'm jealous - on the wrong coast (Boston)!

mike kenny (2008-09-11 18:26:54)  
cool! maybe your group could set up a wikipedia of self-experimentation, or the like. apparently there are free services on the web.

Alexandra Carmichael (2008-09-12 04:27:52)  
Thanks Seth, for recording such a fabulous evening! Sorry we had to duck out before your talk - your discoveries sound fascinating and I'd love to hear more. A couple of minor name corrections: Melanie Swan Lisa Betts-LaCroix Daniel Reda Looking forward to next time! Alexandra Carmichael Co-Founder, <http://www.CureTogether.com>

Stephen M (Ethesis) (2008-09-12 05:14:59)  
Athletes and body builders are compulsive self-experimenters. Unfortunately, as Sports Illustrated noted a while back, at the elite level, that also includes protocols and close to universal use of illegal drugs. It used to be a few sports (weight class based sports) were immune. I still remember my brother talking about how everyone at Nike was amazed by the wrestler who was on their endorsement list, was going to the Olympics and wasn't using steroids - while it made sense to my brother, steroids would increase his weight. Now, well, they have better steroids. Not to mention, they've discovered regimens that improve recovery time without increasing weight/muscle mass. But it looks like you've got a great group. Next post on them, please do post the blog link in the post (for the lazy ones among us who don't want to work through looking in the side bar or on google ;)).

Justin (2008-09-12 08:29:59)  
Seth, Your standing for better sleep comments are intriguing to me. Could you comment on what exactly it means to stand on one leg to exhaustion? Is this the point at which you can't maintain balance while standing on one foot? Is the whole regiment to do two sets in a day whereby each set is stand-to-exhaustion on each leg? Thanks for the intell- Justin

seth (2008-09-12 09:40:58)  
Justin, what I mean by "standing on one leg to exhaustion" has nothing to do with balance - I usually touch something to make it easy to balance. I mean I stand on one leg until it becomes difficult due to muscles getting tired. I never actually endure pain or even discomfort but I go right up to the point where I would start to if I continued. In the beginning I could only do this for 2-3 minutes; now it's up to about 11 minutes. At the moment the "whole regimen" is what you call one set: standing on each leg to exhaustion once. In other words, left leg once, right leg once.

seth (2008-09-12 18:57:34)  
Thanks for the corrections, Alexandra.

Standing can improve sleep? | the Justin Owings page (2011-07-25 09:40:56)

## **I Love This (2008-09-12 09:35)**

In late July, JemSparkles posted [1]this to the SLD forums:

Ok so I have tried many diets. Here's the list Jenny Craig (10 lbs lost but gained back), Atkins (3 months of phase 1 and nothing lost), Curves (1 year and 10 lbs lost), Herbal Magic, a multitude of diet pills, the Zone, and then simply working out non stop. The weight doesn't want to come off. So here I am with the last attempt that sounds crazy enough to work! I bought the book and this is day two. I am going to start tracking my data and see if I get any results.

Here's to hoping!!!

Ok so I weighed myself for the first time this morning and my starting weight will be 260lbs.

Two weeks later she posted [2]this:

Ok so I haven't seen the fast results that some have seen but I am seeing results which is what matters. And compared to any diet this has been super easy to keep up with.

Today she posted [3]this:

254!!! Yes I am finally down a total of 6 pounds and starting to feel much better. I have been working really hard on this and am not giving up. This diet has been the most effective I have been on to date.

We now return to our regularly-scheduled blogging.

## **If Your Comment Doesn't Appear (2008-09-12 19:10)**

I just found two perfectly good comments in the spam pile, which contains thousands of items. If you post a comment on this blog and it doesn't appear right away it means either

-it's being held for approval by me;

or

-it's been classified as spam, in which case I don't see it. Comments classified as spam usually have one or more links. If your comment has two or more links, it has a good chance of being considered spam.

If you have commented successfully before your comment should appear right away. If it doesn't, please let me know. You can send your comment to me and I will post it or de-spam it.

If you haven't commented before and your comment doesn't appear within a day, please let me know and I will post it or de-spam it.

---

kclane3 (2008-12-08 15:43:11)

Thanks for the post, I have been having the same problems.

### Science in Action: Why Did I Sleep So Well? (part 13) (2008-09-12 20:47)

When I talk about how standing on one leg has helped me sleep better, the inevitable question is how much standing? After I became sure the standing was making a difference, I started to record the durations. I always stood on one leg until it became a little hard to continue. As my legs have become stronger, this has taken more time, as this graph shows:

During the early days on this graph, I didn't include time-of-day information. I usually stood on one leg three or four times per day. More recently, I have included time-of-day info and now stand on one leg only twice most days. In all of the cases shown on the graph, I was pulling my other leg back behind me at the same time, stretching the muscles. (If I don't stretch the other leg, I can stand one-legged much longer.) In the very beginning, I only stood one-legged 2-3 minutes.

I'm sleeping better than any other period in my adult life. My sleep was pretty good before this period but the difference is still huge. Not only am I sleeping better, I suspect I'm also sleeping less (as happened [1]when I improved my sleep by standing a lot).

I suppose one-legged standing counts as "exercise" – that source of so many claimed benefits (longevity, weight loss, less heart disease, etc.). I read today that exercise is supposed to improve your brain. But the differences between what I am doing and what is usually recommended are as large as the difference between the Shangri-La Diet and other diets:

1. Conventional exercise: Requires expanse (for walking) or, usually, special equipment (e.g., gym). Takes one hour or more, when you count changing clothes and showering, not to mention the drive to and from the gym. One-legged standing: Can do almost anywhere. Takes less than 30 minutes, so far.

2. Conventional exercise: Requires discipline if you want a decent workout in a reasonable amount of time. One-legged standing: Almost no pain involved. I can watch TV or read something at the same time.

3. Conventional exercise: Supposed to be aerobic if you want the main benefits. One-legged standing: The opposite of aerobic.

3. Conventional exercise: Some benefits accrue slowly, such as weight loss. Others are hard or impossible to detect, such as longer life. Runners' high goes away, in my experience. One-legged standing: Benefit clear the next morning. Because I am strengthening muscles I use all the time (when I walk or stand) I notice my vastly increased leg strength all the time.

4. Conventional exercise: You want to get stronger. One-legged standing: You don't want to get too strong or else it may take too long to get the effect.

5. Conventional exercise: Often difficult to measure increased strength. Hard to measure improvement in swimming, racquetball, or aerobics classes, for example. One-legged standing: Easy to measure increased strength.

6. Conventional exercise: Helped me fall asleep faster, but didn't solve the problem of too-light sleep. One-legged standing: Utterly solves the problem of too-light sleep.

Could the benefits of conventional exercise have anything to do with the fact that it vaguely resembles one-legged standing?

Maestro (2008-09-13 07:15:35)

Have you tried doing it for shorter periods now that you've built up your leg strength, to see if that matters?

seth (2008-09-13 08:50:20)

Maestro, that's a good idea but I haven't done it yet, no.

Andy McKenzie (2008-09-13 08:51:04)

Could the benefits of one-legged standing have anything to do with the fact that it vaguely resembles conventional exercise? It is hard to posit why either effect would occur evolutionarily since the necessity of sleep in that context is so vague itself. But exercise at least seems to be a biologically relevant activity—running around was probably a common activity during the Paleolithic era, while it is less probable that people were standing on one leg for no apparent reason for thirty minutes at a time. In all likelihood there is a third variable at play that is triggered by both standing on one leg and exercise. Not attempting to be critical, as I find the general effect fascinating, but that last sentence was iffy.

Aaron Blaisdell (2008-09-13 09:00:29)

With a set of two 15 or 20 pound dumbbells, I find that I can get an excellent workout in 30-45 minutes. Three times a week I do the following routine: pushups, situps, two shoulder exercises (shrugs and another involving holding the weight with both hands in front of my hips and bending my elbows to bring the weight straight up almost to my chin - can't remember what these are called), triceps "curls", and bicep curls. After these I do a few stretches to hit most major muscle groups in upper and lower body. After doing this three times a week for two weeks I noticed distinct improvements in sleep, and resting wakefulness (feeling calm and alert during waking hours). I also notice distinct improvements in my muscle tone and how good my upper body looks in a mirror (my wife always laughs at how I will pose in front of a mirror to admire the results). I have to admit that the leg exercises seem even simpler and perhaps I'll give them a try. But the idea that exercise is expensive (e.g., gym membership, special equipment), difficult (requiring high motivation or difficult movements), and time consuming (I do a total of 90-115 minutes per week) are certainly necessarily true. I think a lot of people make things more difficult than need be, and perhaps the media has had a hand in portraying these myths about exercise.

seth (2008-09-13 12:13:22)

Andy, you write: "It is hard to posit why either effect would occur evolutionarily." I think the evolutionary reason that one-legged standing improves sleep is pretty obvious: We sleep more when we need more time to grow muscles. Muscles are better grown when at rest than when being used, thus they are grown during sleep. This is why my one-legged standing causes both muscle growth (as the graph shows) and better sleep. And why I don't think the sleep improvement is likely to occur when the muscle use isn't extreme – isn't extreme enough to cause growth. Aaron, thanks for the exercise details. I'm glad to hear about an exercise routine that's easy to do at home.

MT (2008-09-14 15:13:09)

I don't think the good-sleep effect from standing on one leg is a byproduct of exercise per se, because: 1. Dose effect from standing for nine hours or more suggests biological trigger 2. Many people exercise legs more but don't report similar benefits 3. Seth has exercised more and not reported these benefits (walking and standing over ten hours a day for instance, would be more energy intensive) I suspect that this effect is a fluke of evolution – the good-sleep trigger is hardwired to be set off by something which standing on one leg triggers relatively easily (or it does in Seth – has anyone else had a similar experience yet?). I think it has to do with nerve signals and/or pressure. Alternate hypotheses: 1. the sensory input to the brain from one-legged standing is heavy as the balance requires so much processing, so it simulates normal standing for really long periods, 2. there is a nerve signal produced by one-legged standing that is pressure sensitive. Other people exercise their legs strenuously without profound changes in sleep – myself for instance. I think the theory should account for that difference. I wonder whether anyone has noticed sleep benefits from gymnastics, or other activities where people might train to fatigue while balancing.

seth (2008-09-14 17:52:57)

"Other people exercise their legs strenuously without profound changes in sleep." I think the details matter. I did one particular type of "exercise". I think what I did is a particular efficient way of generating the necessary signal. You can "strenuously exercise" your legs in a hundred different ways and I'd guess that almost all of them less efficiently produce the necessary signal. I think the evolutionary story (better to grow muscles while they are still so they are grown during sleep; thus more growth -> more sleep) is so plausible that the effect could hardly be a "fluke" and is very likely to happen to everyone.

MT (2008-09-15 03:17:46)

Seth, you wrote: "I think the evolutionary reason that one-legged standing improves sleep is pretty obvious," but provided an explanation why exercise would improve sleep - those are different, which my comment was addressing. You quoted my use of "fluke" out of context - I was not referring to sleep and muscle recovery, where the benefits are obvious, I was referring to one-legged standing triggering the better sleep mechanism more efficiently than alternative activities which would confer more evolutionary advantages - like hunting and gathering. So I agree that the details matter - what I'm wondering is whether there is some aspect of the details which can explain why THIS behaviour seems to create the BEST sleep response. A unique connection between balance and savanna behaviour, for instance. I agree that it is likely many or most people would have a similar response, and that it is likely that it is the combination of balance and strain that creates the response.

seth (2008-09-15 06:39:17)

MT, thanks for explaining that. Why does this form of exercise produce the effect more clearly than other forms? My guess is that the answer is: It produces the most muscle growth per unit time (spent exercising). In other forms of exercise, the stress is spread out over several systems (e.g., we become out of breath before our muscles get tired) and is more intermittent, so that there is more recovery. One-legged standing is especially efficient because the muscle-growing system is "isolated" and stressed without any recovery period.

siegfried (2008-09-15 11:26:05)

Hi- balancing on one leg is a common posture in Yoga as well as Tai Chi. Practitioners have long held that it helps with better sleeping. there are other potential connections: Standing on one leg (with a stick to lean on) is a common rest position among aborigines, Massai, etc. Any alternate stimulation on the brain (cf: EMDR) has shown anti-stress potential. S.

MT (2008-09-15 13:13:52)

Sounds reasonable - so the balance element is not relevant with that explanation, it is simply the continuity of the load to exhaustion which matters. That should be testable fairly easily, as bending your legs into a crouch with your upper body as upright as possible (known as a chair sit - had to do them for ice hockey) is quite exhausting (the lower you sit, the harder - you can just crouch a bit for a good effect), and produces a continual load on your legs, like one-legged standing. To shorten the time to exhaustion of one-legged standing you could bend the leg a bit more as well. When doing CROUCHES or SQUATS - you want to KEEP YOUR KNEE BEHIND YOUR TOES, and in a straight line above them - can put too much pressure on the knee otherwise. Such variations could test whether balance is relevant, though I imagine you are interested in training your balance as well. There are inexpensive wobble boards that can add challenge to your balance exercises. There is some evidence that improving balance and coordination can help with aspects of cognition. Perhaps your results from the reaction-time test you devised would improve if you challenge balance and coordination simultaneously for a few weeks.

Chris B. (2008-09-16 09:45:47)

I've tried the one-legged standing twice with disappointing results. It took me about 20 minutes to tire out leg, probably because I cycle for exercise, and I didn't notice any improvement in my sleep. In fact, last night I slept unusually poorly, waking briefly at 12:30, and waking up for good at 5 am. I will give it another try, but it may be one of those things that doesn't work for everyone. Assuming that the effect, for you, has to do with stimulating muscle growth, perhaps I'd be better off exercising some less-developed muscle group. I've been planning to start some upper-body weight training. If/when I do, I'll try to keep records on the connection with sleep patterns.

Tod L. (2008-09-16 19:39:17)

have you tried introducing the variable of crossing your meridian during the stretch? Right hand stretching left leg while standing on right leg while crossing left hand to right shoulder? then visa versa.

cato (2008-09-18 19:48:04)

you might also want to try one legged squats. you stand on a sturdy chair or bench and do a squat on one leg. you don't need the extra weight of a normal squat. maybe the extra intensity will have interesting effects...

MJS (2008-09-20 07:26:53)

I've never posted here before, but I wanted to mention that I've been doing these exercises - standing on one leg - and it's helped my sleep immensely. About a year ago, I went through a pretty traumatic experience that disrupted my sleep patterns. The end result was that I couldn't sleep for longer than 3 or 4 hours at night without waking up. For several months, the lack of sleep was like living in a nightmare, and prescription drugs just made the problem worse. I finally decided to go off medication all together and change my attitude, which worked wonders - I could get back to sleep after I woke up - but I'd still only sleep in 4 hour chunks. About a month ago, I began doing these exercises, and now I'm sleeping 6 to 7 hours at a time. It's amazing; and on the days I don't do them, I don't sleep well at all. It's amazing how easy they are to do - if I find myself standing in line, meeting friends for a happy hour, or even watching tv, I'll do them. Last night I told a friend to do them while he was at a happy hour, and this morning, he said he slept "like a log." So, thanks so much for the suggestion and helping me regain my life/sleep back.

[...] Science in Action: Why Did I Sleep So Well? (part 13) [...]

## **The Case of the Missing Evidence (2008-09-13 10:20)**

The most telling detail in [1]Robin Hanson's lecture about doctors was about a nurse assigned to measure hand-washing rates among surgeons at her hospital. After she measured the hand-washing rates, she - as ordered - correlated them with death rates. It turned out that the surgeon who washed his hands the least had the highest death rate. For reporting this - as she was ordered to - the nurse was fired. Robin learned this story from his wife, who was a friend of the ex-nurse.

I was very impressed by Robin's lecture, which was both accessible and profound, and it was one reason that during my next encounter with a doctor I was more skeptical than most patients. As I [2]blogged earlier:

I have a tiny hernia that I cannot detect but one day my primary-care doctor did. He referred me to Dr. [Eileen] Consorti, a general surgeon [in Berkeley]. She said I should have surgery for it. Why? I asked. Because it could get worse, she said. Eventually I asked: Why do you think it's better to have surgery than not? Surgery is dangerous. (Not to mention expensive and time-consuming.) She said there were clinical trials that showed this. Just use google, you'll find them, she said. I tried to find them. I looked and looked but failed to find any relevant evidence. My mom, who does medical searching for a living, was unable to find any completed clinical trials. One was in progress (which implied the answer to my question wasn't known). I spoke to Dr. Consorti again. I can't find any studies, I said, nor can my mom. Okay, we'll find some and copy them for you, she said, you can come by the office and pick them up. She sounded completely sure the studies existed. I waited. Nothing from Dr. Consorti's office. After a few weeks, I phoned her office and left a message. No reply. I waited a month, phoned again, and left another message. No reply.

Yesterday Dr. Consorti finally got back to me, by posting a comment:

Seth, While I am in the process of finding papers in the literature to satisfy your scientific curiosity on why this hernia should or should not be fixed I am additionally trying to care for around 30 new patients referred to me for their new cancer diagnosis in the last 3 months. This may or may not explain why I have not been motivated to answer your call regarding your ambivalence about fixing your hernia. Yes, it is small and runs the risk of incarceration at some time. I will call you once I clear my desk and do my own literature search. Thanks for the update. Eileen Consorti

Fair enough. She's busy. And I am glad to have her reply and her view of the situation. On the other hand, I am pretty sure the studies she was so sure existed – that justified the surgery – don't exist. To call my curiosity about whether the proposed surgery would do more good than harm "scientific" has a bit of truth: No doubt scientists understand better than others that you can test claims such as "you need this surgery". But it isn't "scientific" in the least to worry that a medical procedure will do more harm than good. Everyone, not just scientists, worries about that. Surgery is scary. Let's set aside the death rate, which is low but non-zero. How many brain cells are killed by general anesthesia? Dr. Consorti doesn't know, nor do I. The number is plausibly more than zero. I suspect a power-law distribution: Most instances of general anesthesia kill a small number, a small fraction kill a large number.

I pointed Robin to Dr. Consorti's response. He replied:

I wonder if she even realizes that she in fact doesn't know why you should get surgery.

What I know and Dr. Consorti, very reasonably, doesn't know, is that my mom was a librarian at the UCSF medical library and has done a vast amount of medical-literature searching. If she can't find any relevant studies, it is very likely they don't exist. And my mom did find a study in progress, which, to repeat myself, shows that my question about cost versus benefit is a good one. Others had the same question and launched a study to answer it. Robin's lecture helped me ask it. Thanks, Robin.

More. Robin's version of the fired-nurse story is [3]here. Thanks to Charles Williams.

Baker (2008-09-13 12:00:55)

it's an agent principal problem, doctors can enrich themselves at the cost of wasting their patients' money, and additionally if they don't conduct every imaginable procedure they run the risk of being sued for malpractice by a trial lawyer, another individual who earns money by wasting their clients' instead of their own, it's no surprise medical care grows more and more expensive when all the incentives are aligned against the patient.

seth (2008-09-13 12:19:46)

Not so much against the patient – I have insurance – as against the insurance company. The proposed surgery would cost me a trivial amount of money.

peter (2008-09-13 12:31:12)

"it's against the patient" in the sense that the patient could take an unnecessary risk of surgery; this risk is present regardless of the financial implications.

sun, too (2008-09-13 13:44:50)

We can all grant that this surgeon stands to make a nice buck in a short amount of time (provided your insurance company pays her) if she does this routine hernia surgery. So she has that incentive. But I don't understand why, in all this Consorti business, no one has acknowledged the elephant in the room, which is the *legal* incentive this surgeon has to advise you to undergo surgery. She knows a little about abdominal anatomy, so it doesn't take a wild flight of fancy to imagine a more substantial hernia developing. And she knows a little bit about malpractice lawsuits (hopefully not from experience), so it's not hard for her to imagine that if she advised you *not* to get surgery, and then you had a major problem with this thing, you might sue her. That seems like it would also be a strong incentive to operate. Where does that play into all this?

Patrik (2008-09-13 14:54:31)

Uhm — odd, that neither you nor Robin mentioned Semmelweis. In broadstrokes, the nurse re-created his seminal findings in Vienna in 1847. For his insight and standing firm against the 'scientific consensus' of the day – he was driven back to Budapest and his reputation thoroughly besmirched. [http://en.wikipedia.org/wiki/Ignaz\\_Semmelweis](http://en.wikipedia.org/wiki/Ignaz_Semmelweis) BTW Crichton and others (myself included) think that are poignant parallels to be drawn from this episode of scientific history and current mainstream scientific consensus's stance on global warming skeptics.

david (2008-09-13 15:55:29)

What peter said and even if you don't pay for it, you still lose time from work for the surgery and recovery.

Tim (2008-09-13 16:08:08)

Hi Seth, here's an interesting article that is related: [http://www.newyorker.com/reporting/2007/12/10/071210fa\\_fact\\_gawande?printable=true](http://www.newyorker.com/reporting/2007/12/10/071210fa_fact_gawande?printable=true)

James (2008-09-14 00:41:57)

Hah, I was going to post the exact link Tim did.

Mark (2008-09-14 02:38:28)

"Robin learned this story from his wife, who was a friend of the ex-nurse." This sentence stuck out for me. There's a subbranch of the field of folklore called "Emergency Room Lore" by anthropologists. These are apocryphal stories passed on by nurses and doctors in hospitals. It's a very rich and developed body of folklore. Jan Harold Brunvand has a section about it in one of his books. The reason why it's so vivid in my memory is that a few days after reading Brunvand's book, a coworker told me about an incident that happened to his mother, an emergency room nurse, which exactly matched one of the examples in the book. I did what I have learned you never should do when you hear an urban legend (and I probably shouldn't be writing this comment!): I challenged the story and related what I had just read in Brunvand's book. The coworker was incensed and asked if I was calling his mother a liar. Before I wised up and shut up, I tried to explain that folklore works because people unconsciously move up the source of information one person when they pass it on. It's always "a friend of a friend." I think if you tried to track this story down, Robin's wife's friend will say, "Yes, it's absolutely true, but it wasn't my friend, but a friend of my friend." And this would repeat as far back as you have patience to follow it.

Dennis Mangan (2008-09-14 06:41:33)

While not impossible that the doctor could get the nurse fired, doctors are not hospital employees or supervisors. The doctor would have to convince an administrator that the woman deserved firing for cause, pretty difficult in this day of employee lawsuits.

seth (2008-09-14 06:59:34)

Mark, Robin's wife did not hear a story about someone else being fired – she heard from the person who was fired.

retired urologist (2008-09-14 07:26:59)

I do not know Robin Hanson personally; I know only the persona he presents on his blog, Overcoming Bias. That persona dislikes doctors on several levels. The justifiable level is that they waste healthcare resources and participate in services that are not helpful, while being paid to do so. It galls him that such a profession enjoys high respect among the general public, because, as he frequently implies, and sometimes states overtly, he believes doctors harm their patients intentionally for money. The persona on his blog is a little out of control on this issue, as the "nurse story" illustrates (he used it in a major blog post). Dr. Hanson is so precise when it comes to the economic evidence he presents (he has persuaded me completely about the lack of value of my profession overall), yet he allows his brilliant (I mean that term literally) mind to fall into the same trap as a lesser human when he passes along such gibberish (as Mark and Dennis Mangan point out correctly). This story is so untrue on so many levels, and obviously so to any informed person, that both Hanson and his wife should be embarrassed for having passed it along. By the way, vigorous scrubbing has been on its way out for several years. Current topical solutions work better without it. Dr. Consorti should have been more honest with you about her lack of evidence regarding hernia surgery. This "doctor arrogance" is what causes Hanson to lose his professional perspective about the doctors. What Dr. Consorti \*did\* know is that tiny hernias are more likely to become acutely incarcerated causing a life-threatening emergency, frequently requiring partial bowel resection. She cannot say what your individual chances of that are, for as you have noted, the studies are not available. I'm not sure how they could be, especially in this litigious age. She recommended the surgery, because she feels the outcome is better when done electively as opposed to the emergency situation I described. Now, she's off the legal hook, and you are free to decide as you see fit.

seth (2008-09-14 10:10:51)

"Dr. Consorti should have been more honest with you about her lack of evidence regarding hernia surgery." This is unfair to Dr. Consorti. She honestly believed the evidence existed, I'm sure. However, the fact that she was wrong about the state of the evidence is a serious problem whether she is honest or not.

retired urologist (2008-09-14 13:31:16)

Here's a link to another of Robin Hanson's econ colleagues on Overcoming Bias, writing on a topic almost exactly like yours. <http://www.overcomingbias.com/2008/08/doctor-there-ar.html>

Kirk (2008-09-14 15:37:39)

I wonder if it would be possible to develop one's own risk-assessment? This would be possible if there were the following numbers (all per year) a) the number of emergency operations for incarcerated or strangulated hernias b) the number of people who die due to incarcerated or strangulated hernias c) the number of people who have hernias each year As for me, fifteen years ago I had an emergency hernia surgery and it scared me seriously. That's why I am having another hernia surgery soon, even though my last one had its problems. But then, my current hernia is large and hurts when I sneeze. It would be a much more difficult decision for a small hernia. I wish you the best of luck.

Stephen M (Ethesis) (2008-09-15 10:40:21)

Dennis Mangan – it really depends on the hospital. In some hospitals, nurses are subjected to constant and incredible levels of hostility and harassment and can be readily fired if they displease any doctor who draws in revenue. In other hospitals, swearing once at a nurse will get your credentials revoked. Abuse from doctors is a huge issue in the nursing profession and the subject of a great deal of literature. You would think that they could file hostile work environment claims, but it doesn't seem to be the case.

retired urologist (2008-09-15 13:00:32)

*You would think that they could file hostile work environment claims, but it doesn't seem to be the case.* Disclaimer: Anecdote Twenty years ago, the technically-best and highest revenue-producing cardiovascular surgeon in town was brought before the executive committee at my community hospital. A nurse had brought a summons indicating a lawsuit against the

hospital and the doctor for habitual "sexual harassment" (sexual only in the sense that his verbal abuse was aimed at someone of another gender). She agreed from the outset to drop the suit if the doctor were removed from the staff. He was, and from the other local hospital staffs as well. As you say, perhaps it varies. I think there's more to the "nurse story" than she revealed to Mrs. Hanson.

Vesna (2008-09-15 16:45:31)

1. Seth, your post refers to a link to the full fired-nurse story, but I can't find it. Could you have left it out? 2. About urban legends: yes, Robin reports that his wife spoke to the actual nurse. However, Mark is saying that this is exactly the classic form of the transmission of urban legends. Whenever you hear that someone heard something from only a single link away (a friend of a friend, or FOAF), it's a red flag. When that single link is followed, too often it leads to another link, and another, and another. Did Robin talk to the nurse himself? Does he know (even if he's keeping it private for whatever reason) the name of the hospital, what year this happened, and so forth? 3. Patrik, I think the reason Semmelweis wasn't mentioned was simply that the connection was so plain and obvious, not because no one knows about Semmelweis and the birth of the germ theory of disease. Besides, the moral I got from the reported correlation between death and less hand washing was this: less careful doctors provide worse care overall. I didn't think the story was supposed to point to hygiene, specifically.

seth (2008-09-15 17:38:13)

Vesna, thanks for pointing out the missing link. I fixed it. As for your Point #2, I'm sure "my wife knows the person involved" is not the classic form of urban legends.

Vesna (2008-09-16 18:52:16)

Thanks for fixing the link! I notice that Robin doesn't say "my wife knows the person involved," but "a colleague of my wife." Which could mean someone that she doesn't actually know. I posted a comment on Robin's blog asking if he could clarify. Now I'm curious!

retired urologist (2008-09-17 06:52:29)

@Seth: my question about cost versus benefit is a good one. It seems that when all the evidence was weighed, it was the anecdotal, experiential bias of the surgery profession versus a study in progress. With nothing else to go on, what did you decide to do, and what does your decision tell us about dealing with matters for which there is not perfect rational evidence?

seth (2008-09-17 07:49:56)

I decided to wait for the surgeon to tell me about the studies she told me she would find. If she never find those studies (or at least never calls me back), I'll wait for the study in progress to finish. A few days ago my mom found a study of a different (larger) type of asymptomatic hernia which found that doing nothing ("watchful waiting") was a good option. If no more evidence surfaces, I'll do nothing.

Medicine as a guild « It's Not Hard... but it could be (2008-09-18 09:32:57)

[...] Recently, I was involved in the comments on a couple of blog posts that are quite revealing about the "art" aspect of a medical practice: here, by Dr. David J. Balan, a prominent economist, and here, by Dr. Seth Roberts, a prominent psychologist. In both cases, intelligent members of guilds not associated with the guild of medicine were given medical advice. In each case, they asked for rational evidence to support the recommendation. In each case, they were told that such evidence existed and that it confirmed the sagacity of the advice. In both cases, the doctors were wrong (about the existence of evidence). They knew that a keystone facilitated an arch, but they weren't sure why. That's not science. This sort of encounter is becoming more common among doctors and their patients of equal or superior intelligence. The medical guild has published all their information on the Internet. Good for the patients, bad for the guild. The next thing you know, the patients will want limited guild-privileges to treat themselves. Actually, they've already voiced this opinion. And since the margin of elective US medical care is zero maybe they have a point. [...]

J Thomas (2008-09-20 06:10:17)

*This sort of encounter is becoming more common among doctors and their patients of equal or superior intelligence. The medical guild has published all their information on the Internet.* Well, no. They haven't published all their information. They've published the information they bother to publish. Some years ago my girlfriend had a deep venous thrombosis. It started out extremely serious and then it stabilized. She'd need to use a pressure bandage for the rest of her life and maybe have some circulation problems etc. I did a lit search and the results were pretty horrendous. I was upset. She got a referral to a prestigious surgeon who reassured us. "Why do you think there's any problem here?" "I did a lit search and the published literature was pretty scary." "Why do you think you could understand about that?" "I'm a biomathematician. I can follow the literature but I don't actually have any experience." "Well I do. I see DVTs \*all the time\*. There's nothing to worry about." My girlfriend started a regular exercise program. Pretty soon she was feeling mostly recovered. The trouble was, they didn't publish about it unless it was something serious. There's a great big publication bias. If you go to a plumber he won't have engineering studies that show the way he does his work is the best way. There are probably engineering studies that show everything he does is sub-optimal, that there are newer methods that work better. But he has a big body of experience, most of it handed down to him, that says what he does works. Doctors are a lot more like plumbers than they are like doctors or engineers. When you consult a doctor you are depending on his experience and his training. Hardly any of that is published or publishable. It is deeply unscientific. But on average the doctor has some idea how well it works, although you can't depend on him to truthfully tell you how well it is likely to work.

retired urologist (2008-09-21 10:17:43)

Google "deep vein thrombosis" and 560,000 hits appear. Each of those have multiple references to other (or cross) references. Contrary to what you say, almost every thought that goes through doctors' minds has been published somewhere. Much of it is locked behind subscription-only journals, but even these are available in medical and hospital libraries.

J Thomas (2008-09-21 14:40:09)

RU, I googled 'deep venous thrombosis' and got 1.5 million hits. I googled "post phlebitic syndrome" and got only 28,000 hits. Years ago when I did that search it was only 9000. The ones I looked at emphasized the worst cases. Maybe my search was biased but I tried to include lots of randomness to pick up things I didn't know I was looking for. I believe the bias was in the literature and not much in my search of the literature. The prestigious surgeon we talked to had not published anything about DVT that I could find. But he had sufficient experience to say that her PPS would probably subside with no problems. And he turned out to be right. DVT was not a research interest for him, it was just a complication he saw a lot.

retired urologist (2008-09-21 16:18:54)

J Thomas: "only 28,000 hits" on post-phlebitic syndrome". Yep, sounds like a conspiracy to hide info to me. The "medical guild", for a surgical specialist, requires a minimum of 13 years training, at little or no pay. Chances are your knowledge and experience (and that of your biomathematician girlfriend) may still fall short of that of a surgical specialist, even after hours of "lit search". I would also suggest that the two of you not do any complicated plumbing based on a lit search. Nor any complicated engineering. God knows what they may be hiding from you.

J Thomas (2008-09-21 17:24:26)

*Chances are your knowledge and experience (and that of your biomathematician girlfriend) may still fall short of that of a surgical specialist, even after hours of lit search.* RU, that was my point. My understanding of statistics etc from my biomath training might give me a much better ability to understand randomized trials than most physicians – a large portion of them wind up not at all showing what the authors think they do. But that's no substitute for experience. I couldn't look at her leg and tell whether her PPS was really serious. All I had to go on were a few pictures and a lot of wordy descriptions. The surgeon could tell at a glance that it wasn't that bad because he had experience. He had DVT and PPS as complications for his surgery patients **all the time**. I wouldn't be surprised if I knew much more of the literature about those topics than he did. But that was no substitute for experience, and I knew it. *The medical guild has published all their information on the Internet. Good for the patients, bad for the guild.* It isn't that simple.

retired urologist (2008-09-22 05:11:25)

J thomas, we are in complete agreement about the unscientific conclusions drawn from randomized studies by the medical profession. It is the central idea behind the original post to which you are responding , as well as a facet of several of my other posts at "It's Not Hard". I'm having a little trouble understanding the source of your displeasure. it sounds as if you were upset that your lit search led you to believe your girlfriend's situation was dire, while you are relieved that the doctor visit changed your impression. It sounds as if you would have eliminated the anxiety by seeing the surgeon to begin with, rather than researching it on your own. That's the way the way the system has always worked, pre-Internet.

J Thomas (2008-09-22 06:37:54)

RU, I suspect we're pretty much in agreement all round. I did my own lit search because that was what I knew how to do. I had access to a medical library, so I could get any paper that wasn't too obscure. I knew how to do lit searches quickly and efficiently and I was quick to pick up the material. But that was no substitute for direct experience. I had no idea that my girlfriend's symptoms would subside in 6 months. It wasn't true for the people in the studies. But those people were chosen because their symptoms were serious enough to deserve careful attention. I could tell after the fact that she was a plausible candidate for DVT. She was on estrogen, and was somewhat overweight. She got a bad bruise on a mountaineering trip and then drove long hours with no rest break. But I'd never seen it before. The surgeon, however, gave DVT to over a hundred people a year. He'd seen a lot of cases and he knew what to expect. I'm not complaining about that. I'm just pointing out that doctors are more like plumbers than they're like scientists. When you call a plumber you don't expect the latest scientific results in plumbing. You expect he has the judgement and experience to do the job, and if he doesn't you hope he'll refer you to somebody who does. Same with MDs. We currently have no way to transfer that judgement and experience over the internet or through medical libraries, either one. I can imagine a way to begin to do that. We'd put all patient records into a database, with some attempt to allow anonymity. So then say you have flu symptoms. You put your symptoms into the database and it tells you about what happened to other people with symptoms like that. 97 % of them had flue and got over it. A few had histoplasmosis, a few went on to have coronary disease, a few had this or that other problem. So then you can reduce the search to people who're around your age, and/or gender, and/or your geographical area, and/or whatever else is available, and maybe you get a different result - fuzzier but different. Every few days the database could email you to remind you to tell it how you're doing, and if you don't respond it checks the death records etc to see if you can't respond.... It wouldn't substitute for the personal touch but it would provide a whole lot of data that anybody could mine. We have something like that now for insurers, but the data is mostly private and it's organized around diagnoses more than symptoms and test results.

retired urologist (2008-09-22 07:05:56)

J Thomas: As you can see from all these replies, "retired" means I have a lot of spare time. You sound a lot different now than in your original post. Plumbers=doctors is not only right, it is exactly what I said ("guild"). Your attitude seems a bit naive in that you wish for doctors to promote a system that would somehow transfer the benefit of their experience to the patients without a paid encounter. That's where the guild concept comes in. Doctoring is a *job*, which requires an incredibly long apprenticeship. The doctors plan for you to pay for the service, as much as the traffic will allow, for as long as you are willing to do so. Just like plumbers.

J Thomas (2008-09-22 09:24:19)

RU, the cost for medical care plus insurance overhead etc is something like 16 % of GDP and rising. It's already more than we can afford. I can't expect MDs to do anything that might reduce their guild; privileges, but it's plausible that insurance companies and government might want things to reduce expense. That could include public health measures and improved self-screening approaches. My father is a retired dentist. Back when fluoridation was new he campaigned heavily for it. Some other dentists said that he shouldn't because he'd be cutting back on business. "Cutting his own throat." But he argued that there would be plenty of dental business even after fluoridation, and he was right. Currently, more things to make people ill won't increase medical payments much. The money just isn't there.

retired urologist (2008-09-22 11:01:18)  
agreed

Bias on the hoof: Hanson and RU continued « It's Not Hard... but it could be (2008-10-05 16:44:45)

[...] A reader (not me) saw coverage of the post on the blog of Seth Roberts, and asked Hanson "whether you actually ever met and talked to the fired nurse, how strong her evidence was that she was fired for the reason in the story, etc.? Did your wife actually know her, or know someone who knows her (who might turn out to be someone who knows someone who knows someone), that sort of thing?" Hanson replied: "The nurse was a close co-worker of my wife, who I've met." (Nothing more.) [...]

Mark (2009-01-19 20:49:46)

"Mark, Robin's wife did not hear a story about someone else being fired" she heard from the person who was fired." Yes, FOAF would seem to imply that these stories are two levels away, but many people will move the level up one. It's just an unconscious need to make the story more immediate and vivid and place oneself at the center of the action. In the case of my workmate, his mother knew the person supposedly involved. Now I didn't contact her and ask her about it, but the story (involving a person who fainted from cut-off circulation due to some sort of device in his pants to make it appear that he had larger genitals than he really did) was a classic piece of emergency room lore described by Brunvand. Mind you, I'm not saying that anyone at all is lying. It's just that people's minds play tricks. This is the entire basis of the study of folklore, and not only anthropologists, but many journalists have run across this phenomenon. And I'm not saying that such a study, if actually done, would not turn up the results claimed. It's just that the particular details and person involved are unconsciously fabricated. Why don't you try to actually contact the nurse involved. If it's really just one person away, it shouldn't take much time. And if she was fired, she has nothing to lose and shouldn't mind speaking to you. Make sure to get back to us with your results. ;-) The way I see this is that at some point some medical professional hypothesized to another that if such a study were done such a result would ensue. Then a couple of people down the line, the story became that the study actually was done. Then at some point in passing this fable along, someone made the crack that, yeah, and the nurse would probably get fired for her trouble. And a few levels away from that it wasn't a crack but a fact. And the urban legend went on from there, each time with a little more certainty added to it. (By the way, an excess of details that anticipate objections are one characteristic of urban legends.) The comments to this post show how much interest there is in the medical community about the issues raised by the story. Urban legends flourish the most when they "confirm" the opinions of large numbers of people in the community in which they are passed on.

retired urologist (2009-01-20 09:05:15)

Mark, Thanks for re-opening this discussion. If it did not involve a world-class thinker who states in his widely-read [1]blog that his significant interest is "the rationality of paternalism and other kinds of disagreement", and who makes a living teaching medical economics, perhaps it would have no importance, and bear no further attention. However, a clear thinker like Seth Roberts has said that the incident was "the most telling detail in Robin's lecture about doctors", the result being that he "was very impressed by Robin's lecture". Consequently, I continue to feel that it should be fleshed out for what it is. I tried [2]here and [3]here to get Hanson to reconsider the matter or give evidence, but he would not (see his comments, and judge for yourself).

seth (2009-02-01 23:19:08)

"give evidence"? I guess you mean give more evidence. Doctors' widespread disinterest in evidence is the subject of my latest post. I would be interested in your thoughts on the subject.

retired urologist (2009-02-03 19:42:49)

See comment on your post Feb 1, 2009.

Stephen M (Ethesis) (2009-02-06 21:13:33)

"There's a subbranch of the field of folklore" ... reminds me of the stories of mice in soft drink bottles ... and reading about how that was all folklore, except, of course, I had seen the citations and the actual case law involving those cases on appeal. Or,

in a case closer to home, the actual maggots in the package of crackers I went out and bought my wife when she was pregnant. On a different example, which I will skip the details, you can imagine my surprise at having worked on a case and then having read about it being urban folklore. Since the law suit involved someone suing over the facts being disclosed ... I rather believed the facts were acknowledged, not folklore. Pleadings at the county courthouse. Just a comment.

Seth's blog » Blog Archive » Jane Jacobs and the Trouble with Medicine (2009-08-08 04:48:14)

[...] Are doctors takers or traders? The flaw in trying to improve doctor performance by changing incentives is the balance of power: Doctors have almost all of it. Patients trust doctors. (When I asked my surgeon the basis for her judgment that I needed surgery — treating her as an equal, in other words — she must have been stunned. She certainly didn't respond appropriately.) That's why it's so easy for doctors to do too much or too little. It's the same problem with quota systems for policemen: The policemen have too much power. The current balance of power makes doctors takers rather than traders. [...]

Noumenon (2009-08-22 01:37:02)

FWIW when I had my visible hernia that didn't hurt my doctor here in rural Wisconsin said he'd never seen one he couldn't push back in so I might as well wait for it to incarcerate before I got the surgery. But I eventually got the surgery anyway, and now a nerve in my hip burns when I get tired.

### **New Way to Lose Weight: Don't Eat Till Your Blood Sugar is Low Enough (2008-09-15 05:48)**

[1]Tim Lundeen's sister Miriam wrote this:

Tim and I have been having conversations about health, diet and blood sugars for several years and I figured I was insulin-resistant with mild blood sugar dysregulation, but never was more than interested. About two months ago after a move cross-country with the accompanying stresses, I became more acutely concerned about my metabolic damage and was in a place where I could pay attention and do something about it. At Tim's recommendation, I read Dr. Bernstein's Diabetes Solution and Jenny Ruhl's Blood Sugar 101 and started monitoring my blood sugar with a glucometer. Initially, my morning readings were usually 91-94. Not too bad but not the 83-85 that is "normal" [i.e., optimal]. I started waiting till I was hungry or when I would normally eat and then take my blood sugar again. If it was 85 or below I would eat a normal meal with an awareness of the carb content and eat smaller portions of these foods. Then I would monitor my postprandial (post-meal) blood sugars about every hour and see when and how high my spike was. If it was too high (over 140 for sure, and in the 130's probably) I would adjust the amount of carbs downward. If my blood sugar was over 86 and I wasn't famished I would distract myself with some engaging activity and check my sugar again when I noticed I was hungry. If I became really famished but my sugar was still not under 86, I would have a no-to-low carb snack like almonds, walnuts, left-over meat or a salad. Then I'd wait till I was hungry again. After a few weeks of doing this my morning sugar was consistently 81-85. If I ate off-plan and had an occasional 94, that was fine by me. I was happy about my blood sugars, but the pleasant surprise came when I had a physical exam at my doctor's. I had lost 20 pounds without even noticing! [She is 5 feet 5 inches tall. After losing 20 pounds her weight was 155.] I was amazed since I had tried to diet a number of times over the last 10 years and my weight just kept creeping up. This has been the most fun and healthy weight loss program I could imagine. I am hoping my carbohydrate metabolism will eventually recover and I will again be able to eat more carbs without weight gain and metabolic damage.

I am doing something similar for a few days, too soon to tell the results. About six months ago, to help write a chapter in my self-experimentation book about diabetes, I got a glucometer and started testing myself regularly. I was displeased to find that my morning readings were about 91, like Muriel's, and further displeased to find that eating less

carbs didn't help.

Blood sugar testing isn't cheap, but it's easy and painless. The glucometer I use is Abbott's Freestyle Lite (which is free). It's painless if you get the blood from your arm. The test strips cost about 60 cents each.

1. <http://www.blog.sethroberts.net/2007/02/16/omega-3-and-arithmetic/>

---

John (2008-09-15 06:20:48)

I think this boils down to: Tim went on a low carb diet and lost weight. You don't need to measure your blood sugar to do this, but it does sound like it might be fun.

MT (2008-09-15 06:23:50)

Very interesting results. Seem similar to the benefits of intermittent fasting (eating same daily calories, but in a smaller window of time each day), which seems to lower blood sugar on average.

Andrea (2008-09-15 11:59:54)

Seth, I am really glad that you are looking at diabetes and blood glucose regulation. Let me remind you that current glucose monitors are at best, highly inaccurate and unreliable. I believe that this is because the strips are not individually sealed. When I was first diagnosed, I used the Glucometer Elite (Bayer) recommended by Richard Bernstein. The strips were individually sealed. I now use the Bayer Contour (25 strips in a bottle). I have several monitors all over the house and ordered a free one (I liked the color:-) Here are the readings I got from the same finger on three different monitors during the same ten second period: 104, 122, and 98. Here are the results of the control solution provided by the company to test the meter. Same solution in four different Contour meters: 125, 117, 110, 134. There are NO government standards for accuracy and reliability. If you test at 100, you could be anywhere between 80 and 120. The Freestyle is just as bad if not worse. Dr. Bernstein now recommends the Accucheck Aviva. I doubt that it is any better. The best way to test is using the same meter and at the same site on your body. At least you can see trends because you are certainly not seeing actual glucose levels.

MT (2008-09-15 12:59:45)

Andrea - did you try testing the same meter at the same site? Wondering if there is variability within the same product as well.

seth (2008-09-15 16:12:39)

Andrea, early on I did 10 duplicate tests: measured my blood sugar twice (keeping everything the same). The average difference between the two readings was about 6, if I remember correctly. That gave me a good indication of the accuracy (variability). Now that you bring it up, I have two Freestyle Lite meters and should probably use both of them to see if they are calibrated accurately. Whether they are calibrated identically is a test of that. What your assessment leaves out is that Miriam (a) actually got her morning blood sugar to go down and (b) she lost weight. So whatever the measurement problems, they didn't get in the way of her glucometer being really useful.

Mike (2008-09-15 20:52:20)

I think the real lesson is, measure! I can easily picture someone who tried the same diet but because things were bouncing around and they didn't "notice" their weight drop, to cheat every once in a while, and then to forget it altogether. Putting numbers to the test really makes a diet mean more than just self-regulation practice. Weight takes a while to move, but blood sugar measurements make the effects of the diet almost instantaneous. Even if "wait until your blood sugar is low" wouldn't help some people, if they were rigorous about what's actually going on in their body, maybe that in and of itself would help diet commitment and further the original goal, weight loss.

Mary Lee (2008-09-16 07:54:31)

When my blood sugar gets well within normal range, if I don't eat it begins to rise anyway. What's going on. This happens over night also, so my "fasting" reading is usually hi, sometimes as high as 130's. Doctors don't give me an explanation, but they want to medicate me on the basis of the hi morning readings. Anybody got any clues?

Magicmike (2008-09-16 10:49:34)

In my view this is a bad idea, or more precisely, a case of the cure being worse than the disease. It seems that effects that come with low blood sugar - delayed onset grumpiness, slower reaction times, etc., (to say nothing of less visible effects) are so overwhelming that it is simply nuts to do this. mmmmm.....nuts.....mmmmm

Tom (2008-09-16 22:18:25)

Mary Lee said: *According to Bernstein, it's called the "dawn phenomenon." He experiences it himself: Ordinarily, the liver is constantly removing some insulin from the bloodstream, but during the first few hours after waking, it clears insulin at an accelerated rate. [...] Because of it, my blood glucose can rise even though I haven't eaten.*

catabolic foods (2008-11-26 10:53:38)

Does this have anything to do with catabolic foods at all? I read on that and it seems to be very interesting when you can eat more and lose weight. Any opinions on that?

### **Red State Blue State Rich State Poor State (2008-09-16 05:41)**

To explain why Andrew Gelman et al.'s [1]Red State Blue State Rich State Poor State is such an important book I have to tell two stories.

A few years ago a student did a senior thesis with me that consisted of measuring PMS symptoms day by day in several women. After she collected her data she went to the Psychology Department's statistics consultant (a psychology grad student) to get help with the analysis. The most important thing to do with your data is graph it, I told the student. The statistics consultant didn't know how to do this! There was little demand for it. Almost all the data analyses done in the Psychology Department were standard ANOVAs and t tests. If you look at statistics textbooks aimed at psychologists, you'll see why: They say little or nothing about the importance of graphing your data. Gelman et al.'s book is full of informative graphs and will encourage any reader to plot their data. There are few examples of this sort of thing. That's the obvious contribution. Because graphing data is so important and neglected, that's a big contribution right there.

The other contribution is even more important, but more subtle. Recently I was chatting with a statistics professor whose applied area is finance. What do you think of behavioral economics? she asked. I said I didn't like it. "It's too obvious." (More precisely, it's too confirmatory.) For example, the conclusion that people are loss-averse - fine, I'm sure they are, but it's too clear to be a great discovery. She mentioned prospect theory. Tversky and Kahneman's work has had a big effect on economists - which certainly indicates it wasn't obvious. Yes, it has been very influential, I said. I'm not saying their conclusions were completely obvious - just too obvious. Tversky and Kahneman were/are very smart men who had certain ideas about how the world worked. They did experiments that showed they were right. There's value in such stuff, of course, but I prefer research that shows what I or the researcher never thought of.

Red State Blue State is an example. Andrew and his colleagues didn't begin the research behind the book intending to show what turned out to be the main point (that the red state/blue state difference is due to an interaction - the effect of wealth on tendency to vote Republican varies from state to state). I suspect they got the idea simply by

making good graphs, which is an important way to get new ideas. (Neglect of graphics and neglect of idea generation go together.) Red State Blue State could be used in any class on scientific method to illustrate the incredibly important point that you can get new ideas from your data. There aren't many possible examples.

If I were teaching scientific method, I'd assign a few chapters of Red State Blue State and then have a class discussion about how to explain the results. Not just the state-by-wealth interaction but also the fact (revealed by a scatterplot) that the United States is far more religious than other rich countries – an outlier. Then I'd say: The graphs in the book made you think new thoughts. Your own graphs can do that.

1. <http://press.princeton.edu/titles/8729.html>

---

LemmusLemmus (2008-09-16 14:08:02)

Humans evolved to see pictures. (The real world is like pictures, only three-dimensional), they didn't evolve to work with numbers, let alone advanced statistics. That's why I think graphs are generally preferable. The problem, of course, is that you can't produce a seven-dimensional scatterplot, whereas you can regress a variable on seven other variables.

seth (2008-09-16 14:30:14)

LemmusLemmus, check out the splom command in R. It produces scatterplot matrices: every variable plotted against every other variable.

LemmusLemmus (2008-09-16 16:15:49)

I've never used R. (Maybe I should?) Frankly, I can't imagine what plotting every variable against other variable would look like in a scatterplot. Anyway, thanks for the tip!

## **Treadmill Desks (2008-09-17 11:55)**

As far as I know, I was the first person to [1]have a treadmill desk. I wanted to be able to stand more easily. I had found that if I stand a lot I sleep better. I reasoned it might be easier to stand a long time if you are walking than if you are standing still.

Treadmill desks are now becoming mildly popular, the New York Times [2]reports. I had nothing to do with this. They were popularized by James Levine, a Mayo Clinic endocrinologist, who believes that calorie burning is a good way to lose weight. I used my treadmill desk for a few years. There were two big problems: 1. The noise bothered my neighbors. The Times article says these desks tend to be placed in common areas, where that would be less of a problem. 2. It was tiring. After one or two years I mainly stood on it and rarely walked on it. Finally I replaced it with a standing-height desk.

The article describes non-weight-loss benefits: Walking makes it easier to concentrate.

“I thought it was ridiculous until I tried it,” said Ms. Krivosha, 49, a partner in the law firm of Maslon Edelman Borman & Brand.

Ms. Krivosha said it is tempting to become distracted during conference calls, but when she is exercising, she listens more intently.

“Walking just takes care of the A.D.D. part,” she said.

Allen Neuringer, a professor of mine at Reed College, found that [3]movement helped him learn. I think an urge to be active builds up during inactivity just as thirst builds up when we don’t drink. Being able to be active while you work gets rid of that distraction – and no doubt is healthier in other ways than sitting all day. I would like to be able to use a computer while I am free to move around the room (or larger spaces) and move my arms, not just walk forward with my hands on the keyboard. I’d like to be able to write this blog post while strolling through my neighborhood, for example.

Thanks to Marian Lizzi.

SusanJ (2008-09-17 12:45:12)

You could “write” while strolling by using a voice recorder and either have someone else transcribe it or use software such as Express Scribe to ease the process of transcribing it yourself.

seth (2008-09-17 13:22:43)

When I write I do a lot of revising. And I like to see what I’ve written.

Patrik (2008-09-17 14:49:14)

*They were popularized by James Levine, a Mayo Clinic endocrinologist, who believes that calorie burning is a good way to lose weight.* Levine should read Taubes. While exercise is certainly fun/healthy and may reduce insulin resistance, it does induce greater hunger – demolishing the cal in, cal out fallacy.

Aaron Blaisdell (2008-09-17 16:23:38)

This post reminded me of the David Premack’s research that led to the idea of behavioral bliss points.

Beth (2008-09-18 11:00:40)

Patrik should refer to Levine’s extensive research on NEAT.

Kevin Maloney (2008-09-18 18:54:29)

If this interests you, then you should also check out the [deltabalance.com](http://deltabalance.com) website, where you can see a very interesting take on the stand-up desk that keeps you moving without the mechanics of a treadmill. When you think about many of the ills of our present culture, chairs are probably one of our downfalls.

Adam (2008-09-21 08:41:45)

Treadmill desk may be fun at the start but as time progress you just simply want to do the treadmill first then do your work after or vice versa. Honestly can you enjoy doing treadmills while your fingers are tapping away those keyboard keys, not to mention how about using your mouse? In some form of exercise maybe you can combine work with exercise but honestly using a treadmill and doing your work, not to mention having those low cost treadmills that don't give proper stability while walking or jogging.

Jeff Winkler (2008-10-03 13:45:54)

The books Brain Rules (Medina,2008) and Spark(Ratey,2008) get into this. Basically, more exercise=more oxygen to the brain, increased neuroplasticity, memory consolidation and BDNF. A quick summary from Dr. John Medina - <http://www.youtube.com/watch?v=ck-tQt0S0Os>

Sarah Toms (2008-10-23 13:04:46)

Seth, A treadmill desk? That reminds me of an exercise vest! <http://www.hyperwear.com> My girlfriend has been telling me about this for months now. I might check out your treadmill desk. I'm young and want to stay really nice and fit! hehe Sarah

Exercise Ball (2009-09-24 13:53:49)

I've heard of using exercise balls at your desk as a chair, but this treadmill desk idea has never crossed my mind! I think I'd try it though, but not with my pumps! I can't believe its said to help you concentrate! CRAZY!

jeff (2010-09-17 02:55:49)

While working you can have a fitness workout using a treadmill desk, this is quite unusual but is worth a try. There are people who can think better if they are moving, and there are also people who simply can not concentrate while walking. A treadmill desk is designed to have a minimal workout even while working. It is very beneficial for people who are very busy and can not find time to go out for an exercise. It is true that sitting all day long will give you better fat deposits, you will be happy with it.

## **Do Genes Matter for Health? (2008-09-18 10:42)**

How much disease do genes cause? Sure, they cause some rare diseases that affect very few people but what about major health problems, such as depression, that affect everyone? The notion that genes make a big difference to human health – that some people are healthy and others sick because of genetic differences – was much of the rationale for funding the human genome sequencing project, which cost billions. The founders of the company [1]23andme (23 = 23 human chromosomes) often say genes matter, most recently in [2]The New Yorker:

“It’s very useful if you know that you’re at increased risk for deep-vein thrombosis and you’re on a plane,” she continued. “You might want to stay vigilant about moving around.” Instead of finding out the hard way that their children are allergic to peanuts, parents may someday be able to test their DNA. Even small inherited traits, Avey added, can serve as health clues: “There is some correlation between your ability to metabolize caffeine and your risk for a heart attack.”

There is something breathtaking in the fact that someone who believes you can learn about allergies by studying DNA is taken seriously in The New Yorker.

Some rare non-hype on this issue has recently come [3]from Dr. David Goldstein:

But David B. Goldstein of Duke University, a leading young population geneticist known partly for his research into the genetic roots of Jewish ancestry, says the effort to nail down the genetics of most common diseases is not working. “There is absolutely no question,” he said, “that for the whole hope of personalized medicine [where people with different genes are treated differently], the news has been just about as bleak as it could be.”

The researchers have been unable to find genes that make much difference.

If they had found such genes, I would have been stunned. My self-experimentation has led me to believe that our environments are far from ideal – in non-obvious ways. I believe that people don’t get sick because of their genes, or gene-by-environment interactions, they get sick because of their environments, which lack something essential or include something bad. Animal experiments have given us a decent understanding of nutrition; maybe we know half or more than half of the basic requirements. When it comes to subjects that don’t lend themselves to animal experiments, little is known – about what causes depression, for example. My self-experimentation took over where animal experiments left off; it provided a way to do experiments that generate ideas. (Which is [4]crucial for knowledge advancement, as opposed to career advancement.) I have been able to find one big self-experimental effect after another (most recently, about [5]omega-3s and [6]sleep) related to common health problems only because (a) so little was known and (b) I accidentally picked up an effective tool (self-experimentation) that no one else had used this way (to find new experimental effects).

More from the other side of the debate: 1. [7]Elderly genetics. 2. [8]Google co-founder has Parkinson’s gene. It is hard to find support for my side of the debate in print. It isn’t easy to notice when you don’t get sick (because of advances in the study of nutrition, for example) so it isn’t easy to notice how study of the environment has paid off in concrete ways. I’m in an unusual position: I can easily notice how my life has improved via self-experimentation.

Even more [9]Dean Ornish agrees with me. Thanks to [10]Carl Willat.

stephen (2008-09-18 13:27:29)

seth, have you ever tried to control for placebo effects in your self-experiments? based on something you wrote recently i suspect you think its too difficult. Here’s one method i’ve thought of: you could make identical (gelatin?) capsules containing a dose of flaxseed oil, a placebo (e.g. water) and olive oil. Store them on identical plates (one plate for each) so that they are

indistinguishable from each other by touch alone and then blindfold yourself as you reach down to take one randomly - use a webcam to record which one you're taking. The only problem here is that you know there's a chance of placebo, and as I remember from my health psychology lectures this has been shown to have an effect (infact, some studies indicate that even the doctor knowing they are prescribing a placebo has an effect on the patient - I can probably dig up the reference for this if you want..)

seth (2008-09-18 17:10:10)

"Have you ever tried to control for placebo effects"? Yes, by varying the dose. I like to think that's the sophisticated way to control for expectancy effects. Of course, most experiments use a placebo pill, which generally varies in 20 ways from the treatment. All these differences allow subjects to figure out what group they are in. If subjects figure out what group they are in, the "placebo control" stops controlling for expectancy effects because expectancies are no longer equal.

Gyan (2008-09-18 22:22:55)

I have read that dietary intake of LA downregulates the conversion of ALA to DHA+EPA. If this be true, then consuming large amounts of ALA might be necessary since the body is going to convert only a small amount to DHA+EPA and burn the rest of ALA?.

seth (2008-09-19 09:20:50)

Gyan, yeah, maybe. Because I was able to measure the effects of ALA (in flaxseed oil) I could adjust the amount of ALA I consumed until I got the biggest possible effect.

MT (2008-09-21 09:22:58)

Your questioning of the merit of genetic testing is less commonly heard and useful to highlight, but there are good ways to use information about genetic predispositions as well. If genetic sequencing of test subjects in experiments were mandatory in the FDA approval process it might be possible to link the efficacy of drugs to certain genotypes, and in the process use drugs that are clinically effective and safe for those populations, and/or not use drugs that seem statistically unsafe for others. There are effective drugs which aren't used because they are lethal or unhealthy to small numbers of people, so they are banned, but the source of that lethality may be related to a genetic factor. Similarly some approved drugs could be used more appropriately. A friend of mine had her life destroyed taking Accutane for a mild case of acne, as prescribed by a dermatologist, became severely ill, and has not recovered after five years. This drug is allowed despite such known problems because they are rare. It would be nice to protect people for whom such events are more likely. This is all based on probability, and doesn't account for all other relevant factors, but is still worthwhile.

Jeff Winkler (2008-10-03 13:29:20)

Exercise overriding the FTO "obesity gene": Physical Activity and the Association of Common FTO Gene Variants With Body Mass Index and Obesity Evadnie Rampersaud, MSPH, PhD; Braxton D. Mitchell, PhD; Toni I. Pollin, PhD; Mao Fu, PhD; Haiqing Shen, PhD; Jeffery R. O'Connell, PhD; Julie L. Ducharme, MD; Scott Hines, MD; Paul Sack, MD; Rosalie Naglieri, MD; Alan R. Shuldiner, MD; Soren Snitker, MD, PhD Arch Intern Med. 2008;168(16):1791-1797. Background Common FTO (fat mass and obesity associated) gene variants have recently been associated with body mass index (BMI) and obesity in several large studies. The role of lifestyle factors (such as physical activity) in those with an underlying FTO genetic predisposition is unknown. Methods To determine if FTO variants are associated with BMI in Old Order Amish (OOA) individuals, and to further determine whether the detrimental associations of FTO gene variants can be lessened by increased physical activity, a total of 704 healthy OOA adults were selected from the Heredity and Phenotype Intervention (HAPI) Heart Study, an investigation of gene x environment interactions in cardiovascular disease, for whom objective quantified physical activity measurements were available and for whom 92 single-nucleotide polymorphisms (SNPs) in FTO were genotyped. Results Twenty-six FTO SNPs were associated with BMI (P = .04 to Conclusions Our results strongly suggest that the increased risk of obesity owing to genetic susceptibility by FTO variants can be blunted through physical activity. These findings emphasize the important role of physical activity in public health efforts to combat obesity, particularly in genetically susceptible individuals.

[1]Obesity Genes and Physical Activity, An Interview with Dr. Evadnie Rampersaud - Fitness Rocks Podcast 114

[2]drmonte

In this episode of Fitness Rocks I have a conversation with Dr. Evadnie Rampersaud about the effect of physical activity on the expression of a gene that is associated with obesity. Dr. Rampersaud is an Assistant Professor at the Miami Institute for Human

Genomics at the University of Miami Miller School of Medicine.

### **Park(ing) Day in Berkeley (2008-09-19 21:55)**

[1]Park(ing) Day was today. The first Park(ing) Day was in 2005. You celebrate it by turning a parking place into a park – as in the verb to park. In North Berkeley, around lunchtime, I came across a dozen Landscape Architecture grad students sitting around a long table full of food that filled up two parking places on Shattuck Avenue (a busy street). My big question was where the tables came from – that seemed like the hard part. From Wurster Hall (where the Landscape Architecture Department is). They invited me to join them and the whole thing was so interesting I couldn't resist.

The food was very good. One person brought tomatoes, broccoli, cucumbers, and purslane picked that morning from his garden. Someone else brought homemade salsa.

You might think you could lay claim to a parking spot by putting money in the meter. Not in Berkeley. A parking cop came by and wondered what was going on. Someone had reported "a picnic," the cop said. The cop left. Twenty minutes later he returned. Apparently there had been discussion about how to handle this. The ruling was you need a permit. Parking places are for cars, said the cop. Feeding the meters wasn't enough. The cop gave the students 15 minutes to leave. At that point I left.

### **Science in Action: Why Did I Sleep So Well? (part 14) (2008-09-20 10:57)**

Two more people have gotten results similar to mine. From a [1]comment on an earlier post:

I've been doing these exercises - standing on one leg - and it's helped my sleep immensely. About a year ago, I went through a pretty traumatic experience that disrupted my sleep patterns. The end result was that I couldn't sleep for longer than 3 or 4 hours at night without waking up. For several months, the lack of sleep was like living in a nightmare, and prescription drugs just made the problem worse. I finally decided to go off medication all together and change my attitude, which worked wonders - I could get back to sleep after I woke up - but I'd still only sleep in 4 hour chunks.

About a month ago, I began doing these exercises, and now I'm sleeping 6 to 7 hours at a time. It's amazing; and on the days I don't do them, I don't sleep well at all.

It's amazing how easy they are to do - if I find myself standing in line, meeting friends for a happy hour, or even watching tv, I'll do them.

Last night I told a friend to do them while he was at a happy hour, and this morning, he said he slept like a log."

As [2]Pale Fire says:

If on some nameless island Captain Schmidt  
Sees a new animal and captures it,  
And if, a little later, Captain Smith  
Brings back a skin, that island is no myth.

I have started to measure my sleep with a [3]SleepTracker so I will have another way to measure the effects, in addition to (a) how rested I feel when I awake and (b) how long I sleep.

More The SleepTracker - my second, the first didn't work - worked correctly for the first three nights but failed on the fourth.

1. <http://www.blog.sethroberts.net/2008/09/12/science-in-action-why-did-i-sleep-so-well-part-13/#comment-221418>
2. <http://www.tundrasquid.com/canto3.htm>
3. <http://www.sleeptracker.com/>

---

david (2008-09-20 12:04:07)

The SleepTracker is a neat idea, but I think wearing a watch to bed would make it harder for me to get to sleep. I'm also surprised you have to set the "to bed" time to when you anticipate falling asleep. Should it be able to tell? The way I would want it to work is to push a button when I go to bed, then have it tell me how long it takes me to fall asleep as part of the data it collects.

baker (2008-09-20 19:08:24)

I want to add my name to the list of those getting the same amazing results, since I started the standing on each leg exercise I have been able to go back to sleep if I wake up in the night and feel like I have gotten good rest for the first time in 8 years. Also to check I have intermittently (every couple of weeks or so) not done the exercises for a day or two and without an exception the nights I fail to do the exercise I sleep in only 2 or 3 hour spells, I am so happy to have been made aware of this and thanks for your efforts

mike kenny (2008-09-20 19:55:53)

hm, i've been having trouble getting this to work for me. maybe more time on each foot.

seth (2008-09-20 22:24:32)

David, the SleepTracker has a feature where you press a button when you go to bed and it automatically sets your "to-bed" time to be 30 minutes later. I don't know why it doesn't record for the 1st 30 minutes but it makes sense that it should not start recording until you're very likely to be asleep. Baker, glad to hear it!

Darkhorse (2008-09-21 09:13:41)

I was finding it impossible to do this correctly during the day due to the often frantic nature of my work. I did manage it watching the early morning news and again in the evening. Time to fatigue has increased considerably from less than 1 minute to about 8 minutes, with the effort to actually balance requiring more effort and causing earlier collapse. I worried that just these two instances would not be effective. Then, I gradually realized that the Zopiclone tablet I would reluctantly leave on the table in case I woke again after two hours sleep, and stay awake as I frequently do, was still there after 6 hours. I haven't had 6 hours straight sleep for as long as I can remember. Thank you for this and for all that you have done.

MT (2008-09-21 09:26:07)

Very interested in this – tried it one day on my subway ride, but didn't really get tired over

MT (2008-09-21 09:50:28)

course of days journeys (total about 30 minutes). Will try variations and report back.

Adam (2008-09-21 10:13:49)

Seth (and others), I'm wondering if you have tried closing your eyes while standing. Eyesight is important for balance, so in theory this would make it harder to balance, causing more rapid fatigue, and thus create an exercise more easily fit into hectic schedules. 1-3 minutes instead of 5-15 minutes. I had posted before about having trouble getting fatigued after even 20 minutes. I tried your advice, Seth, and made sure my other foot was positioned far enough up on my leg. This did make a significant difference, simply by shifting the center of gravity and making it harder to balance. But, it still can take upwards of 10-20 minutes to feel any kind of fatigue, and I just haven't had enough time to get any kind of consistent data. Balancing with the eyes closed increases the challenge, but I wonder if the effect remains undiminished.

seth (2008-09-21 18:58:19)

Adam, I don't bother to balance. I hold on to something. I believe what matters is stressing muscles so much that they send out a growth signal. This has little to do with balance, which mostly exercises the brain. While standing on one leg, to get tired more quickly, you might try keeping your standing leg bent all the time.

seth (2008-09-21 22:30:54)

Darkhorse, you're welcome. Thanks for reporting your experience. Yeah, the surprise here is how little it takes to make a big difference.

Seth's blog » Blog Archive » Why Did I Sleep So Well? directory (2008-09-25 06:21:13)

[...] Science in Action: Why Did I Sleep So Well? (part 14) [...]

### **Chocolate is Good For You (part 3) (2008-09-21 10:02)**

A [1]new study in the Journal of Nutrition:

Dark chocolate contains high concentrations of flavonoids and may have antiinflammatory properties. We evaluated the association of dark chocolate intake with serum C-reactive protein (CRP). The Moli-sani Project is an ongoing cohort study of men and women aged 35 y randomly recruited from the general population. By July 2007, 10,994 subjects had been enrolled. Of 4849 subjects apparently free of any chronic disease, 1317 subjects who declared having eaten any chocolate during the past year (mean age  $53 \pm 12$  y; 51 % men) and 824 subjects who ate chocolate regularly in the form of dark chocolate only ( $50 \pm 10$  y; 55 % men) were selected. . . . The European Prospective Investigation into Cancer and Nutrition FFQ was used to evaluate nutritional intake. After adjustment for age, sex, social status, physical

activity, systolic blood pressure, BMI, waist:hip ratio, food groups, and total energy intake, dark chocolate consumption was inversely associated with CRP ( $P = 0.038$ ). When adjusted for nutrient intake, analyses showed similar results ( $P = 0.016$ ). Serum CRP concentrations [geometric mean (95 % CI)] univariate concentrations were 1.32 (1.26–1.39 mg/L) in nonconsumers and 1.10 (1.03–1.17 mg/L) in consumers ( $P < 0.0001$ ). A J-shaped relationship between dark chocolate consumption and serum CRP was observed; consumers of up to 1 serving (20 g) of dark chocolate every 3 d had serum CRP concentrations that were significantly lower than nonconsumers or higher consumers. Our findings suggest that regular consumption of small doses of dark chocolate may reduce inflammation.

These findings, like previous epidemiology of chocolate, suggest that ordinary dark chocolate produces these benefits. You don't have to process the chocolate in special ways or preserve it in special ways. Mars, the company behind Cocoavia, a line of chocolate products that emphasizes health benefits, [2]makes the opposite claim:

Like green tea and red wine, cocoa beans contain naturally occurring compounds called flavanols that scientists believe help promote blood flow, circulation and a healthy heart. But traditional cocoa processing often [emphasis added] destroys these natural compounds. After years of research, the makers of Dove® Brand Chocolates have perfected a breakthrough Cocoapro® process, the only patented process that retains high levels of the flavanols found naturally in cocoa.

Well, how often is "often"? And what fraction of the flavanols are destroyed by ordinary processing? More on the benefits of chocolate: [3]Part 1. [4]Part 2.

---

### Food Fact of the Day (2008-09-21 19:06)

Norway leads the world in frozen pizza consumption. "Why?" I asked the Norwegian who told me this. "We're lazy," she said.

---

### Food versus Nutrients (2008-09-21 20:08)

A few years ago, I learned that persons who apply to the [1]Chez Panisse Foundation for funding are warned by staffers not to use the word nutrition in their applications – Alice Waters hates that word. A more nuanced version of this attitude was expressed in Michael Pollan's *In Defense of Food*. Supposedly we should eat food (= choose our food using food names and categories) rather than nutrients (= choose our food according to nutrient content). [2]Here is Marian Nestle, the prolific and influential NYU professor, on the subject:

Q: How do nutritionists feel about Michael Pollan's idea in "In Defense of Food" that we should be eating food, not nutrients?

A: I can't speak for all nutritionists, but my guess is that we are all jealous of how well he writes. But look around you. Except for people in hospitals who are fed intravenously, I don't know anyone who eats nutrients. Everybody I know eats food.

When I give lectures in Australia or India, as I did last year, I see people eating food - all kinds of food. In Australia, I went to a Chinese restaurant one night and sampled kung pao kangaroo. In India, I ate dosas every chance I got. I never gave the nutrient content of those foods a single thought.

"Everybody I know" indeed. Our understanding of vitamins comes from nutrition research that, contra Waters, Pollan and Nestle, focused on nutrients rather than food. This research has been enormously beneficial, mainly among the poor and institutionalized. From [3] a review article about Vitamin A:

By 1992, most large-scale mortality prevention trials and at least 3 measles treatment trials [in poor countries] were completed. A meeting convened at the Rockefeller retreat in Bellagio reached consensus that vitamin A deficiency increased overall mortality, particularly from measles; improving vitamin A status would reduce overall mortality; and treating children already ill with measles with high-dose vitamin A was an effective means of reducing their risk of complications and death. This "Bellagio Brief," published widely, helped draw attention to the importance of vitamin A. . . . National programs of varying effectiveness have been launched in over 70 countries and vitamin A "coverage" is now one of the core health indicators published annually in the State of the World's Children. By UNICEF's estimate, over one-half a billion vitamin A capsules are distributed every year, preventing 350,000 childhood deaths annually. . . . The World Bank lists vitamin A supplementation as one of the most cost-effective of all medical interventions.

This isn't esoteric knowledge.

3. <http://jn.nutrition.org/cgi/content/full/138/10/1835>

---

Igor Carron (2008-09-22 08:43:33)

Seth, Talking about nutrients, this reminded me another fact you might want to use to reinforce or refute some aspects of the Shangri-la diet (I realize that refuting is not your goal but it might bring a narrow aspect of it to light). In Space, one of the main issue for astronauts is the issue of taste. Most astronauts that have spent some time in orbit will tell you that the food is extremely dull. One of the goal of some of the chefs doing work for the space agencies (US, French or Russian) is to find a way of implementing spicy foods so that they raise the tasting experience. They have to do that and weigh this against the stringent requirements that the food must have a very low bacteriological activity. At the same time, zero-g also brings a whole slew of annoying side effects such as space sickness (which is not the same as sea sickness and will bring down the best people for days -if they ever recover, some people have been known to be sick during their whole trip- ) and bone loss. Many astronauts will also probably tell you that their sleep pattern is not good and most of them do put that on the excitement of the trip. Eventually, it looks like I am noticing that most of what you are mentioning eventually has a strong relation to gravity (standing up for ten hours or one lieg) and taste (the shangri-la diet). Both of which disappear in Orbit. Igor.

peter (2008-09-22 11:39:40)

so gravity affects taste/smell? What strikes me is that space travel (the accompanying lack of gravity) could result in accelerated decrepitude, i.e., loss of taste, loss of bone are both hallmarks of getting older. it makes one wonder what effect space travel would have on mental activities, i.e., could enough space travel result in cognitive impairment.

ram (2008-10-14 05:59:01)

hey seth do you know a lab where i can go with a sample of food and get it checked for nutrient content

seth (2008-10-14 06:21:27)

no I don't.

### Life Imitates Art School (2008-09-22 21:45)

I had lunch with Lisa Goldberg, an adjunct professor in the Statistics Department at Berkeley. Her application area is finance. She said that people in finance have at least as much contempt for academics as academics do for people in finance. Thorstein Veblen, of course, wrote about the latter – people looking down on useful work – but not the former. Perhaps his views were skewed by being an academic himself. I [1]blogged earlier about how students in each major at a San Francisco art school look down on the students in some other major.

Lisa also said she sleeps well. I was surprised – hardly anyone says that. It turns out she exercises heavily. She swims or runs seven days a week and when she swims, she swims 2000 meters. As a former swimmer, I know that's a lot. When I exercised, there was no clear effect on my sleep, apart from falling asleep faster. I still woke up too early in the morning. Maybe I wasn't exercising enough. Anyway, it's one little data point supporting [2]my conclusions from standing on one leg.

mike kenny (2008-09-23 17:55:25)

I wonder if we form a tribe or band with our fellow members of a profession. Professors have offices around each other. They get used to seeing each other regularly and this triggers tribal feelings. "He's one of my group." Ditto students of the same major, and finance people. We see others bands or tribes as competitors for resources whom we signal our dislike of to our friends.

Stephen M (Ethesis) (2008-09-23 20:26:44)

**at least as much contempt for academics as academics do for people in finance** With more numbers ... Somewhat like the way Economists used to look down on "softer" sciences in the 70s when NASA had to go to Econ PhDs to handle linear programming. But yes, there is a solid feel in Finance, especially given the objective measures (e.g. how much money they are paid) that there is a merit system that puts them at the top, easily measured.

MT (2008-09-24 16:07:26)

I've observed that on average every profession and every subculture idealise their profession or subculture and look down on every other profession or subculture. People at each station or position within different sectors tend to do so as well. It is subtle but seems real, and probably relates to some aspect of our need to affiliate – so we do it on the available lines since we don't have true tribes anymore. (note: the following are gross simplifications, and averages with lots of exceptions,

but I think the trends are accurate): Punk rockers look down on hip-hop, and vice-versa, grunge rockers didn't like glam rockers, and vice versa, bankers think academics are not practical enough, academics think bankers are shallow, non-profit workers think corporate people are greedy, corporate people think non-profit people couldn't cut it in the corporate world, etc. It creates a tendency to stay within our tribe that perhaps helps us extract the economic benefits of specialization. If people don't derive status from one thing (say money) they will derive their status from something else. Within the environmental movement (which I've been deeply involved in) it was eco-purity, and money was a bit disdained. People with materialistic predilections (I know lots of millionaires) tend to scorn those with less as ascetics. People who truly cut across areas are few and far between. I've had many dozens of jobs (36 in one ten year period) so a chance to observe this pretty closely.

Stephen M (Ethesis) (2008-09-25 16:11:59)

Let me quote from another blog, just a bit ;)

In 1990, the French sociologist Pierre Bourdieu wrote his wildly entertaining (though obnoxiously esoteric) book, *Homo Academicus* – a sociological study of academics as a social class. He calls his study a “comic scenario, that of Don Juan deceived or the miser robbed.” Lest I sound unkind in my reference, I point to the reality that scholars have made similar characterizations of their subjects for centuries – making labels, classing peoples. Yet I suggest that the analyzers of man might also profitably become the analyzed.

## How Could Epidemiologists Write Better Papers? (2008-09-23 09:29)

Inspired by Andrew Gelman's posting of [1] his discussion of a paper, here is a review I recently wrote of a omega-3 epidemiology paper. The shortcomings – or opportunities for improvement – I point out are so common that I hope this will be of interest to others besides the authors and the editor.

This is an important paper that should be published when the analysis is improved. The data set analyzed was gathered at great cost. The question of the relationship between omega-3 and \*\*\* [\*\*\* = a health measure] is very important and everyone would like to know what this data set has to say about it.

That said, the data analysis has many problems [= opportunities for improvement]. Most of them, perhaps all of them, are very common in epidemiology papers, I realize. Here are the big problems:

1. No figures. The authors should illustrate their main points with figures. They should use lowess – not straight lines – to summarize scatterplots. The relationships are unlikely to be linear.
2. Failure to transform their measures. Every one of their continuous variables should be transformed to be roughly normal or at least symmetrical before further analysis is done. It's very likely that this will get rid of the outliers that led them to treat a continuous variable (omega-3 consumption) as a categorical one.
3. What was the distribution of \*\*\* scores? How did this distribution vary across subgroups? If the distribution isn't normal – and it probably is far from normal – then a transformation might greatly improve the sensitivity of the analysis. Since the distribution is not shown the reader has no idea how much sensitivity was lost by failure to transform.
4. Pointless analyses. It is never explained why they separately analyse EPA and DHA; that is, no data are given to suggest that these two forms of omega-3 have different effects. Rather than analyse separately EPA and DHA they should simply analyze the sum. Nor is there any reason to think that fish consumption per se – apart from its omega-3 content – does anything. (At least I don't know of any reason and this paper doesn't give any reason.) Doing weak tests (fish, EPA alone, DHA alone) dilutes the power of the strongest test (EPA + DHA).

5. Failure to test the claim of interaction. I don't mind separate analyses of large subgroups but if you say an

effect is present in women but not men – which naïve readers will take to mean that men and women respond differently – you should at least do an interaction test and tell readers the result. (You should also provide a graph showing the difference.) Likewise if you are going to claim Caucasians and African-Americans are different, you should do an interaction test. Perhaps the results are different for men and women because \*\*\* – and if so there may not be an interaction. Finding the relationship in women but not men has several possible explanations, only one of which is a difference in the function relating omega-3 intake to \*\*\*. For example, men might have more noise in their omega-3 measurement, or a smaller range of omega-3 intake, or a smaller range of \*\*\*, and so on. The abstract states "the associations were more pronounced in Caucasian women." The same point: When the authors state that something is "more" than something else, they should provide statistical evidence for that – i.e., that it is reliably more.

6. It is unclear if the p values are one-tailed or two-tailed. They should be one-tailed.

7. It is unclear why the data are broken down by race. Why do the authors think that race is likely to affect the results? Nowhere is this explained. Why not stratify the results by age or education or a dozen other variables?

8. The authors have collected a rich data set – measuring many variables, not just sex and race – but they inexplicably do a very simple analysis. If I were analyzing these data I would ask 2 questions: 1. Is there a relation between EPA+DHA and \*\*\*? This is the question of most interest, of course, and should be answered in a simple way. This is a confirmatory analysis. 2. Getting some measure of that relationship, such as a slope, I would ask how that slope or whatever is affected by the many other variables they measured, such as age and so on. This is an exploratory analysis. There are no indications in this paper that the authors understand the value of exploratory analyses (which is to generate new ideas). Yet this is a good data set for such analyses. To fail to do such analyses and report the results, positive or negative, is to throw away a lot of the value in this data set.

9. The single biggest flaw (or to be more positive, opportunity for improvement) is losing most of the info in the \*\*\* measurements by dichotomizing them . . . .

It would also be nice if epidemiologists would stop including those "limitations" comments at the end of most papers. They rarely say something that isn't obvious.

[...] How Could Epidemiologists Write Better Papers? [...]

## **Fake Tans, Sun Blocks, and Self-Experimentation (2008-09-25 05:07)**

I guess [1]this is from a press release:

John M. Pawelek, Ph.D., a senior research scientist in the department of dermatology at the Yale School of Medicine, recently was awarded a U.S. patent entitled Cosmetic Melanins for producing and composing synthetic melanins that may be used in cosmetic products.

Through its Office of Cooperative Research, Yale licensed the Melasyn technology originating in a medical school laboratory to Vion Pharmaceuticals, Inc. of New Haven. This month, Vion announced an exclusive world-wide licensing agreement with San-Mar Laboratories of Elmsford, NY., to manufacture and market products containing Melasyn.

Throughout nature, melanin is used in such diverse areas as protection from ultraviolet radiation, camouflage and species recognition. It is insoluble and difficult to work with, making it impractical for inclusion in creams and lotions. "But we have invented simple methods for creating melanin substitutes that dissolve readily in water and, when incorporated into cosmetic creams, can be spread evenly on the skin to instantly produce a tan," Dr. Pawelek states.

In inventing this unique product, Dr. Pawelek employed one of scientists' historical approaches to research: self-experimentation. "For nearly four years, I have been applying the material daily to my own face, and it produces such a natural-looking tan that it even surprises my dermatologist colleagues at Yale," he quips. "Scarcely a day goes by when someone on an elevator or in a hallway doesn't ask me where I was on vacation." . . .

The Yale laboratory work behind the patenting and licensing offers interesting insight into the process of research and development of potential new products. "It started several years ago with our basic research on skin enzymes that produce melanin," Dr. Pawelek explains. "Melanin usually is insoluble in water and forms a gummy solid in test tubes. One day, however, we noticed that the melanin in one enzyme assay remained dissolved in water," he recalls.

Dr. Pawelek credits his colleague, Jean Bolognia, M.D., who conducts her research in his laboratory, with the idea for cosmetic use of melanin. If the melanin were really soluble, she surmised, it should be useful as a cosmetic. "From that point on," he says, "we began a search for the right combination of ingredients and methods to produce cosmetic melanin.

"We were motivated by the thought that melanin naturally protects our skin from cancer induced by ultraviolet light. Perhaps, we reasoned, synthetic melanin would do the same," he says. "If we could design a melanin that produced a natural-appearing tan, we believed that people might be attracted to the product through its cosmetic qualities and simultaneously apply a sun-protectant, affording them added sun protection and potentially reducing the incidence of sun-induced skin cancer," hopes Dr. Pawelek, a cancer biologist who studies melanoma.

I often do something similar: Use an activity I want to do to motivate something I don't want to do. Drink wine to take vitamin pills, for example.

1. <http://food.blogvis.com/2008/09/24/yale-scientist-invents-cosmetic-melanin-liquid-melanin-moves-closer-to-marketplace/>

---

Nathan Myers (2008-09-25 19:05:12)

I'm just marveling that they didn't say anything about their product enabling people who think they need tans (as some people do, for work) to avoid sun- or tanning bed exposure.

Gyan (2008-09-25 21:35:57)

Dont the skin products need to go through safety trials?.

Nathan Myers (2008-09-26 23:51:33)

Amazingly enough, they don't. They're "cosmetics", and the rules date from when everybody insisted nothing could penetrate skin.

### Science in Action: Why Did I Sleep So Well? (part 15) (2008-09-25 06:14)

Yesterday I went to San Francisco early in the morning.Â Because of my discovery about standing and sleep, I had slept very well. In Berkeley, it looked like morning: empty streets, angle of light. I felt jet-lagged: I should have been tired but I wasn't. On BART, the same mismatch: Everyone looked tired but I was wide awake.

It is taking longer and longer to get enough one-legged standing to generateÂ great sleep. Here's a graph of how long I've been standing:

Each point is a different bout of one-legged standing. Most of the points are from bouts where the standing leg was straight or bent (usually straight) but a few of them ("bent leg") are from bouts where the standing leg was bent the whole time. Most days have two bouts: 1. On the left leg until I get tired. 2. On the right leg until i get tired. I'm pretty sure there's no effect until it becomes difficult - until the muscles are so stressed that they send out a grow signal. The whole thing is pleasant because I watch TV or a movie at the same time but, as the graph shows, it has

become seriously time-consuming.

So I have tested keeping the standing leg always bent. I get tired much sooner (2 minutes versus 20 minutes) but the effect is not quite as strong. Probably because fewer muscles are involved – you use more muscles when you stand on one leg in any possible way than if you stand on one leg in only one way.

I assume there's a steady-state solution. The more muscle you have the more you lose each day. (Just as the theory behind the Shangri-La Diet assumes that the higher your set point, the faster it falls.) Eventually I should have enough muscle and will lose enough in one day so the exercise needed to merely replenish it will be enough to produce great sleep.

---

Methuselah - Pay Now Live Later (2008-09-25 07:29:08)

Seth - have you considered adding weight? Apologies if you have discussed this earlier in the series. Seems like a good way to keep it simple but also keep the time down. A good quality weighted vest might do the job...

Stephen M (Ethesis) (2008-09-25 16:16:19)

You can also do one legged squats once your legs get strong enough. A full range squat is going to work a lot of the muscles in your leg (vs. a partial). You can start with just bodyweight squats, all the way down and up, you don't need to use weight, but eventually switch to single leg squats when you are strong enough. That should get the time down to a much shorter time. Even a hundred body weight squats can be done in a couple-three minutes, and that is a large number.

seth (2008-09-25 18:49:10)

Methuselah & Stephen, thanks for the suggestions. Funny, I just threw away an old backpack...which I have now retrieved from the trash.

Nathan Myers (2008-09-25 19:07:27)

Once you're in good enough shape, two-minute one-armed handstands ought to suffice for quite a while. When you get to the point of tongue-stands, I think you'll need to think of something else.

MT (2008-09-27 08:03:21)

Maybe adding a balance challenge to the one-bent-leg technique would make it more effective. Balance engages a whole host of additional supportive muscles, which may partially account for the original value of this technique (and why it hasn't been reported from more common leg exercises). So perhaps try doing the bent-leg on some kind of wobble-board, being careful to ensure you're safe. Fitness centers sell variations of these devices, they are inexpensive, and balance is a great fitness element to work on anyway. Or a higher level challenge might be to try juggling. The cerebellum controls this type of coordination, and there is evidence of abnormalities in the cerebellum in dyslexia. Some researchers have claimed that very demanding physical challenges (hand-eye coordination at the same time as balancing, for instance) can ameliorate some symptoms of dyslexia, presumably by enhancing the function of this part of the brain. Then add the one-armed handstand.

char (2009-08-11 08:11:04)

that's an interesting graph you have there.

## The Morning Banana Diet (2008-09-26 07:57)

I just googled "[1]morning banana diet" and got only a thousand hits. Surely that will change. It is the most popular diet in Japan right now, so popular, Mark Schrimsher of [2]CalorieLab told me, that "You can't buy bananas in Japan now. It's crazy. We found some little green ones and some really expensive ones, but the rest are sold out." [3]Fytte, a woman's health magazine, has covered it three months in a row. Three books have been written about it.

Like the Shangri-La Diet, it derives from (a) self-experimentation by (b) someone who was not a weight-control expert and (c) was spread by the Internet.

A [4]cartoon.

August (2008-09-26 08:57:54)

An entire country doesn't notice that they are ravenously hungry two hours after breakfast? Or am I just that different?

Willy (2008-09-26 13:13:50)

Maybe a banana is enough because they have dinner late.

Joshua McMichael (2008-09-27 06:42:40)

This appears to be a intermittent fasting type diet. Basically, with the exception of the banana, the Morning Banana Dieter is restricting food intake to between midday and early evening (lunch and an early 6pm dinner). Eating according to this schedule provides a nice 18 hour fast, and will result in weight loss, provided the dieter doesn't gorge during lunch and dinner. I bet one could substitute any 100 calorie low glycemic index food for the banana and observe identical results. I tried this (minus the banana) once over a fairly sedentary 2 month period, and lost about 10 lbs. I'm working right now on getting back into the habit.

Mark (2008-09-27 09:57:13)

You can eat more than one banana. The inventor of the diet eats four bananas at 6 a.m. and a rice ball "o-nigiri" (maybe 200 calories) during his commute at 8 a.m. I think you're allowed to eat something else in the morning if you wait 15 minutes after the bananas and are still hungry (which is defined as under the 80 percent full level, not just not being stuffed). Dinner is supposed to be by 8 p.m., and by 6 p.m. if possible. You need to go to bed by midnight or earlier and leave four hours before dinner and your bedtime, although here too there is an out clause allowing some fruit in the evening if you're hungry. As you can see, the diet is not as simple as it first appears, and I suspect it works partly by just being so complicated that you end up not eating so you can avoid dealing with the complications ... like many diets. :-)

thehova (2008-09-27 11:56:01)

Isn't there a lot of evidence that a lack of sleep leads to obesity? And I know there is a lot of research which suggests that a high level of water intake leads to weight loss. As for eating the banana, itself, I wonder if any type of fruit would work. I know that vegetables and especially fruit help aid the digestion process. Yeah, I don't think there's anything magical about this diet. It works because it's simple and it's the right way to loose weight.

thehova (2008-09-27 12:00:50)

I just noticed that I called the morning banana diet simple and a commenter above specifically said it isn't simple. The morning banana diet has 4 or 5 principals to follow. But if you go to a Barnes & Noble and look in the diet section, you'd be shocked to see how difficult and challenging the diets are.

Kris (2008-10-02 13:59:42)

Like Joshua said: "This appears to be a intermittent fasting type diet." That is the first thing I thought of. The banana would not be a lot of calories, and would not be enough to really "break the fast". On a similar note, I started eating no breakfast and low (or slow) carb for dinner to include a fasting period in my day. Or, as I view it, turn off the insulin machine for long periods of time. It is working great. I had a job in college that was 2nd shift and I felt great and lost weight, but I thought it was because I was so busy I did not have time to eat. After college I got a job on 2nd shift again, same thing lose weight- feel great. The thing in common: little or no breakfast. This fits in with the SLD because banana=not much taste.

Philip (2008-10-17 09:08:35)

This doesn't look like fasting at all to me. It doesn't at all look complicated either. Whether it works is another story. They say you can eat anything you want for the other two meals, just banana and water in the morning. I'll give it a try. Sounds like the least complicated diet I'll have tried and it's certainly not fasting.

Bob (2008-10-17 14:54:50)

The Warrior Diet by Ori Hofmekler is similar, and essentially is a fasting diet, based on the theory that Roman Warriors, and the like, ate little or nothing during the day, and gorged themselves at night.

lori (2008-10-18 19:55:45)

Potassium Pump. Apparently there is a connection between metabolic rate and potassium in the body. If one 'breaks the fast' with bananas they also turn on the "potassium pump" in the body and food metabolizes more completely. With honest sensible eating I think this diet can work very well.

Jerry (2008-10-20 14:48:28)

Bananas help people lose weight because they contain resistant starch, which ferments in your large intestine, creating by-products that block conversion of some carbohydrates into fuel, so replacing ordinary carbs with the resistant starch in bananas can boost fat burning. And banana fiber bulks up in your stomach, so you feel full for longer. There's a healthy way to do the banana diet which makes sense and includes exercise <http://www.dolennutrition.com/bananadiet/bananadiet.htm>

Phyllis (2008-10-21 04:58:24)

Not sure if this has been covered, but a doctor once told my grandmother she was eating too many bananas (she had dementia and was not realizing how many she was eating during the day). She was getting too much potassium in her body. I forget what he said it does, but it wasn't good for her. Just like anything else: too much of anything is not good. For another example: Too much Vit C leads to diarrhea. Never do (or over-do!), without checking with your personal physician. Some foods even counteract medications, so please be careful.

Alison (2008-10-22 14:32:44)

For breakfast, you should eat one or more bananas and drink a glass of lukewarm water. You can have as many bananas as you like until you are full. The reason for the water to be lukewarm is not known and has come under much speculation on the Internet. Most diets suggest that you can burn more calories by drinking cold water. Lunch can be just about anything you like. This diet places no restrictions on what you can or cannot eat. you can eat one snack around 3:00 pm if you are hungry Dinner can be anything you like as long as you eat before 8:00 pm. Avoid ice cream and other dairy products, as well as dessert after dinner One other rule of the diet is that you must go to bed before midnight each and every night. This makes sense because studies have shown that a lack of sleep leads to obesity. And finally, Yes I'm definitely going to give it a try.

CRYSTAL (2008-10-23 08:46:01)

THE REASON FOR LUKE WARM WATER IS THAT IS BURNS FAT NOT CALORIES. AND THAT;S THE GOAL.

Jan711 (2008-10-27 05:06:24)

Is there any real evidence that anyone has truly lost weight on this diet?

wanda chafin (2008-10-28 10:51:24)

I tried the banana diet after hearing about it on the news. Thats all I did was have a banana and warm water ( I warmed mine and had in coffee cup, I didn't know it was supposed to be room temp ?) but the first day I started it I didn't weigh myself and I ate bananas and had a fast food hamburger and fries and regular coke. ( Large hamburger). Then the next morn I weighed myself and I counted calories all that day , did the same for one more day-got on the scales and lost almost 5 lbs..I want to wait until saturday to find out the real loss since saturday will be a week for me ! I love this diet it really works..

Megilla knows (2008-11-02 06:59:39)

Monkeys are laughing at you right now. This was a diet they discovered thousands of years ago and they have lean bodies to show for it.

Chris (2008-11-15 19:09:48)

I'm looking forward to starting this diet.... just one question... do you have to have water? or could you substitute coffee and splenda instead?

elide (2008-11-17 02:21:37)

Yes.me too. I would like to know if you can have coffee instead of worm water.

seth (2008-11-17 06:46:07)

I'm no expert on this diet, so I'm the wrong person to ask.

mararules (2008-11-18 09:14:57)

I started it this morning..I did not weigh myself...but I will tomorrow morning..I will let you know if it works : )

John (2008-11-28 09:15:31)

I agree the morning banana diet is not really suitable for westerners. Having tried it myself I found I was too hungry allot of the time and so I made some modifications to it which works better for the bigger western chap like me! I have still gone from someone that is clinically obese to normal weight within 18 months. I didn't think it would work either. Who'd think it, eating a few bananas would do that lol :-)

Mark (2008-11-29 05:30:59)

Here's a site with details on the diet, slightly Westernized: <http://morningbanana.com>

Cheryl (2008-12-18 19:03:14)

I've been on the banana diet since November 1 and have lost 8 pounds (in 50 days). I have not done the diet perfectly but I have eaten a banana and water at least 45 of the days. I didn't do the diet around Thanksgiving (and gained 2 lbs or so that I had to re-lose). I've also probably eaten more sweets than I should have (due to the holidays). The rules and how I do on them: 1. Eat a banana and lukewarm water (pretty faithful). 2. Eat whatever at lunch. I've had something sweet after lunch probably 1/3 of the 50 days so far (so...I would say partly faithful). 3. Eat a snack at 3 PM (pretty faithful). 4. Eat whatever for dinner (sometimes have sweets; probably 10 days out of the 50-so, more faithful than not). 5. Eat before 8 PM (pretty faithful). 6. Go to bed by midnight (pretty faithful). I guess if I didn't eat the sweets after lunch or dinner, I'd be doing better. I also exercise on average of 4 days per week. I try to walk with some jogging 4-5 miles on some days; lift weights (1 set of about 12 exercises) some days. Losing 8 lbs for me in less than 2 months is amazing as I've gone on every diet imaginable with not great results.

My pants are getting looser and my stomach is flatter. Most of my "muffin top" is gone (just a slight amount of spillover). I'm not sure how/if this will work the same for you as it seems to be working for me. I wish everyone luck with their fight against the bulge!

pride (2009-01-09 23:48:08)

CAN I DRINK MILK WITH THIS DIET??? I need milk lol growing boy =]

allie (2009-01-16 17:08:52)

is there a book you can buy on the banana diet?

Angie (2009-01-26 13:33:49)

All i can say is that as crazy as this diet seems it really works, its all just common sense i guess, things you should be doing already, but most of us don't. Like going to bed at a decent hour, drinking, lunch and snack. Anyways, my quality of life has improved even if it is just a fad diet. Also, after 16 days i had lost 5lbs :) I blog about it if your interested at all.

Shelley (2010-07-30 18:05:40)

This is my 3rd week on the banana diet and I've lost 4 lbs. I took the "eat whatever you want at lunch and dinner" very literally and still lost weight. However, one of the rules is no chips, sweets, ice cream, etc., so I did not eat those for snack or meals. But I did eat chile dogs, hamburgers, etc....things I kind of laid off just having finished 4 months on WW and only losing 10 of the 70 lbs I need to lose. I also have a slight underactive thyroid and get edema (water swelling) in my ankles that is very painful. But, since eating the bananas (potassium, I suppose), that has gone away and I feel much better. I eat 3 bananas. Sometimes I get hungry between breakfast and dinner, but I saw a site that said to also eat a handful of nuts. That would help and I think I will start trying that, but now that I have gotten the junkfood thing out of my system, it's back to whole grains, lean meats, and more veggies for me just because I feel better when eating that way. If you want to know if it works, it has for me. I suggest giving it two weeks.

Shelley (2010-07-30 18:10:06)

Correction to my prior post: "Sometimes I get hungry between breakfast and lunch" not dinner. I did not mean to imply that I am skipping lunch because I am not. I eat until I feel satisfied whatever I feel like that day (sans sweets).

james (2010-10-17 20:43:19)

I think this diet was invented by the folks who import bananas into Japan <http://www.japansugoi.com/wordpress/banana-king-japanese-tvcm/>

## **Games and the Business of Life (2008-09-26 08:14)**

You probably know that plastics were first used for toys. You probably don't know that the first metals were used by artists, as far as archeologists can determine. That's material science, what about non-material science? Here's [1]Tyler Cowen:

I've been thinking of all those old puzzles where a bunch of guys enter the room and only so many of them have smudges on their foreheads and you have to find the algorithm to reveal that information.

The problem is to separate good banks from bad banks, so that good banks can continue business. A big reason I started self-experimentation was Martin Gardner's Mathematical Games column in Scientific American. I could sometimes solve Gardner's made-up puzzles, which gave me confidence when a non-made-up puzzle – waking up too early – came along.

More When I pointed this post out to Tyler, he replied, "Exactly what I was thinking in fact, when I wrote that...I even almost mentioned Martin Gardner."

### **A Little-Known Problem with Vegetarianism (2008-09-26 21:39)**

If you look up [1]vegetarianism in Wikipedia, you'll find references to several health "concerns". You won't find anything about trouble at high altitudes. However, a friend of mine went on a high-altitude camping trip and found himself feeling terrible, with symptoms of altitude sickness. He later learned, when everyone reconvened, that two others in the group of 30 had had similar troubles. All three were vegetarians. They'd done fine on hikes at lower altitudes. None of the other 27 were vegetarians. The correlation makes sense because vegetarians are often much lower in iron – a component of hemoglobin, which transports oxygen – than non-vegetarians.

The interesting question for me is: What can we do with such data? It's obviously useful, but where does it go? Not in a scientific paper, obviously. In a letter to the editor? Of what journal?
